Society of Arts.

AN

✦ ILLUSTRATED ✦ WEEKLY ✦ MAGAZINE ✦

FOR THE

ARCHITECT, ENGINEER, ARCHÆOLOGIST, CONSTRUCTOR,
SANITARY REFORMER, AND ART-LOVER.

CONDUCTED BY

H. H. STATHAM,

FELLOW OF THE ROYAL INSTITUTE OF BRITISH ARCHITECTS.

“Every man's proper mansion-house, and home, being the theater of his hospitality, the seat of self-fruition, the comfortablest part of his own life, the noblest of his sonne's inheritance, a kinde of private princedome, may, to the possessors thereof, an epitome of the whole world, may well deserve, by these attributes, according to the degree of the master, to be decently and delightfully adorned.”

“Architecture can want no commendation, where there are noble men, or noble mindes.”—SIR HENRY WOTTON.

“Our English word TO BUILD is the Anglo-Saxon Bylban, to confirm, to establish, to make firm and sure and fast, to consolidate, to strengthen; and is applicable to all other things as well as to dwelling-places.”—DIVERSIONS OF PURLEY.

“Always be ready to speak your mind, and a base man will avoid you.”—WILLIAM BLAKE.

VOLUME XLVIII.—JANUARY TO JUNE, 1885.

OFFICE: No. 46, CATHERINE STREET, COVENT GARDEN, LONDON, W.C.

Architectural Illustration.

NOT very many years ago the question of the best method of illustrating architectural works in an architectural journal was of necessity a very simple one. There was practically but one available method, that of engraving on wood from a drawing furnished to the engraver, or drawn for him on the wood by the architectural draughtsman. Steel-engraving was for the most part out of the question for periodicals appearing at regular and short intervals, both from the time required to produce the work, and from its costly nature; which latter factor especially would render it commercially impossible, unless as a rarity and in special instances, for any but monthly or quarterly publications giving a comparatively small number of illustrations. Accordingly, for a long time wood-engraving was the recognised medium by which the works of the architect were translated into pictorial illustration for further publicity.

Certain disadvantages are inseparable, no doubt, from this method of illustration. Though so much cheaper and a good deal more expeditious than steel engraving, it is still, under all the circumstances of weekly journalism, a costly and a slow process, and it is one which will not bear being hurried. A more definite drawback to it, from the architect's and artist's point of view, is that it introduces between the original drawing and the final result another hand than that of the original draughtsman: it is not a reproduction of his drawing, but a translation of it into another form. The intro-

duction of lithography offered the means of reproducing the exact styles and artistic manner of the original draughtsman, but this did not make very much way as long as it was weighted by the necessity of drawing on the stone itself. The old system of chalk drawing on a stone with a fretted surface was, indeed, a pleasant one enough to the draughtsman, and allowed all possible freedom of hand; but it is a style of representation eminently unsuited for architectural subjects, except for the representation of ancient or ruinous architecture, in which picturesque effect is the object rather than the clear definition of architectural design and detail in its perfect state; and drawing with a pen or a fine brush on the stone is not a process favourable to freedom of hand or breadth of effect: some practice, too, is necessary to acquire facility in the process of drawing the reverse way on the stone. The introduction of "transfer paper" got over this last difficulty, and enabled the ordinary architectural draughtsman to make his drawing as it was to be finally seen; but it gave him a surface medium even more uninviting than the stone, with the chance of some loss of sharpness and effect in the process of transference. With the introduction of photolithography, whereby the drawing made on paper with ordinary pen and ink could be almost absolutely reproduced line for line and mark for mark, came an important and entirely new opening in the possibilities of architectural illustration. The process was both cheaper and more expeditious than engraving, and the draughtsman's own style and technique appeared in multiplied form with little diminution of its original effect. In some cases, we might say, photolithography afforded even an improvement on the original drawing by its capability of reducing scale, by which a drawing which

originally may have appeared somewhat coarse in execution, acquired in reduction an appearance of delicacy and finish which the original draughtsmanship did by no means convey. This trust in the refining powers of photographic reduction is not, however, to be recommended as a principle of working. To trust to that is to foster artistic indolence and carelessness, as well as to lead to possible disappointment in the final result; for photolithography is capricious in its behaviour in this respect, and sometimes unexpectedly revenges itself on the draughtsman who trusts too much to its kindness in hiding or refining away his deficiencies.

Photolithography, however, has become a great power in architectural illustration, but the many advantages connected with its use have led in many quarters to an exaggerated and perfectly unfair depreciation of wood-engraving as a means of illustration. This has been carried so far that many architects seem to think that the mere fact of an illustration being a wood-engraving is sufficient to render it unworthy their notice. They seem even to forget that as there is good and bad pen drawing, so there is good and bad wood-engraving. This is, of course, mere prejudice, and hardly worth arguing with; but to those who are more reasonable, we may suggest that there are certain undeniable powers and advantages in wood-engraving, which are not to be had by the more recently advanced processes. One practical merit is in the superior certainty and facility of production in large quantities. The printings from a carefully-cut wood-block are far more uniform and certain in result than those from a lithographic stone, when impressions are counted by thousands, and they are produced far more quickly, as far as the mere printing is concerned. In fact, the number of impressions required for a journal like this

could not be produced in reasonable time, except by transferring the impressions and working in duplicate, and such transference involves the risk of some diminution of sharpness and clearness of line. But there are definite artistic points in which carefully-executed wood-engraving has the superiority. It gives a force of effect in contrasts of light and shadow surfaces which can hardly be attained in lithography without a blurred and blotted appearance; it can attain a hardness and brilliancy of texture and sharpness of line which is eminently favourable to the representation of architecture. This, of course, means when it is carefully executed from clean and precisely-defined drawings or photographs. We may safely instance in this respect the engraving of the exterior of Keble College, in the present number; and as another example, those of the Post-office buildings at Rostock, in Germany, in the *Builder* for April 19, 1884. Both these examples were executed in the atelier of Mr. J. D. Cooper, from very clear and well-defined photographs; and the engravings may fairly be said to rival the photographs in clearness of definition, giving at the same time more force of contrast of light and shade. But similar results cannot be expected, of course, when the engraver is not given clear and well-defined originals, whether drawings or photographs, to work from. Another important advantage which engraving has over photolithography from pen drawings, is in the capacity for producing distance and middle-distance tints. In lithography nothing but greater fineness of line can be relied on for distant effect; and as the ink always spreads more or less on the stone, lines which are fine enough in the original drawing come out coarser and thicker on the stone, and in consequence it is hardly possible in lithographed line-drawing to keep the distance or the sky in their places; they always obtrude in such a way as to lose atmospheric effect. In wood engraving the lines do not spread in this way, and (what is a much more important point) the wood-engraving is treated by "over-lays," as they are called, of various thicknesses of paper on the opposing surface, by which the paper is pressed on to the block, so as to print the darker parts more heavily and the distant portions lightly. The first impression of an engraving, before it is "brought up" by this treatment, is a very different thing from the final impression.*

The ordinary processes of photolithography, however, still left the necessity of producing coloured drawings or photographs by engraving. The beautiful processes called "auto-type" and "photogravure" are, from their costliness and slow production, quite out of the question for weekly journalistic illustration. But the perfection by Messrs. Sprague, not very long since, of their "ink-photo" process, was a most important step in facilitating architectural illustration. This process produces a facsimile of a water-colour drawing so far as balance of tone (not colour) is concerned, or of a photograph, at no exorbitant cost, and, as worked by the firm who have introduced it, with great regularity and certainty of production, and in a time not much longer than is required for ordinary photolithography. We give in the present number two examples of their work; one, the stained-glass design by Mr. Burne Jones, reproduced from a photograph; the other, the west front of Tewkesbury Abbey, from a sepia drawing. The process spreads a stipple-like grain over the surface, which in some classes of subjects assists the effect materially; in the Tewkesbury Abbey plate, for example, it actually adds a surface texture to the masonry which materially improves the effect. Essentially it is, therefore, not so suitable for reproducing line drawing; the line tends to lose its sharpness, and the process is a little capricious in this way. We have seen some examples recently in which lines were produced with great sharpness; but something depends on the tone of the paper. If this is at all of a

bluish white, it tends to enhance sharpness of line, as the natural tone of the paper disappears from the result; if the paper employed is at all of a tendency to buff or yellowish tint, this asserts itself in the photographic impression, and gives a more or less blurred effect. In reproducing from photographs, the best results are obtained from those which give opposed masses of light and shadow, and shaded and modelled surfaces, rather than sharply-defined lines or details. Hence it is exceedingly successful in reproducing sculpture photographs; and one eminent sculptor, when we illustrated some of the sculpture in the Academy last year by this process, wrote to us to say that he had never had one of his works so well illustrated. In the treatment of water-colour drawings, of course, the reproduction is subject to the usual difficulties of photography; blues become faint or disappear, yellows become dark, and so on. A coloured drawing which is not made for the purpose of reproduction in this way, therefore, may considerably surprise and disappoint the author if he is not alive to the behaviour of various colours under photography. A sepia drawing, however, can always be trusted to come out well under the process.

It may be useful to add a word as to line drawings for ordinary photolithography, in which mistakes are sometimes made which lead to disappointment. In the first place, consideration should be given to the degree of reduction in size (if any) which is intended. If a large drawing is intended to be reduced, for instance, to one-half or one-third its original size, lines for shading must not be drawn so close that in the reduction they may tend to run into each other: inattention to this often leads to great disappointment in the effect of the lithograph. Spaces which are shaded heavily, unless quite black, should nevertheless be shaded in distinct and clear lines, leaving the interspaces, however small, of untouched white; to scribble or scumble over such shadows with thin lines to give more depth, as some draughtsmen do, is fatal to the lithographic effect, and produces only a "mess" on the plate. It is still supposed by some draughtsmen that drawings must be in black ink for photo-lithography; this is a mistake,—red, or warm brown, such as sepia, take equally well; but it is important that when black ink is used it should be quite black; thinly-mixed ink gets grey, which is an approach to blue, and fails accordingly. For the same reason, ordinary writing ink, which some people like to use for pen-drawing, and which produces a very pleasing effect in the original drawing, is exceedingly risky for photolithography, and should never be used with that object.

We give an example in this number of another photographic method of reproducing coloured drawings in the view of Callendar House, which is a reproduction from a sepia sketch, made mainly for the purpose of experiment. The process, which is carried on in Paris by Messrs. Boussod & Co. (late Goupil), results in the production of a metal engraving in very low and delicate relief, which, mounted on a block, is printed in the same manner as a wood-engraving. As will be seen, the process spreads a grain or stipple over the surface, but in a more mechanical kind of manner than in Sprague's process, and so far inferior. The reproduction of coloured drawings by this method, being by means of photography, is subject to the same partial falsification of effect which enters into all the processes in which photography is used; but the provision of a reproduction of this kind, which will print like an engraving, is often a great convenience. The present plate reproduces very well the effect of the sepia sketch. We have the proof by us of a better and more effective example which it was intended to print with this, but our Parisian friends have not yet acquired those virtues of certainty and punctuality of delivery which so admirably characterise our leading London lithographers, and the block has not arrived in time for press.

The use of new processes, or those which have not been in habitual use for weekly pub-

lications, we have found to be in other cases somewhat hampered by difficulties in regard to speedy and prompt execution. These things arrange themselves in time, however, and further developments in this direction may be looked for, our object being to have for each class of architectural drawing its best and most artistically favourable method of reproduction.

THE TEMPLE OF DIANA, EPHEBUS.

BY J. T. WOOD, F.S.A.

ALTHOUGH the chief results from the discovery of the Temple of Diana at Ephesus have now been before the public for some years in the book I published on the subject in 1877, wherein I described the discoveries made by excavations under the auspices of the Trustees of the British Museum, between the years 1863 and 1874, much remains to be told appertaining to those discoveries, and something more may be added as the results of the excavations which I carried on by private subscription under a committee of noblemen and gentlemen from March, 1883, to February, 1884, excepting the three summer months during which no men can be found to work for a continuance in the pestilential district of Ephesus. Even at the time when the city was in the height of its glory and magnificence, Ephesus was unhealthy by reason of an immense marsh, which all the four rivers which flowed through the plain were not capable of draining, and, we are distinctly told by Strabo, that the Temple was built on a marsh; but now that the city is entirely deserted and consists of nothing more than a number of heaps of ruins of its public buildings, and the river banks being no longer maintained, the whole plain is silted up to a considerable depth, and the marsh north of the city is a source of malaria, which makes its neighbourhood more unhealthy than that of any other of the ruined cities in Asia Minor.

The deadly fever which prevails at Ephesus is one of the great difficulties which present themselves to the explorer who seeks to unearth the treasures of antiquity which lie hidden so many feet below the present surface of the ground.

If it had not been for the fever, I should have carried on the excavations at the Temple during the summer months.

For the first three years of my explorations I worked on without cessation, although I could only get a small gang of men to work for a few days at a time during the hot weather. At the same time, I made my survey of the city, and my life was nearly sacrificed at the end of the third hot season.

But, besides the fever, there are other reasons why the exploration of the Temple cannot go on so well during the summer. The rains in February, March, and April cause the water to rise in the excavations to a height of several feet above the pavement on which rest all the sculptured marble and fragments of architecture which are scattered all over the site. A wet season considerably aggravates this difficulty, and makes it impossible to do more from May to September than to remove the upper strata in preparation for a harvest which can only be reaped in the autumn and winter months.

There is still another difficulty during the summer. Brigandage is rife all over Asia Minor, and the neighbourhood of Ephesus is a favourite resort for the brigands, who are formed in bands of from four or five to twenty-five. These men can live comfortably up in the mountains during the warm months, and the nature of the country is extremely favourable to their evasion of pursuit when they have succeeded in making prisoners, who are taken for a ransom. Even during the winter months I have been obliged for some years to provide myself with a body guard of four cavasses. These men were extremely useful as gangers at the time when I had more than 300 men at work.

The marbles acquired by the excavations during the five years in which I was employed in clearing the site of the Temple are now

* We may add, however, that our experience leads us to discourage wood engraving from small views of large buildings, where the details are necessarily shown to a very small scale. The material is not pian enough to work detail on a small scale.

arranged in the gallery in the British Museum, which has been recently cleared out for their accommodation, and which has been for so many years the Mausoleum Gallery; so the remains of two of the seven wonders of the ancient world have found their home in our National Collection of Grecian Antiquities.

In the Ephesian Gallery will be seen the sculpture on the south side, the architecture on the north. I should have preferred a *vice-versa* arrangement, and would have taken the south light for the sculpture; but my opinion and wishes did not prevail.

The mutilated remains of five sculptured drums are ranged in line; and although they stand much nearer together than they did in the Temple itself, they give the *imaginative* visitor some faint idea of the rich effect which a group of eighteen sculptured columns would have as they were arranged in the pronaos and the posticum of the Temple. The most complete of the five sculptured drums in the Museum is 6 ft. 0½ in. in diameter; but the one next to it, with the upper halves of two figures, is only 5 ft. 6½ in. in diameter. I am obliged, therefore, to conclude that these columns were sculptured to about one-third of their height. The different style of sculpture in these drums is most remarkable.

At each end of the gallery, on a line with the sculptured drums, are two very interesting sculptured blocks, each with an enriched bed mould; the character of these blocks, and the positions in which they were found, induce me to believe that they were the angle blocks of a sculptured frieze. This is a question which can only be cleared up by further excavations. On the upper surface of these blocks are to be seen traces of a curved line, which prove, I think, that they were cut out of the drums of columns of an earlier temple. Opposite the central sculptured drum may be seen the remains of the base of one of the fluted columns, which belonged to the outer line of columns of the peristyle on the south side of the Temple; upon a similar base, I presume, the sculptured columns were placed. The great beauty of the outline of this base is most striking. It is probable that between the two astragals, which are here three times repeated, there was a fillet of gold. I had the good fortune to find an example of two astragals of the same size, which had between them a thin strip of lead doubled, and pressed firmly in between the astragals, and within the folded lead were the remains of a strip of thin gold, which must have formed a narrow fillet. The flutings of the columns were elliptical, and the points from which the extremities of the ellipse were struck were set in 1 in. from the face of the fillet dividing the flutings, the arrises therefore were extremely sharp. The acute angle here, and in the marble fillets of the base which divided the cavetti from the astragals, as well as in many other fragments, is most remarkable. Such work could only be executed with the material of which the Temple was built. On showing a sample of this marble to a London marble merchant, he said that it was too hard to be worked in the present day, even by machinery, and it was quite unmarketable.

On a line with the base I have here described there are two examples of the noble capitals which surmounted the fluted shafts of the columns; in both examples the whole of the abacus has been chopped away, but I fortunately found a fragment of another capital with a portion of the abacus remaining. It consisted of the egg-and-tongue enrichment, 6 in. deep. The eye of the volute of one of the capitals has been cut out, and two pin-holes show that a coloured or gilded disc was inserted to complete the volute. In the other example the eye has not been cut out, and the compass-points remain from which the volute was described; each perfect revolution consisted of eight arcs of circles struck from centres with increasing radii from the eye of the volute.

A large fragment of the architrave was found consisting of three fasciæ and what remains of the capping of the upper fasciæ. The latter has been so much chopped away that it is impossible to restore even the outline,

much less the enrichments of which it was composed. It is much to be deplored that nothing has been found of the cornice but two fragments of the beautiful cymatum, 2 ft. in depth, which is enriched by the honeysuckle ornament, deeply and artistically cut. The largest of these was found in the earlier excavations; the other, which enables me to obtain a correct outline of the whole, was found recently near the spot where the first was found. The gutter for the rain-water cut in this stone shows exactly where the lions' heads occurred which formed the water-spouts. These were placed immediately over the columns.

For lack of the parts I have mentioned it is impossible to restore the order, or to fix the places for the numerous varieties of the bead and reel enrichment which were scattered far and wide with a few ogée and other enrichments. Some of these were of a very large size, and many of them retained traces of colour, which justify me in concluding that the whole of the Temple was painted, excepting, perhaps, some of the fillets which might have been left white. On the same site were found the remains of three temples, built one over another, and, as far as I could ascertain, of the same size, but differing in their details and proportion. My recent excavations, carried on at a time when the water stood at a low level, enabled me to study with advantage some of the details of the earliest of the three temples. On the north side, in the foundation pier of one of the inner columns of the peristyle, I found, after minute examination, the remains of the base of a column of the first temple, which was similar to that of the last, and as the cella wall of this Temple was 6 ft. 3 in. thick and the ante must have had a projection of at least 1½ in., I suppose the columns of this earlier temple were at least 6 ft. 6 in. in diameter. This supposition is justified by the remark of Vitruvius in describing the last temple. He says,—the *improvised* Ionic order was employed in this building; that is, the columns were 8½ diameters in height *exclusive* of the base. I have, therefore, computed their height to have been 55 ft. 8¾ in. with the base.

The number of these columns (100) is decided by the position of the south ante in the pronaos; the cross wall at the west end, the 11-ft. length of the lowest step of the platform on which this temple was raised, and the remains of the surrounding portico at the east end. Vitruvius describes the Temple as octastyle, and this is fully borne out by the discovered remains.

The position of the Temple at the foot of a hill, which rises at a steep angle, at a short distance from it, is hard to account for; there was ample space, however, to allow of a wide road to pass from north to south, and a large open space in addition; but its position in that part of the plain of Ephesus is only accountable by surmising such a circumstance as the finding of an aerolite or meteoric stone (the image which fell down from Jupiter) which had fallen there, and the man to whom the ground belonged might have taken advantage of his opportunity to get a large sum for it.

The allusion to the image in the town-clerk's speech, Acts xix., gives us strong evidence of an authentic tradition.

It is an extraordinary fact that the site of the Temple was a had one. It could not be seen from a single house in the city, nor from the Theatre, nor from the Forum. Situated as it was a mile from the city, and at the foot of the hill at Ayaslouk, its remains were silted up and completely hidden from view many centuries before the time of Sultan Selim, who built a large mosque, and a considerable city in that part of the plain.

In the course of a short and hurried discussion which followed the reading of my paper on the Temple of Diana at the Royal Institute of British Architects on the 9th of June, 1884, my friend, Mr. R. P. Pullan, expressed his opinion that the ancient Greeks did not employ sculpture in the tympana of their *Ionic* temples. I am not at present in a position to prove, beyond doubt, that the Temple at Ephesus had sculpture in that position. I

found an angle of the west tympanum which was quite plain; but even if there had been sculpture in the tympanum, it might not have extended so far into the angle. Mr. Pullan cited three *Ionic* temples which he had dug up, and which were without sculpture in the tympana; but these temples might not have been completed, or they might not have been perfect examples of the most highly-finished temples; such a temple as that at Ephesus, without sculpture in the tympana, but so rich in sculpture elsewhere, would have a very unfinished and incomplete appearance. The Ephesian medal of Hadrian, and a medal of Gordianus, exhibit sculpture in the tympanum. The latter is figured in Professor T. L. Donaldson's "Architectura Numismatica." I found at each end of the Temple at Ephesus legs of statues, life size, in high relief, showing just one small attachment in each case. These might have come from the tympana, or from the frieze, on some other part of the Temple. These fragments of sculpture were some of the results of my recent excavations, which yielded altogether about sixty fragments.

Amongst the remains of the earliest Temple found on taking to pieces the massive piers of rubble masonry, which were built, as I presume, by the early Christians of Ephesus as foundations for an intended church, were two most interesting examples: one is a female head with a peculiar coiffeur and ear adornments, which cannot properly be called ear-rings; the face is of a peculiar and harsher type, with thick lips and broad fleshy nose, the eyes wanting; they had, apparently, been represented by colour. This head was attached to a rounded surface, and it evidently formed part of a sculptured column. The whole was painted. The other fragment is still more interesting. It represents the lower portion of a draped male figure in low relief against a rounded surface; the legs, feet, and close-fitting drapery are so archaic in character that I have no hesitation in saying that this fragment, as well as the female head, must have belonged to a sculptured column of the earliest temple, built by Ctesiphron and his son Metagenes in the sixth century B.C., and to which Cressus has the credit of contributing so generously. In the same foundation-piers were found some very fine examples of lions' heads from the same temple; also one very fine and nearly perfect example of a lion's head, which had formed a gargoyle or water-spout, from the last temple. The archaic fragments above described justified the demolition of the piers of rubble masonry in which they were found, although upon the piers themselves there was imprinted a most interesting record. They had been built against the cella walls of the temple, which remained at the time up to the height of many feet, and before the mortar was quite dry the walls were taken down: the impression of every stone and the joints of the masonry could be seen perfectly upon the rubble piers. I took care to leave undisturbed sufficient of the angle piers to enable any one who wished to do so to check such parts of my restoration of the Temple as formed part of my data. Small portions of the cella wall on the south side and at the west end remain undisturbed, and these are beautiful examples of the masonry of that period, the sixth century B.C. The general surface of the marble was tooled with a sharp-pointed hammer; a margin of 1½ in. was drafted round each stone, and the edge was slightly hevelled to preserve the arrises from injury by earthquake. This beautiful walling had evidently served as part of the foundation of the temples which were raised over it.

As very few of the wall-stones remain loose on the spot, it must be presumed that they were all removed after the destruction of the Temple to construct some neighbouring buildings, and some were taken to the city, as I found six of them in the proscenium of the great theatre. This is no mere surmise, for these stones had upon them twenty-six decrees of the Council and the people of Ephesus, conferring the citizenship upon various persons for their services, and the decrees were ordered to be inscribed on the walls of the Temple, where

similar decrees were inscribed. The date of one of these decrees is 290 B.C.

A question particularly interesting to the architect is whether there was an amphitheatre at Ephesus in which it was possible to have encounters between men and wild beasts. The passage in St. Paul's First Epistle to the Corinthians, 15th chapter, wherein he says,—"If, after the manner of men, I fought with beasts at Ephesus," misleads many people, but the "beasts" that St. Paul fought with must have been wicked men. If he had really fought with lions or other wild beasts, he would have mentioned it in writing afterwards to the Corinthians, 11th chapter of the Second Epistle, where he gives a most pathetic enumeration of all the sufferings he had gone through, including even the number of times that he had been beaten with rods. He would certainly not have omitted to include his encounters with wild beasts, if he had ever been so persecuted. There is no record even that St. Paul was imprisoned at Ephesus. The archons of the city, indeed, appear to have befriended him.

I looked carefully for the remains of an amphitheatre at Ephesus, but found no signs of one. There were, indeed, only two amphitheatres in Asia Minor,—at Pergamos and Cyziens. We may be allowed to suppose that this kind of persecution was not generally practised in Asia Minor.

A curious bas-relief was found in the ground over the site of the Temple, and about 12 ft. from the present surface, having two panels, one representing a man armed with a club, with which he has struck the lion on the head on the second day of his encounter; on the third day the lion has won the victory, the man is prostrate, and the lion is tearing out his bowels. The panel representing what took place on the first day is missing, but the man must have been victorious, as on the second day. This bas-relief is an interesting proof that men sometimes survived more than one encounter with wild beasts.

When the excavations were suspended in 1874 the whole of the site of the Temple had been explored, and the surrounding ground for 31 ft. beyond the lowest step of the platform, excepting at the east end on the north side.

The recent excavation has been undertaken for the purpose of exploring the portico surrounding the Temple area, up to which point it is possible some sculptured drums might have been rolled to clear the road around the Temple which was needed for the removal of the wall-stones. It is also hoped that some more of the frieze may be found, as well as enough of the architrave and cornice to complete the order.

Most of the remains of the last Temple which have hitherto been found are now exhibited in the Ephesian Gallery. It may here be repeated that this was the Temple which was built by Diodotus in the time of Alexander the Great, and which succeeded the Temple built by Ptolemy and burned down by Hierostratus.

My recent excavations, and further study of the foundations and other portions of this Temple remaining *in situ*, have enabled me to modify my plan in a few particulars.

I now place the Temple complete with its customary three steps upon a platform which is approached by a continuous flight of ten steps. The dimension taken on the lowest step from north to south is 239 ft. 4½ in.; the treads of the steps were 22 in.; the height 8 in.; the platform was, therefore, 206 ft. 4½ in. wide. The length of the platform cannot be decided from the results of the present excavations, but if it was 425 ft., as recorded by Pliny, there would be ample space for the altars which I have supposed to have existed in front of the Temple at the west end. The pavement of the peristyle was 9 ft. 5½ in. above the pavement at the foot of the steps.

The Temple itself was 163 ft. 9½ in. in width and 342 ft. 6½ in. in length.

The naos or cella was nearly 70 ft. in width and about 110 ft. in length.

Full particulars of the Temple with illustrations are given in the Transactions of the

Royal Institute of British Architects for the session 1883-84.

The readers of the *Builder* will be glad to hear that a fund for the further prosecution of the excavations on the site of the Temple is being raised, the hon. treasurer of which is Sir John Lubbock.

FINANCING ON THE THAMES.

EW persons, it is probable, are aware that the navigation of the Upper Thames (such as it is), and the degree of attention that is paid to the maintenance of its channel, and to the escape of its flood waters, are mainly provided for by the actual sale of a definite quantity of the water of the river. It is a matter of some importance, both to the riverain residents and to the inhabitants of half London, that it should be known to how great an extent the funds applied to the Conservancy of the river, west of London, are furnished by five of the metropolitan water companies. The fact, however, is undeniable. The authority for the statement will be found in two Parliamentary Returns issued in July last, one of which is a "Return prepared by the Auditor of the Accounts of the Thames Conservancy Board, showing the Income and Expenditure on account of the River from 1777 to 1882," and the other is the "General Report of the Conservators of the River Thames, from 1st January, 1883, to 31st December, 1883."

The powers of the Conservators of the river Thames extend from Yantlet Creek, in the county of Kent, to the City stone above Staines Bridge, and thence to Cricklade, in the county of Wilts. The measured navigable stream, from London to Lechlade, where the Thames and Severn Canal leaves the Thames, is stated by Professor Ansted at 148 miles, and the distance from Lechlade to Cricklade is eleven miles. The first entry of tolls received on this portion of the river on record is the sum of 525*l.* 14*s.* 2*d.* for the five months from May to September, 1777. In 1778 the tolls amounted to 1,518*l.*, and they gradually rose to 2,264*l.* in 1810. In 1811-12 a rapid rise coincided with the construction of the Regent's Canal. In 1813 the receipts were 10,445*l.*, and the improvement continued until 1827, when the maximum of 15,924*l.* was attained. The river traffic, as measured by the tolls, remained tolerably steady until 1841, when the effect of railway competition may first be noted. It was not, however, until 1848, in which year the proposal to carry minerals on the London and North-Western Railway at the charge of ½*d.* per ton per mile was denounced by Mr. Robert Stephenson as a robbery of the railway company, that a very serious decline of the river traffic set in. The tolls in 1848 were 10,951*l.*, or about 500*l.* more than in 1813. At this period the acquisition of the canals by the railway companies, and the obstruction of the inland water traffic, commenced. Five canals were thus acquired in 1845, eleven in 1846, seven in 1847, and three in 1848. The Kennet and Avon Canal was acquired by the Great Western Railway Company in 1852, and the tolls on the Thames fell to 6,403*l.* in the following years. From 1852 to 1871 eighteen more canals were acquired by the railway companies, and the tolls on the Upper Navigation of the Thames reached their minimum of 3,282*l.* in 1873. The effect of the railway policy in abstracting from the rivers and canals of the country a traffic the conduct of which has (some persons maintain) involved a heavy loss to the railway shareholders, while its abstraction has rendered the River Conservators unable to carry out their requisite duties, is thus accurately illustrated by the comparison of the dates above given with the decline in the tolls on the Thames.

Since 1873, in spite of the poverty thus brought on the Conservators of the Thames, the traffic has slightly improved, the receipts standing at 4,135*l.* in 1882. But the cost of maintenance in that year (exclusive of interest on debt) amounted to 17,059*l.* The navigation would thus have become utterly bankrupt but for the contributions of the water com-

panies, aided by the annual payments made by the Grand Junction and the Regent's Canal companies as compensation for loss of tolls.

In 1844 the first payment for water taken from the river, amounting to 50*l.* 19*s.* 5*d.*, was made by the Grand Junction Water Company. The Lambeth Company commenced a series of annual payments of 200*l.* in 1853; the Southwark and Vauxhall and the West Middlesex companies began to pay 300*l.* a year each in 1854; and the Chelsea Company paid a like sum in 1855; in which year the contribution of the Grand Junction Water Company was also of the same amount. In 1867 the contributions from the water companies rose to 5,000*l.*; in 1871 to 6,000*l.*; and in 1879 to the present figure of 12,050*l.* per annum.

During the past year the water companies, taken together, have derived from 80 to 85 millions of gallons daily from the Thames. The payment above stated is about equivalent to a price of 8*s.* per million gallons of water. This is equal to about 40 per cent. of the entire cost of the water supply of the city of Chicago; which, again, is almost identical with that of raising the water of the artesian well of Passy into a reservoir, at the height of 53 metres, at Paris. Thus, while the maintenance of the upper river is now chiefly supported by the contributions of the water companies, it cannot be denied that the payments made by the latter represent a fair equivalent for the quantity of water that they collectively derive from the Thames.

From 1777 to 1834 nearly 5,250*l.* per annum has been spent in improvements of the navigation of the Thames, together with repairs of the locks and towing-path, and wages of the lock-keepers. From 1834 to 1857, the expenditure has risen to upwards of 10,000*l.* per annum, 19,127*l.* having been spent in improvements in the last-named year. From 1857 to 1882, the total expenditure on the Upper Navigation was 266,000*l.*, of which 85,331*l.* is carried to capital account, or, in plain words, represents accumulation of debt. During this period the expenditure which appears to have been actually incurred in the necessary work of maintenance has averaged over 8,800*l.* a year. And out of the total revenue receipts of 185,000*l.*, the contributions of the water companies came to 118,000*l.*

It seems pretty plain that this state of things cannot continue indefinitely. There is small room to wonder why the residents of the Thames Valley suffer so disastrously at one time from flood, and at another from want of water, while the Conservators are thus reduced, by the abstraction of the traffic of the river, to eke out their inefficient funds by the creation of a "capital account." It seems to us to be of no little importance that the public should be made acquainted with the facts above brought together. True, "if it be confessed, it is not redressed"; but confession is a necessary preliminary to redress.

NOTES.

HE renewal of the notices of an application to Parliament for a tunnel under the Channel points to the resumption of a conflict which it is the interest of all persons concerned as to our public works to avoid. It ought to be insisted on that the town authorities and other bodies who may feel compelled to oppose such a Bill should not be put to that expense unless on the condition of the deposit, by the promoters, of a definite estimate of the traffic which they proposed to carry, of the price at which it was to be conveyed, and of the proportion of the resulting profit to the capital cost of the work. In our early railway times such a statement was indispensable to the passing of the preamble of a Bill. The Channel Tunnel projectors have always eschewed this honest preliminary step, and that, as it seems to us, from a consciousness of their want of a case. In the first place, they have to show that they could convey goods from shore to shore at a cost price in any way approaching the cost of ocean transport. In the second place, they would have to show, on the grounds of the definite knowledge that we

possess of the minimum cost and time which would be required for ventilating the tunnel, what gross tonnage could possibly be passed through it in twenty-four hours, and what per centage the charge for the goods so carried would pay on the cost of the line. These are plain questions, and if they are blinled the public may know what opinion to form.

THE removal of the constriction in the great east and west route near the Mansion House, now about to be carried out, is only an attempt to remedy a crying scandal. The constant increase which each year brings upon the traffic through London may reconcile us to the failure to carry out Sir Christopher Wren's plan of reconstruction after the Great Fire. That a well-ordered network of streets, fully adequate for the wants of the London of 1666, with its noble central waterway, would have been designed by the architect of St. Paul's Cathedral, there can be no doubt. But that the width of the streets would have become inadequate for the centre of a province of 5,000,000 inhabitants is no less obvious, and in the very excellence of the work of Wren we should have found a reason against that demolition which is now being effected piecemeal. It is possible that we shall never be able to render the street accommodation of London what it ought to be. But we can, at all events, avoid constrictions, and refuse to allow two wide streets to be turned into one narrow one.

THE Manchester Chamber of Commerce have had under consideration the proposal of the Bridgewater Canal Directors to deepen the River Irwell and the upper part of the Mersey to a depth of 10 ft., so as to provide improved barge access to Manchester. The Chamber has resolved that no such measure will be acceptable to the large interests which they represent unless it be accompanied by substantial guarantees as to a reduction of rates and charges between Liverpool and Manchester. This resolution of the Board has the more significance from the fact, as stated in the discussion, that the effect of the passing of the Bills deposited by several railway companies for the ensuing session of Parliament will be to raise the present charge of 8s. for conveying a ton of cotton from Liverpool to Manchester to 11s. 2½d. With such opposite views entertained by carriers on one side, and by customers on the other, a lively time may be expected by those concerned in Parliamentary Committees.

IT appears from a report by the Superintending Architect of the Metropolitan Board of Works that the gross amount of fees received by District Surveyors during the year 1883 was 46,441l. 19s. 10d. in respect of 26,479 works, from which it would seem that the average fee is 1l. 15s. for every work surveyed. The gross fees show a falling-off in comparison with the amount received in the previous year. The largest sum received as fees by a District Surveyor during the year was 2,443l. 8s. 6d., the amount returned by Mr. Andrew Moseley for the district of Fulham. The next largest sum is 1,628l. 10s. 6d., the gross amount of fees received by Mr. T. E. Knightley for the district of Hammersmith. The district of West Hackney, of which Mr. George Legg is the district surveyor, and the district of St. Giles's, Camberwell, of which Mr. H. Jarvis is the district surveyor, show an annual income of upwards of 1,500l. each. The southern division of Lambeth (Mr. H. Parsons), and the parish of Clapham and the southern division of Battersea (Mr. Edward Panson), produced about 1,200l. in each case. The smallest amount of fees received was that returned by the district surveyor for the detached portion of Clerkenwell, near Muswell Hill (Mr. R. Parkinson), whose annual income from his district was only 14l. 3s. 9d. without deduction for office expenses. The average value of a district appears from this return to be 674l., a sum which, when the usual earnings of surveyors is taken into consideration, must be looked upon as sufficiently remunerative. The oldest

district surveyor in point of standing is Mr. Edmund Woodthorpe, who was appointed to the district of St. Anne, Limehouse, St. John, Wapping, the precinct of St. Katherine, and the Hamlet of Ratcliffe, in 1839.

THE Crystal Palace School of Engineering completed its thirty-sixth term on Saturday, when the certificates awarded to the students by the Examiners were presented by Mr. C. Douglas Fox, M.Inst. C.E. Twelve years ago the school opened with nine students; the number has increased continuously, until, in the year and term just completed, 86 students, the highest number ever reached, have been in attendance. At the end of the first year Mr. Douglas Fox, the chairman of to-day, was one of the Examiners. In the first year Mr. Percy W. Britton, A.I.C.E., was a student in the school, and was assigned by the Examiners, the Principal of the School, and by his fellow students, the honourable position of *primus*. Mr. Britton acts at the end of the thirty-sixth term as one of the Examiners of the work of his successors in the school. His colleague in the examination was Mr. Edward Easton, M.I.C.E., M.I.M.E. Both of the Examiners' reports are highly favourable as regards the scope of the instruction given and the methods adopted. Of the Civil Engineering section Mr. Britton says:—"I believe the system followed, as the result of long experience of the best methods, to be unsurpassed in its thoroughness."

PHOTOTYPES of the beautiful bust of Dr. Ernst Curtius, executed in commemoration of his seventieth birthday, and recently completed and presented to him, have just reached English subscribers. The bust is of Carrara marble, by Professor G. Schaper, and admirably reproduces the beautiful but austere features which in real life have much of the set fixity of marble. Each phototype is accompanied by a text containing a short account of the life and work of Dr. Curtius, an account of the proceedings on the festival day, and a list of subscribers. We are glad to see that out of a list of two hundred and fifty-nine, ninety-three are from England and America. In addition to the bust, four offerings in literary form were made.—1. A collection of twenty-seven essays (by pupils and admirers), some of which have been already noticed in the *Builder*. For these essays Dr. Curtius returns special thanks in graceful pentameter verse. 2. An account of his childhood and school-life, printed as manuscript. 3. An important memoir on the Pergamon altar frieze, which we hope to notice shortly. 4. A plate representing a view of the Acropolis and, very appropriately,—the Altis of Olympia; between them a dedication in Greek. This tribute was offered to Dr. Curtius by a deputation of Greeks resident in Germany, at their head Dr. Herr Rangabé, Greek Minister at Berlin.

A BUST of Mr. Gladstone, executed by Mr. A. Bruce Joy, has just been presented to the corporation of Liverpool by Mr. S. Stitt, and accepted by them. Sir James Pieton, speaking for the corporation, characterised the bust as being admirable both in execution and as a likeness.

IT appears that the working men are strongly in favour of the proposed new subway from the Marble Arch to the City. They consider it would provide quick and cheap travelling accommodation between East and West London, which is not now to be had, and for want of which many men are wasting time and strength in walking "nine or ten miles to their daily employment." The "nine or ten miles," we presume, must mean counting going and returning. This is one side of the matter, and an important one. Cheap as the omnibus conveyance seems to the City clerk, it is too expensive for the working man, and consumes a good deal of time too. Mr. Greathead, the engineer for the proposed subway, states that no disturbance of the roadway would be occasioned in making it, except at a few points where the stations would ultimately be placed. But we imagine the disturbance

at those "points" would be very considerable, and not at all restricted within the mathematical definition of a point. Still, the working-men's interest, if correctly represented, is very important, and should have every consideration.

THE Canadian Pacific Railway is the great Canadian road from the Atlantic to the Pacific, and will become the shortest route from England to China and Japan. From Montreal to Vancouver, the east and west posts, is a stretch of rail of about 2,900 miles, passing over the Rocky Mountains at an altitude of 5,300 ft. above the sea, through the grandest mountain scenery, over boundless prairies, and opening up the finest wheat-growing and grazing countries in the world. The rail route is not yet complete, and traffic during the open season is carried across the lakes from Owen Sound to Port Arthur on the north-western side of Lake Superior. The stations along the line are at present of the simplest and rudest class of building, the country being but sparsely settled or reclaimed from its primeval wildness. Eagle River station is about midway between Port Arthur and Winnipeg, picturesquely situated amongst the hills.

ON the 31st of December the *Times* devoted ten columns and more to a review of the principal events of the passing year, ranging from questions of domestic and foreign policy of the highest interest to the deaths of the ballet-danceurs Tagioni and Fanny Elssler. The Garroyle breach-of-promise case and the Adams-Coleridge libel-case were thought worthy of a place in the long record, in which even the ex-convict Orton is not forgotten. But from first to last there is not a word about art. Such trifling matters as the decision of the judges in the Government Offices competition, the re-building of the tower of Peterborough Cathedral, and the restoration of Westminster Hall, were, it is presumed, too insignificant for notice. Strange fatuity, which thus ignores works which will for good or evil endure ages after the political and social squabbles of the day shall have been buried in oblivion!

YESTERDAY (Friday, January 2nd) was the anniversary of the foundation of the Institution of Civil Engineers, which was established on the 2nd of January, 1818. From a new list of members just printed, it appears that there are now on the books 20 Honorary Members, 1,447 Members, 1,889 Associate-Members, 508 Associates, and 804 Students,—together 4,668, against a total at the same date last year of 4,443.

THE exhibition of the Gainsborough Collection at the Grosvenor Gallery is of exceptional interest, and an admirable pendant to the previous exhibition of the works of Reynolds in the same Gallery. We will notice it in detail next week.

A BILL is to be applied for in Parliament next session by the local authorities of Kingston for the dissolution of the Lower Thames Valley Main Sewerage Board, and for the provision for the formation of separate Boards, to be called respectively the Richmond District Main Sewerage Board, the Kingston-upon-Thames Main Sewerage Board, and the Molesey, Hampton, &c., Main Sewerage Board. The stated object is to convey the sewage to some convenient place where it may be purified by application to land or by chemical treatment, and rendered fit for discharge into any stream or watercourse beyond the action of the Rivers Pollution Act or of the Thames Conservancy Acts. Apparently this points to the adoption of the same principles as were recommended in the Report of the Royal Commission on Sewage,—the chemical treatment of the solids and the reduction of the liquids to a comparatively innoxious effluent.

IN reference to this said sewage subject, Sir John Lawes startles us by a long letter in the *Times* of the 29th ult., urging that the most remunerative way of disposing of the

sewage of London is by pouring it into the river or into the sea, which will do as well. "It largely increases the production of fish, provided it is sufficiently diluted, and does not interfere with their health." It supplies a large proportion of the chemical ingredients,—nitrogen, phosphoric acid, and potash,—which are carried away by the fish, and which, in fact, form part of their composition. If this can be established, it is a delightfully easy solution of the problem. Only let us have it carried further out to sea to feed the fishes, and not make the larder under our very noses, as it were. "A long shot, Sir John, if you love us!"

THE TOWER AT THE CLOSE OF THE SIXTEENTH CENTURY.

A short time back we gave a description of the ancient residences of our monarchs at Westminster, and we now propose to say a few words respecting their chief city residence "The Tower." Our intention is simply to convey to our readers some notion of its appearance towards the close of the sixteenth century,* and not in any way to deal with its history, a subject so voluminous and so full of interest that to write it would be little short of undertaking a history of England.

Although "The Tower" still preserves a good deal of its Mediaeval arrangements, and in this respect differs widely from the "Old Palace of Westminster," yet it must not be supposed that it has not suffered very numerous and regrettable alterations and degradations during the past three centuries. In one respect its aspect and plan are greatly changed, and that in a most important feature. We allude to the entire and complete destruction of the noble "palace" which stood within its walls: not one trace of this building now exists! The "White Tower," or Norman keep of Gundulf, still rears its lofty walls in the midst of the fortress; the outer hallum, with its bastions and towers, is still tolerably perfect; the inner hallum is, for the most part, entire; the old Chapel of St. Peter ad Vincula, the house of the Lieutenant, the "Bloody Tower," of fearful notoriety, the Beauchamp Tower, carved with the memorials of many an ill-fated prisoner, are still to be seen; but what has become of the palace of our kings? Alas! not one stone of it remains.

By a kind of poetical justice the inscriptions, mottoes, and names of the victims of tyranny and oppression, carved by their own hands, are everywhere to be seen and read, but the noble palace of those who were too often the oppressors has so thoroughly disappeared that, were it not for ancient documents and drawings, its very existence might be a matter of doubt! It is a most singular fact that the Mediaeval palaces of our kings in and near the metropolis have almost entirely disappeared. Of the ancient palace of Westminster the Hall alone remains; of the Brixwell not one stone exists; of the two "Nonsuches" not a vestige; of Baynard's Castle nothing whatever; of Kennington even the site is doubtful; of Richmond a single gateway; of Whitehall the doubtful foundations of a wall; of Greenwich nothing whatever; of the Savoy the Chapel; and of St. James's the gateway, possibly the chapel, and portions of the court-yard. The only Mediaeval palace which remains in anything like a state of entirety is Hampton Court, and that does exist as a monument of shame and infamy, a terrible sermon upon the text, "Put not your trust in princes!"

The Tower differed from all the other palaces in the fact that it was at once a citadel, a fortress, and a palace. Probably, as originally erected, the Keep, or White Tower, was used as the residence of royalty, though, looking at its great plainness, almost rudeness of construction and detail, it is difficult to believe that it could have been intended for a royal residence except during times of war or civil commotion, and there seems to have been a separate palace, erected at a very early period, probably even as early as the time of William Rufus. The buildings were, however, re-erected and greatly added to by that "Builder-King" Henry III., and, however we may disapprove of that monarch's political acts, it is but just to acknowledge that he was a most munificent

patron of the arts, especially architecture. Apart from the "White Tower," most incorrectly called "Caesar's Tower," the larger portion of the Tower of London dates from his reign.

Of the original buildings of the Tower, Gundulf's Keep, called the "White Tower," is the only important edifice now existing. It is an interesting rather than a fine example of Early Norman work, but vastly inferior both in design and construction to many of our Norman castles. It is singularly plain and devoid of ornament. The chapel alone possesses anything in the way of architectural detail; four of the original windows exist; they are almost rude in their simplicity and bear little resemblance to the windows lately executed by way of restoration.

The great palace of the Tower was situated to the south and east of the White Tower; it was bounded to the west by the wall leading from the "Garden Tower," now called the "Bloody Tower," at the north end of which, close to the White Tower, was a gate called "Cold Harbour," which gave admittance to the court of the palace, immediately in front of the White Tower; facing south was the jewel-house; on the opposite side of the courtyard was the Great Hall, erected by Henry III.; to the east was a series of buildings called the Queen's Lodgings, in which was a gate passing to the second court, or Privy Court of the Palace. This court formed an irregular square with a tower at each angle. Those on the north side were called the Wardrobe Tower and the Broad-arrow Tower (the latter still exists); between these was a range of buildings called "The Wardrobe." The wall of the inner ballium connected the "Broad-arrow Tower" with the "Salt Tower." Probably there was a gallery or row of buildings within the wall. The Salt Tower is the only existing tower which may possibly be regarded as a portion of the old palace, though it does not appear to have contained any of the apartments of the royal residence. In documents of the reign of Henry VIII. the Salt Tower is called "Julius Cesar Tower." The curtain wall of the inner ballium did not return to the south parallel to the outer ballium, but was carried straight on to the "Well Tower," where it joined the outer ballium (that is to say, if ancient plans and representations are correct). A building, called the "Queen's Gallery," which appears to have been partly of wood, or post-and-pan work, went in an oblique direction from the Salt Tower to the "Lanthon Tower," and another building, called the "King's Gallery," extended from the Lanthon Tower to the outer ballium, which, with the walls and buildings previously mentioned, enclosed an irregular court planted as a garden, and called the "Privy Garden." In order to make up for the absence of the inner ballium or wall, in this part of the palace, the outer hallum was defended by two extra towers, the "Cradle Tower" and another "tower adjoining the King's Privy Closet." It is singular that no name is given to this tower in the survey of the 23rd of Henry VIII.

There seems to be evidence that some of the buildings composing the palace were partly of wood, because in the survey for repairs made in the 23rd Henry VIII., before alluded to, we find the following items mentioned:—"A great curval window of wood in the Queen's dining-chamber";—wooden buildings existed in other parts of the Tower,—for instance, the seven houses of office which stood near the Bloody Tower, until about a quarter of a century back, and were very interesting examples of timber-work. There is also an account for "a placement of timber on the west side of 'the Wardyn Gate.'" This is undoubtedly the old timber and post-and-pan work existing on the east side of the Byward Gate, which is proved from this to date from the reign of Henry VIII., and deserves to be preserved, as one of the only examples of the kind left at the Tower. These wooden erections were by no means uncommon in ancient castles. The beautiful Horse-shoe Cloister at Windsor is a charming example, and we cannot be too grateful to the late Sir Gilbert Scott for the care with which he preserved and restored this interesting feature of Windsor Castle.

It is not our object to describe the various alterations which have from time to time taken place at the Tower. Every one is willing to acknowledge that the earlier attempts at "restoration" were dismal failures, and did

much to rob the noble old fortress of its genuineness and its historical interest. Two of these works are particularly regrettable,—they are the removal of the picturesque old gabled buildings, called "the Seven houses of office," which stood between the White Tower and the Bloody Tower, erected, as is proved, by the survey of 23rd of Henry VIII., at that date, and thus being amongst the earliest examples of Domestic work in London. Their site is now occupied by a kind of open arcade of the most dismal design,—a sad exchange for the quaint old gables, pretty bow-windows, tiled roof, and red-brick chimneys, which formed such a favourite subject for artists thirty years ago. Another work which we deeply regret is the re-working of the entire surface of the interesting old Chapel of St. John in the White Tower. This chapel was probably the most perfect example of an early Norman building in England, but it had been disfigured by being filled with cases for the records which were kept here, and its walls were covered with whitewash. Now it was undoubtedly right to remove the shelves and other modern obstructions, and the whitewash might very properly have been removed, but, when this was done, the greatest possible care should have been taken not to destroy the ancient surface beneath it, because we have distinct documentary evidence that Henry III. decorated this chapel with colour, and vestiges of that scheme of colouring were absolutely to be traced, and were seen by the writer of this article in the years 1848, 1849, and 1850. That no trace of ancient decoration now exists is not to be wondered at, as the ancient surface of the walls and columns has been scraped away and renewed! nor is this the only case in which ancient decoration has been obliterated at the Tower, for in the embrasure of the easternmost window of the Wakefield Tower which evidently served as an oratory, before the altar of which Henry VI. is traditionally asserted to have been kneeling when he was murdered, the traces of two figures were visible before the restoration. The whole restoration of this apartment, now used as a jewel-chamber, is to be regretted, as there can be little doubt that the east window which lighted the oratory was a large one, and the others were mere slits, but, as now restored, all the windows are the same size. It should be noticed that the arrangement of this prison in the Wakefield Tower, with the chapel or oratory formed in the embrasure of the easternmost window, is identical with that of the crypt of the Chapter-house of Westminster Abbey, with the exception that at Westminster there is a central column.

Although the latter restorations are probably more in accordance with ancient precedent than the earlier ones, yet we cannot help asking the question why restore the Tower at all? Why not leave it to tell its own story in its own way, with all its imperfections, incongruities, and patchings up, but with each portion genuine, and not made to look supernaturally Mediaeval. If we want to see Mediaeval castles we can see them elsewhere, but it is a mistake to carry out conjectural ideas of Mediaeval castellated architecture at the expense of a building so historically interesting as the Tower.

We may, of course, be told that "some kind of restoration is necessary in order to render the building practically useful." In other words, to make it serve as a barrack or a store for arms. But why attempt to find such uses for the venerable structure? To our minds, it has a far higher and far nobler use. We are yearly expending millions upon "educating the masses." Now, we would ask, does the Tower teach nothing? Do not its grim walls contain veritable "sermons in stones"? Sermons which preach to us the shortsightedness of human tyranny, and the dignity and nobility of patient suffering for conscience sake? Upon the walls of the Beauchamp Tower is still to be deciphered, the bold signature of Philip Howard (Earl of Arundell), a victim either to the jealousy of Elizabeth or the suspicious tyranny of her ministers; below that signature, and written in another hand, are the words, "*Gloria et honore coronandi cum.*" The palace of the Tower has passed away and is forgotten. The dynasty which put this man to death has ceased to exist, and is chiefly recollected for its cruelty and tyranny; yet this epitaph, though only scratched with a nail, remains more touching in its dignity and simplicity than any in Westminster Abbey!

* See illustration in the present number.

We who enjoy the blessings of liberty of conscience and freedom are, in our ease and luxury, too apt to forget at what a high price those blessings have been bought for us. In putting away from us the thoughts of ancient tyranny and cruelty, we are too apt to overlook the heroism and fortitude with which they were met. The patience under affliction, the long imprisonment, heavily borne, the endurance of torture, nay, even of death, rather than the abandonment of the truth, are lessons taught by many an inscription, device, or monogram in the Tower; and we would ask whether any school can teach nobler lessons, and whether, therefore, the Tower does not deserve to be preserved as a great public teacher and a preacher of the noblest morality? Surely our countrymen must begin to feel that there are things above mere commercial requirements; that public buildings and monuments may be useful and valuable, although you cannot "turn a penny" out of them, or convert them to suit the practical requirements of the age.

H. W. B.

THE IRON TRADE IN 1884.

In reviewing, in these columns, the state of the English iron trade during 1883 at the beginning of last year, the hope was expressed that the new year might not prove worse than its predecessor. It must now be acknowledged that that feeling was doomed to disappointment, for 1884 will take its place as one of the worst years through which the iron trade of Great Britain has yet passed. In 1883 there was still, if not abundance, at least sufficiency, of work; during the past year the falling-off in exports, to which we shall presently refer, not merely reduced the values of every description of iron and steel to a great extent, but it also seriously curtailed employment, and thus brought with it dead loss to the manufacturer and want to his workman. Shipbuilding especially presents a sorry chapter in the industrial history of 1884, the returns from the chief building centres showing a very large reduction in the tonnage produced. It is estimated that the total output of ships, including ports producing small tonnages, has been about 500,000 tons less in 1884 than in the preceding year. This unexampled depression in trade has proved a general calamity to thousands of willing hands and their families, who have been made to feel the pinch of hard times; whilst the restricted inquiry for ship-building material has reduced prices to their lowest level. The failure of the demand from America and the competition of foreigners in markets hitherto considered our own also helped to render the state of the British metallurgical industry still more critical. As in 1883, railway construction in the United States has been comparatively restricted, whilst the producing capacity of American works has grown steadily. As a result, our iron and steel exports to the States in the eleven months ending November 30th last show a total falling-off of 222,000 tons. In this total the decline in exports of hardware and cutlery, as well as of machinery, are not included. In value the total decrease in the eleven months of our iron and steel exports to the United States was 1,662,207. But while the past year has been one of unexampled severity for all engaged in the iron trade, there is every appearance that the worst time has passed, and there exist some grounds for hoping that the year upon which we have just entered will see an amelioration.

The Board of Trade Returns for the first eleven months of the past year show that we exported of pig-iron 262,531 tons less than in the corresponding period of 1883, and it may be safely predicted that the total exports of crude iron for the whole year will fall short by about 300,000 tons. The total deficit in our iron and steel exports for the eleven months ending November 30, 1884, as compared with the previous year, amounts to 497,702 tons. A decline in the exports means decreased production, and, to some extent, increased stocks. The total estimated production of Scotch pig-iron during the year was 998,000 tons, a falling-off of 141,000 tons as compared with 1883, and of 188,000 tons if a comparison be made with the most productive year, 1851. The output of Cleveland pig is about 830,000 tons less than in 1883, having been in 1884, in round numbers, 1,930,000 tons, against 2,760,740 tons in the preceding year. The production of crude iron in other districts has been reduced to a similar extent. The stocks of pig-iron at the end of

1884 were very considerable, and would probably have been the largest ever known if a reduction in the make had not been resolved upon early in the year. There were, in Conall stores, on December 25, 1884, of Scotch pig-iron, 821,000 tons, as against 835,000 tons at the same date in 1883, while the stocks of Cleveland pig have increased some 50,000 tons, notwithstanding the reduced make. The total shipments of Cleveland pig-iron for the year 1884 amounted to 927,456 tons, against 992,815 tons in 1883; of Scotch pig, they were 534,000 tons, against 617,000 tons in 1883.

If we now turn to the subject of prices obtained in 1884 for the various descriptions of iron, we find that the decline in value has been general. And it may be observed here that, although prices dropped much more in 1883 than in 1884, the depreciation in the former year was felt not nearly so much as in the latter, because that year was, on the whole, a better one. Rates had not then reached their bottom, and as there was a comparative abundance of work, manufacturers had not to face the collapse of consumption which was only too palpable last year. It did not matter what reduction they were willing to submit to in the matter of prices, even the most extensive concessions on their part would not have brought them orders, for there was no demand for their products. In the beginning of 1884, on the shutting down of eighteen blast-furnaces in Cleveland, as agreed on by the makers, prices of Cleveland pig went up about 1s. 6d., whilst Scotch pig rose about 9d. per ton. Cleveland No. 3 thus began the year at 37s. f.o.b., and the fluctuations have since then been very trifling; but, notwithstanding the restriction of make and the resistance of producers to reductions,—a resistance which only gave way in the last quarter of the year, as far as price was concerned,—the general tendency of trade has brought the value of Cleveland pig down to about 36s. Scotch pig iron,—that is to say, warrants,—opened at 43s. 9d. in January; from that month the price began slowly to recede, until in June it had reached 41s., when it again took a turn upwards, and, under the effect of speculative influences, reached 44s. 4d. in November; but at the end of the year it had settled down again to 42s. 3d. cash per ton. Amongst finished products, shipbuilding iron, from causes only too well known, has lost most heavily; but it should be pointed out that the growing use of steel instead of iron for ships has also had a lowering effect on ship material. The depreciation that has taken place will be best understood when it is stated that, whilst in December, 1883, the net average price in the North of England of bars, plates, angles, and rails (iron), was 5s. 7s. 11d. per ton, at the end of October, 1884, it had gone down to 5s. 1s. 8½d. The price of common bars in Scotland has declined from 5l. 12s. 6d. to 5l. The price of marked bars in the Black Country was 7l. 10s. in the beginning of the year; at its close, they are nominally the same, but it is a fact well known to the trade that good orders may now be secured at from 10s. to 20s. less per ton. The prices of plates, girders, and bars in Staffordshire have been much affected throughout the year by the competition of ironmasters from the North of England and South Wales, who have imported them at 20s. below native rates. In Lancashire the absence of activity has forced down the price of bars about 10s. per ton below what they were quoted at the beginning of 1884. Bars fetching in January last 6l. to 6l. 2s. 6d. may now be had at 5l. 10s. to 5l. 11s. 3d.

There was one satisfactory feature with regard to the English iron trade in 1884 which should not be overlooked. The rail makers of Great Britain, seeing the profound dullness in the rail trade, agreed early in the year to maintain prices and restrict production. This agreement, together with the establishment of the international syndicate of the rail manufacturers of England, Belgium, and Germany, having a similar aim, has had the effect of raising the price of steel rails from 4l. 5s. to 4l. 15s. per ton in this country, from 120 fr. to 130 fr. in Belgium, whilst in Germany they have maintained their value. The firmness in the rail market has had a beneficial effect on other steel products; but, on the whole, if we except compound armor-plates, and one or two of the industries turning out light steel manufactures, the business done has been unremunerative. There is very little to add concerning the related branches of the iron trade. Ship-

building has been, as we know, as bad as it could well have been. Engineers, if they have not done quite so well as in 1883, have at least had their fair share of work. The triplate trade, on the whole, has been satisfactory, if not prosperous. Fair prices were realised during the first half of 1884, but the declining demand from the United States latterly has depressed rates very much. The hardware industry, owing to keen competition and underselling, has had a bad year, and prices have ruled which must have entailed loss on the manufacturer. But it is now generally conceded that the new year will be a better one for this branch of trade than its predecessor. There have been a few trifling wages disputes in the iron trade, the men having had to submit to the inevitable.

Briefly stated, although the year as a whole has been one of the worst known for some time, the condition of the English iron trade at its close is not much worse than at its beginning. There has been a serious falling-off in exports, and home consumers have been buying only to meet pressing requirements. But when it is considered that the year began with a heavy weight of stocks on hand, and that there has been an unexampled depression in ship-building, the wonder is that the year just closed has not been of a more calamitous nature. There is really no room for despair; the stability of most of our great iron manufacturing firms proves that, if they have not been able to do a flourishing trade, they have secured at least a sound business. They have weathered the storm, and it is this fact which causes us to look with renewed hope to the future.

A few words respecting the condition of the iron trade of the Continent during the past year will not be out of place here. Notwithstanding prohibitive tariffs and protective syndicates, continental iron manufacturers have suffered quite as much as our own. Whether we look to the most "protected" countries,—Austria, France, and Germany,—or to a country where import duties on iron and steel are of the slightest nature, such as Belgium, there has been a general reduction of values. As hitherto, the iron market of this country still asserts its old influence over those of the Continent, although the metallurgical industries of foreign countries have developed immensely during the last twenty years. In Austria, the good times of previous years have been followed by a period of depression, due to various causes, chief amongst which are the gradual emancipation, industrially, of Hungary from the Silesian portion of the Austrian Empire, a diminution in railway construction, the inability of agriculturists to sell their harvest, and the crisis in the sugar trade. But there are various signs that the Austrian iron trade will soon recover its previous activity. The iron manufacturers of Belgium have had a bad year, one of the worst of recent times; the principal hardship with them being not so much an absence of demand, but the large reduction in the value of all descriptions of iron, excepting steel rails, which, from causes already pointed out, have gained. In France the downward course of prices which was a characteristic feature of 1883 has not been arrested in 1884, and iron and steel are now cheaper than ever they have been before in that country. To quote one example. Steel rails, which were sold at the end of 1883 at 170 fr. at works, have recently been disposed of at 120 fr., which is a reduction in price of nearly 30 per cent. German producers have, perhaps, fared best of all. The output of iron and steel, as far as can be ascertained, has not fallen below that of 1883. The decline of the value of products has also not been what could be called ruinous, between 2 and 5 marks per ton, over-production and consequent competition being chiefly responsible for the reduction in value.

Buildings for Poor-Law Administration.—The Guardians of the Poor of the parish of Lambeth have instructed their architect, Mr. T. W. Aldwinckle, to prepare plans for the extension of the laundry and receiving-wards at the new workhouse, Brook-street, Kennington-road.—The Guardians of St. George-in-the-East had before them, at their last meeting, plans prepared by their architects, Messrs. Wilson, Son, & Aldwinckle, for the extension of the workhouse and infirmary, at an estimated cost of 9,500l. The plans were adopted and ordered to be forwarded to the Local Government Board for approval.

FROM PARIS.

The year 1884 has closed rather gloomily in Paris, and the terrors of an epidemic, which remained otherwise extremely mild in character, dealt a fatal blow at Parisian industry, usually so active during the last quarter. Art is affected by the general dulness. The theatres exhibit an alarming decrease in their receipts; public sales, no longer having for their object the famous Basilewski collection, which Russia has carried off from us by the expenditure of millions, are reduced almost to none; private building, but lately so active, has nearly everywhere ceased; in short, all manufacturers, merchants, sculptors, painters, and architects complain bitterly of the uneasiness produced by this unusual stagnation.

It is, then, to be desired that a little vitality should be given to trade by some large enterprise, and for this reason it is much wished here that the sanction of the State should be promptly given to an important undertaking which the Company of the Western Railway proposes to execute with the financial concurrence of the Parisian Municipality. We allude to the opening out and enlarging of the St. Lazare Station, well known to all travellers entering France via Folkestone and Boulogne, and convenient, from its central situation, to both foreign visitors and Parisians. We propose to give later on a drawing of the new buildings, but will confine ourselves at present to saying that an expense of twenty millions will be involved, that the aspect of a rich and populous quarter will be much modified, and a large workshop be open for some years to artisans now without employment.

It is certainly not for the sake of restoring a commercial value to art that a certain number of artists, calling themselves "Independents," have just opened an exhibition of their works in the Champs Elysées; a collection of pictures void of talent or originality, which cannot even pretend to rank with that of the "Impressionists." The "Independents" are nearly all drawn amongst what may be called the dried-up fruits of painting, excluded for ever from the splendid Petit Gallery, Rue de Sèze, has been warmly received by the public. It contains, besides works by Carl Vernet, Gérault, and Ondry, pictures by the most celebrated modern masters (Grôme, Lewis Brown, Jadin, &c.). No other exhibitions are mentioned. The State and the city are arranging for the reception in a building still to be constructed in the Place d'Jena, of the Oriental Museum, generously offered to Paris by M. Guimet, a rich collector, of Lyons. The Government is also occupied in elaborating the plan for the International Exhibition of 1889, of which the site seems to be definitely fixed. It will occupy the Champs de Mars, the Trocadéro, the Invalides, and all that part of the river between the bridges of Jena and the Invalides. We shall often have occasion to return to this subject, connected as it is with international commerce.

As usual, the municipal administration here is giving the impulse to artistic works. It is actively engaged on the new buildings for the School of Medicine, and preparations are being made to lay the foundation-stone of the Sorbonne, of which, later on, we shall furnish a complete view. At the same time, the old orangery of the Luxembourg Gardens is being enlarged and altered to contain the museum of living artists, which the exigencies of parliamentary life have displaced from the ancient palace of the Medici.

On the other hand, the interior of the Hôtel de Ville is nearly completed, and the reception-rooms will soon be put into the hands of decorators and historical painters. In the square of the Hôtel de Ville (to be opened to the public in a few days) a pedestal is being constructed for the statue of Etienne Marcel, executed by M. Jdrac, after a competition. On the quay, not far from the Institute, Conti is also raising a statue of Voltaire on a beautiful pedestal, designed by M. Formigé, a young architect of great talent.

When we have called attention in this rapid review to the restoration of the admirable window glass of St. Etienne du Mont, the incomparable work of our painters on glass of the fifteenth and sixteenth centuries; when we have mentioned the beautiful decoration of the Salle des Maréchaux just finished, by M. Thirion, at the Ministry for War; and when, lastly, we

have announced that M. Ditts, architect of the Hôtel Dieu, has been elected member of the Academy of Fine Art, and that M. Daumet, to whom we owe the splendid Chateau of Chantilly, has been chosen to continue the works at the Church of the Sacré Cœur at Montmartre, begun by the late M. Abadie, we shall have pointed out the chief events of the month just ended.

We cannot conclude without mentioning the irreparable loss which French art has just sustained in the person of Bastien Lepage, dead in the full force of his youth and talent. This artist, so justly appreciated in London, took a marked place here in the new school of painting, which, leaving on one side the traditions of the Roman school, covets itself earnestly to the reproduction of nature in her simplest and truest forms.

Bastien Lepage was only thirty-nine, and his short life was entirely devoted to art, which contained for him the sum of joy and ambition.

A NOTABLE OLD MANSION.

CALENDAR HOUSE, STIRLINGSHIRE.

SCATTERED over the face of the country, ancient castles and Mediaeval family mansions in ruins are well-nigh as plentiful as modern county seats of all grades are, and certainly more plentiful than those distinctly occupying the first and second ranks; but of specimens well mellowed with age, yet still enjoying a condition of habitable usefulness, there are comparatively few to be encountered. Of strongholds of a really remote date handed down to the nineteenth century through an unbroken succession of living and life-like occupants, there are fewer still. A remarkable and now comparatively little noted specimen of the latter exceedingly rare class is to be found in Calendar House, Stirlingshire, the ancient seat of the noble family of the Livingstones, attained after the abortive rising of 1715, and now in possession (mansion-house and estates as well) of the Forbes family. Calendar House, or Calendar Castle as it was formerly called, stands almost on the brink of the renowned Roman barrier constructed from eastern to western seas A.D. 140 by the Emperor Antoninus Pius. Its spacious park marches with the great north road and the main Edinburgh and Glasgow turnpike, which are here one; and the entire message is in the immediate neighbourhood of the municipal burgh of Falkirk, the chief intermediate seat of population between these two cities. Tradition indirectly assigns an exceptionally remote age to the first occupancy of the site as the central rallying-point of a great territorial domain. According to this rather shadowy authority, Kalynter Castle, under some other name perhaps, was a place of strength at the time the Picts found themselves thrust out of that part of the country, and it is left to be inferred that it had been so a long time before that epoch, since there is no traditional or other mention of any kind respecting the first setting up of this ancient fortress, which afterwards received the name of Kalynter or Calendar and has retained it down through the centuries to our own day. Something slightly less intangible than tradition has it that Kalynter was held by the Romans as the villa or place of residence for certain successive officers of the army of invasion and on the line of the military road which accompanied the barrier at a distance of a few hundred yards more or less to the southward, and it is, therefore, safe to assume that while the occupation lasted it could hardly be in other possession than that of the Romans. The invaders were forced to finally abandon the Forth and Clyde line towards the close of the fifth century, and from that time, for some centuries, there is no mention of Kalynter, or of its fortunes while passing through this the most obscure portion of the Scottish annals. Towards the dawning of Mediaeval or modern authentic history, Calendar emerges as the seat of a powerful thanedom, the only instance of the kind ever existing to the south of the Forth. How long this thanedom of Calentyr flourished prior to the first historical mention of it must be matter of conjecture merely. The Calentyr family of that ilk is on record as in possession of title and property at the beginning of the thirteenth century, with the reputation of an establishment so firm that it may well have dated several centuries to the lack of that, if

not actually to a period following shortly on the Roman evacuation. The family stronghold then stood on the same site as that occupied by the Calendar House of our day, and as the structural record of the building has consisted from the earliest traditional and historical times of repairs, enlargements, and alterations only, and never of anything of the nature of a renewal complete, it is altogether probable that some masonry remnant of the original erection of stone succeeding the log fortress of the remote era of the great Caladonian forest, yet lingers within the casing of the existing edifice. It is this feature which is one of the chief attractions of Calendar House for a certain order of mind. The family found in possession in the dawning light of the earlier part of the thirteenth century was that of the Calentyrs, Kalynters, Callenters, or Callenders, regarding whom it is an open question whether they gave their name to the castle and property, or took it therefrom after consolidating proprietary rights. The name first mentioned is Malcolm, to whom succeeded his son, Alwin, and afterwards his grandson Patrick. The latter, espousing the faded cause of Balliol, in the succession wars, was eventually deprived of title and estates by the victorious Bruce, who bestowed them upon Sir Wm. Livingstone, a scion of the Livingstone family of West Lothian, and a tried benchman of his own. This founder of the noble Livingstone family had the craft to secure in marriage Christiane de Calentyr the only child of the forfeited Patrick, and so confirmed his new possession by right of ancient succession, as well as by royal charter. The castle which thus, along with a vast though comparatively worthless acreage there, fell to Bruce's follower, was a strong fortress, as strength was at that time estimated.

The "keep" was a heavy square structure of considerable elevation and immediately protected by a projecting outwork of massive proportions. A deep moat surrounded the castle beyond, at the distance of two or three hundred yards and enclosing some garden and croftland ground, rose a strongly-fortified wall of stone and lime, called the Barbican and quite encircling the fortress proper, access being obtained by one gate only, pointing to the north and jealously strengthened. In this form, affected only by the casual repairs rendered necessary from time to time, the castle of Calendar existed for about four centuries thereafter.

The Livingstones of Calendar gradually grew in power and fame until they vied with the Douglases themselves for the position of premier family of Scotland. Sir Alexander, early in the fifteenth century, figures as regent of the kingdom and custodian of the person of the infant King James II. Sir James, in 1453, was sworn Privy Councillor, and appointed Master of the Royal Household and Great Chamberlain of Scotland, preferments which in that rude age and unsettled country not usually fell to him who was powerful enough to command them. He was afterwards raised to the peerage under the title of Lord Livingstone, and finally closed his career by the side of his royal master on the fatal field of Flodden. Alexander Lord Livingstone, his son, was co-guardian with Lord Erskine of the infant Queen Mary, with full charge of her education. It was he who thwarted the designs of Henry VIII. with regard to the betrothal of the child princess to the English heir, the deed binding the Scottish confederates to an opposition entrance having been signed at Calendar Castle itself. Lord Alexander accompanied the child queen when she went to France upon her thirteenth years of sojourn there, and it is worth mentioning that his youngest daughter, Lady Mary Livingstone of Calendar, was one of the celebrated four Maries chosen when infants to grow to womanhood in the constant companionship of their royal playmate. Lord Alexander died in France, and to him succeeded his eldest son William, brother to the Mary mentioned. On the return of the widowed queen there ensued frequent royal visits to Calendar Castle, the scene of part of her stay during childhood and the home of her fast friends the Livingstones. She died there August 12th, 1502, while upon one of her northern progresses and some time before the king-consort. She was present again in the following year at the christening of an heir to the noble house of Calendar, and only three weeks after her marriage with Darnley the pair

arrived at Callendar over night in passing from Glasgow to Stirling. In December, 1566, the queen, by that time in open rupture with Darnley, touched at Callendar on her way to the christening of the infant James at Stirling, and four weeks subsequently she and her newly-christened child, the future James VI. of Scotland and I. of England, slept one night there. Only ten days subsequently the queen with retinue once again sought the hospitality of her Callendar friends while speeding to the side of her graceless husband, then stricken with small-pox at Glasgow; within a week thereafter returning that way, *en route* for Edinburgh, with the recovering but now sorely-disfigured patient in a travelling litter, on which occasion a night's halt was called at the same always welcome and welcoming refuge. Less than a fortnight subsequently the poor king-consort met his still mysterious fate at Kirk-of-Field, Edinburgh. Six weeks afterwards Queen Mary while on her way from Stirling to Holyrood visited for the last time the familiar battlements of Callendar. She halted but an hour or so, and her small cavalcade had spurred eastwards little more than another hour, when, at Linlithgow, Botwell with 1,000 men at arms at his back swooped down upon his prey, and carried Mary off to a fatal, though only temporary, captivity.

The Lord of Callendar remained a staunch Queen's man in the troubles that ensued; fought at Langside, and accompanied his unhappy mistress on her flight into England. Being afterwards joined by his wife in this voluntary exile, the faithful pair shared the captivity of their mistress up to the very eve of Fotheringay, returning to Callendar only at last to die. Lord Alexander, the son and heir of these, inherited the well-earned confidence of the Stuart family, and when children came of the marriage of young King James with Princess Anne of Denmark, he and Lady Livingstone were solicited to undertake, within their own household, the tutelage and upbringing of the elder born. Under this arrangement the Princess Elizabeth spent her infancy and youth within the family circle of the Livingstones at Callendar Castle, along with a younger sister, who, however, appears to have died early. This Princess Elizabeth afterwards became by foreign marriage Electress Palatine and Queen of Bohemia, and it is through her the present reigning dynasty of Great Britain and Ireland makes good its title to the throne. For these offices and general faithful service and adherence, James raised the house to the dignity of an earldom under the title of Linlithgow, to be shortly followed by the erection of Callendar itself to the rank of an earldom also. One of the most noted members of this remarkable family was James, second son of Alexander the first earl, and afterwards chief of the stock himself. While quite young he entered the service of the great Gustavus of Sweden with a troop of Falkirk volunteers, and there remained for many years, covering himself and his following with widespread renown. On his return, the fame he had carved out for himself was endorsed by the king raising him to a separate peerage as Lord Livingstone of Almond and Falkirk, the Callendar earldom also subsequently falling to him through the failure of his elder brother's line. In the troubles which ensued between Crown and Parliament Earl James remained faithful to the former, first fighting by the side of Montrose, both in Scotland and in England, and then with his personal following at his back sharing in the Scottish raid upon the English Parliamentarians, known as the "Hamilton engagement." After the execution of Charles at Whitehall and Montrose at Edinburgh, Charles II. thought to retrieve fortune by means of the forces of the Scottish estates. On invitation he came from Paris to Scotland and entered upon a disastrous campaign, during a few days of which himself and suite occupied as head-quarters a part of Callendar Castle. On the approach of Cromwell from the east, Charles and the Scottish army withdrew northwards, leaving Callendar in the keeping of a garrison partly made up of the fighting townsmen of Falkirk. Cromwell carried the castle by storm, after a vigorous resistance during which its defenders were cut down almost to a man, the occurrence forming the first recorded instance of Callendar Castle succumbing to an attack of the enemy, though menaced many scores of times before. Earl James was the while with the king within the Scottish lines barely three miles away; and when it was resolved to shirk an issue with the

victorious Cromwell, and rather make for England by forced marches in the hopes of exciting a royalist rising there, Callendar accompanied the enterprise, shared in the Worcester defeat, which followed, and finally accompanied the king on his flight to the Continent where he remained for ten long years, until the epoch of the Restoration. Monk, as Cromwell's Lieutenant in Scotland, occupied the dismantled fortress of Callendar as a residence during the space of no less than five years, and it was from this quarter that, after the death of Cromwell, he marched southward upon London and took crafty order for a masterful restoration of the monarchy. Earl James returned with his sovereign, and in the comparatively peaceful times which followed set himself to the repair of the old castle. The conditions of assault and defence had entirely changed, and no effort was now made to restore it to the grade of an efficient place of strength. The ruins of the outer wall or barbican were removed; the moat began to be filled up gradually; the inner defending curtains were also fully rooted out; and the ancient massive keep of the disrated fortress eventually stood confessed, in the repairs and trifling additions the restored possessor had seen fit to execute. The famous Earl James died peaceably at home after all his wanderings and adventures, and being without issue, was succeeded by his nephew Alexander, who afterwards strange to note sided with the Covenanters against the king, and shared in the misfortunes which fell upon that cause. Deprived, by way of penance, of the old hereditary powers of bailiery and judiciary, &c., Earl Alexander directed his attention to the further improvement of the family mansion, putting such a general face upon it as was destined to remain practically undisturbed for more than a century thereafter. Alexander was succeeded by his son James, fourth Earl of Callendar, who afterwards, through the decease of his uncle without heirs, became also fourth Earl of Linlithgow. James was the last of this noble line. With the customary genius of the family for espousing the side destined to lose, he threw in his lot with the old Pretender in 1715, and for reward had his family attainted; he himself escaping with bare life to the Continent, where ten years afterwards he died, leaving one daughter only. At the date of the attaint, the three earldoms of Callendar, Linlithgow, and Newburgh, along with numerous baronies and other minor honours. The disinherited daughter of the house, Lady Anne Livingstone, afterwards married Earl Kilmarnock. Callendar House and property passed as a purchase speculation from the Crown into the hands of a London concern, called the York Buildings Company; but this syndicate finding it impossible to draw rents from the tenantry, who clamoured for the re-instatement of the old family, concluded a financial agreement with Lord and Lady Kilmarnock, whereby they entered upon a long lease of occupancy with all the functional rights of proprietorship, an arrangement which worked to mutual satisfaction while it lasted. Earl Kilmarnock became implicated in the rising of 1745. The famous battle of Falkirk was fought on the Callendar estate itself, and Prince Charlie, under the very shortlived glimpse of success which immediately succeeded that event, tasted the hospitality of the mansion so familiarly known to his ancestors. The play ended, however, after Culloden, with misguided Kilmarnock on the scaffold at Tower Hill; the widowed Countess of Kilmarnock continued the leasehold of Callendar a few years longer, and then the place knew the ancient family no more.

Callendar House and estates were, in 1780, purchased by a scion of the Forbes family of Colquhany, Aberdeenshire, and in this possession they still remain. Mr. William Forbes, the present proprietor, being the third of the new dynasty and the grandson of the original purchaser. In 1842 the Queen and Prince Albert, shortly after the royal marriage, honoured Callendar with a visit on their way from Stirling to Edinburgh, and were received by Lady Louise Forbes and her son William, the present proprietor, at that time a lad, the lord of the manor himself forming part of the escorting *cortège*. The first of the new line, who wisely refrained from building on a new site though tempted to do so, added wings to the old-fashioned looking mansion, relieved the ancient baldness of the façade by octagonal towers, and remodelled the roof. The second Mr. Forbes

(who for some years sat in Parliament for the county in the Conservative interest) contrived a projection of the central wall of the façade, and erected a new porch and entrance-hall, all with good effect; but to the present proprietor has been left the main work of addition, renewal, and renovation, covering a series of years and finally completed about five years ago only. Callendar House, though the same building in its foundations and principal masonry as that which Cromwell took by storm, is now vastly transformed in the appearance presented to the eye. It is a handsome and spacious edifice unquestionably, yet with a distinct, unmistakable, and very precious flavour of the unceremonious centuries through whose rudeness and hard knocks it has come down undestroyed to our own day. The style may be called Old Baronial, though it cannot be said that the architectural canons have been rigidly adhered to in details. The evidences of conspicuous antiquity are much more numerous inside the edifice than outside. "Queen Mary's Room" which is still maintained in ordinary habitable occupation, shows walls fully 7 ft. thick, a massiveness which is quite matched, if not exceeded, in other parts of the building. The mansion is surrounded by 500 acres of beautifully-wooded grounds, interspersed with orchard, vinery, and garden patches, and rejoicing in various specimens of water ornamentation. The Callendar estate, in its entirety, extends to about 15,000 acres, now for the most part under remunerative cultivation, while beneath the surface valuable mineral strata are abundant.

CIRCULAR HOSPITAL WARDS.

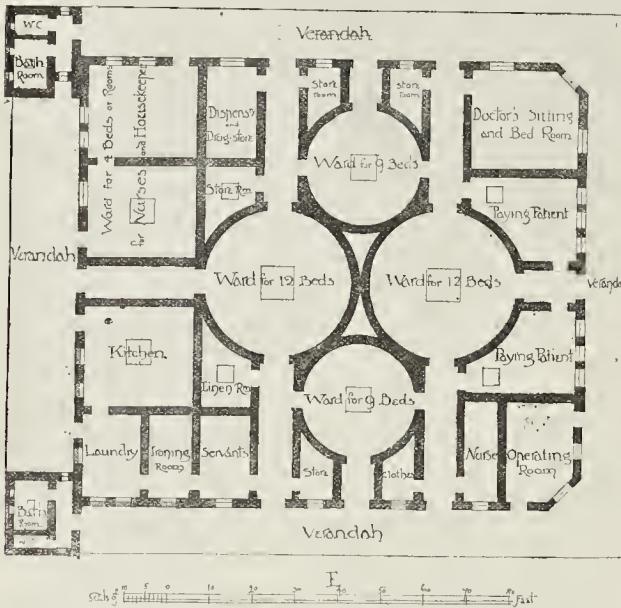

SIR,—In forwarding you, with Lady Strangford's instantly granted and hearty acquiescence, her ladyship's plan for a hospital with circular wards, which is proposed to be built at Fort Said, for our sailors and marines, and is, possibly, to be repeated at Constantinople, I will ask leave to append a few remarks.

Lady Strangford's design is intentionally adapted throughout for an Oriental and hot climate. It is a one-storied building. The four circular wards are placed in the centre of the establishment, so as to be protected from the heat and glare of the sun; with a similar intention, and also to insure quietude, these wards have no windows in their surrounding walls, but they are lighted from above by a lantern-shaped window or opening, which can be completely shuttered on the south; the arrangement by which each ward will admit of three air-currents from the outside is very simple, and most ingeniously carried out; the upward ventilation, characteristic of a domed circular apartment, is here aimed at, and will, I believe, assuredly be effected. The position, size, and mode of appropriation of the several rooms situated around the circular wards have evidently been most carefully thought out. The special sanitary accommodation is judiciously provided for, and the enclosing verandah forms an essential feature of an entirely admirable design, remarkable alike for its symmetry and completeness.

In a letter to me, accompanying her plan, Lady Strangford alludes to the fact that in the East, in Egypt especially, every house "above the peasant's mud cabin has all its rooms domed, except the smallest. The opening above has a lantern-shaped frame for windows, which are seldom put in; the opening is mostly left open to the north, the south being often closed with a board."

But, although Egyptian dwelling-rooms are domed, they are not themselves necessarily or usually circular; and it is the introduction of the circular form for the ward itself, and its completion into the dome above, which constitute the chief element of novelty in Lady Strangford's design. This special adaptation of a "windowless" circle to the requirements of a hospital ward in a hot climate, affords a most interesting example of the application of the circular principle in ward-construction.

Looking at the subject from a purely Oriental standpoint, Lady Strangford remarks that "it must be difficult to render them [circular wards] cheerful" in England. "A windowless room," she observes, "in these climates, and under our terrible skies, is usually very depressing. But in the East, where my practical experience in building has mostly lain, the case is different; and you may like to know that in

HOSPITAL OF ONE STORY, WITH CIRCULAR WARDS, FOR EGYPT,

DESIGNED BY THE VISCOUNTESS STRANGFORD, 1884.

123 ft. by 106 ft. externally.	Walls, 2 ft. thick throughout.
2 circular wards,	12 beds each, equal to 24 beds.
2 " " "	" " 18 "
2 paying-patient wards, 1 or 2 "	" " 2 or 4 beds.
1 ward, if necessary	4 " " 4 "
	41 or 50 beds.

my hospital at Cairo, where we had such an inner domed room, we invariably found, to our surprise, our patients did better there than in any other ward, and were always the most cheerful."

I need hardly point out the emphatic testimony hereby offered against the imputation, or prophecy rather, that a circular ward would be monotonous and depressing. Even when such a ward is "windowless," as in Egypt, this is not found to be the case; and, in England or Belgium, where circular wards are abundantly "windowed," it is quite inconceivable that it should be so, unless, indeed, on the supposition that a very square patient might feel ill at ease in a round place. In relation to this point permit me here to emphasise as strongly as I can the expressions of surprise and delight which I made use of in my address the other evening at the singularly light and cheerful aspect of the interior of one of the large circular wards in the Antwerp Hospital, which I visited last September. Three ladies, members of my family, were equally pleased and astonished.

As to the objection of the possible want of light for the purposes of operation or dressing surgical patients, I may say that it is one which I always thought had no force in it, and it appears to me to be one of those which really have little force except that which every assertion gains by being repeated and repeated. I tested this question at Antwerp. I imagined myself operating, and I placed myself on each side and at the foot of a bed, on which there was a spring-wire mattress, and I found that I could see every wire most distinctly. It seems to me that not only do the numerous cross-lights account for this, but probably, also, there is much light reflected in every direction from the inner smooth and light-coloured surface of the circular walls.

In conclusion, I must thank you for the more than ample justice which you have done to my oral address at the meeting of the Hospital's Association on the 17th inst.;* and I hope that you will allow me on another occasion to communicate to you a few observations on the ventilation of a circular ward.

But I am forgetting Lady Strangford's plan.

* See *Builder* for Dec. 20, 1884.

Lantern of each Room: Windows taken out nearly all the Year.

It is stated in her letter, that it is "drawn for Egypt as the builders there would understand it, and where the construction of domes is extremely cheap and easy."

Lady Strangford tells me that she proposes once a year to strip the circular wards of their destructible contents, to burn these latter outside the building, and to renew them. I suggested that the cremation should take place in the middle of the wards, and by the addition of sulphur or other fumigants, the fire itself would act as a purifier.

I have, indeed, often suggested that circular wards might be built, in sections, of iron, just as large caissons are; and then that they could be lined with wood or other material, which might periodically be burned and renewed.

JOHN MARSHALL, F.R.S.

Royal Institution of Great Britain.

The following are the probable arrangements for the Friday evening meetings before Easter, 1885:—Jan. 10th, Professor Tyndall on Living Contagion; Jan. 23rd, Professor H. N. Mosely, the Fauna of the Sea Shores; Jan. 30th, Professor Ernst Pauer, a short Review of the Works of Living Composers for the Pianoforte (with musical illustrations by Mr. Max Pauer); Feb. 6th, Mr. G. Johnstone Stoney, How Thought presents itself among the Phenomena of Nature; Feb. 13th, Sir John Lubbock, Bart., the Forms of Leaves; Feb. 20th, Mr. William Huggins, the Solar Corona; Feb. 27th, Professor E. Ray Lankester, a Marine Biological Laboratory; March 6th, Charles T. Newton, C.B., the German Discoveries at Pergamun; March 13th, Sir Frederick A. Abel (subject not announced); March 20th, Professor A. W. Bueker, Liquid Films,—a soap bubble; March 27th, Professor Sir Henry E. Roscoe, the Sources of the Coal Tar Colours.

Illustrations.

WINDOW IN SOUTH CHOIR AISLE, SALISBURY.

THE two figures given here form a portion of a window executed by Messrs. Wm. Morris & Co. from the designs of Mr. E. Burne Jones. Colour, alas! is wanting in the representation, but we believe all stained-glass artists will concur with us that attempts to render the glow of translucent glass by means of any sort of colour-printing are little likely to be attended with success. We gave last year a chromolithograph of some decorative design by Mr. Poynter, of which a diaper window formed a part; but in that case the glass was only a subordinate part of the scheme, and only a simple pattern in two or three colours. Mr. Burne Jones's colour is not reducible to the same simple elements, and is, therefore, better not attempted. The other half of the window, containing the two other figures, will follow, and we are enabled, by the kind permission of Mr. Burne Jones and Messrs. Morris, to promise a short series of Mr. Burne Jones's executed designs for stained glass,—a form of art in which his peculiar genius, with its tendency towards simplicity of form combined with richness of colour, seems specially to shine, even more than in his easel paintings.

KEBLE COLLEGE CHAPEL.

ALTHOUGH this chapel has now been in existence for some years, we are not aware that it has been illustrated, and as a specially rich example of modern church architecture, in which an elaborate system of decoration has been carried out, it is a building of which we wish to have a record in our pages. Mr. Butterfield, from whose designs, as is well known, it was erected, sends us the following particulars in regard to the chapel and its decoration.

The principal features of the decoration of the interior are painted glass in the windows, and mosaics in panels on the walls. These illustrate,—as completely as the space will allow, and in some sort after the manner of the Christian year,—the successive dealings of God with His Church; Patriarchal, Jewish, and Christian. They bring out, by means of type and antitype, the relationship of the Old to the New Testament, and show the process of God's gradual revelation of Himself in Christ.

The histories of Noah, Abraham, Joseph, and Moses in twelve of the side panels of the western half or nave of the chapel, with the figures of the twelve minor prophets in the four windows above, and of the four greater prophets with David, Solomon, Samuel, and Elijah in the west window, refer to the earlier dispensations.

A series of events from the New Testament, viz., the Annunciation, the Nativity, Baptism, Crucifixion, and Resurrection of our Lord, represented in mosaic, are placed in panels in the eastern half or choir of the chapel. The Ascension of our Lord is represented in the glass of the east window.

The series of mosaics is continued and completed in a mosaic quatrefoil panel, above the altar-piece below the east window, which represents our Lord as He finally revealed Himself after His Ascension to St. John, in the Isle of Patmos, "one like unto the Son of Man," present in His Church now and till the end, the Church being symbolised by the seven candlesticks around Him, and her chief ministers by the seven stars in His right hand. It conveys to the eye the promise given of His perpetual presence in her.

Christian saints, in mosaic panels on either side of this centre figure, support it. The Greek and Latin Doctors are represented in the four side windows above, the Latin Doctors being in the two windows on the north side.

In the north and south transept windows are central figures of St. Peter and St. Paul, with one of the four Evangelists on either side of each Apostle.

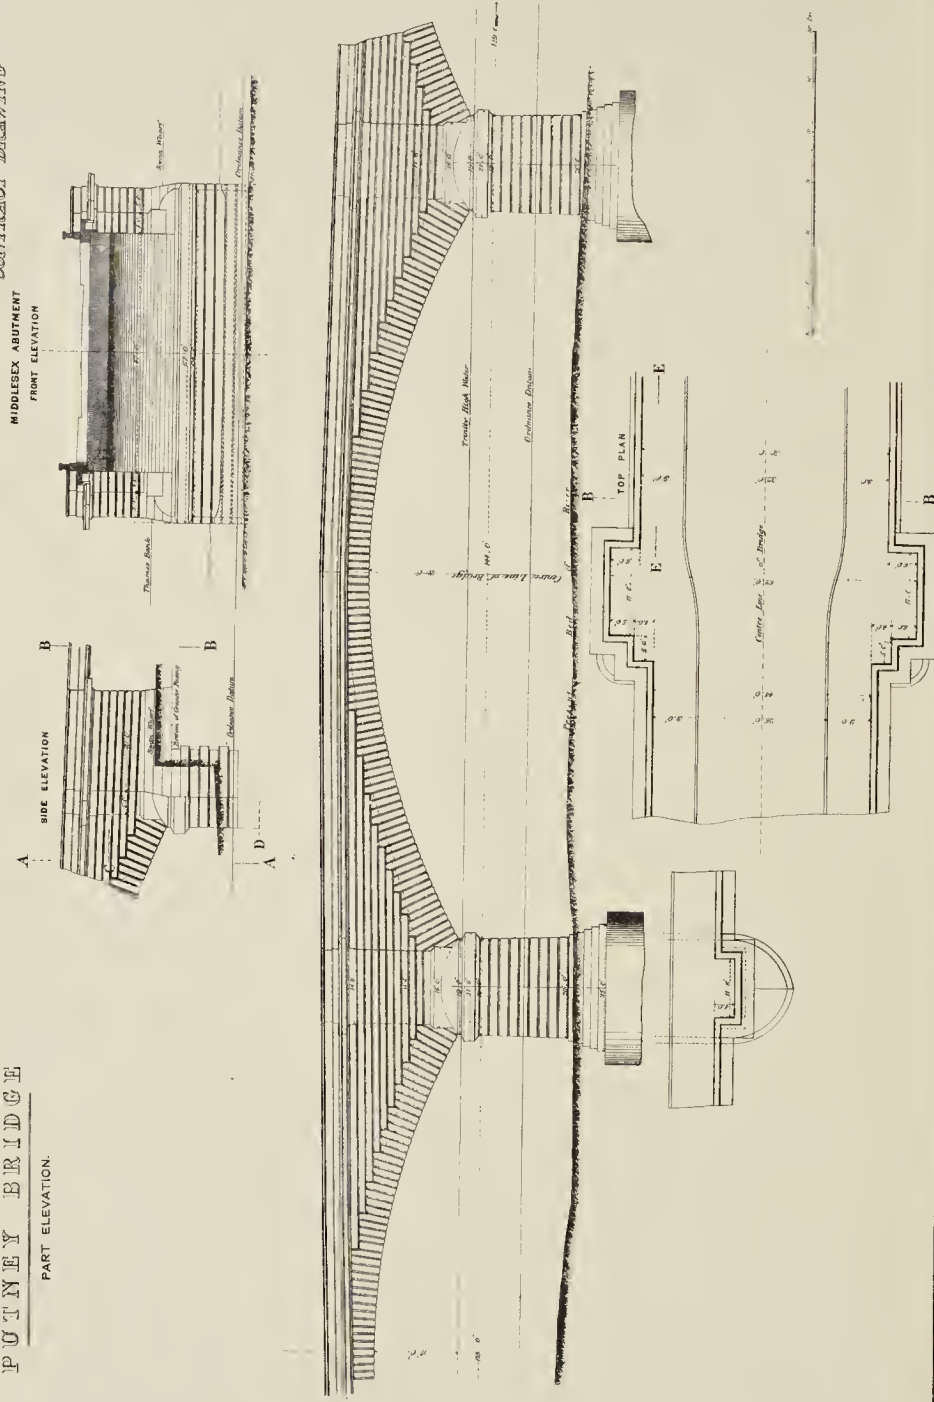

Along the entire west end of the chapel is depicted in three mosaic panels, that future second coming of our Lord to judgment. He is enthroned with the Apostles, and is attended by angels, bearing the instruments of His Passion, the cross, the crown of thorns, the spear, and the nails. The figure of St. Michael the Archangel in the centre of the lower part of this

ture divides the saved on the right hand from a lost upon the left hand of our Lord. Along the foot of the middle panel are the words, Hereafter ye shall see the Son of Man sitting at the right hand of power, and coming in the clouds of heaven."

The outside sculptures are a large figure of St. Michael and the Dragon as a final to the 10th porch; and in the two larger and lower niches at the east end are figures of St. Mary on a buttress and the Archangel Gabriel in a niche to represent the Annunciation.

A figure of Archbishop Longley, the Archbishop of Canterbury, who laid the first stone of the College buildings, which adjoin the chapel, its west end, occurs in the south-west niche that front. A large Agnus Dei in relief surmounts the south entrance doorway.

The chapel was the gift of Mr. W. Gibbs, of Wyntesfield.

The engravings have been executed, from photographs, in the atelier of Mr. J. D. Cooper.

WEST FRONT, TEWKESBURY ABBEY.

This is from a sepia drawing (made some time ago by the present Editor of this Journal) of careful sketches on the spot) of the west front, with its great Norman arch of six orders." It shows the interpolated west window of debased Perpendicular work, about which, and the propriety of taking it out and replacing it by something in keeping with the character of the Norman architecture, there is been much ink shed, and will probably be more. As a matter of fact, the window is either a dilapidated affair, as some people have asserted, nor a fine specimen of late work, as others have still more rashly maintained; it is a bad window in good repair. Such as it is, therefore, it had better be left till it becomes dilapidated, when it will be time to consider how to replace it.

The effect of shadow in the deeply-recessed arch is a reminiscence of the actual effect at a time in the afternoon when the western sun just outlined each arch with a line of rich golden light, emphasising by contrast the overtones recesses of the shadowed portions of the arch, an effect not to be readily forgotten.

DRAWINGS OF ST. STEPHEN'S, WALBROOK.

THESE drawings, by Mr. Edmund H. Sedding, obtained the first Academy Medal for Architectural Drawing this year. As good and careful drawings they merit publication, and may be useful as a trustworthy delineation of the plan and section and main decorative features of Wren's celebrated church, which, as it has been observed, "has given to the narrow lanes of Walbrook a European celebrity," and has received more praise and attention than any building of the same size since the Greek temples,—praise well bestowed on its finely-revised plan and section and spacious appearance, but which must be moderated when we come to consider its decorative detail. However, here is enough in it for modern church-builders to learn a good deal from, when once they will take to planning churches on true architectural and not on archaeological methods.

PUTNEY NEW BRIDGE.

WE give this week reduced fac-similes of a portion of the working drawings for the fine new bridge which is in course of construction at Putney, to replace the old picturesque timber bridge, dear to artists, but for some time past in a shaky state in regard to land traffic (heavy weights, such as steam rollers, have been long since forbidden to cross it), and which has always, from its crowded congeries of piles, and its narrow arches, formed a serious obstruction to the water traffic, more felt as its traffic has been more developed.

Speaking as architects, we may in the first place express our satisfaction that the new bridge is to be of masonry, and not an iron structure. Such a bridge is not only a finer and more monumental-looking object in itself than any form of iron girder bridge can be, but it is in reality far more enduring, and likely to last on the lives of a good many iron bridges. The architectural treatment of the details is particularly striking or original,—if the sole design is not, in its effect, all that some of us think a bridge might be made, even in accordance with the strictest engineering re-

quirements, we may at least feel gratified that the structure is simple, solid, and unpretending, with no false display or striving after effect about it. In this respect it will be the most worthy companion to London and Waterloo bridges which has been erected of late years over the Thames, and is some compensation for the gewgaw sham Gothic of Blackfriars Bridge.

We take from the specification a few notes in regard to the plan and construction of the bridge. The approaches on each side are carried on brick arches with the spandrels filled up solid with concrete. The bridge itself is of granite; the skewbacks of abutments and piers to be composed of blocks of the form and dimensions shown, and not less than 4 ft. on the bed, measuring across the axis of the bridge; the voussoirs are the same minimum width. In setting the stones, vertical strips of lead $\frac{1}{2}$ in. thick, 2 in. wide, and the full depth of the stones in length, are inserted at a distance of 6 in. from each end of each stone, and as each course is completed the joints are filled in between the lead strips with Portland cement and sharp Thames sand (1 and 1).

The whole of the five arches are being carried on simultaneously, so that no arch is at any time more than one course in advance of another. The whole surface of the extrados and skewbacks, on completion, will be covered with Klaridge's asphalt half an inch in thickness, and turned up 6 in. against the inner surface of the outer spandrel walls, the inner spandrel walls being then built of brick. A platform of Bradford landings 9 in. thick will then be laid over the whole. For the carriage-way this will be surmounted by a layer of concrete, and on this the carriage-way will be formed with granite sets. The foot platforms will be formed of 8-in. York stone flagging, and between this and the 6-in. Bradford landings will be laid the water-pipes which are now carried on an aqueduct parallel to the old bridge, allowing room for a future water-main to be laid eventually by the Chelsea waterworks company. The space round the pipes to be filled up with sand, on which the flags will be bedded. This is all clearly shown in the section of the bridge.

The cement used is Portland of the best quality; the briquettes to stand a tensile strain of 170 lb. per square inch twenty-eight days after they are made. All lime is from the lower or hardened beds of blue lias formation. Cement concrete, one of cement to eight of ballast; lime concrete, one of lime to six of ballast. Concrete filling to be in layers of not more than 12 in., each layer to lie at least three days before the next is added.

In making the foundations iron caissons in two lengths, with a detachable but water-tight joint, have been used. The lower caisson, constructed with a cutting edge at the bottom, was principally to facilitate the excavation of soil, the upper one to shield the piers while building. The lower caissons, three to each pier (see smaller section drawing), consist of two skins of rolled wrought-iron plates, the outer skin $\frac{1}{2}$ in., the inner one $\frac{3}{8}$ in., with a space of 3 ft. 6 in. between them. As the caissons were separately lowered by four lowering screws to each caisson, their weight was increased by filling the space between the skins with concrete. When each caisson was on its final foundation level the cutting edges were underpinned with Bramley Fall stones, 4 ft. by 4 ft. by 2 ft. on a bed of 12 in. of concrete between the stones and the river clay, the caissons were gradually filled up internally with successive 12 in. layers of concrete level with their rims, and the brick-footing laid on this basis.

The arches are being turned on nine wrought-iron ribs to each arch, as shown on the drawings, the ironwork being specified to be "of as good and finished a quality as if it were intended for permanent work." The sight of these business-like girders has led some people to suppose the bridge was to be of iron construction; it is so referred to by Mr. Ernest George in the note to his etching of the old Battersea Bridge. He will probably be glad to find he is mistaken. The iron centres are carried, as will be seen, on a series of piled timber piers, which in themselves have formed no slight piece of work, the necessity of keeping an open waterway throwing some extra difficulty in the way. We give *verbatim* a part of the specification referring to this portion of the work:—

"When the eight piles are driven to their proper depth, they are to be securely cramped together with twenty wrought-iron timber dogs to each support, and are then to have their collars removed and the heads sawn off level,

so as to give a perfectly true and even bearing to the cross-head-piece, which is to be set true and carefully on each of four piles, so as to distribute the weight uniformly on each single pile. All piles are to be shod with wrought-iron shoes, not less than 15 lb. each, and strong iron hoops also to the heads, the iron 4 in. broad by 1 in. thick. On the top of these cross heads, of which there are two to each support, is to be set the lower and upper sill, both of elm, and to be carefully-selected timber, as between these sills are to be placed the wedges, and the bearing surfaces between the wedges and that come on the cross heads must be adzed to a true and accurate line so as to allow of the same thickness of wedges throughout, and the parts that are directly under the cast-iron bed-plate to be of one uniform level. When the lower sill is fixed in position and securely fastened with dogs, driven in the sides and to each cross head, the wedges are to be placed longitudinally with it, and care taken to have them fixed across the centre line of the girders. These wedges are to be of oak, selected timber fully seasoned, and are to be carefully sawn to the given form, and a template is to be submitted for the Engineer's approval before they are fixed. When the wedges are fixed the top sill is to be placed in position on the top of them, but care must be taken that the distance between the sills before the girders are fixed is not less than 1 ft., so as to have as little raising of the girders by the wedges as possible, and to have as much lowering space for the girders as can be obtained when the centres are 'struck.' Between the main support and the single pile that carries the end of the girder an intermediate set of piles or supports to be driven under the same conditions as those heretofore described, and in the same line, and to be dugged securely together. The single pile next to the masonry is to be placed upright in position and in the pocket left in the masonry, and the foot of the pile sawn off square, so as to allow of the giving its full bearing on the concrete. When all the piles are fixed in their proper position, the 12 in. by 12 in. 'stringers' are to be fixed, care being taken that the faces or parts of timber that are in contact are to come close together to allow of their being bolted together with 1-in. wrought-iron bolts, with 4-in. square washers $\frac{1}{2}$ in. thick, and in no case any small packing or make-up pieces are to be used. In every alternate bay, or 11 ft. 4 in. apart, is to be fixed crossed single hacing 12 ft. by 6 ft. as shown, bolted securely to the top, and half-way down the piles, and fixed between the 12 ft. by 12 ft. stringers. The entire face of the 60-ft. opening are to be covered with 12 ft. by 6 ft. sling pieces, fixed 12 in. apart, and to be securely spiked to the main piles, and all corners or unsecured openings are to be enabled a smooth evenness is to be adzed off, so as to enable a smooth passage to any craft going through the opening. When all the piles are driven, and all bracing or wallings are fixed complete, the girders A may be fixed or built in their places, namely 5 ft. 8 in. apart from centre to centre, care being taken that the cast-iron bed-plates come over the centre of the supports."

The approaches have been protected, as shown on the drawings, by "dolphins" consisting of five main piles, canting outwards from the 20-ft. waterway left under the centering, and by floating booms rising and falling in guides, with the tide. The ends only of these booms are seen on the drawing.

The contract includes the entire removal of old Putney Bridge, the materials of which are to become the property of the contractor.

It is expected that the new bridge will be completed within a year from this time.

The design of the bridge is by Sir J. Bazalgette, Chief Engineer to the Board of Works, and Mr. E. Bazalgette has had the immediate direction of the works. The contractor is Mr. John Waddell, of Edinburgh, and the amount of the contract is £24,000.

THE TOWER OF LONDON IN THE TIME OF ELIZABETH.

Paris International Exhibition, 1885.—

It is the intention of the Minister of Commerce to have exhibited a collection of teaching material and specimens of results from French schools. The Educational Section in Group V. (Classes 33 to 44) will comprise plans, models, &c., of schools and other institutions, teaching appliances, gymnastics, military exercises, and equipments, &c., printing and books, stationery, office furniture, photography, and musical instruments. In the scientific annex will be included geology, ethnography, discoveries, instruments and apparatus for medicine, surgery, astronomy, geography, weights and measures, and money of different nations. The artistic annex is to comprise paintings, sculptures, architectural models and designs, reproduction of ancient and modern monuments, paintings on enamel, porcelain, medals, &c., and the industrial arts. The London offices are at 1, Castle-street, Holborn, where applications for the remaining available space and all communications from British exhibitors should be addressed to Mr. Edmund Johnson, Commissaire Délégué.

THE INSTITUTION OF CIVIL
ENGINEERS.

In conformity with the by-laws, the annual general meeting was held on the 23rd of December, "being the Tuesday previous to Christmas Eve," the President, Sir J. W. Bazalgette, C.B., in the chair.

In the report of the Council it was remarked that it might be convenient to take, as a starting-point, the condition of the Institution when the present by-laws were enacted on the 2nd of December, 1878. Then the strength consisted, irrespective of the students, of 2,815 of all other classes, now that number was 3,782, or an increase of 34 per cent. in six years. During the past session there had been 279 elections, while the deductions from deaths, resignations, and erasures, were 85, leaving a net effective increase of 194, or 5½ per cent. in the twelve months. Out of the elections 100 candidates were resident beyond the sea, a proof that engineers in the Colonies were well satisfied with the way in which the affairs of the Institution were conducted and administered.

The death of Mr. Charles Manby, who was for seventeen years the secretary, and had since 1856 been the honorary secretary, had removed from the books one who had taken for many years a leading part in the conduct of the affairs of the Institution. By his tact and energy at an early and critical period of its history, he had managed to secure the co-operation of the principal members of the profession, and of scientific men generally, and thus laid the foundation for its present reputation and success.

The changes in the class of students had been very numerous; for, although there were 170 admissions, exactly the same number had disappeared from the list, of whom 71 had become Associate Members. The total remained the same, 722, as at the close of last year. Of the 1,984 Students admitted since the creation of the class seventeen years ago, 48 were now Members, 515 Associate Members, and 6 Associates. As greater activity had of late been displayed by the students, the Council had sanctioned, as an experiment, the announcement of twelve meetings for Students only for the Session 1884-85, three before Christmas, and nine afterwards, at fortnightly intervals. No paper would, after the current session, be received from a student, in competition for the Miller Scholarship and the Miller Prizes, when he was qualified by age, viz., twenty-five years, for election into the Corporation.

As there seemed to be a strong desire, among many non-resident members, that the day for holding the Annual General Meeting should be altered, the out-going Council expressed the hope that its successor would see fit to convene a Special General Meeting, at an early and convenient date, for the purpose of considering the propriety, and, if approved, of making the necessary alteration in the By-laws to effect the change.

The statement of receipts and payments, for the year ended the 30th of November, showed that the income proper had amounted to 14,202. 17s. 3d., of which 1,769. 17s. 5d. arose from dividends on Institution investments, aggregating 48,000., and mainly placed in Debenture Stocks of British Railway Companies. There had also been received 3,495. 9s. from life compositions and the admission fees of new members, which were treated as capital, and 432. 11s. 2d. from dividends on Trust investments, the total of which was represented by 14,612. 13s. 10d., almost entirely standing in Government Stocks. On the other side of the account, the general expenditure had been 12,470. 18s. 5d., of which 6,193. 15s. 5d. had been applied in the production of the publications, about 25,000 volumes in all, which were delivered free of charge to all members wherever resident. The capital investments during the year had amounted to 5,322. 3s. 8d., and the premiums under trust had absorbed 516. 11s. 11d.

The Council were directed to arrange for the publication of the papers read at the Ordinary Meetings, and of such other documents as might be calculated to advance professional knowledge, in aid of the public and scientific objects for which the Society was founded.

The ballot for Council for the ensuing year resulted in the election of Sir Frederick Bramwell, F.R.S., as President; of Mr. E. Woods, Mr. G. B. Bruce, Sir John Coode, and Mr. G. Berkeley, as Vice-presidents; and of Mr. B. Baker, Mr. J. W. Barry, Sir Henry Bossemer,

Lamp-Standard. Eaton Hall.

F.R.S., Mr. E. A. Cowper, Sir James N. Douglass, Mr. C. D. Fox, Mr. A. Giles, M.P., Mr. H. Hayter, Dr. W. Pole, F.R.S., Mr. W. H. Preece, F.R.S., Sir Robert Rawlinson, C.B., Sir E. J. Reed, K.C.B., P.R.S., M.P., Mr. F. C. Stileman, Sir William Thomson, F.R.S., and Sir Joseph Whitworth, bart., F.R.S., as other members of Council.

Earthquakes in Spain.—Accounts from the southern provinces represent the earthquake on Christmas Day as much more serious than it was at first reported. In many towns and villages of the provinces of Granada and Malaga buildings were completely razed to the ground, and many more damaged beyond repair. In the town of Albuquerques half the houses are said to be destroyed. The loss of life is considerable. A private letter from Malaga says that seven distinct shocks were felt in the town, the first being very severe and lasting quite fifteen seconds. The Government Commissioners, who have begun their visit to the rural districts, state that 102 houses have been buried at Alhama. At Albuquerques 1,000 dwellings were destroyed. In the Academy of Arts, in Madrid, on Tuesday night, a report was read showing that the earthquake inflicted only slight damage upon the cathedrals at Seville and Granada, and that all other monuments escaped.

WROUGHT-IRON LAMP STANDARD,
EATON HALL.

The standard is 30 ft. high. The panels are symbolical of the arms of the Grosvenor family, the portcullis with the attendant chains forming part of the ornament. The Tudor rose above is skilfully wrought out of sheet-iron enclosed in a frame-work. The column terminates with four arms. The lamps are surmounted by dual strawberry leaves; the top terminates with a thistle, his Grace being a Knight of the Thistle. The lamps are supported by an elaborate spandrel. The weight of the whole fabric is over two tons, and is entirely of wrought-iron, and in no case has cast or malleable iron been introduced. The whole was designed by Mr. Fairfax B. Wade, and is one of a series now being erected on the terrace in front of Eaton Hall, Chester. The work has been carried out by Messrs. Alfred Newman & Co.

Change of Address.—Mr. A. Newman, some of whose work we illustrate in another column, has just removed his forge from Marlborough-mews to Archer-street, Haymarket, as he informs us by means of a characteristically Medieval circular.

A NEW HAND-SAW FILING MACHINE.

AN efficient hand-saw filing machine has long been a want in the building and kindred trades, and this want appears to be fully supplied in the very ingenious machine introduced to the public by Messrs. Selig, Sonenthal, & Co., of Queen Victoria-street. It is an American invention, and it may be stated at once that the machine is not intended to supersede the file, but to use it with better effect, and with a saving in the cost of files, hand-saws, and wages. Amongst its chief advantages, it files with an ordinary $\frac{5}{16}$ in. taper saw file, or with any other file of the same length suitable for the shape of the tooth. It can be worked by hand or steam power. It is easily adjustable to various widths of saw-blades, up to $2\frac{1}{2}$ in., and to different pitches of teeth. It files eighty teeth per minute, doing the work regularly, and saving the tedious process of finishing the blades. The machine only occupies a small space, 16 in. by 22 in. In mounting or fixing for use, it is screwed to a table, or down on an ordinary bench, wooden supports being placed on each side to guide the saw. To the left of the machine, revolving easily upon a fixed vertical spindle, a wooden disc is necessary to the support, the saw-blade running round the disc during the filing, and passing in its circuit transversely through the vice of the machine. The blade being adjusted in the vice, and the motive power applied, the file must commence to cut in the centre of the inclined or sloping part of the tooth, and, as it moves forward, is brought on to the upright or cutting edge. The principle of the cam is effectively applied, and the filing action through which the file is raised and withdrawn after each filing operation, to be again instantly moved forward to its work, is singularly steady and regular.

By means of the accompanying illustration, the chief points of the machine may be clearly seen. Before fixing the blade in the vice, A, and commencing operations, the spring, B, in the movable arm, C, must be raised and turned slightly to the left, when the arm can be raised vertically. The thumbscrew, D, on the spindle of the hand-wheel, E, is next loosened and the hand-wheel turned so as to bring down the adjustable carriers in the vice. The blade is then pressed down between the vice and the spring on to the corners and the hand-wheel turned so that the teeth may be sufficiently protruded to allow the file to clear the vice, after which the thumbscrew is tightened up. The movable arm is rested upon the screw-head, F, which latter must be raised enough to keep the file from touching the saw. On to the blade the feed-pawl, G, is then dropped, its stroke being regulated by the graduated quadrant, H, to the length of about a tooth and a half to one revolution of the pulley. The screw holding the index-head must be securely tightened, and the screw-head, F, lowered sufficiently to give the file the light or heavy cut required; then tighten when adjusted. When the file moves from the centre of the tooth and is brought forward in its action to the upright or cutting edge, the latter cut, if it be too heavy, is remedied by moving up the front spring on Standard I. (If too light the back spring is screwed up), but not so tightly as to prevent the file after the cut from easily leaving the tooth. When the file is worn, or so far used up that it loses its bite, the spring, B, must be replaced on the movable arm and regulated by the screw. If it should occur that the file springs out work easily against the upright edge of the tooth, it may be that the pawl makes too long a stroke, which can easily be shortened. It will be found while the file is sharp the weight of the arm is sufficient, unless the longer teeth of uneven blades are to be filed off quickly, but by

keeping the arm upon the screw-head, F, the cut will be prevented from being irregular. It will be necessary to keep the journals of the machine well lubricated, including both ends of the eccentric rod, K, the sliding pieces, L, the hole in the pawl, the pin in the small disc, M, and the eccentric, O.

In filing uneven blades, the machine should be adjusted for taking off the larger teeth first, passing the blade through several times, until it is found that the teeth are of uniform height; but new blades, or blades finished in the machine, are sharpened by passing through once.

On the whole, we are favourably impressed with the construction and working of the machine.

EDINBURGH.

DR. ROWAND ANDERSON has completed the plans for the building to be erected in Queen-street for the joint accommodation of the National Portrait Gallery and the Museum of Antiquities, and they have been approved of. The design is carried out in the thirteenth-century Gothic style which the architect has adopted by considerations of utility as well as beauty, the style being one which readily adapts itself to the providing of sufficient window openings for such of the galleries as require to be lighted from the sides. The elevation is divided into three stories, the lower two of which are lighted by large pointed windows, the third story presenting a broad unperforated surface, the light of the third floor being entirely derived from the roof. The entrance is in the centre of the north front, and consists of a deeply-recessed pointed doorway, having a row of niches over it, above which appears a triplet window, the whole culminating in a gable. The piers between the windows of the first floor are formed into niches with pinnacled canopies, in which it is proposed to place life-size statues of celebrities. Provision is made in the design for future extensions in the form of wings, and alternative elevations of these proposed additions are shown, one having angle turrets at the four corners and the other without these features. A temporary structure of brick lined with wood is to be placed on part of the ground to be used as a place of exhibition pending the erection of the permanent galleries.

The Scottish admirers of the late Dean Stanley, desirous of showing their sympathy with the liberal and enlightened opinions of the Dean in regard to the civil and ecclesiastical history of Scotland, have arranged that a suitable memorial of him should be placed in St. Giles's Cathedral. This is to take the form of a mural tablet having as its principal feature a replica of the profile in bronze of the Dean which has been placed in St. George's Chapel, Windsor. The site of the memorial is in the south transept, adjoining the royal pew. Three new stained-glass windows are at present being placed in the south transept, and it has been found that the royal pew will obstruct the view of these. This pew originally stood facing the chancel, having at its back the bare, unperforated wall, which cut off the choir from the rest of the interior. It is much too cumbersome

for its present position, and it is proposed to utilise it in forming a screen across the interior of the west doorway. A new pew, of a less ponderous description, will take its place, and this, like the original one, will be of oak, with appropriate carved decoration.

Two new police stations have been sanctioned, both of considerable dimensions. One of these, in the West Port, has been in hand for some time, and the other, in the Causewayside, will be commenced forthwith. They are both designed in Scottish Baronial style, by Mr. Robert Morham, city architect. Objection was made to the design of these buildings by a member of the Town Council, on the ground that they were ornamental, but one of the magistrates, who is himself a practical builder, said that the estimates for the buildings were very moderate, considering the amount of accommodation required; and the Lord Provost remarked that a public building should have some distinguishing mark, and that it would not be appropriate without ornamentation of some kind.

BELL-RINGING.

SIR,—Having received my *Builder* to-day, and during twenty years past, I am greatly astounded at the "Note" about church bells. On a recent occasion, in back issues, several letters appeared, relative to suggestions to "gentlemen ringers" about fifteen years back. It must not be forgotten that changing-ringing is the only recreation for a great many young men, in large and small towns. In the country, the tower is generally in the hands of a set of sulky louts, who will neither learn the elements of the science nor let others more intelligent make the attempt to do so.

With respect to Kensington, the matter is perfectly remedial; as, in fact, everywhere else.

Let the architect provide shutters to the inside of the bell-chamber windows, and during ringing, and heavy storms keep them all shut. During ringing, in this instance the sound will pass up the spire, and fall, not in the nearest windows, but half a mile distant.

Having applied this scheme to my own parish church, where the bells are heavy, and often practised, the residents round the church cannot hear the bells at all in their shops and private dwellings.

This has been also carried into effect at Sir G. Scott's cathedral in Edinburgh, which what effect I cannot say, but am informed that the disagreeable clang due to re-echo against near walls is entirely removed.

Surely it is far better to have a good ring in one place, such as an important parish church, than having bell-lovers like myself erecting light rings in their own dwellings, which result would certainly follow any legislation against church bells. Greater nuisances than changing-ringing require putting down, such as organ grinding and piano-playing all night. The most the Kensington people have to put up with is but two hours in each week,—probably much less. The grand ring of ten at St. Clement Danes was never complained of by the patients in King's College Hospital; nor, as far as I know, any of the well-known bells round other hospitals.

FRANCIS GRAYLING, F.R.C.P.,
Member of the Ancient Society of Church Youths,
Sittingbourne, Dec. 25.

DR. JOHNSON'S HOUSE IN BOLT COURT.

SIR,—There is a slight inaccuracy in your number for Dec. 13 [p. 787] with reference to the Stationers' Company's School in Bolt-court and the house in which Dr. Johnson lived and died. I would point out that the school premises proper and the school-house or residence of the head-master (generally supposed to be Dr. Johnson's old house) are two distinct buildings, and of different dates. The former, which is quite a modern structure, of not more than twenty-five or twenty-six years old, was erected by the Stationers' Company expressly for their school; but the latter,—the school-house,—was purchased by them as it now stands, and is a much older structure altogether. It is a large old-fashioned residential building, and, from the general character of its architecture and its internal fittings, would seem to be of a date contemporary with Dr. Johnson. The house in which the Doctor died you state was completely destroyed by fire in 1819, which I am inclined to doubt, because that would make the present house which stands on its site not much more than thirty years old,—that is, supposing it to have been rebuilt immediately after the fire. But the house in question has all the appearance of being much older than that. From the size and number of the rooms, the thickness of the walls, the old-fashioned doors and window-shutters, &c., I should conclude that the old house was not so completely destroyed by fire as you state, but that, though greatly damaged, it was afterwards restored to much of its original condition, in which case the present school-house may fairly be considered as very nearly identical with the house in which the Doctor breathed his last.

With regard to the numbering of the houses, there has evidently been at some time an alteration in the houses in the court, and a little confusion has been thus introduced into the numbers, which I am not in any way able to elucidate.

F. HOWARD,
Assistant Master, Stationers' School.

** We fail to discover what inaccuracy Mr. Howard would correct. The facts are as stated. As to No. 6, Bolt-court, there is certainly one room,—the class-room on the ground-floor to the left,—which has an eighteenth-century air. We find nothing else to warrant Mr. Howard's conclusion as to the age of the interior, which, however, is substantial and old-fashioned. Then as to No. 8, Bolt-court, contrasting the new house from without with,—

(a) The coloured drawing, signed and dated "C. Tomkins, 1801," in vol. viii., Crowle Pennant, showing a dark brick house with red brick vousoirs over windows;

(b) The view of 1810 (G. Shepherd, delin.; S. Rawles, sculpt.), in the Crace Collection, British Museum;

(c) The view in Soane Museum; and

(d) The view by C. J. Smith in vol. vii., Croker's "Boswell," Bonn, 1848.

It will appear how the front elevation,—like in those,—differs from the present; and strikingly in that the central line windows which light the staircase in the existing house are upon a different level from the other windows, and have deep round-headed reveals.

Moreover, conclusive proof of what we said will be found in *All the Year Round* for the 9th of July, 1859. Therein is quoted a passage supplied to Dickens by Mr. Bensley, son and successor to the Bensley who succeeded Sam. Richardson and Allen, Johnson's friend. Born in Johnson's house, Bensley lived there, and in the house which replaced it after the fire of 1819 until the sale to the Stationer's Company, 1858. He says, *inter alia*, that the fire totally consumed Johnson's residence.

Cassell's "Old and New London" makes a hash of the whole thing, vol. i., pp. 112-13. Thornbury's blunders (for he, we believe, wrote the earlier part of that work) are crowned by the illustration. This, professing "No. 8," is in reality No. 3, a house on the eastern side of the court, which has always belonged to the Medical Society of London (lately removed to Chandos-street, W.), and where until lately their meetings were held. The original rooms are now occupied by Mr. Parker, a surgeon. The house is distinguished by the figured medallion over the door, once gilt. It is a much older house than No. 6, the Stationers' School-house.

It may be added that in the *Builder* for Sept. 12, 1857, there were given views of Dr. Johnson's chambers in Hare-court and Inner Temple-lane.

RATES IN THE INNS OF COURT.

SIR,—In your "Notes" of last week [p. 839] I observe a statement is put forth that the Inns of Court and some other Inns are exempted from any payment of local rates, being themselves extra-parochial. So far as regards one of the places mentioned, *viz.*, Gray's Inn, I for one can speak quite feelingly to the contrary, having myself contributed as lessee and occupier of a set of chambers in this Inn,—year by year for nearly ten years past,—my quota to the Poor, School Board, and other rates, which are duly made and levied by the constituted authorities at least twice a year.

LEONARD F. CLOW.

PROVINCIAL NEWS.

Bristol.—The extensive factory which the well-known firm of Messrs. W. D. and H. O. Wills, tobacco manufacturers, of Redcliff-street, are about to erect in East-street, Bedminster, has been commenced, and the work is now in full operation. The site is that formerly occupied by Rake's tannery, and the building when erected will be one of the largest tobacco factories in the country. It will have a frontage to East-street of 260 ft., and a depth of 295 ft. The front elevation will be Gothic in character, and the materials used will be Cattybrook faced bricks, with freestone dressings. Mr. Frank Wills is the architect, and the general building contract has been let to Mr. A. J. Beaven, of Bedminster, and Mr. Henry Sampson, also of Bedminster, is the contractor for the iron-work and fire-proof floors, the amount of their joint tender being 27,900l.

Boston.—On the 15th ult. a new dock was opened at Boston, Lincolnshire. The dock, which is situate near to the town and close to the people's Park, is 825 ft. long and 450 ft. wide, the water area being upwards of seven acres. The lock is 300 ft. long and 50 ft. wide, having two pairs of gates. The walls of the dock are vertical, 32 ft. 6 in. high from floor to coping, and 15 ft. thick at the base, built of concrete, the upper part, where the ships come in contact with the walls, being lined with

Staffordshire blue bricks. The coping is hard sandstone. The dock is connected with the Great Northern Railway by a swing bridge across the haven of the river Witham, and the quays are provided with sidings in connexion with the railway. There are capacious granaries for storing purposes, travelling cranes, large fixed cranes, &c. A coal hoist, worked by hydraulic power, and capable of filling a ship of a thousand tons during one tide, has been erected on one of the quays. The hoist is capable of discharging either drop, bottom, or end delivery trucks, and is so arranged as to deliver the coal with as little breakage as possible. The foundation of the lock is composed of cement concrete, and rests on a bed of very hard clay. The invert is of sandstone, and the walls of concrete, lined with Staffordshire bricks. The sills and hollow quoins are of granite. The lock gates are of pitch-pine, with greenheart heel-posts, mitre-posts, and bottom ribs. Each gate is 29 ft. 6 in. long, 32 ft. high, and 2 ft. 7 in. thick. The sluices are disposed in the side walls, and so arranged as to scour the mud from the back of the gates and lock pits. A wooden pier extends from the mouth of the lock to the channel with hollards, and there are other conveniences for getting vessels in and out. A jetty extends from the lock wall along the river parallel with the dock, with landing-stages, stops, and sidings to the railway. The swing-bridge is of wrought iron, 126 ft. long and 13 ft. wide. It swings on an oval-shaped cast-iron pier sunk in the middle of the river. It is expected that a large coal transport trade will take place from Boston, which is now by far the nearest port to the collieries of Nottingham and South Yorkshire, and also the nearest port for the great commercial centres of the midland counties. Arrangements have already been made for a large import timber trade from the Baltic, a considerable portion of the dock quays having already been taken for storing. The port will be useful for fishing-smack purposes, and a large fishing trade is anticipated. The cost of the dock, including hydraulic power, warehouses, &c., has been about 120,000l. The plans for the dock were prepared by Mr. W. H. Wheeler, C.E., the borough engineer, and the consulting engineer has been Mr. J. Abernethy, Past-President of the Society of Engineers. The improvement of the outfall has been recently completed at a cost of 100,000l., a new channel having been cut through the clays at the mouth of the Witham. On the following day a new iron railway bridge, 300 ft. long, crossing the Witham near the Grand Sluice at Boston, was tested and opened for traffic. The bridge, which has cost from 12,000l. to 14,000l., has been constructed by Mr. Matthew Pitts, of Leeds, from designs by Mr. Richard Johnson, chief engineer of the Great Northern Railway, and carried out under the supervision of Mr. Charles Kirby, district engineer. It crosses the river in three spans. The central supports are six cylinders, sunk 25 ft. below the bed of the river, and brick abutments resting on piles form the end supports.

Leicester.—A new hosiery factory, which has been taken by Messrs. I. & R. Morley, has just been erected by Mr. Thomas Jones. The builder was Mr. Harry Bland, of Oxford-street, Leicester. The new building, a lofty structure of three storeys, occupies a site opposite the Board schools and chapel, covering an area of about 1,200 yards. The basement is fitted up as a "strong room," 110 ft. by 42 ft., for the storage of yarn and manufactured goods. At the rear of the warehouse stands the ground-floor factory, 110 ft. by 42 ft. and the engine room, containing two 30-h.p. boilers by Hawksley, Wild, & Co., of Sheffield, and a ponderous engine by Mr. T. Bates, of Sowerby Bridge, Lancashire. Connected with the boiler-house is a chimney, the dimensions of which are, height 120 ft., diameter at base 11 ft., and at summit 5 ft. The chimney stands upon a foundation of fifty tons of stone, and is constructed of pressed Coalville bricks, with blue brick angles. The cap is a speciality, being designed in pressed brick relieved with Derbyshire stone; it is altogether devoid of projections. The first floor is divided into warehouse and factory, the former 64 ft. by 32 ft., and the latter 120 ft. by 43 ft. Each department is fitted with separate lavatories, &c., in fact, this remark applies to the whole building. The second and third storeys are also devoted to a factory and warehouse upon each floor. The rooms

are lofty, and ventilation is obtained by means of forty Tobin shafts, in connexion with which are a number of extraction tubes. The rooms are heated by steam apparatus supplied by Mr. F. Ashwell, Leicester. Externally the building is in the Elizabethan style. The following are the sub-contractors:—For plumbing and glazing, Messrs. Norman and Underwood, Frieschool-lane; iron-work, Messrs. Gimson and Co., Vulcan-street; plastering, Mr. T. Nicholls, Crafon-street.—The Walker Memorial Hall, erected on the Highfields by Messrs. Walker, hosiery manufacturers, Rutland-street, in memory of their father, the late Mr. Robert Walker, was opened on the 20th ult. The edifice occupies a commanding site fronting the Melbourne-road, contiguous to the Melbourne Hall. It has been built from designs prepared by Messrs. Goddard & Paget, architects, and is composed of red sand bricks. On the ground-floor is a spacious hall, 45 feet by 44 feet, flanked by two large class-rooms. The class-room adjacent to the front entrance is fitted up as a coffee and reading room. The contractor for the work was Mr. Bentley, and the sub-contractor for the brickwork, Mr. Butteris.

CHURCH BUILDING NEWS.

Alcester.—The chancel of Arrow Church has received an addition in the shape of an elaborate rood in polished alabaster. It is given by the Dowager Marchioness in memory of the late Marquis of Hertford, K.G. It extends the whole width of the east wall. In the centre, under a tracery and crocketed canopy, is the Cross in bold relief, on a diapered background, enclosed by buttresses supporting angels. On either side are double arches containing emblems of the four Evangelists, and at each of the ends are other arches filled with carvings of the wheat and vine, also divided by buttresses carrying angels, between which are gabled canopies enclosing the pelican and young and the Agnus Dei. All the arches are supported by marble columns, affording an agreeable contrast to the alabaster. The work has been executed by Messrs. Earp, Son, & Hobbs, of London and Manchester.

Deane (Lancashire).—The ancient church of St. Mary, in the hamlet and manor of Deane, near the growing town of Bolton, was reopened on the 22nd ult., after having undergone a repair. In 1833, when the late Canon Gridlesome was vicar of the parish, the sermons state of decay into which portions of the edifice had fallen rendered considerable restoration necessary. This work was carried out in such a manner as to cover and completely hide many of the most striking features of the interior. The work of restoration now completed has been, so far as it had gone, of a thorough character. The new roof is an exact reproduction of the original roof, with the exception that the panels, instead of being filled in with plaster, are of oak boarding. The pillars and arches, which had been badly cut and notched in many places for the insertion of the gallery beams, have been repaired so far as was required for stability, without interfering with the ancient appearance of the stonework. The galleries have been removed. The arch in the tower at the west-end has been opened out, and the tower fresh fitted for the bell ringers. The removal of the old stonework leading to the galleries has very much improved the appearance of the interior of the church, besides adding to the accommodation on the ground floor. The chancel has been lengthened some 10 ft., allowing room for the erection of choir stalls. In the extension of the chancel the old work has been carefully copied, old stone having been used, as far as possible, so as to avoid any appearance of patching; and in design the extension harmonises with the rest of the building. In taking down the east end the remains of earlier windows were found embedded in the wall under the late east window, and in the reconstruction the exact lines of the former window have been retained, and the detail enriched in accordance with the portions of the older window found. In removing the plaster on the side walls of the chancel, the old sumary was found, and on both sides were traces of black letter inscriptions and coloured decorations,—about 4 ft. by 3 ft.,—enclosed in ornamental illuminated scroll-work. The fitting of the new roof and other principal work has been executed by Messrs. John Statham & Sons, of Pendleton. The

network has been carried out under the direction of that firm by Mr. James Bowden, of Kent's lane. The oakwork in the Hulton "pew" by Mr. James Hatch, of Lancaster. The sole of the work of restoration has been rigid out under the direction of Mr. R. K. Seaman, architect, of Bolton.

Eastbourne.—Some decorative work is just completed in the apse and sanctuary of its church. The ornamentation is wholly Byzantine in style, the ruling principle throughout being that the architectural structure is everywhere closely followed and emphasised, so as to aim being to decorate the stonework, and reserve its texture, even when coloured, and road spaces of the original stone are purposely left untouched between the decorated portions. The general features of the system of decoration adopted are as follow:—A double background to all colours, either absolute gold or old colour, with white upon the gold before peaving the figures, or *vice versa*. The patterns are chiefly conventional forms of flowers and foliage, wrought into panels, or formed into flowing bands following the architectural lines. The general design is due to Mr. Alfred Strong, architect of the church, and the work has been carried out by Mr. George Howe, of Wigmore-street, Cavendish-square.

Wigan.—A reredos, designed by Mr. A. E. Street, has just been erected in St. Michael's Church, Wigan. It is in three divisions, occupying the whole extent of the east wall. The central portion has a wide crocketed gable of Irish green marble, inclosing three arches, the centre one containing the sculpture of the Crucifixion, with the figures of the Virgin and St. John, and the arches on either side the figures of Saints Michael and Gabriel, all executed in white alabaster on a diapered background, the moulded jambs and multans and slinth dividing them being of Greek red marble, with hands of black marble. Under them and above the super altar is a panelled dado of Irish green marble, pierced by quatrefoils inlaid with coloured marbles, the whole resting on a solid moulded thick slab of Isle of Man black marble on a wall of alabaster. The two end divisions are panelled with a moulded and inlaid framework of polished alabaster, having in its divisions sets of Garrard's embossed and enamelled tiles, the moulded plinths and cappings being of Isle of Man black marble. The wall above and around the east window is richly treated with mural decoration. This work has been executed by Messrs. Earp, Son, & Hobbs.

Hampstead.—The interior of Hampstead Old Church (St. John's) has just been enriched by a marble font, designed and presented by Mr. Alfred Bell, one of the Churchwardens. A cover of appropriate design is about to follow. Mr. Forsyth, of Finchley-road, Hampstead, was the sculptor.

London.—An elaborate wrought-iron chancel screen was added to St. Saviour's Church, St. George's-square, Belgravia, on Christmas Day. The work was executed by Mr. Barford, of Maidenhead, from the designs of Messrs. Romaine-Walker & Tanner, architects, of Buckingham-street, Adelphi.

DISSENTING CHURCH-BUILDING NEWS.

Leek.—A new Primitive Methodist Chapel and Schools have been opened here. On the ground-floor is a schoolroom 34 ft. square, with six convenient class-rooms abutting upon it and divided off by glazed screens, with separate yards for boys and girls. There is an additional classroom in the tower, and there is abundant room for some 350 to 400 scholars. The first floor, which is used as the chapel, is 52 ft. by 35 ft. This has a gallery at the eastern end. The opposite end is occupied by a rostrum. Haden's warm fresh-air apparatus is used for this apartment. There is a vestry, with private stair, which can upon occasion be thrown into the chapel as a kind of small transept. Exclusive of this the total sittings are about 330 in the area, and some 70 more in the gallery. The works have been carried out by Messrs. Sugden & Son, architects. The builders were Mr. Herbert Hall, Mr. William Knowles, and Mr. Isaac Heath.

Water Supply, Andover.—Messrs. C. Isler & Co., of Southwark-street, have received orders to deepen the existing well for the supply of the town of Andover by means of a 15-inch artesian-bored tube well.

SCHOOL-BUILDING NEWS.

Croydon.—Extensive alterations and additions have lately been made to the Brighton-road Board Schools, from plans by Mr. Robert Ridge, the architect and surveyor to the Board. The largest, and perhaps the most complete, addition is to the senior boys' department, approached at the western end by a flight of stone steps, leading to a large lobby, which gives access to the cloak-rooms, lavatories, and also direct to the boys' main schools and class-rooms. The desks in the principal boys' room are Lascelles' dual desks, the back rows being on raised platforms. Generally, Donlon's patent automatic flushing-tanks and stoneware ranges have been adopted for the latrines. The whole of the work has been carried out by Mr. W. Marriage, of the Oval, Croydon.

Bristol.—New Sunday Schools are being erected in connexion with Hebron Chapel, Bedminster, Bristol, from designs prepared by Mr. A. Slaughter, honorary architect, and they will shortly be completed. The work is being carried out by Mr. A. J. Beaven, of Bristol, the cost being 2,500l.

The Student's Column.

LIME, CEMENT, AND THEIR USES.—I.

It will be evident that irrespective of the quality and strength of the stone or bricks to be used in the construction of a building, the mortar which unites them will exert considerable influence in the strength and permanency of the whole structure. Too much importance, therefore, cannot be attached to the selection of the materials, cement or lime and sand, of which the mortar is composed, and to the manner in which the mortar is compounded and used.

To enable a proper and judicious choice of materials being made it is essential that, at all events, a rudimentary knowledge should be possessed of the component parts of each; for it is impossible to make choice of a material of which nothing but its outward appearance is known. The very slight knowledge of weaving, for instance, possessed by the generality of people enables an opinion to be at once formed as to whether a piece of material is of properly woven thread or is what is generally termed "shoddy," so a slight knowledge of the components of a cement or lime, and of their manufacture, may assist in enabling a just opinion to be formed as to whether the sample under consideration is a good honest material, capable of giving good results under proper treatment, or is worthless as a material for construction.

All cements used in building from the earliest ages have lime as a base combined with silica and alumina in varying proportions, or are what, for practical purposes, may be considered pure limes.

The limes have been divided by Vicat into five classes, and as the classification satisfies the distinctive qualities of each in a very perfect manner, there seems no reason why it should be distrubed. Ho classifies them as follows:—

- No. 1. The rich limes.
- No. 2. The poor limes.
- No. 3. The slightly hydraulic limes.
- No. 4. The hydraulic limes.
- No. 5. The eminently hydraulic limes.

The eminently hydraulic, the hydraulic, and the slightly hydraulic limes are those which set more or less freely in water.

These are all produced by the simple calcination of limestones, containing different proportions of lime, silica, and alumina, in a state of chemical or only mechanical combination. Thus, the rich limes, or what are often called fat limes, are produced from the simple calcination of limestone, which, for practical purposes, a pure carbonate of lime, such as a good white chalk. The poor lime is the result of calcining a limestone which contains a larger or smaller proportion of inert material; that is, silica in the form of sand, or other materials, which are only combined mechanically with the base of carbonate of lime. Coming, then, to the hydraulic limes, they are produced from limestones which contain silica and alumina in varying proportions in actual chemical combination with the base; the slightly hydraulic having but a small percentage of silica and alumina, while the eminently hydraulic may have as much as 20 per cent. of the two. For instance, the

slightly hydraulic lime would be produced by the calcination of the grey chalk, and the eminently hydraulic from the limestone in the blue lias formation. In addition to the above, there is the lime produced from the dolomites or magnesian limestones.

The process of manufacture or the burning of lime is simple. The limestone, reduced to pieces of convenient size, is placed in alternate layers with coal in kilns and burned. The chemical action resulting from the calcination is the expulsion of the carbonic acid from the limestone, resulting in the production of quicklime; this, again, has to be converted into a hydrate of lime by the addition of water when required for use. The proper methods of doing this will be described later on.

Cement, or what is known as Portland cement, has also, as has been already said, a base of lime, but contains a considerably larger percentage of silica and alumina in chemical combination with the base than any of the limes, and the calcination is carried out at a much higher temperature. The manufacture of cement is, further, not of such a simple character as that of lime. It is seldom that in nature a limestone is found that possesses the exact proportions of lime, silica, and alumina, for the production of Portland cement. The desired combination has, therefore, to be produced artificially by mixing materials which contain the required ingredients. This is generally attained by incorporating with a limestone a clay which contains the silica and alumina in proper proportions.

Portland cement may be produced from any raw materials which contain the requisite proportion of each ingredient. Some, however, are, of course, more easily treated and manipulated than others; while, for purely commercial reasons, it would be impossible to use some of them.

Chalk and clay are the materials which lend themselves most readily to manipulation. A description of the manner in which they are treated for the production of Portland cement will give a very general idea of some of the difficulties attending its manufacture, and enable just conclusions to be formed as to the causes of peculiarities which may be developed in any samples under consideration, or in any cement that may be used.

The chemical properties of the chalk and clay which the manufacturer uses having been determined, they are mechanically mixed with the addition of water in a wash-mill,—the resulting slip, or, as it is technically called, "sinny," passes through a sieve as it leaves the wash-mill, and is then, according to the most advanced process of manufacture, passed through mill-stones, and ground. From the mill-stones it is either pumped or run by gravitation on to large floors (under which are arranged hoes), and dried. When all the moisture has been expelled, it is loaded into the kilns in alternate layers with coke, and burned. The resulting clinker, which should be dark in colour, and calcined almost to vitrefaction, is then broken into pieces the size of walnuts, and ground in mill-stones to the desired fineness; the result being the Portland cement of commerce. Thus the difficulties of manufacture will be appreciated. An error in the mixture of the due proportion of the raw materials, or in their proper and perfect mechanical admixture, or an error in the calcination, will result in a more or less imperfect cement, which, when used, will give indifferent or absolutely bad results.

The limits within which the chemical analysis of a Portland cement may vary is but small, not more than about five per cent. in the quantity of lime, and even this small difference, though not of itself sufficient to render a cement unsound, will make a cement either slow or quick setting, according to whether it contains the maximum or the minimum quantity. The amount of calcination to which a cement has been subjected will also, within certain limits, render it slow or quick setting, according as it has been hard or light burned.

Though theoretically a cement as it leaves the mill-stones is fit to use, practically it should be warehoused for some time, and allowed to cool before it is used. Theory and practice are often at variance without any assignable cause; but in this case the cause is easy to determine if the action which takes place by calcination is examined. Unlike the limestones, which by calcination are only deprived of their carbonic acid, the calcination of a raw cement effects in addition to the expulsion of the carbonic

acid, the chemical combination of the lime, silica, and alumina, which previously were only in a state of intimate mechanical admixture. If, therefore, this chemical combination has not been absolutely perfected, and except in a laboratory this is practically impossible, there will remain in the cement a small percentage (it may be only one or two per cent.) of lime which, though deprived of its carbonic acid, has not entered into chemical combination with the silica and alumina, and which remains, therefore, in a state of quicklime; and the action of adding water to it in this condition would cause it to expand, which, it is needless to say, would be detrimental to any work in which it was used. The object gained, therefore, by allowing a cement to be warehoused for a considerable time is to allow these small particles of free lime to "air slack,"—that is, to abstract carbonic acid from the atmosphere, and become so many inert particles in the cement. The presence of a small percentage of inert air-slacked lime is not detrimental to a cement; but of necessity the presence of free lime in any large quantity would render it, when fresh, very dangerous to use; and when aged, the presence of this inert lime would become an adulterant, and proportionately reduce its strength.

Given that the cement is properly proportioned and calcinated, the finer it is ground the better will be the result obtained with it in practice. There are, however, certain limits which it is not possible for the manufacturer to exceed economically, i.e., it is more economical to use a larger proportion of cement than pay the manufacturer the extra cost necessitated by finer grinding; the economical point is attained when a cement will, when sifted through a sieve having fifty holes to the linear inch (2,500 to the square inch) leave a residue on the sieve of only 10 per cent. This degree of fineness is sufficient for almost any purpose for which cement is used.

A cement may be slow or quick-setting according to the purpose for which it is required. The quick-setting cements attain great strength in a short time, but afterwards do not improve much, while the slower-setting, though longer in developing their strength, continue to improve for a long period, and ultimately attain greater strength than the quick-setting ones. A cement should carry at least 175 lb. per square inch when three days old, and should show an increase of at least 50 per cent. when seven days old, but the minimum strength at seven days should be 350 lb. A slow-setting cement will generally increase more than this, but at the seven days a quick-setting cement will generally be stronger than a slow-setting one. A cement is quick setting when it sets in less than an hour; a slow-setting cement will take five or more hours to attain the same hardness. Cements that take from one to five hours to set are comparatively more or less quick or slow setting. The time which a cement takes to set is determined by the clamping between the time of gauging it with water and until it will resist the pressure of the thumb-nail.

The quality of a cement is determined by

1. Its fineness.
2. The time it takes to set.
3. Its tensile strength at the expiration of three and seven days from gauging.
4. Its freedom from either expansion or contraction, or, in other words, its soundness.

To carry out a cement test satisfactorily, a considerable amount of skill, and, above all, of experience, is required. It is very easy indeed to obtain false results, more especially in testing the tensile strength; and as a false result means a comparatively bad one,—a test, unless carried out by an experienced person, may mean the condemnation of a really good material, resulting in disputes, references to arbitrators, perhaps to legal proceedings, and, at all events, to much unpleasantness. The general instructions which follow for carrying out a cement test are given, therefore, not for the purpose of enabling the user to carry out his own tests,—which, by the way, he could not do without the necessary plant,—but to enable him to have sufficient knowledge to direct the manner in which a test should be carried out, and to enable him to draw up a specification which shall coincide with his requirements and the capabilities of a cement. It is worse than useless to draw up a specification which cannot be complied with.

On all important works the cement should

be tested before being used, not after it has been put in the work. It is more satisfactory, and fairer to the manufacturer to know that the cement he is supplying is approved of or rejected before the complication of claims for labour expended and for pulling down and loss of time can have arisen; and it is certainly equally satisfactory to the user to know that the cement he is going to use is of the desired quality, and that he is certain of obtaining good work, if only the manipulation is carried out properly.

The fineness, time of setting, and soundness of a cement are absolute properties. The tensile strength is varying within certain limits, according to the skill of the operator in making the test blocks, but it must be understood that in testing the tensile strength, the object is to obtain the very best results possible.

The sample for testing should not be taken from one sack, but from at least half a dozen, and well mixed before commencing the test. The fineness should be first ascertained by weighing out a certain quantity, say 25 ounces, or 12½ ounces. It is best to reckon by ounces, and to take either of these quantities, because, in the first instance, 1 ounce, and in the latter case, 1 ounce, is equal to 1 per cent. Having weighed out the cement, and placed it in the sieve of the proper mesh (50 by 50), it must be sifted through until nothing more will pass, when what is left in the sieve must be weighed, and the percentage at once determined. This experiment should be carried out twice, with different portions of cement, in order to ensure accuracy, and to be certain that a fair sample of the cement has been taken, and if there is any serious discrepancy in the results, a third experiment must be made.

Books.

Russian Art. By ALFRED MASSELL.
London: Chapman & Hall.

THE above work, published for the Committee and Council on Education, forms one of an excellent series of handbooks to the art treasures preserved in the South Kensington Museum. Its main object is to supply a guide to the reproductions of Russian objects of art belonging to the Museum; but it includes a general survey of Russian art. The writer has a competent personal knowledge of the subject, and a wide acquaintance with its literature in the several European languages, and in his acknowledgment of obligations to other writers makes special mention of the *Art Russe*, of that prolific author and incomparable artist, the late M. Viollet-le-Duc. The first part of the book is devoted to a description,—with appropriate commentaries,—of the numerous art objects in the Russian Collections at St. Petersburg and Moscow, with interesting accounts of the circumstances attending the various "finds" at Kertell, Novo-Teberka, and elsewhere. The second part takes up the subject of religious art in Russia, and enters at length into the architecture and sacred vessels, ornaments, and decorations of Russian churches. A separate section of the work deals with arms and armour, and another on the collections of English and other plate in the Russian Imperial palaces. The whole is copiously and carefully illustrated. We have rarely met with a more interesting handbook. It is written with a full acquaintance with the subject, and in style is both concise and lucid; and it is a pleasure to be able to congratulate the author, without reserve, upon the accomplishment of what has evidently been to him a congenial task.

The Oriental character of Early Russian art is brought prominently forward, and the art of Russia, though possessing an unmistakable character of its own, is shown to be the result of the influence of every nation on earth. "We know for certain that in the earliest days of Russian art foreign artists and workmen abounded. They came from India, Persia, Byzantium. Lombard architects came to build churches, and not only Germans, Poles, and Hungarians poured in, but also French and English." Although the bulk of the art objects found in the various tombs are undoubtedly of high antiquity, their exact or even approximate date is almost always more or less problematical. Inscriptions are extremely rare indeed, almost unknown, and thus one valuable aid in the determination of age is wanting. In the very few cases in which any inscribed words are forthcoming,

they unfortunately add perplexity to what was sufficiently doubtful before. A remarkable instance of this is given in the case of a cup in the collection of Count Onvroroff, at Moscow. It was discovered in 1864, by a mere accident, and on its lip, amongst a series of dotted letters, the well-known Christian symbol occurs. The question of date was submitted to the Vatican, and Cardinal Pitra laid it before the Academy at Rome. Opinion were varied, and the cup was severally referred to a period three or four centuries before Christ, and to the fourth or fifth century of the Christian era. The Moscow savants were of opinion that the symbols simply declared the weight of the cup, and the balance of opinion was on their side. The conservative nature of the Christian art of the Russian Church is noteworthy. For eight hundred years it has maintained the same character in the disposition of its churches and their decoration, and in its ritual and symbolism. "There is but one school and one epoch. The artist does not create, but reproduces; and the painter knows but one costume for all times and places." Everything is fixed by tradition. The remarks upon Russian iconography are of the deepest interest, and this branch of his subject is treated by Mr. Maskell at considerable length. Those whose business it was to make works of art for religious purposes were enjoined to be "godly, steady, and not given to laughing,—not a thief, nor a slanderer." He was to be pure in body and soul, to fast and pray, and then he might hope to find the grace of God, and the clover in his work. "If a disciple paint badly, the master is to be reprimanded" and the pupil is not to meddle any more with what is above his reach. If a teacher hide his art from his disciples "he shall be tortured in hell-fire, as was done to him who hid the talent." If, moreover, a painter paint badly or not according to the given model, or if he shall live impurely, he must be made to give up icon-painting, as there are other trades for such as he. The precision with which the given model was fixed is very singular,—some saints having always white faces, others green, and so on. The Black Madonnas of the Greek Church are known to everybody. But notwithstanding the efforts which have been made to preserve the ecclesiastical art of Russia from innovation, Western progress and Western ideas have made their mark. Stained glass from Munich has found its way into the modern churches, and even sculptured figures and groups are tolerated. We have only one suggestion to make by way of improving this manual,—the marginal addition of dates. The work is supposed to have been framed as a guide to the curious public as well as for students who have a more or less close acquaintance with Russian art. Much of the interest of the objects exhibited hinges upon their remote antiquity, and to the ordinary visitor it is not of much use to be told that a silver bowl is "of the epoch of the Persian dynasty of the Sassanians." With this hint at a possible improvement we have nothing but praise for Mr. Maskell's "Russian Art."

A Treatise on Steam Boiler Incrustation, &c.
By CHARLES THOMAS DAVIS. London: Sampson Low, Marston, & Co.

THE necessity for preventing corrosion in steam-boilers has long been one of the consideration of engineers, and we can hardly agree with Mr. Davis in his view that it is a subject which has received but little attention in comparison with its importance, for, in his present work, he has taken great pains to describe several inventions for which patents have been taken out; and enumerates no less than ninety compositions for preventing and loosening incrustation, besides 150 mechanical appliances for removing the same. But Mr. Davis's present contribution conveys additional and valuable hints on the subject, and, as he truly observes, many boiler accidents which are often described in the newspapers as "mysterious" could often be fully explained in the two words "natural results." Corrosion, which is the most common agent in promoting explosions, is frequently hastened by culpable negligence or ignorance in exposing the boiler plate unnecessarily to action which causes a wasting away of the iron; and, what is frequently charged to "wear and tear" is really due to external corrosion, pure and simple, resulting from sheer carelessness either in

final construction or in subsequent super-
 on. The author dwells rightly on the great
 importance of "flue-cleaning" to both engineer
 proprietor, giving an instance within his
 wledge where the time of raising steam in
 morning was 50 per cent. longer when the
 es were unswept for one week than when
 were swept three times a week. The
 cyclone flue-cleaner," of which an engraving
 given, and which is manufactured by the
 rescent Company, Cleveland, Ohio," is repre-
 sented to be an effective machine, "adapted to
 rine, stationary, portable, upright, and loco-
 tive boilers." The vast amount of earthy
 ter and impurities which are deposited
 locomotive boilers, is not generally realised
 by those who are supposed to be
 versant with the subject. By way of
 stration, the instance is quoted of the
 omotive on the New York Central Rail-
 y, which runs forty miles and takes in 1,800
 tons of water, or 45 gallons per mile, con-
 taining 1½ ounce of earthy matter per gallon,
 which, consequently, during its run of
 only 2,000 miles per month, receives no less
 than 2,904 lb. of incrusting matter annually.
 The observations on the effect of water on
 sam boilers are very instructive, and amongst
 materials used to prevent corrosion, Mr. Davis
 states that zinc has proved the most efficacious,
 and that it is used by some of the most pro-
 moted of Liverpool engineers in their steel
 boilers. The mode of applying zinc patented
 by Mr. Hannay, of Glasgow, is spoken of as a
 very effective adaptation of the material. The
 apters allotted to a description of the various
 achines invented for purifying water for
 silers, are well worthy of study, as also the
 marks on anti-incrustation compounds, as well
 as those on the mistake which is commonly
 ad in drawing the fires at the end of the
 eek's work, and at once blowing off water and
 eam instead of only closing the damper and
 eep-it doors, and allowing everything to remain
 until morning, when the water can be let off, and
 e inside of the boiler be got at and thoroughly
 eaned out. In cases where hand cleaning is
 ot practicable, Hotchkiss's mechanical boiler-
 esner is declared to be the most effective in-
 strument yet manufactured. We cannot doubt
 that Mr. Davis's work will be appreciated as
 a valuable contribution to the special subject
 of which it treats.

London and Provincial Water Supplies. By
 ARTHUR SILVERTHORNE, A.M.I.C.E. London:
 Crosby Lockwood & Co.
 We have lately had before us several pamphlets
 relating to the water supply of London in its
 various aspects, and in so far as statistical in-
 formation is concerned no new facts are brought
 forward by Mr. SilvertHORNE which call for par-
 ticular notice; but by combining the statements
 of the provincial water supplies in the same
 volume, he renders possible a comparison of the
 results of the London Water Companies with
 those of other private undertakings, and of the
 schemes which have been carried out by various
 corporations. One result of such a comparison
 is to show that most of the provincial towns,
 though charging higher rates, furnish in no
 cases rentals even approaching a corresponding
 extent to those yielded by the London districts.
 The large discrepancy observable would, it is
 said, on careful inquiry, be found to result from
 the existence in the metropolis of a multiplicity
 of charges, beyond the mere rate per cent.
 on annual value, which are made on consumers
 but have no existence elsewhere, but which
 contribute materially in the aggregate to swell
 the rental to undue proportions.

Seeing that the metropolitan companies in
 1882-83 divided no less than 8.75 per cent.
 amongst their shareholders, and that there is a
 large annual increase to their business, the com-
 panies may fairly look for material concessions
 from them; and to this end might submit their
 representations to the Legislature, who, though
 not likely at present to alter the statutory rates
 originally settled, may yet, at no distant date,
 see the way to insisting on a reduction.

The principal interest of this publication lies
 in the particulars afforded of the provincial
 supplies. It appears that neither the old-estab-
 lished companies nor the corporations pay
 larger dividends than five or six per cent.
 This is accounted for by their having to meet
 two requirements from which the London
 companies are exempt, viz., the redemption of
 capital, and the compensation clauses which
 Parliament compels the towns to submit to in

cases where large extensions have had to be
 made to such schemes as, originally insufficient
 in their own resources, have been bought up
 by municipalities at a high premium, thereby
 greatly enhancing their cost. The compensation
 frequently far exceeds the supply applicable to
 the district, notably so in the town of Bolton,
 where it amounts to nearly double the volume
 delivered to the town itself for all purposes. In
 the course of his remarks, Mr. SilvertHORNE
 reproduces a part of the address given a few
 years ago by the late Sir W. Ferguson to the
 British Medical Association at King's College,
 on the subject of an efficient water supply, the
 perusal of which we would commend to the
 attention of all those consumers who may have
 become alarmed by the forebodings which have
 recently been so thoughtlessly advanced on the
 question of water purity. A fund of useful in-
 formation will be found in the carefully-
 tabulated statements relating to the provincial
 supplies which make up the greater portion of
 the volume.

VARIORUM.

The miniature memorandum-book noticed by
 us with approval a fortnight ago is entitled:
 "Smith's Tables, Memoranda, and Calculated
 Results," selected and arranged by Francis
 Smith. The publishers are Messrs. Crosby
 Lockwood & Co.—Sprague's Pocket Diary
 (Sprague & Co., Martin's-lane, Cannon-street)
 is a combination of the ordinary pocket
 diary in leather case, with a number of tables
 of formulæ and memoranda such as are
 useful to architects and surveyors. A great
 deal is got into a small compass, and the
 book is a very handy and convenient one.

Messrs. T. J. & J. Smith (Queen-street, Cheap-
 side), send us a parcel of their useful diaries,
 of which there is a good variety. Their "Scrib-
 bling Diary," No. 7, interleaved with blotting-
 paper, and their small ditto, No. 6, each of
 which is sold for a shilling, are among the
 cheapest and best of their kind. Their "Tablet
 Diary," which can be hung up, is so arranged
 as to show a whole week's engagements at a
 glance, and is exceedingly useful.—"The
 Prince of Palms," by W. P. Treloar (Sampson
 Low & Co.), is a description of the cocoa-nut
 palm-tree, with some account of its industrial
 applications, in the development of which
 Messrs. Treloar & Sons have taken a lead-
 ing part. The book contains some well-
 executed illustrations.—Messrs. Cassell &
 Company (Limited) send us a packet of their
 monthly publications. The "Technical
 Educator" contains lessons in object-drawing
 and perspective, freehand drawing for stone-
 masons, and papers by Dr. Dresser on the prin-
 ciples of design.—"The Practical Dictionary of
 Mechanics," by Edward H. Knight, G.F.S., is a
 very useful but very voluminous work of refer-
 ence; for, although the part now to hand is the
 97th, the work has not yet gone beyond the
 letter D. It is fully illustrated, and authorities
 and references are given apparently with great
 care.

The work is of American origin, and
 this will account for some eccentricities of
 spelling. Cassell's "Universal History" has
 reached its 40th part, and "Picturesque
 America," its 40th part,—the latter including
 illustrations of scenes in Chicago, which afford
 glimpses of the street architecture of that
 newly-built city.

RECENT PATENTS.

ABSTRACTS OF SPECIFICATIONS.

2,374, Improvements in Zinc Roofing. J. &
 J. Mould.

In this adaptation of corrugated roofing to flat
 surfaces, simplicity and ease of construction have
 been considered as well as the desirability of making
 a roof which shall be water-tight. The edge of
 each sheet is turned upwards into a double curve
 and corrugated flange, the edge itself finishing with an
 outward curve from the rafter ridge or other pro-
 jections, as the case may be. Over the upper curls
 or corrugations formed by the flanges of two such
 sheets coming together on each side of a rafter or
 other projection, two or more saddles are made with
 a slight curve at the top, and the sides returning
 inwards, so as to spring under the upper curl of each
 plate, the edges of the saddles then spreading out-
 wards, and lying smoothly upon the roof of the
 smoothness of action is allowed to the sheets.
 These saddles are secured in their position by means
 of zinc intermediate blocks, which rest on the
 rafters or other projections, and support the saddles
 under the upper part, screws passing through both

the saddle and zinc block into the rafters or ridges
 or other projections secure the saddle down at
 the top, but leave the sides perfectly free.
 Lateral movement is prevented by securing the ribs,
 and a cover plate is provided at the junctions.

2,907, Improvements in Bricks. H. W. Hart.

This is an extension of a somewhat similar inven-
 tion of the same patentee, wherein the bedding and
 butting faces of bricks used for building are formed
 alternately with broad grooves or recesses tapered
 at the sides and with projecting pieces or joggles to
 fit into these recesses. To reduce the quantity of
 mortar or cement required in laying such bricks and
 to cheapen their cost, and increase their strength,
 two square pockets, the sides of which are tapered,
 are formed, and two corresponding projections or
 joggles are also formed on the opposite side. These
 projections and recesses being made in each brick,
 a great saving of mortar or cement is effected, and
 the bricks being laid much closer, their strength is
 greatly increased.

3,329, Improvements in Fixing Rainwater
 Gutters, &c. G. Kay.

The ordinary half-round gutters are laid loosely
 into the hooks, which are fixed to the roof, but in
 this invention a hoop-iron circular clasp, sprung on
 the same bolt as the spigot and faucet, hangs down
 the guttering and prevents its removal by storms or
 pressure from rains or wind.

4,725, Flushing Sowers. P. Burke.

Relates to flushing, cleaning, and purifying sewers.
 Piles of waste material usually accumulate on level
 parts of sewer; a pipe runs along the roof of sewer,
 from the underside of which short curved nozzles,
 which direct the water jets in the direction of flow
 of the liquid in the sewer. Manholes are provided
 for clearing out the solid waste, and short sections
 of flushing pipes are provided into which water is
 successively turned.

APPLICATIONS FOR LETTERS PATENT.

Dec. 19, 1884.—16,670, J. C. Webb and F. D.
 Smith, Screw Collar Joint for Sewer and Drain
 Pipes.—16,672, E. G. Wright, Chimney Cowl and
 Ventilator.—16,673, G. Collins, Improved Sash
 Fastener.—16,687, H. C. Bridge, Apparatus for
 Facilitating the Sharpening of Plane Irons, Chisels,
 and other Edge Tools.—16,696, F. H. Moore, Im-
 provements in Fire Crates, Stoves, &c.—16,709,
 J. White, Chimney Cows and Ventilators.—16,712,
 H. H. Lake, Improvements in Flooring Cramps.

Dec. 20.—16,740, J. C. Bloomfield, Method and
 Material for Joining Earthenware Pipes.—16,745,
 C. F. Veit, Improvements in Locks.—16,754, A. A.
 King, Fastening Water-closet Doors.

Dec. 22.—16,771, T. Brounball and J. Brounball,
 Sash Fastener, also applicable to other purposes.—
 16,772, J. Walker, Box Slides for Door Chains.—
 16,774, H. Sutcliffe, Machine for the Manufacture
 of Lavatory Basins or Cabinet Stands.—16,775, H.
 Smith, Fireproof Passage, &c.—16,781, J. Walker,
 Window Sash Fastener.—16,790, U. A. Williams, Im-
 proved Window Sash Fastener.—16,791, P. R. Shill,
 Apparatus for Cutting or Planing Wood.—16,792, G.
 Ross, Laying and Securing Slates.—16,812, J. L.
 Lobley, Ventilation.—16,817, R. Adams, Opening
 and Closing Fanlights, Skylights, Ventilators, &c.—
 16,818, M. P. Ismay, Automatic Closing of Doors.

Dec. 23.—16,821, J. H. Hubert and T. Colley,
 Sash Bar Cramps for Carpenters, Joiners, &c.—
 16,831, A. Emley, Improvements in Cooking Ranges.—
 16,850, H. N. Marks, Self-soaking Water Closet.—
 16,862, G. Pepper, Improvements in Lavatory or
 Washhand Basins.

PROVISIONAL SPECIFICATIONS ACCEPTED.

9,405, W. H. Luther, Sash-bars or Astragals. —
 15,161, W. Scott Morton, Embossed Canvas for
 Decorating Walls or other Surfaces.—15,450, E. C.
 Murray, Room-to-room Communicator.—15,520,
 H. J. Hadden, Limestone and Cement Kilt-
 15,825, J. Walker, Manufacture of Turn Buttons
 and Plates for Fastening Doors and Windows.—
 15,928, G. Heward, Improvements in Cooking and
 other Kitchen Ranges.—15,945, J. J. Talman,
 Attaching Door-lock Handles to their Spindles.—
 15,955, W. H. Willett and T. C. Wakeling, Im-
 provements in Fire-grates.—15,976, E. R. Hollands,
 Open Stoves or Fire-grates.—16,075, J. B. Better,
 Improvements in Chimney-tops.—16,187,
 Williams and W. C. Horne, Luminous Letters and
 Signs.

COMPLETE SPECIFICATIONS ACCEPTED.

Open to opposition for two months.

296, J. Walsh, Improved Ventilator.—3,521, C.
 Schlickelsohn, Improvements in Roofing Tiles.—
 4,164, H. Toth and S. Preston, Opening and Closing
 Window-sashes and Fanlights.—4,533, J. King,
 Chimney Cows and Ventilators.—4,523, W.
 Reynolds, Combination Tool.—7,620, T. Abbott
 and M. Hawthorthwaite, Flushing Apparatus for
 Water-closets and Sewers.—13,341, J. Ennals,
 Combination Water-closet and Dust-hin.

Re-Valuation for Assessment.—The
 Assessment Committee of the Bean Union
 (Kent) have selected Mr. Chas. F. Jones, F.S.J.,
 to re-value the railways, and gas and water
 works companies throughout their Union.

MEETINGS.

FRIDAY, JANUARY 2.

Architectural Association.—Discussion on "The Best System of Professional Education for Architectural Students, and How the Work of the Association might be Rendered More Efficient." 7:30 p.m.

SATURDAY, JANUARY 3.

Association of Public Sanitary Inspectors (1, Adm. street, Adelphi).—Mr. Edward C. Robins, F.R.I.B.A., will read a paper entitled "The Growing Importance and Responsibility of Public Sanitary Inspectors explained, and their relative Improvement in Education, Position, and Emoluments considered." 6 p.m.

MONDAY, JAN. 5.

Royal Institute of British Architects.—Business Meeting. The Report of a Visit to Vienna and Buda-Pesth by Mr. F. R. Farrow, holder of the Godwin Bursary, will be presented. 8 p.m.

WEDNESDAY, JAN. 7.

British Museum.—Mr. W. St. Chad Beeswain on "Assyrian and Babylonian Antiquities." 2:30 p.m.
British Archaeological Association.—Mr. C. Lysons on "Recent Excavations at Hulton Abbey." 8 p.m.

THURSDAY, JAN. 8.

Society of Antiquaries.—Ballot for Election of Fellows. 8:30 p.m.

Miscellaneous.

Building on Disused Burial-Grounds.

Taken in conjunction with the ravages and recent decline of cholera in Paris and on the Continent generally, and with our own immunity so far from that justly dreaded disease, the recent judgment by Mr. Hannay, since confirmed by a superior court, with reference to the opening up of the Old Peel Burial-ground in Bechnal-green must appear to be one of very questionable propriety. In opposition to the Metropolitan Board of Works, he has maintained that the area in dispute does not come within the operation of a by-law of the Board, which forbids the use for building purposes of land impregnated with animal or vegetable matter before the removal of the soil so affected, and he has accordingly sanctioned the erection of buildings upon it. Now, the Old Peel Burial-ground was during the cholera epidemic of 1849 literally packed with the remains of the victims of this malady. There is nothing to show to what extent the contagion then entombed has been starved out of existence during the subsequent period in which the ground has been unused. It may very well be that, under the favouring conditions of sufficient heat and moisture which the earth of cemeteries is known to furnish, the germs of disease are still preserving a subterranean life. There is no slight risk in such a case that the drainage and water-supply of the houses to be built at this spot will become the conduits of infection. It were therefore better, in our view, that a soil once so impure should be left altogether undisturbed; but if the time for this possibility is past, there only remains the greater necessity for the removal of all contaminating matters and the thorough disinfection of the sites to be occupied. These observations, which apply in a special degree to the case before us, have, moreover, a practical significance which should not be forgotten in dealing with the same subject in all its aspects.—*Lancet*.

New Artisans' Dwellings in Lambeth.

A block of buildings for the industrial classes has just been erected in Walnut Tree Walk, off Kennington-road, Lambeth. The buildings, which are in two blocks, have a frontage to Walnut Tree Walk 40 ft. in length, and extend to a depth of 100 ft. They contain four floors, and are 50 ft. in height. The elevation is faced with white Suffolk brick, and the frontage is ornamented with moulded and cut brick panels by Mr. James Brown, of Finchbury. The keystones, copings, and finials are in Portland stone. Each floor contains four sets of apartments, in suites of three rooms each, consisting of living-room, bedroom, and kitchen, with separate water-closets to each suite. The living-rooms are fitted with two cupboards, and there is one in each of the bedrooms, whilst the kitchens, in addition to dressers and cupboards, are supplied with coppers, sink, and coal bunker. There are stone staircases from the ground to the upper floor. The open flat roof, which is intended for both drying and recreation purposes, is constructed of concrete slabs and cement, and enclosed by a parapet wall 4 ft. in height. Messrs. Stock, Page, & Stock, of Duke-street, London Bridge, are the architects, and Messrs. J. Ford & Sons, of Denmark-hill, are the contractors. The cost of the buildings, which have been erected for Mr. Mackenzie, is 4,000l.

Civil and Mechanical Engineers' Society.

—An Ordinary Meeting of this Society was held on the 31st ult., the President, Mr. Thomas Cole, in the chair, when a paper was read by Mr. J. Tertius Wood, C.E., entitled "Criticisms on the Storage of Towns Water."

The author said that the introduction of subsidiary ponds to catch what would otherwise be flood or waste water, was a feature introduced by him to equalise as far as possible the unequal distribution of rainfall during the year, and assist in employing the utmost available yield from a surface-drainage catchment-area, and remarked that of course an open reservoir can be constructed to hold a volume of water calculated to expend itself during a considerable period of abnormally dry weather; but such a reservoir might, for many months, be in a low and somewhat stagnant condition; so similar results may be obtained by having covered ponds adjacent to the reservoirs, and connected therewith by culverts, having floor-levels on the same horizontal plane as the sill of the overflow; that, when the reservoir had reached its limit of capacity, the ponds therein contained would be removed from the separate rays, and kept cool and wholesome. The author further remarked that it has now become necessary that steps should be taken to institute a thorough inquiry into the whole question of water supply, and, as a sanitary unit, he kept parallel with the use to which it has to be applied; and he said that this past year has been fruitful in causes and effects, and has practically illustrated the dangers likely to arise from a forgetfulness of its importance as a social and mercantile commodity.

Armenian Architecture.—A typical Armenian church has a character of its own which it is impossible to mistake. As a rule, a square tower at the west end and an octagonal tower in the middle suggest to an English eye a faint analogy to Ely or Wymondham. Very faint, indeed, the analogy is to either; still the square and the octagon are there, however much their proportions may differ from the proportions of the square and the octagon in the only two English churches with which we can compare them. The Armenian central octagon has a strange look in the way in which it rises, not immediately from the four limbs of the church, but from a kind of oblong base which it is not easy to describe, but which is one of the most marked characteristics of the style, within and without. The truth is that the innermost bay, so to speak, of each transept, those which in the ground-plan range with the aisles of the eastern and western limb, are carried up to the full height of the lantern. Outside, this gives the tower this broad base to spring from; if the tower was away, it would have a good deal of the effect of the high choirs of the Cistercian churches in Sicily. Inside, it increases the effect of height, and it further supplies a new pair of lofty arches to increase the complication of grouping, and of arches crossing one another, some measure of which is necessarily found in every cross church. The effect of this very singular arrangement is, to our taste, certainly much better inside than it is without.—"E. A. F." in the *Guardian*.

Lowe's Wood-block Flooring.—The excellent wood-block flooring patented by Mr. R. L. Lowe, of Faruworth, near Bolton, has been used for the following, among many other new buildings, viz.,—corridors and council-chamber at Hyde Town-hall, Messrs. J. W. & F. R. Beaumont, architects, Manchester; Hanley Town-hall, Mr. J. Lobley, surveyor; Girls' High School, Exeter, Messrs. Maynard & Son, architects, Exeter; dispensing-room, Beckett's Hospital, Barnsley, Messrs. Dixon & Moxon, architects, Barnsley; floor of chapel in oak, also kitchen in red pine, Memorial Home, Liverpool, Mr. A. Waterhouse, architect, London; restaurant, Hatchett's Hotel, Piccadilly, Messrs. Weatherley & Jones, architects; waiting-room, Leamington Avenue Station, Leamington, for the London and North-Western Railway Company, Mr. H. Woodhouse, C.E., Stafford. It has been largely used for school floors, and has given great satisfaction.

Obituary.—It is with regret that we have to announce the death of Mr. John Fraser, jun., which took place on Monday last, after a lingering illness, at his residence, Don Cottage, Woodside, Aberdeen. He was thirty-five years of age and was one of the firm of John Fraser & Son, Granite Quarry owners and workers of that city.

New Buildings in Queen Victoria-street.

A lofty block of new buildings is at present in course of erection at the junction of Queen Victoria-street and Upper Thames-street, on the site of Muggersidge's granaries. With the view of widening Upper Thames-street at its western entrance, the Corporation some time ago purchased the old buildings, which were taken down, and the greater part of the site has been let on a building lease. Upper Thames-street at its western entrance will be widened to the extent of 4 ft. The new building will have three lofty frontages, one facing Queen Victoria-street, another on the west side, and the third on the south side, in Upper Thames-street. The Queen Victoria-street and west frontages will be 68 ft. in height from the street line, and will contain five lofty floors in addition to the basement, whilst the Upper Thames-street frontage will (owing to difference of level) be 78 ft. high, containing six floors and basement. The Queen Victoria-street frontage is 60 ft. in length, and is faced with Portland stone. The west frontage, 40 ft. in length, is strictly uniform with the Queen Victoria-street elevation. The Upper Thames-street frontage is faced with white Suffolk brick and Portland stone dressings. The lower part of this frontage contains what is termed the lower ground-floor,—the Thames-street level being much lower than that in Queen Victoria-street,—and that in Queen Victoria-street the upper ground-floor. Mr. W. Wible is the architect, and Mr. W. Brass, of Old-street, is the contractor. Mr. Hayes is clerk of the works, and Mr. Eyo the foreman. The cost of the building will be about 15,000l.

The Destruction of Bricks through the Action of Bacteria.—The *Riga Industrielle Zeitung* has lately commented upon the statement on the above subject (quoted in the *Builder* of May 31, 1884, p. 802), which has been circulated by the technical press of the Continent. Herr Glasenapp considers that in the assertion referred to cause and effect have been confounded, as such germs can only be developed where they find nourishing-grounds containing organic substances in abundance, and how a brick which has been burned in the normal manner should contain germs it is hard to understand. If, however, the brick has been injured by the weather, becoming soft and porous, it is easily penetrated by dust (which may be partly organic), and if damp then supervenes the necessary conditions are present for the development of bacteria, which by their action hasten the process of the destruction. It has even been proposed to disinfect bricks, but this, it is remarked, would be as devoid of efficacy as the proposed disinfection of coins. In fact, any object exposed to the air for a short time would be found on microscopic examination to contain bacteria, many of which are perfectly harmless. It is considered probable that the germ in question is the *Bacterium termo* (Cohn), which is found on most articles of food, and is the germ of decomposition *par excellence*.

Dry-Rot in Wood.—The official *Zeitschrift für Bauwesen* contains a treatise on the above subject by Professor Sorokin, of Kajan, dealing with the various parasitical destroyers of wood, and particularly the dry-rot (*Merulius lacrymans*). The anatomical structure and other details as to this parasite are described with clearness, and a series of twenty-seven illustrations gives views of infected wood and representations of the parasite in various stages of its development. The remedies proposed are described as follows.—1. A current of air destroys the parasite in twenty-four hours. 2. Light is also an obstacle to its growth. When exposed to the simultaneous action of light and a draught of air, drying up ensues within a few hours. 3. The sprinkling of wood with a solution of common salt prevents the appearance of dry-rot. The greater the concentration, the more durable is the protective effect. 4. A solution of sulphate of copper (particularly if concentrated) is preferable to the solution of common salt. 5. Carbolic acid destroys the *merulius* very rapidly. 6. Ordinary birch-tar is a very efficacious agent against dry-rot. The beams and interior surface of the boards should be coated with it. Its economy and the simplicity of its application render birch-tar one of the most convenient and practical means of obviating the entire necessity of the other remedies.

Lectern for Aston Church.—A polished-brass eck lectern has just been presented to the ancient parish church of Aston, near Birmingham. It has been manufactured by Messrs. Jones & Willis, of Birmingham and London.

locks.—The locks at Hatchett's Hotel were let by Messrs. Hobbs, Hart, & Co., for special key to pass each floor separately, with a special key for each lock, all distinct throughout building, and a principal master-key to pass all as throughout the hotel, which is a similar arrangement to those carried out by the same firm to the Grand Hotel, Claring-cross (over 4000 locks), and the First Avenue Hotel, in Holborn (over 500 locks). Messrs. Hobbs, Hart, & Co. are now making a similar arrangement for the Metropolitan, in Northumberland Avenue (over 750 locks), consisting of eight distinct special master-keys for the various floors, and special keys to differ to each lock throughout, and principal master-key to pass all, proprietors' use in case of fire, or otherwise obtain access to all doors throughout the hotel.

Kenby Winter Garden.—A short time since the town of Tenby, in South Wales, decided to set sufficient funds to erect a winter palace, den, concert-hall, salt-water swimming-baths, &c. The matter was warmly taken up by the inhabitants, and an influential committee is formed to carry out the project. The first

step to enable the committee to carry out the undertaking was to obtain designs for the scheme. This they decided should be by open competition among engineers and architects, and several designs were sent in. The committee charged with the selection of a design has chosen the one sent in by Messrs. Whitmore & Reeves, architects, Devonshire-square, Bishopsgate, London, and Chelmsford, who have been instructed to prepare working plans, and complete the designs of the undertaking to place before the Board of Trade.

Covers for Manholes, &c.—Mr. T. Durrans, architect, sends us the specification and drawing of his patent cover for manholes and other openings to cesspools, sewers, &c., which is, in fact, a screw cover, with either truly turned bevelled edge and seat, or with an elastic compressible medium to secure tightness of the joint.

Erratum.—The premiated design for the Newcastle Infectious Hospital, illustrated last week, was by "Messrs. Bradshaw & Gass," architects, of Bolton, and not by "Mr. J. Bradshaw Gass."

All communications respecting literary and artistic matters should be addressed to THE EDITOR; all communications relating to advertisements and other exclusively business matters should be addressed to THE PUBLISHER, and not to the Editor.

Fest Bath Stone.
WESTWOOD GROUND,
Box Ground, Combe Down,
Corsham Down,
And Farleigh Down.
BANDELL, SAUNDERS, & CO., Limited,
Corsham, Wilts. [Adv.]

Dry Corsham Stone.
150,000 FEET CUBE.
PICTOR & SONS,
BOX, WILTS. [Adv.]

Doubling Freestone.
The stone from these quarries is known as the "Weather Beds," and is of a very fine-grained nature, and is quite the best of the most durable stones in England.

THE CHELYNCH STONE.
It is of the same crystalline nature as the "holyach Stone," but finer in texture, and more suitable for architectural work.

THE BRAMBLEDITCH STONE.
It is of the same crystalline nature as the "holyach Stone," but finer in texture, and more suitable for architectural work.

HAM HILL STONE.
Greater facilities have been provided for working these quarries, and the stone can be supplied in large quantities at short notice.

Prices, and every information given, on application to **CHARLES TRASK & SONS,** Norton-sub-Hamdon, near Ilminster, Somerset. London Agent—Mr. E. WILLIAMS, 16, Craven-street, Strand, W.C. [Adv.]

Doubling Free Stone For prices, &c., address S. & J. STAPLE, Quarry Owners, Stone and Lime Merchants, Ilminster. [Adv.]

BLUE LIAS LIME (Ground or Lump), Ilminster. [Adv.]

Ham Hill Stone! Ham Hill Stone!!!
For Ham Hill Stone of best quality and workmanship, apply to **JOHN HANN & SON,** Quarry Owners, Montacute, Ilminster. Established 1837. Agents, **MATTHEWS & GEARD,** Albany Wharf, Regent's Park Basin, N.W. [Adv.]

Asphalte.—The Seyssel and Metallic Lava Asphaltic Company (Mr. E. Glenn), Office, 38, Bowly, E.C.—The best and cheapest materials for damp courses, railway arches, warehouse floors, flat roofs, stables, cow-sheds, and milk-rooms, granaries, tum-rooms, and terraces. [Adv.]

Magazines for the New Year

THE QUIVER
For JANUARY. Price 6d. contains—
Thoughts for the New Year. By the Lord Bishop of Bath and Wells.
The Marks of the Lord Jesus. By Rev. Horace Bonar, D.D.
Popular American Preachers. By the Rev. L. L. Bevan, D.D.
Scotland in 1884-5. By the Rev. Prof. Blackie, D.D.
A Bible Grant Story. By Rev. Gordon Calhoun, M.A.
The Mount of Forgiveness. By Rev. M. Guy Pearce.
New Parables from Nature. By Lady Laura Hampton Greichen. Short Story.
"When I Survey the Wondrous Cross." New Music. The Cedars and the Candlesticks. By the Rev. H. Macmillan, D.D.
Sunday in Hudson's Bay.
The World and Christ. By Rev. W. Meredith Johnston, M.A.
In Vychef's Land.
"The Quiver" Bible Class.
MOLLIE'S MAIDENS. Serial Story.
A POOR MAN'S WIFE. Serial Story. &c.
A safe and more interesting magazine we do not know than "The Quiver."
"The Quiver" contains a library of good reading.—*See item.*

CASSELL'S MAGAZINE

For JANUARY. Price 2d. contains:—
Brother Jonathan's Womankind.
Our Autograph Books.
The Secret of Making Clear Soups.
How Rumpus was Done.
His Son's Wife. Short Story.
"The Quiver" Magazine. A famous short-hand Champion.
How I Furnished for 10/6.
New Music: The Forgotten Song. By Humphrey J. Star.
The Fortress of Life. The Bugbear Cold.
A Historic Corner of an Historic County.
Sir Richard Owen and His Work.
Our Model Reading Club.
How We Live in Regent's Inn. (Things that are Going to be.)
These Christmas Voices. A Story.
Velvet and Furs: Chit-Chat on Dress.
The Gulliver.
A DIAMOND IN THE ROUGH. By Alice O'Hanlon. Serial Story.
SWEET CHRISTABEL. By Arabella M. Hopkinson. Serial Story. &c.
"The stories in Cassell's Magazine are good, the pictures clever, and the contents are unusually attractive."—*Times*.

LITTLE FOLKS

For JANUARY. Price 1d. forms the FIRST PART of a NEW VOLUME, and contains:—
A BEAUTIFUL COLOURED PICTURE, entitled "Three Little Kittens."
NOT FOUND OUT. New Serial Story.
KING CHARLES'S PAGE; or, Two Children's Adventures in the Time of the Commonwealth. New Serial Story. By Henry Frith.
Queen Anne's Adventure.
Seven Special Prize Competitions for 1885.
Indoor Cricket and How to Play it. (A New Game.)
Mother Carey's Chicken. A Fairy Story.
A Peep at the Soudan.
Fun in the Barony. Illustrated by Palmer Cox.
England's Forests in Days of Old. Windsor Forest and Park.
Legends and Stories of Famous Rivers. The Mississippi, Saved from the Flood.
Music. A Christmas Hymn.
"Little Folks" Proverb Punting Book "Competition Particulars."
Page for very little folks.
Prize Puzzle Competition.
With Illustrations on nearly every Page.
"Little Folks" is the best Magazine for Children."—*Graphic*.

THE MAGAZINE OF ART

For JANUARY. Price 1s. contains:—
Frontispiece in Colour: "Lady Mary Waldegrave," reproduced in Facsimile from a Drawing by J. Dowman, A.R.A.
Picture in Colour: "In Arcady." By Cosmo Monkhouse and E. F. Brentnall.
The Romance of Art: A Question of Copyright. By F. Mabel Robinson.
A Round in France. By Veer d'King.
Artists' Homes: Mr. Pett's, at Hampstead, by Helen Zimmern.
Pompeii in Black and White. By Jane E. Harrison.
Some Oriental Fresco Work. By Madeline A. Waller-Dunlop.
The Marvelous Madonna. By William Archer.
Elbu Vedder. By A. Mary F. Robinson.
"Little Maria Waldegrave." By Fm. Sidney Colvin.
With Forty-five Illustrations.
"The only Art Magazine which at all keeps pace with the moving current of Art."—*Academy*.

NOTICE.
A CLASSIFIED CATALOGUE,
Giving particulars of nearly ONE THOUSAND VOLUMES, published by Messrs. Cassell & Company, ranging in price from SIXPENCE TO TWENTY-FIVE GUINEAS, will be sent on request post free to any address.
CASSELL & CO., Lim., Ludgate-hill, London.

ARTISTIC VENTILATION.
SHARP & CO.
HYGIENIC AND HYDRAULIC ENGINEERS.

TESTIMONIAL
From **WALTER REID, Esq., M.D., &c.** (who conducted Tests for GOVERNMENT).

GENTLEMEN,—I have completed experiments with your Ventilator. I consider it a most effective Ventilator.—Yours truly,
(Signed) **WALTER REID.**

SPECIALITY.—"CONTINUOUS" System of House-Drain Ventilation. Up and Down-cast Ventilators, to suit every style of architecture.

HYDRAULIC RAMS (Fyfe's Patent) AND SANITARY APPLIANCES.

HEALTH EXHIBITION AWARDS.
1 GOLD, 1 SILVER, 4 BRONZE MEDALS.

11, Holborn Circus, London, E.C.

CALLNDAR HOUSE

JANUARY 3, 1885.

Peterborough Cathedral Restoration.

THE collision of various opposing minds in regard to the proper moral and architectural manner of carrying on the rebuilding at the crossing of Peterborough Cathedral has, like

the collision of opposing bodies in physics, generated heat, in sufficient degree to cause a boiling over, or, at least, a very pretty simmering, of which the outward and visible signs have manifested themselves during the last few years in the chullion of letters in that particular daily journal which a wise and merciful Providence has devised as a safety-valve for overcharged human vessels. Except religion itself, there seems to be no subject about which people are so ready to fall foul of each other as the treatment of religious buildings, and the series of letters which have appeared in the *Times* afford an odd exemplification of the apparently constitutional incapacity of restorers and anti-restorers to see two sides of the subject, or to believe that any one who differs from themselves can possibly have any sense or right on his side, or any claim to a hearing. The projected building of towers has been a cause of confusion of tongues from an early period of recorded human history; and the case of Peterborough seems to indicate that we have made little improvement in that respect since that mismanaged affair at Babel which led to the sudden stoppage of the contractor's operations.

The foundation of this quarrel was laid about seven centuries ago; or rather, to speak more exactly, the foundation was not laid, since that is "the very defect of the matter." Some little time ago we gave an illustration* of the extraordinary and scandalous construction of the Norman crossing-piers, mere skins of stone filled up with rubble, which, assisted by the want of any properly-prepared foundation, led to that failure of the tower which has rendered the present operations necessary. As early as the fourteenth century the results of this way of building had shown themselves. At that period the eastern and western arches of the crossing had to be rebuilt, and were of course rebuilt by the fourteenth-century builders in the style of their own time, as pointed arches, and with the mouldings that were in fashion at that period. The pointed arch originated in the practical effort to render the arch stronger at the crown, and no doubt

the adoption of this form rendered the task of the fourteenth-century repairers easier, but they would have adopted the form in any case: it would never have occurred to them that it was necessary to depart from their habit of building all arches pointed, in order to preserve the unity of design at the crossing. Of this more anon. At the same time the tower, having been partially taken down, was reinstated without the arcaded stage which formerly supervened over the great arches, and was proportionally lowered and lightened, from considerations of safety. Dean Kipling, at the beginning of the present century, made a well-intended effort to give more finish and outline to the tower by the four lean, lanky turrets which were such an eyesore to the beholder, and which, from any point of view in which they were prominent, gave an air of gimcrack to the whole centre portion of the building.* Two years ago ensued the hurried taking down of the tower, in the fear of an imminent catastrophe, and the revelation of that style of execution in the substructure which really rendered it matter for wonder how the tower had contrived to stand on its tottering legs for so long. The eastern piers alone were at first condemned, but further examination led to the condemnation of the western piers also. It was then considered the simplest matter to take down the whole tower; though, of course, modern engineering would have been equal to the support of the tower while the piers were rebuilt. Whether there was any architectural *arrière pensée* in this getting rid of the tower we cannot, of course, pretend to know. The accounts which got into the papers, directly or indirectly (for there has been a mysterious secrecy in the carrying on of the deliberations on the subject till this recent outbreak of letter writing), conveyed the impression that every stone was to be numbered and replaced as before. The numbering, we believe, has been duly carried out. However, the demolition was extended beyond what was at first thought necessary, and the contract was enlarged accordingly. The original contract provided simply for a restoration of the tower as it stood (all but Kipling's turrets), and the incongruity of two round and two pointed arches in close partnership was to be reproduced. But there were found, in the course of the demolition, carelessly stowed inside the fourteenth-century skin as mere packing, many of the moulded stones which had composed the two Norman

arches, and portions of the arcading condemned at the period of that old restoration. These discoveries formed the subject of much informal conversation between members of the Chapter and the Cathedral architect, Mr. J. L. Pearson. Mr. Pearson became most strongly of opinion that, in view of these discoveries, and on all accounts indeed, the opportunity should not be missed of restoring the twelfth-century design in its integrity. Accordingly, in August last, he submitted to the Chapter and the Restoration Committee a plan showing the tower restored on the four Norman arches, with the restored arcading stage inserted immediately above the arches, the lantern itself rising over this, and the whole surmounted by a lofty spire. By this time the work of rebuilding had so far progressed as to make it impossible to go a step further without being fully pledged to the one plan or the other, and accordingly operations ceased. At a meeting on September 24th, the Dean and Chapter considered Mr. Pearson's new plan. It was understood that in view of the scarcity of finances, and the amount of necessary repair work on other parts of the Minster, which work was still unestimated and uncontracted for, the Chapter could not adopt the architect's proposals. The Restoration Committee, on the other hand, met on October 13th, and after discussion, resolved to recommend the adoption of Mr. Pearson's views to the extent of restoring the two round Norman arches and the Norman arcading stage formerly resting on it; the lantern, as recently in position, to rise from the restored stage, and the architect's spire to be meanwhile held in abeyance. The Chapter met again on October 27th, and (the Dean dissenting) disallowed the above recommendation, formally contending that the still unestimated work, viz., "the underpinning of the transepts and repairs of the roofs, the restoration of the choir, and the securing and strengthening of the west front," was more urgent in character than any mere central tower amplification. The controversy thus took definite form: the Restoration Committee, with an important ally from the Chapter in the Dean himself, favouring the architect's views, while the Canons, who formed the bulk of the Chapter, adhered firmly to the rebuilding plan as originally settled and contracted for. Bishop Magee sided with the Canons (although on no footing of authority, not being a member of the Chapter), and so strongly as to threaten the withdrawal of his subscription to the restoration fund unless the existing contract were carried out unchanged. Hereupon ensued a general *émeute*.

The Chapter met again on the 10th of December, adhering more firmly than ever to

* *Builder*, May 17, 1884.

* We gave a drawing of the tower, by Mr. Brewer, in the *Builder* for January 27, 1883. Mr. Brewer, however, unconsciously improved the effect of the turrets a little, as compared with a recent photograph shown.

their former resolution, the Dean alone dissenting. The Restoration Committee met a few days subsequently, and reiterated its partiality for Mr. Pearson's proposals in a modified form. A further meeting of the Chapter was held on the 22nd of December, at which the canons agreed to the insertion of the single stage of the Norman arcading, provided the necessary funds be forthcoming; but still refusing consent to the substitution of Norman for Pointed arches. The Chapter is nominally the responsible body, but as the money has to come from the general public and through the Restoration Committee, the autonomy of the minister executive is more a matter of theory than practice, and hence the stoppage of building proceedings all these weeks, in direct opposition to the wishes of the Chapter.

The recent boiling over on the subject has been specially stirred up by Sir E. Beckett, who appears to have received a commission from the Dean of Peterborough to demolish the views of the Chapter. Here was an opportunity for abusing a number of respectable people and calling them "lunatics," and so forth, which was not to be let slip. In some former expression of ill-temper (it cannot be called opinion) Sir E. Beckett represented an architect, who had extended the restoring operations on a church, as a person who had been making a job for himself. We have no doubt he would have represented Mr. Pearson in the same light, had he been retained on the other side. As it is, he supports the architect for once, as there are more people to quarrel with on the other side. A few weeks back, in another letter in the *Times*, Sir E. Beckett referred with contempt to the doings of Scott as a restorer; but in the present letter he cites in favour of his views the evidence of "the very able clerk of works at Peterborough, who has restored cathedrals under Scott," and who has "discovered," according to Sir E. Beckett, that the "two intruding pointed arches were nothing but an *ex post facto* makeshift of the fourteenth-century builders." It needed neither the clerk of works nor Sir E. Beckett to tell us that. Without following out, however, Sir E. Beckett's ebullitions against everything and everybody who is opposed to his view at the moment, it is sufficient to say that he supports entirely the most extensive scheme, spire and all. To him follows Mr. Freeman, who hoists with equal pertinacity the "historic" standard, and objects to having any tampering with the Peterborough Cathedral which he has known all his life. Architecture is history to Mr. Freeman, history before anything else. Then comes Canon Davys, of St. Alban's, who is for rebuilding, not for restoration; but who being also, it appears, an amateur architect, has designs of his own, and accordingly calls Mr. Pearson's spires "monstrosities," a remark which is little less than impertinent as well as ill-mannered. The amateur doctors do not agree, however, for Canon Davys, though recommending an octagonal lantern, appears to have made a design for a spire on the top of the lantern, which Sir E. Beckett told him had the slight defect that it could not stand; and very likely Sir Edmund was right.

Into the morality of the question, whether the legal custodians of the cathedral have a right to use, for a new design, money which was subscribed for mere rebuilding of the numbered stones after strengthening the piers, we do not here enter, especially since satisfactory evidence is not forthcoming as to whether such an understanding really existed. Between the Canons and Sir E. Beckett the matter seems to be rather like the arguments of children,—"Did!" "Didn't!" and so on. They must settle that among their own collective consciences. But as to the case between what may be called the historical and the architectural view, the matter seems to stand thus. The tower which was recently taken down was a very poor concern; too low, because it had been deprived of its former arcade story against which the roofs should have abutted, in order to diminish the weight on the old weak piers. The belfry stage was accordingly crowded on the roof, which cuts across

the window lines. The turrets, which Mr. Freeman praises as good in outline,—a judgment which says little for his sense of architectural design,—we have no hesitation in saying were wretched affairs, and no architect in his senses would want to see them up again: like the child's doll, "for old sake's sake they are dear" to some people, and that is all that can be said for them. As they and their tower are down, we should hold that as a fortunate excuse for getting rid of them and doing something better. The question of the pointed arches is a more difficult one. They are not "good-for-nothing" arches, as Sir E. Beckett calls them; they represent good fourteenth-century building, and there are their moulded voussours lying ready to be put up again. We quite understand the feeling of many persons against leaving them "to spoil." The insertion of these arches was undoubtedly, as Mr. Freeman views it, an interesting piece of architectural history, and they should certainly not have been removed for merely architectural reasons. But the case is a good deal altered when they have actually been taken down; and here comes in the architectural side of the question. It has been urged that we have no right to interpolate our ideas of building, in the same way in which fourteenth-century architects interpolated theirs amid the works of their predecessors, because we have no characteristic nineteenth-century style. But we have one quality which the fourteenth-century builders had not, but which we imagine the Greek builders had, viz., the sense of artistic fitness and congruity of design. Architecture is not *only* history, *pace* Mr. Freeman; it is also art. From this point of view there is no doubt that when the fourteenth-century builders interpolated their work in the complete Norman design of the crossing; they committed what an American would call an "almighty blunder." They spoiled the architectural unity of the crossing; and, after turning the matter over every way, our conclusion is that we should regard the demolition of the whole centre of the Cathedral as an opportunity for correcting this blunder, and for restoring on the new sound and solidly founded piers the complete homogeneous design of the crossing, and let that be the contribution of this generation to the history of Peterborough. The rebuilding of the arcaded stage of the lantern, which would complete this part of the design, and which furnishes the intermediate or triforium stage against which the roof should abut externally, follows equally on the same grounds. It is doubtful if it could be logically urged, if the pointed arches were rebuilt. To rebuild them and then restore the Norman triforium (which seems now to be the compromise proposed), into which the pointed arches would cut, seems to us a foolish and irrational proceeding, good neither as history nor as architecture; a jumble of both in the attempt to make two ends meet which will not meet.

The rebuilding of the lantern stage should then be continued, using the old millions, window jambs, and tracery, &c., so far as they are complete for the purpose. Mr. Pearson's new tower and spire design, we believe, does not allow of this, this stage having been modified so far as to render a new spacing of the windows necessary. On the face of it this appears to us to be unnecessary and undesirable. As to what should be further done with the central feature of the cathedral is another difficult question. Mr. Freeman's argument, that the great west front is really the predominant feature of the building,—that it is the Greek portico translated into Gothic (a perfectly rational and comprehensible way of putting it, which Sir E. Beckett does not seem to understand),—appears to us to be sound in so far as this, that a lofty spire,—and it must be a very lofty one to be an adequate centre to Peterborough Cathedral,—would be out of keeping with the grave and severe lines of the building generally. Mr. T. G. Jackson, who contributes a note to the discussion, goes further and says he does not know or care whether the new design would be an improve-

ment or not. If it made the cathedral doubly beautiful, he says, it ought not to be done (or historical grounds). Is this the way for an architect to write? But our feeling is that a square central tower, with, perhaps, an octagonal lantern, would harmonise best with the cathedral. We utterly repudiate the argument that a superior central feature would injure the effect of the west front, or that because the cathedral has an exceptionally grand west front, it should have no central feature. That appears to us to be little short of nonsense. But we doubt whether a spire would add anything to the cathedral worth its cost, and whether it would not even detract from it. But there is a more practical reason for leaving the spire at present in abeyance. There are more important things to be thought of. It is probable that the west front itself is in a precarious condition. The examination and strengthening of that should be the next business, and the next thing for which subscriptions are asked. In the meantime, the building of the Norman arches and the arcade story should be proceeded with; and the committee would, perhaps, do wisely to ask Mr. Pearson for a design for completing the tower with the lantern stage and new angle turrets only, and another for superimposing an octagonal lantern without a spire. We imagine general opinion would be in favour of the latter. But it ought, of course, to be decided on before the lantern stage is rebuilt, as the style of final completion would undoubtedly affect the treatment of the lantern stage.

The Restoration Committee, we may add, would probably receive more support, pecuniary and otherwise, and perhaps receive more suggestions that would be worth considering if, in what is really a work of national interest, they took the public more into their confidence, instead of leaving the matter to be fought out according to the prejudices of opposing cliques and the *animus* of lawyers, clergymen, and other *dilettanti*.

COMMUNICATIONS.

BY LIEUT.-GEN. F. H. RUNDALL, C.S.I., R.E.,
LATE INSPECTOR-GENERAL OF CANALS
FOR THE GOVERNMENT OF INDIA.

NE of the first symptoms of an un-civilised country emerging from a state of barbarism is an attempt to open out lines of communication first within its own borders, and then with its neighbours, and just in proportion as its civilisation progresses, so does the desire grow for increased facilities of intercourse with the rest of the world, cause and effect thus reacting one on the other till it becomes difficult to discriminate between them. That which distinguished the invasions of the Roman Empire from the incursions of those barbaric hordes from the East, which over-ran the greater part of Europe in the fifth century, was, that wherever Rome carried her conquering legions she left behind at least one unmistakable trace of civilisation in the shape of magnificent roads, whereas the tracks of Attila and his Huns were marked only by devastation and ruin. That, in Europe, at all events, the Romans were pre-eminently the constructor of communications is attested by the excellent preservation in which the remains of many of their roads in various countries have been found. In China, which is said to have enjoyed a high degree of civilisation centuries before the Western nations emerged from barbarism, there existed a ramification of internal lines in the shape of navigable rivers and canals, the geographical features of the country in its case determining the character of the communications. In India the Mahomedan conquerors signalled their rule by the construction of both land and water ways, but in America the pioneers of civilisation found but few traces of any artificially-made lines, though the magnificent series of navigable rivers and lakes were speedily made use of and constitute to the present day, notwithstanding the extensive network of railways, the chief routes and means of transport for the produce of the countries which they respectively drain.

The object of this paper being to draw attention to the important subject of communications general, rather than to technical details of construction, I purpose to refer principally to their fiscal and political aspects, and to the principles which ought to govern the development of communications in countries in proportion to their different degrees of civilisation. There is perhaps, no subject on which greater misconceptions exist, and greater mistakes are made, than that of designing internal communications, the chief misapprehension being one that is continually recurring, viz., that traffic makes the communication, whereas it is perfectly certain, and is being continually demonstrated, that the exact opposite is the case, and that the traffic follows the communications. A curious instance of the inability of men, even in high positions, to appreciate this fact occurred in years gone by in one of the districts in South India, where the chief English official, on being directed by the Government to forward a list of the roads which were needed in the province under his control, replied that it would be a mere waste of money to incur any outlay on roads, for that one at all were wanted was evidenced by the fact that there was not a cart in his district to go upon them! But another instance, though in an opposite direction, is to be found nearer home, in the petition made less than 150 years ago to Parliament by some of the counties in the neighbourhood of London, to the effect that the turnpike-roads might not be extended into the remote counties for fear that the produce raised by the cheaper labour in the latter might undersell their own in the London markets!

Obviously, however, there exists a necessity for the exercise of discretion in the first election and construction, as well as in the after-development, of lines of communication. The first consideration should be the existing circumstances of the locality to be served, its poverty or its wealth, the scantiness or the redundancy of its population, as well as of their respective industries, the nature of its resources,—agricultural or mineral,—the chief object to be obtained, political or commercial, or both, and the general geographical position and features of the country, the proportional extent to which they must govern the character of the communications, such as proximity or remoteness from the coast, and the relative distances which produce would have to be carried for shipment.

It is clear why, in the first place, the wealth or otherwise of a country must determine the kind of communication to be provided; for a poor country would not be able to stand the capital outlay attendant on costly works, and the high rate of charges which must necessarily be levied in order to meet the interest and working expenses; and if, in addition, its population be scanty, there will be still less ability to meet a high rate. It is evident, also, how the main products must govern, in a great measure, the transit arrangements; for what would be suitable for light and valuable raw products would be wholly the reverse for bulky articles of small value; while a mineral district would require entirely different provision from a purely agricultural tract. But one element which bears more or less essentially on every description of goods to be carried is that of distance: for where, as in the case of America and India, the distances are very great, even a moderate charge is sufficient to make the difference between the ability of delivering goods with an available margin for profit, or of preventing their being moved at all. Indeed, there is a certain low class of goods which at present is rarely moved at all, except along very short distances, owing to the cost of transport not being sufficiently low; but were it capable of being reduced to little more than a nominal rate the enormous quantities that would be set in motion would require such extensive provision for their carriage that, great as the traffic in many countries already is, it would exceed our present ideas as much as the existing traffic in the closing years of this century exceeds what it was at its beginning.

When, however, a nation has to provide for its political necessities as well as for its com-

mercial interests, a new factor is introduced which must override all others; and the element of economy, indispensable for its commercial aspects, must then give way to the higher interests of imperial safety, otherwise a neglect to secure the latter may tend to the destruction of the entire resources of the kingdom's wealth, and consequently disable it to offer a successful resistance to the aggression of its foes.

The means of internal transit at present existing may be briefly stated as the River, the Road, and the Rail; but that great encircling international highway, the Ocean, which enables all the countries in the world to carry on a friendly interchange of commercial requirements must ever remain the principal and the most efficient, because the cheapest means of communication. Whether, as science advances, the air may be laid under contribution to meet the locomotive convenience or necessities of mankind, it is at present useless to speculate. It will be sufficient for present purposes to make the most of the means at disposal, and it is to the interest, not only of England, but of every nation, to see that there is not a misapplication of those means, but that they are in every instance adapted respectively to the end desired to be gained,—an end which should not be allowed to fall short of effecting the greatest good to the greatest number of the people directly interested.

A review of the several extensions and improvements in communications which have been made during the current century in the four quarters of the globe would far exceed the limits of this paper, and therefore it will be possible only to glance at a few of the more prominent instances. First of all, the wonderful stride which has been made in ocean navigation would be scarcely credible were it not presented to us so tangibly. The venture some commander of the first cockle-shell that put to sea, whose hardihood has been immortalised by Horace, would scarcely trust his senses could he be suddenly recalled to life and placed on the deck of one of our armoured war-ships; much less would he have believed any prophet who could have foretold the dimensions of some of our mercantile fleet which now ply to east and west and north and south of the inhabited world. Half a century has scarcely passed since the possibility of steaming across the Atlantic was stigmatised as a dream by some of our men of science, but now the advancement of the age will not be satisfied until the voyage from Liverpool to New York is performed within the week. The great Ocean Highway remains the same that it ever was and ever will be. It is merely the means of traversing it that have been improved, and the remarkable part of the improvement is, that in spite of the law that increased speed entails more than a proportional increase of cost, the actual charges both for passengers and goods have been reduced in an inverse ratio to the increase in speed. Science has taught us how, while we enlarge the carrying capacity of vessels we can simultaneously reduce their resistance, the limits of which, moreover, have not even yet been reached, for it is a comparatively recent discovery which has shown us that by far the greater part of a vessel's resistance is due not to the midship section but to surface, or, as it is termed, "skin friction." Year by year some improvement is being made in steam machinery by which the consumption of fuel is diminished, while the application of the calorific engine to sundry purposes, and of compressed air to the propulsion of vehicles, not to mention the daily discoveries in electricity, indicate the possibility of a complete revolution in motive powers in the not very distant future. Every shilling expended in the improvement of Ocean transit is a shilling gained, inasmuch as it is infallibly accompanied by a reduction in cost and charges, and is, therefore, a benefit conferred, not only on the shareholders of Steam Companies only, but on every inhabitant of the world, inasmuch as whatever tends to lower the cost of transport, cheapens the price of every article carried to the consumer without at the same time lessening the profit of the manufacturer or producer.

Competition must and will always regulate freights. Combination such as has been effected in the railway companies, can never take place in ocean navigation, and thus the public are safeguarded from ever being left at the mercy of a great carrying monopoly. As the great carrier of the world, England has an especial interest in the improvement of Ocean transit, with regard to which she has most markedly performed her duty, having had the chief share in originating and perfecting the improvements as yet effected therein. She has thus not only added to the wealth of her own children, but has been the means of conferring inestimable boons on the rest of the civilised world. The question naturally suggests itself at the present time, will she continue to lead the van on that great highway, of which, up till now, she has been permitted to retain the command? The rest of the maritime nations, if report be true, are making rapid strides to come up with her, if they have not already overtaken her so far as war-ships are concerned; but with the great reserve of power in her as yet unrivalled mercantile fleet, many of the finest vessels in which have been specially built with a view of being utilised as armed cruisers, and with the old naval spirit reanimating her sons, there need be little fear, if sufficient war vessels are provided, but that she will continue to retain the supremacy on the great line of sea-communication.

Passing on now from the ocean to the land, from steam propulsion on water to steam traction on the rail, we arrive at the most important and the most extraordinary development of communications in the world's history. The encircling the globe with iron roads has attracted greater attention and more of the world's admiration than the progress which has been made in ocean navigation; probably because railways have been brought under the individual cognizance and personal experience of so much larger a proportion of the world's inhabitants, but in reality the actual facts accomplished, if measured by the results, are really not more, if so wonderful, as those attained by a single ocean steamer which traverses far greater distances than any individual line of railway yet constructed. Nevertheless the first discovery and the subsequent growth of the railway system is deservedly classed as the wonder of the age. The total revolution which it has created in the locomotive habits of mankind, and the desire which it has first implanted and then gratified for a continual running to and fro of the inhabitants of every country in which railways have been constructed, has far exceeded the most sanguine anticipations that could ever have been formed. The enormous reduction in the cost of internal transport of goods and in the conveyance of passengers of which it has effected over the old methods of locomotion naturally led the world to consider that the limit of economy had at length been reached, and to sit down contented with the result which had been achieved, while all classes of the community, producers, carriers, and consumers congratulated each other on the prosperity which they were one and all to reap without the least interference with each other's individual interests.

Experience, however, has begun to demonstrate that there is a limit, and a very sensible limit, to the reduction in the cost of carriage by railways; that there are not the same possibilities for reducing the rates as in ocean transit; that increase of speed in their case necessitates increased charges to meet the additional outlay; while the essential difference in capital cost for the item of permanent way alone presents an insuperable obstacle to a diminution of charges, and the wear and tear to which it is exposed, rendering obligatory a large outlay for its efficient maintenance, is so directly proportioned to the increase in traffic as to effectually prevent any material reduction in working expenses. Hence, with a minimum mileage rate, below which it is impossible to carry except at a loss, the element of distance materially affects the practicability of carrying articles of low value; for it is obvious that when the expense of moving a ton of goods such as cotton worth 50L., and a ton of

road material worth 5s., is the same, as long as they must both travel at the same speed, the distance to which the latter can be conveyed at even the minimum rate must be very limited. Hence railway carriage cannot be applicable under all circumstances, more especially in those countries, or those localities in the same country, where a cheaper mode of conveyance is possible and practicable. The aphorism, that "the iron horse is the pioneer of civilisation," has been and is still so often repeated that it has come to be considered as an indisputable axiom; but, nevertheless, it is misleading, and it would be more accurate to say that "the iron horse is the rear-guard of civilisation"; for railways are a product of highly-civilised communities, and the outcome of advanced scientific refinements. Before, therefore, determining on the introduction of railways as the best means of communication in new or only partially civilised States, there are, it will be seen, a number of points to be carefully considered, and, amongst others, that of the existing modes of conveyance, their suitability to prevailing circumstances and surroundings, and their possible improvement.

These considerations lead to the subject of water-carriage in those countries which are furnished with navigable rivers. Where such magnificent arterial highways exist as in the great continents of America, India, China, and Africa, and even in some parts of Europe, it will be found that they still convey the bulk of the traffic, especially that class of goods that can only bear transportation at the lowest possible rates; for, since the perfecting of the various modes of carriage has brought all parts of the globe into close intercommunication, the value, both intrinsic and relative, of every article of consumption has become so much equalised as to leave but a very small margin of profit to the producer and manufacturer; so much so, that the trifling extra charge for conveyance over long distances is now sufficient to turn the scale. A notable instance in point is the article of wheat, which is now almost entirely kept in the hands of the Americans, because the rate of internal transport in India is still too high to admit of its carriage over the long distance between the place of its production and the ports of shipment. Undoubtedly the railways have enormously reduced the cost of carriage below that which formerly obtained, and, when fairly high prices rule in the London market, render the sale of Indian wheat possible; but it is beyond dispute that had one-tenth part of the 143 millions expended on them been devoted to connecting and perfecting the existing water lines between the interior and the ports, so as to have rendered them available as first-class

Navigations, the cost of carriage could have been reduced to a level with the American markets being supplied with Indian wheat, and so ensured the circulation of our capital amongst, and not away, as at present, from our own possessions, besides preserving the enormous additional advantage of independence of foreign countries in a time of war. For this calling out capital for railway extension in India, to the prejudice and exclusion of water-carriage, is, in the opinion of many who are well qualified to judge of the commercial interests of our Indian Empire, a most unfortunate and mistaken policy, to which may be most appropriately applied the injunction, "This ought ye to have done, and not to leave the other undone."

The relative economies of rail and water carriage in different countries have been so plainly and exhaustively set forth in the evidence given before the Parliamentary Committee on Canals in 1853, that those readers of the *Builder* who may be desirous of information on the subject will find all the particulars in the Blue Book. It would exceed the limits assigned to this paper to enter into such details, and therefore I would only add, that in England even, there are not wanting symptoms of dissatisfaction with the result of the railway system of combination, the most recent action of which, so far from bringing relief to the trading community, seems likely to tighten the screw

as regards rates, and unless manufacturers and producers co-operate to "enfranchise" and to "reconstruct," on the most efficient system possible, the Water-lines which first wrought such prosperity for England, they will inevitably be brought under the thralldom of a gigantic monopoly, from which extrication hereafter will be almost impossible. Hence the miscarriage of such an enterprise as the Manchester Ship Canal is much to be deplored, while it is a decided blot upon our modes of procedure that a fine of 100,000*l.* should have been inflicted on the public-spirited promoters of so valuable an enterprise by what was seemingly little more than opposition of self-interested parties.

The subject of Communications embraces so wide a scope that it is impossible to deal with it exhaustively in a single article. I will, therefore, not enter now upon any remarks on the relative merits of Road, River, and Canal transit, but leave that portion of the question to be dealt with on some future occasion.

GAINSBOROUGH AT THE GROSVENOR GALLERY.

THE proprietors of the Grosvenor Gallery have added largely to the debt of gratitude the public already owe them. The collection of the works of Sir Joshua Reynolds brought together last year was one of the most important and instructive exhibitions of pictures ever shown in London. Followed, as it now is, after an interval of nine months, and whilst it is still fresh in our memories, by a similar collection of the works of Reynolds's great contemporary, we have the materials before us for the formation of a sound and lasting judgment on the merits of the two great leaders of English art. Reynolds we have learned to know as a master in the rendering of character. He was essentially a man of insight,—many-sided himself, and capable, therefore, of understanding men of different sorts and kinds. The feature that was most striking to a visitor entering last year's exhibition was the varied character of his work, the different styles which in some cases succeeded one another, and in other cases were employed simultaneously by him. The present collection of Gainsborough's works, though not quite so numerous (the catalogue contains 216 numbers), is large enough for all purposes of comparison. In contrast with Reynolds, Gainsborough impresses us by the uniformity of his style. From childhood to age he developed along one line of advance; and, were the pictures hung chronologically, or were facilities given to the visitor to pass in chronological sequence from group to group, as by numbering, or in many other ways, might have been done, the steady and even progress of the artist would be visible to the least experienced. Holding, as we know, that the only way an artist can really be known, is by learning how he grew on from stage to stage, how he learned and how he forgot; and, considering how seldom it is possible for the public (the pictures of each artist being in the nature of things scattered about) to see such a development for themselves from beginning to end, it can be regarded as nothing less than a calamity that these two great exhibitions have not been used to produce the educational effect upon the public understanding which they might have been made to produce.

The contrast between Gainsborough and Reynolds can be readily seen by comparing the portrait of Johnson (No. 119) here with Reynolds's Johnson in the National Gallery, pictured in words. He visibly expressed upon the canvas the struggling, overburdened, yet victorious intellect, penetrating through the gloom of his fleshly incubation. Gainsborough, on the contrary, altogether fails to grip the character of his subject. He produces a flabby likeness of him at his worst. He takes him at a moment when the flesh had won the upper hand and when the mind was sluggish or asleep. The tyrant of conversation here looks miserable beyond words, for all the

world as though some one had just poured a little cold water down his back. Doubtless he often did look like this, but a portrait-painter's business is to show his subject not at his worst, but when his mind is awake, and we can see what manner of man he was and what capabilities he had within him. As a contrast to this picture, in which Gainsborough failed, the portrait of Tenducci, the cunuch singer, may be quoted as a great success. It is the best, indeed almost the only satisfactory representation of a person singing we anywhere remember. The man holds his music before him and is lightly beating time to his own singing, his face suffused with a rather feeble and apparently habitual smile. The transitory aspect of the man is caught as though he had been photographed by lightning, and herein lies Gainsborough's peculiar gift. If he fails to render depths of character he succeeds in catching the fleeting traces of expression. That amount of a person's nature which is manifested in a fleeting glance, a passing smile, a hurried gesture, is always seen and shown by this artist.

It is an unavoidable misfortune that the first edition of the catalogue should present a great many gaps and imperfections, especially in the wholesale omission of accurate or even approximate dates. It is excellent as far as it goes, and even in its least complete portions it is superior to the best parts of the Burlington House catalogues. At present, therefore, a student will find it rather hard to trace the origin and development of Gainsborough's style. We shall, therefore, endeavour to save him time and annoyance by pointing out a few guide-posts of the way. Gainsborough was born at Sudbury, in Suffolk, in 1727. The earliest of his exhibited pictures (c. 1735-40) is the "Head of a Man looking over a Wall" (No. 395). Its story is fully told in the catalogue. It is painted on panel, and the wood is cut away, round the edge of the hat, face, and shoulders, like a silhouette. The paint is laid on heavily and quickly, the colours being thick, and the touch determined. The posture of the figure is caught with skill. Passing to the portrait of Mrs. Hingston (No. 89), which was painted about 1744, after the young artist had returned from his studies in London, and during his residence at Ipswich, here we see him working in the ordinary style of the day, the same style as that employed by men of the Peter Vandeyck stamp. The upright and precise lady is uprightly and precisely painted, and her expression is well caught. The embryo powers of the young artist can be traced in the work, but at present they do little more than inspire with something of brightness and life, the otherwise dead lump of school imitation. Far freer, as was but natural, is the portrait of Gainsborough's destined wife, Miss Margaret Burr, which was painted about the same time. She is placed in the same position, and the light falls upon her from the same point as in the preceding picture, but already in the arrangement and treatment of her costume and in the landscape background there is a distinct forecast of what was to come. The young lady is stout and good-humoured, but by no means beautiful of aspect. She is one of those people whose character year by year moulded her countenance to a continually ripening beauty as a comparison with her other portraits (Nos. 80 and 175, the latter not included in the index) will show. Passing to 1761, the year after Gainsborough had made the important move of his life to Bath, we must pause before the whole-length seated portrait of Earl Nugent (No. 204). It was this picture, exhibited at the Gallery of the Society of Artists of Great Britain in the thirty-fourth year of Gainsborough's life, which established his fame for him on a permanent basis. Compared to his later productions, it does not possess the attractive charm which was afterwards to be his prerogative, but as a sound and solid piece of likeness-making it is as good as anything he ever did. The stout and smiling old country gentleman, seated substantially in his chair in a corner of his room by the window, well at ease with all the

world, is a wholly satisfactory creation. The visitor may be advised at this point to go aside for a moment to the picture of Sir Benjamin Truman (No. 12). By a comparison of these two works Gainsborough's method of showing character by means of momentary expression will become perfectly clear. The picture of David Garrick (No. 7), painted in 1766, about the same time as that of Sir Harbord Harbord (No. 37), marks Gainsborough's attainment of the final development of his powers. Henceforward he progressed steadily and unflinchingly, but his pictures are always of this kind, and possess the qualities here definitely manifested. Garrick is out of doors in a park. He is leaning against a pedestal, and has his arm thrown round the foot of a bust of Shakspeare. His head is bare, and he looks upwards with a bright expression of countenance. The face is visibly of a mobile kind, changeful, but momentarily fixed by the painter's art. Overhead there is a rapidly-painted mass of foliage, and the landscape background and turbid sky are likewise thrown in rather than painted. Gainsborough did not wish you to look at his backgrounds, but to concentrate your attention upon the persons. The artist shows remarkable skill in directing the spectator's glance away from what he is not to look at and towards the point of chief importance. In the portrait of George III. (No. 34), for example, it is to the clever management of the lights that the figure owes a dignity which in real life it can never have possessed. It requires a distinct effort of will to look at the face. The eye is naturally attracted to the broad, sunlit expanse of the waistcoat, and what delight it receives is from the colouring and texture of the fine costume and the brilliancy of the illumination; the man within and behind it all is of no account whatever.

As a rule, Gainsborough's full-length portraits of men are not his finest works. Some of them, such as that of Fisher, the composer (112), are spoiled by the kind of affectation which only adds another charm to the portraits of ladies. A conspicuous exception is a picture, which on reference to the catalogue turns out to represent a parson of the old school, to wit, Sir Henry Bate Dudley, known as "Fighting Parson Bate" (171). He was a remarkable person, famous for his gallantry and his enterprise. He started successful journalistic enterprises in London, fought duels, and was the friend of the wits of the day. He afterwards became a country rector, in which capacity he reclaimed land from the sea, improved agriculture in his neighbourhood, and made himself generally useful in the world. He was created a baronet as a mark of recognition for his public services. He lived in a day when a country parson might dress as he liked, and being a man of handsome appearance, he did not fail to make the best of himself. The portrait exhibits just the kind of man we should expect,—a strong, capable person, full of vigour of body and mind, healthy and human, and well fitted to play a useful part upon the stage of life. The picture was exhibited at Burlington House last year, and attracted considerable attention.

Gainsborough's pictures of children, though in some cases excellent, do not rival the work of Sir Joshua in this line. The little three-quarter length (No. 184) of Georgiana Spencer, afterwards the famous Duchess of Devonshire, was painted about the year 1763. The child, dressed in a white frock with pink ribbons, looks a bright intelligent little soul, but the picture has no technical charm, and the subject is stiffly though conscientiously treated. The portrait of Juliet Mott (No. 162) is more advanced, and possesses promise, of which the little oval of Edward Gardiner (No. 132) is a charming fulfilment, the sweetness of the face and the softness of the hair being beautifully rendered. The best child's picture, however, is the "Cottage Girl" (No. 173), of which Leslie said that it is "unequaled by anything of the kind in the world." It represents a little bare-footed, ragged clothed child, walking to the well with a chipped brown pinner in the right hand, and a pet dog carried, in resigned discomfort, under the left arm. The child's face tells of care: she is early wise and

wistful, though still a perfect child. We are told that she is really a portrait in character, but unlike the ordinary run of such productions, Gainsborough has made her look honestly a beggar, and has removed every trace of the young lady far from her.

But the class of pictures here exhibited, which will attract the largest share of observation and praise, is that including the larger, and especially the full-length, portraits of ladies in beautiful attire. All the best of these were painted just a century ago during the last decade of Gainsborough's life (1780 to 1788). It is not easy to select, out of some half-dozen, which is absolutely the finest. The Lady Sheffield (No. 47), dressed in a costume of glossy blues and whites, such as Gainsborough loved, is standing in the foreground of a landscape. Her face is set beneath a mass of powdered ringlets crowned by a large blue hat with a conspicuous blue bow. The charm of the picture is not the personality or beauty of the lady, but the skill with which the artist has treated her dress and the lights and dusky colours about her. In almost all his fine portraits he makes the textures of the dress glossy and the background dusky, and the contrast is always very effective, though, of course, when a multitude of such pictures are brought together a certain lack of variety becomes evident. As fine if not finer than the preceding is the portrait of "Parson Bate's" Wife (No. 75), which is familiar to all who visited the "old masters" exhibition last year. The chord of colour and the combination of textures in both these pictures is the same. They are both remarkable for dignity and grace of posture and a flow of line which the beautiful drawing of the arms and hands does much to emphasise. The same flow and rhythm of line is likewise one of the chief characteristics of the portrait of Georgiana, Duchess of Devonshire. She was a lady often painted and much written about. Sir Joshua undoubtedly has left us the best record of her, but this picture possesses qualities of grace and sweetness of expression that Sir Joshua did not aim at rendering. As a piece of painting the portrait of Mrs. Basset (No. 59) is one of the finest things in the collection. The choice and rendering of accessories is superb. The feathers and the pearls and the silk form a combination in which the eye of the beholder revels without weariness or surfeit. The full-length portrait of the painter's daughters (91) is a good proof of how much he could do with costume. The ladies are of little beauty, but standing affectionately together in the open air, as they do, on a wooded hill-side, though they look fanciful in their low-necked beautifully coloured dresses and bare heads, they produce upon the beholder an effect which he does not at first perceive to be due, not to their personal attractions, but to the painter's art.

Gainsborough felt the influence of Vandyck even more than Sir Joshua did. His last words spoken to his great rival mark the tendency of his art as well as the happiness of his disposition,—“We are all going to heaven, and Vandyck is of the party.” All his life long he looked up to and strove to imitate the great Netherlander, and two or more copies made by Gainsborough from his work are evidences of this study, if, indeed, such a picture as the "Blue Boy" (62) were not evidence enough. When that picture was exhibited at the Royal Academy in 1870, it gave rise to an ardent discussion, from which no general agreement resulted. It has been commonly stated that Gainsborough painted the portrait in this peculiar chord of colour, with cold blue lights, and a dark, warm massive background of lurid sky, in order to refute a dictum of Sir Joshua's, laid down in his eighth Discourse. This story is of the usual kind of amateur gossip about art and artists, and probably has but slight foundation in fact. At any rate, this picture is of the style of Gainsborough's workmanship about 1770, and is even traditionally asserted to have been at the Academy Exhibition that year. The discourse in question was not delivered till the end of 1778. Sir Joshua's dictum may have been suggested by the picture, but certainly the picture was

not prompted by antagonism against the Discourse.

In the history of English art Gainsborough is even more important as a landscape-painter than as a portraitist. Certain examples of his work here exhibited cast much light upon the development of his style. A sketch of a rough road through a wooded country (109), and still more "A Woodland Scene" (24), show the influence of Du Jardin. The woody landscape (15), on the contrary, is strongly reminiscent of Hobbema; the foreground is very brown, the distance grey, the sky a grey-blue, with threatening clouds. In such more advanced pictures as the "Landscape with Figures and Cattle" (54) the influence of Claude is unmistakable, though by that time Gainsborough's own style was formed, and his vigorous touch and rapid handling smite a unity into the whole. Throughout his life he never forgot Suffolk, and whatever view is before him, it is really Suffolk that he paints. The special quality of his landscape work is its suggestiveness. He does not endeavour accurately and truly to reproduce a scene, he strives alone, to convey to a beholder the impression which a scene made upon himself. Thus, in his best landscapes, such as the "Harvest Waggon" (No. 33; No. 174 is the sketch for it) or the "Cottage Door" (Nos. 45, 98, 192), every object introduced works together towards the single idea, and colour and *chiaroscuro* are handled solely to the same end. The persistence with which this unity is always kept in view,—the unswerving directness with which the goal is aimed at,—are the secrets of Gainsborough's success. The painter to whom he comes nearest in spirit as a landscapist is Rubens.

The "Coast Scene" (No. 152) is an example of the application of the same method to the sea. The rollers come tumbling in with a kind of frolicsomeness racing after the joyous breeze. Likely enough this is the picture Walpole referred to, in which, he said, the sea was "so free and natural that one steps back for fear of being splashed." People were so little accustomed to that kind of thing in Walpole's day that the language of appreciation for it had not been invented, and even an art critic had to fall back upon the statement that the picture looked real!

We have not space here to treat of the 170 frames containing drawings in water-colour or pencil by Richard Doyle. They form a most fascinating collection, and ought to be hung round a large room at a low level for the delight of all the children of London. Every one of them is full of true, genuine, and wholesome fun and frolic, and many of the assemblages of fairies and children are of real artistic merit. As a colourist Doyle did not excel; he was essentially a delineator, and was at his best when designing for the wood-cutter. Visitors will be interested to see the several designs for the title-page of *Punch* (Nos. 220 and 221). Almost everything shown is charming, but the charm is one that must be felt and cannot be translated into words.

NOTES.

THE undecided and undecisive Report on the disposal of the sewage of London has called forth a cloud of letters in the daily press, each explaining, to the full satisfaction of the writer, how the particular process in which he happens to be interested affords the one only solution of this portentous question. That a certain amount of chemical value attaches to sewage is of course true. This, however, has long been known, not only as a fact, but as to the outside value attainable per unit of the contributory population. And that the cost of extracting this maximum value is, as a rule, higher than the value itself, is also so true, that we have been accustomed to attribute the backward state of the general question as being mainly due to the repeated attempts to make a profit, instead of to destroy a nuisance. It is, of course, possible that this view may have to be modified. But we cannot but think that if one unimpeachable case of success under circumstances of ordinary

o casion had taken place, it would have afforded an illustration of the proverb that "Good wine needs no bush." Be that so or not, of what use, we may ask is the Local Government Board as to this main portion of its functions? If, after authorising and reporting on an annual outlay of ten millions a year on sanitation the Board is not in a position to say, "Such and such a process is so good that we recommend its adoption, such and such a process is a failure," we cannot but think that the verdict of the majority of plain-dealing people will be that the Board itself is as great a failure as any of the plans as to which it has nothing to say.

FROM correspondence in some daily papers which has been sent to us, we are glad to find that the subject of the enfranchisement of leaseholders is attracting more and more attention. We have already commented upon it in several of our past volumes, and have pointed out the great difficulties which exist in regard to it. To turn tenurable leaseholds into perpetual leaseholds, as in Scotland, is distinctly a more practical scheme than to turn them into freeholds by compulsion of law. The crucial point of difficulty is the point at which the law is to be brought into operation, for if a tenant for seven years, for example, is given the right of becoming a perpetual leaseholder, it puts an end to short leases altogether, which are often a convenience. We have always expressed our opinion that the first and most urgent reform is to give tenants compensation for permanent improvements to their houses. This would at once very greatly improve the sanitary condition of the country, since landlords often will not, and tenants cannot afford to, make sanitary improvements when they cannot be sure that the landlord will not reap three-fourths of the benefit without putting his hand into his pocket.

THERE seems no doubt that the breakage of the axle which caused the lamentable Penistone accident was owing to one of those flaws which nothing but breakage detects; but it would be very important that we should know how long the axle had been running. There will probably be some difficulty if not impossibility in ascertaining this, as the wagon was a private one, and presumably had not its history kept as it would have had as part of a railway company's rolling stock. It is known that iron tends to deteriorate in fibre, or even develop absolute flaws, through the process of continued shaking and jarring on a railway; and if the average life of an axle under these circumstances is known, it becomes a matter of absolute duty to the public that wagons which have exceeded the safe conjectural limit of running-time should be removed from the road or have new axles. Under the circumstances, no other verdict than accidental death could well have been returned; but in an article on the former Penistone accident (*Builder*, 26th July last) we suggested the possibility of Hughes's "magnetic balance" being used to detect hidden flaws. Some effort ought to be made to provide against a danger the results of which are so terrible.

THE central hall of the New Stock Exchange Building, which has been built from the designs of Mr. J. J. Cole, was open to inspection by invitation on Tuesday last. The central hall is an octagonal room, 75 ft. in diameter, covered by a dome with iron ribs. The drum beneath the springing of the dome is also a segment of an arch and falls in, to some extent, within the line of springing of the dome, thus assisting in neutralising or balancing the thrust of the dome, which is further provided against by a system of massive iron ties round the base. The piers are of red granite, and the walls are faced with blocks of Pavonazza marble, the rest of the interior being constructed of Portland and Aubigny stone. The staircases are all faced with marble also. The large hall is lighted by seventy-six incandescent electric lamps of fifty candle-power, the majority of the light coming from standards on the cornice round the springing of the dome. Beneath the main hall is a settling room, and on the same floor are the engine-rooms for driving the

ventilating and heating machinery and the electric apparatus. The air is heated in winter and cooled in summer, and delivered through vertical tubes, the vitiated air being removed by an exhaust-fan. The central hall is a fine apartment, and the whole of the details have been carried out in a remarkably thorough and workmanlike manner; the joinery is admirable, the doors being formed at the hanging stile with a vertical roll moulding working in a concave moulding on the door frame, so that in any position of the door there is no air-space between the door and the frame, and the outer edge of each door, is worked into an ogee moulding closing against a similar inverted moulding on the casing, so that the door shuts almost air-tight. The whole building is the work of a thoroughly practical architect. The contractor is Mr. Shaw; the ventilating apparatus has been put in by Messrs. Rosser & Russell; the electric lighting arrangements have been carried out by Messrs. Woodhouse and Rawson; and the plaster work has been done on Hitchin's patent fire-proof system.

IT is satisfactory to learn from the annual report lately issued by the Rector of Whitechapel that the sinister prophecies of the probable collapse of his parish church owing to the railway running under it have proved to be false; they originated in the fact that there is some settlement, which the rector says, is being carefully attended to, and adds "there is no danger." St. Mary Matfion has successively given her name to four Whitechapel parish churches, two of which have come to untimely ends, one being removed in 1872 on account of insecurity, and another being destroyed by fire in 1880. We sincerely trust that Mr. Ernest C. Lee's very fine church may be spared the addition of another tragic chapter to her history.

THE new Turkish Bath on Savoy-hill, Strand, of which Mr. Phipps is the architect, was open for inspection by visitors on Thursday afternoon. It occupies the lower floor of Lancaster House, and is entirely on one level within. The warm rooms have the walls lined with glazed bricks of various colours, floors of marble mosaic, and white marble seats. The ceilings are well treated in plaster design in raised moulded ribs. The large first room of the Caledarium, 48 ft. long, is a very pleasant-looking apartment for the purpose; this will have a temperature of 120° to 130°, leading to three rooms beyond, rising to 160°, 180°, and 220°. The bath is lighted for dark days and at night by incandescent electric lamps. The electric light installation is carried out by Mr. Taylor Smith, and other employed on the work have been Messrs. Patman & Potheringham, for the general builders' work; Messrs. Geo. Jackson & Sons, for the plaster ceilings; Messrs. Strode & Co., for the gas work; Messrs. Shoobred & Co., for the furnishing; Messrs. Clements, Jeakes, & Co., for the coffee-maker's stove; Messrs. Doulton & Co., for the sanitary fittings; Mr. R. Davison, for the marble floors, marble lavatories, and fountain; Mr. Constantine (of Manchester), for the convoluted heating-stoves and the hot-water supply. Mr. Max Clarke, the architect's assistant, has acted as superintendent of the works.

BY the early and sudden death of Philip Westlake his family and a large circle of artistic friends lose a very talented and most amiable artist. He died on Monday, the 29th of December, in his fortieth year, after a few hours' illness. His funeral took place at St. Mary's, Kensal Green, on Thursday, January 1, and a number of old friends who had been fellow students attended, amongst whom were members of the Royal Academies of Art and Music, the Society of Antiquaries, the Institute of British Architects, the Royal Institute of Painters, the Society of British Artists, &c. He was a Latin Prize boy of the City of London School, and obtained a premium for antique drawing at the Royal Academy. His practice in painting and designing was confined generally to ecclesiastical art. At some future date we propose to give a short account of his principal works.

He was a brother of Mr. N. H. J. Westlake, some of whose work is represented in this week's issue.

THE building materials of Nos. 17, 18, and 19, Greville-street, Hatton-garden, were sold by auction by Messrs. Home, Son, & Eversfield on Friday, the 2nd inst. The house No. 19 was a fine house of the Queen Anne period, with the usual lofty story or *piano nobile* on the first floor, which had an elaborate ceiling in worked plaster, a carved mantelpiece of considerable merit, and panelled walls. The rooms on the ground-floor were also handsomely decorated, and there was a fine carved oak staircase. This house is erroneously described in the auctioneers' catalogue as having been formerly the residence of Lord Greville. The street in which the house is situated certainly derives its name from Fulke Greville, Lord Brooke, "servant to Queen Elizabeth, counsellor to King James, and friend to Sir Philip Sidney," as he is described in his epitaph; but his London house, which has been long since destroyed, was in Brooke-street hard by, and it was there that he was murdered by his attendant, Ralph Haywood, Sept. 1st, 1628. An extensive addition in the rear of Wood's Hotel, Furnival's Inn, for Mr. J. Whaley, on the site of Nos. 20 and 21, Greville-street, Hatton-garden, consisting of a large smoking-room on the ground-floor, with a range of bed-chambers over, is in progress. The architects are Messrs. Isaacs & Florence.

FROM Newark, New Jersey, we receive a description of "a new system of transportation," by means of which it is proposed "to carry overland freight of certain kinds and sufficient quantity" for the cost of half a crown per ton per thousand miles. The author of the scheme, Mr. J. S. Baldwin, does not undervalue the resources of civilisation, as he proposes to carry a stream of freight flowing at the rate of 111 tons per minute, or twenty times the volume of that borne on the most active English railway. This he intends to effect by inverting all the appliances which the experience of the last fifty years has evolved. He recommends "stationary power instead of locomotive, one vehicle instead of a train, fixed shelter and fixed running gear instead of movable, and a solid road bed instead of one that is adjustable." A series of endless chains, running on rollers of which there are to be 54,000 to the mile, and propelled by stationary engines half a mile distant from each other, are to give motion to a flexible trough, 3,000 ft. long, in which the freight is to be packed according to its nature. The cost is "assumed" as 25,000l. per mile, and the "cost of operation and maintaining one mile for one day is 98'85 dolrs." What is wanted is a number of sealed proposals for the demonstration of the practicability of the plan, the accepted one out of which is to be rewarded by the executive committee which is to be formed, with the sum of 500,000 dolrs. For the benefit of those of our readers who may be disposed to compete we may add that the pamphlet describing the whole plan is published by Storms & Co., Market-street, Newark, N.S.

THE turn of architectural feeling in regard to the Westminster Hall restoration appears to be now setting in favour of a one-storied cloister, leaving the carved corbels and flying buttresses exposed to view. This, whether the west side is ultimately left exposed or not, will certainly be a great improvement on Mr. Pearson's original proposition of a double storied cloister cutting through the flying buttresses and blocking up the whole perspective of the buttresses, with rooms in it which would be practically nearly useless. The buttresses, if they are really doing any work, want something between them on practical or constructive grounds, to assist their stability. On this head we hope we shall not shock any one very much if we ask, what work are those buttresses really doing in supporting or resisting the thrust of the roof? Theoretically they are supposed to do so no doubt, and were built with that notion, but we very much doubt whether they have much to do with it now.

NOTES ON TUNIS.

TUNIS has been called, somewhat inaptly, a second Constantinople. To those who have steamed up the Sea of Marmora, and watched the domes and minarets rise, one by one, above the surface of the blue waters, there will be a feeling of disappointment at the first glimpse of the whitened walls of the great Berber City, rounding the headland of old Carthage. And this disappointment will not be lessened even after a closer acquaintance. The rank accorded to Tunis among the chief cities of antiquity, the progress of its commercial relations with other cities of modern growth, and the retention of its manners and customs during many hundreds of years, entitle it to a position that no other cities can claim. Twice during its long history Tunis has stood with scarcely a rival among the cities of Northern Africa. When the Arabs overran the country in the seventh century, they carried with them new arts and fresh industries. Agriculture, that had been raised to a science during the five centuries of Roman occupation, and had been long suspended, then received fresh impetus, and Tunis became for a long series of years the greatest commercial outlet for the produce of a vast territory. Again in the thirteenth century, after the overthrow of the Moors in Sicily and their expulsion from various parts of Spain brought to the shores of Africa a people renowned in art, and possessing a culture far in advance of other nations on the shores of the Mediterranean, Tunis took rank not only as a centre of industrial art, but as the chief city of a kingdom that extended from Tripoli as far westward as Cherchel, the ancient capital of Mauritania. With such a history, and so long a record of continuous though varied prosperity, it is surprising that Tunis does not possess within the city walls more monuments of interest to the traveller as well as to the antiquary. But it must be borne in mind that all the cities peopled by those enterprising Phœnician navigators were strictly commercial. And although Carthage, the most important of their settlements, reached the envious position of being one of the most renowned cities of antiquity, it must not be forgotten that it was coveted, not for its magnificence, but for its situation as a stronghold, its command of the waters, and the fabulous wealth of its merchant inhabitants.

It is not within the compass of these few notes to investigate those points in history that relate either to the decay of Carthage or the rise of Tunis; but the history of one is almost inseparable from that of the other. If one may judge from the scattered remains of the greater city that are to be seen in the labyrinth of streets of modern Tunis, it was only the remnant that fell to the lot of its commercial neighbour. The history of a town is generally written on its stones. It would be difficult, indeed, to write a history of Tunis on the bare records of stone or marble. Here and there, in seeming incongruity with the whitened walls, are shafts of marble or porphyry; and magnificent slabs from those Numidian quarries that are still worked in the present day may be found in many a mosque and on many a palace wall. With the wealth of Tunis grew the number of religious edifices; but out of the 150 mosques that were in existence two centuries ago, there are but few left to arrest attention. None of these are remarkable externally for that delicacy of workmanship and grace of outline that characterised the edifices of the Moors in other parts of their dominions. Of the interiors it is impossible to speak, except from hearsay. The unbeliever is not only rigidly excluded from all parts of the mosques, but the very steps are forbidden to his unholy tread. Prompted by curiosity to obtain a glimpse within an outer doorway, I placed a foot incautiously on the bottom step. The gentle hand of a slipped Moor, passing by with a light tread, was placed on my arm, with a polite indication that I was committing a trespass on holy ground. This reverence for the sanctuary and all its surroundings is mixed up with a good deal of superstition that may be found here in a greater degree than in most Mohammedan cities. Tunis is to-day one of the most Oriental of Oriental towns, and its traditions, many of them the remnant of superstitions of its primitive inhabitants, are upheld with becoming reverence. The most noticeable among these is the sign of "the hand," with four fingers extended. You find it everywhere, generally daubed on the

wall with some crude pigment of red or black. It is on the house of the humblest Mussulman, the rude tenement of the Jew, and the palace of the Bey. You find it on the vanishing of an arcade, on the keystone of an arch; and in the every-day jewellery of the peasant it forms a pendant to the girdle or necklet in silver filigree or in stamped metal. "It is the hand of fate," we are accustomed to say, when speaking of any act beyond the control of human agency. "It is the hand of Fatima," says the devout Mussulman, "the mother of all true prophets,—one of the three wise and good women to whom the prophet commanded that homage should be rendered to all time." "It is the hand of Tanith," said the Phœnician, and many a votive tablet unearthed from the hill of Carthage bears testimony to the prevalence of this ancient cult. And so we may trace this symbol of power, this averter of the evil eye, this "marî béniâsant," till we are landed in the mysteries of the heathen Ashtaroth, of the Roman Astarte, and of those sensual rites under which the goddess was worshipped as Venus Calectis.

Intimately connected with this superstition is the employment of black stone or marble in the voussiers of arch construction. They tell you that the black stone, especially when it occurs as the keystone of an arch, the one black spot where all else is dazzling whiteness, is symbolical of sin. No human work is perfect. To attempt perfection would be an act of defiance to the spirit of evil, whose powers of destruction are illimitable. The black stone, emblem of imperfection, becomes a homage or sign of concession to this power, and thus secures the protection of all the other stones of the fabric, the white stones without spot or blemish. Passing from this pretty legend there is yet another form of superstition, unmistakably Oriental in its origin. It is the reverence for serpents. "Blessed is the habitation," say they, "where the serpent dwells." Neither hunger nor thirst is ever known to this member of a family. His food is prepared and his presence expected before the commencement of the daily meal. No one eats till the serpent has finished and has crept back satisfied to his hole. If he is not the ruler of the house, he possesses an importance the owner himself does not even attempt to share.

All Oriental cities have a charm and a colouring of their own differing essentially from what is commonly termed "the picturesque" when speaking of European towns. In spite of its dearth of architectural monuments, Tunis, with its labyrinth of streets, its flying arches from house to house across the narrow thoroughfares, its doorways with their delicate carvings in stone or marble,* its wilderness of shops, their wooden columns painted with spiral bands in gaudy colours of blue and red and green, has much to charm the eye, and colouring enough to balance the wearying monotony of whitewash. Very curious, too, and characteristic, are the wooden doors of ordinary Moorish houses, with their quaint patterns formed with round-headed nails. Crescents and crosses, graceful curves, and crude imitations of symbols of deities of long-forgotten Phœnician origin, are mixed together in endless variety. Like the horse-shoe hung on the cottage wall in our own country, these nails, a remnant of a still older superstition, are regarded as a protection to the abode and a charm to keep off the evil eye.

It is not to be expected that a city so strictly commercial in its origin and progress should have attained great pre-eminence in art-industries during any period of its long career. The arts of Tunis, as they exist in the present day, were derived principally from the Moors of Spain and Sicily. The beautiful plaster vaulting and arabesque tracery, the carved wood ceilings and gilded decorations that reached such perfection in Seville and Granada, and that found their way across the Mediterranean, received but little encouragement here, if one may judge from the few specimens to be found in Tunis. That they flourished in the country at one period there is ample evidence in the decorations of the numerous mosques in the holy city of Kerouan; and in the town palace of the Bey of Tunis are some gems of architectural decoration unsurpassed in elegance and richness by anything in the more-famed Alhambra or the Alcazar at Seville. Amidst the constant fluctuations of fashion and the tide of European civilisation ever advancing eastward, more

rapidly now than at any period in the world's history, it is sad to think of the gradual extinction of the beautiful handicrafts taught us by the Moors, soon likely to be numbered among the lost arts. The persistency with which the Moor and the Arab cling to their antiquated methods of workmanship, their simple hand-looms, their latbes, and other implements, and their utter disregard of all mechanical appliances that shorten labour and cheapen work, is a curious phase of Orientalism that seems almost incomprehensible. In the souks or bazaars of Tunis, which will bear comparison in variety, if not in extent, with those of Stamboul, the fabricator and the shopkeeper sit side by side on the same matting. The workers in embroidery and in leather, the weaver of carpets, and the worker in silver carry on their antiquated trades amid the hum and bustle of an active ever-moving population. Here are swarthy Moors with their gay girdles and waistcoats of silk embroidered with gold; stately Arabs in striped berboones; negroes from the Soudan; Holy Marabouts, picturesque in their rags and tatters; dignified Jews; black-veiled Moorish women; and comely Jewesses, innocent of skirts, and with their limbs swathed in gaiters of silk resplendent with gold. How far this picturesque population and their gay surroundings are likely to be affected by closer contact with Europeans and their ways is an unsolved problem. The café and the drummer-boy, those precursors of French civilisation, have already taken possession of the outskirts of the city; markets and factories are springing up in the business quarters, and courtyards of Moorish houses are being converted into stores for goods from Lyons and Manchester. Tunis has had a long past. It bids fair to have a long and prosperous future, and an importance, as a commercial centre, equal to that which it enjoyed centuries ago. Whether the whole Regency of Tunis will reap the benefit of an extended colonisation over the vast tracts of land that are now the shifting abode of roaming Arabs. What this territory was during the long period of Roman occupation is not difficult to conjecture. The Roman watered, and the Roman planted, and great was the increase upon this wonderfully fertile soil. The Arab to-day neither planteth nor watereth. He scratches the soil with his rude implements of husbandry; he gathers his crop, and passes on with his flocks and his herds. Long centuries of ignorance and neglect have done their worst. Vast plains that are now sweet with rosemary and wild thyme, and over which caravans still thread their way, were once a main source of grain supply to a great empire. It remains for European nations, with their more advanced agriculture, to make this corner of Northern Africa once more a granary of Europe.

Among the nations of antiquity perhaps none have left so many records of their power and the extent of their dominion as the Romans. Wherever the Roman set his foot, there he left an enduring mark. For this reason the whole Regency of Tunis offers to the architect and the antiquary a vast field for research. The monuments still left to us attest not only the wealth and magnificence of this fertile colony, but they show the unity of the empire and the authority of Rome; and how each city and each town, however remote, was only a miniature of the great metropolis of the Caesars.

The archaeology of North Africa, and a more faithful and comprehensive record of its monumental remains, have yet to be written. It is to be hoped that English travellers, who have already done much to throw light on the subject, will be induced to add many more pages to the history of this interesting country.

ALEX. GRAHAM.

New Congregational Hall at Wandsworth.—A new hall, in connexion with the Congregational Church at East Hill, Wandsworth, has just been erected in Earlsfield-road, Garrett-lane. The building is of red brick, with a roof of red tiles. The interior is faced with yellow and red brick, and has an open-timbered roof in stained pitch pine. It is fitted with Tohn's ventilators. The foundation walls are built of sufficient strength to carry an additional story should it be required. The building will hold a congregation of 600 persons. Mr. E. W. Monntford, of Buckingham-street, Strand, is the architect, and Mr. Smith, of Kensington, is the contractor.

* See Illustrations in this number.

PROJECTED RAILWAYS, TRAMWAYS,
DOCKS, AND OTHER PUBLIC WORKS.

The Parliamentary Committee on Private Bills, during the session of 1885, will have to deal with a large number of projected public works of a varied character, several of which involve an unusually heavy expenditure. The total number of undertakings, as represented by copies of Bills and plans deposited at the Private Bill Office on the 20th of December (the last day allowed by the Standing Orders for such Bills to be filed), is 252. This shows that seventeen undertakings have already been withdrawn after passing through the initial stage only, the number of notices deposited on the 29th of November being 269. Of the entire number of those 252 undertakings which remain, 121, or nearly one-half of the whole, are connected with railway projects. Of this class of Bills fifty-six are promoted by existing companies, and sixty-five by new companies. There are twenty-one tramway Bills; twenty-three connected with gas and water supply, four only being gas projects, while nineteen in respect of water supply; seven subway Bills; twenty-one town improvement Bills; twenty-five Bills in respect of docks, harbours, and piers; and thirty-four Bills of a miscellaneous character. It should be added that as respects tramways and gas and water supply, there are several undertakings promoted by Board of Trade applications for provisional orders.

An unusually large proportion of the Bills have reference to undertakings directly connected with the metropolis. Nine of these Bills seek powers for the construction of new railways in north, south, and west London, and include projected new lines between Latimer-road and Acton; Ealing, Harrow, and Edgware; Notting-hill and Shepherd's-bush; Charing-cross and Euston (the estimated cost of this line being 1,600,000*l.*); Croydon Direct; a new line from London, Chatham, and Dover line to the Crystal Palace; the Crystal Palace and South-Eastern and Metropolitan; Nantwich, Shortlands, and Beckenham; and the Charing-cross and Waterloo Electric Extension. The additional power Bills of seven of the leading companies likewise contain clauses authorising the construction of new and extended works in the Metropolis. The London and South-Western Company's Bill empowers the Company to make large purchases of houses and land in the neighbourhoods of York-street, Griffin-street, and Westminster Bridge-road for the still further enlargement of the Waterloo Station, which already contains an area of upwards of twenty acres. Also powers to purchase houses, lands, and premises at Nine Elms, Wandsworth-road, Battersea, Clapham Junction, and Earl's-field, for similar enlargement purposes. The Great Eastern Company's Bill empowers the Company to widen their main line at Mile End and Old Town, and also from Longhoughton to Epping, with powers to purchase lands and property at Canning Town, West Ham, and Leyton, for additional works and station enlargement purposes. The London and North-Western Company's Bill seeks powers to purchase property in Shoreditch and Bishopsgate, and also property in St. Pancras belonging to the Duke of Bedford, for the purpose of enlarging their Broad-street and Euston Stations. The Midland Company's Bill seeks similar powers of purchase in Islington and Hampstead-road for extension works in those localities. The South-Eastern Company's Bill empowers the Company to purchase lands and premises for the widening of their lines and constructing new branch lines in Lewisham, Dentford, Caterham, and Croydon. The London and Blackwall Company seek powers for the widening and improving of their line between Fenchurch-street and Stepney Junction. The North London Company powers to widen the line, with sidings, into Columbia Market; whilst the London, Tilbury, and Southend Company promote a Bill empowering them to purchase the German Church and site in Whitechapel, with powers to remove the bodies, and to erect warehouses and offices on the site. Eleven of the tramway Bills seek powers for the construction of tramways in different parts of the metropolis. The North Metropolitan Company are the promoters of three Bills, which seek powers for laying down lines in the districts of Clerkenwell, Gray's Inn-road, Theobald's-road, Goswell-road, Hackney, Clapton, and Bethnal-green. The other Bills promoted are those designated the Metropolitan Central, the North-West Metropolitan, the Clerkenwell and Isling-

ton, the Highgate, Finchley, and Barnet, the Peckham and East Dulwich, the London-street, the Crystal Palace and Gipsy-hill, and the Brentford and District Tramways. A novel feature in the Bills consists of the large number of projects—six in number,—for the construction of subways in the metropolis. Amongst them is a Bill seeking powers for a subway from the Angel at Islington to Moorgate-street, passing in a south-easterly and south direction under and parallel with the City-road, from a point in front of the Angel at the junction of the City-road and Belvidere-road, to its proposed terminus in Moorgate-street, near Lothbury and the Bank. The rails proposed to be laid down are the standard railway gauge line now in general use on all the railways. Locomotive engines are not to be used, the proposal being to work the traffic with stationary engines, on the cable traction system. Subways on a similar principle are also proposed to be constructed between the Marble Arch and Cornhill, and between King's-cross and Charing-cross. There is likewise a fourth Bill for the construction of a subway between King's-cross, Charing-cross, and Waterloo railway station, by means of which the railways south of the Thames would be brought into close communication with the Midland and Great Northern lines. The estimated cost of this proposed subway, which would pass under the Thames, is set down at between 750,000*l.* and 800,000*l.* A fifth Bill seeks powers to construct a subway between High-street, Clapham, near Clapham-common, and the Elephant and Castle, where it would form a junction with the Southwark and City of London subway, terminating in King William-street, Parliamentary powers for which were obtained last session. This proposed subway would be nearly two miles and a half in length, and its estimated cost is set down at 650,000*l.*, or about 232,000*l.* per mile. The aggregate estimated cost of these several subways is little short of 3,500,000*l.*, that of the three first-named being 2,100,000*l.* In addition to the above there is also a Bill for the construction of a subway between Millwall and Greenwich. There are likewise twelve Bills of a miscellaneous character relating to undertakings connected with the metropolis, one of which is the Various Powers Bill promoted by the Metropolitan Board of Works. This Bill, amongst other powers sought, contains clauses empowering the Board to construct a new street between Gray's Inn-road and St. John's-street-road; * also powers for maintaining steam ferries between Greenwich and Poplar and Woolwich; likewise powers as to the construction of a new park at Dulwich, and the control of open spaces at Highbury-fields and Inacey Downs. The Board also promote a second Bill authorising them and the two Vestries of St. Martin's and St. George's, Hanover-square, to maintain the Hyde Park Corner improvement works. The Corporation promote two Bills, one sanctioning the construction of a bridge across the Thames between the Tower and Horsely-down; and the other empowering the Corporation to purchase land to erect a City of London School for Girls, out of Ward's bequest. There are also Bills for the construction of the Thames Duplex Bridge and the Thames Floating Bridge. Another Bill seeks extensive powers of purchase for the widening and improvement of Parliament-street by a company proposed to be incorporated, whilst the Post-office authorities also apply for large powers of purchase to carry out post-office extensions.† The Southwark and Vauxhall Water Company promote a Bill for the construction of new service reservoirs at Camberwell and Lewisham, covering an area of three acres and a half; also powers to lay down lines of pipes from the reservoir at Forest-hill; likewise powers to lay down further lines of pipes from Hampton to Streatham, Merton, and Totterdown-road, Twickenham. There is also a Bill promoted by the Albert Palace Company in reference to working arrangements; another Bill for electric lighting in Chelsea; and one by the River-side Fish Market Company at Shadwell. There are thus no less than thirty-four Bills in respect of works directly connected with the metropolis.

A special feature in the railway bills is that nine of the great companies having their termini in the metropolis, and also the North-Eastern Company, all promote bills for the consolidation of rates and charges, as well as those for additional powers in respect of new works, and

as there are fourteen Bills in reference to the abandonment of authorised works, extension of time, sale, and arbitration, the number of Bills promoted by existing companies in respect of actual works, is reduced to thirty-two. The bills promoted by the London and North-Western and Lancashire and Yorkshire Companies seek powers for extensive works at different points on their system, more particularly in the neighbourhoods of Liverpool, Manchester, and other parts of Lancashire and Yorkshire; and the same remarks apply to the bills of the Great Western, Midland, and South-Western Companies.

The Bills in respect of docks, harbours, and piers contain several projects of a formidable and costly character, involving a heavy amount of engineering work. The Cheshire Deep Water Docks Company, proposed to be incorporated, are the promoters of a Bill for the construction of a comprehensive series of dock and river works on the banks of the Dee, in the parishes of West Kirby, Moreton, and Bidston. These works embrace two sea walls and embankments in West Kirby, on the foreshore of the river and the Irish Sea, 4,000 yards in length; also dredging for a distance of 700 yards to a depth of 30 ft. below the low-water level of the bed of the channel known as the Rock Channel; also the dredging and excavation of a new channel, 1,450 yards in length and 270 yards in width, to a depth of 30 ft. below low-water mark. The Bill likewise seeks powers for the construction of extensive dock works, one of which, in the parish of West Kirby, is to be 600 yards in length and 270 yards in width; and another dock, with locks and entrances, partly in the parish of West Kirby and partly in the parish of Moreton, 1,615 yards in length and 225 yards in width, the two docks covering an area of 75 acres. The undertaking also includes a graving-dock in the parish of Moreton, 295 yards in length and 25 yards in width, together with the construction of quays, wharfs, and piers, with hydraulic and other machinery, and the erection of warehouses and sheds. In connexion with the Bill for the construction of a railway commencing in the parish of Bidston by a junction with the Hoylake Railway, and terminating by a junction with the authorised Wirral Railway. Another Bill is promoted by a company proposed to be incorporated, with powers to construct docks and other works at Northfleet. The undertaking embraces the construction of a main dock 417 yards long, and 200 yards wide, with two main branch docks, each 400 yards in length, and 83 yards in width, with lock and tidal basin, and an entrance from the river Thames at Northfleet; also a river wall or embankment, three furlongs and five chains in length, with an opening into the tidal basin; also two piers or jetties, one 134 yards and the other 150 yards in length. The Bill likewise provides for the construction of graving docks, slip docks, lift docks, telescope and other bridges, wharfs, quays, landing-places, warehouses, sheds, and other buildings, and hydraulic lifts. The undertaking also includes the construction of three railways in connexion with the works, two of which are to be in communication with the South Eastern and London, Chatham, and Dover Railways, and the third with the authorised Tilbury and Gravesend Tunnel Railway. Powers are also sought in the Bill for hiring steam tugs for towing purposes.—A Bill is promoted for the construction of a pier, jetty, and landing and shipping stages, at St. Leonard's, together with sea walls, groynes, and other buildings and works for the accommodation of steam and other vessels, and the embarking and landing of passengers, goods, and merchandise. The Bill also takes powers for the construction of a promenade, commencing near the Marina, and extending 1,000 ft. eastward.—A Bill for the improvement of Christchurch harbour seeks powers to construct training walls, breakwaters, and landing-stages; also powers to construct piers, and to dredge. There are four Bills in connexion with the deepening and improvement of the river Dee, with powers to deepen the river, by the construction of training-walls and dredging, to the mouth of the sea. One of the Bills also provides for the construction of new docks near Chester.—The London and North-Western Company's General Powers Bill contains clauses authorising the company to construct new docks and other works at Garston; while the South-Eastern Company's

* Fully described in the *Builder*, Dec. 13, pp. 789, 790.
† See *Builder*, Nov. 23, 1884, p. 680.

Bill also contains clauses authorising the company to construct a new pier and other works at Folkestone.—There are also Bills in connexion with the Butte Docks, and the improvement of the docks, and other works, at Southampton and Port Glasgow.—The Manchester Ship Canal project will, no doubt, again undergo a prolonged investigation before the Parliamentary Committees.

The Town Improvement Bills are both numerous and comprehensive in their character, involving the erection of several public buildings. Amongst others the new Borough of Eastbourne promotes a Bill in which powers are sought for the widening of ten streets, and the construction of a sea-wall on the east side of the circular Redoubt. Powers are likewise included in the Bill for the Corporation to enclose and convert to agricultural or building purposes all or any portion of the land and foreshore which may be enclosed by the sea-wall. The Bill also provides extensive powers with regard to the erection of houses and other premises, with control as to the frontages, foundations, and materials of all houses to be built. Similar powers are likewise sought for in sanitary arrangements.

The Bill also contains clauses empowering the Corporation to erect new markets, a public library, museum, picture gallery, and school of science and art; also public baths and washhouses; with powers to lay out parks and pleasure-grounds, gymnasiums, bowling-greens, and to give other facilities for recreation.—The Corporation of the neighbouring town of Hastings also promotes a similar Bill, in which stringent control over buildings and sanitary matters is applied for. Powers for the regulation of bicycles, tricycles, and other vehicles are sought; likewise powers over street musicians, and the exhibition of advertisements in public thoroughfares, and also powers to regulate the use of the foreshore and Parade. The Bill also authorises the Corporation to purchase land for the erection of a public library and museum, new municipal offices, a new market, public baths and washhouses, and slaughter-houses; also powers to acquire East and West Hill for the purposes of a public park.—The Corporation of Bradford promote a Bill which, amongst other powers, contains clauses authorising the construction of extensive additions to the existing waterworks, including several new reservoirs. The widening of streets and the construction of new streets is a prominent feature of the Bill, which contains clauses for widening twenty-two streets, and constructing five new streets. The Bill also authorises the construction of a new park on Bradford Moor; powers as to the facilities for ingress and egress to and from places of entertainment; powers to extend and enlarge the present municipal buildings, including the council-chamber, justices' room, coroner's court, and court of quarter sessions offices. Largely increased powers over buildings and sanitary arrangements are also provided in the Bill.—The Corporation of Southport promote a Bill which contains clauses authorising them to make very extensive purchases of land for the improvement of the borough. The Bill empowers the corporation to acquire 4,739 acres of land on the foreshore of the sea and estuary of the river Ribbles; also to construct a cut or channel, with training walls and embankment, three miles in length, for sewage purposes, and in connexion the construction of sluices, culverts, and arches. Powers are also sought for the formation of a new recreation ground on land conveyed to the corporation by the Southport and Cheshire lines extension Railway Company; likewise powers to erect a new building to be used as a Museum and School of Science and Art, on lands bequeathed to the corporation by the executors of the late Charles and W. Frederick Scarisbrick, Mr. Naylor Leyland and Dr. Wood. Powers are also sought in the Bill to purchase the frontages of houses and premises whenever such houses are converted into shops or business premises.

The Liverpool Corporation promote a Bill which contains clauses for the construction of several new streets, including one in continuation of a street at present in course of construction by the Lancashire and Yorkshire Railway Company; a new street from Paradise-street southward, in constructing which the bodies in St. Thomas's Churchyard will have to be removed. The Bill likewise contains powers relating to alterations in the boundaries of the wards; and also powers over shooting-galleries, swing-boats, and whirl-grounds.—A Bill,

promoted by the Corporation of Bury, contains powers for the purchase of lands for parks and recreation-grounds; and also stringent powers over buildings, drainage, and ventilation.—Similar Bills, with greatly increased powers over buildings, and sanitary works, are promoted by the municipal authorities of Sunderland, Whitehaven, Longton, Hull, Oxford, Kemsate, Southampton, Wakefield, Wigan, and other towns.

Amongst the Bills of a miscellaneous character is one promoted on behalf of the ecclesiastical authorities, containing clauses empowering the Bishop of Liverpool and others to enter into negotiations with the corporation for the purpose of acquiring St. John's Church and churchyard, with the view of erecting a new cathedral on the site. The Bill also contains powers to the ecclesiastical authorities to erect a new church of St. John's in place of the existing church to be taken down.

ARCHITECTURAL EDUCATION AND THE EXAMINATION IN ARCHITECTURE.*

The subject of education is one which in all civilised society has excited the greatest interest with those who are interested in the progress of mankind, and especially in these latter days has this been the case. The schoolmaster is abroad, and busy in his work with the lowest to the highest strata of society. The introduction of the subject for our discussion this evening needs, therefore, no excuse or apology. We must be content, however, to confine ourselves to that branch of education to which we prefix the title "professional"; all else we must pass over, or the subject will be too wide a one to compass in the short time at our disposal. I will ask you, however, to bear in mind that the influence of the Board schools, of the Oxford and Cambridge Local Examinations, the institution of High Schools, and the multiplication of others of all grades, have so raised the standard of scholastic attainments, that to succeed, or even to hold a place, in any rank of life, needs, and increasingly calls for, those qualifications which only a good education can give. Here and there we find men who, with very little scholastic attainments, have gained distinction in the various walks of life: men who can do little more than sign their names to a cheque or document; but such instances are nowadays rare, and are the exceptions which prove the rule.

If we glance at what the different learned professions are doing for the education of their members, we may see on all hands a tendency upwards, and that admission to their ranks is through study and examinations which only the most diligent attention will suffice to succeed in. In divinity, law, physic, science, the army, navy, or a commission in the volunteers, special qualifications are demanded, and though examinations are not compulsory in all the branches of civil engineering, no man can hope to succeed in rising to high distinction in that profession who has not devoted his best energies to acquiring his education and study that theoretical and technical knowledge, which, perhaps, is the greatest of the practical science of our days demands from those who practise it.

In architecture, I think, we have been too content to follow on the old lines, and have not recognised the fact that such enormous progress has been made in education. The establishment of the Architectural Association some quarter of a century ago is an index of the want felt at that time for the better education of architects in the art and science of their profession. The establishment in 1855 of a compulsory examination for district surveyors, and the recent establishment of an examination for admission to the Royal Institute of British Architects, together with the discussion on education at the last Conference, and the important contributions previously made to that subject, are proofs that, as a body, we are waking up to the fact that if we are to hold any place at all in society as a learned profession we must do as others are doing: throw aside our lethargy and endeavour by all means in our power to qualify ourselves so as to be armed at all points for the conflict with the difficulties which beset modern practice. Warnings have not been wanting; specialists have sprung up, outside our ranks, to do the

* A paper read before the Architectural Association by Mr. Cole A. Adams, President, on the 2nd inst., as elsewhere mentioned.

work which we have neglected; work which formerly was comprehended under the practice of architects has drifted into other channels. The engineer, with a keener insight into modern requirements, has taken up work which formerly was done by the architect. Ironwork, which now so largely enters into use in the science of building construction, is looked upon, and rightly, for we have neglected to study and make use of the material scientifically,—as the special province of the engineer. Bridge architecture forms now no part of our work, and much else, where the science of construction on a large scale is concerned, has drifted away. In sanitary science a large class of practitioners have arisen to do the work which we ought to be the best qualified to undertake. Decoration is in the hands of specialists who are not architects, or is carried out by advertising tradespeople; and so little by little the field of architecture has been invaded.

The blame for all this lies mainly with ourselves, and the remedy also. If we are to win back what legitimately belongs to us and gain that respect which should be our aim, we must be able to conclusively prove to our masters, the public, that we are competent to execute such work as legitimately belongs to the profession of architecture.

It is a favourite argument with those men who, to their credit be it said, have, with untiring energy, zeal, and natural ability, succeeded in any walk of life, to say that any systematic course of education partaking of an academical character is, in their opinion, unnecessary, and too often they throw their weight into the scale against those who are in favour of it. Especially is this the case in our own profession. Formerly this line of argument found more supporters than it is likely to now, but a glance at what the other professions are doing in shutting their doors against only those who will enter them with the golden key of knowledge should be, I think, sufficient evidence that the day for such an argument is past and gone, and that nothing short of special and exact training will enable the members of any profession nowadays to maintain its position and to resist the encroachments of outsiders. In art and literature it is easy to point to men who, solely by their own efforts, have won a foremost place without any passing of enforced examinations, and it may be easy to prove that in these special walks of life the man who succeeds must be born and cannot be made. This is, in a great measure, perfectly true, but the profession of architecture embraces science as a perfectly necessary part of it, and science can and must be taught by system. Even if we take the men, no matter in what walk of life, who have gained eminence, is there one who could not say that his work would have been more thorough, his range much wider, if he had had the advantage of a better and more systematic course of education placed at his disposal when a youth? I think the fact that so many have succeeded in spite of the greatest drawbacks goes no way to prove that a systematic training is unnecessary. The tendency of all modern thought here and abroad is against such an assumption, and the action taken by men in other professions proves the value which is placed upon special education for their varied pursuits. Take for instance the army and navy. Formerly admission was an easy thing, position, interest, money, pluck, and daring were the only passports necessary; now to obtain admission and to succeed a man must have a special and scientific acquaintance with military and naval tactics, so largely has science become a part of warfare. The marvellous success of the Germans in their war with France has effected a revolution in the art of warfare all over the civilised world. Our brethren in the medical and legal professions are, happily for us, now compelled to pass the strictest examinations before they can practise, and it would be easy to multiply similar instances. Why, then, should it be left to those who enter the field of architecture,—a profession dealing with the health, well-being, and prosperity of the nation,—to pick up their knowledge in a haphazard way, without any recognised system?

The effect of education upon society generally is to make men more thoughtful, to open their eyes, cause them to inquire into the why and wherefore of things, and not to be content with taking everything for granted, and the fierce light of criticism is cast in all directions. The great attention given to health, arising from

the dangers which beset modern civilisation and the gathering of large masses of people together, necessitate special provision in modern architecture which are the natural outcome of these conditions and the knowledge of sanitation and its importance, which the medical profession has brought to light. Can these conditions be met by natural instinct in those who adopt the profession of architecture, or by a slipshod system? There can be but one answer. Architects must be qualified to meet the difficulties daily presented to them in this aspect of their work alone. The public demands that special knowledge should be brought to bear, and, as I have before remarked in this room, from our neglect of sanitary science, specialists have arisen to do it. I know it will be said that too much stress is laid upon this subject of sanitation, and that architects do now attend to such matters. I grant that many do, but I doubt if the profession at large is sufficiently in earnest about it, or recognises the vast and far-reaching importance of this subject, and I instance it as one of many others requiring study to master, and what a necessity it is to bring this before our students in a practical and scientific form.

Now the question, as I understand it, before us this evening is,—Can the education of the architect be raised; and, if so, how?

In the few suggestions and ideas which I have to offer, I shall endeavour to point out how, in my opinion, this is possible; and I doubt not that the remarks and observations of many of those who are here this evening,—who are far better able to speak upon the subject than I,—will add much to the solution of the question, and I trust make this new year we have just entered upon memorable as a fresh starting-point in the furtherance of the professional education of architects.

We shall one day, I hope, have in this country something of the system adopted in France and other countries, and members of the Association who have not yet read the important contributions on the subject made by Mr. William H. White, Mr. R. Phémé Spiers, Mr. Arthur Cates, and others, I would strongly advise, if they have the matter at heart, to do so.

For a profession to hold a high place in the estimation of the public, it is necessary that the standard of general excellence should be a high one. It is not enough that here and there should be found distinguished men. What we want, therefore, is some system which will enable our architectural students to so qualify themselves as to be able to undertake and carry out with credit the work which in the ordinary course of business falls to them, and that the standard of requirements shall be such that no man without special study and training shall be able to compete for work. It should not be possible for any man, in a properly qualified, to set up a brass plate, call himself architect or surveyor, and bring disrepute upon our profession; perhaps some day legitimate practitioners may have the protection granted to other professions.

We, as members of the Architectural Association, may feel justly proud of the work which it has accomplished, and which it was established to do, but since its establishment the world has been moving on with rapid strides, and we are now considering how our system may be improved and made more effective. You are aware that within the last three years or so we have instituted two courses of lectures on the history of architecture and the science of construction. The gentlemen who have undertaken these courses receive some small remuneration, in no way commensurate with the skill and time, the preparation and delivery of their lectures demand. These lectures were started almost, it may be said, for the sole purpose of preparing candidates for the obligatory examination for admission to the Institute. Observe, that the basis upon which these lectures are established is a departure from the voluntary and honorary basis upon which all other instruction in the Association rests. It need be no surprise to any one that this is so, and I think no regret; it was the natural outcome of the examination set on foot by the Institute, and has been of the greatest service to our members. From a careful consideration of the whole matter, and a perusal of the answers given to the questions issued to some of the members, I feel persuaded that the time has come for extending this basis. Our classes, presided over and conducted by voluntary and honorary teachers, have done excellent work, but it must necessarily fall somewhat in producing any

uniform standard of excellence. Teaching and conveying to others the knowledge which is to be imparted, is a gift which few possess; it is, in fact, a gift which requires special cultivation, hardly likely to be found in a purely voluntary system. Here and there we find it, but still as another necessity of this voluntary system, we change our teachers constantly, for men can hardly be expected to give their services year after year for the benefit of others. This being so, and I think you will agree with me that it is true, comes the question how are you going to supplement our work, and make the instruction given in the Architectural Association more thorough? I believe there is only one answer, and however much it may go against the grain of those who would adhere entirely to the present voluntary system, it must be given. It is by securing the services of men, qualified professors of the subjects they teach. By all means let us keep our classes, careful only in the selection of those who preside over them, but let us go further and try and obtain lecturers to deal with those special subjects, which can only be properly taught by men trained to speak with the authority of experience, and qualified to impart their knowledge to our students. We are at once met with the question, Where is the money to come from that will make it worth while for men capable of teaching to give up their time to undertake the post of lecturers? I think, if we are in earnest about it, the thing may be done. The Royal Institute of British Architects was founded for the promotion of the art of architecture; but beyond establishing an examination for admission to its ranks, it has done, as far as I can gather, nothing for education. Mr. Christian, the President, in his admirable address in November last, remarked, "And I would ask,—Is it certain that we have done all that in us lay [quoting from the Charter] for the general advancement of civil architecture, and for promoting and facilitating the acquirement of the knowledge of the various arts and sciences connected therewith?" To which I venture to answer, a hundred times, No. Is not the present time, when such great changes in its constitution are under discussion, one for meeting this question of education? To what better use could the Institute funds be put? How better can it raise itself in the eyes of the profession, gather men into its body, and make itself great, powerful, and respected, than in extending by its funds the opportunities for acquiring knowledge? The fact that an examination for admission to the Institute is compulsory surely demands that the Institute should place before students some of the means for passing that examination.

I believe that an educational scheme would commend itself to the members of both bodies, and that if a committee of the Institute and the Association were formed, and ways and means discussed, the two bodies would be drawn together, on a footing which would not in any way interfere with the constitution and independence of either, but only result in good for both, and a closer alliance for strength and resistance against those who have made and are busy making inroads upon us. Hear, again, what Mr. Christian says, speaking of the work done in the Architectural Association,—“And if by any means the work of that valuable institution could be supplemented and aided by our elder body, in liberally sharing with them any advantages which our more material status may enable us to supply, I think it would be advisable for both, and should by us be ungrudgingly given.” That the autonomy, so to speak, of each body should be preserved, all of us will, I think, agree.

The proposition I have made, one not made for the first time, will be met with the old arguments, and those who are in favour of a closer alliance for the objects I have sketched had better be prepared to hear that the Association had better keep to its old lines, work apart from the Institute, and not suffer any interference from it, or that the Institute should stand clear, and leave the Association to do its own work, and continue to spend its funds mainly on conversation and printing. I hope sincerely the day has gone by for listening to such counsel. A new departure has been made in both institutions. Time has softened down any asperity that may have existed in days gone by. There is no rivalry between the two sisters, if I may use the expression; and, to follow out the simile, the younger has now grown to woman's estate, and may fairly demand some

help from her elder sister in the education of her sons, without loss of dignity or pleading *in forma pauperis*. I am sanguine that the Institute would gain in popularity, would commend itself more to the sympathy and support of its members and the profession, and gather students to its meetings and lectures; while the Association would be more valued for the increased advantages that it could offer, and admission to its ranks would be even more sought after than it is at present. If this be so, the standard of education would be raised, and the men who came under the influence of it, would in their turn make it felt abroad, and so little by little the public would come to recognise the great fact, that to be an architect, properly qualified to carry out the work entrusted to him, requires that a man shall be properly and systematically educated in the various branches of his profession; and that only those who possess this knowledge will stand a fair chance of employment.

I do not suppose that if we succeeded in establishing a course of instruction, with the aid of the Institute, everything would be accomplished that we seek for; but it would be a large measure towards it, and the influence of this would permeate. There is no reason why in the large centres of industry in the provinces, a modified system, such as I have sketched, should not be established, and ways of doing this world, I think, be suggested were architects to set themselves to work to do it. One thing is clear, if we do not, no one else will. If it is a question of funds, and the providing of the sinews of war generally resolves itself into that, why should not, without any great hardship, the subscription membership in our own body be doubled? We doubled the entrance fee not long ago, but it has not deterred fresh members from joining. A guinea a year for the advantages to be gained by students joining the Association is really a very small sum, and I do not think that it would be objected to. Some might resign, a few be deterred from joining; but if you decreed that it should become a by-law, a large increase of revenue would result, and means thus be found for extending the advantages of education, not only to those resident in London, but to those in the provinces also.

It will be advanced, that at King's College and University College courses of lectures in the art and science of architecture are given, and that to multiply lecturers and lectures will be to run in excess of the demand. I believe there is room for all, and that, by a careful selection of times and subjects for instruction, students will be found to avail themselves of the opportunities offered. Let the experiment, at all events, have a fair trial: no harm can result from doing so, and if it be instituted and carried out with energy and vigour, without which failure is a foregone conclusion, success will follow. The special subjects which might be taken up and taught will take too long for me to touch on now. Doubtless those who follow me will do so. No doubt need be felt but what men will be forthcoming to teach if a demand exists, and some adequate remuneration is provided.

The Royal Academy has enlarged its borders, but, after all, cares but little to encourage and foster the mother art of architecture. South Kensington is busy, but its system of teaching architecture finds but little favour, I think, with the profession. Still, it has a marvellous store-house of art, which is at our service, and which we may make better use of than we do now. Technical education is an established fact, may not our own professors take a more leading part in furthering it? I fear it must be conceded that, as a profession, there is an absence of culture among the members of it, and of that refinement which is found in other learned callings. This is not much to be wondered at under a system which allows the most illiterate person to adopt the name of architect, and, "Heaven save the mark," to practise the art. It is this state of things which "makes us traduced, and tax'd of other nations." But the entrance to our profession, as has been done to others, by the test of skill and attainments, and I believe good would result, benefiting the public and profession alike. A diploma may one day become as accomplished a fact, to institute and promote greater facilities for education is a step towards it, and combination to effect this is required. Call this combination, trade unionism, if you will; nothing is to be done without it. We live in an era of "big concerns," and as long as men seek to gain

their legitimate aims in a law-abiding way, they can afford to smile at the charge of adopting trade nomenclature as the means to that end. And the tone of the individual, make admission to a profession an honour and a distinction, and we shall tempt better men to join it, and deter the inferior ones. Reform, with or without the diploma, must be a matter of time, but it does not let that difficulty deter us.

Are we in this age of restless activity to remain simply looking on, or to be up and doing? This is the question which, as a profession, we must endeavour to answer, and then, as best we may, carry the reform into execution. It is possible now to put our house in order, and, though to many who have passed their youth, the personal advantage can be gained by losing the standard of professional education, those who are to take our places have a claim upon us, and we must be careful how we neglect it. But I have trespassed a great deal on your time, and though conscious of many shortcomings, I have ventured to offer with boldness my own imperfect views of an important subject in the hope that we may this evening see the inauguration, perhaps, of an improved professional education for architects.

A report of the discussion which followed will be found in another column.

Illustrations.

DECORATIVE PAINTINGS: "THE ANNUNCIATION."

THE two figures which we give this week, and which collectively illustrate the story of "The Annunciation," are produced from two paintings executed by Mr. N. H. J. Westlake for the Church of Our Lady, St. John's Wood. One figure is placed on each side of the large window. They are rather over life-size, and with the accessory ornament, which is not given in the plate, occupy about 12 ft. by 3 ft.

STAIRCASE DESIGN.

This design, by Mr. J. Atwood Slater, received the first premium of 25*l.* given by the Royal Academy for the treatment of the subject specified,—an internal staircase for a dwelling-house. We commented on it at the time we announced the prizes. We may add that the author is to be commended for having given so much attention to constructive detail, sometimes urged over in designs made for prizes and not for execution.

SHOPS, &c., OLDHAM.

THESE premises are situated in Union-street, Oldham, and have been erected from designs by Messrs. Mangnall & Littlewoods, architects, of Manchester and Oldham. The front elevation above the shop windows are faced with red terra cotta made by Mr. Thompson, of Northwich, the plain surfaces being built with blocks of iron, deep, bonded and backed up with brickwork, dormers and pediments being built of solid terra cotta without any lacing.

The necessity for providing a large open glass out-ledge has confined the effect mainly to the upper part of the building, the ground-floor being glass, with cast-iron ornamental pilasters at intervals supporting the Bressummer beams. The internal arrangements provide for lofty show-rooms on the ground, first, and second floors, all of which are well lighted; the upper part of the first-floor window and the staircase are tinted glass lead lights, effective and subdued in tone of colour.

The contractors for the works were Messrs. Robert Neill & Sons, of Manchester.

HOUSE, NOTTINGHAM PARK.

THIS house forms one of the numerous residences which have been built in Chamber-essent, in the admirably laid-out residential suburb called the "Nottingham Park Estate," which skirts a considerable portion of the town, and for the general laying out of which, as well as for the design of a large proportion of the houses erected on it, Mr. T. C. Hine, of Nottingham (now T. C. Hine & Son), has been responsible. The house is built with red brick and eryshing stone dressings. There are two series of bed-rooms above the ground-floor, one being partly in the roof, and the accommodation includes library, smoking-room, and the

usual offices. The house is one of the more recent additions to the neighbourhood, having been very long completed.

SKETCHES IN TUNIS.

For descriptive article see p. 63.

STAPLE INN.

"... I have this (as) mored my things, and you are now to direct me at Staple Inn, London. . . . I am going to publish a little story-book, which I will send you when it is out."—Sam. Johnson to Lucy Porter, March 23rd, 1759.

THE south-eastern corner of Southampton-buildings opens by a footway on to one of the prettiest little gardens in London. With well-stocked flower-beds and one or two fine trees, and adjoining St. Andrew's Holborn parish, it lies between the hall and the new buildings of Staple Inn, one of the two Inns of Chancery,—Barnard's Inn, its neighbour, being the other,—that belonged to Gray's Inn. Stow says he is ignorant why it should be so called. Some would derive the name from the two staples with a cross bar, which John Breton, custos of London, temp. Edward I., put across the then Chancellor's-lane, for the greater security of those who should attempt what Strype terms its foul and miry way.* But this would hardly seem to be the case; whilst the fact remains that the Inn arose in or just before King Henry V.'s reign, upon Staple Hall, an exchange or bourse for the wool merchants or staplers whom King Richard II. had transferred hither from their settlement by his New Palace Yard, Westminster. The society (who have ever retained their device or emblem of the woolpack) at that time held the property by lease. The first grant of the inheritance to the ancients of Gray's Inn is by an indenture of bargain and sale, dated the 10th of November, 29 Henry VIII., from one John Keighton and Alice his wife, to other benefactors followed. For on the 4th of June, 1623, Sir Francis Bacon, Knight, then Lord Verulam and Viscount St. Alban, confests the college by the style of "all the messuage or inn of Chancery commonly called Staple Inn, and one garden thereunto adjoining . . . to the only use and behoof" of Sir Edward Moseley, knight, attorney of the Lancaster Duchy, with others the ancients of Gray's Inn, their heirs and assigns for ever. Bacon had been co-feeoffee under a deed dated the 18th of May, 32 Elizabeth. Like to that of Barnard's Inn, the hall is a relic from the Great Fire. Some of the window glass dates from 1500. Sir George Buc mentions the new building of the existing hall, against which the fig-trees yet stand, and of parts of the two courts, besides other lodgings,—the gentlemen of the House thereby making it "the fayrest Inn of Chancery in this universitic." The second, or garden, court and much of the first court were rebuilt about one hundred and sixty years ago. But the northern side of the latter is considerably older, being conspicuous for its charming Holborn front, whose picturesque and unique elevation is fully displayed by the demolition of Middle Row (once famous for its wig-makers) some twenty-five years since.

Staple Inn is associated with a tender episode in the life of Dr. Johnson. Having broken up his solitary home in Gough-square, where his wife had died in 1752 (just three days after the issue of the last "Rambler"), on finding, as Hawkins tells us, the balance of the account for his Dictionary against him, he retired to Gray's Inn, where he lived in all the indigent pride and dignity of literature, and thence on the 23rd of March, 1759, removed to Staple Inn.† In January of this year his aged mother died at Lichfield. Johnson had, as he himself writes, been unable to visit her, his disability arising doubtless from his narrow circumstances, since "The Idler" then formed his sole source of an income in which to the last his mother largely shared. His letters to her and to Miss Porter at this juncture are pathetically expressive of his filial solicitude and grief for the rending of the most sacred of human ties. Settled at Staple Inn he set to work upon, and, as he told Sir Joshua Reynolds, wrote in the evenings of one week what he mentions as his little story-book, the allegory of Rasselas, wherewith to

defray the funeral and testamentary expenses, with some debts his mother owed. For this essay, once as popular as was "Clarissa" throughout Europe, he received 100*l.* from R. and J. Dodsley and W. Johnston, the booksellers, who gave him 25*l.* more for the second edition. A reprint of the original edition has just been published by Mr. Elliot Stock. In Staple Inn, too, resided Isaac Reed, in whose chambers Stevens used to correct in the early morning hours the proof sheets for his edition of Shakspeare. We may here, upon good authority, contradict a statement circulated by the press to the effect that the Inn, as purchased by Messrs. Geo. Trollope & Sons, is about to be transformed into a carrier's yard.

Ranging with the southern side of the inner court, and separated therefrom by an elegant terrace, are Nos. 12 and 13, built in 1843, from the designs of Messrs. Wigg & Pownall, architects. Though altogether out of harmony with its surroundings this block is a tasteful and pure example, in white Suffolk brick with stone dressings, of domestic Jacobean architecture. The two stone doorways, each with an oriel above, and the gables, are highly effective. Until lately the rooms were occupied by the Taxing Masters in Chancery and the Land Registry. This building is being gradually acquired for the accommodation of the Patent Office, which now forms a department of the Board of Trade. Consequently upon the radical changes introduced by Mr. Chamberlain's new Patent Act, large and costly additions have been made to the examining branch, for whom quarters are found in the spacious and well-constructed rooms formerly occupied by the Chancery Registrars, immediately underneath the Patent Office library.

ARCHITECTURAL ASSOCIATION.

THE usual meeting was held at the rooms in Conduit-street, Regent-street, on Friday, Jan. 2. Mr. Cole A. Adams, President, in the chair.

Mr. John Slater, architect, F.R.I.B.A., was elected a member by acclamation.

The Honorary Secretary announced that in the unavoidable absence of the author of the paper intended to have been read that evening, the President had prepared a paper bearing on the subject of "The Best System of Education for Young Architects, and how the Work of the Architectural Association may be rendered more efficient."

The President then read the paper, which will be found on p. 65.

In the discussion which followed,—

Mr. A. B. Pite said he had some difficulty in opening the discussion, as he had been requested, to do, because he did not see completely in what special points English architects wanted education. Architecture was an art, and buildings erected were judged by their artistic or non-artistic qualities. The law of the survival of the fittest was seen in architecture by the survival of the most beautiful. Doubtless during the period of the classic architecture of Greece, and during the thirteenth century, ugly buildings had been erected, but they naturally had disappeared, because had architecture was bound to die within a short period. Art was a living power, and all lovers of it regarded only the beautiful and eliminated all that was disagreeable. This explained why all the Mediaeval architecture now existing was so beautiful. He thought the public wanted education more than the architects, and was glad to see the public awaking to the fact that there was a style in art. This feeling was now fostered in our schools of art. The systems of educating architects in France and Germany did not appear to him to have shown by their results any superiority to the English method. Having had opportunities of inspecting the architecture of France, Germany, and Italy, he did not fear a comparison between it and that of the English school. In fact, English architecture was infinitely the best. In methods of education those countries might excel, but the expected results in the better quality of the art were not produced. Our greatest architects had had a sort of haphazard training, but had done better probably than if they had been put into a sort of mill and turned out on hard-and-fast lines, which every one with an appreciation of art would abhor. A student might well enough be trained in certain branches of science connected with the profession, but that would not make him an architect, because his art was a gift which must be born with him, and could

* Chancery-lane was not paved in its whole length until 1549.

† The writer failed on inquiry to identify Johnson's chambers here.

not be crammed into him by any system of training. They might educate a man to be a builder, but they could not make him an artist, and to find out whether a student had art in him was a most difficult thing; and although at the Royal Academy they had a method which they supposed would do that, yet it was utterly futile. The Architectural Association was, in his opinion, already in a happy and satisfactory state, and he advised that things should be allowed to continue as they are. If any change were made, he would suggest some stimulus to competition by enhancing the value of the prizes. In conclusion, he desired to propose a vote of thanks to the President for his paper.

Mr. Millard, in seconding the vote of thanks, referred to the waste of time now involved in the training of an architect. More time than was necessary was taken to learn what was required to be learned in an architect's office. The pupillage system might be advantageously altered, and he would suggest that pupils be taken by the year instead of for periods of five years. There was no doubt much to be learned in an office, but it might be done more quickly by taking the subjects in some methodical manner than by engaging in a number of subjects simultaneously. He would advocate the sending of the student to a School of Art before articling him to an architect; and that would result in ascertaining his artistic abilities, which, under the present system, were swamped by the practical questions that came before him. When the artistic feeling of the student had been aroused, he would soon acquire the practical parts of his business, because he would then see the necessity of doing so. Then, before an article pupil left the office of his master, some arrangement should be made for his having an experience in carrying out completely one work, however small, from beginning to end, under his sole control; but, of course, under the eye of the master. The Association might help a student if it could arrange for placing him in a thoroughly good office with a leader in the profession, and this might probably be done by founding scholarships with that object, and such scholarships would be more useful perhaps than travelling studentships. There was, he believed, plenty of enthusiasm among students, but they wanted a guide to tell them how to go to work,—a sort of man like Arnold, Newman, or Gordon,—and to whom they could look as their leader. When once the curiosity, enthusiasm, and ambition of a student had been roused, such a leader could do anything with him.

Mr. Farrow could not agree with Mr. Pite that beauty was the test of lasting buildings, because in all ages good building and artistic designing had been concurrent; and so in our days the speculative building would be swept away whilst buildings like the Law Courts would exist for many generations. As to haphazard education, men like Street and Burges had had to undergo incessant and arduous study while pursuing their daily work as architects; but if their education had been systematic he believed their lives would have been prolonged, because their work would have been easier to them. It was natural for Mr. Pite to exalt the artistic side of the profession of an architect, but the profession not only involved art, but science also. Art was, no doubt, born with a man, but he had to acquire a knowledge of science, which should, therefore, be taught systematically and carefully. In other professions both theory and practice were studied,—separately as in the Army, Navy, the Church, and in Medicine,—but combined as in Law. In architecture they should be taken separately. That was done in the training of architectural students in Vienna. It was argued by some persons that such a training would bring all students to a dead level, but that was not found to be the case, as each student soon discovered the particular branch of the profession for which he was best adapted, and the number of specialists in Austria appeared to an Englishman extraordinary. In Vienna the student passed five years in a technical school, and then went for three years to the Academy of Fine Arts, afterwards working as a practical bricklayer and carpenter for one year. Then he went into the office of an architect for three or four years before commencing practice for himself. As to the work to be done by this Association, its chief object, he believed, should be to prepare members for the examination required by the Institute of British Architects; and to do that they would require to remodel

the Association and sketch out a definite course of instruction, which should extend, perhaps, over seven years, and by means of study and lectures should be made to cover the whole programme set forth by the Institute. The question of payment of lecturers might not be a difficult one if the subscription to the Association were raised, and if some of the lecturers gave their gratuitous services as they had done already.

Mr. Blashill (who sent a letter which was read by the Honorary Secretary) was of opinion that the only way to educate a student was to bring him face to face with the work in an architect's office, as no books, pictures, lectures, or associations were of any value in comparison with practical work. The student was trained rather by overcoming obstacles than by having facilities put before him.

Mr. Henry Lovegrove advocated an academic training, such as had been described as existing on the Continent, because if the English architect received full instruction in all branches of the profession, he would come to the front, as he did now, whenever he happened to possess artistic talent. A man who wrote poetry was no worse poet because he happened to be an M.A. as well. He would especially like to see every student of architecture taught the principles of design, apart from style; and the student would also do well to pay great attention to colour decoration. The Association should aim at helping towards a more thorough and complete training of the student, so that he might find himself more in harmony with the general culture around him.

Mr. J. Slater said, as regarded the preliminary education of the student, he believed that they now left school much too early, with their minds not sufficiently trained for the work they had afterwards to learn. For instance, one candidate for the Institute examination had served his articles before he was twenty-one years of age. The study of languages was not sufficiently attended to by students, and he had endeavoured to get the Institute to allow some marks for foreign languages, but his suggestion was not adopted. Valuable works on architecture existed in French, German, and Italian, but these were sealed books to most of the students of architecture in England. In regard to the classes of the Architectural Association, the reason why more students did not attend them was that many young students did not know what to do to get the knowledge to be obtained in those classes. The career of the student was usually the choice of his parents, and not of the young man himself. He hoped the Association would do all it could to give such young men information about the classes. To be a good draughtsman was not everything in an architect, because when he was in practice that work was usually delegated to some one else. Professor Roger Smith had said that the first, second, and third essential for an architect was drawing; but there were some other essentials he (Mr. Slater) thought, inasmuch as architects ought to be trained to do the work which engineers and others had taken from the profession. He had been a witness to the good result of the introduction of practical questions in the classes, and some other matters might with advantage be initiated in the scheme the President had foreshadowed.

Professor Roger Smith said he had always taken great interest in the professional education of the students of architecture. He agreed that it was of the utmost importance that everything possible should be done to advance the standard of knowledge, because no doubt competition would be even more severe in the future than in the present. No one should think of entering the profession without a large amount of education and culture. It would not be too much to demand that every student should be able to pass one of the matriculation examinations before taking up the profession of an architect. But after that, the best education for an architect was in the office of an architect under articles, when he would be brought into contact with practical work. That was the only way he knew of to acquire practical knowledge. It would be a good thing, before entering an office, to attend a school of art and learn drawing. He had known that done with great advantage. He would also advise that six months should be spent at the beach to learn how to make doors and windows, so that the working-drawings might be well understood afterwards. One advantage of the course pursued by him at University College was that the

teaching was tolerably systematic and continuous. And so the classes of the Association would be the more valuable the more they could systematise them and make them continuous. The students, no doubt, wanted guidance as to which classes to join first, and to this end some one might be appointed who might be called "The Student's Friend." As to the essential of drawing, he regarded it as such because they could only fix their ideas with the pencil and communicate them to the workman; and, moreover, the student would not learn freehand drawing in an architect's office, but must acquire it elsewhere. He would suggest that the Association should, if possible, arrange for the practice of students in a joiner's shop. He agreed in what had been said as to the value of foreign languages, as there was most valuable information in French, German, and Italian books and publications.

Mr. Tarver agreed fully with the last observation of Professor Roger Smith; also in the suggestion made by another speaker that pupils should be articled by the year. He pointed out that to the student every house he passed should have some interest, and from some of them over fifty years old he might learn much. He would advise students to study as much as possible, but to imitate as little as possible.

Mr. L. Harvey urged that before students entered an office they should be grounded in all the sciences applicable to building and construction. He remarked that many parents put their sons to the profession of an architect because they thought it a good paying business, but he could assure them it was quite a mistake to think so.

The vote of thanks having been passed by acclamation,

The President said some valuable remarks had been made. He quite agreed that an artist was born, not made; but at the same time it was essential that at the present time any one proposing to enter the architectural profession should be cultured and well grounded in the scientific portion of his work.

The proceedings then ended.

THE ULSTER REFORM CLUB, BELFAST.

THIS new club-house was opened to the use of the members on New Year's Day, although the formal opening ceremony will not take place until about Easter. The major part of the ground-floor is intended to be used for business chambers. The entrance to the Club is by the stone porch under the cupola, and thence through a vestibule into the staircase-hall. The principal rooms of the Club are on the first floor. The morning-room adjoins the dining-room, and is connected thereto by broad swing doors, and having the advantage of a southern aspect and of the large bow window, commanding fine views of Royal-avenue, High-street, and Donegal-place, it will always be a cheerful and pleasant room. The other rooms on this floor are the strangers' room and the private dining and drawing rooms. The billiard-room, upon the third floor, is the largest apartment in the building. It has been designed to hold four tables. The roof is of open timber, carried on elaborate iron principals. The walls are covered for some height with a panelled and polished pitch-pine diado; the upper parts of the windows are filled in with coloured glass; and the tables are by Messrs. Barraghes & Watts of London. Every room has an open fireplace, but in addition to this, there is an extensive system of hot-water pipes, carried under every window in such a way as to warm the outside fresh air as it is admitted to the building. The heating apparatus has been supplied by Mr. Wagstaffe, of Duckfield. The kitchens are situated on the topmost floor of the house, and have been fitted up by Messrs. Elliott, Edminson, & Olney, of Manchester. Messrs. Gillow, of Lancaster, have provided the furniture throughout, and Messrs. Robertson, Ferguson, Ledlie, & Co., of Belfast, the carpets and linoleum. Messrs. Patterson carried out the internal plumbing, bellhanging, &c. Messrs. Kiddel supplied and fixed the grates and much of the internal ironmongery. The stained glass is by Messrs. Edmundson, the tiling and parquetry floors by Mr. Oppenheimer, both of Manchester; and the hoists are by Messrs. Stephen, of Glasgow. The contract for the building and most of the interior finishing has been carried out by Mr. James Henry, of

elfast, from the plans and under the superintendence of the architects, Messrs. Maxwell & Peke, of Manchester, who have also superintended the furnishing of the club throughout.

OBITUARY.

Mr. R. M. Phipson, F.S.A.—We record with great regret the sudden death of Mr. Richard (Laklwa) Phipson, architect, and County Surveyor for Norfolk, which took place on the 9th ult. at his residence, Surrey-street, Norwich, from heart disease. Mr. Phipson, who was in his fifty-eighth year, commenced his practice as an architect at an early age in London, and in the following year (1849) took an office at Ipswich, where he obtained considerable professional employment in Suffolk and also in Norfolk, among other works being the restoration of the interior of St. Peter Mancroft Church, Norwich. In 1850, on the post of Surveyor for the County of Norfolk becoming vacant, he was successful in being appointed in competition with nineteen others. He was also one of the Diocesan Surveyors under the Ecclesiastical Dilapidations Act of 1871. A great deal of the work of church restoration in Norfolk and Suffolk, which has been done during the last quarter of a century, was entrusted to him. He was the architect of the Norwich City Asylum, but whether the misapprehensions that have befallen that building were due to his plans, or to the fact that he had to modify his original designs to suit the economical demands of the committee, is a matter in which (says the *Norfolk Chronicle*) probably there will be different opinions. Mr. Phipson was a Fellow of the Society of Antiquaries, and also took great interest in the local Archaeological Association, to whose journal he was an occasional contributor, his last paper being an interesting one on "Carrow Abbey." He was elected an Associate of the Royal Institute of British Architects in 1850, and a Fellow in 1859. In private life he was highly esteemed.

Mr. Alfred Tylor.—Mr. Alfred Tylor, F.G.S., S.A., who died on the 31st of December, at his home, Shepley House, Carshalton, aged sixty-one, was well known in commercial circles as a metal manufacturer (he was a member of the firm of Tylor & Son, Warwick-lane) and as a colliery-owner in South Wales. He was also well known for his efforts on behalf of technical education, which he was induced to advocate from his experience as a juror at the Paris Exhibition of 1855 and the London Exhibition of 1862. Mr. Tylor was connected with many institutions for the promotion of knowledge, and in particular took an important part in raising the London Institution to its present state of public usefulness. His papers are to be found in the *Journal of the Geological Society*, the *Geological Magazine*, the *Journal of the Anthropological Institute*, &c. One of his latest publications is his description in the *Archæologia*, vol. xviii., of the remarkable Roman remains excavated on land in Warwick-square, and now deposited in the British Museum. On the fourth page of our last volume we briefly commented on some of Mr. Tylor's archaeological researches, and frequent notices of his lectures have appeared in our columns.

THE ACTON DRAINAGE SCHEME.

The principal contract for the construction of the Acton Drainage Scheme, described in our columns some time ago, has been placed in the hands of Messrs. Nowell & Robson, and amounts to £35,938l. About 10,000l. of this sum will be spent in laying an effluent-water sewer from the precipitating works in the parish, through Bishopwick to the river. About 15,000l. has been paid for the land which has been acquired in connection with the scheme, which has been assigned by Sir Joseph Bazalgette, assisted by the local surveyor, Mr. Wm. Nicholson Sibley. Pressure has been brought to bear so strongly upon the Acton Local Board from all sides that it has been compelled at the last moment to accept tenders for a distinct and separate scheme of its own, even in the face of the conclusions or recommendations contained in the report issued in connexion with the Kingston inquiry, that the sewage conduit of any combined system should, if possible, be of sufficient capacity to carry the sewage of all the towns round the west of London.

As it is stated in the report that Sir Joseph Bazalgette confirms this conclusion or view, some warm discussion naturally arose at the meeting of the Acton Board on Tuesday night last as to the apparent contradiction, or want of harmony between his evidence at the Kingston Inquiry and the principles which he is carrying out in connexion with the Acton drainage scheme, which includes a new and independent outfall to the river Thames, and which, as stated, is to cost 16,000l. A motion to consult again Sir Joseph Bazalgette to ascertain whether he is of the same opinion as when he designed the Acton scheme, and to make application to the Metropolitan Board of Works for a drainage outlet into the central system, was lost by a large majority.

ROYAL ACADEMY.

LIST OF ADMISSIONS, JANUARY, 1885.

Upper School.—F. S. Capon, H. Cresswell, E. J. G. Dawber, G. Horsley, A. B. Pite, A. D. Smith, and H. J. Westell.
Lower School.—P. Anderson, N. W. Allen, R. S. Ayling, W. H. Boevey, W. A. Burr, W. L. Buxton, F. M. Day, H. P. B. Downing, L. Dennis, H. Drury, L. R. Ford, C. Gill, G. Harvey, T. H. Hitchin, W. H. Howie, H. Hutchings, A. H. Jemmett, A. J. Lancaster, W. Leck, H. G. Manning, F. W. Marks, F. Mascy, C. L. Moadway, W. Newton, R. O. B. North, W. R. Schultz, A. Steadhal, Van Straaten, A. Sykes, A. S. Taylor, G. B. Thorpe, and F. G. Webb.
Probationers.—W. Alford, A. E. Barnsley, F. D. Bedford, W. T. Cave, F. Davison, C. D. Fitzroy, P. N. Ginham, J. E. Inglis, F. J. James, G. L. Jones, G. T. McCombie, and R. F. McDonald.

RECORDS OF CHANGES IN LONDON.

Sir,—It has often occurred to me, in reviewing the numerous and rapid changes that are daily taking place in the streets of the metropolis, where one day we see a row of tumble-down houses, and, in passing the same locality a few months later, we find instead a row of palatial-looking shops, that it would be advantageous if some means could be taken for recording those changes, and it is with this object that I now venture to ask you to allow me to trespass on your valuable space.

What is proposed is that a committee or society be formed for the purpose of making drawings of, or photographing to a small but uniform scale, the elevations of all buildings as they stand in relation to each other in the important thoroughfares of London, and of those streets likely to be demolished or affected by metropolitan improvements, so that each street could be seen at a glance.

This idea may seem to some to be chimerical, and the labour of such a work almost superhuman, but I venture to think that, if done systematically, and taken in hand by a few architects, who would work at it with zeal and energy, that in the course of a few years an invaluable record would be obtained, such as would be interesting to the artist and antiquary, and useful to the architect, lawyer, and surveyor, in dealing with cases of light and air, or in settling many of the numerous disputes which arise out of town property.

It would probably be in the City and the main West-end thoroughfares that this system of streetography (if I may be allowed to coin a word for want of a better) would be most useful; but, if the system were once started, I think its future development would be an easy task.

Whether the drawings should be published or only issued to members of the society, on payment of a subscription, or whether architects assisting in the formation of the record should be entitled to rank as members without payment, are matters which might hereafter be discussed, if the idea should find favour with the profession; suffice it to say that I have already found architects who would be willing to assist in the furtherance of the scheme.

Only imagine the interest which would now be taken in a record such as this if it had been commenced three or four hundred years ago; in those days such a work would have been almost impossible, but modern science has made the task easy.

It has been said that Augustus found Rome built of brick and left it in marble, and future

generations will say that Victoria found London in brick and left it in stone, and if we neglect to preserve the records of brick-built London we shall be neglecting a duty which posterity will lament, even if it does not convict us of culpable negligence. W. HILTON NASH, No. 5, Adelaide-place, E.C., Jan. 6th, 1885.

A CAUTION.

Sir,—It was with some considerable pain that I listened to the remarks which fell from Professor Kerr, at the business meeting of the Institute on the 5th inst., suggesting the advisability of converting some of the rooms at 9, Conduit-street, to the uses and privileges of a "club."

Fortunately his remarks were submitted only as a "suggestion" and by that discretion may, perhaps, be overlooked.

It need not be contended how injuriously such an innovation might operate, and I sincerely hope that Professor Kerr's suggestion will be as barren in effect as it deserves.

Had this pernicious suggestion come from one not of established reputation, it might have been excused; but coming, as it does, from an eminent, learned professor, to whom juniors are accustomed to look for advice and wisdom, its birth is of too much importance to ignore the possibility of danger. Not!

AREAS OF BOROUGHES.

Sir,—Will any of your readers kindly inform me, either personally or through your paper, which borough in England has the largest area?

Sheffield is 19,650 a. 1 r., and I am informed that there is a borough with a larger area, but as yet I have been unable to find out which.

I am desirous of ascertaining this as I require the information to prepare some statistics; hence my reason for troubling you.

FREDERICK A. KEMP, Assistant Borough Surveyor.

Sheffield.

NON-CONDUCTORS OF SOUND.

Sir,—Can any of your numerous readers say from experience what is the best non-conductor of sound through party-walls?

I have a 14-inch wall dividing a printing-office from surgeons' consulting-rooms. I have isolated floor-bearings, also erected wooden partition 9 in. from wall, filled in with sawdust, which does not keep back the sound. B. & C.

CHURCH-BUILDING NEWS.

Winslow (Bucks).—The parish church, dedicated to St. Laurence, and possessing many interesting architectural features, dating from the end of the thirteenth century downwards, was re-opened on the 30th ult. It has been closed since February last; and during the interval has been carefully restored under the direction of Mr. John Oldrid Scott, M.A., architect, London. During the progress of the work Mr. Scott has been represented on the spot by one of his late father's trusty clerks of works, Mr. George Hannaford; and Mr. George Cooper, of Aylesbury, was the contractor who undertook the general renovation of the fabric. The masonry has all been well cared for. The ancient chancel oak roof has been opened out, and new roofs, also of oak, have been placed over the nave and south aisles. The floors in the nave and aisles are laid with wood blocks, in geometrical designs, and the space is temporarily seated by chairs. The avenues are paved with Godwin's red and black tiles, and the chancel and the space under the western tower are laid with encaustic tiles by the same firm, and therein stands a new Caen stone font on Purbeck columns. The altar is raised five steps above the nave line. The reredos and double set of stalls are of oak, and so are all the doors. The ironwork on the latter are by Mr. W. Skidmore, of Coventry. The reredos is decorated by Messrs. Burlison & Grylls, of London. The brass standards are by Messrs. Barratt, of Birmingham. There is a statue of St. Laurence in the south porch; this is by Mr. Harry Hems, of Exeter, who has also executed the stone and wood-carving generally. The total cost of the work is 3,500l.

Hulme (Manchester).—Great improvements have been made in the chancel of St. Mary's Church, Hulme. A reredos has just been erected, and a new altar and foot-piece of oak have replaced the old ones. The reredos is in the form of a triptych, with wings. There are three recessed panels, which will shortly be filled with paintings by Messrs. Clayton & Bell.

Above these are carved and perforated gables, the centre one rising to a height of more than 20 ft. The whole has been executed in oak by Messrs. Earp, Son, & Hobbs, of London and Manchester, from designs by Mr. J. S. Crowther, of Manchester. A frontal has also been presented for the new altar. It is of cream silk damask, embroidered all over with a rich trailing pattern. It has been entirely the work of three ladies (sisters).

Lewisham.—A further addition to the parish church here is the new pulpit designed by A. W. Blomfield, M.A. It rises to a height of 12 ft. (this being necessitated by the galleries) and rests on a plinth of Portland and red Mansfield stones. Four columns of Shap granite with carved capitals support the arched and corbelled consoles which carry the body of the pulpit, which on its three wider faces contain semicircular arches subdivided into smaller open arches with marble columns, the three narrower faces being niches filled with the angels Michael, Gabriel, and that of the Everlasting Gospel, the whole composition being terminated with a moulded carved and polished alabaster cornice. It has been executed by Messrs. Earp, Son, & Hobbs; the open iron staircase being the work of Messrs. Hart, Son, Peard, & Co.

STAINED GLASS.

Louth.—A stained-glass window has been placed in St. Michael's Church, the subject of which is "To Thee all Angels cry Aloud." The whole of the lights are filled with adoring angels, except the top, which contains the Agnus Dei. The window has been given by the congregation in memory of one who was an active worker in the parish, and the design has been carried out by Messrs. Mayer & Co., of Munich and New Bond-street.

Trefnant.—Three windows, by Messrs. Burdison & Grylls, have been placed in the parish church of Trefnant, diocese of St. Asaph, as a memorial of Mr. Townshend Mainwaring, for many years M.P. for the Denbigh Boroughs, who died on Christmas Day, 1883. The church was built by the Mainwaring family from designs by the late Sir Gilbert Scott. One of the windows has been contributed by Mr. Mainwaring's family, and the other two by his numerous friends.

Scarning.—A window, by Wailes, of Newcastle, has been placed in the chancel at Scarning, Norfolk, by Miss Warcup, former inhabitant of the parish, in memory of her father, a physician of large local practice, who was one of the landowners there. This is the fourth window which members of this family have at various times presented to the church.

Sewage as Food for Fishes.—Sir John Lawes, whose distinguished services to agriculture and agricultural chemistry entitle his words to the most respectful hearing, suggests that it may, after all, be more profitable to throw the sewage into the sea than to apply it to land. To the broad line of Sir John Lawes's argument no exception can be taken. Enormous quantities of fish are removed from the sea near our shores, and in them enormous quantities of phosphate of lime, potash, and nitrogen. Now, phosphate of lime exists in sea-water in very minute quantity, and yet it is as essential an article of food to fishes as to mammals. If, then, as Sir John Lawes contends, the sewage of large towns gives back to the sea enough, or more than enough, to compensate for the food material annually taken from it, it may well be that continued and even increased prosperity may accrue to the fisheries. Of course, there would be no need to continue the present disgusting system of throwing the sewage in a raw state into a river used as the highway of nations. Even after defecation the sewage would still retain nearly all the nitrogen and much of the mineral constituents. In one respect, indeed, such a defecation would be a great advantage to the fishes; for it was proved in evidence before the late Royal Commission that the sewage throughout a largo area of the Thames absorbs, practically, the whole of the dissolved oxygen, on which the respiration of fishes depends. This evil would be diminished by defecation, but would only be cured entirely by a much greater dilution. The speculation is a very interesting and important one, but a great deal of further inquiry will be necessary before it can be adopted as a basis for action.—*Lancet.*

The Student's Column.

LIME, CEMENT, AND THEIR USES.—II.

HAVING determined the fineness, the next thing to do is to find out if the cement is quick or slow setting, and how much water it requires to gauge it to a proper consistency, i.e., a stiff mass, that will remain in any form into which it is worked. To do this, weigh out 10 ounces of cement, and put it on the gauging table, measure out 3 ounces of water in a measuring glass, add the water gradually to the cement, working it with the trowel the whole time till it is evenly gauged throughout, and of the desired consistency; divide it into three parts, and make a neat pat of each; put each on a separate piece of glass, and number them 1, 2, and 3, and note the amount of water used, which will probably be from 1.75 to 2.25 ounces. Pat No. 1 is to be left in the air, pat No. 2 is to be put into water as soon as it is set. The object of pat No. 3 will be referred to later on. Having made this little experiment with the cement, whether it is quick or slow setting, the general character of the cement are ascertained, and the experimenter is in a position to make his test-pieces, or briquettes, as they are generally called, so as to obtain the best results. The briquettes are now always made with an area of 1 square inch at the smallest section, which is, of course, the point of fracture; but it will be readily understood that different forms will give different results,—the one which is now generally adopted is according to the annexed sketch, the clips or jaws of the testing

machine holding it at the points marked A A A A,—the section of smallest area being on the line B C.

No test for tensile strength should be determined by the result obtained from only one briquette, as air-bubbles, inequality in gauging, and other circumstances may render an individual briquette imperfect, and the result obtained would consequently not be just. Ten briquettes at least should be made,—five to be broken at the expiration of each of the dates named (three and seven days from gauging), and the average of each five taken as representing the strength of the sample at each date. It is convenient to have five moulds put together in one nest, and enough cement gauged to fill the five moulds at once; five moulds of the form given require rather less than 30 ounces of cement to fill them. As 10 ounces of cement were used for making the pats, if 30 ounces are taken for the briquettes, then, by multiplying the amount of water used in making the pats by three, the exact quantity required for gauging the briquettes is known, and the measure must be filled with exactly that quantity. The cement is then to be gauged in the same manner as already described for gauging, the pats and put into the moulds; it should then be lightly rammed and shaken so as to get rid of all air-bubbles, smoothed off on the surface, put on one side, and not again touched or shaken in any way for twenty-four hours. The briquettes should then be taken out of the moulds and put into water, where they must remain until they are to be broken. It is almost needless to add that the water both for gauging and that in the tank should be perfectly clean and fresh.

The operation of gauging the cement and putting it in the moulds should not exceed five or six minutes, and with some quick-setting cements it should not occupy more than three or four. The difficulty of getting the thirty ounces to an even and proper consistency with the minimum of water in this short time is great, and the knack can only be acquired after

considerable practice and experience, and different results will often be obtained even by two expert gaugers. To obviate this a small machine has lately been brought out for gauging the cement. It consists of a small pan, into which the cement and water are placed, and by merely turning a handle, the stirrers in the machine, which revolve on their own axes, as well as round the pan, thoroughly gauge the cement in one or two minutes.

When the briquettes are to be tested, they are taken out of the water, wiped dry, and put into the testing-machine, and broken at once. The testing-machine should be so regulated that the strain is put on to the briquettes evenly and without jerks, and at the uniform speed of 100 lb. every 15 seconds; for it has been proved that very different results, amounting to as much as 25 per cent., may be obtained by applying the strain at different speeds.

The fineness, time of setting, and the strength of the cement are now known, but the pats have still to be examined to know if the cement is sound. Cement does not, as a rule, show signs of "blowing," i.e., disintegrating, for a considerable time when allowed to remain in the air. It shows it quicker when put into water as soon as it is set, and, quickest of all, when subjected to moisture and heat combined. A good sound cement will not blow under any of these conditions. Many cements will blow simply because they are too fresh, and, if kept for a short time, would be found to be perfectly sound. The reason of this has already been explained.

Pats No. 1 and No. 2 should be examined every day. The first indication of the cement being unsound is detected by the appearance of small cracks, commencing on the edges next to the glass. It would, however, be a very bad cement indeed that would blow under these conditions in a week. Pat No. 3 may, therefore, be subjected to the moisture and heat combined, as by this means an absolute result may be obtained in twenty-four hours. This test, however, can only be carried out in special apparatus, and requires to be very judiciously and carefully manipulated. The operation consists in subjecting the pat directly to the steam of vapour rising from water of 100° temperature Fahr., where it is left for three or four hours. It is then put into a bath of water which is maintained at an even temperature of 110°, and the pat examined twenty-four hours after gauging; if the pat then shows no signs of blowing the cement may be relied upon as being perfectly sound. Great accuracy is required in maintaining even temperatures, for, if lower temperatures are used, the test is not so decided, while almost any cement will blow if the temperature has been much exceeded. The great value of this test is that it enables an opinion to be formed in a few hours as to whether the sample under consideration is sound or unsound; and, disregarding strength, if it is a safe cement to use.

The principal difference to be observed between limo and cement, is that whereas lime has strong adhesive powers and small cohesive powers, cement possesses the reverse properties. Lime, therefore, is improved in strength by the addition of a suitable sand, while the strength of cement is greatest when it is used by itself. To determine the constructive value of a sample of limo by means of laboratory or testing-room experiments, is much more difficult than the carrying out of an ordinary cement test. In fact, such tests are seldom adopted, for from a knowledge of the components of the limestone from which the limo is burned, and from its general appearance, a very just opinion can be formed as to its suitability for the work for which it is intended to be used, and it is only necessary to ensure that it is worked in a proper manner.

When, however, a test is made, it is simply the hardness which the sample attains after gauging that is determined, and this is done by what is known as a Vicat needle. A Vicat needle is an instrument consisting of a needle with a flat point fixed to a light rod, which slides in the framework of the machine; the needle, being weighted to the required amount, is allowed to fall from a certain height on to the pat of limo, and the indentation measured by means of a Vernier scale on the guide-rod. It is usual to make the pat to be tested of one part limo to three parts of clean sharp sand, about 3 in. square and at least 1½ in. thick; the needle should have a diameter at the point of 0.1 inch and should weigh with the rod and

chments 4 oz.; the fall should be 6 in., and experiment carried out seven days after setting the pat.

The knowledge of the analysis of the lime (or even generally its geological position) in which the lime under consideration has been burned, will at once decide whether it is a hydraulic lime, and an examination will decide if it is well burned and fresh. The order of burning can be, in the matter of rich limes, easily determined by taking a small quantity of it, dipping it into water, and then putting on one side for a short time. If it all falls to a white impalpable powder it is a sure indication that the lime is properly burned. If, on the other hand, hard lumps remain, this is an indication that it is not well burned, and a few more tests should be taken from different parts of the bulk and the same experiment carried out. In the foregoing, it need not be forgotten, refers to rich limes only; the hydraulic and eminently hydraulic limes take a much longer time to "burn," some of them as much as a week or more, or even longer; in fact, from the experience of "slacking them" they are generally ground to facilitate the operation. The freshness of the lime is essential, because lime that has become "killed" by absorption of carbonic acid from the atmosphere will not make good mortar. If all the lumps of lime are clean sharp edges without cracks or any indication of powdering it is in a perfect condition for use. Lime is supplied from the manufacturer as "lump" lime or ground. The rich limes are generally supplied as lump lime, and the hydraulic limes are generally ground; but, less it is to be used at once, it is preferable to have it in lumps, as in that condition it will keep longer time in good condition.

Roman cement, plaster of Paris, parian and Keene's cement, though not used for purely constructive purposes as are lime and Portland cement, are still of the same category. Roman cement is the immediate forerunner of Portland cement. It was no doubt called Roman because it was thought that in it had been rediscovered the cement used by the Romans, and to which it has given such a high reputation; it is, however, needless to say that the Romans were ignorant of Roman cement. It is an essentially hydraulic cement, containing considerably less silica than Portland cement, and a correspondingly increased quantity of silica and alumina, and it is burned at a much lower temperature. It is produced by the simple calcination of an argillaceous limestone, which is found in many parts along the English coast. The principal seat of the industry was in the Isle of Sheppey, where large quantities of the stone were found; it has been entirely superseded by Portland cement, and very little is now made. It is of a dark brown colour, and sets very quickly, whether left in air or put in water. It attains its maximum strength in a very short time, and when tested for tensile strength in the same way as Portland cement, breaks at about 200 lb. per square inch when seven days old, and it never increases much more. Medina, lias, and other cements are simply variations of it.

Plaster of Paris is calcined alabaster or gypsum, and is sulphate of lime, containing not one-third part of water. The object of calcination is, therefore, only to expel the combined moisture. The calcination is carried out at a very low temperature, and it is then ground to the desired fineness. In some districts the gypsum is first ground to powder, and the moisture evaporated from it by placing it on hot plates. Plaster of Paris sets very quickly when water is added to it. It is used only for internal work, as it never attains any very great strength or hardness. For ornamental carvings, &c., in rooms it is often mixed with lime-patty to make it slower setting. Keene's, Martin's, and parian cement are all manufactured from plaster of Paris by the addition thereto of alum, sulphate of potash, or borax. By these additions in the proper proportion the plaster is rendered extremely hard on the surface, and is capable of taking a certain amount of polish. Many of the artificial marbles are made with one or another of them as a base, with colouring matter added to give the vein of the stone or marble it is intended to imitate.

Having now become acquainted with the qualities and properties of the cements and plasters in general use, the study of their manipulation and treatment in practical constructional work next deserves attention, but before describing the manner in which the different

matrices are used to the best advantage, the following general rules and instructions should be carefully studied and invariably adhered to.

As to the choice of materials. It is often impossible to obtain the particular lime or cement that is desired. In that case experiments should be made with those that are available, the result of each noted, and the advantages and disadvantages of each carefully considered before a determination to use either one or another is arrived at. In carrying out such experiments it must not be forgotten that they are essentially comparative, and that therefore each material must be tested in such a manner as will enable the best result to be obtained from it. Every detail of each experiment must in itself be an experiment. Never jump at a conclusion; but, no matter how good or how bad a result seems likely to come out of the experiment, follow it to the end, and be sure that the true value of the material has been arrived at. If a certain result is wished for, nobody is easier to deceive than oneself, and a certain result is always wished for if a preconceived opinion is formed; begin the experiments, therefore, without an opinion, and finish them by having a strong and a true one.

Having decided the proper and best manner in which a material is to be used, give instructions and directions in a clear and practical manner, and, above all, see that those instructions are carried out. Good materials are of no value if they are spoiled in the handling. The cement or lime is to give strength and adherence to the whole structure,—and it is, with the addition of sand or other material, formed into a compound material, the strength of which and its power of adhesion to the materials it is intended to unite, depends on every detail of its make and use being carried out in accordance with the instruction given. It should never be forgotten that the manufacture of a cement or lime is a chemical and not merely mechanical operation; that as soon as water is added to either for the purpose of reduction to the form required for use, a further chemical action is commenced, which must be carried out and completed in as careful and perfect a manner as was the former of manufacture. The completion and perfection of any chemical action is much more difficult of attainment than where a merely mechanical mixture is desired. It is, therefore, all the more necessary that the greatest care, supervision, and common sense should be used in the manufacture of a chemical compound.

No amount of supervision and care will ensure the making of a good mortar unless the necessary appliances are at hand. Makeshifts may answer in many instances, but they are not desirable: always, therefore, see that the plant is sufficient for the purpose. A man cannot do more than a day's work, and if his time is taken up in unnecessary labour, he does not do so much of the necessary work, and, further, that work is not done so well. By all means substitute machinery for manual labour if it does as good work; for it is more certain and reliable in its result, and requires less supervision. Again, be careful in the manipulation of every detail in the making of mortar, and discard the idea that the oldest man and the youngest boy in the builder's employ are the two most eligible persons to perform that duty.

Mortar is a combination of one of the limes or cements,—the properties of which have already been considered,—and sand; if to this stones of varying size and shape are added, the result is concrete. The lime or cement is called the matrix, and the sand, or sand and stones, the aggregate. Mortars and concretes may be made with varying proportions of matrix and aggregate, according to the structural strength required, the strength of the matrix, and the properties and power of the aggregates to receive the adhesion of the cement.

The sand just merits attention because it enters into the composition of both mortars and concretes. In a few words, the sand should be clean, sharp, and neither too large nor too small in grain, nor should the grains be of equal size.

The sand should be clean, because in that condition it has been deprived of all loam and organic or greasy matters, which, by their nature, act detrimentally in all limes and concretes, depriving them of their power of setting, reducing their strength, and rendering them more or less friable. A clean sand is, so far as its use in building is concerned, an insoluble

and unchanging material, which does not absorb moisture. It is, in fact, a purely inert material, acting in no way either chemically or otherwise in the matrix, merely allowing itself to be made into a concrete mass when combined with the lime or cement, the strength of which depends, independently of the strength of the cement, on the favourable or unfavourable shape and size of the grains to receive the adhesion of the lime or cement, and it will be readily understood that the more angular or "sharper" the grains of sand are the better they will key with each other, when made into a mortar, as well as offer a larger surface for the adhesion of the cement, than if the grains are rounded.

SIR,—Having read with much interest the lessons on perspective in the "Student's Column" of the *Builder*, I venture to suggest that another lesson on bird's-eye views and also one on the projection of shadows would be most acceptable to a large number of your readers.

HISKETH BARLOW.

** The bird's-eye perspective subject shall be treated when space serves. The subject of projection in drawing (including shadow) will be specially dealt with at some length shortly.

RECENT PATENTS.

ABSTRACTS OF SPECIFICATIONS.

10,434, Improvements in Domestic Fireplaces. G. H. and A. Brown.

It is usual in domestic fireplaces to fasten the range to the long front and short front by means of bolts and nuts, which is inconvenient, as parts of the grate are then difficult of access, and expensive to repair. Fire space is also generally reduced by using false bottoms, or by raising the bottom bars. This invention is designed to provide a grate which is easy of access, and also capable of having the fire-space readily reduced. On the long and short fronts a vertical groove or slide is cast, into which a movable sliding range is easily moved up or down so as to reduce the size of the fire-space, or it may be lifted out bodily, so as to obtain access to the other parts of the fireplace. Some improvements are also made in the fastening together of the parts of the range by means of long pins or screws, which pass through the movable slide, and fix the range in the proper position.

2,777, Improvements in Wall Ties. W. Monney.

The improvements consist mainly in forming serrations or corrugations upon the branches or arms of wall-ties, whereby the holding power is greatly increased. The serrations are so formed that any contraction of the tie tends to draw the two sections of the wall closer together, by reason of the vertical faces being directed towards the centre. Any expansion of the tie does not separate the two walls, as only the inclined surface of the serrations comes into contact with the surrounding material. Shoulders are also formed to prevent the wall collapsing under external pressure.

3,214, Improvements in Soil and Waste Pipes. F. W. Hagen.

The branch soil or waste pipe is made longitudinally to rise towards the vertical soil-pipe, and thus it becomes self-ventilating, and is accessible from the outside of the building. A screw cap is placed in such a position opposite the junction with the main pipe, that it may be readily got at. The opposite end of the branch pipe is below the water seal of the fittings.

1,465, Trellis Work, D. Karritschoner.

The trellis-work is made of wrought iron in bent or straight bars jointed together by a lazy tongs arrangement and furnished with gilded rosettes at the joints and elsewhere if desired. It can be extended or contracted.

5,002, Metallising and Polishing Wooden Articles. C. W. Rees.

The surface of the article is prepared as for French polishing, and sized with white lead or plaster of Paris. It is then French polished with a ground-colour suitable to the metallised appearance required, as, for instance, using ground turmeric for brass, &c. A glaze is then applied and allowed to stand until hard, when the surface is rubbed over with a transparent polish, dabbing the rubber in bronze or other powder. A slight coat of transparent polish is then applied to the surface which is next spirited up.

6,127, Connecting Water-closets, &c., with Ventilated Soil-pipes.

The objects are to avoid the use of syphon or similar traps between a water-closet and the soil-pipe, and to provide a connexion which will prevent the return of sewer-gases from the soil-pipe into the closet, and to avoid the necessity for the use of a separate pipe or pipes other than the soil-pipe for carrying away waste water from a house. The closets on the various floors are connected, two or more together, to a cast-iron, lead, or other receiver, covered by a grating. These receivers communicate with the soil-pipe through a flap-valve opening outwards, over which there is a cover to allow of easy

access to the valve. The receiver being closed from the soil-pipe and open at the top, bath, sink, and other water-pipes may be led into it without liability of sewer-gas escaping up them.

APPLICATIONS FOR LETTERS PATENT.

Dec. 24.—16,866, J. Craven, Improvements in Cases or Holts.—16,872, T. Lythgoe, Improved Sanitary Slop Stone.—16,873, J. Smith, Composition for producing Imitations of Carved and Moulded Woodwork.—16,876, C. C. Brodie and J. D. Prior, Improvements in Cooking-ranges.—16,882, H. Hasall, Furnaces for Pottery or Brick Kilns.—16,883, J. Gillespie, Internal Walls of Furnaces.—16,884, J. Gillespie, Improvements in Brick Garden Walls.

Dec. 27.—16,922, P. Corcoran, Machinery for Dressing Stone.—16,943, S. Willett, Securing the Meeting-bar of Sash-fasteners and holding same.—16,950, W. Smith, Manufacture of Portland Cement.—16,951, S. S. Hazeland, Machinery for Planing Wood.—16,952, J. Watts, Testing Draught-pipes.—16,968, J. Griffin, Construction of Wrought-iron Window-frames.

Dec. 29.—16,999, T. R. Shillito, Improvements in Locks.

Dec. 30.—17,018, J. J. Jones, Manufacture of Hinges.—17,024, F. E. Bond, Pervious Fire-bricks.—17,031, W. P. Thompson, Apparatus for Drawing Ellipses.

Dec. 31.—17,066, W. Parr, Apparatus for Preventing the Passage of Air, Dust, and Water past Doors.—17,076, E. Verity and J. M. Verity, Improved Terminal for Preventing Down-draught and Inducing Up-draught in Chimneys, Ventilators, &c.—17,085, R. C. Jones and J. W. Cunningham, Locks or Fastenings.—17,103, A. Muljord, Venetian Window-blind Laths.

Jan. 1.—3, James Hill, Improvements in Rim Locks, Drawback Locks, and Latches.—21, J. W. Mathews, Improvements in Hydrants.—23, D. Aubert, Ventilating Apparatus for Opening, Holding, and Closing Sashes, Ventilators, &c.—39, S. R. Hooper, Manufacture of Paints.—43, V. Bitzenhofer, Joining Inlaid Floors by Steel Pins.—60, H. W. Robinson, Improvements in Roofing Tiles.

PROVISIONAL SPECIFICATIONS ACCEPTED.

15,166, C. Wiltshire and J. Wiltshire, Glazing Skylights, Windows, &c.—15,203, J. Matthews, Electric Horse Belts.—15,232, R. H. Heyhurst, Gully for Sanitary Purposes.—15,275, J. T. Welch, Manufacture of Bricks, Tiles, &c.—15,375, J. Gilchrist, Water-closet Cisterns.—15,441, T. M. Bear and H. Ransom, Combined Circular Saw, Fret Saw, and Drill.—15,468, J. Rettie, Cutting and Dressing Stone.—15,469, E. Edwards, Slow-combustion Stoves.—15,586, E. Y. Carriner, Manufacture of White Lead.—15,603, J. B. Robinson, Improvements in Window Sashes.—16,257 and 16,258, H. Wainwright, Supplying Water to Water-closets, Urinals, &c.—15,468, H. J. Hadden, Machinery for Sawing or Dressing Stone.—15,730, W. G. Margetts, Manufacture of Portland Cement.—16,214, T. G. Downing, Apparatus for Heating and Ventilating Apartments.—16,348, D. J. Jones, Improvements in Window Frames.

COMPLETE SPECIFICATIONS ACCEPTED.

Open to opposition for two months.

578, M. Williams, Wood Staining and Varnishing.—2,816, E. Taylor, Improvements in Fireplaces.—3,737, C. Cooper and W. Cooper, Manufacture of Bricks.—3,763, C. Allen and W. Allen, Glazing Horticultural Buildings.—4,051, W. Thompson, Moulds for Concrete Foundations, Walls, and Blocks.—7,055, M. Syer, Pneumatic Flushing Apparatus.—9,607, W. A. Leppner, Electric Bell Pushes, &c.—304, W. Parry, Bricks for Preventing Wet from Permeating Walls.—6,506, T. Wood, Device for Facilitating the Cleansing of Cisterns.—15,353, R. Murray, Joint for Lead or other Soft Metal Pipes.

MEETINGS.

MONDAY, JAN. 12.

London and Middlesex Archaeological Society (King's College, Strand).—(1) Professor J. W. Hales, M.A., on "Two Anglo-Saxon Charters relating to Hampstead." (2) Mr. Charles Beach Smith, F.S.A., "On the late Discoveries in the Wall of London." 8 p.m. Society of Arts (Cantor Lectures).—Dr. G. V. Poore on "Climate and its Relation to Health."—I. 8 p.m. Inventors' Institute. 8 p.m. Leeds and Yorkshire Architectural Society.—Mr. J. A. Gitch on "English Homes in the Seventeenth Century." Edinburgh Architectural Association.—Mr. John Kinross on "The Study and Progress of Architecture." 8.30 p.m.

TUESDAY, JAN. 13.

Institution of Civil Engineers.—Inaugural Address by the President, Sir Frederick I. Bramwell, F.R.S. 6 p.m. St. Paul's Ecclesiological Society.—Mr. J. C. L. Stahlshmidt on "Church Bells." 7.30 p.m. Society of Biblical Archaeology.—Paper by Mr. Theo. G. Pinches. 8 p.m. Anthropological Institute.—Papers by Mr. Oldfield Thomas and Mr. A. L. Cameron. 8 p.m.

WEDNESDAY, JAN. 14.

Civil and Mechanical Engineers' Society.—Mr. G. Richards Julian, A.R.I.B.A., on "The Appropriate Ornamentation of Works in Iron." 7.30 p.m.

British Museum.—Mr. W. St. Chad Boscawen on "Assyrian and Babylonian Antiquities." 2.30 p.m. Society of Arts.—Mr. R. H. Tweddell on "The Employment of Hydraulic Machinery in Engineering Workshops." (Sir Frederick Bramwell in the chair.) 8 p.m.

THURSDAY, JAN. 15.

Society for the Encouragement of the Fine Arts.—Conversations at the Galleries of the Royal Institute of Painters in Oil Colours, Piccadilly. 8 p.m. Society of Antiquaries.—8.30 p.m. Institution of Civil Engineers.—Mr. John Evans on "The Science and Practice of Hydro-Mechanics." I. 8 p.m.

FRIDAY, JAN. 16.

Royal Institution.—Professor Lyndall on "Living Conflagra." 9 p.m. Architectural Association.—Mr. F. R. Farrow on "The Ventilation of Public Buildings." 7.30 p.m. Institution of Civil Engineers.—(Students' Meeting).—Mr. F. Geere Howard on "Secondary Batteries." 7.30 p.m.

SATURDAY, JAN. 17.

Royal Institution.—Dr. Waldstein on "Greek Sculpture from Phidias to the Roman Era."

Miscellaneous.

Kenilworth New Waterworks.—The Kenilworth Waterworks, constructed to meet the growing requirements of the town, were publicly opened on the 1st inst. The new waterworks have been provided by a private company, with a capital of 10,000*l.* in 5*l.* shares, of which 1,500 have been issued. The water supply is obtained from a sandstone rock by driving into a hill-side, and adit 5 ft. wide and 16 ft. deep for a distance of 275 ft. This yields an ample supply of remarkably good water, estimated at from 12,000 to 16,000 gallons per hour. This is raised from a well 22 ft. deep to the top of a tower on Lady's-hill by two 12-h.p. gas engines, by Messrs. Lude Stern. The tower, which is 667 yards from the well, is 92 ft. high, and on the top of it there has been constructed a circular wrought-iron tank, another 12 ft. in height, capable of storing 27,000 gallons of water. The tower is considerably above the level of the highest house in the town, and the supply will be by gravitation. The pumps were supplied by Messrs. Percy & Co., of Birmingham; and the total lift, from the well to the surface level of the tank, is 136 ft. The mains, between five and six miles in length, extend all over the town, and are fitted with sluice-valves, fire-hydrants, and stand-posts. The rising main is 7 in. in diameter, and the service pipes vary from 7 in. to 3 in. The works altogether have cost about 8,500*l.*, but this includes some capital expended for the purposes of the Local Board, upon which that body will pay interest. The engineer, Mr. E. Pritchard, C.E., of Birmingham and London, designed and superintended the execution of the works, for which Messrs. E. Smith & Sons, of Kenilworth, were the contractors. The Glenfield Company, Kilmarnock, supplied the whole of the hydraulic fittings; and the pipes were furnished by Messrs. G. & S. Roberts, of West Bromwich.

Prices of Steel.—Steel for structures continues to approximate in price to iron, and, for large sections is as cheap. Steel sheets are increasing in use for tin plates, and steel hoops are likely to altogether supersede iron hoops for baling purposes. The following table summarises the fluctuations in value during the last five years—

Table with 10 columns (years 1880-1885) and 10 rows (various steel products like Steam Coal, Pig Iron, etc.) showing prices per ton.

Scrap-iron and steel remain at the low prices of the summer, namely, about 45*l.* for heavy scrap-iron, f.o.b.; old spring-steel, about 43*l.*; old iron rails, about 53*l.*; old double-head steel rails, about 54*l.* Italy has lately been the best foreign customer; the export to the United States has nearly ceased, most of the few shipments thither have been to San Francisco.—Matheson & Grant's Engineering Trades Report.

The World Tree.—The tree of mystery springs from the primordial alyas, where the mountain Asgard is the centre of the world. The tree itself forms with its leaves and branches the heavens and the earth, the cardinal winds are stags that run about, the air itself is an eagle in the midst thereof, and the storms that disturb the firmament are typhids in the squirrel that plays in the branches. The Indian idea is the same in a remoter form; the world tree is the tree of Paradise, the ambrosial tree yielding immortal food. In the Rig Veda the tree is Brahma himself made visible, having as companions two birds, which represent day and night. This cosmogonic tree is the rose-apple that grows in the lake Ara, the lake sacred to Brahma, filled with the waters of eternal youth. The Eastern idea permeates all primal talk of men; the Buddhists have the Ambrosial tree that abounds in knowledge; the Iranian tree of the fire-worshippers is a vine-producing immortal drink, and it is associated with another tree which is called the Impassive or Inviolable. These are the two trees of refreshment and knowledge, the parallels of those that appear in the narrative of the Fall, and while in one sense they represent day and night, so in another they stand for good and evil. In the Assyrian legends they are combined, and the manner of representing the one sacred tree or Asperal on the Nimvite marbles gives us a direct key to the so-called honey-suckle ornament of Greek sculpture, for this is not the honey-suckle at all, but a far off and degraded symbol, and once more we are reminded of our figure of the five-stemmed ash.—Gardener's Magazine.

Manchester Architectural Association. At the ordinary meeting, held at the Old Town Hall, January 6th, 1885, Mr. J. Spencer Hodgson in the chair, Mr. A. H. Davies-Colley read a paper on "Stained-glass Windows." He described the different processes of colouring glass, together with the characteristics of the various periods. He considered the drawing should be as good as possible, and strong in outline, bringing out the true character of the design; the shading of figures to be avoided as much as possible, which should be entrusted to artists. Windows to the north should be warmer in tone than those to the south. A discussion followed in which Messrs. Barker, Chadwick, Ward, Charleywood, and Hodgson took part.

Altars and Reredoses.—A new high altar and reredos is in course of construction at St. Francis Church, West Crompton. It is being worked on the spot under the superintendence of Brother Patrick, O.S.F. When completed it will be one of the largest in England. It is designed by Messrs. Pugin & Pugin, of Westminster.—A new Lady altar has just been placed in the Convent Church of St. Leonard's. It has been executed by Mr. Boulton, of Cheltenham, from the designs of Messrs. Pugin & Pugin.—A new reredos has just been erected at St. Austin's Catholic Church, Stafford, from the designs of the same architects, by Mr. Wall, of Cheltenham.

Union of German Builders.—A central organisation of German builders was lately formed at Meiningen. The objects of the association include the elevation of the social and economical position of the German building industry, the protection of trade interests in legal and other matters, the organisation of labour and tenders, the improvement of credit relations, &c.

Sir Frederick Bramwell, F.R.S., the newly-elected President of the Civil Engineers, and who is also the Chairman of the Executive Council of the Inventions Exhibition, has chosen the subject of "Engineering Inventions since 1852" as the subject of his inaugural address, to be delivered on Tuesday evening next (Jan. 13th), at the Society's house in Great George-street, Westminster.

For school buildings, Stoughton, Guildford, for the Guildford School Board:—

Alfred Gale	£3,500 0 0
Wells, Martin, & Co.	3,430 0 0
Mower	3,417 0 0
H. J. Sanders	3,403 0 0
George Stalard	3,350 0 0
Stephens & Bastow	3,330 0 0
W. Tribe	3,148 0 0
John Bottrell	3,140 0 0
Greenwood	3,100 0 0
C. Smith & Sons	3,094 0 0
C. Claridge	3,050 0 0
H. Kuperlet	3,025 0 0
H. Ingram	3,007 10 8
Woolgar & Son	3,0 0 0
Samuel Woods	2,985 0 0
Peter Peters	2,924 0 0

For alterations, &c., at St. Andrew-street, Holborn, for the Liverpool Victoria Legal Friendly Society. Mr. F. G. Smith, architect. Quantities by Mr. Walter Barnett:—
Wm. Shurman (accepted)..... £3,958 0 0
[For full list, see p. 869, Dec. 27, 1884.]

For alterations to the Ivy House, &c., Hoxton, for Messrs. B. & G. Hyman, Mr. Edward Brown, architect, Hanbury-street, Spitalfields:—

Riddle & son	£2,325 0 0
Salt	2,175 0 0
J. Anley	1,960 0 0
R. Mayr	1,945 0 0
W. Shurman	1,944 0 0
Hawkins	1,897 0 0
Jackson & Todd	1,797 0 0

For alterations to show-rooms at 138, High-street, Hounslow, for Mr. Henry Easley. Mr. J. K. Morgan, architect:—

Shawyer	£738 0 0
Hogben	248 0 0
Danels (accepted)	230 0 0
Billins	210 0 0

For the erection of St. James's Catholic Chapel, Twickenham, for Cardinal Manning. Messrs. Joseph Stanlatus Hanson and C. George Kemp, joint architects. Quantities by Mr. Henry Smith, 5, John-street, Adelphi:—

Hatman & Fotheringham	£2,773 0 0
Gibbs & Fiew	2,500 0 0
McManus	2,497 0 0
Colls & Son	2,326 0 0
J. Tyrman	2,300 0 0
C. Claridge	2,295 0 0
Messom	2,232 0 0
R. & E. Evans, Peckham (accepted) ..	2,215 0 0

For the erection of two pairs of semi-detached villas at New Malden, for Mr. Edwin C. Somerville, architect, Claremont House, Lower Sydenham:—

Collier, Torkington	£1,480 0 0
Moorman	1,430 0 0
W. H. Langman, Anerley	1,283 0 0
Thorpe, Malden	1,187 10 0

For the erection of three warehouses, Whitecross, Errol, and Dufferin streets, E.C. Mr. Charles Bell, architect. Quantities by Mr. Henry Lovegrove:—
Allen & Sons, Kilburn (accepted), ..
total about

Accepted for new house in Hamilton-road, Reading, for Mr. C. Batho. Messrs. Morris & Stalwood, architects:—
John Bottrell..... £967 10 0
[No competition.]

For new house at Sandhurst, for Mrs. Osborne, Mr. Withers, architect, Adam-street:—

Lang, London	£3,395 0 0
Searle Reading	3,143 0 0
Boxey, London	3,079 0 0
Dove, London	3,075 0 0
Pattam & Fotheringham, London ..	2,973 0 0
Cowland, London	2,879 0 0
Bottrell, Reading	2,820 0 0
Spier & King (accepted)	2,600 0 0

For new house in Southcote-crescent, Reading, for Mr. J. Morris. Messrs. Morris & Stalwood, architects, Reading:—

	House.	Stables.
Higgs, Reading	£1,108 0 0	... 495 0 0
Goodchild, Reading	1,111 0 0	... 84 17 8
Woodroffe, Reading	1,017 0 0	... 77 0 0
Bottrell, Reading	830 0 0	... 69 0 0

* Accepted.

For the erection of new grocery premises, dwelling-house, warehouse, stables, and granary, for Mr. E. B. Green, Lincoln. Mr. William Mortimer, architect. Quantities applied:—

Martin & Sims, Lincoln	£1,790 0 0
Baines, Newark	1,781 0 0
Oreswood, Mansfield	1,710 0 0
Hatchiffe, Billingham	1,688 0 0
Otter & Broughton, Lincoln	1,620 0 0
Crosby & Sons, Lincoln	1,578 0 0
Greenham, Brantson	1,540 0 0
Biens Bros., Lincoln	1,525 0 0
Harrison, Sands, Lincoln	1,523 0 0
H. S. & W. Cole, Lincoln	1,489 0 0
Wright, Lincoln	1,487 0 0
Horton Bros., Lincoln	1,483 0 0
J. B. Harrison, Lincoln	1,482 0 0
Coven & Lansdowne, Lincoln	1,340 0 0
J. M. Harrison, Lincoln (accepted) ..	1,295 0 0

Accepted, for six-tight cases, counters, and fittings for show-rooms, for Messrs. William Hutton & Sons, Sheffield. F. Sage & Co. £1,000 0 0

SPECIAL NOTICE.—Lists of Tenders frequently reach us too late for insertion. They should be delivered at our Office, 38, Catherine-street, W.C., not later than Four p.m. on THURSDAYS.

TO CORRESPONDENTS.
H. T.—A. B.—C. H. J.—T. G. J.—E. L. R.—R. T.—J. S. H.—A. C.—G. & Co.—C. O. H.—N. H. J.—A. & G.—T. & G.—W. A. (but within our province).—A. W.—J. F. D.—W. T.—D. R.—Lacy S.—& Co.—P.—J.—D.

All statements of facts lists of tenders, &c., must be accompanied by the name and address of the sender, not necessarily for publication. We are compelled to decline pointing out books and giving addresses.

Note.—The responsibility of signed articles, and papers read at public meetings, rests, of course, with the authors.

We cannot undertake to return rejected communications.

Letters or communications for our more than 1000 names which have been duplicated for other journals, are NOT DESIRED.

All communications regarding literary and artistic matters should be addressed to THE EDITOR; all communications relating to advertisements and other exclusively business matters should be addressed to THE PUBLISHER, and not to the Editor.

PUBLISHER'S NOTICES.

THE INDEX and TITLE-PAGE for Volume XLVII (July to December, 1884) is given as a Supplement with this Number.

A COLOURED TITLE-PAGE may be had, gratis, on personal application at the Office.

CLOTH CASES for Binding the Numbers are now ready, price 2s. 6d. each; also

READING-CASES (Cloth), with Strings, to hold a Month's Numbers, price 2s. each; also

THE FORTY-SEVENTH VOLUME of "The Builder" (bound), price Twelve Shillings and Sixpence.

SUBSCRIBERS' VOLUMES, on being sent to the Office, will be bound at a cost of 2s. 6d. each.

CHARGES FOR ADVERTISEMENTS.

SITUATIONS VACANT, PARTNERSHIPS, APPRENTICESHIPS, TRADE, AND GENERAL ADVERTISEMENTS.

Six lines (about fifty words) or under

Advertisements for the current week's issue must reach the Office before THREE o'clock p.m. on THURSDAY.

The Publisher cannot be responsible for DRAWINGS, TESTIMONIALS, &c. left at the Office in reply to Advertisements, and strongly recommends that of the latter COPIES ONLY should be sent.

SPECIAL.—ALTERATIONS IN STANDING ADVERTISEMENTS or ORDERS TO DISCONTINUE same, must reach the Office before TEN o'clock on WEDNESDAY noonings.

PERSONS Advertising in "The Builder," may have Copies addressed to the Office, 38, Catherine-street, Covent-garden, W.C., free of charge. Letters will be forwarded if addressed envelopes are sent, together with sufficient stamps to cover the postage.

TERMS OF SUBSCRIPTION.
"THE BUILDER" is supplied direct from the office to residents in any part of the United Kingdom at the rate of 12s. per annum, Postpaid. To countries within the Postal Union, 20s. per annum. Remittances payable to DOUGLAS FOURDRINER, Publisher, No. 38, Catherine-street, W.C.

Best Bath Stone.
WESTWOOD GROUND,
Box Ground, Combe Down,
Corsham Down,
And Farleigh Down.
RANDELL, SAUNDERS, & CO., Limited,
Corsham, Wilts. [ADVT.]

Dry Corsham Stone.
150,000 FEET CUBE.
PICTOR & SONS,
BOX, WILTS. [ADVT.]

Doubling Freestone and Ham Hill Stone of best quality, in blocks, or prepared ready for fixing. An inspection of the Doubling Quarries is respectfully solicited; and Architects and others are CAUTIONED against inferior stone. Prices, delivered to any part of the United Kingdom, given on application to CHARLES TRASK & SONS, Norton-sub-Hamdon, Ilminster, Somerset.—Agent, Mr. E. WILLIAMS, No. 16, Craven-street, Strand, W.C. [ADVT.]

Doubling Free Stone For prices, &c., address S. & J. STAPLE, Quarry Owners, Stone and Lime Merchants, Stoke-under-Ham, Ilminster. [ADVT.]

Asphalte.—The Scyssel and Metallic Lava Asphalte Company (Mr. H. Glenn), Office, 38, Poultry, E.C.—The best and cheapest materials for damp courses, railway arches, warehouse floors, flat roofs, stables, cow-sheds, and milk-rooms, granaries, tun-rooms, and terraces. [ADVT.]

Asphalte. Scyssel, Patent Metallic Lava, and White Asphaltes. M. STODART & CO. Office: No. 107, Cannon-street, E.C. [ADVT.]

EVERY DESCRIPTION OF Seasoned Woods and Veneers in very large quantities.

The Tenure of Land in Foreign Countries.

CIRCULAR was addressed in the spring of last year by the British Foreign Office to the various representatives of her Majesty on the Continent, with a view to obtain information as to the tenure of land abroad, and principally to ascertain whether the custom of letting land on long building leases prevailed in foreign countries. Replies have been received from twenty-two ambassadors or their secretaries, accompanied in some cases by a short sketch of the law with regard to land in the country referred to, and these documents have been recently printed, by order of the House of Commons.

It appears from this return, which relates to Austria, Baden, Bavaria, Belgium, Denmark, France, Germany, Greece, Italy, Holland, Portugal, Roumania, Russia, Coburg, Servia, Spain, Sweden and Norway, Switzerland, Turkey, and Wurtemberg, that our system of letting land on long leases for building purposes is practically unknown upon the Continent. In Belgium, however, the practice has lately come into vogue, but is confined to Brussels, where the system was introduced by a French contractor, who erected buildings on certain sites in the central boulevards, which are the property of the municipality. As a rule, houses in Belgium are built upon freehold land, which is paid for either on entry into possession, or by instalments, or by annuities. The vendor has a lien on the building as long as the site has not been fully paid for. Companies have been formed in Belgium for the construction of artisans' dwellings, the tenant having the option of becoming the owner of the house he inhabits, by paying annually as rent a sum equal to the interest upon, and a sinking fund for the repayment of, the capital expended on the acquisition of the ground and the construction of the building.

In France freehold tenure is the rule, but in the capital and in most of the large towns land is frequently let upon building leases for varying lengths of term, dependent upon the commercial, industrial, and social conditions of the several localities. All feudal tenures were abolished by the Revolution of 1789, and all real property in France, whether urban or rural, is held in fee simple (*franc-aleu*); that is to say, as long as there is no contravention of public law, the right of owners is absolute to deal with it as they think fit.

According to recent statistics, land in France consists of some 28 million holdings, divided amongst 5 million owners. Each of these holdings can be sold or let at the pleasure of the owner; entail does not exist in France, and real as well as personal estate is divided equally.

In Germany and Austria leasehold tenure for a number of years is unknown. In Bavaria, the land is held by about 458,416 independent landowners (with 1,047,596 labourers), ranging from the small farmer owning only a few cows, and the peasant who works on his own land with his labourers, to the owner of large estates, whose possessions may be almost compared to those of English landlords. The average size of an estate, arable land or wood, in Bavaria is only 5.75 hectares, or about 14 English acres; in Hanover and Pomerania, 20.93 hectares, or about 52 acres; in Silesia and Brandenburg, 16.36 hectares, or about 41 acres; whereas in England, out of a total area of 13,205,406 hectares, or about 33 million acres, not less than two-thirds are in the hands of 10,207 persons, each of whom owns more than 200 hectares, or about 500 acres. In Bavaria small estates are the rule, and when the electoral lists were prepared in accordance with the law of the 26th of May, 1818, there were only 7,182 landowners qualified to vote, that is, landowners possessing estates of the value of from 8,000 to 10,000 florins, or about 68*l.* to 857*l.* Apart from some instances of property being entailed, which can only occur among the nobility, the ownership of land in Bavaria has been treated since 1848 not according to fental principles, but according to the principles of common law, which allows the owner the greatest liberty with regard to the disposal of his property.

In Germany generally house property is invariably held upon freehold tenure, and the system of letting land upon long building leases is practically unknown. This is, no doubt, due to the fact that, as a general rule of German law, now obsolete so far as Prussia is concerned, "sale breaks lease," and this being so, no person would be disposed to erect at his own cost a permanent structure upon land held upon such an uncertain tenure as a lease.

In Denmark it is the custom to purchase small plots of freehold ground for the purpose of building houses, and the leasing of land for a term of years upon condition that it is built over is altogether foreign to the Danish practice. It is, however, customary to lease lands and tenements for two lives, but in this case the tenements built by the lessee do not escheat to the landlord at the end of the term; the landlord has the choice of purchasing the buildings at a price determined by an official

valuer, or of ordering their removal. Under this system of tenure, which is called *lifsaeste*, the tenant acquires the property for his own life, and, if married, the widow has an interest in it for the term of her life. It frequently happens in Denmark that a peasant or cottager holding under this tenure marries a very young woman in his declining years or even upon his death-bed in order to extend the term of his lease. In this tenure rack-renting is not only illegal, but is opposed to popular custom. Land is also held in what is called *arvefaeste*, which is a kind of freehold or hereditary tenure. Of this there are two categories; one simple, whereby the lessee and his heirs, on payment of a yearly or quit-rental, enjoys a perpetual lease, barred only by failure of issue, in which case the property reverts to the lessor; the second is *in infinitum*, which leaves the tenant free to hypothecate or even to sell the property, subject, of course, to the payment of the rent. This tenure bears some resemblance to Ulster tenant-right and to the *caphtzweis* of the Roman law.

In former times it was not uncommon in Denmark for estates to be parcelled out into small holdings, which were let for building purposes on long leases sometimes extending over hundreds of years; but the tendency of recent legislation has been to discourage the creation of leaseholds and to promote the acquisition of freeholds. By a law passed in 1847, no part of a landed estate can be legally leased for a term exceeding fifty years, except under the two-lives tenure. In the moorlands of Jutland, however, it is not unusual for small holdings to be let for shorter terms for building; the tenements erected on these holdings by the tenant remain his property, and do not revert to the landlord. This custom is peculiar to Jutland, and the reason why these leases are preferred to purchasing the land outright, is that the expense of the stamp and registration expenses upon transfer of the freehold is avoided. In certain suburban districts of the capital it is customary to sell plots of ground for building encumbered by certain conditions called *servitut*, and this word is to be noted as one of the few instances in which a non-Scandinavian term is employed in Danish jurisprudence. The *servitut*, although a very comprehensive term, usually applies to the obstruction of the view, the erection of unsafe or unsightly buildings, or the carrying on of noxious businesses.

In Norway land is let at an annual ground-rent for building purposes either for a term of years or in perpetuity. On the expiration of the lease for a term of years the tenant remains the owner of any buildings built upon the ground, which he is at liberty to remove.

The system of letting land on lease for

building terms does not prevail to any great extent in Sweden: in the larger towns where the houses are built and let in flats the system does not obtain, the houses being invariably built on freehold ground; but in the country leases are not uncommon, though this is usually for agricultural purposes. The tenant has the right to remove any buildings erected by himself, all other improvements, such as cultivation, fencing, planting, &c., reverting to the landlord. The natural tendency of this state of the law is, if the buildings erected are useful and substantial, to bring about an agreement between the landlord and tenant, for the former to take the buildings over from the latter at a valuation. The only cases in which leases for building dwelling-houses are usual in this country are for plots in the neighbourhood of large towns or summer resorts. The general term for a building lease is fifty years, but shorter terms are not unfrequent, also for the life of the lessee and his wife if married, as in Denmark.

The condition of tenants in Greece appears to be more favourable than on the Continent generally, the landlord being bound to keep the house in repair and to pay all rates and taxes. Freehold property is the almost universal tenure in Greece, every Greek being anxious to have a house of his own, and by law the sale of a house to a third party, as in Germany, determines the lease, and may lead to the expulsion of the tenant, who, however, has his remedy against the owner, and may claim damages.

The custom in the Ionian Islands with regard to the tenure of land differs from that which prevails in other parts of Greece. In the towns perpetual leases and leases for terms of years are granted; in the latter case, the term must not be for less than twenty years. If the lease is perpetual, no alteration can be made in the rent; the lessee in either case pays all taxes. The tenant is allowed to mortgage the premises in his occupation, but in the event of the landlord resuming possession, the latter is not liable for the mortgage. The tenant may transfer the property to a third person after having notified his intention to the landlord, who must give his decision within a month of receiving such notification. The new tenant must enter into a contract with the landlord with regard to the rent, and, failing this, the property reverts to the landlord. If the rent reserved is not paid within two months of its becoming due, the landlord has a right to eject the tenant. By a law passed in 1868 the tenant may become the owner of his house by paying the landlord the value, the rent being capitalised on the 6 per cent. table, or eighteen years' purchase. The practice of letting ground on building leases is at present unknown in Greece.

It appears from the report of Consul Franz, Her Majesty's Consul at Rome, that in Italy the system of letting houses and ground upon lease has been generally abandoned, in consequence of the facilities afforded by the laws of the country for the redemption of rent, which may be redeemed by the tenant on payment of a sum equivalent to twenty times the amount of the annual value of the premises in his occupation. Leases in the ordinary form are not permitted for a term exceeding thirty years by the Italian Civil Code, and it may be assumed from this fact that building leases are practically unknown in Italy.

With regard to the Netherlands, it appears from the short but extremely explicit report by Mr. Fenton, Secretary of Legation at the Hague, that property in land or houses in that country is held by the proprietor as freehold, no limited ownership such as copyhold or other similar tenure such as exists in England being known, and the system of letting or hiring land on building leases finds no favour and may be said to be almost, if not absolutely, non-existent in that country.

In Switzerland the English notion of degrees of ownership in land is not only absent from Swiss law, but is almost incomprehensible to the Swiss mind. Absolute ownership is the only condition known to them, and they can conceive no idea of such tenures as exist in England, such as leasehold for terms of years,

copyhold estate in tail, and so forth. The question of farm leases is a separate matter: these are, in general, for short terms, and are generally renewed from year to year. It would be contrary to the Constitution of the country in many cantons, and notably in Berne, to subject land to periodical and irredeemable payments, such a practice savouring too much of feudalism. In the case of an intending purchaser being unable to pay the purchase-money or the interest thereon, the vendor is not entitled to resume possession of the land, but must recover the money as if it were an ordinary debt.

The laws regulating property in land in Spain and Portugal are similar in character. The practice of letting land on building leases is practically unknown in these countries; but there are certain distinctions with regard to tenures of real property. The feudal system of tenure never struck deep root in the Peninsula, and least of all in the ancient kingdoms of Castile and Leon, where it can scarcely be said to have existed at all. Spanish real estate was not wanting at the beginning of this century in certain characteristics, which bore some resemblance to a feudal relation to an over-lord, and which distinguished it from the more purely allodial and free tenures of the present day. Every trace of these ancient tenures was swept away by the Cortes of Cadiz in 1811, since which date real property in Spain has been untrammelled by any charges or conditions, with the exception of those arising from the testamentary disposition of the owner, or from contract with other parties. Spanish lawyers distinguish, however, between *dominio pleno*, or freehold, and *dominio menos pleno*, which is analogous in part to leasehold. The former term relates to property which is held absolutely and unencumbered by any extraneous charge or burden. The latter species of tenure is subdivided into (1) a tenure in which a periodical charge is imposed without a contract, and (2) a tenure by which an annual rent is paid to the landlord under a contract. Absolutely freehold is the tenure which most generally prevails in Spain, both as regards land and buildings, and there is no difference between town and country property. Land in this manner is transferred by sale, donation, or will, and no further relation exists after such transfer between the old owners and the new. In certain provinces, however, estates are more commonly held on conditional tenures, that is, subject to a periodical payment, called in Spanish *censo*, or to an ordinary rent. The tenure by payment of *censo* is subdivided into (a) *foros*, which is for a term, generally for three reigns and twenty-nine years more; and (b) *emphyteusis*, which is of a similar nature to the former tenure, but is of permanent duration. The tenant may alienate his holding on the understanding that the new tenant undertakes to hold the property on the same terms as his predecessor. The landlord has the right of pre-emption in the case of a tenant wishing to dispose of his interest.

The law with regard to land in Portugal is similar to that in Spain, and in this country, as in Spain, leases for a building term are unknown. *Aforamento* or *emphyteusis*, in the language of the Portuguese civil code, is the transfer in perpetuity by the owner of any real property of his right of use to another person, who undertakes to pay him annually a certain fixed sum. The rent is to be fixed by mutual agreement, not by any custom; the emphyteutic estate, although hereditary, cannot be divided among the heirs of the tenant except with the landlord's consent; the value of the tenant's interest in an estate is determined by an official valuation, and is distributed among the heirs of the tenant according to law. The heirs are required to decide among themselves upon which of them the estate shall devolve, and in case of dispute the question is decided by a court of law; if none of them desire to hold it, the estate is sold and the proceeds divided equally. A tenant may mortgage his interest in an estate without his landlord's consent, provided the amount raised by mortgage do not exceed the capitalised rent with one-fifth added. In the event of a sale by the tenant the landlord has a right of pre-

emption, and in a similar manner the tenant has a right of pre-emption in the case of the sale by the landlord of his seigniorial rights.

Owing to the want of statistical data with regard to Russia, it is almost impossible to obtain trustworthy information as to the tenure of land and buildings in that country, but it may be safely asserted that tenements in general, and especially in towns, are freehold, and it would also appear that the system of letting land upon building agreements does not prevail in Russia. From the circumstance that Russia is comparatively a thinly-populated country, with imperfectly developed means of communication between the towns, land is cheap, and the conditions of sale and tenures of real property are less complicated than in more thickly-populated countries. In Russia Proper mortgages are frequent; but there is no official register of these transactions. In Poland, on the contrary, an official record is kept of all transactions with regard to the transfer of land, and it is stated, on the authority of her Majesty's Consul-General at Warsaw, that the system of hypothec in force in Poland is admirable, and could hardly be improved upon. Generally speaking, every Pole lives upon his own freehold, which is almost invariably mortgaged at 5 per cent., with a sinking-fund, to the *Crédit Foncier*. The civil law in vigour in the Baltic provinces is based upon the Roman law, that in Finland upon the Swedish law, and that in Poland on the French Code Napoléon.

Landed property in Turkey is classified as follows: *mulk*, or freehold property belonging entirely to private persons; *mirî*, or Crown land; *mefcûlî*, or endowed property; *metrukî*, or land given up to the public for forming roads or common pasture; and *meat* or waste land. *Mulk* property is of four kinds, viz., (1) that which lies within a commune or district, or within a limit not exceeding about a quarter of an acre outside the boundary of the same; (2) land, formerly Crown land, given to private individuals; (3) *Ushri*, or titheable land divided at the time of the conquest of the country among the soldiery; and (4) *Haradjî*, or land the possession of which has been confirmed to non-Muslim inhabitants. Land in Turkey is generally sold in small lots, so as to enable persons to build houses for themselves, but it is sometimes let for terms of years at a small annual rent, the buildings erected upon the land becoming the property of the landlord at the expiration of the term for which the land is demised. Such leases are rare in towns, but more rare in the country as distinguished from the neighbourhood of towns.

In Servia and Roumania building leases are unknown. In Roumania, the legislation is based upon the French civil code, the sale of land is unconditional, and reservations of rent are never made. At Bucharest, a large building society (La Société de Construction) has extensively stimulated the erection of new houses in that city, and for this purpose building sites have to be acquired which are invariably freehold, and cost from 1,000l. to 2,000l. and upwards, according to their situation.

Emphyteusis, literally an "in-planting," is a perpetual right in a piece of land which is the property of another: the right consists in the legal power to cultivate it, and to treat it as one's own, on condition of cultivating it properly and paying a fixed sum at stated times. Although the emphyteuta had not the ownership of the land, he had an almost unlimited right in the enjoyment of it, unless there were special agreements limiting his right. . . . He could sell his interest in the land, after giving notice to the owner, who had the power of choosing whether he would buy the tenant's interest at the price which the intended purchaser was willing to give. In the case of the lessee's interest being transferred to a third party, a fifth part of the price, or of the value of the property, when the nature of the transfer did not require a price to be fixed, was payable to the owner on the admission of the new emphyteuta, which, as a general rule, was paid by him. If the owner of the land refused to admit the proposed

new tenant, the seller could, after certain formalities had been complied with, transfer all his rights without the consent of the owner. The lessee was bound by the Roman law to pay all public charges and imposts, and to keep the property in proper order, and to pay the rent regularly. The tenant could dispose of his interest by will, and, in case of intestacy, it passed to his heirs in the same manner as other property. The lessee might lose his rights by surrender to the owner, by failure of issue, by injuring the property, by non-payment of rent or taxes, or by alienation without the consent of the owner.

RECENT RESTORATIONS OF THE PERGAMENE ALTAR.

BY JANE E. HARRISON.

NTIL the opening of the South Kensington Cast Museum the fame of the sculptures of the great altar of Pergamene was in England, to all but professional ears, little more than a rumour. Visitors to the British Museum will have seen in the archaic room two startling fragments, a pain-stricken giant, and a torso ending in snake coils; but in their isolation these fragments have been more wonderful than comprehensible. Now, at South Kensington, the two principal, and in a way central, groups of the frieze may be seen side by side in their entirety, and a fair notion of the general scope and style of the sculptures may readily be formed,—I say may, but I might easily say must; for, of all the varied contents of the Cast Museum these colossal slabs are, with their sensational style of beauty, most sure to catch and rivet the eye of the untrained gazer. The literature of the Pergamene altar is likely from this time on to be a matter of public as well as professional interest.

The two books* before us are of widely different import and character; the first is professedly popular, the second learned and technical. I take them advisedly together, because my advice is, read the first that you may understand the second. Dr. Trendelburg's work (offered as homage to Dr. Curtius on his seventieth birthday) consists of six beautiful phototype plates, representing groups from the frieze, and an accompanying text. The plates are taken from the six principal groups, as restored by A. Touleux. It need scarcely be said that the originals have been left untouched, and the restoration attempted only on casts. Dr. Trendelburg hopes that his work will serve a double purpose: first, it will make the Pergamene altar known, in intelligible form, to those lovers of art to whom the originals, and even the casts, are inaccessible; and, secondly, it will facilitate the enjoyment of, and even the scientific study of, the fragmentary originals. Any who have pored laboriously over these shattered originals will be ready to thank Dr. Trendelburg, and to add their testimony to the usefulness of his work. In looking from fragment to fragment, the eye and the imagination and the reason are all heavily taxed, and to have the effort of one's fancy caught and permanently visualised is no light gain. Of course in any matter of restoration there will be differences of opinion as to details: these the archaeologist will weigh and ponder for himself; but for the general student a clear idea of the composition, even if a detail or two be faulty, is of the highest importance, and even to the archaeologist himself is a help not to be disdained. The way to use Dr. Trendelburg's excellent book to the best advantage is to place side by side with his restored plates photographs of the original fragmentary slabs, and then to judge for oneself of the justice of his restorations.

Though Dr. Trendelburg's book is avowedly a popular one, the text does not confine itself to a mere explanation of the plates and enu-

meration of the restorations. The introduction is occupied with the altar as a whole, the meaning of the Gigantomachia frieze, and its relation to certain architectural peculiarities in the structure. Further, with reference to each of the restored slabs, we have a great deal of valuable criticism on the composition of the groups, the technical treatment of the reliefs, some light thrown on the position of the sculptures in the history of art; and last, but not least, more than one *excursus* into the somewhat obscure and unknown tracts of Pergamene mythology. The book is an excellent proof that it is possible to be very learned without being the least unreadable.

I shall confine myself, in the main, to Dr. Trendelburg's remarks on the two groups now to be seen in the South Kensington Cast Museum. I have said that these two groups are, in a sense, the central groups of the frieze; but, of course, to speak of the central group of a frieze would be to condemn the composition offhand; rather, as Dr. Trendelburg beautifully suggests, we may regard the two groups as two richly-wrought clasps that bind together a lovely, sculptured girdle. Their place was, no doubt, in the east, *i.e.*, the principal front of the altar. The two groups are manifestly composed to balance each other, and each represents the moment of supreme victory; the one the victory of Zeus, the Saviour, to whom the altar was dedicated; the other, of Athene, the Victory-bringer (Nikephoros), his warlike daughter. The composition of the Zeus group sways to the left, that of the Athene group to the right, though each is finely balanced within itself. The Zeus group claims our first attention. To Zeus, and Zeus only in all the Olympian phalanx, are allotted three opponent giants; such was the convention of Greek art from the time of black-figured vase-painting. In the three opponents there is a fine gradation of defeat. To the left, utter defeat in the figure of the prostrate young giant, beautiful and in completely human form, smitten in the thigh by the burning thunderbolt whose flames are already bursting out to catch the giant's shield. Probably in the original this flaming thunderbolt was a good deal helped out by paint. To the right of Zeus is a second giant, also of human form, just smitten, but by no thunderbolt; he bears no weapon himself, and Dr. Trendelburg thinks he has cast away sword and shield that he may spring forward to seize and bear away the ægis of Zeus, but too late, for already the Gorgon's eye is upon him, and he stiffens into stone. To give in stone the effect of stiffening into stone was a *tour de force* which just suited the Pergamene artistic temper. The third giant is still in mid-fight, but defeat is obvious and certain: against the second thunderbolt of Zeus he can only uplift a helpless stone. This giant's form ends in serpent coils, and the triple contest is somewhat quaintly closed by a fourth impending fight. The eagle of Zeus, alert with open beak, watches to pounce, if need be, on the head of the angry rearing snake. This little episode occurs more than once in the frieze. Prominence is given to the figure of Zeus very simply, but finely and effectively. He is taller than his opponents, and alone towers erect above them. He is with his body full face, and both arms are wide outstretched so as to fill as much as possible of the field. The dying giant is in profile, the gorgon-struck giant is turned three-quarters face. The giant with the stone in actual conflict with Zeus turns his full back, with outstretched arms to balance his divine opponent,—everywhere a balance of pose and line, which is, to say the least, astonishingly clever. The actual opponent of Zeus is a bearded giant,—maturity fitly contends with maturity. The eye of this same giant is hollowed out, and probably contained a pupil of enamel, or some fiery precious stone, which would greatly enhance the wild and terrible look of the face.

In the corresponding group of Athene, the victory-bringer, we have composed in similar fashion the goddess and three figures to balance her. But not three combatants; though she is goddess of war, Athene is a woman, and it is enough if she contend with one giant, and he the youngest of the brood.

He holds no weapon, his hope is only in flight: he has two swift wings, but his form is otherwise human; the goddess has overtaken him and caught him by the hand, but it is not she who slays him,—she sends her sacred snake to bite him in the breast. In the remainder of the frieze we see many goddesses deal death-blow, sometimes in very brutal fashion, to their foes, and we feel that it was a fine thought that gave to Athene only victory the end, not slaughter the means. Athene strides on to the right, and balancing her the figure of Nike, goddess of victory, flies to the left to crown Athene. Between them necessarily is left a large triangular space. The sculptor has skilfully filled it by the most pathetic figure in the whole frieze. The giants are earth-horn, and in this their last extremity, when her youngest son is in dire peril, out of the earth comes his mother, Ge herself, with uplifted hands. But the mother pleads in vain to the—

"Daughter without mother, born of god."

Athene vouchsafes not even a look, but passes swiftly on in her triumph. It is Dr. Trendelburg's fancy that the giant is Ge's youngest, best-loved son, most like his mother in the face, and the fancy is so charming that I scarcely like to say I do not feel sure it is founded on fact. Ge has her name written near her, and her customary attribute the cornucopia; her character as earth-mother is well shown in the full figure and rich abundant hair. The wings of the Victory cleverly balance the wings of the falling giant.

The remaining groups I must note only in passing. By far the most beautiful is that of Helios, the sun-god, rising in his chariot from the waves, a motive clear to all lovers of the Parthenon marbles; beneath the horses of Helios lies a prostrate giant, perhaps the most beautiful figure in the whole frieze. A giant confronts the chariot horses, and seeks in vain to check them in their course. To the Greeks the myth had its obvious interpretation; in vain was the onset of barbarism and darkness against the dawn and clear shining of Hellenic light and culture and freedom. To the left preceding the sun-god rides his herald the Dawn (Hêc). Her horse looks back to the coming sun, and the face of the dawn-goddess herself should, as Dr. Trendelburg rightly observes, be turned back, though the restorer has made it face forwards. The deities of light abound throughout the frieze.

Another noticeable slash shows the conflict between the triple-bodied Hekate, with her flaming torch, and a giant upheaving a huge rock; also the fight of Orion and Artemis, in which, as the story went, the young giant was disarmed and vanquished by love for the maiden goddess. Only one other group I must note, because to its understanding Dr. Trendelburg makes an important contribution. This group contains the figure of a goddess who has become familiar to German critics by the not too commodious name of the snake-encircled vessel-hurler (*Schlangehtöpfwerferin*). A tall, powerful, matronly-looking woman seizes a half-giant by the shield with her left hand; with her right she is about to hurl at him a round vessel, something like a curved flower-pot with a small snake curling round it. She is aided in her attack by a huge serpent. This figure has long been a crux to archaeologists. It was not difficult to give a name to goddesses who carried such customary emblems as sword and spear, torch and bow, but this snake-encircled vessel was not of so easy interpretation. Some, judging from the snakes, called her a fury; others a Bacchant; a third party held that we have here a recantite allusion to an attack made on the navy of Eumenes by an enemy armed with vases full of snakes. Dr. Trendelburg breaks new ground. He thinks, in the first place, that sufficient attention has not been paid to the sacred fillets (*επιπυρατα*) with which the head of the goddess is adorned. These would make her out as of some solemn special import, a deity of some definite ritual significance. Further, the shape of the vessel, he thinks, is such that it could have been used neither for drinking out of nor for drawing water;

* Die Gigantomachie des Pergamenschen Altars, Skizzen zur Wiederherstellung derselben, entworfen von Alexander Touleux, erlindert von Adolf Trendelburg. Berlin: Wasmuth, 1884.

Ueber die Kunstgeschichtliche Stellung der Pergamenschen Gigantomachie von Henrich Büttner. Berlin: Weidmannsche Buchhandlung, 1884.

it is of considerable thickness and weight. In a word, he concludes it was a mortar.* The mortar was an attribute naturally of the gods and goddesses of healing; in the mortar, as we know from the comedy of Aristophanes, the *Phoitos* (which lets us into so many of the mysteries of ancient medical practice), the god Asklepios compounded his medicines. The female goddess Hygieia is the daughter and constant companion of Asklepios, but the Pergamene figure is too manly for Hygieia, the maiden. Dr. Trendelburg thinks it may represent Epione, the wife of Asklepios, a less frequent figure in ancient art. All he asserts positively, however, is that a goddess, wearing fillets and carrying a mortar, round which is curled a snake, attended also by a large serpent, must belong to the cycle of the medicine deities. The conjecture is doubly interesting, because from its temperate climate, fine situation, and abundant water supply, the place was a natural medical resort: it had medicinal springs and great facilities for sea and river bathing, and, in fact, a regular hydropathic establishment sacred to Asklepios. The subject of Asklepios worship in connexion with Pergamene worship has been recently discussed by Mr. Warwick Wroth, who has made the mythology of Asklepios peculiarly his own, and it will be interesting to know if he confirms Dr. Trendelburg's conjecture.

Turning to Dr. Brunn's monograph, one is in a different atmosphere, and at first in a controversial one. It is well known that it was the peculiar merit of Dr. Brunn that in his history of the Greek artists, published in 1857, he collected together, with considerable insight and an instinct almost prophetic, all the scattered evidence, literary and monumental, of the Pergamene school. He, and at first he only, saw the unity of style, which linked together, as the outcome of one tendency, work so seemingly different as the Laocöon, the Farnese Bull, the so-called Dying Gladiator, the Ludovisi Gaul, and the votive groups of Attalus. Now, nearly thirty years later, comes the discovery of the great altar of Pergamos, and threatens with sudden eclipse the conclusions so laboriously arrived at from these scattered statues. Dr. Couze asserts, with a boldness he probably now regrets, that if we would concern ourselves with the art of Hellenistic times, this altar of Eumenes must be the centre point of our study. It is scarcely to be wondered at that in the joy of so great a discovery, and so splendid an acquisition, sound judgment was thus led astray.

Dr. Brunn was not likely to let such a statement pass unchallenged; valuable he owns these altar sculptures are, but they are, after all, mere decorative work, and cannot rank as a standard by which to judge sculpture in the round; and, still more important point,—these sculptures are securely dated in the reign of Eumenes II. (196-175 B.C.). How absurd, then, to use them as criteria for the Alexandrian art of the third century B.C. Dr. Brunn passes from his polemic against Dr. Couze to an elaborate analysis of the sculptures themselves; this it would be fruitless for me to follow as it can only be appreciated when the sculptures themselves or complete casts from them are before our eyes. But his conclusions I may shortly summarise. Thirty years ago Dr. Brunn distinctly affirmed that in the art of the early Pergamene and Rhodian schools, the art which produced such works as the "Dying Gladiator," the possibilities of pathetic expression had reached their utmost goal, any further manifestation must degenerate into affected mannerism or fantastic licence. This dictum Dr. Brunn holds is fully borne out by the discovery of the Eumenes altar frieze of the second century B.C. In spite of its undeniably sensational splendour, we have in it no fresh outcome of the Greek spirit; it is but an ingenious compilation of foregone artistic motives. The style of such a compilation is at best but a skillful mannerism. Dr. Brunn illustrates his point by an ingenious comparison

between sculpture and rhetoric. In Asia Minor, during the third century, B.C. there was a school of rhetoric, the chief representative of which was Hegesias of Magnesia; of him it was said that he sought to give effect to his oratory by the ingenious manipulation of the rhythm of his sentences, altering the natural order of the words for the sake of effecting a recondite juxtaposition. Such eloquence might startle the attention of the hearer, but it could neither persuade his intellect nor kindle his emotion; it was, in fact, no true eloquence at all, but mere effective declamation. As was the Magnesian rhetoric to the true Athenian eloquence, so was this later Pergamene art to the ideal creations of Pheidias. It created nothing, it did but dexterously manipulate already-existing material with a view to sensational effect. It laid hold of an artistic vocabulary already complete, and expended it with a prodigality that was often vulgar, always wasteful (*ritiosa abundantia*, Cic.); it decked out a trite and commonplace thought with the apparatus of ready-made artistic formularies; having within itself no luminous thought to convince, no passion to persuade, it sought to dazzle the spectator with the flash of mere meretricious splendour, to goad his emotion with the constant stimulus of mere physical pathos.

Having thus dealt hard,—but I believe perfectly just,—measure to the Pergamene sculptures as expressive art, Dr. Brunn does not deny to them their full meed of praise as effective decorations. Their fantastic manner, which is expressly so barren, is often decoratively successful and perfectly permissible; wings not meant for the earth-born giants to fly with, and therefore expressly bad, yet fill the given space with excellent decorative effect; the more fantastic the form often the better it is as a mere complex of lines,—a mere pattern. How essentially decorative the frieze is, how little a part of the tectonic framework of the building, one can see at a glance; it is not born out of the basis it encircles, it is rather stuck on to it. Its nearest analogy is, as Dr. Brunn shows, the frieze of the Erechtheion. In the Erechtheion the architectural frieze is of dark Eleusinian stone, the sculptured decoration is clamped on and made of different material, i.e., white marble; obviously no integral unity was intended. In fact, both in the Erechtheion and in the Pergamene altar the frieze appears, so to speak, in duplicate, the background of solid stone, and the vitalised version of it rendered into sculpture. This double rendering gives to the frieze a strength and substantiality which, in the case of the Pergamene altar, is much needed, as the heavy weight of the superimposed Ionic colonnade would to the eye seem otherwise insupportable. The sculptures of a frieze so composed, not being part of the architectural structure, are not really in relief, and are therefore free to a great extent from the laws of relief composition. Hence the prevalence of startling full-front and back views in the Pergamene frieze, and also, so far as can be judged from the fragments in the Erechtheion frieze, contrasting so markedly with the "profile" composition of the Parthenon. If one may regard, as Dr. Brunn does, this Pergamene frieze as a sort of second rendering of its own background, not as worked in relief on that background, certainly all the decorative distress of the composition disappears; from a mechanical point of view the grouping is successful: it is static, well balanced, and therefore well suited as a support for the heavy superimposed weight. But probably many will think Dr. Brunn's theory fanciful, though they had better read his criticism in detail before they disallow it.

To sum up, he characterises the Pergamene frieze as a great epideiktic effort, a sort of final and sensational panorama of the outside aspects of the art of the past, and, concluding with a second ingenious metaphor, he adds:—"Comparing Greek art as a whole to an architectural structure, we may say, with a double significance, that the younger Pergamene school in the sculptures of the Gigantomachia effected thus much,—to the proud edifice of the history of Greek art it added a new decorative member which was at once its crown and its close."

IMPROVED WATER SUPPLY FOR THE METROPOLIS.

THE important Parliamentary paper recently issued under this title, contains a report* by Mr. J. Thornhill Harrison on a project designed by himself by which the metropolis is to be furnished with what is considered to be a perfectly pure water in lieu of the present supplies from the Thames, which are complained of as impure. As far as the report goes, the project deals only with the volume now drawn from that river, which contributes 50 per cent. of the whole quantity. That taken from the basin of the river Lea, amounting to 38 per cent., does not come under consideration. The proposal is recommended on the grounds,—

First. Of the *quality* of the water, which is said must be of the purest, inasmuch as it will be drawn directly from the chalk at a depth of from 10 ft. to 20 ft. below the surface, through which it has filtered from a widespread and elevated gathering-ground.

Secondly. That, as regards the *volume* obtainable, it is asserted that there is at command at least double the volume at present withdrawn from the Thames; and

Thirdly. That there will be an annual saving in cost, owing to the absence of any necessity for filtration, and to a large reduction in the expense of pumping, while the area now employed for reservoirs and filter-beds would be left at the disposal of the companies for other purposes. It is thought also that Parliament would relieve the companies from the present annual payments of 10,000*l.* to the Thames Conservancy Board.

The proposed source of supply is that part of the chalk formation within the watershed of the Thames lying to the north and west of Windsor, including the areas within the basins of the rivers Kennet and Colne, and measuring about 1,100 square miles, the elevation of which varies from 100 ft. to 600 ft. above Ordnance datum. The rainfall within that area ranges from 24 in. to 36 in., from which it is calculated 400 million gallons are daily discharged into the Thames; but as the water absorbed into the chalk travels through it very slowly, it is probable that months, perhaps years, may elapse before some of the rain falling and absorbed on the highest portions of the chalk area would find its way to the river, and consequently in that area there exists a very large subterranean reservoir, which, it is conjectured, forms the gathering ground for the chief perennial supply of water to the Thames below Wallingford.

In support of that theory Mr. Harrison affords an interesting explanation of the present geological features and of the disturbances which must have occurred to create the faults which exist in the chalk formation, and which, by intercepting the subterranean flow, help to form the great reservoir of water contained in it. In order to illustrate more clearly the character of the district whence he proposes to gather the required volume, he prepared a model, representing an area of twelve square miles, with Windsor in the centre, and showing the inclination of the chalk formation with superincumbent beds, and the manner in which the drainage from it must flow into the Thames on the assumption that it cannot escape to the sea by passing under London.

The mode in which the water is to be collected consists in constructing a large receiving well at "Black Pots," near the main road from Eton and Upton to Datchet, with an overflow into the Thames, below the Windsor Lock. From this it is proposed to drive a tunnel below the summer level of the Thames, in the chalk, and below the gravel, westward to the river near Bray, the dimensions of which are to be 12 ft. in diameter, gradually diminishing to 6 ft., with a slope of 1½ ft. per mile. In regard to the quantity of water obtainable at Windsor, Mr. Harrison

* Since the above was written a paper has appeared in the last issue of the *Archäologische Zeitung*, in which Dr. O. Puchstein contends that the supposed mortar is really a fragmentary hydria. This is a question for experts to decide.

* Return to an Order of the Honourable the House of Commons, dated Dec. 2nd, 1884, for Copies of Reports made to the President of the Local Government Board by Mr. John T. Harrison, M.I.C.E., as to "Sources of Water Supply for the Metropolis." London: Henry Hansard & Son.

ives the results of certain gaugings taken in April and July last year, from which the variation between Windsor and Datchet is calculated to have been 250 million gallons in April, and 55 millions in July, which last, however, he considers to be too low, and himself estimates at 116 million gallons. In order to convey the water to the works of the Companies, who now pump their supply direct on the Thames, the suggestion made is to build a main-carrier 12 ft. diameter from the well at Black Pots to Hampton, eleven miles in length, with shafts at every quarter of a mile, and an "overflow-weir" placed several feet above the summer level of the river, so that the water may be conveyed in 4 ft. iron mains to the pumping wells of each company, the mains having to be carried across the Thames. The whole cost of the scheme, inclusive of land and distribution works, is estimated at 700,000l.

Mr. Harrison himself is careful to explain that he abstains from expressing any opinion on the objections to the quality of the present supply, and therefore he may or may not acknowledge their validity. Were the supply of London a subject of discussion now or the first time, or were it simply a question of an additional volume, this scheme would, of course, deserve serious consideration, especially when put forward by such an authority as Mr. Harrison, but in its present shape it is unquestionably open to the fatal objection of having half the metropolis exposed to the contingency of having its water supply suddenly cut off by injury to its single main duct, arising either from accident or design. In these days of dastardly and secret outrage, when miscreants do not hesitate to attempt the destruction of a massive structure like London Bridge, the much simpler proceeding of blowing up the main water conduit at one of the quarter-mile shafts, and so depriving two millions of inhabitants of a daily necessary of life, would be much too fascinating a crime to be withstood. It was a possibility of this kind which was urged as one main objection to the proposal of leading water to London from distant sources like the lakes on the Welsh mountains. It must be remembered, too, that one of the set-offs to the cost of the proposed scheme is the abolition of reservoirs and the conversion of the areas now occupied by them to some other profitable use, so that there will be no storage in reserve whence a supply could be drawn pending a stoppage in the aqueduct.

But what proportion of the consumers constitute the "many" who are said to complain of the quality of the existing supply? The probability is that the objectors would be found to represent a very small percentage of the community.

After all, as has been often pointed out in the columns of the *Builder*, the main criterion of the wholesomeness or otherwise of the water is the actual, not the possible, mortality, which is traceable to the present supply, not that which gets defiled in the cisterns in which it is allowed to stagnate in close proximity to sewer or other foul gas, but to that which is drawn direct from the Companies' mains.

There is, moreover, a doubt as to the available volume of water at Windsor, as measured by the quantity said to imperceptibly enter the Thames between Maidenhead and Ditton, and to vary from 250 to 55 billion gallons. Mr. Harrison's estimate of 16 million gallons is apparently obtained by assuming that the previously recorded minimum of 350 millions is not so correct as Messrs. Taylor's measurements last year. But it is at least possible that that recorded minimum may, after all, be correct, and in that case the estimated quantity of 116 millions would be an excess by 100 millions. If so, then what will be the state of London as regards water if it is to be dependent on the springs which furnish a portion of that volume?

But there remains the further question as to the effect which will be produced in the district from which the supply is proposed to be drawn. Protests on that score have already begun to appear against the scheme as projected, and though the effect on the Thames itself below Teddington Weir will be the same

whether the present daily volume of 80 million gallons be drawn by the Companies direct from the springs at Bray or from the river itself at Hampton, it is quite possible that so large a draft on the higher level may make a very serious difference to the navigation of the intermediate reaches, and should it therefore be found that the quantity of water so withdrawn affects the general contribution of the springs to the river, its conservators would scarcely consent to forego the annual 10,000l. which they now receive from the companies, even if they did not insist on a restoration of the volume necessary to maintain the navigation in its present state. Whatever other shape it may be capable of being worked into on further consideration, the scheme does not, as it now stands, commend itself as a substitute for existing arrangements.

NOTES.

FROM the letter of "One of the Chapter" in the *Times* of Wednesday, in continuation of the Peterborough Cathedral dispute, and the subsequent admissions of the Dean, it seems pretty plain that not only the Canons, but the Dean himself, did very distinctly give the world to understand, when they first asked publicly for funds for the repair of the tower, that nothing was intended beyond numbering the stones, taking them down, and rebuilding them as they stood. Of course, it is quite open to the Dean and the Restoration Committee to say, "Behold, we show unto you a more excellent way"; but it can hardly be open to them to say, or let Sir E. Beckett say for them, that there was no such understanding. The argument, if so it can be called where argument there is little, is continued by a long letter from Mr. Thackeray Turner, who seems to think his position as hon. secretary to the "Anti-Scrape" Society constitutes him an authority on architecture, and who effuses over the beauties and perfections of the levelled tower. It is remarkable by what class of correspondents the *Times* columns are always crowded in these cases.

A lawyer, whose foible is omniscience; a sketching parson, who draws towers of his own and calls those of Mr. Pearson monstrosities; and the amateur secretary of a society that talks twaddle over every old wall that is pulled down,—these are our architectural instructors in the leading journal. However, the conductors of that print, from the leader on the subject last week, do seem to have a dawning sense that it is possible to have enough of Sir E. Beckett's letters. From the latest of these effusions, by the way, it appears that Sir Edmund rates each man's right to an opinion on the subject in proportion to the money he has subscribed; a "canon of taste" certainly worthy of its author.

IT appears from a return recently presented to both Houses of Parliament that the practice of letting land upon building leases for long terms is almost entirely unknown upon the Continent, and that in the few countries where the custom prevails it is only to a very limited extent in large towns and their neighbourhood, and that the buildings erected by the tenant upon the ground demised do not escheat to the owner at the expiration of the lease, as is the case in Great Britain. The tenant is, moreover, in most Continental countries protected by a custom resembling Ulster tenant-right; he can dispose of his holding by giving notice to the landlord, and has the right of pre-emption at a fixed number of years' purchase of the annual rent. The most common tenure of land in foreign countries is freehold, and no evils appear to have resulted from the absence of leases with restrictive covenants, which are relied upon by the opponents of land reform in this country as being necessary for the welfare of the community, and the protection of the weak against the strong. There do not appear to be any records to fix the date when the custom of leasing land for terms of 99 years took rise in England, but it is not improbable that it began in the latter part of the

sixteenth century, when the nobility gave up their London houses and removed westward. Their estates being entailed it was, of course, impossible to sell the ground in parcels if it had been desired to do so, and it is readily conceivable that the practice of letting upon a long building lease originated under these circumstances, and being found convenient, the practice was followed by corporations, and afterwards by private persons.

AT the meeting of the Royal Institute of British Architects last week (theoretically a private meeting), a very important donation was announced, that of a coloured copy of the great work got up by the French Institute, under the auspices of Napoleon, as a memorial of the expedition to Egypt at the close of the last century. The work, entitled "Description de l'Égypte, ou Recueil des Observations et des Recherches qui ont été faites pendant l'expédition de l'Armée Française," consists of twenty-three volumes, dealing with antiquities, natural history, and geology, &c. It is on record that a company of the most eminent scientific men of the day accompanied the army, and carried their paraphernalia on donkeys, and when the regiment formed square to repel an attack, the cry was, "*Savants* and asses to the centre." However, the doings of the *savants* are now more important to us than those of the soldiers. At the same meeting a member put forward a suggestion that the library-books should be open to all comers to take them down for reference, instead of obtaining them through the librarian. There would soon be a fine confusion in the library if that were done. Those members who quoted the example of the British Museum Reading-room must have had scant experience there, if they suppose every reader replaces a reference-book when he has used it. There is an absolute want of conscience on the part of many readers in this respect; books are constantly taken out and kept the whole day by readers who only wanted them for a single reference. The Institute Library will be of far more use to members if the books are kept in thorough order, and they never will be except under the tutelary care of the librarian. A very few careless and disorderly persons would soon introduce hopeless confusion in the placing of the books. Mr. F. R. Farrow, the holder of the Godwin Bursary for 1884, read part of the report of his tour, which will be published in the *Transactions* shortly. The report was very highly spoken of by Mr. P. Anson and others.

UNREMITTING efforts are being made by the Railway and Canal Traders' Association to bring before the public the effect of the proposed new Railway Bills. With a view of disseminating information on the subject, prior to the Cannon-street Hotel conference they circulated a very exhaustive statement showing the principles and aims of the Bills, which are condemned most vigorously. It is stated that they are not even what they profess to be in the preambles,—they do not provide a "simplified system of charge,"—and an elaborate appendix is given to prove this. The mileage rates of five of the eight companies concerned are identical, two more have a slightly differing scheme, and one,—the North-Eastern,—an entirely different one. There can be no doubt that this want of uniformity will go far to destroy the usefulness claimed by the companies for the measures, and until they all agree and all the other lines adopt the same system, there must be endless confusion, especially as regards through rates in which several lines are interested. The fact that the companies seek for powers to charge for "terminals" is looked upon by the Association as rendering the mileage scheme quite worthless, as there would be so much vagueness about these additions that the public would be as much in the dark as before as to the real extent of their charging powers. But the companies offer to show in their rate-books at each station or wharf a statement of the amount of terminal charges at that station or wharf. This is a step in the right direction, and the Association ought to give the companies credit for it. It is notice-

able that the companies introduce into these schemes the classification of goods as compiled by the Railway Clearing House. This divides all goods traffic into eight classes, and, though it has long been used by the railways, it has never received Parliamentary sanction.

THOSE of our readers who have read what Mr. Ruskin calls the terminal letter of "Pors Clavigera," with the dainty little frontispiece by Miss Kate Greenaway, may remember "the beautiful city of Bassano on the Brenta between the mountain and the plain," where the Signora Zanchetta passed the eighty-five years of her busy, happy, and useful life, and where, if we can credit Mr. Ruskin's gossiping correspondent, people occasionally live to more than one hundred, and not unfrequently to eighty or ninety years. The municipal authorities are about to demolish the fortifications of this singularly favoured city, which date from the fourteenth century, and are said to be in an excellent state of preservation. The proposed action of the municipality has given rise to some opposition on the part of the local archaeologists and artists, and Signor Giacomo Boni, a Venetian architect of some repute, referred to the proposal in terms of disapprobation at the inaugural meeting of the winter session of the Venice Athenæum. The Italians, as a rule, have very slight regard for Medieval antiquities, and only recently a large portion of the walls of Brescia was pulled down in order to provide a suitable entrance on the occasion of a contemplated visit from the King, which, however, did not take place.

THE Japanese village which has been conveniently arranged under cover in the vicinity of Albert Gate will probably be an object of attention, and a sort of agreeable lounge for the curious, until the more important attractions of the season are in full swing. For those who would go to such an exhibition for the study of Japanese art or domestic architecture there is not really much to attract. They can see a carver transferring a design to wood by cutting through the thin paper on which the design is traced, and which overlays the wood; a carpenter planing by drawing his plane to him instead of pushing it from him (Japanese do everything the reverse way to other people); he can see studious silent persons painting fans with the left hand or right hand indifferently; and he can see for himself the lath and paper kind of dolls' house construction which is used in ordinary Japanese habitations, and how the houses stand on so many legs like a stool. It was amusing, too, in the theatre, to witness a kind of pantomime dance executed by a heavily-draped lady with a fan in her hand, and to realise how much nearer to life some of the Japanese drawings of men and women really are than might have been supposed, even to the peculiar twist or "kick-out" of the skirts of the dress which is so familiar to us in Japanese drawings of women. But, of course, the best class of Japanese art-workmen do not come over in this kind of *entourage*; and a good deal of modern work may be seen which seems to represent the *Soho* bazaar element of Japanese work. Nor do we much admire the system of arranging men and women in booths to make a show of them. They do not look as if they liked it; but that, we suppose, is considered in the bill.

COUNT ENRICO GRITTI has recently presented to the city museum at Venice the banner which was carried on the prow of the barge of his ancestor the Doge Andrea Gritti.

ACCORDING to the *Courier de l'Art*, the "Société des Artistes Français" is in considerable alarm in regard to the possible effect on the *Salon* of the establishment by the State of a *Salon triennal*, the first opening of which will take place next year, so that there will be two *Salons* in Paris in that year. They are in some fear lest the triennial *Salon* should injure the old and recognised annual *Salon*, both in drawing away works which would otherwise have been sent to the annual *Salon*, and possibly

in encroaching upon the space hitherto allowed to the latter in the rooms of the Palais de l'Industrie.

A MEDAL has been awarded by the jury of the "Exposition des Arts Décoratifs" at Paris, to M. Adolphe Guillon, whose admirable drawings from the sculpture at Vézelay we had the pleasure of publishing in December, for "reproductions des vieux carreaux."

THE new number of the *Edinburgh Review* contains a paper of considerable interest on "Recent Discoveries in the Roman Forum."

A COURSE of free evening lectures on subjects connected with building is announced to take place at Carpenters' Hall, London-wall, in the months of February and March. The lecturers will be Professors Kerr (of King's College), Church (of the Royal Academy), and Bonney, Corfield, Kennedy, and Roger Smith (of University College), with Mr. Blashill and Mr. Slater. The subjects will be of a nature to interest and instruct not only artisans, for whose benefit the course is primarily intended, but also students of architecture, surveying, and building; and the Carpenters' Company wish it to be distinctly understood that the attendance of all persons in any way interested in, or connected with, the art of building is cordially invited. These lectures form a kind of sequel to the exhibition of carpentry and joinery held last year by the Carpenters' and Joiners' Companies in the same Hall; and should they prove successful it is likely that they may be followed by other efforts to promote a knowledge of the principles of good building among those whose occupations render such knowledge of importance to them.

M. EUGENE MÜNTZ, *lauréat* of the Institute of France, and curator of the Library and Museum of the Ecole Nationale des Beaux-Arts, was appointed to succeed M. Taine in the "Cours d'Histoire et de l'Art," and gave his opening lecture on Wednesday, the 7th, in the Hemicycle of the school. After a tribute to his predecessor, he entered into the subject of the part played by archaeology, history, and æsthetic in the study of the monuments of the past, combating what he considered to be the false antagonism which has been set up between archaeology and æsthetic. In speaking further of the varied influences of climate, race, and tradition on the development of the fine arts, he emphasised the part which was to be attributed to the constant and regulated discipline of the French school, in the artistic excellence of that country, and after sketching briefly the succession of the great schools of art in Europe, concluded by a concise review of the principal historians of art, from Pliny the elder to our own day. M. Müntz will take for his subject for the year "La première Renaissance Italienne."

A SOCIETY, calling itself the Strand Improvement Association, has issued a coloured lithograph from a drawing by Mr. H. W. Brewer showing in a bird's-eye view a suggested alteration in the thoroughfare of the Strand between Somerset House and the Courts of Justice. The proposal is of an ambitious character, and apparently aims at nothing less than the entire reconstruction of the northern side of the Strand between St. Mary-le-Strand and the gateway of Clifford's Inn. A crescent is proposed to be formed on the north side of the Church of St. Mary-le-Strand, and an enclosed garden laid out in front of the Church of St. Clement's Danes, Temple Bar being reconstructed and made into a gateway to the garden. The total cost of this improvement is roughly estimated at one million and a half, but as there is no plan showing the extent of the property which would be affected it is impossible to offer any opinion as to the sufficiency of this estimate. No provision is made for supplying what is really an urgent want, namely, a new approach to the Courts of Justice from the north, and the only effect of the suggested improvement would probably be to still further increase the congestion of traffic at Temple Bar.

THE *Semaine des Constructeurs* (Jan. 10th) comments sarcastically on the bold project for erecting a colossal tower, in connexion with the forthcoming International Exhibition, of a height of 300 mètres (nearly twice that of Cologne spires). M. Bourdais is the architect responsible for the proposed scheme. *La Semaine* admits it to be a bold idea, but "l'audace coûte très cher," and our contemporary wants to know the advantage of it. There is to be an electric light on it to light all Paris; but considering that intensity of light diminishes as the square of the distance, one will be 900 times less lighted than by distributed lights placed at a height of 10 metres, for example; besides "nos rues resteraient plongées dans la plus noire obscurité, tandis que les toits de nos maisons offriraien aux seuls habitants des caves parages, les chats, les promenes les plus vivement illuminés." M. Bourdais, however, is equal to the occasion, and proposes mirrors to direct the light to the places where it is wanted. So there is a new entertainment offered to visitors.

WE have received what may be called a pamphlet *de luxe*, under the title "Who Spoils our New English Books?" a question asked and answered in a paper read at a meeting of the Library Association at Cambridge, in 1882, by Mr. Henry Stevens, among whose various titles, arranged in wedge-form on the title-page, are included "Citizen of Noviomagus" and member of "Blackballed Athenæum Club." Mr. Stevens is of the opinion (which we do not contest) that the art of printing, binding, and generally getting up books in the best manner, is woefully decaying in England, and enumerates ten different classes of sinners (for list, see the book*), the Purchaser or Consumer, in his ignorance and indifference, being the greatest. We were wondering the other day how a poet like Lord Tennyson could consent to let his latest drama come out in a uniform harsh green, repellent to the eye, and of a texture equally disagreeable to the touch. For works of the higher order of literature, no doubt, it is supposed that simplicity in binding is in the best taste,—the value lying in the contents; but then there is all the difference between a noble and an ignoble simplicity. Mr. Stevens's booklet, we presume, is meant as an example how to get books up. They pe and paper are admirable; the page shows a wide margin on the bottom and outside edges, which is really in accordance with practical considerations, since it is by those edges that we turn the pages; but it is a little overdone; the print seems rather squeezed into a corner. But is it an element in the best way of producing books, to leave the pages un-numbered? The reader will not thank the Noviomagian for that. Among a number of miscellaneous tags of quotations referring to books and the book-trade, with which the title-page and fly-leaves are garnished, occurs the following brief but comprehensive criticism extracted from the New Testament—"Whom Satan hath bound."

A New Air-heater.—At the meeting of the Royal Scottish Society of Arts, on Monday night, Mr. James Gowans, Vice-president, in the chair, Dr. W. G. Black exhibited and explained the action of an air-heater, contrived by himself, for warming the air of rooms. The apparatus consists of a chamber of sheet-iron, so constructed that it can be fitted on the top of a stove. Air, allowed to enter it by one pipe, is heated in passing through, and discharged by another pipe of the same dimensions, in such a way that it will ascend towards the ceiling, and thence descend gradually and diffuse itself through the apartment. This method, Dr. Black submitted, did not involve any admixture of smoke with the heated air; it dried the air during the time it was in the chamber, and it would have a sanitary effect in destroying organic germs. Some discussion followed, in which Dr. Macadam said he did not see that the apparatus could provide for the ventilation of a room; but as far as the heating of the air was concerned, he had no doubt it would have that effect. Mr. Sang then submitted "An elementary view of the strains on the Forth Bridge due to the shifting load."

ROYAL ACADEMY OF ARTS.

EXHIBITION OF WORKS BY THE OLD MASTERS: SIXTEENTH YEAR.

The present exhibition is not marked by the appearance of any picture of absolutely the best rank of merit, it at all events possesses a large number of works of more than average interest and value. We shall take the somewhat unusual course of commencing with works of the English school. This winter, in the halls of English art, belongs especially to insuborough. The artist has now been enabled to form a better estimate of his value by the specific of distance. The Grosvenor Gallery sends us with the materials for tracing the growth and compass of his powers, but the best of his larger works has to be sought in the rooms of the Academy. It is the extensive series (195) bearing the full-length portraits of Squire Hilliard and his wife, painted in the ten years of the artist's life. The youthful and handsome pair are walking gracefully and surely along arm in arm. Their attention is just being attracted to some moderately-tant object. The dog by their side, as with Gainsborough's dogs, is an expectant animal, full of affection for his master. The lady is, indeed, rather a nymph than a woman of flesh and blood, but the squire is completely human. A three-quarter length portrait of Mrs. Albert is not less excellent in the skillful arrangement and selection of drapery; it is a picture of the same type as the portrait of Mrs. Basset (59 at the Grosvenor). Of Sir Gainsborough's, the portraits of two ladies, Ladies Erne and Dillon, painted and dated together, exemplify the style of a somewhat earlier period (circa 1770) of the artist's career, whilst the best portrait of Lady Mulavey (47) once more represents his advanced years.

Reynolds is again brought before us in numerous beautiful works, no less, indeed, than twenty-four, none of which appeared at the Grosvenor last year. Of these the fascinating portrait of little Penelope Boothby (55) is shown to every one through the medium of engravings. The self-portrait of the artist, holding his hand to his ear (39) and wearing a bright, yet conscious expression that plainly tells of deafness, is to us a more satisfactory picture than the better-known one with the ear trumpet. Here the face stands out of a warm surrounding darkness with remarkable brilliancy and animation. The full-lengths of John Underhill (189) and his wife (198) are likewise splendid examples of the master's style. The husband is simply and effectively presented, standing in an open landscape, before a mottled sky. The beholder's eye is at a low level, and the figure rises before him in a striking fashion. A great part of the picture is clearly the work of assistants, but the head has been carefully finished by Sir Joshua's own hand. There are other portraits of Mrs. Masters in the collection, one (143) a half-length, likewise by Sir Joshua, the other (25), a bust, by Romney. A comparison between all three is interesting.

There are in all eight of Romney's pictures shown. Undoubtedly the best is the full-length of Lady Brooke (102) in the long room. In certain not altogether pleasant qualities of colour, in the long rhythmically-flowing curves of the dress, and still more in the presentation of character, this is one of Romney's most characteristic works. The brightness of the face and the excellent rendering of the rich hair are examples of the painter's special gifts. Strictly speaking, we ought to have mentioned Hogarth before the inseparable triad, and as an artist he stands so much alone that we take him at any time and in any sequence. A few of the Old Masters Exhibitions has been so well represented as here. Five of his works are before us, and amongst them some of his best. First comes the strong and solid, rather than attractive, portrait (6) of James Quin, the actor. The face looks forth with a certain lightness out of the nebulous importance of a full-bottomed wig. More generally pleasing is the group of little figures in a room, entitled "A Conversation at Wanstead House" (28). The persons represented are the first Lord Tynley and "many of his vassals and dependents." The picture contains high artistic qualities of light and colour, about which, owing to the badness of illumination at the time, we are unable to say more. The faces are in many instances bright and expressive, and,

though the grouping is formal, the result is good. The background of the room is dark; the faces stand out from it in full light, handled with much skill. Two of the series of pictures entitled the "Four Times of the Day" put in a welcome appearance. Unfortunately, the owner of the companion pair could not be persuaded to gratify the public with a sight of them. The two shown, "Morning" (44) and "Night" (48), make us additionally anxious to behold the others. Both represent scenes in London, treated in the fearlessly satirical vein of the artist. Both are full of vigorous treatment, of strong delineations of character, and of that apparently accidental juxtaposition of incidents out of which the moral of the work arises. The "Southwark Fair" (144) is a larger picture, of a character almost Shakespearean. To treat, however, any of these pictures with justice would require more pages than we have lines to spare. Of the other great English artist, J. M. W. Turner, there are four examples. The "Burning of the Houses of Parliament" (197) is the most striking of them. It stands forth like a flaring incarnation of rage. On the one hand rises an indignant cloud of flame, with the Abbey towers seen like hot iron through the mist; on the other is the long stretch of bridge lighted up by the fire, with a multitude of folk, just visible if you fix your gaze on them, though the light dazzles so much that you can hardly see anything else but it. Lawrence, Stothard, Constable, and many other English painters are more or less well represented, but we cannot now pause over their work. "The Boulogne Fish Market" (3) is a good Bonington.

It was from the Low Country painters of the seventeenth century that English art derived its chief impulse. It is not without fitness, therefore, that at these annual exhibitions the second room is always reserved for them. It contains a small but hold sketch by Rubens of St. Peter and St. Paul (78), standing each in an archway. It is a design either for stained glass or for a wall-decoration, one would suppose, but whether it was ever carried out we cannot say. The finest Rubens occupy the position of honour in the long room. They are three important works from the Blenheim collection, possibly now making their last public appearance in England. The best of the three is certainly the portrait of Anne of Austria (117). She is seen as a seated three-quarter figure, in a black dress, with a large white ruff. The white complexion, for which she was famed, and the too much ruff she used to wear, are both shown by the painter, who has likewise treated with evident delight the arms and hands, of which it was said that all Europe knew the fame. The "Venus and Adonis" (146) manifests much of the artist's power and some of his weaknesses. The colour is unsatisfactory. The head of Venus is of extraordinary beauty, tender and fair, and her hair is splendid for quantity and glossy flow. She sits in a shady place under the trees, and would gladly restrain her lover, but the youth will away after his dogs, though baby Cupid lung his leg never so hard. The "Lot and his Daughters" (148) is much less attractive. The composition is poor, and of the heads only those of Lot and his wife are fine. She is weeping and miserable, just passing by a suggestive pillar.

Of Vandyck there is one very fine work, which throws the other three into the shade. It is the full-length portrait of Strafford in armour (188). Here we feel that the man himself stands before us, the strong governor, the relentless politician. In his face is a mastiff-like strength; the pose of his figure marks unhesitating decision of character. The "Buckingham Family" (145) from Blenheim is likewise a fine work, full of the "gloss of satin and glimmer of pearl." The equestrian portrait of Charles I. (183) is a school picture, if we mistake not, designed undoubtedly by the master. The slaty tones of the horse were never laid by Vandyck's brush.

There are many very excellent examples of the Dutch painters of the seventeenth century. To begin with Franz Hals, Lord Braybrooke's "Fiddler" (94) is a work which neither requires signature nor date (1630) to attest its genuineness. The same may be said of the "Dutch Lady," painted five years later. Both are examples in their different way of the grip the artist had of his subject and the forcefulness of his expression. Mr. Huis's "Conversation Piece" by Dirk Hals (136, dated 1614) is a beautiful piece of colour,

the dresses of the two ladies on the left forming together a very pleasing passage. At first sight this set of long-legged folk almost seem like a joke of the artist's; but the length of limb is found on examination to be apparent rather than real, and is the result of the sartorial fashion of the time. Van Goyen has been better represented on other occasions than in the three pictures now brought together. Solomon Ruysdael, on the contrary, could scarcely be seen to better advantage. Most important for size and of excellent quality is the "River Scene" (152). A dark clump of trees in the midst of the shadowed foreground renders the light behind all the more luminous, whilst the cloud-drift across the sky gives the distance an animation which in the foreground is effected by the presence of one of the artist's favourite ferry-boats. The large Albert Cuyp (101) is a conventional and indifferent work. More satisfactory is the "Landscape with Cows" (93), which breathes the quiet sentiment of evening and approaching rest. The little "Sultry Morning on the Maas" (107) is, perhaps, the best of all. One canvas only claims to have felt the touch of Rembrandt. The subject, "Tobit and the Angel" (135), is undoubtedly treated in his style, but the faces seem to want that fire of feeling which he never failed to infuse into them. A picture by Solomon Koning (82, dated 1635) is an early example of that artist under Rembrandt's influence. It is called "A Merchant," and the catalogue states that the table is covered with "papers and documents." In reality it represents an author writing, and the huge tomes spread out before him are monuments of stored learning and not musty account-books. "An Old Woman" (137), by G. van den Eeckhout, is a poor work inspired by the same great master. We cannot expect every year to see such a magnificent Terburg as that which delighted us last winter. The "Lady at her Toilet" (121), though not in such perfect preservation as the "Letter," is, nevertheless, a fine work. It manifests the painter's faultless understanding of the use of colour,—what it can do and what it cannot,—and, as a piece of workmanship, is as fine as anything can be. The Queen's Metron, "Le Corset Bleu" (109), is a picture possessing similar qualities and worthy of the closest examination. The so-called "Water Doctor" (76) is quite up to the average of Gerard Dow, the lights being handled with much skill, and the accessories, brass things and books, being of course finely finished and well chosen for harmony of colour. Art van der Neer is only too unpleasantly prominent; none of his exhibited works, except the "River Scene in Guelderland" (108), being possessed of charm. The exception, however, is a work of merit. Jan van de Capelle's "Calm" (117) is of his usual style. In former years, however, we have been shown works which throw this into the shade. Paul Potter's "Sportsmen" (119), though a small picture, is one of the painter's best works; the figures on horse and foot are well grouped together; the whole is good in light and colour, and well worked out. Of Jan Steen's works we have had a more attractive display than those shown this year. All of them are unpleasant in colour and some in subject, though in none is the artist anything but himself, individual and original as he always was. "The Month of a River" (141), by William van de Velde, is a pleasant little piece, worth comparing with one or two other treatments of a similar subject by different artists in the same room.

The fifteenth and early sixteenth century schools of Northern Europe are not numerously represented this year. The earliest picture is a "Marriage of the Virgin" (215), foolishly ascribed to Van Eyck, but in reality a Cologne work of about 1480. This is followed, in point of time, by the most important work in the Exhibition, the famous "Adoration of the Magi," by Mabuse, from Castle Howard (230). Mabuse was an artist of the School of Bruges, who, up to nearly the fortieth year of his life, was subject only to Flemish influences. His picture represents him at the height of his native power, and before that power had been corrupted by the pernicious influence of Italy. Had he but stayed at home and gone on painting in this fashion, gathering increase of experience and dexterity, the last twenty years of his life might have produced as rich a harvest of mature work as Dürer himself gave forth. The fates determined otherwise. For perfection of finish, definite knowledge of what to do

and how to do it, few pictures in the world surpass this extraordinary work.

The styles of Bernard van Orley and Mostaert appear in two pictures, a lady's portrait (153), ascribed to the former, and a "Magdalen" (202) by the latter. Of sixteenth-century German artists there are a few works of the second rank. Two wings of some altar-piece (219 and 221), ascribed to a certain Hans Braun, unknown to us, are in reality good specimens of the style of Bartholomew de Bruyn. From the Dublin National Gallery come two South German portraits, that of Margaret Knoblauchin (174) by a Swiss follower of Holbein, and that of Anthony Handertpfundt (175), by Wolfgang Hauber, a conscientious imitator of Dürer.

Coming now to Italian pictures, there are none of great merit belonging to the early schools. The North Italians are best represented. First comes an unpleasant, but seemingly genuine, work of Bartolomeo Vivarini (206), painted under Paduan influence. The "Madonna" (207) is a signed picture by a rare pupil of Bellini, Giovanni Manuetti. The "Madonna with Saints" (211) is an early work by some other pupil of Bellini's, just possibly Cima. "Diana and the Fishermen" (205) and the "Battle Piece" (258) are both good pictures, and show the influence, though not the handiwork, of Giorgione. Far less excellent is the "Three Kings" (227), falsely ascribed to Catena. It is by some Germanising Venetian of small importance. The "Punishment of Actæon" (159) is rightly ascribed to Veronese, though at first glance it more resembles a painting by Titoreto. It contains no splendour of drapery and no elaborate architecture. The charm of it is the play of light upon the nude, which is inspired by Titoreto, and the rare harmony of colour, which is Veronese's own. The other picture ascribed to the same artist (168) is a poor school work. An animated representation of the "Piazza Colonna" (154) is a really good example of the powers of Francesco Guardi.

The front of a *casone* (218) is a rare piece of work, probably from the studio of Vittore Pisano. The "St. Catherine" (216) is one of Crivelli's most pleasing productions, full of tender sentiment and graceful design. It is in perfect preservation. The bust portrait in profile (209) is rightly given to Ambrogio Borgognone. It shows him under the influence of Antonello, and is one of the best specimens of his work. Very close to him are the panels forming a further instalment of the decorative frieze belonging to Mr. Willett, some of which were shown last year. They are exceedingly interesting, and quite up to the average of what we saw before. The "Madonna" (222) is of the ordinary Milanese type.

The "Holy Family" (173) comes from the period, though not the hand, of Marco d'Oggione. The so-called Bottinone (228) is likewise a Milanese painting with strong Florentine elements, and treated in an archaic manner. A good and well-conserved example of Francia appears in the "S. Roch" (176), which is both signed and dated (1502).

Some interesting Florentine pictures are placed in the Fourth Gallery. None of the works of the school of Giotto are of any importance. The little "Journey of the Three Kings" (250) shows the combined influences of Angelico and G. da Fabriano. An "Allegory" (254), ascribed to Signorelli, is probably by Piero di Cosimo, who had a liking for such subjects; by no possibility is it a Signorelli. The lunette (235) is by Botticelli, and thoroughly characteristic of his early period. The round "Madonna" (244) is a school-work. The eight little pilaster panels bearing saints (252, 250) are good school pictures from a master's design. There is a very simple and beautiful "Madonna," by Albertinelli (225), and four little paintings (213) are likewise ascribed to him. A half-length "St. George" (208) is only of Ghirlandajo's school. The little round "Madonna and Saints" (203), ascribed to Raffaellino del Garbo, is at least a most charming work of the late fifteenth-century Florentine school. The *casone* front (212) and the "Entombment" (217) are poor anonymous works of the same period, showing Botticelli's influence. There are several anonymous fifteenth-century Sienese pictures (232, 213, 251), and one, a "Madonna" (210), with which the name of Matteo da Siena is in all probability justly associated.

The authorship of the picture of a "Choir-master" (180) is a problem to the solution of

which we can offer no help. The work is certainly fine, probably Italian, and painted in the last part of the sixteenth century.

The best Spanish picture is a "Madonna in Glory" (161), by Murillo, of his usual kind, though better than usual in treatment. We prefer it above the famous but vulgar work in the Louvre. The so-called "Portrait of a Genoese Noble" (150), really a picture of a Man-at-arms, is a thoroughly sound and effective piece of workmanship. Velasquez's hand had no share in the painting of the "Head of a Man" (181), though his influence is apparent throughout it. Zurbaran is accredited with the unattractive "Franciscan Friar" (162).

The "Assumption" (172) is a genuine piece of Nicholas Poussin's work. The definiteness of the artist's intention, and the easy skill by which he attains his ends, are the good points in a picture which is not likely to be popular in these days. Two "Fêtes Champêtres" (115 and 128) are good examples of what was possible to Jean Baptiste Pater, one of the best followers of Watteau.

THE LATE MR. JOHN WHICHCORD.

It is with great regret that we record the death of Mr. John Whichcord, F.S.A., architect, and past-President of the Royal Institute of British Architects. He died at his residence, 23, Inverness-terrace, on the 9th inst., after a short illness, the cause of death being inflammation of the lungs, terminating with paralysis of the heart.

Mr. Whichcord was born on Nov. 11, 1823, so that he had but recently entered on his sixty-second year. His native place was Maidstone, where his father (who died in 1800) carried on a large practice, besides holding the position of County Surveyor. The future President of the Institute was educated at Maidstone, and afterwards at King's College, London, under Dr. Lonsdale. He commenced his professional work as his father's pupil in January, 1840, and became a student at the Royal Academy in 1844. In the same year he was elected an Associate of the Institute. In these early years of his professional life he assisted in the erection of public buildings in Canterbury, Maidstone, Rochester, and other towns. He also made surveys for railways intersecting the county of Kent, and took part in the construction of locks, bridges, and other hydraulic works on the River Medway. He went abroad in 1846, passing through France to Italy, and proceeding to the Ionian Islands, Greece, and Turkey. Having got so far, it is not to be wondered at that he was seized with a strong inclination to visit Syria and the Holy Land. He travelled for a lengthened period in Turkey in Asia as an Arab, living with a tribe, and making a journey to the Euphrates. Returning to Syria, he made a visit to every known spot mentioned in the life of our Saviour. Having acquired the language and assumed the costume of their custodians, he was enabled to visit the Mahometan holy places and mosques without hindrance. Departing from Syria, he went into Egypt, proceeding as far up the Nile as the Third Cataract. He returned to Europe in the early part of the year 1850, but went abroad again the same year for a shorter tour in France, Italy, Germany, and Denmark. As may be supposed, he made a large number of sketches while on his travels. On his return he entered into partnership with the late Mr. Arthur Ashpitel, in conjunction with whom he carried out several important works, of an engineering as well as of an architectural character, not only in England, but in Italy, France, and Germany. This partnership was terminated in 1858, and Mr. Ashpitel died in 1869. In 1851 (a year before the Metropolitan Board of Works was created) he was appointed by the magistrates District Surveyor for Deptford. He was elected a Fellow of the Institute in 1850, and President in 1879, holding office for two years. Mr. Whichcord's work as President of the Institute was characterised by his usual energy and business capacity; and whatever differences of opinion may be entertained as to the policy continued under his régime, those who differed most from that policy will be the first to admit that in his guidance of the affairs of the Institute he was actuated by an earnest desire to promote the welfare of architects and the prosperity of architecture. It was mainly due to his efforts that the Obli-

gatory Examination was put on an effective footing. He was an admirable chairman, displaying great tact, and always keeping a meeting over which he presided well in hand. He was elected President of the Architects' Benevolent Society in 1881, in succession to Mr. T. H. Wyatt. He held the appointment of consulting architect to the Colonial Government in respect of the new Houses of Parliament at Cape Town, and designed the internal fittings of those buildings. He was one of the surveyors to the Railway Department of the Board of Trade. The principal buildings with which his name is associated as architect are St. Stephen's Club House, Westminster, the National Safe Deposit Company's building, and the New Zealand Banking House, Queen Victoria-street, besides numerous buildings for mercantile purposes in the City of London, including the large block of offices known as No. 9, Mining-lane; No. 24, Leeward-street; No. 8, Old Jewry; Mansion House Chambers, Queen Victoria-street; and Messrs. Brown, Janson, & Co.'s Banking House, Achurch-lane. He was architect of the Hotel Hotel at Brighton, the Clarence Grand, Dover, and other buildings of the kind. He was also architect of St. Mary's Church and parsonage, Shortlands, Kent. Of recent years Mr. Whichcord has been largely occupied as arbitrator in reference and compensation cases, being frequently employed in those matters by the Government, the Metropolitan Board of Works, and railway companies. He was the author of "The History and Antiquities of Christ Church, Maidstone," "The History and Antiquities of St. Mary's, Aldermanbury," "Polychromy of the Middle Ages," besides several other works. He contributed many valuable papers to the Transactions of the Royal Institute of British Architects. In conjunction with his partner, the late Mr. Arthur Ashpitel, he published a work entitled "Observations on Baths and Wash-houses," and also a companion work on the "Erection of Fireproof Houses in Flats." He was a Fellow of the Society of Antiquaries (elected in 1818) and a member of the Institution of Surveyors.

Mr. Whichcord was, in 1865, a candidate for the representation of Barnstable in Parliament. He contested the borough on Conservative principles, but unsuccessfully. He took an active interest in the Volunteer movement, and in 1869 became a captain in the 1st Middlesex Artillery Volunteers, having previously served in the Kent Yeomanry. For the first-mentioned corps he, in conjunction with Sir John Monckton, raised a battery mainly composed of young architects and lawyers. He took an active part in Freemasonry, having been initiated into the "Jerusalem" Lodge in 1845.

Mr. Whichcord was twice married. By his first wife (an Italian lady) he had no issue. By his second wife (whom he married in 1860, and who survives him) he had a family of seven children, five of whom are living.

The funeral took place on Thursday last at Kensal Green Cemetery, and was attended by the President and several members of the Council of the Royal Institute of British Architects, besides deputations from the District Surveyors' Association, the Surveyors' Association, the Institution of Civil Engineers, and the "Jerusalem" Lodge. Amongst those present were the following:—Sir John Monckton, Sir Charles Hutton Gregory, C.E., K.C.M.G.; Major Davies; and Messrs. Ewan Christian, E. R. Robson, J. Macvicar Anderson, W. H. White, Thomas Chaffield Clarke, Octavius Hansard, Alfred Conder, J. Tavenor Perry, Henry Curry, Joseph Clarke, Arthur Cates, Professor Hayter Lewis, Benjamin Tahherer, John Clarkson, Banister Fletcher, Robert Walker, William Cunningham Glen, C. L. Enslake, and Cole A. Adams, President of the Architectural Association.

The Builders' Ball.—The thirty-seventh annual ball in aid of the funds of the Builders' Benevolent Institution is to take place at Willis's Rooms, King-street, St. James's, on Thursday next, the 22nd inst.

* For illustrations and description see *Builder*, vol. xxxii. (1874), pp. 308, 309, 311.

† In conjunction with the same gentleman, Mr. Whichcord was architect of the Lambeth Baths, Westminster Bridge-road, one of the earliest and largest establishments of its kind in London.

Illustrations.

WINDOW IN SOUTH CHOIR AISLE, SALISBURY.

WE give this week two more of Mr. Burne Jones's figures from a window in the south choir aisle, Salisbury Cathedral. Two figures from the same window were illustrated in the *Builder* for January 3rd.

ALL SAINTS' CHURCH, UPPER HOLLOWAY.

THIS church, now being erected from the designs of Mr. J. E. K. Cutts, which were selected in a limited competition of five architects,—Mr. Ewan Christian being the professional referee,—consists of nave, chancel, organ-chamber, large west porch, and large vestries. It is faced on the outside with red bricks, the interior being plastered with arches, quoins, jambs, and reveals of red brick. The stone of the pillars, tracery, &c., is from the Monks Quarry. The roofs and vaults are of pitch pine, and the paving of the nave of wooden blocks. Messrs. Dove Bros. are the contractors, whose tender for the work is complete was 4,975*l.* The church provides 18 sittings.

THE CHURCH OF ST. MARY, GEDDING, SUFFOLK.

THIS interesting and quaint little church, which lies in the immediate neighbourhood of the Architectural Association this year, is being restored under the supervision of Mr. E. F. Bisschopp, architect.

The general features are of Decorated character, though there are evidences of a much earlier date. Traces of the moat, which originally surrounded the church, are still distinctly perceptible.

After various patchwork repairs, executed during the dark age of the last two centuries, the building had fallen into a most deplorable condition, the nave being quite unfit for divine service. Upon being instituted to the office, the new rector, the Rev. J. Sidney Tucker, set most energetically to work on the restoration. This has been carried out strictly to the founder's lines, reverentially preserving every original feature, and substituting no modern patchwork for ancient solidity of construction. So that Gedding, with its Norman apertures, lepers' grating, triple chancel arch, &c., will amply maintain its character for being not only one of the oldest, but most interesting churches in the kingdom.

The nave roof has been taken off, reframed, and refixed, all the sound old oak timber having been re-used. In hacking off the plaster which figured the outside face of the walls, two Norman windows were discovered, one on either side of the nave, north and south. These have been carefully opened up and glazed. The upper window in the chancel has been exposed to view, together with its original ironwork upon therein. The triple chancel arch is being restored, some of the stonework having been removed and made good in brick. There are slight remains of the rood-screen, and the six ancient benches left will be refixed.

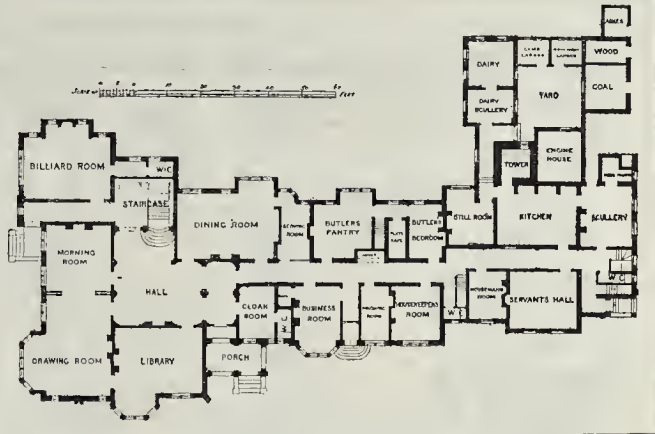

The upper part of the tower, if ever erected, has disappeared, and is now of brickwork, with a hipped tiled roof. The restoration of the tower and the porch, shown in the view to replace one in white brick, pulled down, is not included in the present contract.

The contractor is Mr. R. Tooley, of Ipswich.

HOUSE AT MATTHEW'S GREEN, WOKINGHAM.

THIS house, which has been erected from the designs and under the superintendence of Mr. Ravenscroft, of Reading, is situated in well-wooded and pleasantly-placed grounds near Wokingham.

It occupies the site of an older house, which not only was devoid of interest, but in such a condition that the enlargement of it first contemplated was found to be impracticable. The present house, with lodge, conservatory, &c., all designed to be in harmony, was carried out by Mr. Filewood, formerly of Reading, but now of the firm of Silver, Son, & Filewood, of Maidenhead, for the proprietor. The whole cost was about 7,000*l.*

Askham Hall, near York.—Ground Plan.

ASKHAM HALL.

THE new Hall is to replace an existing one, of no special interest, which was not convenient in arrangements or good in its sanitary conditions. The present building, which is in process of construction, is planned with all the advantages of our now extended knowledge of hygienic requirements. The whole structure is underlaid with a stratum of cement concrete; the drainage has arrangements for automatic flushing; and the methods of heating and ventilating the house are of a very complete character. The view and plan speak for themselves as to the designing and planning of the building. Externally no attempt has been made at elaboration of detail beyond what is necessary to emphasise the reception portion of the house. A certain picturesqueness of grouping has been sought for as suitable to the position which it occupies, embosomed in trees, and the dominant feature in the little village whose old-fashioned green and rural pond it overlooks. Internally the principal feature is the central hall, around which the reception-rooms are ranged. This portion of the dwelling is carried up two stories, is lighted by a domed ceiling, and is treated with some little amount of detail. The materials of which the hall is built are red bricks and tiles, with Bolton Wood stone dressings. The dwelling will be the country seat of Sir Andrew Fairbairn, Member for the Eastern Division of the county of York, and has been designed, and is being carried out, by Messrs. Chorley & Connon, architects, of 15, Park-row, Leeds.

IMPERIAL HOUSES OF PARLIAMENT, BERLIN.

PRIZE SCHEME FOR HEATING AND VENTILATION.

WE give here the plans of the system of heating apparatus and ventilation to which the prize was awarded during the past year in a competition for the best design. The scheme is by Mr. D. Grove, and the following is a translation of so much of his report as is requisite to render the scheme intelligible:—

Draining-in of the Air.—Besides the disposition of the openings for the entrance of fresh air in the walls of the slopes of the west front, the use of the fountain in the Königsplatz (see fig. 4) is proposed as a point for taking in the air. As the bottoms of the necessary channels should only be 1.8 metre (about 5 ft. 10 in.) below the surface, the difficulty arises of constructing them large enough to pass the requisite quantity of air. By using the best wood-paving immediately over the vault of the channel, or over cast-iron pipes with an under-bedding of concrete, the depth of the construction of the channel covering can be limited from 25 to 15 centimetres (about 10 in. to 6 in.), so that the channel can have a clear height of 1.55 to 1.65 metre (5 ft. to 5 ft. 4 in.). It remains desirable to raise the ground at this point as much as possible, or to lower the bottom of the basin. The uprising and misty stream of the fountain so lowers the temperature of the body of air

over the basin that there results a rapid descending stream from the upper clean air strata to the lower; this takes the air into the openings arranged around the inner border of the basin. The sectional area of these may be taken as 33 square metres (about 391 square yards). The water flowing off is conducted to the ends of the channels by the slopes, there distributed in open shallow gutters of galvanised sheet iron, of which four in each of the twelve channels are arranged with slight falls back towards the fountain. The area of the water-surface amounts, with 40 metres (about 151 ft.) length of channel, in the whole to 800 square metres (about 928 square yards). If the water of the fountain, the quantity of which according to data amounts to 50 cubic metres (about 1,766 cubic feet) per hour, experiences a warming in the whole of about 6° Centigrade (108° Fahr.); it draws from the air per hour 300,000 units of warmth,* and thus effects for 250,000 cubic metres (over 8,000,000 cubic feet), a moderation of the temperature of 4° Centigrade (7.2° Fahr.). An alteration of the warmth by evaporation is not to be calculated on, as the thawing point under circumstances is higher than the temperature of the water. With a strong and ensured change of air, a very considerable lowering of the temperature in summer is not requisite; but for times of particularly great heat the arrangement is so contrived that the coils of pipes in the air-collecting room, serving during the winter as heating bodies, can be connected with a cold-water supply according to the system of Linde, with a freezing-machine in the boiler-house. These pipes have a diameter of 50 millimetres (nearly 2 in.), and an outer surface of 3,360 square metres in area (about 4,018 square yards).

Purifying of the Air.—By utilising the whole height of the cellar and basement stories for the collecting-room for the air under the hall of the west front, a moderating of the speed of the air stream to 0.6 m. (about 2 ft.) per second is aimed at, and room is gained for abundant filter surfaces, 300 square metres (about 359 sq. yds.). The filters are wooden frames spanned with porous stuffs specially manufactured for the purpose, and can be removed for purposes of cleaning. The dust is already partly beaten down by the water spray before reaching the filters.

Tempering of the Air.—The groups of heating pipes behind the filters serve for raising the warmth of the air 12° Cent. (21.6° Fahr.). These can be shut off singly, are far reaching, arranged at all places for easy access, and contain the necessary heating surface to deliver the amount of warmth requisite for moistening it. Vertical and movable door-valves make possible the conducting and regulating of the streams of the colder and warmer air strata.

Moistening of the Air.—The air thus raised 12° Cent. is nearly completely saturated with

* Translator's note. The unit of warmth, according to the German standard, is the amount transmitted in one hour per cubic metre (10.754 square feet) through a body with parallel surfaces.

ST. MARY'S, GEDDINGTON, SUFFOLK. RESTORATION.—MR. E. F. BISHOPP, ARCHITECT.

ASKHAM HALL, N^o YORK.
FOR SIR ANDREW FAIRBAIRN, M. P.
MESS^{rs} CHURCHILL & CONNOR, Auctioneers,
4, Pall Mall, London.

Fig. 3.—Section of Centre Portion.

Fig. 4.—Site of the Future Reichstags-gebäude, with immediate Surrounding.

NOTE.—The shaded surface as shown marks the definite site of the Reichstags-gebäude; that with dotted outline, marked with the letters A B C D, the site for the competition of 1872. The letter X marks the fountain proposed to be utilised.

moisture by abundant water spray and evaporation. By the further warming which follows on this the degree of saturation is raised to the required percentage. By means of fixed hygrometers this is controlled, and variations are equalised with the aid of a second moistening apparatus behind the second group of heating bodies.

Further Warming and Distribution of the Air.—Before distribution in the principal channels of the individual parts of the building, the further warming of the air takes place in special chambers up to + 20° C. (68° F.), and for the large hall up to + 17° C. (62° F.).

Ventilators.—The ventilators are separated for the large hall and the four corner groups of the building; their capability of action is strictly measured with a view to loss by pressure.

Principal Channels.—The size of the principal channels is adapted to the constructional planning of the cellar story; the dimensions in the clear resulting from this, 4 metres wide and 2.1 metres high (about 13 ft. 1 in. wide by 6 ft. 10 in. high), are so full that with a more complete occupation of the whole building and full effect of the ventilation at the same time for all the rooms, the rapidity of the air stream in the principal channels will not exceed the measure of 2 metres (about 6 ft. 7 in.).

Vertical Channels.—The sections of the vertical channels are all measured for full effect at an external temperature of + 5° C. (41° F.), and entered in the drawings according to brick dimensions (rounded above). The existing thicknesses of the walls are sufficient in all places for providing for the channels. Should it appear desirable to the building authorities to diminish certain of the sections, this is very easily possible in those rooms which do not require the full effect without propulsion at an outer temperature of + 5° C. (41° F.), as in the chambers for the sittings.

Carrying off the Air.—The same principles were suitable for the arrangement of the channels for carrying off the air as for the channels for bringing it in. By bringing these together in the cellars, and by the arrangement of two aspiration shafts, of 35 metres (about 114 ft. 10 in.) in height, and together 26 square metres (about 215½ square feet) in section, which will be warmed by the steam going off from the engine, eventually by direct steam, as also two exhausters, the full effect can be reached with safety at all times, independently of external influences, and without raising the pressure of air in the rooms.

Closest Ventilation.—By the complete separation of the inlet and outlet of the air for the closets from that of the other rooms, perfect security against the entrance of closet air, &c., into the corridors, &c., is attained. The air is carried off as well under the seats as at the ceilings, furthered by gas-burners and exhausters (worked by the water for flushing).

Engine for Steam Service.—The service of steam follows from the boiler-house through two pipes, the dimensions of which are so chosen that under ordinary circumstances one suffices for action. The steam-pipes are freed from water in the ordinary way by self-acting condensed water flow-off pipes. The to and from services are arranged separately for the distinct heating groups: all division and return valves, condensed water flow-off pipes and collecting vessels are united in the control room under the vestibule and principal staircase of the east front, so that from there the circulation of the steam can be conducted to all parts, shut off, and regulated. In the same place is situated the engine for driving the ventilators (50-h.p. horizontal, with Colman's distributing valve motion) and the main transmission.

Air heated by Steam.—There is a special heating-chamber for each individual room arranged perpendicularly under the same. The heating-chambers are situated, suitably marked, in a continuous row by the wall of the principal channels, and are therefore accessible in the easiest manner; the front wall is formed movable, the dimensions so measured that the medium speed of the stream in the same does not exceed 0.5 metre (about 19 in.).

Regulation of the Heating of the Air by Steam. The regulating valves are intended to be constructed in a most simple manner, close-shutting, balanced, with bronze framing and adjusting apparatus; the detail is reserved for special working out. The permissible maxima and minima of the temperature are signalled

both in the heating-chamber and in the office of the officials having the oversight thereof; then follows the insertion of the flap-valves and valves in the simplest and most sure manner in the heating-chamber itself by the officers in charge of it. For indications of the temperature, electrical connexions with signals from the maxima and minima thermometers to the decided-on points are allowed for afterwards, and considered in the estimate. Direct speaking-tubes are also provided for between the engineer's office and the points where the principal channels commence, the principal hall, &c., telephonic communication with the upper stories, and a pneumatic-tube from the mixing chamber to the office for entering the trials of the air.

Hot-water Heating.—Each of the four groups for the heating parts of the building is divided into two systems with separate boilers; one of which serves in each case for the library, office, dwellings, and closets, the other for the remaining rooms, so that the first can be warmed independently of the action of the whole arrangement. Both boilers and systems are connected with each other, provided with valves, and can be put in action at pleasure, either singly or together.

Arrangement in the individual Rooms.—The air streams into the individual rooms at a suitable height above the floor, near the ceiling or the floor, as needed, and in turn goes from them. Close-shutting flap-valves, simply constructed, are provided everywhere. In the larger rooms the internal architecture will give the possibility to introduce a further division of the air. Proposals for these, however, must remain reserved for special working out, as with these the constructional considerations are of corresponding influence, and detailed working drawings, for instance, are not yet to the present time before us.

Principal Hall.—For the principal hall, the possibility of bringing in the air direct in the most simple and natural manner follows from the existence of a fixed situation, and of a large area at disposal under the floor, viz., equally distributed under all the seats. As the air streaming in is tempered to 20° C. (68° F.), and enters with a minimum speed under the seats, every possibility of a troublesome draught is excluded. By the warmth of the human body, and the products of respiration, the temperature of the air is raised. This rises to the ceiling, and there immediately follows the carrying away of it in accordance with natural laws. The arrangement of the principal hall is disposed to correspond with this. As, however, a good effect can also be attained by another situation for the inlets, the choice of one or other of the arrangements may depend on personal views. [It appears that the author of the scheme contemplated having the power of reversing the localities of inlet and outlet for the great hall or Parliament House proper, and prepared a special section showing the air propelled or allowed to rise through upcast shafts first and entering through the cove in the ceiling, being then drawn off through the floor. The section (fig. 3) indicating this arrangement is the one that has been sent to us for illustration of the scheme, somewhat illogically. It shows, however, the three tiers of chambers under the floor of the great hall, as described; but in regarding it as an illustration of the scheme as above described, the direction of the arrows at the cornice and floor of the hall must be regarded as reversed, and the "inlet-canal" (inlet shaft) shown at the left of the section of the hall must be regarded as a descending exhaust shaft communicating with the main exhaust shafts ("inlet-candle") shown on the extreme right and left of the section. These apparently remain the same in both cases; but in the scheme which the author (rightly, we think) prefers, of admitting the warmed air below and taking it out above, the vitiated air is drawn down first and sent up again through the main exhaust chimneys. In the second or alternative scheme it passes direct from the floor of the hall to the "inlet" chimney.—Ed.] The following may yet be noted with regard to the arrangements chosen in the scheme before you to make possible an exact control of the temperature of the air entering through the floor. An air-reservoir must be formed under the hall, in which the air is already found at its proper temperature; further, we must be able to effectuate quickly and surely the regulating during changes in the sitting of the House; for

example, during divisions. For this purpose two stories, sufficiently high to pass through, are to be formed over the cellar story, between the floors of the lower story and of the hall, by the insertion of a middle floor. The freshly-warmed air (tempered to about 17° Cent., say 62° Fabr.) streams out of the preliminary warming-chambers to the ventilators in the cellar story. From these the air is passed on to the next story, where it is divided into two rooms situated in a parallel line against each other, of which one is heated. Around the other, between the heated and unheated chambers, is left a passage, 1 metre (about 3 ft. 4 in.) wide, that can be placed in communication with the more or less warmed chambers by means of regulating slides (the slides are movable outwards from one position by means of simple rollers and draw apparatus). These mixing passages open upwards towards the third story, the control-room. According to the height of the control thermometer, less or more warm air is admitted to the mixing passages, and by this means the proper temperature is already formed below the floor for every part of the hall. One part of the control-room is separated for the Tribunes, that the temperature of those may be independently regulated. Corresponding to this special carrying-off channels are arranged. The thermometers are connected electrically with signals in the engine-room and control-office. The warming-chambers of the hall are provided with warm-water heating (low-pressure), to regulate with certainty the mildest tempering of the air, and to gain a constant supply of moderately warm air for regulating purposes. The draw-off channels are led down to the lower story, having a total sectional area of 6.25 square metres (about 67½ square feet) for both sides of the hall united there by the shortest route and connected with the aspiration shafts. During the heating of the hall it would not be advantageous to take off the warm air at the ceiling. The disposition hit upon makes possible in the simplest manner the carrying off of the air at the floor by reversing the valves to the suction-channels leading past at the sides. Lastly, the position of these channels affords the advantage still, of no small value, of being able to attain during the cleaning of the hall a complete and sure removal of all dust particles. For this object the control-room is placed in connexion with the suction-channels by large (closely-shut) openings. When these openings are set free, and at the same time the doors and skylight over the hall opened, a streaming in of fresh air, but weak, is maintained thereby towards the control-room by a corresponding fixing in of the slide-valves to the air-chambers, and when, in the last place, both suction-shafts are claimed for the hall alone at the same time, by shutting off the other parts of the building, it is possible to effect the most thorough cleansing and the removal of all dust particles directly towards the suction-shafts.

Total Cost.—The total cost of this design is indicated in the estimate of cost, according to which it amounts to about 482,500 marks (about 23,652,100). To this it should be noted that all dimensions are calculated for the attainment of an effect according to the programme (conditions) at the same time in all rooms.

Action.—In making use of a centralised scheme of the importance of the one projected, it is not sufficient so to manage the working that any irregularities which may happen can be remedied in a supplementary way; measures should be taken to prevent complaints at the first. This is only possible when the working is carried out with regard to all the conditions coming under observation, number of the rooms used, frequency of their use, external temperature, height of the barometer, degree of moisture, direction of the wind, &c., on the basis of a continuous observation of the working in every part of the general arrangements. An engineer should for that reason be appointed on whom the responsible superintendence is incumbent, who works at and revises regularly the reports on the course of all the apparatus, determines in the first place the principles for regulating it on the basis of actual observations, and issues special instructions for particular cases. The general management of the apparatus follows from the disposition thereof without anything further. Subordinate to the engineer, besides the staff of the boiler-house, who are not to be considered here, are an engine attendant (chief stoker), two permanent stokers, and an

assistant stoker (as a reserve and for educating as a substitute during changes in the staff). The management of the complete practical service is subject to the chief stoker, according to the directions of the engineer. The three stokers attend to the separate parts of the building (middle building, north and south), with a relief or respectively a change so that each becomes acquainted with all the parts; prepare the reports on the height of the thermometer, hygrometer, anemometer; and look after the cleaning and maintenance of all apparatus and working-rooms. When in full working order a regular round should be organised through all the rooms, and specially through the principal air-galleries and heating-chambers."

THE ROYAL ARMS.

We have a modern version of the herald's visitations of the latter part of the Middle Ages in our Government calling upon all tradesmen (and their name is legion) using the Royal arms to showily what authority they do so. We therefore venture in this article to give a short account of the origin and history of our national shield and its accessories.

"Let us begin at the beginning," says Planché in "The Pursuivant of Arms," &c. We cannot do better than follow such advice. But where is the beginning? Well, putting aside all conjecture and all tradition that are unsupported by examples, we cannot give an earlier origin to "the Royal coat" than the reign of Richard I., whose seal is engraved with the three "lions of England," even as we now behold them on every side of us.

And here we must pause to add that perhaps, strictly speaking, according to the rules of heraldry, our Royal animals are only leopards. Much has been written on this point, and it has been very hotly contested, but lions they have ever been in the paths of our enemies and lions they must ever remain.

This shield of our "Cœur de Lion" was borne by his unworthy successor John, by Henry III., Edward I., II., and III., until the thirteenth year of the latter's reign, when he quartered the "four-de-lis" with the lions, thus showing his claim to the throne of France through his mother, who was a French princess, and this quartering was retained by us till the present century. And here we must pause again to put the unanswerable question,—What is the "four-de-lis"? Well, some writers have held that it represents a flower, others say the head of a sceptre, others again assume it to be the point of a spear, and yet again it is claimed as a frog or a toad! Books upon books have been written on this mystery and we are as much in the dark as ever.

The shield assumed by Edward III. "bolds good" until about the year 1405, when the number of the *fleurs-de-lis* was reduced to three in each quartering to correspond with the alteration made by the French, and commonly known as "France modern," as distinguished from "France ancient," the former quartering. We have now reached the reign of Henry IV.

This shield of "France modern" and England quarterly will carry us on to the reign of James I., who brought in the Scottish lion rampant, the origin of which, as a writer observes, "is veiled by the mists of antiquity." The Irish harp was introduced at the same time. These "arms of the Stuarts" will run till May 1st, 1707, when Anne bore England impaling Scotland, France modern, and Ireland.

The "Arms of Hanover" came with George I., and were retained until the accession of Queen Victoria.

The "fleurs-de-lis" were removed from the Royal shield of Great Britain on the 1st of January, 1801.

The Royal crest is a lion standing on a crown, and wearing a crown, and was first borne by Edward III. on a cap of estate. We must say a few words about the "supporters" of our Royal arms, and here we have no authority for going farther back than Henry VI., who bore two white antelopes, also a lion and a panther, or an antelope. Edward IV., a lion and a bull, or a lion and a hart. Richard III., a lion and a boar, or two boars. Henry VII., a dragon and a greyhound, or two greyhounds, or a lion and a dragon, and all the Tudors bore the same supporters with slight variations.

The familiar "Horn and unicorn" date from the accession of James I., and have remained undisturbed until the present day.

The origin of supporters is another of the many disputed points in heraldry into which we cannot enter. They are of great service in determining the date of any building that bears them. The motto, "Dieu et mon droit" was assumed by Henry VI., and has held its ground ever since. It was an ancient English war-cry.

With regard to the crown, all our monarchs since Henry IV.'s time have worn it with two arches, with the exception of Henry VI. and Charles I., who arched their crowns three times, and this is sometimes a clue to a date.

The Royal banners or standards are charged with the bearings of the shield of arms for the time being.

We cannot tell why Wales should have been left out in the cold, but it is a fact that the Principality has never been represented on the national shield, and it is a fact to be regretted.

INSTITUTION OF CIVIL ENGINEERS: THE PRESIDENT'S ADDRESS.

SIR FREDERICK BRAMWELL delivered a very able and interesting address on Tuesday evening last, on taking the chair, for the first time since his election, as President of the Institution of Civil Engineers. We make the following extracts from it,—Principles are generally very soon determined, and progress ensues, not by additions to the principles, but by improvement in the methods of giving to those principles a practical shape, or by combining in one structure principles of construction which had hitherto used apart. So far as novelty in the principle of girder-construction is concerned, I must confine myself to that combination of principles which is represented by the suspended cantilever, of which the Forth Bridge, only now in course of construction, affords the most notable instance. It is difficult to see how a rigid bridge, with 1,700 ft. spans, and with the necessity for so much clear-headway below, could have been constructed without the application of this principle. The St. Louis Bridge of Mr. Eads may, I think, be fairly said to embody a principle of construction novel since 1862, that of employing for the arch-ribs tubes composed of steel staves hooped together. In suspension bridges there has been introduced that which I think is fairly entitled to rank among principles of construction, the light upper chain, from which are suspended the linked truss-roads, doing the actual work of supporting the load, the rods being maintained in straight lines, and without the flexure at the joints due to their weight. In the East River-bridge, New York, there was also introduced that which I believe was a novelty in the mode of applying the wire cables. These were not made as untwisted cables, and then hoisted into place, thereby imposing severe strains upon many of the wires composing the cable, through their flexure over the saddles and elsewhere, but the individual wires were led over from side to side, each one having the length appropriate to its position, and all, therefore, when the bridge was erected, having the same initial strain and the same fair play. The employment of testing machines has come into the daily practice of the engineer. In lieu of such machines being used, by the few, and at rare intervals upon small specimens, for experimental purposes, they are now employed in daily practice and on a large scale. In harbour work we have had the principle of construction employed by Mr. Stoney at Dublin, where cement masonry is moulded into the form of the wall, for its whole height and thickness. By a very carefully thought-out apparatus blocks are raised off the seats whereon they have been made, and are transported to their destination. It is no simple undertaking (even in these days) to raise (otherwise than hydraulically) a weight of 350 tons, which is the weight of the blocks with which Mr. Stoney deals. An extremely ingenious mode of dealing with the slack chain prevents its becoming fouled and not paying out properly when the block is being lowered. This is accomplished by reeving the slack of each chain over two fixed sets of multiple sheaves, and, automatically, the slack is kept clear. A noteworthy instance of the use of pneumatic appliances in cylinder-sinking for foundations is that in progress at the Forth-bridge. The wrought-iron cylinders are 70 ft. in diameter at the cutting edge, and have a taper of about 1 in 46. At their bottoms there is a roofed chamber, into which the air is pumped, and in which the men work when

excavating, this roof being supported by ample main and cross lattice girders. At the Tay-bridge, also now in course of construction, the cylinders are sunk, while being guided through wrought-iron pontoons, which are floated to their berths and are then secured at the desired spot by the protrusion, hydraulically, of four legs, which bear upon the bottom, and thus, until they are withdrawn, convert the pontoon from a floating into a fixed structure. Modes of "cut and cover" have been proposed for the performance of sub-aqueous work, sometimes by means of cofferdams, and with the work therefore open to the daylight during execution, and sometimes by moveable pneumatic appliances. A construction known to very few is the diving apparatus known as the "Bâteau-plongeur," and used at the "barrage" on the Nile. This consists of a barge fitted with an air-tight cabin, provided with an air-lock, and baving in the centre of its floor a large oval opening, surrounded by a casing standing up above the water-line. In this casing another casing slides telescopically, the upper part of which is connected to the top of the fixed casing by a leather "slieve." When it is desired to examine the bottom of the river the telescopic tube is lowered till it touches the bottom, and then air is pumped into the cabin until the pressure is sufficient to drive out the water, and thus to expose the bottom. This appears to be a very convenient arrangement for shallow draughts of water. Mr. Stoney uses for the greater depths he has to deal with, when preparing the bed to receive his blocks, a diving apparatus which (while easily accessible at all times) dispenses with the necessity of raising and lowering, needed in an ordinary diving-bell, to allow of the entrance and exit of the workmen. Mr. Stoney employs a bell of adequate size, from the summit of which rises a hollow cylinder, furnished at the top with an air-lock, by which access can be obtained to the submerged bell. In the dress of the diver there has been general improvement in detail and manufacture, in the application of the telephone, and in the introduction of the chemical system of respiration, the invention of Mr. Fleuss. He has succeeded in devising a perfectly portable apparatus containing a chemical filter, by means of which the exhaled breath of the diver is deprived of its carbonic acid; the diver also carries a supply of compressed oxygen from which to add to the remaining nitrogen oxygen in substitution for that which has been burned up in the process of respiration. Armed with this apparatus a diver is enabled to follow his avocations without any air-tube connecting with the surface; indeed, without any connexion whatever. A notable instance of a most courageous use of this apparatus was afforded by a diver named Lambert, who, during one of the inundations which occurred in the construction of the Severn Tunnel, descended into the heading, and, proceeding along it for some 330 yards (with the water standing some 35 ft. above him), closed a sluice door through which the water was entering the excavations, and thus enabled the pumps to mowater the tunnel. Altogether on this occasion this man was under the water and without any communication with those above for one hour and twenty-five minutes. The apparatus has also proved to be of great utility in cases of explosion in collieries, enabling the wearer to safely penetrate the workings, even when they have been filled with the fatal choke-damp, to rescue the injured or to remove the dead. In sub-aqueous work, where the influx of water is a source of great difficulty, perhaps nothing has been devised so ingenious as the Thames Tunnel shield; improvement has, however, been made by the application of compressed air. In the instance of the Hudson River Tunnel, the work was done in the manner proposed so long ago as the year 1830 by Lord Cochrane (Earl Dundonald). There are, happily, cases of sub-aqueous tunnelling where the water can be dealt with by ordinary pumping power, more or less extensive, and where the material is capable of being cut by a tunnelling-machine. This was so in the Mersey Tunnel and would be in the Channel Tunnel. In the Mersey Tunnel and in the experimental work of the Channel Tunnel Colonel Beaumont and Major English's tunnelling-machine has done most admirable work. In the 7 ft. 4 in. diameter heading in the new red sandstone of the Mersey Tunnel a speed of as much as 10 yards forwards in twenty-four hours has been averaged, while a maximum of

of 11 yards 2 ft. has been attained, while in the 7 ft. heading for the Channel Tunnel, in the grey chalk, a *maximum* speed of as much as 24 yards forwards in the twenty-four hours has been attained on the English side, and with the later machine put to work at the French end a *maximum* speed of as much as 27 yards 1 ft. forwards in the twenty-four hours has been effected. In ordinary land tunnelling since 1862 there has been great progress by the substitution of dynamite and preparations of a similar nature for gunpowder, and by the improvements in the rock-drills worked by compressed air, which are used in making the holes into which the explosive is charged. For boring for water and for many other purposes the diamond drill has proved of great service, and most certainly its advent should be welcomed by the geologist, as it has enabled specimens of the stratum passed through to be taken in the natural unbroken condition, exhibiting not only the material and the very structure of the rock, but the direction and the angle of the dip of the beds. . . . In the days of Brindley and of Smeaton canals and canalised rivers formed the only mode of internal transit. The competing railway was in a position to take away even the local traffic of the canal. Canal proprietors have from time to time endeavoured to improve the rate of transport, and with this object have introduced steam in lieu of horse haulage, and by structural improvements have diminished the number of lockages. By inclined planes barges were transferred from one level to another, but an important improvement is the application of direct vertically-lifting hydraulic power. This system reduces the consumption of water and the expenditure of time to a *minimum*. With respect to canalised rivers, if means could be devised for giving full effect to the river channels for flood purposes, while maintaining them for the provision of motive power and of navigation, it is desirable that this should be done. The great step in this direction appears to be the employment of ready, or it may be of automatically, movable weirs. Messrs. Vernon Harcourt and R. B. Buckley, in the session of 1879-80, dealt with foreign, notably with French and Indian, examples. An instance of improvement since then has been the construction by Mr. Wiswall, the Engineer to the Bridgewater Navigation Company (on the Mersey and Irwell section of that navigation), of the movable Throstle Nest Weir at Manchester. By the adoption of movable weirs, rivers in ordinary times may be dammed up to retain sufficient water to admit of a paying navigation and water for the mills on their banks, while in times of flood they shall allow channels as efficient for relief as if every weir had been swept away. The great feature of late years in canal engineering is the provision of canals for saving circuitous journeys in passing from one sea to another, or for taking ocean steamers many miles inland. But the old fight between the canal engineer and the railway engineer, or, more properly speaking, between the engineer when he has his canal "stop" on and the same individual when he has his railway "stop" on was revived, even in the case of the transporting of ocean vessels from sea to sea, for Mr. Eads is proposing to connect the Atlantic and the Pacific Oceans by means of a ship-railway across the Isthmus of Panama. He suggests that the largest vessels should be raised out of the water in the manner commonly employed in floating docks, and should then be transferred to a truck-like cradle on wheels, fitted with hydraulic bearing-blocks (this being, however, not a new proposition as applied to graving docks), so as to obtain practical equality of support for the ship, notwithstanding slight irregularities in the roadway; while he proposes to deal with the question of changes of direction by the avoidance of curves and by the substitution of angles, having at the point of junction of the two sides turntables on which the cradle and ship will be drawn. These can be moved with perfect ease, notwithstanding the heavy load, because the turntables will be floating in water contained in circular tanks. The question of preserving the level of the turntables, whether unloaded, partially loaded, or loaded, is happily met by an arrangement of water ballast and of pumping. Mr. Eads has so dealt with the mouth of the Mississippi as to cause that river to scour and maintain a channel 30 ft. deep at low water, instead of that at 8 ft. deep which prevailed there before his skillful treatment. Sir Charles Hartley has

been successful in improving the navigation of the Danube, and one of the lectures of the forthcoming series, on "Inland Navigation," is to be delivered by him. There are many improved machines for excavating, to be used either below water or on dry land. . . . Probably few materials have been found more generally useful to the civil engineer in works which are not of metal than has been Portland cement. During the last twenty-two years great improvements have been made in the grinding and in the quality of the cement. The artificial material, brick, cannot in these days be said to surpass in quality the bricks used by the Romans in this island 1,900 years ago, but as regards the mode of manufacture and the materials employed there is progress to be noted. The brick-making machine and the Hoffmann kiln have economised labour and fuel, while attempts have been made, which I trust may prove successful, for utilising the clay which is to be found in the form of slate in those enormous mounds of waste which disfigure the landscape in the neighbourhood of slate quarries. Certain artificial stones, moreover, appear at last to be made with a uniformity and a power of endurance, and in respect of these qualities compare favourably with the best natural stone, and still more favourably having regard to the fact that they can be made of the desired dimensions and shape, thus being ready for use without labour of preparation. Of timber in new countries the engineer is commonly glad to avail himself to an extent which among us is unknown. Owing to the ready adaptability of metals to the uses of the engineer the employment of wood is decreasing. Many attempts have been made to render timber proof against the two great defects of rapid decay and of ready combustibility. The asbestos paint is used to coat the wooden structures of the Inventions Exhibition. To the employment of this it is not too much to say those buildings owed their escape in last year's very dry summer from being consumed by a fire that broke out in an exhibitor's stand, destroying every object on that stand, but, happily, not setting the painted woodwork on fire, although it was charred below the surface. A surface application may not enable wood to resist the effects of a continued exposure to fire, but it does appear that it can prevent its ready ignition. Eight years since I delivered at the Royal Institution a lecture on "The Future of Steel," and every year that has passed has justified the opinions I then ventured to put forward as to the way in which steel, made by fusion, would supersede iron made by the puddling process; and I am not afraid to repeat my prophecy that the time will come when the use of iron made by that process will be restricted to the manufacture of the small articles produced by the hand labour of the village blacksmith, for whose art its plastic character and ready power of welding eminently fit it. . . . Excepting in the magnitude of the work and the excellence of the design, of which the new Liverpool waterworks now in progress may well stand as a typical example, there is not much to say as regards progress in those waterworks which are dependent upon storage. In the United States and Canada the waste of water that takes place not only causes the mains to be incapable of keeping up the pressure under the excessive draught, but renders sources of supply insufficient which otherwise would be ample for years to come. Progress has been made here in the matter of house-fittings, by which waste has been greatly checked, and the risk of contamination that formerly existed with certain closet-fittings is ended. This question of house-fittings has always been a difficult one, and cannot be grappled with by water authorities such as those in the United States and in Canada, i.e., municipal authorities afraid of offending the voter. We owe it, however, to Mr. Deacon, the engineer of an English municipal water authority, that it is now possible to deal with the correction of household fittings at a minimum of cost, and, what is equally important, with a minimum of annoyance to the householder. By the employment of the waste-water meter, situated under the flagstones of the footway, and controlling a group of houses, it is possible to find out the total waste in the whole of those houses, and on the mains supplying them; then to localise that waste so as to attribute its true proportion to the houses that are the offenders, and to attribute the proportion, if any, to the pipes of the suppliers of water.

Having ascertained these facts, not only can the suppliers of water cure the defects in their pipe system, but they are enabled to cure the household waste, not by the expensive and annoying process of an inspection of the fittings throughout the whole district, involving the annoyance of, say ninety householders whose fittings are in perfect order to detect the ten householders whose fittings are in a reprehensible condition, but by the mere visitation of those ten who are in default, and who cannot, therefore, complain of the visitation. In most of our towns the supply is satisfactory, but in spite of the alarm raised by the suggestion of double mains, we might do well in many cases where there is a pure but limited supply to have a dual system of mains, and thus to distribute the pure water separately and for potable purposes. The Parisians, at least, have recognised the expediency of thus sorting their supply when that supply is of varying quality, and when the best of it is limited in quantity. In cases where there appears to be no thoroughly satisfactory source of water, the experience of the efficacy of iron purification, as practised at Antwerp, does hold out very considerable promise.

THE APPLICABLE ORNAMENTATION OF WORKS IN IRON.

The following is a portion of a paper read last Wednesday evening, at the Civil and Mechanical Engineers' Society, by Mr. Richards, J. U. —

"Before coming to the subject of exposed or visible ironwork, I should like to say a few words on the covering of such structural ironwork as is necessarily concealed, I mean in buildings which it is desired to render fireproof. In these cases it is now generally accepted as an axiom, "that no building can be fireproof unless all constructive ironwork is protected", and here arises a strong temptation, in protecting the construction with concrete or terra cotta, to assume that one is at liberty to imitate the forms of stonework, and to revert to old and well-established proportions. The argument commonly advanced is: that in such a case your ironwork is the skeleton only, and that as in the human body the bones are clothed with a beautiful form unlike themselves, we may clothe our iron skeleton in any beautiful form that we like; but the analogy, as commonly applied, will not hold good; to cover the iron construction with an imitation of stone construction, is to cover a skeleton of iron, which is supposed to be ugly, with a sham skeleton proper to another body, which is held to be beautiful, instead of surrounding the bones with a beautiful exterior that shall still indicate their forms and proportions.

The application of our principles to such cases will lead us to indicate the forms of our construction, if, for instance, we have to protect a station of the H-form, its general outline being a square or an oblong, suggests a clothing of similar form; if of the + pattern, the plan

of its covering should preserve the cruciform shape in its faces while the angles might be filled in with splays or moldings: such treatments are truthful, exhibit thoughtful design, and better preserve the proportions of the constructive forms.

A circular column would naturally have a circular encasement, but again the proportion should not be destroyed, and direct imitation of stone columns should be avoided as far as possible. Girders and cantilevers should be dealt with in the same manner.

The faces of the casing can, of course, be decorated with panelling, banding, and so on, in any way suitable to the material used for the purpose, and to its position. We thus see that, even where our ironwork is hidden, attention to artistic principles will guide us to original and appropriate ornamentation.

Coming now to exposed or visible ironwork, let us first glance at the natural treatment of wrought iron. We have here a material which can be rolled, hammered and forged, bent, twisted, or perforated, built up or framed and jointed, in various ways: the webs of plate girders and of cantilevers can be ornamented by perforation, while in built-up girders of the lattice or the Warren kind the actual construction often gives an ornamental form; the

various parts,—the lattices, for instance,—might often be made decorative by being fashioned or cut, especially where they are formed from plates rather than angle or T-irons, and the joints should receive more consideration artistically than is usually bestowed upon them; although no unnecessary features are to be added for the mere sake of ornament, a few pounds weight of iron added to the necessary features, to allow of their being made ornamental, as well as useful, is perfectly legitimate. The application of hammered scrollwork to some of the parts of built-up structures, if not overdone, is an evident means of obtaining beauty and giving interest to the work.

In large roofs, or in bridges, I look to the further development of the combination of cast with wrought iron, as opening a wide field for ornamental treatment.

When we turn to cast iron, we are dealing with a material which, as used for structural purposes, is but little older than the century in which we live, and for the treatment of which there is no direct precedent. Here we have a material which, as its name indicates, is cast in a mould, and which, consequently, shares with other materials, which are similarly treated, the liability,—owing to the cheapness with which such decoration may be produced,—to be ornamented with imitations of carved and band-wrought work. There are, however, difficulties of manufacture connected with the casting of iron, especially in large pieces for structural purposes, which will guide and limit us in seeking for the appropriate ornamentation of it. One principal point is that in designing for cast iron, the material must, as far as possible, be of uniform thickness throughout, otherwise we shall have cracks and flaws in the process of cooling; this shows at once that our ornament should avoid anything like undercut carving, any system of design that calls for projecting knobs or blocks, which cannot be easily cored; it also shows that, for the same reason, our mouldings and surface ornament should be of slight projection, and without deep sinkings or hollows, unless the back of the casting can be made to follow the face surface, without affecting the strength, and without adding undue difficulty to the process of manufacture.

In designing a column or stanchion for execution in cast iron, we will consider first its form on plan. The circular hollow form gives, of course, the most economical use of material, but has certain disadvantages. You cannot get at the interior for examination or for painting, and you cannot easily see that you have the necessary uniform thickness of material throughout. For these reasons I am inclined to prefer the stanchion, as being better suited to the character of the material.

If, however, a hollow column be used, other forms than the circle may be adopted, such as the square, with rounded or moulded angles; the regular octagon, with or without projecting faces; the irregular octagon,—that is, one with four main faces and four subordinate ones, which may be moulded,—and others which will suggest themselves to you. The advantages of these forms of plan are, less likelihood of imitation of stone details, greater appearance of stability, owing to the actual increase in size, as well as to the apparent increase when such forms are seen in perspective, and the advantage which flat faces offer for the proper treatment of the capitals. The last reason also suggests that where circular columns are adopted, slightly projecting vertical fillets should be added, carrying down the lines of the brackets at the top, and giving an appearance of rigidity to the shaft.

In detached stanchions the cross-with-equal-arms plan seems the best in ordinary circumstances, but often the form of the stanchion should, I venture to think, be suggested by the superstructure which it has to carry.

In dealing with these supports in elevation, I will speak first of the capital or top. A capital, in the ordinary sense, as applied to a stone column, is not wanted at all; such a capital is a separate block of stone placed on the shaft, and ornamented by moulding or carving cut into its solid mass; these have, however, formed the types from which cast-iron capitals have been generally derived, and most unsatisfactory we all know their effect to be; for instance, we see a Corinthian capital, or some approach to one, in such a position; now, from association of ideas, we expect to find below a Corinthian capital a column of the usual Corinthian proportion, that is, about ten diameters high, in-

cluding the eap and base: so by putting this capital, we challenge comparison between the proportion of our iron column and the old stone one, and the consequence is that the iron is denounced as a wretched, skinny abortion, or in some other equally uncomplimentary phrase.

In designing the top of a column or a stanchion for pure utility, as in some position where it is not to be seen, what do you do? You put at the top a projecting flange, somewhat like what we architects call the shanks, but with projection enough to allow of the proper bolting of the girder, or whatever else is to be carried; you then arrange brackets, cast on, to carry this top flange. Let us treat our ornamental capitals on the same lines and we shall satisfy our artistic principles, and not set a-going any invidious comparisons between our works and those of the masons.

I have ventured to prepare a sheet of illustrations showing how this may be attempted. I do not, of course, put these designs of mine forward as being perfect, or claim for them anything more than that they are attempts to grapple with the problem of uniting to sensible and natural construction such ornament as is appropriate to the nature of the material. You will see that I have everywhere used what I will call the bracket form of capital and shown how it may be applied to different kinds of columns and stanchions.

In dealing with the shafts all the edges may well be moulded in a very simple and refined manner. This is almost suggested by the difficulty of obtaining absolute squareness in section when you have to withdraw a casting from a mould. The surfaces may be panelled and the panels enriched, but all sinkings should, of course, be very slight, not only for the practical reason to which I have already referred, but because this again suggests the character of the material and its method of manufacture. Plates running the entire length of the column should certainly be avoided; it is difficult to get true lines in them. They make a small column look smaller and taller than it really is, and they are imitations of a familiar form of stone ornament. Horizontal bands around the columns, however, will always tend to increase the apparent diameter, and so are valuable. Short lengths of fluting between these bands, and in such positions as the tops of the columns, where they add apparent stiffness and power to support the weight, may be used, but they should be small and sharp in section, instead of wide and flat, as in stonework, as they then suggest the hardness of the material.

In the cross-shaped stanchion you will see that I have introduced small horizontal stiffeners or flanges, and endeavoured to treat them ornamentally; although these only add slightly to the actual strength, they are very valuable artistically, as seeming to bind the whole together; they also serve the same purpose as the bands on the columns, by adding apparent breadth.

When foliated ornament is used, although we should not imitate stone or wood carving, we can hardly expect to invent an entirely new system of foliage for our purpose; and it is not only quite legitimate to turn to the works of the past for suggestions, but it is our duty to do so, otherwise we throw away a part of our heritage.

In what direction should we make our investigations? We require low relief, and that sharpness and crispness of outline which should accompany it, if it is to be effective. This we shall find in the early Greek work which was executed in a hard material, in the Byzantine work, which inherited the traditions of the Greek, and,—for surface and panelled decoration,—in much of the early Renaissance detail; learning from these beautiful works of former ages, we may, without servile imitation, obtain in time a modified and consistent system of iron foliated ornament. One word more under this head: Our foliated ornament must be conventional; naturalistic decoration is seldom satisfactory in effect when applied to any part of a structure which appears to be doing work,—that is, carrying a load, or resisting a thrust, and never, unless it comes direct from the hand of the artist, in the form of carving or of painting.

The remarks which I have made as to mouldings generally apply of course to the ornamental bases of columns; these should have very slight projection, and be in no way imitations of the ordinary stone base, with its deep hollows, and bold rounds. The use of

stanchions will get over all this difficulty, as each face would have its own projecting mouldings, possibly connected by a horizontal band.

In cantilevers or large brackets, modelled or perforated ornamentation will be used in the spandril panels, which the forms of these features will suggest. Such ornament might be arranged with projections, producing the effect on one side, and sinkings on the other, so that the thickness of the whole might be fairly uniform in all its parts. Cantilevers should never be cast hollow, but always with a visible web of the necessary thickness only.

In America whole fronts of business premises are sometimes constructed of iron; and in many cases, in our own city, where every inch of window space is of importance, the same system might be adopted with advantage. Such fronts, to be artistically good, will need very careful designing. We must cast ourselves loose from old traditions, and work in the spirit which I have tried to indicate to you. There must be no great hollow sham cornices and strings carried on hollow, closely-spaced cantilevers, such as I have read of in accounts of the American examples. With a sheet of drawing-paper and time to spare I think that I might work out something that should obey the laws of art, but, until I have done that, I am afraid that I can hardly launch into a detailed description of such a front. I should certainly start with honest stanchions and girders, and where I had any surfaces to cover, I think that wrought-iron plates with ornamentally-cut edges, or cast-iron modelled panels, would be the line I should first try."

THE SURVEYORS' INSTITUTION EXAMINATIONS, 1885.

UPWARDS of 100 candidates have entered their names for this year's examinations. Of these, fifty-five offer themselves for the Students' Entrance Examination, on the 20th and 21st inst., and the remainder for the professional examinations in April next for land agents, valuers, and building surveyors. Under the provisions of the Charter, candidates for the Professional Associateship can now enter by examination only. The Compulsory Examination for the Fellowship does not come into force for several years to come, but a considerable number of candidates who have already passed the Professional Associates' Examination have offered themselves for the voluntary examination for this class.

LINE OF FRONTAGE.

At the Hammersmith Police Court Mr. William Pears, of Houghton-place, Amplehill-square, was summoned by the Metropolitan Board of Works for unlawfully, and without the consent in writing of the Board, erecting or causing to be erected certain buildings or structures known as Nos. 2 and 3, Elysium-row, King's-road, Chelsea, beyond the general line of buildings in the said row, contrary to 25 & 26 Vict., c. 102, sec. 75. Mr. Burton, solicitor, appeared for the Board, and Mr. Glyn for the defendant.

Mr. Geo. Vulliamy, the Superintending Architect, having been called to prove his certificate, stated that the buildings were 5 ft. in advance of the general line of buildings, and he had so certified.

Mr. Glyn raised an objection that the Board were out of time in taking their proceedings, six months having elapsed since the buildings were commenced, and that the shops were erected on ground previously occupied by old buildings; and called evidence to show that the works commenced in April last, and notice thereof given to the District Surveyor, and that the shops were erected upon the old site.

Mr. Paget said he should hold the objections good, and dismissed the Board's summons, with 5*l.* 5*s.* costs.

"Wolves in Sheep's Clothing."—Under this title our monthly contemporary, the *Plumber and Decorator*, makes a good onslaught on sham plumbers and their ways, and calls attention to a number of little insidious dodges, and the nature of the men who practice them. "The following announcement will give some idea of what manner of man the so-called plumber frequently is:—'X. Y. Z. buys all sorts of old furniture, &c., &c., at the best prices. If you want a plumber or general house repainer, go to X. Y. Z., who will execute the work and take any old lumber in exchange.' The man is disguised under the above initials, but we have reason to believe his name to be legion."

ARCHITECTURAL SOCIETIES.

Birmingham Architectural Association.—The third ordinary meeting of the current session took place at Queen's College on Tuesday evening last, when Mr. W. H. Kendrick, Vice-president, was in the chair. Mr. J. Goodman was nominated as an ordinary member. A paper was read by Mr. W. Hawley Lloyd, on "Four Years' Experiences of the Restoration of a Cathedral Church." The lecture was illustrated with a large plan of Worcester Cathedral, and several views and sketches made by the author during the period of the restoration. A vote of thanks, proposed by Mr. J. King James, seconded by Mr. J. Cotton, and supported by the Vice-president, was unanimously accorded to the lecturer for his interesting paper. On the motion of the Vice-president, seconded by Mr. Victor Scruton (hon. sec.), it was requested that Mr. Hawley Lloyd be good enough to supplement his remarks by conducting the members of the Association over Worcester Cathedral some time during the present session. The lecturer agreed to do so.

Edinburgh Architectural Association.—At the meeting of this society on Monday evening last, Mr. Washington Browne in the chair, Mr. John Kinross read a paper on the subject of "The Study and Progress of Architecture." After a humorous reference to the way in which many young men found themselves in what he called an "ill-paid profession," Mr. Kinross proceeded to notice the chaotic state in which the question of style was at present, and the difficulties which that presented to a student in determining what style he should devote his attention to. For a comprehensive study of architecture time and means were necessary, and he advocated, if that were possible, the study of the noble works of Italy and Greece, not merely from drawings, but as they stand on Italian and Grecian soil. The refining effect of such study could not be over-estimated. He differed from Fergusson in thinking that Scottish work was not worthy of study. There was much beautiful early work still remaining in Scotland, and also admirable domestic work, which, perhaps, deserved to be studied more than any other kind of Scottish work. Scottish country mansion-houses seemed to grow out of the ground; they fitted in to nature; and the proportion of their rooms and the beautiful detail that was in them made them worthy of study. In speaking of modern progress, Mr. Kinross said they had in Edinburgh a very brilliant example as to the effect of very careful study of the Italian Renaissance and a judicious use of the best materials; and they had a very fine example of what the study of their old Scottish would lead to in the new block built by Mr. Finlay at the Water of Leith. These buildings, though in very different styles, showed beautiful results of careful study and good taste. In England, it was remarked, great progress had been made during the last twenty years, and of that some account was given,—the work of the leading architects being referred to.

Leeds and Yorkshire Architectural Society.—On Monday evening Mr. J. A. Gotch delivered a lecture to the members of this Society at their rooms in Albion-street, Leeds, on "English Houses in the Seventeenth Century." The accommodation in those days was very much the same as it was now, but it was arranged in a much less convenient manner. Magnificence was the chief characteristic, and for this purpose a good deal of comfort was sacrificed. The lecture was illustrated by means of diagrams, one of which represented a place built by the Earl of Dorset, who succeeded Lord Brough in the office of Lord High Treasurer; another illustrated the house of a squire of the time, such as Francis Tresham, who was implicated in the Gunpowder Plot; and a third showed the house of Sir Walter Raleigh. The lecturer quoted from the works of poets of the seventeenth century, thus bringing contemporary witnesses to give their evidence with regard to the home life of the period. The President of the Society (Mr. Edward Birchall), who occupied the chair, said it was intended to have brought forward the question of the proposed incorporation of the society at that meeting, but the subject had been postponed.

Mr. Alfred Meeson, architect of the first Alexandra Palace, died at his residence, No. 4, Harley-road, South Hampstead, on Jan. 12th, 1885, aged 76 years.

A CLUB-ROOM AT THE INSTITUTE.

SIR,—Your correspondent last week (p. 85) appears to misunderstand me. For a number of years past the question has been brought up in a decided way from time to time, whether the architectural profession could be provided with a *rendezvous*, of the nature of a club-room, probably at the Institute; and my proposal is that those who are in favour of such a measure might, perhaps, be encouraged at the present time to consider how far the recently-acquired and little-used "arbitration room" could be made available for this purpose. This purpose, as I understand, is simply to have a room at headquarters set apart during two or three hours in the afternoon for a casual *rendezvous*, where a member, having anything on his mind, might expect to meet some other members to compare notes with. I am told this would be useful to many in business, and agreeable to many more in respect of fraternal intercourse. For my own part, I am disposed to support the principle to the utmost. I feel that our profession is sadly in want of some bond of real practical union, which this might be made to supply. The formal meetings of the Institute are not enough. I cannot help thinking that in my younger days we had more true fellowship amongst us than we have now. As we expand in numbers, our cohesiveness diminishes. Anything, therefore, that would serve to bring us together, not merely formally once a fortnight, but informally any day, would be a step in the right direction. Surely no one can dispute this in principle; how to accomplish the object, and under what restrictions, I regard as matters of detail.

ROBERT KERR.

RIGHT OF WAY.

SIR,—Can any of your readers inform me if there is a fixed width for a private right-of-way entrance for carts and vans over one field to another for agricultural purposes? If so, what is the width, and do you measure from hedge or ditch, or where could I get the information? It is an acquired right by user, not by grant, and is situate in Essex.

I am about to lay a field out for building, and this entrance is on one side of it, next the ditch, and I want to know what width I must give. A. B.

CHURCH-BUILDING NEWS.

Macclesfield.—The parish church, dedicated to St. Michael, was re-opened, after partial restoration, on the 7th inst. Probably the only part of the original edifice is some portion of the basement of the tower. This tower, and the two chapels on the south side (one belonging to the Leghs of Lyme and the other erected by Thomas Savage, archbishop of York, who died A.D. 1507), are the only portions of the edifice which boast of anything like antiquity. It is intended to thoroughly restore the church in sections, and this present section, No. 1, just completed, embraced, in the main, the extension of the chancel and north aisle eastward, and the additions of clergy and choir vestries on the south side. The state of the vaults by which the basement of the edifice is everywhere fairly boneycombed, gave rise to many unexpected difficulties, but all the work is now well got over. Tegsnose, Cefo, and Alderley stones are used in the new masonry, and the roofs are of oak. There is a handsome mosaic floor in the chancel, into which a large figure of St. Michael is skillfully introduced. This is by Messrs. Patterson, of Manchester. The stone carving is by Mr. Harry Hems, of Exeter, and the heating apparatus, which has been placed under the north chapel, has been supplied by Mr. Harlow. Mr. Westwood did the gas-fitting, and Messrs. Martin, Ferrar, and Mellor the glazing. The general contractor was Mr. H. S. Aspinall, of Macclesfield, and the architect under whom the works have been carried out was Mr. James Stevens, F.R.I.B.A., of Mosley-street, Manchester, and Macclesfield.

Chipping Norton.—In connexion with the restoration of St. Mary's Church, Chipping Norton, a handsome marble mosaic pavement has been laid in the chancel, also Irish fossil steps. The whole of the aisles, &c., have been laid with marble mosaic, the work being done by Mr. Jos. F. Ebner, Clerkenwell-road, Hatton Garden, London.

Bronpton (Hunts).—A new reredos, designed by Mr. A. W. Blomfield, was fixed in this church for the Christmas festival. It is executed in rich-coloured alabaster. In the centre arch is the Crucifixion, and in the side arches Dorcas and Mary of Bethany, the nobleman of Capernaum and Cornelius; these are of painted tiles and mosaic, by Messrs. Powell & Sons, of Whitefriars; and the alabaster work is by Messrs. Earp, Son, & Hobbs, of London and Manchester.

Hornhill.—The ancient and picturesque parish

church of Hornhill, Kent, was the scene of an interesting service on the 3rd inst., the occasion being the dedication of a reredos, which has been presented to the church by Mrs. Warton, of Kemsdale. The nave of the church was restored some six years ago, but the cast end of the chancel presented a somewhat bare and unfinished appearance. This is now remedied by the erection of the reredos, which is of Caen stone, with pillars and facings of marble. A special interest attaches to this material, as it was procured from the ruins of Rome. The reredos was designed and executed under the direction of Mr. James Forsyth, of Hampstead, whose works in our cathedrals and elsewhere are well known. The design includes the various Evangelical symbols; the Alpha and Omega, at the extremities; and the Latin and Greek monograms of our Lord's titles, on each side of the central compartment, in which is represented the Archangel Michael,—the parish church being dedicated in his name. Curtains, which were manufactured by Messrs. Helbrouner, are hung between the reredos and the north and south walls. The reredos has been erected as a memorial of the late Mr. Charles Warton, J.P., by his widow.

The Student's Column.

LIME, CEMENT, AND THEIR USES.—III.

THE theory of a lime-mortar is not quite the same as the theory of a cement-mortar, for the reason stated when describing the natures of limes and cements. The cement being strongest when used by itself, it necessarily follows that all additions of sand reduce the strength of the mortar, and that the quantity of sand added determines the strength which is required of the mortar; in fact, the cement is "let down" to the desired strength by the addition of the sand. A lime-mortar is different; it has been explained that limes, more especially the rich limes, have but little power of cohesion, therefore when used neat they are at their weakest; but by the addition of sand in a proper proportion the lime, by adhering to each particle, is enabled to develop its full power of adhesion, while the requirements of cohesion are reduced to the minimum, or that a lime is "worked up" to the desired strength by the addition of the sand. Thus, though the desired result is obtained by the same means, whether using cement or lime as a matrix, the action in the one case is exactly the reverse of the other. The object to be obtained is, of course, the maximum of strength at the minimum of cost.

It will now be seen in what manner the size and form of the grains of sand act in producing a strong and economic mortar. Whether it be a cement or lime mortar which is being made, the object is to surround each grain with a coating of the matrix, that the coating of matrix shall be even in thickness throughout the mass, and that there shall be no space between the grains of sand, which must either be left vacant, or must be filled with the matrix. In the former case they would be a source of weakness, and in the latter there would be a waste of material. A round globular grain is evidently, therefore, the worst that can be used; if a perfectly square grain of even size could be found, and it could be ensured that the grains would all lay square with each other, the minimum of matrix would be required, for the mortar would be itself like a piece of masonry. This, however, is impossible, even if it were desirable. Now if a sand is obtained which is composed of sharp irregular-shaped grains, of varying size, it can be well understood that the matrix can be so intimately mixed with it that while in some cases the larger pieces are in juxtaposition on some part of their surface, the smaller grains would fill up those voids caused by their irregular form, and a thoroughly homogeneous mass secured, which would contain the maximum of sand with the minimum of matrix.

There has lately been a considerable correspondence in the columns of the *Builder* as to the value of sea sand as a building material,—the question asked being whether the salt would not act deleteriously on the mortar made with it. It may be at once stated that if the sand is to be used for concrete underground, or anywhere out of sight, where the efflorescence arising from the presence of the salt is of no importance, sea sand has the same value as other

which value would be determined in ordinary way by its sharpness and size; for it must not be assumed that sand is always the same,—it varies in all things in nature. As a rule, however, and is mechanically a good building sand, or the purposes of ordinary work it must be used with clear water, and washed well, in order to remove from it all traces of salt; otherwise the salt will continually work out to the surface of the work, and spoil it by efflorescence and dampness. For this reason only must the salt be eliminated. As a matter of construction a partially-washed sea sand will be of more value than one perfectly clean, for chloride of sodium in sea salt, in all quantities, though it retracts the setting limes and cements, eventually increases its hardness.

The larger pieces of stone or aggregate which are used to make a concrete deserve equal, if greater, care in their selection than the smaller. The definition of a sound concrete is the same as that of a mortar, with the difference that in the case of concrete the mortar, the combination of cement or lime and sand, may be considered as the matrix and the stones as the aggregate; it follows, therefore, that no two pieces of aggregate must be in contact, but each must be surrounded by the matrix, and each grain of sand in a mortar.

The aggregate should be strong, as it is impossible to make strong work with weak materials; it should be irregular and angular in shape, and it should be clean. The definition of "clean" is not so differently understood, as many are under the impression that if a quantity of stone or rock is crushed or broken to a desired size, the resulting crushed stone is clean. Now, for practical purposes, such is not the case. In crushing or breaking a stone a certain amount of fine impalpable powder is produced, and this is as detrimental to the production of a good concrete, as is loam or any other earthy matter. An aggregate, therefore, should always be washed after, and not before, and should be reduced to the proper size.

In selecting an aggregate smooth glassy surfaces should be avoided,—rough and uneven surfaces, having a certain porosity, make the best concrete, owing to the better adhesion which the matrix has to them. For this reason, when a river ballast or shingle is used it should always be broken in order to break up and destroy the rounded and even surfaces,—but shaly or shingle does not under any conditions make the best concrete, and should only be used for foundations, and similar work where it is likely to have to withstand anything but a pushing force. The best concrete is produced by aggregates possessing the already-mentioned desired properties, such as hard limestones, granites, &c.

The size of the aggregate must vary according to the magnitude of the work in which it is used; the larger the aggregate the less matrix is required, resulting in economy in cost; in foundations, and backing of retaining walls, very large aggregate may be used, provided it is of sufficient strength to withstand the crushing weight put upon it; but in more finished work, where appearances have to be considered, and here it is subjected to other strains besides that of crushing, such, for instance, as walls, doors, &c., it is generally advisable to crush the aggregate to such a size that it will all pass through a ring 2 in. in diameter, for paving slabs, window-sills, steps, and other purpose-made concrete it is usual to crush the aggregate so that it will all pass through a sieve having holes $\frac{3}{8}$ in. square.

The proportion of aggregate to matrix is a matter which requires care in determining in order to obtain the best results; the proportion is determined primarily by the strength required, and secondly by the attainment of that strength at the minimum of cost. The point where strength and economy are attained is when the larger and smaller aggregates and the matrix are so balanced that a solid concrete is produced, without excess of matrix. A very good way of arriving at the amount of matrix required is to take a fair sample of the aggregate which it is proposed to use, divide it by means of sieves into three portions; first, the one representing the sand, which would form with the cement the matrix; secondly, the smaller pieces of aggregate; and thirdly, the larger pieces of aggregate. If sufficient of the larger aggregate be now taken to fill a bucket, or other similar vessel, and water poured into

it until it is full, and the water then measured into another vessel, the exact quantity of smaller aggregate and matrix required to fill the interstices between the larger is ascertained. The height of the water in the measure should be marked and the measure emptied; the smaller aggregate should then be placed in it up to that mark, and water again poured in until the aggregate is just covered; this water, if again poured into a measure, will determine the amount of matrix, i.e., the sand and cement, required to fill the interstices between the smaller aggregate; to the quantities thus arrived at it is necessary to add from 10 to 15 per cent. to allow for the matrix which would be required to go between each piece of aggregate. The quantities of matrix can then be composed wholly of cement or lime, or of one of cement to any proportion of sand which it is thought will be sufficient to give the desired strength. It is perhaps right to mention that the separation of the aggregates into three parts in order to determine the proportion of matrix required, varies somewhat from the usual practice, which is to measure the aggregate in one only; but though taking slightly more trouble, it has the advantage of determining the proportion which the fine, small, and large aggregates bear to each other, and allows of a correction being made in the preparation of the aggregate, should either one be found to preponderate, or be deficient in quantity, and thus a better and sounder concrete is obtained.

The knowledge of the whole of the materials of which mortar is composed having been acquired, the proper means of using them must be studied in order that good and economical results shall be obtained, and the way in which a mortar or concrete is made has as much to do with the result obtained as the choice of good materials; for though it is impossible to obtain a satisfactory result from bad materials, it is always possible to obtain a bad result from the very best materials if they are improperly used.

Errata.—In the second paper on this subject, given by us last week, the reader will, perhaps, note the following corrections:—Page 87, col. 1, line 20 from top, for "need not" read "must not." In the same column, line 34 from bottom, read "never increases much more in strength." On same page, centre column, line 13 from bottom, for "just merits attention" read "first merits attention."

RECENT PATENTS.

ABSTRACTS OF SPECIFICATIONS.

5,936, Improvements in Flooring Cramps. T. Thornton.

The improvements over the ordinary form of flooring cramp are chiefly that the distance between the fulcrum and the weight is lessened by means of a movable end added to the sliding bar, whereby greater leverage is obtained. There are also points of novelty and usefulness in an improved wedge attachment for releasing the bar, and in the tongue until the spring actuating it. A movable end or falling piece is attached to a sliding bar; this piece falls below the end of the bar against a projection or abutment under the bar. A ledge or rim is made on the underside of the wedge to move in a corresponding groove in the sides of the box for the purpose of keeping the wedge when slack or free from the tongue. The tongue is made longer than in the ordinary form of flooring cramp, and some small details of construction are introduced which may be generally regarded as improvements.

2,338, Improvements in Ornamenting Glass. J. Sherrin.

Pieces of glass of various colours are cemented on sheets of glass blinds to doors and windows, and for similar purposes. The pieces are cut into different shapes, and on each piece is put a little cement; it is then placed on a sheet of glass the size of the window, and various pieces added in the same way until the pattern is complete.

2,012, Improvements in the Construction of Sash Pulleys. W. J. Penny.

The object of the invention is to afford a ready means of taking out the pulley-wheel from a sash or other pulley, which would greatly facilitate the execution of repairs when needed. The pulley-wheel is cast with a short central spindle on which are afterwards formed two rims or shoulders, one on each side. The face-plate and pulley-hox is cast in one with two recessed apertures and bearings in the sides of the pulley-hox. The opening in the face-plate, wherein the pulley-wheel, is inserted is recessed to a sufficient width to allow the arms of the pulley-spindle to pass through and drop down into the recessed apertures in the sides of the pulley-hox. When the pulley-wheel is to be removed a Bradawl or other pointed tool is inserted

in a hole made in the periphery of the pulley-wheel, and the pulley-spindle is then lifted over the recessed bearings and the pulley-wheel taken out.

822, Chimney Cowl and Roof Ventilator. A. C. Smith.

The ventilator head is made with any required number of concentric conical guard-rings tapering inward and upward, and with bands fixed to their edges. The first guard-ring overlaps the top of the main shaft, and they are formed so as to leave a central passage upward for the smoke, &c. Vertical guides, at equal distances apart, are fixed between the guard-rings, reaching in an oblique direction from the outer edge almost to the inner edge of the guard-rings, thus causing wind and air to take an upward course. The top may be provided with a cap, with or without a depending curtain.

4,161, Chain Pulleys. R. J. Smith.

Relates to the means of renewing the working parts. For this purpose, in the case of large pulleys the teeth are bolted separately or in series inside the groove of a suitably-turned drum. In the case of smaller pulleys semicircular faced pieces having cupped recesses are bolted against the sides of a central groove. In either case the grooved pulley has radial feathers, wearing-pieces, and key-ways for the same, for the purpose of rendering them immovable in their position.

APPLICATIONS FOR LETTERS PATENT.

Jan. 2.—70, E. R. Wethered, Improvements in Door Lock Furniture.—73, W. Sanderson and T. A. Moffit, Door Latches and Catches.—77, J. H. Stone, Improvements in Call and other Bells.—82, H. Curzon, Preventing the Bursting of Water-pipes from Frost.

Jan. 3.—108, F. Thompson, Improvements in Pocket Saws.—117, J. Bennison, Chimney Pots for Preventing Down-draught and Curing Smoky Chimneys.—136, A. M. Clark, an Improved Girder.—145, J. Tulloch and T. Tulloch, Incombustible Composition for Finishing the Interiors of Buildings.—160, T. E. Fielder, Brick Mould Stock.

Jan. 6.—171, L. Coke, Improvements in Stoves.—202, A. J. Boulton, Improvements in Sieves.—212, H. Salomo, Carrier for Wood-turning Lathe.—217, W. Court, Wood-block Flooring.

Jan. 7.—230, B. Goulton, Improvements in Locks.

Jan. 8.—255, T. Thornton, Window Fasteners.—264, J. Walker, Cupboards and other Door Fastenings.

PROVISIONAL SPECIFICATIONS ACCEPTED.

8,103, W. M. Hawkins, Improvements in the Construction of Buildings.—11,888, W. B. Lake, Protection of Wood or other Materials from Fire.—14,522, F. Jupp, Pneumatic Door-closer.—14,648, J. Samuel, Metallic Roofing Slate.—14,712, J. Meorath, Erection of Fireproof Buildings.—14,847, T. Hawkins, Improved Method of Glazing.—14,908, P. Bowden, Machinery for the Manufacture of Bricks and Tiles.—15,324, G. Usill, Pipe Joints and Joining.—15,334, F. Hobbs, Cement for Lead Light Glazing.—15,927, J. King, Apparatus for Closing and Preventing the Slamming of Doors.—16,154, J. Ball, J. Rawson, and F. Rawson, Manufacture of Chisels, Gouges, and Augers.—15,197, E. Turner and J. Reynolds, Combined Circular Rack and Band Machine for Sawing Timber.—15,204, W. Clynno, with Stop Chamfer and other Wood-working Machines for Shaping or Sharpening the Teeth of Saws.—15,488, C. Hett, Connexion for Water-closets.—15,753, J. Campbell, Ladders or Steps.—15,954, M. Ker, Raising and Suspending Venetian Blinds.—16,068, B. Turner, Door Springs.—16,670, J. Webb and F. Smith, Collar-joint for Sewer and Drain Pipes.—16,950, W. Smith, Manufacture of Portland Cement.

COMPLETE SPECIFICATIONS ACCEPTED.

Open to opposition for two months.

1,322, F. Oldfield, Improvements in Sliding Windows or Sashes.—2,413, D. Griffiths, Improved Roofs.—3,814, W. H. Tylor, Drain Traps.—3,971, E. Pearson, Water-closets.—4,578, A. Chesterman, Improvements in Hinges.—4,720, S. Wilding, Machines for Shaping or Sharpening the Teeth of Saws.—5,050, W. Cunliffe, Imitation Stained Glass.—5,172, W. Greenwood, C. Mitchell, and H. Lund, Weather Bars for Doors.—14,087, J. Farthing and J. Lorrimer, Artificial Asphalte.—3,352, F. Howcroft, Supporting Window Sashes.—4,063, J. Phillips, Gully Tank and Trap.—4,570, S. Slater, Door-sill, Brasses and Securing Same.—4,649, G. Paine, Apparatus for Opening and Closing Swing Sashes, Shutters, and Doors.—4,877, A. Bicknell, Apparatus for Cutting or Surfacing Wood Pavement.—4,973, S. Skinner, Sawing Machinery.—8,749, J. Adams, Door Springs.—15,354, J. Holroyd, Construction of Sewers.—15,720, M. Adams, Ventilating and Disinfecting Apparatus for Sewers, Drains, &c.

The Institution of Civil Engineers.

The newly-elected Council have re-appointed Mr. H. L. Antrobus, the senior partner of Messrs. Conitts & Co., as treasurer, and Mr. James Forrest as the secretary. At the same time Dr. William Pole, F.R.S., was appointed honorary secretary, in the room of the late Mr. Charles Manhy.

RECENT SALES OF PROPERTY.

ESTATE EXCHANGE REPORT.

JANUARY 5.

By W. H. S. GILBERT & Co.
Green Street-green, Kent.—Five freehold cottages... £750

JANUARY 7.

By S. WALKER & RENTZ.
Rotherhithe—14, 16, and 18, Trident-street, 66 years, ground-rent 7l. 4s. 415
23 to 33, odd, Trident-street, 46 years, ground-rent 15l. 665
Shepherd's bush—138, Coningham-road, 79 years, ground-rent 9l. 270

By SCOTFIELD, OMBS, & BUCKLEY.
The reversion of one-fourth of one-eighth share of a ground-rent of 250l. a year, also to the same share of the premises falling due in 1840. 68

JANUARY 8.

By E. & S. SMITH.
Stoke Newington—51, Green-lanes, 30 years, ground-rent 5l. 5s. 245
Enfield, Upper Marston-road.—Two plots of freehold land 60

JANUARY 12.

By J. SPARROW.
Homerton—49, High-street, freehold 400
By E. E. CROUCHER & Co.
Dalston—2, Fasset-road, 67 years, ground-rent 4l. 10s. 340
Clerkenwell—19 & 11, Wilmington-place, and a ground-rent of 4l. per annum, 80 years, ground-rent 3s. 4d. 270

JANUARY 13.

By VENTON, HULL, & COOPER.
Bayswater—56, Chestnut Villas, freehold 1,325
Hastings (near)—Fairlight Cottage, with meadow, 27 years, ground-rent 1l. 10s. 500

By G. F. CALVERT.
New North-road—83 & 81, Street-road, and South Cottage in the rear, 24 years, ground-rent 13l. 10s. 456

JANUARY 14.

By E. W. RICHARDSON.
Clapton—3, Castlewood-road, 34 years, ground-rent 12l. 550
Bow—51, Turner's-road, 80 years, ground-rent, 4l. 10s. 300
Bethnal-green—129, 124, 124, & 126, Old Bethnal-green-road, and 1, Georgestreet, 73 years, ground-rent 65l. 1,206

By TOSKIN & HANBING.
Lewisham—Freehold building site, containing 2a. 0r. 18p. 2,430

By W. B. CRAWFIELD.
Enfield—Bycullah-road, Geldard House, freehold... 1,350

MEETINGS.

MONDAY, JAN. 19.

Royal Institute of British Architects.—Mr. William White on "The Fireproof Closing of Openings in Party-walls under the Metropolitan Building Act." 8 p.m.
Royal Asiatic Society.—8 p.m.
Society of Arts (Continental Lectures).—Dr. G. V. Poore on "Climate and its Relation to Health" (11. "The Effects of Soil, Drainage, and Vegetation upon Climate"). 8 p.m.

TUESDAY, JAN. 20.

Institution of Civil Engineers.—Mr. A. Hamilton-Smythe on "A Comparison of British and Metric Measures for Engineering Purposes." 8 p.m.
Statistical Society.—Dr. Robert Giffen will read some "Further Notes on the Progress of the Working Classes." 7.45 p.m.

WEDNESDAY, JAN. 21.

Builders' Foremen and Clerks of Works Institution (9, Conduit-street, W.).—Annual Meeting. 8.30 p.m.
British Archaeological Association.—(1) Mr. H. Syer-Cuning on "St. Albans, Abbess of Wessex." (2) Mr. C. Lynam on "The Inscription on the Carew Cross." 8 p.m.
Royal Meteorological Society.—Annual Meeting. 7 p.m.
Society of Arts.—Mr. D. Pilson on "Labour and Wages in the United States." 8 p.m.

THURSDAY, JAN. 22.

Society of Antiquaries.—8.30 p.m.
Society of Arts (Howard Lectures).—Mr. W. Anderson on "The Conversion of Heat into Useful Work." 1V. 8 p.m.

SATURDAY, JAN. 24.

Architectural Association.—Visit to St. Marylebone Parish Church. 3 p.m.

Miscellaneous.

Middlesex Hospital Extension.—The hydrofuge parquet, which is damp-proof, sound-proof, and fire-proof, and the mosaic pavements at the above, have been executed by Mr. Jos. F. Ebner, Clerkenwell-road, London.

Liverpool.—The Turner Memorial Home for Incurables, designed by Mr. A. Waterhouse, A.R.A., is now approaching completion, and has had erected in the chapel a reredos of alabaster. In the three central compartments, carved in white alabaster, are the subjects of Christ Healing the Sick and Lame, Christ giving Speech to the Dumb, and Christ restoring Sight to the Blind. This work has been executed by Messrs. Earp, Son, & Holbs, of London and Manchester.

Baptist Church, Hendon.—The committee for building a new Baptist Chapel at Hendon have referred the designs received in competition to a professional assessor for advice, having for that purpose appointed Mr. Banister Fletcher.

British Archaeological Association.—At the meeting on Wednesday, the 7th inst., Mr. Geo. R. Wright, F.S.A., in the chair, Mr. C. Lynam sent a cast of the inscription on the cross at Carew, and drawings of another cross at Penally, visited during the Congress. Mr. J. H. Whieldon sent further details of the Roman Bath at Collingham, which will be published in the next part of the *Journal*. The Chairman referred to some seventeenth-century carvings which were taken down from Goat-hurst Church, Somerset, and which, although still in the building, were now for sale. The importance of retaining these in the church was urged by many speakers. Mr. Lofins Brock, F.S.A., referred to the collection of baluster shafts found in the walls of Jarrow Church during the rebuilding, and now preserved in the porch. A Saxon date has been given to these, but their resemblance to Roman work was pointed out. They were probably derived from the Roman buildings in the locality, as was the case at the Saxon Church, Dover, and the transepts of St. Alban's Abbey. The discussion upon the charities of the Royal Abnury, adjourned from the last meeting, was brought to a close. A paper was then read by Mr. C. Lynam on the recent excavation of the site of the Abbey of Ilulton, Staffordshire. The whole arrangement of the church and the conventual buildings has been recovered, and the site has been again filled in after careful measurement, the plans being produced.

International Inventions Exhibition.—The Council of the Society of Arts announce that they will award the following Gold Medals in connexion with the International Inventions Exhibition.—Under the Joint Stock Trust, one Gold Medal for the best application of Photography to a Permanent Printing Process; Group XXVII, Class 149; Group XXIX., Class 159. Under the Howard Trust, five Gold Medals for the best exhibits (coming within the terms of the Trust) in the following classes.—One for the best exhibit in Group IV., "Prime Movers," Class 26.—Steam Engines and Boilers; one for the best exhibit in Group IV., Class 27.—Gas and Air Engines; one for the best exhibit in Group IV., Class 28.—Means of Utilising Natural Forces; one for the best exhibit in Group XI., "Hydraulic Machines," &c., Classes 59 to 62; one for the best exhibit in Group XIII., "Electricity," Class 72.—Distribution and Utilisation of Power." Under the Fothergill Trust, one Gold Medal for the most novel and best exhibit in Group XXVIII., "Philosophical Instruments and Apparatus," Classes 148 to 158. Under the Alfred Davis Trust, three Gold Medals to be awarded in Division II. of the Exhibition (Music), Groups XXXII. to XXXIV., Classes 166 to 180. The Council propose to ask the juries in each class to recommend for their consideration either two or three exhibits which they might consider deserving a prize. It will not be necessary for any special application to be made in respect of these prizes. The medals are each of the value of 20l.

The Widening of New Broad Street.—Several new buildings are at present in course of erection in connexion with the widening of New Broad-street to the extent of 8 ft. Nearly all the premises required for the purpose of widening the street have now been taken down, and amongst other new structures now in progress is an extensive block of buildings at the corner of New Broad-street West, and Old Broad-street, having a frontage to the first-named street of about 45 ft. in length, and running southwards along Old Broad-street, in the direction of London Wall. The buildings are faced with red brick and Portland stone, and are intended for offices. Mr. Edwin T. Hall, of Moorgate-street, is the architect, and Messrs. V. Bangs & Co., of Bow, are the contractors.

A New Architectural Work.—Mr. Owen W. Davis, architect, is (as will be seen by an advertisement in another column) about to publish, by subscription, "Art and Work," containing about 550 examples of antique, Italian, Renaissance, "Adam," Oriental, and modern work, in marble, stone, metal, wood, colour, &c.

West Sussex County Surveyorship.—At the Court of Quarter Sessions for West Sussex held on the 8th inst., Mr. Ellice-Clark, M. Inst. C.E., was unanimously elected County Surveyor. Mr. Ellice-Clark will continue to hold his position as Engineer and Surveyor to the Hove Commissioners.

London and Middlesex Archaeological Society.—At a meeting of this Society on Monday evening at King's College, Alfred White presiding, Professor John Hales read a paper entitled, "Notes on Anglo-Saxon Charters relating to Hampstead." Professor Hales said that it was a curious fact that what was now to be the borough of Hatfield had existed within the same boundaries the manor of Hampstead one hundred years before the Norman conquest. The first charter relating to Hampstead was granted by King Edgar, and the second by King Athelred. The date of the first was 986; it had been known for many years, and the original itself exists in the archives of Westminster. The second charter, which had been only lately known, was amongst the Ashburnham manuscripts which had been secured to the nation, and were now in the British Museum. Mr. Hales, in his history of Hampstead, had proposed that the charter of Athelred was forged, but he (Professor Hales) thought it might fairly believe in its genuineness. It is the signature of the king's wife Elfrida, who granted the manor of Hampstead to a certain person named Mangola, whose identity had hitherto been traced. The second charter confirmed the grant of the first, which set out the limits of Hampstead. Mr. E. P. Seaton, resident engineer of the Metropolitan (Inner Circle) Railway, read a paper on the discoveries made in the excavations in forming the extension of the new line to the Tower.

The Supply of Natural Gas in America. There exists a belief that the natural gas supply of the United States will soon be exhausted, but, from what has recently been stated by American contemporaries, this does not appear to be the case. Within the last few weeks reports have been received from Pittsburgh, Pennsylvania, Cleveland and Findlay, Ohio, Mitchell, Dakota Territory, and at least five points in Alabama, announcing the discovery of natural gas wells. Scarcely a day is said to pass without the discovery of a new well, some portion of the country. The remarkable deposits in western Pennsylvania and east Ohio are well known to the reading public, and a great and growing industry is in process of development. Possibly it may be an extravagant statement, but it is believed that the discovery of natural gas in Pennsylvania is only second in importance to that of oil. It is a well-attested fact that the town of Fredonia, New York, has been lighted by same gas well for more than forty years, and we are told that the Chinese have been using certain gas-wells for 4,000 years, and that they still yield a good supply. It is only a few months since American geologists affirmed that the natural-gas belt did not extend beyond Pittsburgh, and yet successful wells are now in operation at Cleveland, Steubenville, Findlay, and other points in Ohio.—*Iron.*

Free Lectures to Artisans.—The Company announce a course of eight lectures to be given at their Hall, London-venue, to artisans and others connected with the building trade. The first will be delivered by Professor Kerr, of King's College, on Wednesday, February 11th, at eight o'clock, when the subject will be "The Comparative Anatomy of Beams, Trusses, and Arches." Tickets for the course can be obtained at the Hall of the Company after January 21st.

Royal Victoria Coffee-hall.—The quenters of the Science Lectures at the above hall will be glad to learn that they were resumed on Jan. 13th, when Prof. H. G. Seeley, F.R.S., lectured on "More about the Sun"; on Jan. 27th Commander Cameron will lecture on "How I got from the East to the West Coast of Africa."

Albo-Carbon Light.—We understand that the Italian Church, Hatton Garden, has just been lighted with the Albo-Carbon light by Sanitary Engineering and Ventilation Company of Westminster, who also recently applied the same system of lighting to the New Oratory, South Kensington, and several picture galleries.

Incorporated Society of British Artists.—At a special assembly of the Incorporated Society of British Artists, held on Monday evening last, Mr. W. T. Dannat was elected a member.

School Furniture.—We learn that North of England School Furnishing Company (Limited), of Darlington and Newcastle, has opened a London depot at 121, Newgate-street.

Climate in its Relation to Health." First of three Cantor Lectures, on the state in its Relation to Health," was given in the rooms of the Society of Arts, on Monday last, by Dr. G. V. Poore. The lecturer, by directing attention to the chemical composition of the atmosphere, and its com-

Directories.—The progress of electric work in commercial importance is strikingly indicated in the volume in which Berly's "Universal Electrical Directory for 1885" is comprised. It professes to be a complete record of all the industries directly or indirectly connected with electricity and magnetism, and is a most voluminous and almost alarming compilation. Among other works of the same class, we have the "Railway Diary and Officials' Directory for the present year," giving the returns of traffic and particulars of the constitution and the official staff of every railway company, &c.

Church Clocks.—A large clock has just been completed at Alston Church, Staffordshire, by Messrs. John Smith & Sons, Midland Steam Clock Works, Derby. It strikes the hours upon a large bell, and has two dials facing south and west. The same firm have also just erected a similar clock at Rolleston Church, Staffordshire.—At Helpston, Peterborough, a large clock has just been erected in the church by Messrs. Smith. It strikes the hours upon a large bell and has one large dial. These clocks are fitted with all the latest improvements, and are not to vary more than fifteen seconds a month.

CONTRACTS AND PUBLIC APPOINTMENTS.

Epitome of Advertisements in this Number.

CONTRACTS.

Table with 5 columns: Nature of Work, By whom required, Architect, Surveyor, or Engineer, Tenders to be delivered, Page. Rows include Execution of Works and Supply of Materials, Erection of Warehouse, Granite Kerb, Kenish Flint, Pipes, &c., Supply of Broken Granite Kerb, Cubes, Broken Flints, and for Laying Pavement, &c., Glass for Locomotives and Windows of Railway Carriages, Execution of Works, Erection of Two small Bridges, New Granite Carriage-way, &c., Excavating, &c., Beulah Park Estate, Painting Work, and Repairs to Swimming Bath, Brick & Stone Work, Bricklayer, Mason, Carpenter's, &c., work, Darlington, Corporation Sewage Works.

PUBLIC APPOINTMENTS.

Table with 5 columns: Nature of Appointment, By whom Advertised, Salary, Applications to be in, Page. Rows include Town Surveyor and Inspector of Nuisances, County Surveyor.

TENDERS.

Table for alterations at the Public Baths and Washhouses, Spa-road, Hammersmith. Lists names of contractors and amounts: W. J. Botterill £2,328 0 0, Scrivener & Co. 6,454 0 0, B. E. Nightingale 5,323 0 0, W. Johnson 6,273 0 0, J. Marsland 6,105 0 0, J. Bentley 6,081 0 0, J. C. Boyver 6,025 0 0, W. Martin 5,930 0 0, H. L. Holloway 5,875 0 0, Tarrant & Son 5,793 0 0, J. Tyerman 5,735 0 0, Smith & Sons 5,720 0 0, Howell & Son 5,687 0 0, D. D. & A. Brown 5,683 0 0, Hann & Co. 5,660 0 0, F. Dixon 5,400 0 0, F. Higgs 5,257 0 0, G. Stephenson 5,193 0 0, Smith & Barnes 5,083 0 0, J. Bullers 4,995 0 0, W. Smith 4,905 0 0, W. Schofield 4,675 0 0, J. Stayner (accepted) 4,669 0 0.

Table for Porcelain, Iron Baths, and Gear. Lists names and amounts: Jeakes £3,400 0 0, Bradford & Co. 2,727 0 0, Frazer 2,695 0 0, Batrill 2,153 0 0, Bushby 2,134 0 0, Smith & Barnes 2,012 0 0, Thomas & Taylor 1,987 0 0, G. Elliot 1,948 0 0, Seaton 1,916 0 0, May 1,909 13 0, Pratt & Reynolds 1,825 0 0, Thompson, Leeds 1,950 0 0.

Contract No. 2. For the erection of a new house, &c., at Sandhurst, Berks, for Lieut.-Col. Harvey. Mr. W. Ravenscroft, architect, & Market-place, Reading. Quantities supplied by Messrs. Cooper & Sons, surveyors, Mailhead and Reading: Botrill, Reading £8,591 16 10

Table for new wards, &c., to the Infectious Hospital, Hillingdon, for the Uxbridge Joint Hospital Board. Lists names and amounts: Freeman, Surveyor to the Board. No quantities: Ham & Co., Windsor £2,182 0 0, C. F. Keasley, Uxbridge 1,618 0 0, J. Hardy, Cowley 1,447 0 0, F. T. Taylor, Uxbridge 1,443 0 0, W. Brown, Southall 1,435 0 0, C. Brown, Harfield 1,350 0 0, P. Bell, Southall 1,295 0 0, Schellen & Williams, South Reading 1,287 0 0, A. & B. Hanson, Southall 1,274 0 0, F. Quinton, Southall 1,150 0 0.

Table for the erection of new schools, including teachers' residences, boundary walls gates, &c., proposed to be erected by the Egham School Board, at Egham Hythe. Mr. E. Harner, architect, John-street, Adelphi: Knight & Sons, Chertsey £4,900 0 0, W. Keavell, Windsor 4,542 0 0, G. Reavell, Staines 4,380 0 0, Green Bros., Colnbrook 3,885 17 6, F. A. Key, Windsor 3,414 0 0, A. L. Oates & Sons, Egham 3,655 0 0, A. Simpson, Egham 3,615 0 0, Hann & Co., Old Windsor 3,474 0 0.

For the erection of two houses on the Earlsfield Estate, S.W., for Mr. H. W. Keatch. Mr. Wm. P. Miller, architect, Wandsworth-common: Spencer (accepted) £750 0 0

Table for the erection of a house and shop at Barmouth, for Mrs. Edwards. Mr. Thomas Roberts, Assoc.-Archit., Inst. C.E. architect: Jones, Criecheth £1,727 11 0, Hughes, Portmadoc 1,660 0 0, Griffiths, Criecheth 1,570 0 0, Edwards, Barmouth 1,557 0 0, Jones, Portmadoc 1,553 0 0, Thomas & Parry, Llanbedr 1,512 0 0, Davies, Barmouth 1,469 0 0, Evans, Harlech 1,445 0 0, Jones & Edwards, Barmouth 1,411 11 0, Roberts & Williams, Talsarman and Harlech 1,420 0 0, Owens, Barmouth 1,384 0 0. [Architect's estimate, 1,449.]

Table for King's Heath and Greenhill sewer, for the King's Norton Rural Sanitary Authority. Mr. R. Godfrey, engineer. Quantities supplied: W. Heaps, jun., Birmingham £7,234 13 4, Currall & Lewis, Birmingham 6,926 5 0, J. White, Handsworth 6,755 6 0, Pearson & Goughly, Birmingham 6,754 8 7, Cooke & Co., London 6,272 7 4, G. Law, Kidderminster 5,701 18 7, J. Biggs, Handsworth (accepted) 5,510 14 6. [Engineer's estimate, 6,121. 15s.]

Table for the erection of offices for the Guarantee Society, 19, Birch Lane, E.C. Mr. Edwin A. B. Crooket, architect, 16, Mark-lane. Quantities supplied: Holland & Bannen £8,998 0 0, Colls & Son 8,360 0 0, Bangs & Co. (executors) 8,300 0 0, E. Conder 8,199 0 0, W. Brass 7,593 0 0, Rider & Sons 7,451 0 0, Lawrence & Sons 7,450 0 0, J. & J. Greenwood 7,449 0 0, Ashby & Horner (accepted) 7,249 0 0.

Table for detached house, Farnham-road, Guildford, for Mr. S. Farnfield. Mr. A. B. Harding, architect: Hill & Downes £945 0 0, Newdick 925 0 0, Currington & Peto 915 0 0, Kingierlee 897 0 0, T. Downes 890 0 0, Bannam 839 0 0, G. & R. Smith (accepted) 837 0 0.

lyling Ambulances in Paris.—Dr. Henri Nactel, though an American, has succeeded in winning an agitation in Paris in favour of providing town ambulances on the American model. An influential temporary committee was formed for this purpose, on which were the names of Dr. Pasteur, Dr. Berthelot, Guérin, Dr. Bédard, Baron Larrey, Senator Rubin Schwartz, the former Prime Minister Jules Simon, and the well-known journalists E. Lockroy, John Lemoine, E. Maguier, &c. Recent meeting of this committee was held under the presidency of M. Jules Simon, when Nactel exposed his scheme. He proposed to establish two methods of communicating in the hospitals in case of accidents. First, on there is no extreme urgency, the local ambulance station would supply means of telephoning to the nearest hospital to send an ambulance. Secondly, when there is not a moment to be lost, or the case is too serious to transport to the police station, telegraphic posts, similar to the fire alarms used in the streets, might be employed. A number of red boxes or pillars in all the principal streets could be opened by a key kept in the nearest shop, and the alarm given. On the receipt of this signal an ambulance should be ready to start in forty-two seconds, horses being kept day and night in harness. The ambulance would accompany the ambulance. It was further proposed to raise a fund by voluntary subscriptions to start this service; and a magnificent fête will forthwith be organised, the proceeds to be devoted to this purpose.—Lancet.

Iron Girders.—We have received Messrs. Messures Bros.' annual calendar card, containing numbered sections of girders and other ironwork; a useful form of list for immediate reference. We observe that Messrs. Messures, in their sections of iron and concrete floors, retain the same with the usual upper flange section. It is a question at least of some theorists think there is a question about it) whether this is not waste weight and material in the iron, concrete covering, of course, a very considerable resistance to compression strain, which must naturally help the upper flange of the beam, and then if it do not abrogate the necessity for an upper flange at all. The error is one on the side of strength, no doubt, but not on that of economy.

Hydraulic Lift, Eastcheap.—Messrs. Reichald Smith & Stevens, of Queen's-road, Eastcheap, have been instructed by the A-rated read Company to erect at their new premises, Eastcheap House, Eastcheap, one of Stevens & Major's Patent Hydraulic Balance Passenger Lifts, with compensating apparatus for reducing the amount of water used. The architect of the building is Mr. George Edwards, ofrompton-road.

For Montem-street Schools, for the London. Mr. E. R. Robson, architect.

Acton Main Drainage.—Mr. Rowles writes to say that his total should be 36,723l., not 37,623l.

SPECIAL NOTICE.—Lists of Tenders frequently reach us too late for insertion. They should be delivered at our Office, 16, Catherine-street, W.C., not later than Four p.m. on THURSDAYS.

TO CORRESPONDENTS.

N. H. J. W. (Ishaks)—F. & G. H. A. H. J.—E. S. R.—M. and T.—W. H. B.—H. H. S. (too late for this week)—C. R. A.—T. S.—G. G. W.—A. F. O.—W. S. S.—W. & J. R. C.—A. W.

All statements of facts lists of tenders, &c., must be accompanied by the name and address of the sender, not necessarily for publication.

We are compelled to decline pointing out books and giving addresses.

Note.—The responsibility of signed articles, and papers read at public meetings, rests, of course, with the authors.

We cannot undertake to return rejected communications.

Letters or communications (beyond mere news-items) which have been duplicated for other journals, are NOT DESIRED.

All communications regarding literary and artistic matters should be addressed to THE EDITOR; all communications relating to advertisements and other exclusively business matters should be addressed to THE PUBLISHER, and not to the Editor.

PUBLISHER'S NOTICES.

THE INDEX and TITLE-PAGE for Volume XLVII. (July to December, 1884) were given, as a supplement, with the Number for January 10.

A COLOURED TITLE-PAGE may be had, gratis, on personal application at the Office.

CLOTH CASES for Binding the Numbers are now ready, price 2s. each; 3s. 6d.

READING-CASES (Cloth, with Straps, to hold a Month's Numbers, price 2s. each) also.

THE FORTY-SIXTH VOLUME of "The Builder" (bound), price Twelve shillings and Sixpence.

SUBSCRIBERS' VOLUMES, on being sent to the Office, will be bound at a cost of 3s. 6d. each.

CHARGES FOR ADVERTISEMENTS.

SITUATIONS VACANT, PARTNERSHIPS, APRENTICESHIPS, TRADE, AND GENERAL ADVERTISEMENTS.

Six lines about 100 words of matter..... 4s. 6d.

Each additional line (about ten words)..... 6s. 6d.

Fees for Series of Trade advertisements, and Special Advertisements on front page, Competitions, Contracts, Sales by Auction, &c., may be obtained on application to the Publisher.

FOUR LINES (about THIRTY words) or under..... 2s. 6d.

Each additional line (about ten words)..... 3s. 6d.

PREPAYMENT IS ABSOLUTELY NECESSARY.

Stamps must not be sent, but all small sums should be credited by Cash in Registered Letter or by Money Order, payable at the Post-Office, Covent-garden, W.C. to DOUGLAS FOUNDRINER, Publisher.

Advertisements for the current week's issue must reach the Office before THREE o'clock p.m. on THURSDAY.

The Publisher cannot be responsible for DRAWINGS, TESTIMONIALS, &c. left at the Office in reply to Advertisements, and strongly recommends that of the latter COPIES ONLY should be sent.

ALTERATIONS IN STANDING ADVERTISEMENTS or ORDERS TO DISCONTINUE same, must reach the Office before TEN o'clock on WEDNESDAY mornings.

PERSONS Advertising in "The Builder," may have Replies addressed to the Office, 16, Catherine-street, Covent-garden, W.C. Free of charge. Letters will be forwarded if addressed in duplicate, and sent, together with sufficient stamps to cover the postage.

TERMS OF SUBSCRIPTION.

"THE BUILDER" is supplied direct from the Office to residents in any part of the United Kingdom at the rate of 12s. per annum, PREPAID. To countries within the Postal Union, 26s. per annum. Remittances payable to DOUGLAS FOUNDRINER, Publisher, No. 16, Catherine-street, W.C.

Best Bath Stone.

WESTWOOD GROUND,
Box Ground, Combe Down,
Corsham Down,
And Farleigh Down.

RADELL, SAUNDERS, & CO., Limited,
Corsham, Wilts. [ADVT.]

Dry Corsham Stone.
150,000 FEET CUBE.

PICTOR & SONS,
BOX, WILTS. [ADVT.]

Doubling Freestone.

THE CHELYNCH STONE.

THE BRAMBLEDITCH STONE.

HAM HILL STONE.

Greater facilities have been provided for working these quarries, and the stone can be supplied in large quantities at short notice.

Prices, and every information given, on application to CHARLES TRASK & SON, Norton-sub-Hamdon, near Ilminster, Somerset, London Agent.—Mr. E. WILLIAMS, 16, Craven-street, Strand, W.C. [ADVT.]

Doubling Free Stone.

For prices, &c., apply to Dress S. & J. STAPLE, Quarry Owners, Stoke and Lime Merchants, Stoke-under-Ham, (Ground or Lump), Ilminster. [ADVT.]

Ham Hill Stone! Ham Hill Stone! For Ham Hill Stone of best quality and workmanship, apply to JOHN HANX & SON, Quarry Owners, Montacute, Ilminster. Established 1837. Agents, MATTHEWS & GEARD, Abchurch Wharf, Regent's Park Basin, N.W. [ADVT.]

Asphalte.—The Seyssel and Metallic London Asphaltic Company (Mr. H. Glenn), Office, 1, Poultry, E.C.—The best and cheapest material for damp courses, railway arches, warehouse floors, flat roofs, stables, cow-sheds, and mill-rooms, granaries, tin-rooms, and terraces. [ADVT.]

Asphalte. Seyssel, Patent Metallic Lava, and White Asphaltes. M. STODART & CO. Office: No. 90, Cannon-street, E.C. [ADVT.]

EVERY DESCRIPTION OF Seasoned Woods and Veneers in very large quantities.

R. J. HUDSON & SONS, Whitfield-street, W., Store-street, W., and Great Peter-street, S.W., London. Telephone No. 3,654, and Private Wire connecting Business Premises.

JUST PUBLISHED. J. A. BERLYS UNIVERSAL ELECTRICAL DIRECTORY. Price 10s. For 1885. [Price 10s.] This book contains, amongst other trades, very complete list of Manufacturers of Electric Bells, Alarms, and other Electrical Domestic Appliances. WM. DAWSON & SONS, Nos. 148-9, UPPER THAMES STREET, LONDON, E.C.

BANNER VENTILATORS.

The Strongest Exhaust Ventilators for all Buildings, Public Halls, Churches, Billiard-Rooms, &c.

HIGHEST PRIZES at all the most important Exhibitions.

BANNER SYSTEM OF SANITATION AND SANITARY APPLIANCES

WERE AWARDED AT THE International Health Exhibition, 1884, One Gold Medal, Three Silver Medals, and One Bronze.

For further Particulars and Prices apply to BANNER BROS. & CO. Sanitary and Ventilating Engineers 11, BILLITER SQUARE, LONDON, E.C.

The Builder.

Vol. XLVIII. No. 2190.

SATURDAY, JANUARY 24, 1885.

The Antiseptic Treatment of Timber.

HERE can be but two opinions as to the growing importance of studying the question of timber preservation, having regard more particularly to the reckless manner in which our own forests have disappeared and the

little care that is bestowed on the forests of our colonies and the United States,—forests as yet of vast area, but nevertheless thinning so rapidly as to be palpable to the most casual observer. It is true that the substitution of iron and steel for wood in the navies of the world has largely diminished the call for timber in that direction, but this diminution is made up for by the enormous extension of the railway system and the demand for sleepers and telegraph-poles, as also for the piles necessary for the great harbour and reclamation works that are so numerous at the present day. Any information concerning the practical preservation of wood is, therefore, of extreme value, and Mr. Boulton's pamphlet* (the result of a paper read last autumn before the Institution of Civil Engineers) is one which deserves careful study.

The appearance, on a large scale, of the dry rot in the ships of the British Navy, at a time when they really were the wooden walls of old England, was naturally a subject of considerable alarm, when we know that a single seventy-gun ship required for its construction the oaks of forty acres of forest, and, therefore, it was not to be wondered at, that, as early as the beginning of this century, various proposals were made to stem the evil by the use of various salts of metals. The inquiry assumed more definite proportions, however, when the railway era was fairly inaugurated, and it was found that stone sleepers were too rigid to be useful; and several materials were experimented upon for timber preservation with more or less success. The first system of treatment was called Kyanisising, after its inventor, Mr. Kyan, and consisted of the use of corrosive sublimate. It answered the purpose very fairly, especially when the timber was in a dry situation, though it failed when tried under water, and particularly under sea water. Moreover, corrosive sublimate was found to be rather too volatile at ordinary temperatures, and to be injurious to those who had to handle it. Margaryising, the system adopted by Mr. Margary, was the

employment of the sulphate of copper, which appears to be the most reliable of all the metallic salts, and is still in use in France. Burnettising (after Sir William Burnett) was the adoption of chloride of zinc, a good timber antiseptic, but very soluble in water. It is still in favour in Germany and Holland. Finally came Mr. Bethell's celebrated patent for creosoting,—a bad name for the existing process by coal tar, as in reality creosote is a product of the destructive distillation of wood, which has never been used for timber preservation; and the only excuse (a very far-fetched one) for the name was because somebody discovered carbolic acid or phenol in both coal-tar and wood distillation. "There is a river in Macedonia and a river at Monmouth, and there be salmons in both"; so that it must be understood that creosote, in its popular application to wood-preserving, is not creosote, but oil of tar.

The basis of the action of all these remedies was supposed to be that they coagulated the albumen of the sap, and formed insoluble compounds that arrested decay; but as it has been proved by experience that the salts of metals are not so efficacious or so permanent as the tar-oils, the so-called creosoting process has now for a considerable period outlived its competitors. Even in France, where the sulphate of copper has held its own longer than anywhere else, partly because there was a difficulty of getting the creosote, partly because Dr. Boucherie injected the sulphate in a peculiarly ingenious manner, and partly because it was noted that the salts of metals became washed out in damp situations, even there the creosoting process has met with great approbation, since Mr. Forestiere observed how thoroughly the timber was protected against that most troublesome pest, the *Teredo navalis*. The oil used in creosoting is thus prepared. When coal is carbonised for gas-making, the products given off are four, viz., illuminating gas, ammoniacal or gas liquor, coal-tar, and coke,—all of them, in their several ways, of extraordinary commercial value, though, in the present case, the coal tar, a black treacly-looking substance, is all that we have to deal with. It may be mentioned, however, incidentally, that the waste or gas-liquor is the parent whence the ammonia group is manufactured on a large scale. By distilling the coal tar, three separate groups of products are obtained:—first, the oils which are lighter than water, such as the naphthas, which are of incalculable importance to the country, as from them are ultimately procured the aniline dyes; secondly, the oils which are heavier than water; and, thirdly, the pitch, which is the residuum of the distillation. The lighter oils form a category of themselves

quite distinct from the heavier ones, and have never been used for creosoting purposes; but they are extremely rich in their own particular constituents, yielding, amongst other results, the benzoles from which the aniline is obtained, the toluols, the solvent and burning naphthas, and carbolic acid, whence is derived the picric acid, used for fulminating purposes. The heavy or "dead" oils form the creosote of the timber-yard, and they were formerly treated *en masse*, though now each constituent can be separately removed according to its volatility. These dead oils are divided by the trade into two kinds,—"London" and "country,"—the former being the distillation from the best Newcastle coals, which are usually supplied to the South of England, and are much richer than other coals in semi-solid substances, such as anthracene, naphthalene, &c. The country oils, on the other hand, are distilled from the Midland coals, and are more volatile, besides containing a larger proportion of tar acids. In the earlier days of Bethell's patent, the heavy or dead oils were alone used, it being considered that the crude naphthas were useless as antiseptics, and that the pitch, from its solidity, would form an impediment to the injection; but the fashion gradually came into use of mixing a small percentage of country with the London oils, as diluents of the more solid material; and, in point of fact, the country oils became popular and mentioned in specifications.

The inspectors liked them, because they were thinner and injected with less trouble, and also because the timber thus treated looked cleaner and less muddy. The late Dr. Letheby, too, gave a great impetus to the growing use of the country oils, as he considered that the carbolic acid (which had been discovered in coal tar by Runge in 1834) was the key of the whole position, and that the efficacy of the treatment consisted in the percentage of carbolic acid. It was his object, therefore, to exclude the naphthalene and para-naphthalene of no value, but to include the lighter portions of the oils, viz., those which distilled between 360° and 490° Fahr., as containing the tar acids in the greatest abundance. Here again, incidentally, we may mention that this para-naphthalene, useless in timber preserving, has been found to ultimately yield anthracene, the parent of alizarine, that beautiful red dye, that has so completely superseded madder in textile operations.

Dr. Letheby, however, did not have it all his own way, for the investigations of De Gemini and Rottier, in France, and of M. Coisne, in Belgium, seemed to entirely disprove his conclusions. The latter gentleman an engineer in the service of the Belgian Government, placed shavings in a putrefying

* Boulton on "The Antiseptic Treatment of Timber."

pit for four years, saturated with creosote containing respectively 15 per cent., 8 per cent., and 7 per cent. of tar acid, while one sample was of heavy specific gravity, and held no tar acid whatever. This last experiment, however, was the most successful of all, and throughout the whole series it was evident that the results were in favour of the heavy oils, and that the tar acids were of no use at all. The Belgian Government accepted M. Coisne's statement, and does not stipulate, in its railway specifications, for any tar acids, though it allows 30 per cent. of naphthalene, one of the very substances discarded by Dr. Lethely. Following an inverse method of examination, M. Coisne procured and analysed some creosoted sleepers that had resisted decay for twenty years, and he found no tar acids, but, on the contrary, plenty of naphthalene. Similar experiments were undertaken by Mr. Boulton, in 1882, on sleepers from various railways which had been in use for from sixteen to thirty-two years, and his analysis proved four things:—1. That no tar acids were detected by the ordinary methods. 2. In the majority of cases the semi-solid constituents, such as naphthalene, were present. 3. Only small percentages remained of oils distilling below 450° Fahr.: all these facts proving that it was through the action of the heaviest and most solid portions of the oils that the preservation was effected. 4. He detected an alkaloid called acridine, which, he thought, played an important part in the action, it being undoubtedly a powerful germicide and solidifying within the pores of the timber, without evaporating or being washed out. Mr. Greville Williams also came to the conclusion that the antiseptic results of creosote were due more to the basis of alkaloids than to the tar acids, the former remaining while the latter seem to disappear. It is, therefore, most probable that it is this unfortunate quality of evaporation that disqualifies the tar acids, seeing that, taken *per se*, there is no doubt but that these acids are powerful antiseptics, and that their presence arrests decay. Mr. Boulton's experiments show that if tar acids and naphthalene be separately exposed at the same temperatures, the former will evaporate much more quickly than the latter; indeed, by repeated washings with cold water, both carbolic acid and cresylic acid (its near relation and a constituent of tar oil) can be completely disposed of, a most important fact in connexion with the exposure of timber to sea-water.

Viewing all these facts in their bearings upon specifications, it would seem as if the London oils, as they come from the still, are not sufficiently volatile, nor do they comply with the requirement as regards the percentage of tar acids. A pressure is, therefore, put upon the manufacturer to meet the case by taking out some of the heavier portions, by which the bulk is rendered lighter and the proportion of the tar acids to the diminished bulk is increased. But Mr. Boulton considers that this is a mistake, and would rather relegate the lighter portions of the tar acids, and especially carbolic acid, to their proper position as sanitary antiseptics, for which they are unrivalled, and would encourage the use of the heavier portions. He also agrees with the joint creosoting specification of Sir Frederick Abel and Dr. Tidy, who resolved to exclude no semi-solid bodies which completely melt at 100° Fahr., and further changed the standard of volatility from 90 per cent. at 600° Fahr. to 75 per cent.

Without going into the vexed regions as to the exact relations of putrefaction and the germ theory, the conclusions drawn are,—that the best antiseptics for timber are to be found amongst oils and bitumens, which fill up the pores of the wood. Of such bodies, those that contain germicides are to be preferred, and other properties being equal, those which either solidify in the pores of the wood, or which require an extremely high temperature to volatilise them, and which are insoluble in water, are the best of all. With regard to the creosoting process, Mr. Boulton lays great stress on the hygrometric condition of the timber at the time of injection, neglect of which has often been the cause of failure.

The power of absorption of moisture in woody fibres is so great,—fir timber being able to take up as much as from 60 to 150 gallons of water to the load of 50 cubic feet,—that it has always proved a great difficulty in the way of treatment, as the subjecting of the timber to a dry heat invariably results in injury to it. Mr. Boulton has, however, successfully met the difficulty by a most ingenious combination of air-pump action with the use of creosote heated up to 213° Fahr. With charges of very wet sleepers, he has withdrawn water equal in volume to 50 gallons per load of timber, the water being replaced with an equal volume of creosote by the action of the air-pump alone.

THE RELATION OF THE COLOUR-SENSE TO ART.

BY CHARLES ROBERTS, F.R.C.S.

OUR short English proverb "Tastes differ," which often winds up a discussion on aesthetic subjects, assumes a somewhat wider form among the French, and is to the effect that it is useless to dispute about questions of taste and colour. One of the chief reasons for differences of opinion is that, although taste and colour are at bottom mental conceptions, people do not see their physical incidents with the same eyes. Take the case of the beauty of the human form, for instance. A short-sighted person sees only an average of the most conspicuous features in the hazy condition of one of Mr. F. Galton's compound photographs, while an acute-sighted person detects all their minute imperfections: hence the openings for a long discussion on personal beauty. With regard to colour the opportunities for disagreement are still larger, as the variations of the colour-sense in different individuals are greater and of a more subtle kind than those of the refraction of the structures of the eyeball. There are, for instance, a few persons in the world (two of whom have come under my own notice), who can form no notion of colours except as mere shades of black and white. There are others, again, whose scale of colour is deficient in one of its fundamental elements, and not only does the red, or the green, or the violet, as the case may be, disappear in its true form and in its various combinations, but the elements which do remain produce colour-scales entirely different from our own. Farther, there is a condition of the colour-sense which, although recognising all the colours of the spectrum in their purer and more intense forms, is quite unequal to distinguishing the lighter shades one from another, or greens from various forms of grey and the dull tints which are affected by many aesthetes of the present day. Finally, there is a considerable variation in the fine appreciation of shades of colours among persons who possess a good colour-sense, so that no one should venture to criticise, much less to ridicule, another person's colouring, until his own colour-sense has been proved to be good by a proper scientific examination. It is, indeed, very probable that the colour-sense varies as much in different persons as does any other physical quality of the body,—the stature, for example,—and that not only are there giants and dwarfs, so to speak, of colour-perception, but the intermediate stages are grouped, according to the theory of probabilities, increasing from a minimum of complete colour-blindness in larger and larger numbers to an average colour-sense, and diminishing from the average to a maximum of the higher colour perception, the groups forming the usual binomial curve.

The more decided forms of colour-blindness are easily detected by several well-known methods of procedure, and the finer differences by an instrument devised by Lord Rayleigh for demonstrating the truth of what many artists are slow to believe, that yellow is a compound colour composed of red and green light. The instrument consists of an arrangement to superimpose red and green light upon each other in different proportions, together with a pure yellow light as a test colour. It is in the efforts to produce a match to the test colour that the quality of the colour-sense of different persons is proved. Some persons require a larger

amount of red light than others to neutralise the green, or, on the other hand, more green light than red, so that to some persons the spectrum yellow is almost orange, while it is pale green to others. Here, again, we have the observations forming a binomial curve between the extremes of orange and pea green, pure yellow being the average of all the observations. A similar variation occurs, no doubt, with all the other colours of the spectrum.

It might be thought that persons who are colour-blind, or who labour from any deficiency of the colour-sense, would take little interest in either the practice or the enjoyment of art, as colour forms so large and important an element in most artistic productions. Yet this is far from being the case. Not only do many persons so affected take a great interest in pictures, and endeavour to paint them, but, it is strange to say, it is in the region of art as engravers, &c., that such persons have found a profitable and enjoyable occupation. Many persons first learn of the existence of their chromatic defect by the artistic instinct endeavouring to assert itself, and when failure is the result much ingenuity is displayed in overcoming the impediment. Professor Wilson records the case of a gentleman who was a skilful draughtsman who in early life discovered his inability to arrange his own palette, and was accustomed to rely on a relative to select his colours, which he had then not difficulty in using, or mixing to the shades he required. This person's account of his colour-sensations is very instructive, because as an educated man he appears to have made himself familiar with the names of many colours and shades of colours which are not commonly recognised by persons with a good colour-sense. It must not be inferred, however, that a person who applies the proper names to colours is not colour-blind, as the names may have been learned from other characters than their colour; and, on the other hand, a person may be ignorant of the names of colours and yet possess a perfect chromatic sense. The vagueness of the language employed by colour-blind persons shows also that there is no distinct line drawn between a good and an imperfect colour-sense, as is popularly supposed. The gentleman I have referred to could distinguish the orange, yellow, and blue in the rainbow, but he could not see the green, and he was very uncertain about the red. On one occasion he was surprised to find that a letter he had written home during his absence was half in black and the other half in red ink. Red cabbage, growing or in infusion were of the most beautiful blue to him, and it was by not observing any change by acids in the infusion when attending Professor Hopley's chemistry class, when he used to stare for the whole hour expecting to see a change, that he became fully convinced of his defect. Red (pick) in the lips, cheeks, or nose appeared blue to him; and pinks, lilacs, purples, and blues were the same colour only differing in intensity. Browns, russets, maroons, olives, citrons, and a host of others, were just any thing he could guess at, and he never spoke of colours if he could avoid doing so.

Now this person was red-blind; that is to say, his retina, according to Young's theory of colour sensation, did not possess the nerve element which recognises or responds to the stimulus of the waves of light of the greatest wave length, and which produce the sensation of red. Hence red in its purest and most intense form disappeared from his chromatic scale, and in its lighter shades appeared grey, while in its combination with other colours,—as, for instance, in purple, which is a mixture of red and blue or violet,—it was overwhelmed by the blue, which explains why to his eyes a change was wrought in the red cabbage infusion by the acids. In like manner, the retina is sometimes deficient in the nerve element which recognises the medium rays of light, and green-blindness is the consequence; while a similar fault with regard to the short rays results in violet-blindness. For differentiating these various kinds of colour-blindness, we employ purple, because it holds the unique position of appearing of a different colour

each kind. It is blue to the red-blind, because the red cannot be detected in its composition; it is red to the violet-blind, because the violet or blue cannot be detected in it; and grey (theoretically white) to the green-blind, because it is composed of his two (instead of our three) fundamental colours. The confusion of red and green by some colour-blind persons is explained on the Young theory by supposing that the nerve fibres of the retina devoted to the recognition of the red and of the green colours overlap each other, and rays of light failing to excite one set,—say the red,—excite to a less extent the next set, or green ones.

It is in consequence of the disposition of colour-blind persons to see many colours as grey, or mere shades of light and darkness, that art affords openings for the occupation of such persons. The engraver and other artists in black-and-white, engaged in reproducing coloured pictures, experience considerable difficulty in estimating the "shade value" of many colours which does not occur to the colour-blind. The following statement, also taken from Professor Wilson's list of cases, of the experience of a colour-blind engraver, will serve to illustrate this point, and perhaps, encourage others labouring under similar chromatic defects to turn them to good account. "Strange as it may appear, my defective vision is, to a certain extent, a useful and valuable quality. Thus: an engraver has two negative colours to deal with; that is, white and black. Now, when I look at a picture I see it only in white and black, or light and shade; and any want of harmony in the colouring of a picture is immediately made manifest by a corresponding discord in the arrangement of its light and shade, or, as artists term it, 'the effect.' I find at times many of my brother engravers in doubt how to translate certain colours of pictures, which to me are matters of certainty and ease. . . . The appreciation of the various shades of colour, or the weight of colour, as I may term it, is exceedingly nice and critical with me."

It is a singular fact, not without interest to persons engaged in arts and manufactures, that the decided forms of colour-blindness are much more common among men than women (in the proportion of ten to one), and that it is more common among the uneducated than the educated classes. At public schools and universities it exists to the extent of 2.5 per cent. while among the criminal classes it reaches the high rate of 11 per cent. This evidence points to a close connexion between colour-blindness and colour-ignorance, and shows the great necessity there is for the systematic teaching of colours in schools. To the majority of persons the very alphabet of colour is unknown; and even among artists, old and exploded theories of chromatics are obstinately retained in spite of the advances which the science has made in recent years.

THE MONUMENTS OF ATHENS.*

MANDBOOKS dealing with the topography and monuments of ancient Athens have of late become plentiful. German readers are now in possession of Baedeker's excellent guide, and for English readers there is Mr. Murray's new handbook. The little work before us has a somewhat different claim on our attention. It is, so far as we know, the first attempt by a Greek to make the antiquities of his own country intelligible to his own countrymen. With this laudable end in view, M. Kastromenos tells us in his preface, he has "ventured to collect his feeble studies into the present treatise." If the studies have been feeble, we must own that the treatise has the merit of consistency; we regret this the more because the book is dedicated to the author's sister, M^{me}. Schliemann, a lady whose just fame deserved a worthier tribute. "She it was," says M. Kastromenos, "who first took me by the hand and breathed into me a passionate love for the splendid monuments of antiquity,

changing thus my original devotion to the Hermes of gain into a worship of the Hermes of learning." If the studies of M. Kastromenos correspond to his treatise, and both are "feeble," we must further allow to the translator a third correspondence. We remember Miss Agnes Smith as the author of a pleasant book of travels in Greece. When an adventurous lady tells us brightly the story of her tour through the difficult Peloponnese, we readily pardon a good deal of blundering over the names of gods and heroes, but when the same lady proceeds to translate an archaeological book, and to give us renderings (very free "renderings") of inscriptions, we are bound to ask for a little care in spelling and translation. The book will, no doubt, be in considerable demand among non-classically educated travellers, both American and English, and though we can scarcely share the high hopes of the translator, that the intelligent seeing of the monuments will inspire these tourists "with a sense of the worth of humanity, and therefore the worth of their own individual life" (is this last needed?), yet they will find their archaeological studies less irksome if they avail themselves of some such handbook as M. Kastromenos has prepared for them. Only, in the name of archaeology, we implore Miss Smith to get her second edition revised by some scholar not wholly guiltless of elementary accident. Was it wise without note or comment to translate *Ακαμαντις παύων νῆα*,—"the hoys of Acauanantis were victorious?" (p. 67). The monument of Lycistrates, from which the inscription is taken, gives rise to a good deal of unfortunate writing. It went by the name, as every one knows, of the Lantern of Demosthenes. No one who has seen the monument will wonder much at it being called a lantern, or get much help if he needs it from a sentence like this:—"It nevertheless appears that the name arose from the whole outer shape of the monument, which, in conjunction with the tradition about Diogenes, was compared to the lantern and referred to the philosopher" (p. 65).* A little further on we meet with the following rather hazy piece of information:—"The reward of victory in the Dionysiac festival at Athens was called a tripod. It was of bronze, and was termed choragic." At a certain festival we learn the spectators wore "what were termed *ἠηθιστοὶ πῆρασοι*, or broad-brimmed sun-hats"; a schoolboy who construed in this fashion would be promptly asked, which was "broad-brimmed" and which was "sun-hats," and would become manifestly uncomfortable. Even archaeologists have their luck, but we are tempted to incredulity when we read,— "The forms of which we have spoken [*i.e.*, pulpitum, dromos, &c.] were distinctly shown when the theatre was uncovered in 1862 by the architect Shack, with the help of a bronze coin, on which the Dionysiac theatre was engraved." Is this a survival of the use of the divining-rod? Our suspicions are confirmed by many instances of very naive logic, *e.g.*, "We have, therefore, no excuse for calling the monument the Arch of Hadrian, *inasmuch as the said name means something quite different.*" This arch of Hadrian has a chapter to itself; albeit, we are told "it is of no great interest, though it is not wanting in value nor in grace of execution or style." Fearing, we suppose, the charge of pedantry, Miss Smith docks Herodes Atticus of a syllable, and renders two respectable elegiacs thus (p. 49):—

"Herod Atticus, of Marathon, had all that is here: He lies in this grave, and his name we revere."

Of him, among other things, we learn that he completed the Panathenaic Stadium, "giving it greater magnificence with Pentelic marble." Perhaps the mention of "Herod Atticus" engenders the Biblical phraseology, for we are told of the "sanctuary" of the Eumenides. "The Turks called this place *Karason*, which, being interpreted, means 'black water.'" Miss Smith has the sanction of the Health Exhibition when she writes "*Hygeia*" (p. 8); hut it might be well to remember that, though the form occurs, it is confined to late authors and inscriptions.

* The italics are throughout our own.

There is really, we hope, nothing psychical or astral or otherwise ghostly about the Parthenon, but why are we assured that "it was built on the ruins and foundations of a more ancient temple, which may still be plainly seen, because the later one was 3 in. or 4 in. larger, by a visible addition" (p. 10)? We are sorry to hear that probably in the very earliest years of Christianity the masterpieces of classical art "quite lost their glitter"; hut, after all, nothing is certain in this world, when "the fact of the temple having been built between B.C. 406 and B.C. 393 is only a supposition arising from a passage in Xenophon." The arrangement of the Erechtheion has always been considered somewhat problematic; perhaps the following sentence will throw some light on it. "We are unable to say anything either about the doorway or about the eastern wall, but we observe that at the ante of the long walls on the northern and southern sides there exist, towards the interior, smaller pilasters opposite to them, and that this looks like the beginning of a wall which, nevertheless, probably never existed. Yet there are railings."

As the translation of this book "has had the benefit of the author's supervision," we would gladly shift as much as may be of the blame on to the broader shoulders. The modern Greek language is, indeed, the outcome of centuries of degradation, and is little fitted to be the vehicle of exact ratiocination, or, indeed, precise statement of fact. But, if the book is to be of use,—which, if it were thoroughly rewritten, it might be,—to English readers, it must not do other despite to the language into which it is translated.

NOTES ON WORKMEN'S HOUSES.

ONE of the latest of those most excellent volumes which have been the outcome of the last American census, is an article on the factory question by Col. Carroll Wright, the able chief of the Massachusetts Bureau of Industrial Statistics. It is replete with comparative information as to the position of the factory classes, not only in the United States, but in other countries as well, and some interesting information is given, the results of inquiries made by him on the Continent, as to the cost and style of artisans' dwellings, particularly in Belgium, Germany, and France. Taking these countries in the order named, we find that at Verviers, which is a busy clothing town, the workmen earn from 2s. 6d. to 3s. 3d. a day and the women 1s. 6d. to 2s. 6d., and they can rent four rooms and a small garden for 12l. per annum; two rooms on the second floor for 7s. 3d. per month, or two on the third floor for 3s. 8d. per month. The tenements are small, though comfortable, and, as a rule, the cottages are much better than the flats, which prevail to a considerable extent. Many of the houses, with four rooms, cellars, and scullery, let for 12s. per month. They have separate hall-ways and are generally well finished.

At Essen, in Prussia, the seat of Herr Krupp's gigantic steel and cannon-making works, a foreman gun-maker earns 9l. per month, and pays just that sum per annum for his house, which includes four rooms, a drying-place on the roof, a cellar, and a garden. An ordinary workman, earning 3s. a day, pays about 7 guineas a year for three large rooms, drying-place, cellar, and garden. For 20l. per annum an excellent tenement can be had, consisting of seven large rooms and the usual appurtenances. Every workman belonging to the place is housed in dwellings belonging to Herr Krupp, so that he can control all the sanitary arrangements and see that everything is done properly. There are three colonies of residents, each with its special name and laid out with parks, schools, churches, chapels, and stores. The housing of the single men at Essen is on the barrack principle. At Chemnitz, in Saxony, where men earn in the factories from 10s. to 20s. per week, working twelve hours a day, very good flats of three rooms can be got on second and third floors for 7l. per annum.

At Noisiel, in France, the seat of the Menier Chocolate Works, in the department of Seine et Marne, the selling price of an artisan's

* "The Monuments of Athens: an Historical and Archaeological Description." By Pangiotis E. Kastromenos, translated from the Greek by Agnes Smith. London: Edward Stanford.

dwelling is about 149l., payable part down and the remainder by annual instalments. They are excellent houses,—the roof covered with Holland tiles, the gutters of zinc, and the window-sills and staircases of stone. The heating is carried out by stoves, the chimney-pipes being taken up the walls in a hollowed groove. The floors of the upper stories are of pine, and the interior staircases of beech, the ceiling above the cellar being plastered, and the kitchen paved with tile or brick. The price of these Noisiel houses has recently been raised, for the purpose of preventing speculators from buying them in the name of working men, and also to prevent sub-letting.

The factory town of Mulhouse, in Alsace-Lorraine, offers great advantages in the direction of housing the working classes, partly on account of the well-known care devoted to the subject by the employers, and partly from the number of industrial societies. The usual plan here is to build four separate houses under one roof in a square, each fourth part constituting a dwelling. The average cost of a house here is 86l., plus the price of 192 square yards, which is nearly 6l. The yearly rent is 7l., the tenant becoming owner at the end of fifteen years by paying in addition 4s. 6d. per month. The houses are coated with mortar made of hydraulic stone and river sand, coloured white, yellow, or gray. The sills of the windows and the threshold of the floors are of stone, the lintel bars of round iron, and the houses are separated by lattices made of oak laths. The area covered by the house is 38 square yards. The framing of the windows is of stone without projections; the chimney-shaft is of brick, and the roof is covered with tiles. The privies are always placed in the garden, and the inside of the drains is covered with cement, the bottom being of concrete. The refuse water of the household runs into the main sewer, and the water supply is from pumps set over well-holes 20 ft. deep. The smoke-pipe is of sheet iron, and after it leaves the stove in the dining-room it connects with a pipe of double-burnt earthenware, so as to avoid condensation in going through the kitchen.

In the United States considerable attention is now being paid by employers to the subject of workmen's dwellings, and particularly in New England, where the bulk of the factory labour is congregated. Foremost in this direction is the Willimantic Linen Company in Connecticut State, which has recently built some really charming sets of cottages with large gardens, ranging from 19l. to 25l. per annum rental. As no two are alike, they offer real facilities for inculcating amongst the inhabitants a taste for art decoration.

NOTES.

In the *Times* of Tuesday last the Dean of Peterborough enters into a pretty long defence of his position in regard to the restoration, a defence which appears very rational and complete. The Dean can write common sense on the matter without vilifying other people, and is in a much better position as his own advocate than when allowing Sir E. Beckett's amenities to interpret for him. From this letter it appears that the present position is, that the Chapter have agreed to allow raising the tower, on condition of having the pointed arches rebuilt. This is, as we have already said, an illogical and half-and-half measure, which is good neither architecturally nor archaeologically. The Dean says very pertinently that he has had several offers of additional funds on condition the Norman arches are restored, "but who will contribute towards a patchwork of this kind?" If this be done, a foolish and irrational thing will be done, which future generations will vainly regret. Mr. Freeman endeavours to draw a distinction between Chichester and Peterborough, because in the former case the tower fell, in the latter it has been taken down to prevent it falling. This is rather too fine-drawn a distinction for most of us to see. Mr. T. G. Jackson, who reiterates his conservative protest, justly complains of Sir E. Beckett referring to him as an "amateur" (which may have been either ignorance or

impertinence),* but when he persists that to build up the old tower, stone for stone, is "the best we can now do," though we admire his modesty, surely we may ask him to be content with speaking for himself.

THE conference presided over by Lord Henniker on the 14th inst. proved most unmistakably that the proposed new railway Bills will be very strongly opposed in Parliament. Five M.P.'s, representing various trading interests, were present, the resolution pledging the meeting to oppose the measures being moved by Mr. Barclay, M.P. The closer the schemes of the companies are examined the more reason there seems for regret that they are so overreaching as to provoke such hostility. There is evidence of an immense amount of trouble and care having been expended in their production, and that every point has been exhaustively considered. It is quite time, too, that the Railway Clearing-House Classification (which we referred to last week as having never been legalised) should receive Parliamentary revision and sanction. This is continually fluctuating, and the trader is never secure from having his particular manufactures suddenly moved up a class. The radical changes recently made in the "small's" and "owners' risk" systems were so damaging to the traders that they would, doubtless, be much relieved to find the classification more of a fixture. There is much that is useful in the measures, but the powers sought for would bring the companies' maximum rates up so high that they will hardly be allowed to pass a second reading. The resolution passed by the meeting was forwarded to the President of the Board of Trade, with a request that the views of the Government should be stated at the earliest opportunity, and it will be interesting to know how Mr. Chamberlain and his colleagues regard the state of affairs.

ONE item in the news contained in the *Archäologische Zeitung*, the publication issued yearly by the Archaeological Institute of the German Empire, is a full and precise account of the acquisitions of the British Museum during the past year. The account is extracted from Mr. Newton's annual report to Parliament, and records not only newly-acquired statues, but gems, terracottas, vases and all miscellaneous antiquities. Would not the *Journal* of the Hellenic Society be doing good service if, in one of its two annual issues, it published a similar report? And could it not place itself in connexion with all Continental museums under state control and publish yearly, at least, an abstract of their official report? One of the great difficulties in archaeological research is the getting together of the necessary material, and, indeed, often the uncertainty as to where that material exists. With respect to private and small municipal collections, we fear that difficulty must long exist, but with State collections the information is to be had, and only needs to be made accessible. If we may be pardoned a second suggestion, we believe that the Hellenic Society's *Journal* would do good service if it further devoted a couple of pages yearly to the enumeration of the contents of the various German, French, Russian, and modern Greek archaeological periodicals, and to the citation of all important monographs, such as are not always accessible even in University libraries.

IN reference to the subject of building leases, it may be observed that these are almost unknown in Scotland, and the consequence is that the general run of buildings erected there are of a substantial and permanent nature. The practice is to build upon a feu contract, under which the feudal superior, the owner of the land, grants to the feu a permanent right to the holding upon payment of a fixed annual

feu-duty. A plan of the ground to be feued is prepared by the architect of the superior, and if streets are to be erected thereon he generally also prepares the elevations, a copy of which he is bound to give to those who take a portion of the ground upon payment of a stipulated fee. When the ground is laid out for villas, each villa must cost not less than a certain minimum, and the plan be approved of by the ground architect. In the southern district of Edinburgh the annual feu-duty asked is now double the amount given about twenty years ago. It was then at about the rate of 20l. per acre, and is now about 40l. This of course enhances the value of the older feus to the holders, as the superior cannot demand more than the sum stipulated in the contract. The feus for streets are based upon the frontage generally from 1l. per foot and upwards. Feu duties are considered most eligible investments, many of them being purchased by insurance companies, and for endowed institutions they form a first claim upon the property, and are easily collected. In some instances a "duplicand," or twice the annual value, is exacted every twenty years, but this practice is now, we believe, falling into desuetude. There is generally a clause in the feu contract under which the feu can redeem the annual duty upon payment of a certain number of years' purchase-money. The system is found to work easily, and does not lead to the evils which supervene upon terminating building leases.

ON Wednesday morning, the 7th inst., a large crowd of unemployed working-men, estimated at between 200 and 300, many of whom belong to the building trade, assembled in front of the Council-house, Birmingham, for the purpose of seeking an interview with the Mayor, with a view to getting employment by which they and their families might continue to live. The Mayor (Alderman Martineau, a nephew of the great authoress) declined to see them, and referred them to his secretary, who, after hearing the statements of a small deputation, told them that the Mayor had no power to give them employment, and referred them to the Public Works Committee as represented by the Borough Surveyor. This did not satisfy the men, and they then sought to see the Mayor at his private residence at Edgbaston, but there they were met by the police, who drove them away. These unfortunate ignoramuses in distress protested that they had supposed the functions of Mayor to be of a less ornamental character than it appeared. Since that time mass meetings of the unemployed have been held, at which from 4,000 to 5,000 men have attended, and processions through the town have taken place with the object of calling public attention to the prevailing distress, with the result that the Public Works Committee have hired the stone-yard attached to the Workhouse from the Guardians and set some score or two of men breaking stone for the roads, a very small result as yet, and one not likely to meet the necessities of the case, seeing that many of the distressed are jewellers and others whose work has been of a similar light nature, and whose hands and general physique are not suited to such employment. Meantime the distress is increasing. It is reported that the Messrs. Tangye (Limited) have discharged some hundreds of their workmen, and placed many others on short time, and many factories in the district have not half enough to do.

THE London, Tilbury, and Southend Railway Company obtained powers last session to acquire certain property at Whitechapel for the purpose of their undertaking, and this property, which included the German Reform Church on the east side of Hooper's-square, Leman-street, Whitechapel, and the Seventh-Day Baptist Chapel, Mill-yard, Leman-street, with the disused graveyard in the rear, was purchased by the Company. There appears to be some difficulty in dealing with the ground as building land, and a clause has been introduced into a Bill promoted by the Railway Company to exempt the portions of the

* From a subsequent letter, even more insolent than usual, it appears to have been ignorance. We should have supposed Mr. Jackson's name was pretty well known; but his reputation is in connexion with the artistic side of architecture, of which Sir E. Beckett knows nothing; and besides, Mr. Jackson does not write letters to the *Times* to advertise his own books and buildings, and his own greatness generally, as Sir E. Beckett is allowed to do.

premises referred to from the operation of the Dissused Burial Grounds Act, 1884. This will be good news for the Society with the lengthy name of which Lord Brabazon is chairman, and it seems to show that the Act in question is not entirely inoperative. The dissused burial-ground contains about a quarter of an acre, it is situated in a densely-populated neighbourhood, and would, no doubt, be an acquisition as an open space; but it would be too much to expect the Railway Company to relinquish it, after having paid for it as building land, for the value which would be paid for it as ground which is not capable of being built over.

THE new volume of the Architectural Association Sketch Book contains a great deal of interesting matter, and is quite an important addition to an architect's library, whether only to turn over for pleasure, or to use for the higher and more rational end of "cribbing." There appears to be rather less of clean and highly-finished drawing than there used to be in some old numbers, but a great deal of admirable and sufficiently clean sketching. Opinions, as practically shown, differ about the relations of lines to actual facts. One draughtsman conceiveth himself that he shall show the inner angle where a wall meets, a buttress, for instance, by a thick dark line; yet there is no line at such a place in the building itself, saying that formed by the difference of the incidence of light on two different planes of wall. Another will be for leaving out all lines except the joints of the masonry, and showing those as thick as ropes, so that the drawing is all joints and no angles. This is called "force." There are many drawings that keep a sensible medium, and represent accurately and with balance what line, without shading, can represent. There are some brush drawings reproduced by Sprague's process, among which certain by Mr. Lethaby are pre-eminent in artistic feeling. We do not think the border of the title-page very happy; the straight zigzagged main lines of the floral design are too stiff, and, moreover, they look rather as if they were pulled over the circular medallions as over pulleys. Some of the buildings sketched remind us how deficient is our modern architecture, most of it, in simplicity and breadth of style: the Holstein Tower, Lubek, for instance, with its great unbroken round towers, and the arcaded work between them.

DR. WALDSTEIN, the curator of the Fitzwilliam Museum, commenced, on Saturday last, a course of three afternoon lectures at the Royal Institution, on Greek Sculpture from Pheidias to the Roman era. His view of the subject turned more especially on the relation between the sculptor's aim and the sculptor's material; the archaic age showing a want of harmony in one direction, the imperfect rendering of natural facts, which obtruded on us the idea of stone or bronze, of rigid material rather than of life; and the sculpture of the decadence showing a want of harmony in the opposite direction, in a too great realism, and in the representation of momentary and complicated action which was unsuited to the condition of sculptural material. The canon or type of human sculptural form, as evolved by Polykleitos, was illustrated by casts of the existing copies of his "Doryphoros" and "Diadumenos" (spear-bearer and diadem-wearer), and the lecture concluded by a reference to the statue ascribed to Kephisodotos the elder, and formerly called "Leucothea" (a female with a child in her arms), and its recent identification by Dr. Brunn with the subject of "Eirene and the infant Plutos." The next lecture, to-day (Saturday), goes into comparison between the age of Pheidias and that of Skopas and Praxiteles, and the special qualities of the latter; and the third lecture, on the following Saturday, will be devoted to the age of Individualism, and to Græco-Roman art.

IN a letter to the *Athenæum* of last week Mr. Albert Hartshorne draws attention to the announcement that subscriptions have been started for the restoration of the Eleanor Cross

at Northampton, which was restored, in a very conservative manner, only forty years ago by Blore. That it should now need restoration or repair again is attributed by Mr. Hartshorne to the manner in which it has been maltreated by missiles thrown at the figures in the ingenious sports of the youthful inhabitants. He expresses a hope, which we share, that the old figures, though dilapidated, may not be removed with the view of setting up restored imitations. Such a proceeding would be simple Vandalism. Purely architectural detail which has been damaged, and of which some portions remain as models, may be restored in a sense; but the work of the sculptor stands in quite a different category. No one can restore that.

WE learn with much pleasure that Miss J. E. Harrison, whose critique on the Pergamene altar we published last week, has "received a call" from the managers of the Museum at Leicester to deliver a course of lectures on "Greek Art." For some time past Miss Harrison has been attracting ever-increasing classes to her lectures at the British Museum, and the success she has met with there bears witness not less to the interest of her subjects than to her powers as a lecturer. When Miss Harrison some three or four years ago, under the strong insistence of Mr. Newton, C.B., and other competent judges, made her first attempt to raise the interest of ladies in the treasures of Greek art in the British Museum, some ten or twelve "amateurs" were with difficulty got together. In her course brought to a conclusion at Christmas more than eighty "students" were regular in their attendance, and there is every reason to suppose that both the elementary and advanced classes which will meet in the Archaic Room of the British Museum during the next six weeks will not be less fully attended.

THE "Society of Painter-Etchers" announce their Exhibition for this year to take place at the Dudley Gallery, opening May 25th. All forms of engraving on metal, whether by the burin, the etching-needle, by mezzotint or aquatint, or by whatever other process the artist may choose as a means of original expression, are understood to be included in the term "painter-etching," and are eligible for exhibition, provided that they are *bona-fide* original works, not reproductions.

A COURSE of fifteen lectures on Practical Surveying, with special reference to the forthcoming examination at the Surveyors' Institution, will be commenced by Mr. G. W. Usill on February 2nd. Seven will be on office work, and eight in the field on Saturday afternoons.

FROM a correspondence in the *Dundee Advertiser*, which has been forwarded to us, it appears that at a meeting in connexion with the Dundee Institute of Architecture, Science, and Art, the other day, the Rev. G. Mure Smith gave a lecture on bells and bell-music, especially dwelling on the beauty of old tunes chimed upon bells, carillon-fashion. Whereupon Mr. G. S. Aitken, architect, writes to the *Advertiser* (which gave a good report of the lecture) to the effect that bells were not meant for playing tunes upon, but rather for a "mosaic of sound," and that change-ringing was a far more suitable way of using bells than chiming. We are with Mr. Aitken entirely. Bells are not really musical instruments; they are too uncertain both in time and tone, and destitute of expression; they are an "effect," that is all. Moreover, we never heard a carillon tune that was properly its tune; and people in this country do not seem to know, or to mind, whether they are or not. Indeed, at one church in the vicinity of Aldgate there is a tune-playing carillon which plays more than one well-known hymn-tune with absolutely wrong notes in certain places, in order to escape the expense of another bell to give the note wanted. It is difficult to know in this case whether the people who made the peal, or those who accepted it in this form, were the greater idiots. But at the best, carillon-playing is only trying to make bells do what they are not fitted for.

UNDER the title of "Salon Parisien," a collection of paintings, of which the bulk are by M. Jan Van Beers, has been opened at 160, New Bond-street. There is no work there equal to his "Soir d'Été," which we specially noticed in last year's Royal Academy; but there is a great deal of exceedingly clever painting of figures and costumes, the most marked characteristic of the exhibition being a number of studies of exceedingly over-dressed young women of a very *demimonde* type (in some cases we might say not even "demimonde"), varied by some which are the reverse of over-dressed, sprawling on sofas and chairs in such attitudes as may best exhibit the artist's powers of drawing and foreshortening. Some of these, as "Mécanolie" (4), and "Fatigue" (14), are as clever in execution as anything in realistic art that is to be seen at present. Occasionally there is a higher note struck, and some of the larger quarter-length paintings, such as "Stella" and "Irma" (24, 26), are very sweet in expression as well as beautifully finished in execution. The "Portrait of Peter Benoit" (28) is admirable as a realistic portrait, and one or two works seem to indicate that M. Van Beers could paint a lady if he chose. As it is, the collection stands as one of the cleverest and one of the most intensely vulgar picture exhibitions which have been seen in London. The very title-page of the catalogue (drawn by the artist), across which prances a *danseuse* of the lowest type, is enough to frighten away respectable people, and suggests the idea of its being a "music-hall" programme rather than the catalogue of a picture exhibition. We will not insult our neighbours by accepting this exhibition as representing *l'Art Parisien*, but it represents a certain type of French art of which there has been a great deal too much of late years.

RECENT DISCOVERIES BY THE AUSTRIANS IN LYCIA.

THE book that lies before us,* the official account and publication of discoveries made during the two recent expeditions made by the Austrians to Lycia and Caria, has long been eagerly looked for,—nowhere, perhaps, with such eagerness as in England. Englishmen were the first to penetrate the mountain fastnesses of Southern Asia Minor. We have had first Fellows, then Spratt, Forbes, and Daniell, later Waddington and Falkener. The British Museum is rich beyond any other collection in Lycian marbles. We have the matchless Harpy tomb, the most wonderful and beautiful monument that archaic art has left us; we have the Nereid Monument of Xanthos from Caria; thanks to the skill and energy of their present guardian, we have the Mausoleum marbles now worthily housed in their new and splendid hall. To the long series from Lycia, some of us feel, very bitterly, that England might have added the two great friezes from the Heroon at Djölhaschi, friezes which are now the chief treasure of the Museum of Antiquities at Vienna. It would have been for the advantage of all archaeological Europe could these sculptures have been seen side by side with our already exciting Lycian collection. But England was too poor or too niggardly or too ignorant,—which was it? The time is gone by for lamentations. It remains for us now to learn from the publications of the Austrian Government what was the treasure which might have been ours, and to console ourselves, as best we may, by the cheering fact that our nation possesses a cast of part of these Lycian marbles, set up in the Kensington Museum.

We may as well say at once that this Djölhaschi Heroon, which has brought such honour and glory to the Austrian nation, and which weighs so heavily on some British consciences, is not the subject of the present volume. The Heroon and the sculptures that adorned it are to have a separate book to themselves. The re-discovery and removal of these sculptures was, indeed, the object of a separate and special expedition, which started in 1882, the

* *Reisen in Lykien und Karien, angeführt im Auftrage des K. K. Ministeriums für Cultus und Unterricht unter dienstlicher Förderung durch Seine Majestät Kaiser Franz Joseph I., Commandant Fürst Wrede beschrieben von Otto Benndorf und George Niemann, mit einer Karte von Heinrich Kiepert, 49 Tafeln, zahlreichen Illustrationen im Text.* Wien, Carl Gerold. 1884.

funds for which were supplied, as is well known, by private subscriptions among a few Viennese nobles and gentlemen. All the at present accessible information about this Heron has already been made known in the *Builder* in the reports of Professor Newton's lecture on Djölhaschi, at University College; for the rest, we have to wait the appearance of the promised book. The volume we have at present in hand is the first of two. In these two (the second of which is to be edited by Drs. Petersen and Felix von Luschan) are to be contained the whole account of the discoveries of the two expeditions in 1881 and 1882 respectively, excepting the *Djölhaschi Heron*. The present volume takes the expedition of 1881, but its statements are corrected when necessary by the experience of 1882.

To Dr. Benndorf, in the main, is due the first inspiration. The Lycian Apollo had long haunted him with prophetic signs and omens. At last, when the Austrian excavations at Samothrace were closed, the suggestion often made to the Government by Dr. Benndorf took shape and became active. In the spring of 1881 Dr. Benndorf, with, as his colleagues, Professor Niemann for architecture, Dr. Felix von Luschan for natural history, and last, but not least, the Court photographer, Wilhelm Burger, set out for Constantinople. We may well give honourable mention to Wilhelm Burger, for to his skill are due the forty-nine exquisite photographs heliographed for the book. In a country like Lycia, where topography and architecture and sculpture are so implicated, these beautiful illustrations are of the first importance. We may say, before turning to the substance of the book, that it is printed in luxurious folio; that, besides the heliographs, there are eighty-nine woodcuts and 132 facsimiles of inscriptions, all published for the first time. To these we must add a beautiful map embodying the latest corrections and additions to the map of Spratt.

The man-of-war *Taurus*, in which the expedition started, was not destined to go straight to the land of the Chimæra. Putting in at Smyrna on the 4th April, the explorers were met by the terrible news of the great earthquake at Chios, and they charitably turned aside to carry help to the sufferers. Dr. Benndorf devotes a whole chapter to this Chios earthquake. We may as well say once for all that the reader who expects to find in this book a purely archaeological treatise will be, according to his individual taste, agreeably or disagreeably disappointed. Drs. Benndorf and Niemann write advisedly in a somewhat popular style, more after the fashion of the bygone *dilettante* traveller than the modern archaeologist. Their book is pleasant reading to the amateur, for many inscriptions and architectural measurements are plentifully besprinkled with details of Lycian modern life and customs, but particulars about the number of miles, the weather, and the roads are to the specialist somewhat irritating.

These we omit. After four days' delay at Chios, the voyage was continued; the explorers availed themselves of facilities for landing on the way to Lycia, and stopped for a short time at Halicarnassus, Cos, and Cnidus, Loryma, and Rhodes. At Halicarnassus, Dr. Benndorf copied three inscriptions, and was so fortunate as to buy a sculptured bas-relief of white marble, which now, with all the other results of the expedition, is to be seen at Vienna. The slab is no great size, but from its style, and from iron clamps still remaining on it, it must have formed part of a frieze. It represents two youths on horseback; they wear short chitons girdled, and from the symmetrical way in which they sit, they seem to be engaged in some formal race or competition. The relief is in bad preservation, the heads of both riders almost effaced. It was found in a courtyard of the Greek quarter of Halicarnassos, and Dr. Benndorf conjectures that it may once have belonged to the palace of Mausolos, the site of which, according to Mr. Newton, is to be sought for close to the present Greek quarter.

The 10th of April found the explorers at Cos. The modern wonder of the town of Cos is its huge plane-trees (beautifully reproduced in phototype L). It stands in the place of Hippocrates, with its huge ancient branches supported by wooden stays and stone pillars. Two Turkish *caffés*, the resort of all the town, find shade and shelter beneath it.

Leaving the town proper, the explorers passed to the castle by the sea. At the entrance,

over the first door, Dr. Niemann noted and sketched some slabs of marble, sculptured with masks and festoons of very late Greek style, and built into the rough stone wall. The masks are Satyr types not unlike those on the round Dionysos altar at Athens. Inside the castle (entrance to which was only obtained with difficulty) Dr. Niemann found three interesting slabs with figures sculptured in high relief. The slabs lead into two walls standing at right angles to each other in a garden within the castle walls. These slabs had been seen by Mr. Newton in his researches at Cos, and he conjectures that they may have been taken away from a temple at Cnidus by the Knights of St. John and built into the wall of this fortress of Theus at Cos. The slabs had, since Mr. Newton's visit, been heard of, but not seen, by Ludwig Ross, who failed to obtain access to the castle, and they were somehow passed over unnoticed by M. Oliver Rayet, though he noticed some similar slabs outside the castle wall. Dr. Benndorf now publishes the slabs in full. The sculptures represent three figures in excited motion between an altar and a cista. Near the cista is a large snake rearing upwards in many coils. The figure nearest the left is advancing to the cista and extends her right hand to the snake; in her left she holds something, which is probably a thyrsos; she is dressed in a long sleeveless chiton and a *himation*, which forms an arch behind her head. To the right, at the opposite end to the cista is an altar, near which a male figure takes refuge, leaning on the altar with his left hand. He raises his right as if in fear or astonishment. The lower part of his body is draped by a *himation*, which, as in the case of the woman, forms an arch behind his head. Between the man and woman stands a female figure, with both arms outstretched as if in interposition. It seems probable that we have here a scene from the life of the semi-Hellonic semi-Oriental god whose worship was so popular in Phrygia, Dionysos Sabazios. His worship was closely connected with that of Rhea and with the Orphic mysteries. Apollodoros (III. 5, 1) tells us Hera,—who never seems to have been happy unless she was persecuting some one else,—drove Dionysos mad, and made him wander from place to place, till at last he came to the goddess Rhea. She purified him from his guilt, and taught him the mysteries. It may be that here we have the scene of reconciliation and purification. The snake was specially sacred to this Dionysos Sabazios; a golden snake was given to the initiated in his mysteries ("Aureus coluber in sinu dimititur consecratis et eximitur rursus ab inferioribus partibus atque imis."—*Arnob.* 5, 21). The two other slabs seem to form one composition. On the one slab, to the right, are three figures dancing, two of which at least seem to be Satyrs; on the second slab, to the left of the Satyrs, a tree, and near it a male and female figure, both standing; the woman seems to have her arm about the neck of the man. The group probably represents Dionysos and Ariadne; to the left two figures, probably dancing Satyrs. The whole relief is much effaced.

So much for the sculptured remains inside the castle. On the outside built into the wall of a bastion near the sea are further analogous fragments reproduced in Plate IV. exactly as they now stand in the bastion. The topmost piece of frieze was built in concrete of two slabs, in each of which are four figures. On the left-hand slab is a group of two seated figures; a bearded god, with a *himation* across his knee, sits leaning on his left elbow, and holds in his right hand something which may be a sceptre or more likely a thyrsos; a goddess, richly draped, sits by his side, holding in her left hand some attribute too much mutilated to be made out. To the group there advances from the right a woman figure, and offers to them some large object she holds in her hand. To the right of this figure, and on the second slab, a Satyr is dancing with three Maenads. One of the Maenads plays the cithara, the Satyr plays the flute, a second Maenad the tambourine, while the third swings the thyrsos. Lower down on the bastion is a second bit of frieze, the subject of which is barely recognisable; a Satyr may be made out with a panther skin waving behind him; he seems to be holding a shallow cup in front of some wild beast to tempt him on. Two other Satyrs are busy about a preparation for a drinking bout, one is emptying a wine-skin which he carries on his shoulder into a krater held by the other Satyr by the

rim. It is interesting to compare these frieze fragments, now that we have authentic photographs of them before us, with the similar fragments that Mr. Newton describes as seen at Cnidus ("History of Discoveries," p. 449). Dr. Benndorf cites as follows: "A seated female figure, her lower limbs enveloped in a peplos. She looks towards a Satyr, who stands before her brandishing in his right hand what appears to be a thyrsos; his left is extended towards the female figure, and has probably been enveloped in a mantle. On the left of this group is another Satyr moving away from the scene, but looking back. In the other relief a female figure is seated on rocks before an altar. The lower half of her body is clad in a peplos; in her left hand she holds some uncertain object. She is looking back. Behind her stands a female figure, having a peplos wound round the lower half of her body. The seated figure in this group may, perhaps, represent Ariadne." Mr. Newton adds that the execution of the work is poor, and dates it as late Roman. A comparison of the now published figures at Cos, with this description of the fragments of Cnidus, leads almost inevitably to the conclusion that Mr. Newton's conjecture was correct, that all the fragments of the frieze came originally from Cnidus, and that some portions were carried as building material to Cos, by the Knights of St. John; further, that as the subjects are so manifestly Dionysiac, the original source of the frieze must have been the temple at Cnidus, which stood close to the theatre, and was, therefore, in all likelihood, sacred to Dionysos. The male and female figure twice found in conjunction would then of course be Dionysos and Ariadne, not, as has been suggested,—in consequence of the snake,—Asklepios and Hygieia.

The explorers spent the remainder of their time at Cos in investigating the plain west of the town where M. Rayet ("Milet de la Golfo Latmique") believed he had detected the remains of an ancient Asklepeion. Their efforts were in vain, but in their wanderings, they came across inscriptions and countless architectural remains, notably a number of funeral monuments in the form of cylindrical altars surrounded by sculptured wreaths in Hellenistic and Roman fashion. Some of these were well preserved, others completely in fragments, and these fragments built into modern walls. Of one curious marble slab Dr. Niemann took a sketch. The slab is finely worked, and has on the upper part a round shield in relief; it probably formed the side-wall of an adicula. Coming back to the town they came across the remains of a Roman aqueduct, also the foundations of a theatre a considerable size. Near the theatre they found a fragment of a colossal female head; probably, from the treatment of the hand, the portrait of a Roman empress. In the town itself they bought two pieces of sculpture in marble, now in Vienna. A seated figure in a sort of archway in relief, no doubt representing Cybele. The goddess has her feet on a footstool, and is dressed in a gilded chiton and a *himation* thrown over the knees and the left shoulder. Under the left arm she holds a tympanon; her right, much mutilated no doubt, held a cup. On her knee reposes a lion. This relief is interesting because its restoration is certain; because, as the marble of which it is made closely resembles the Pentelic marble. The type of the goddess mother, seated in a little shrine with a lion on her knee, a cup in her left hand, and a tympanon supported upright on her right, and leaning against the right arm, occurs with extraordinary frequency in Attica, and in isolated instances outside Attica, where, as a rule, exportation can be manifestly proved. It was a common custom among the ancients in any place where a special cult prevailed for little copies of the shrine of the god or goddess, containing the sacred image, to be cheaply multiplied. For example, in Sicily, countless little terra-cotta figures are to be found in every collection, public or private, representing a goddess of somewhat archaic type, sometimes seated, sometimes standing, a modius on her head, and in her arms either a dove or a pig; in the one case she represents Aphrodite, in the other Demeter. Such images were probably not for temple service,—they never bear inscriptions,—but for daily household reverence. We have only to recall the silver shrines made for Diana of the Ephesians, and, indeed, the modern trade in Madonnas. The cult of the goddess Cybele, mother

of the gods, was, we know, much revered at Athens. Pheidias, or his contemporary, Agoracritus, made a statue of the goddess for her temple at Metroon. In all probability it is a rough copy of this statue in the Metroon that we possess in the Cybele figured by Dr. Beunhoff, and repeated in countless replicas, many of which may be seen in the public museums of Athens. About them all, rough though they are, there hangs something of the grand ideal manner. The cult of Cybele, like all other Oriental forms of worship, became, as is well known, very popular in the fourth and third centuries B.C. Probably it was during these Hellenistic days that the copies were made for private worship.

The second piece of sculpture obtained at Cos is less interesting in subject, but far better preserved. It is of coarse white marble, a figure of a woman, and reproduces the familiar motive popularised by Niobe's daughters,—a maiden bending forward as she moves away, and lifting up her robe.

Leaving Cos the *Taurus* passed on to Cnidus. Little could be done there but to follow in the footsteps of Mr. Newton and to find that many sites and remains described by him had already disappeared. A few coins and fragments of terra cotta were collected, the best of which represents the youthful Heracles with bow and quiver, lion's skin, and club (an apparatus unusually complete, the bow and quiver belonging to his early, the lion's skin and club to his later, accoutrements). Dr. Beunhoff found his chief interest at Cnidus in investigating modern life: he gives a very full and elaborate account of the weaving processes of the Carian peasantry, an account instructive, because of certain analogies between ancient and modern processes. At Loryma Dr. Niemann made careful architectural investigations about the fortress on the Acropolis, which seems to have served in turn the purposes of Carian, Rhodian and Rhodian conquerors. The remains of these successive systems of building are still recognisable. At Rhodes the explorers were received by the Italian Vice-Consul Bibotti, and obtained from his collection some valuable vases and terra cottas, chiefly archaic. An account of the whole collection is promised in a later publication. At Rhodes Dr. Beunhoff parted from the civilised world; his discoveries in the wild highlands of Lycia we must postpone to another time.

THE LATE MR. SAMUEL HUGGINS.

We regret to have to record the death, at Chester, on the 10th inst., of Mr. Samuel Huggins, whose name will be known to many of our readers. Mr. Huggins was born at Deal in 1811, but spent most of his life in Liverpool. He was educated as an architect, and had a keen love of architecture as an art, and a great knowledge of its history, as well as a very clear-seeing critical intellect. He was, however, a sensitive and retiring man, and never seemed able, or even inclined, to try for success in the field of active professional work; but it is a mistake to suppose (as from some notices of him in local papers seems to have been supposed) that he was only a writer and a critic. He was, during a great period of his life, a frequent and diligent designer, but his designs were for his own pleasure and study merely,—at least, they mostly did not take practical form; but some of them would be very interesting to architects. Mr. Huggins was a devoted Classicist, but he did not consider that Classic architecture in the present day consisted in copying orders or Italian details; on the contrary, he was always urging the study of new combinations, and had portfolios full of small studies of his own, mostly shaded in Indian ink, of numerous "variations" on columnar architecture, in the form of designs for imaginary buildings and monuments. Our impression from recollection (it is many years since we had the pleasure of looking over them) is that many of these are worth publishing in some form. At one time, we remember, their author contemplated offering them to the Library of the Institute of Architects.

Mr. Huggins put together, in 1863, a chart of architectural history, showing the relation and progress of the leading styles in the form of a river; it was very well done, and in a way that made it a good memorandum also for dates of architectural epochs. It was accompanied by a small book entitled "The Course and

Current of Architecture," giving a very well-written critical review of the leading styles.

Mr. Huggins took a very active part in the protest against restoration which commenced a few years ago, and was, like some other "protestants," rather one-sided in his views on the matter. He has also the distinction of having made one of the very best-arranged catalogues of a library, that of the Liverpool Free Library, which could be met with: a kind of good work for which all students of books ought to hold a man's memory in good repute.

Mr. Huggins wrote a good deal in our columns at one time, mostly under his own signature, and he was a frequent and very excellent contributor to the Transactions of various learned or literary societies. Personally he was a man of very high and unselfish character; his own advantage, either in the form of money or reputation, seemed to be the last thing he ever thought of; he was of a very reverential turn of mind, though holding very "advanced" views both in religion and politics; and he had an ardent love of nature. He was a good and intellectual, though not a strong or a successful man. *Requiescat in pace.*

THE VENTILATION OF PUBLIC BUILDINGS.*

The subject of ventilation is usually looked upon as practical rather than artistic, in spite of the fact that the architectural journals now contain an advertisement of "Artistic Ventilation," but it is to the art-loving section of our body that I would particularly address myself rather than to the so-called "practical men." If we will only study the fundamental principles of these sanitary questions, we shall be able to combine the science which is demanded of us with the art that we love.

The subject divides naturally into two parts, the principles and the practice of ventilation.

The following appear to me to be the fundamental principles of all ventilation, and as they are seven in number, we may, if you please, call them the "seven lamps of ventilation."

1. Ventilation is the substitution of foul air by fresh air, and is only successfully effected when without draught.
2. Foul air is air vitiated to a certain definite extent.
3. Fresh air is air in a normal state of purity.
4. Draught is the unpleasant contact of moving air with the person.
5. Air is a fluid and a gas.
6. Heated air is lighter than cold air of equal purity.
7. Foul air is heavier than fresh air of equal temperature.

Before passing on to the practical application of these principles, we may profitably spend a little time in considering each of our "lamps."

We first said that "Ventilation is the substitution of foul air by fresh air, and is only successfully effected when without draught." Many, indeed the majority of the public, imagine that the object and aim of ventilation is solely to produce an agreeable temperature, and, if the room is too hot, they exclaim against the want of ventilation; if too cold, they find fault with the excess of ventilation; but we must remember that purity of the air it is that depends on ventilation, and that temperature is no criterion of the purity of the atmosphere. Note also that ventilation is the substitution and not the dilution of foul air by fresh air. When the air has become vitiated we must not simply dilute the air with fresh, but remove it altogether, and substitute fresh air in its place. Such is the ideal view of ventilation, but, owing to the natural laws of gaseous fluids, we shall find that an approximation only to this requirement is possible. It is, however, an end to be aimed at, even if we can only partly attain to the realisation.

The necessity for the fresh air is found in our dependence upon a pure atmosphere for our health and vigour. The inhabitants of close rooms, persons who breathe air which has already been breathed, are subject to diseases which may cause death, amongst which may be mentioned pulmonary consumption and certain classes of fevers. But whilst some persons may be killed outright by breathing air which has been polluted by the breath of other

persons, the majority are subject to a low condition of health. The reason of this is partly because the oxygen of the air is necessary for keeping in activity the chemical processes upon which life depends, and that, in the act of breathing, the oxygen in the air is taken up by the lungs, and the expelled air is thus deprived of its oxygen; and partly because an individual in expelling the air from the lungs expels with the air carbonic acid gas as well as a large quantity of organic matter, i.e., a portion of the body, which latter has a tendency to putrefy rapidly in stagnant air, and which may thus become a dangerous poison.

We said that ventilation "is only successfully effected when without draught," the reason of this provision is obvious: if draught is felt, the public at once prefer to have no ventilation at all than to have it with draught, for the evil effects of foul air are slow and insidious, the effects of draught are palpable and immediate.

Our second definition was that "Foul air is air vitiated to a certain definite extent."

We have already noticed that air is vitiated by the extraction of oxygen by the lungs and also by the production of organic impurities. But in addition to that expelled from the lungs, carbonic acid and organic impurities are given off continuously by transpiration from the skin. The amount of the carbonic acid is about one-fourth or one-fifth of that exhaled from the lungs, while the organic impurities vary both in amount and character according to the activity or the state of feeling of the individual, and the exercise of varying emotions; so that, for example, a theatre will require more ventilation during the performance of a tragedy than a comedy, so also with a church. It is, however, hardly advisable to so plan our ventilation scheme that its regulation by an ordinary specimen of the genus *verger* shall depend upon the pænetic, joyful, or mournful character of the sermon.

The carbonic acid and the organic exhalations are not the only additions to the atmosphere made by individuals. A large increase of watery vapour is caused by the expiration of moisture from the lungs, and also by insensible perspiration from the skin. This added moisture vitiates the air in a twofold manner, first, by inducing more rapid decomposition of the organic impurities and the consequent formation of unpleasant and injurious gases; and, secondly, by hindering the proper evaporation from the skin, which is essential to prevent the unhealthy rise of the bodily temperature which we call fever.

Thus we see that air is vitiated by the changing of its oxygen into carbonic acid, by the addition of organic impurities, and by the increase of its humidity.

We have next to consider what degree of impurity can be admitted in the atmosphere of public buildings.

The amount of air expelled from the lungs and skin per minute is '33 to '35 of a cubic foot, and contains 4 per cent. of carbonic acid, while about 4 cubic feet of air are saturated with moisture by each person in the same time of one minute, so that a supply of 4½ cubic feet per minute for each individual would be sufficient, could we ensure that he would receive this fresh air, and no other each minute. To do this, however, it would be necessary to enclose each one standing in an upright case, with about 4 in. or 5 in. clear all round, and to admit the fresh air at one end, and remove it immediately when exhaled at the other. Only under these conditions would the supply of 4 cubic feet per minute be sufficient, as advocated by early writers on ventilation.

Air is, however, as our fifth lamp shows us, a gas, and hence is subject to the law of the diffusion of gases, so that the exhaled air at once mingles with the surrounding atmosphere, and is thus diluted and spread over a large area.

Although it is true that the carbonic acid is one and half times as heavy as pure air, yet the heat imparted to it by the lungs renders it lighter, so that it is rapidly diffused, and when once diffused no length of time effects the least settlement or separation.

Thus the air of any apartment will rapidly approach a condition of equable impurity, and the point which we must seek to elucidate is the extent to which air may be vitiated without becoming foul, that is, injurious to health or unpleasant to the senses.

We have seen that the exhalation both of

* A paper read before the Architectural Association by Mr. F. E. Farrow, on the 16th inst.

water vapour and of organic impurities is variable in the case of every individual and the circumstances of his bodily and mental condition; it is therefore usually thought advisable to take the amount of carbonic acid in the air as a test of purity, and as a general rule it may be assumed that the admissible amount of carbonic acid is twice that of the normal atmosphere, that is '8 per 1,000 in volume. This degree of pollution will be attained in a continuously occupied room at the rate of 32 cubic feet per minute. In rooms occupied for a short time only, as in schools, churches, and chapels, a less supply of air is sufficient in practice, both because the cubic contents of the room will supply the needs of the inmates to a certain extent, and also because there is usually a continual leakage through windows, doors, and walls, and the occupancy of the room being for a short time only a greater degree of vitiation may be neither hurtful nor offensive, provided that the humidity of the fresh air be not excessive.

Dr. Reid, who devised the original system of ventilation for the Houses of Parliament, considered that under ordinary circumstances a well-distributed supply of 10 cubic feet per minute was ample.

In Germany the usual practice is to supply 10 to 12 cubic feet per minute for schools, 20 to 25 cubic feet for meeting-rooms, and 40 to 75 cubic feet for hospital wards.

The Austrians provide from 15 cubic feet for theatres and banqueting-halls, to 25 cubic feet for ball-rooms, council-chambers, &c.

In America from 10 to 30 cubic feet, according to the purposes of the room, are given, with an increase to 60 cubic feet in the case of hospitals.

These figures of course make no allowance for the vitiation of air by gas lighting, or other extraneous causes. Each burner requires 45 cubic feet per minute, which must be provided in addition to that supplied for the audience.

Our third definition was "Fresh air is air in a normal state of purity." Now by "normal state of purity" we must not understand the condition of the external atmosphere at any given moment in such a city as London, where the air is so frequently laden with that noxious compound which we call fog, and is always, more or less, impregnated with organic and other impurities, which we term dust. In a state of normal purity the air should contain 21 per cent. of oxygen, and 79 per cent. of nitrogen nearly, with '4 per 1,000 of carbonic acid, and one fifty-millionth part of organic impurities. Such a measure of purity is, however, almost unattainable in a town atmosphere, but an approximation should be made thereto by washing the air with a waterspray, and filtering through cotton-wool.

Our fourth definition was "Draught is the unpleasant contact of fresh air with the person." This unpleasant contact usually produces the sensation of cold; but we must not forget that there is such a thing as an unpleasant hot draught, though it is neither so injurious nor so offensive as the cold draught, the bugbear of all ventilators, and the dread of the ventilated.

Cold draught from the incoming fresh air arises from four sources:—1, Over rapidity of current; 2, Lowness of temperature; 3, Too great humidity; 4, Too little humidity. Each of these causes produces the sensation of cold by lowering the temperature of the surface of the body, the first and fourth by causing excessive evaporation from the skin, the second by the increased radiation of heat from the body to warm the surrounding atmosphere, and the third, by the extraction of the corporeal heat to maintain the undue suspension of watery vapour.

Fresh air should never enter at a greater rapidity of current than 2 ft. per second, while a rate of 1 ft. per second is perceptible at the point of entry. Nor should the temperature for our climate and hygrometric conditions be less than 50° F., this being lower by 20° than is possible in America.

Cold draught may be caused not only by the incoming fresh air, but also by local currents induced by the cooling of the internal atmosphere and its consequent descent; these local currents are especially caused by skylights, windows, and open roofs, and their presence may often serve to condemn in the eyes of the public an otherwise carefully-planned and satisfactory system of ventilation.

The last three of our "lamps" or principles we may consider together, as they are inti-

mately connected. "Air is a fluid and a gas," and is therefore subject to the laws of diffusion of gases and expansion of fluids, consequently "heated air is lighter than cold air of equal purity," and "foul air is heavier than fresh air of equal temperature." The consideration of these principles at once brings us face to face with one of the most important and most warmly contested points in ventilation, the position of the inlets and outlets for the supply of the fresh and the removal of the vitiated air. Are we to introduce our fresh air at the lower part of the hall and extract it at the top? or are we to bring in our fresh air at the top and take it out at the bottom? The different views taken of these questions have led to many a fight between the advocates of the upward and downward systems of ventilation. Let us examine the two methods by the light of our "lamps." The advocates of the downward system claim that foul air is heavier than fresh air, and therefore we should extract the foul air at the lower level, but we must remember that our principle is that foul air is heavier than fresh air of equal temperature, and if we look at the source of foul air we see that it is exhaled by the individual, whether from the lungs or from the skin, at a temperature of 90°, and therefore, except at this temperature, has *primæ facie* a tendency to rise in respect of its warmth, though there is doubtless a counteracting influence by reason of its impurity. Accordingly we conclude that foul air on its production has a tendency to rise, unless the difference in temperature between it and the surrounding atmosphere is insufficient to counterbalance the increased weight of its impurity. The point at which the weight of exhaled air at 90° is balanced by the weight of fresh air is at a temperature of 85° for this latter. If, then, the surrounding temperature is below 85°, the foul air commences to rise and will continue to rise until it loses so much of its heat as to render it specifically heavier than the normal atmosphere. During this ascensive process, however, it must not be forgotten that, as air is a gas, diffusion is taking place rapidly, and the foul air is therefore, while losing heat, losing weight also by the dilution of its impurities with the purer atmosphere. The impurities produced by gas-lighting are even more ascensive in their character, owing to the great amount of heat developed in combustion. Therefore we can readily see that if fresh air be admitted at the top of the hall it will meet these ascensive columns of vitiated air and become itself adulterated before reaching the occupants, and this adulteration will be in a continually increasing degree until the air breathed by the occupants will be the most vitiated possible for any given supply of fresh air. The descending system has, however, advantages in the avoidance of draught and the equitable supply of air to all parts of the room alike.

The universal system in Germany and Austria is to introduce the fresh air at the upper part of the room in winter and at the lower part of the room in summer, the extraction being in a contrary direction, so that the warm air in winter, cooling naturally, descends, while the cool air in summer, becoming heated, rises. This method and the argument in favour of it depend to a very considerable extent on a very high dew-point, so that there is a far greater chance of success than there would be here in England with a low dew-point.

In the case of a hall without ventilation there is a constant rolling stream of air passing upwards from the heating apparatus to the top of the room; then, cooling, it again descends on the other side of the hall, and so keeps up a constant circulation. Now if ventilation is introduced to such a hall and is insufficient to carry off the whole stream of heated air as it ascends, the roll of the atmosphere will not be wholly diverted, but will still continue, and thus there may be with advantage an extraction of air at the lower level. But this method of extraction can only be justified for adoption when artificial heating is abundant, and when no gas lighting is in use to vitiate and heat the upper strata of air. This will accordingly limit the effectiveness of the method to the day-time of a portion only of the winter months, and hence may, I consider, be practically inadvisable in our country.

To summarise the lessons we gather from a consideration of the principles of ventilation:—First, we learn that our object in ventilating a public building should be to provide an

adequate supply of fresh air, uncontaminated as far as possible by contact with foul air, which latter should be removed as speedily as may be; and, further, that an adequate supply may, in ordinary cases, be taken to mean from a minimum of 10 cubic feet per minute for each individual, rising to about 30 cubic feet, according to the use and circumstances of the building.

Next, we learn that draught must be avoided by careful regulation of the rate of current, temperature, and humidity of the fresh air, and that vitiation of the instreaming atmosphere will be best obviated by bringing in the fresh air at the lower part of the hall, and extracting the foul air at the upper part.

We have now to consider the best method of achieving the desiderata at which we have arrived, and the application of principles to practical work.

Our object is the introduction of fresh air and the extraction of foul air, and this object we must attain with certain conditions already formulated. There are three distinct methods by which our object may be attained:—(1) We may force in the fresh air, and allow the foul air to escape by the propulsive force of such fresh air; (2) we may draw out the foul air and allow the fresh air to enter and to supply its place; or (3) we may both force in the fresh air and draw out the foul air. Which of these three methods we should adopt must depend both upon the peculiarities of each individual case, and upon the means which we propose to employ to obtain our end.

These means may be divided into two classes, natural and artificial. By natural ventilation is understood that obtained by means simply of the natural power of air under certain conditions to produce and sustain motion. Artificial ventilation is the adoption of mechanical or other artificial agency to produce the desired currents of air.

Natural ventilation depends chiefly upon the difference in temperature between the incoming and outgoing air, if this difference be considerable the flow will accordingly be greater than when little difference exists. If some of the openings be exposed to the direct action of the wind, this will also tend to produce a current, and this is the operative principle in what is termed the "cross-ventilation" of hospital wards. The air pressure on two sides of a ward is rarely if ever equal, and hence if windows be open on opposite sides, a current will nearly always be maintained, and frequently a very strong current. Similarly, if there be two openings or two series of openings at the upper and lower part of a room or hall, a current of some kind will be almost always found to exist. Thus, we have in this way a very simple and cheap method of ventilation, but it can hardly be called desirable or satisfactory. The varying pressure, whether of the wind or of temperature-difference, will cause a constantly-varying rate of flow in current, so that if provision be made for ample ventilation when the current is sluggish, a swift current will produce an unbearable rapidity of change unless means are provided for reducing the area of the openings, but even then constant alteration will be required to meet the constant change of motion. The direction of the currents, too, will be always liable to sudden and unexpected reversal, and above all it is practically impossible to sufficiently regulate any heating arrangements to accommodate the varying exigencies of the moment.

Natural ventilation may be usefully adopted in private buildings, but for the large supply and other requirements of public buildings it is almost out of the question.

There is, however, one form of natural ventilation which may be with advantage employed in public buildings occupied for a short space of time only, and by a number of persons, small in comparison with the cubic contents of the apartment, that is, by a thorough freshening and renewal of the atmosphere during the times between the occupancy of the room; as, for example, in some schoolrooms, where the children are frequently sent out for a short space of time, when the windows and doors may be all opened, and the air freshened up for the next session.

Artificial or mechanical means of ventilation may be classed in three groups:—

1. Mechanical means, needing no attention, i.e., self-acting.
2. Mechanical means, needing a small amount of attention.

3. Mechanical means, needing constant attention.

The first group of these are of varying character, but all depend for their action on the fact that air is a fluid, and for the most part derive their motive power from the wind.

One of the oldest, and for a long time most esteemed, of self-acting appliances is the so-called "syphon" ventilator of Charles Watson, which consists, as most of us probably know, of two tubes of unequal length, enclosed in the snugly casing so dear to ventilating tradesmen.

If all other openings into the apartment, as doors and windows, were closed, an upward current of the internal air was established in the longer tube, and a downward current in the shorter, similar to the action through the legs of a syphon, but not, mark you, by reason of the principle of the syphon, but from the difference of temperature of the air in the two tubes. In the event of any more ready access of the air, the apparatus simply acted as an ordinary atrial outlet. The great success of this device can only be understood by remembering that it was the first substitute for no ventilation; for the evils of its action are apparent in the old introduction of a cold descending stream coming directly down upon the heads of the inmates, and passing through, and consequently cooling and mixing with the ascending current of foul air. A cooler atmosphere was, of course, produced, but this we have already determined is not ventilation.

The next series in this group of self-acting ventilators are those various modifications of the "Archimedean screw" system rejoicing in the high-sounding titles of "Empress," "Imperial," and the like. These consist of a wind turbine connected to the upper end of a spindle whose lower extremity is furnished with screw blades, two or more in number; the turbine, actuated upon by the wind, revolves, and with it the spindle and screw, by which a current is induced of greater or lesser intensity. When once erected these, of course, need no further attention until from the wearing out or rusting of the moving parts or increase of friction they come to a dead stop, but as their moving parts continually decrease in smoothness of working they rapidly lose in efficiency, and at the best are but feeble in their action except under strong wind pressure.

Our third series in this group have of late far surpassed other competitors in the field of "self-acting" ventilators. They are based on the principle of the kinetics of a fluid across the mouth of an open pipe, and their effect can never be greater than would be obtained by a simple open pipe provided that the stream of crossing air always passed in a favourable and equable direction; but as this is, under the circumstances, never experienced, means have been devised in the construction of mechanical appliances of this kind to provide for the regulation and direction of all wind currents in the desirable course.

Two well-known typical examples of this series will suffice to enable us to understand the general principles.—Banner's cowl and Boyle's so-called "air-pump" ventilator. Banner's cowl consists of a horizontal trumpet-mouthed tube, arranged with a wind-sail, so as to revolve over the mouth of a vertical tube, in order that the wind may be always received in the conical mouth, and directed horizontally across the mouth of the open tube. Nothing could be simpler and nothing more effectual, as long as the cowl revolves freely and the wind blows.

Boyle's ventilator has no moving parts, but consists of a skilful arrangement of curved plates and cross diaphragms, so disposed as to divert any wind-current into such a direction that the principle we are considering may come into operation.

We are, doubtless, most of us aware of the worthy strife which has been waged between the partisans of these last two inventions; but, looking at it dispassionately, we may fairly admit that each is logical in its idea and efficient in its action. Personally, of the two, I prefer Boyle's ventilator, because it has no moving parts to get out of order, and is more easily enclosed in a turret or flèche, to obviate the fearful ugliness from which all these devices suffer.

I do not propose to weary you with descriptions of the numerous modifications of these types, of which there seems to be an increasing supply every month. If we do but rightly understand the principles involved we shall be

able to judge for ourselves of the respective merits and advantages of each for our particular purpose, and to decide which will in any one case give the best value for our client's money.

We should, however, consider the peculiar advantages and drawbacks of the group of "self-acting" ventilators. As we have seen, they depend upon the wind for their primary motive power, and hence they are, naturally, irregular and spasmodic in their action; for instance, in the experiments made by Professor Corfield, Mr. Rogers Field, and others, on Boyle's ventilators at the Custom House, it was found that on two successive days the extracting action of the 3 ft. ventilators varied from 1,347 cubic feet per minute on the first day to 535 cubic feet per minute on the second. Such variation as this at once shows the great difficulty of using any "self-acting" ventilator where satisfactory ventilation is aimed at. Not only will there be an ever-varying speed of current, but the heating arrangements will require special provision to meet this variation, and must, therefore, be adapted for a large reserve of power. Some current will almost always be attainable unless the moving parts are checked by friction, dust, or wear, as the movement of the air is very rarely less than six miles an hour, and averages twelve miles an hour.

Our next group of mechanical contrivances are those which are not self-acting, but require a small amount of attention.

The first class in this group consists of those arrangements for supplementing the action of natural ventilation by the creation of an artificial difference of temperature by means of columns of air rarefied by adventitious heat. For example, we may adopt a large fire with a heating furnace at the bottom, and into this admit channels from the apartment to be ventilated. Similarly, the use of a series of gas-jets or of hot-water coils will induce an artificial current, and are usually of easier application than a regular extraction-flue. Arrangements such as this have the advantage of far more equable and certain action than those of the first group ("self-acting" ventilators), and it is possible to make a calculation of the effective power that can be attained by the consumption of a certain amount of heating power which shall be fairly near the truth. These devices are, however, occasionally liable to failure when severely tested by strong and sudden gusts of wind or cold air unless provision be made for such contingencies.

The whole of the types we have already noticed are, you will have observed, adapted only as exhausters, the foul air being drawn out by these means, while fresh air is allowed to enter by suitable inlets, and with proper provision made for warming the same on admission to the apartment. The methods of warming the fresh air are almost numberless, and may consist of close stoves, hot-water or steam pipes, gas stoves or ordinary fireplaces, as may be best adapted to the particular case in question.

The remaining mechanical means of inducing currents both in this and in the third group, may be applied either as exhausters or injectors. Thus in this group we have first those mechanical aids, which consist of arrangements for driving fans by means of water-power. This type of apparatus comprises a horizontal turbine, fixed at one end of a spindle, with fan blades at the other. The spindle revolves on accurately-fitted centres of hard material, as phosphor bronze, and are supplied with ample lubricating jets; the turbine is driven by the impact of fine jets of water, and thus works the fan.

Verity Bros.' patent ventilator is a good example of this type of apparatus, while another, called the *Aërophor*, is being introduced from Germany by the agents of Messrs. Treutler & Schwarz, of Berlin. The results and the cost of both these inventions are very nearly equal. Messrs. Verity's apparatus works with a pressure of 35 lb. to 50 lb. on the square inch, and their medium size with the consumption, or rather use, as the water is not wasted, of ten gallons an hour propels from 350 to 450 cubic feet of air per minute; with smaller pressure, of course, a larger amount of water must be used to obtain similar results. The *Aërophor* is rather cheaper in first cost, especially in the larger sizes, than Verity's patent, but requires a rather larger amount and higher pressure of water to obtain equal power. Where a constant supply of water is provided, this type of apparatus may well be employed, as the pres-

sure in the mains is usually about 60 lb. to the square inch, otherwise the requisite pressure must be obtained by the use of cisterns.

These appliances have many advantages, from the small amount of attention they require, the simplicity of their working, and the ease with which they can be regulated or stopped at will, the turning of a stop-cock being all that is needed to start or regulate them. Their disadvantages are the liability to failure during frost for want of water and the small amount of power attainable, the largest specimen ever made by Messrs. Verity being an extractor of only 4,000 cubic feet a minute, and the largest stock size of the *Aërophor* exhausting only 3,000 cubic feet a minute, with 120 gallons of water per hour.

Another instance of the employment of water-power for inducing current is seen in the "*Acolus*" waterspray ventilator, though in this case there is no moving mechanism, but simply a conical spray shower of water from a downward vertical jet under considerable pressure, which, acting within a tube, causes a corresponding downward current of air. Thus, the action is simpler even than the turbine ventilators, while the consumption of water is naturally greater, and the full power is not great, the largest size extracting 5,000 cubic feet a minute, with 200 gallons per hour at 45 lb. pressure.

We now come to the third group of mechanical means, those which require constant attention. These universally consist of rotary fans driven by steam or gas engines, and so needing a continual attention. I do not propose to go into the question of the merits of various forms of fans, still less into the consideration of the different types of steam or gas engines, because firstly, these are strictly within the province of the mechanical engineer; secondly, because to take up this branch of the subject thoroughly would of itself occupy a long evening; and, thirdly, because there is very little difference in the comparative effect of different forms of fan for any given horse-power. Our province is to consider what are the necessary requirements of the ducts or air-passages, their form and their dimensions. The desirable rate of flow for a forced current in a main channel is about 600 ft. a minute, while the inlet or suction air-passage to a fan should have one and a half times the area of the outlet or distributing duct. To compensate for resistance of air in passage along the channels, and yet to preserve the smallest efficient areas of distributing ducts and passages, their sectional area should be increased by $\frac{1}{10}$ for every foot of distance from the fan, added to a constant increase of one-fourth for each square foot in area of the main channel to allow for the great resistance of small passages.

The air-channels must be exclusively devoted to their purposes, and should not be used or even be made so as to be available for passages. They must be clear, unobstructed, and smooth, with all angles rounded, all corners filled in, and all enlargements avoided, so as to present the least of resistance to the flow of air.

This third group of mechanical means is, of course, by far the most preferable where the expense both of first cost and of maintenance can be borne, and it is indeed the only way of providing a thoroughly sufficient and efficient scheme of ventilation for a large or complicated public building.

We have now glanced at the various types of apparatus which we may employ to force the fresh air into our hall or to expel it when vitiated. We will now consider a little further the advisability of using any one of the three methods of directing a current which we saw to exist, i.e., whether it is better to force in the fresh air or to force out the foul air or both.

One point we must never forget: whichever method we adopt, we must have both inlets and outlets, separate and distinct, and without any doubt as to which function they discharge. So many of the public have an idea that if they have an exhausting apparatus at work, the fresh air will come in somehow and somewhere. It will undoubtedly, to a certain extent, through windows and doors, in fitful gusts and piercing draughts.

Many of the mechanical means we have discussed are, as we saw, adapted only as exhausters, and, therefore, if we use them, we shall probably simply supplement them by free inlets for the fresh air without injecting power. This method has the great advantage of easy applicability. It is such a simple thing

ust to put up an exhauster and knock a few holes in the wall for the fresh air to come in as it lieth. But there is with this method the great drawback that the inlets will not be at the same distance from the exhaust, and, moreover, will be subject to different atmospheric pressure according to the direction of the wind, with the result that the entry of the fresh air will be greater at some points than at others, and, moreover, will be changing and fickle according to the varying circumstances of the inlets. If the exhaust system be adopted care must be taken to neutralise, as far as possible, the tendency to unequal action of the inlets.

Suppose, however, that we force in the fresh air and allow the foul air to pass out merely by the propulsive force of the entering air, what is the result?

We shall be able to maintain an equable, well-distributed, and regular stream of inflowing air, but our outlets will be liable to be more or less overpowered by great difference of temperature or strong wind pressure, and this will especially be the case if the outlets are too large or too numerous, points which must be carefully attended to, together with the adoption of carefully-planned baffles for the wind.

Thus we see that both of these methods are liable to cause draught, from the peculiar dangers to which they are each exposed, and we therefore come to the conclusion that if our scheme of ventilation is to be relied on to give satisfactory results we must employ both of these methods,—we must both force in the fresh air and force out the foul air. Of course we may possibly often use for one of these purposes, especially for the expulsion of the foul air, means which are not altogether satisfactory in themselves, but will give good results when combined with good impulsive power.

The question of the position of inlets and outlets we have already touched upon, as regards the direction of the current, but it is important to remember that other points in relation to the openings demand our attention. The rate of entry of the fresh air will, of course, decide the area of the inlet openings, but this area should be subdivided to the fullest extent, and distributed as evenly as possible throughout the apartment. On no account should the stream of fresh air be able to enter in a mass, and pass compactly through the hall, for if so the parts of the atmosphere over the direct stream will be stagnant, or nearly so, just as one sees in a mill-pond where, in spite of a swift current through the centre, the corners are almost quiescent; for, remember, air is a fluid as much as water is.

So important do I think this equable distribution of the inlets that I personally believe it is better to endure the disadvantages of floor-gratings rather than have the currents at the sides of the room only. Here is one of the advantages of the downward current arrangement, as the air can be evenly distributed without the disadvantages of gratings.

It is preferable that the direction of the openings should be in all cases vertical, as horizontal entry of the air is very apt to cause troublesome local currents of greater intensity than the fresh-air flow, and thus produce the ever-dreaded draught.

A capital device for preventing draught is the construction of a sub-hall, in which the fresh air can be both properly prepared and warmed, so as to be quite ready to enter the main apartment. Here the draught, if there be any, will be expended, and the fresh air enter in an even and regular flow.

The different means of heating the fresh air would take too long now to describe, but it must be remembered that the fresh air should always be warmed when entering before entering, or immediately on entering the hall, so as to prevent the feeling of draught. Warming a building by a current of warmed air, which speedily is expelled as foul with a scheme of ventilation, is, of course, more expensive than the usual heating and re-heating of one body of air only, but if the public are to have ventilation, they must be prepared to pay for it, and this loss of heat is merely one item of the cost.

I have thus endeavoured to bring before you and the readers of the science of ventilation, and to enunciate its governing principles. The application of these principles will vary in almost every case, and each of us must decide for himself what is the best method of dealing with any particular building with the means at his disposal, and this may, with care and expe-

rience, be well accomplished without placing ourselves at the mercy of the sanitary tradesmen, and allowing them to place forests of pipes and other monstrosities in the most conspicuous position.

Mr. Farrow at the close of his paper explained some drawings exhibited on the walls. One was a plan of the Rathhaus in Vienna, showing the ventilation of a large ball-room capable of accommodating 3,000 persons. The ventilation scheme is divided into two equal and similar halves. The fresh air enters the cellar, and is driven by fans along passages in the basement. It then enters several heating-chambers, in which the air is warmed by contact with steam-pipes; it passes upwards through a large vertical shaft to the roof of the ball-room, and falls on the heads of the inmates at the rate of about 1 ft. per second. The foul air is extracted by several shafts let into the cellar and is expelled by another fan. A similar plan of ventilation is adopted in the Banqueting Hall. Mr. Farrow also explained the ventilation of the Vienna Opera House, and of several works in this country on which he had been engaged.

For a report of the discussion which followed, see p. 151.]

DESIGN FOR THE COMPLETION OF THE HOUSES OF PARLIAMENT.

WE give this week a view of the completion of the Houses of Parliament as intended by Sir Charles Barry, a scheme to which considerable reference was made during the recent sittings of the committee on the "restoration" of Westminster Hall. It was then stated by Mr. C. Barry that plans by his father were in existence for an extensive addition, commencing at the clock-tower and returning along the line of St. Margaret-street, which it had always been his wish to see carried out at some future time. Plans for this addition were made by him, and a view of the proposed addition is given as a plate in Dr. Barry's "Life" of Sir Charles Barry. The present view has been drawn afresh from those plans and the elevations and sketches existing. Some modifications, however, have been made by Mr. C. Barry. The plan, which we published a few weeks ago (December 13) is drawn more inwards, towards Westminster Hall, at the southern end, so as to leave St. Margaret-street wider at that point; the original plan would have left rather a narrow gut in the roadway at that point. The crowning feature over the gateway is altered from a small lantern, as in the original design, to a larger octagonal lantern, raising the centre, which was formerly rather depressed between the two flanking towers.

The original design was made at the time when Sir C. Barry foresaw the probable removal of the Law Courts at no distant date. It thus represents what he would have regarded as the best use to make of the space, architecturally and practically, whenever that removal took place. He was well aware that greater space would eventually be required for rooms and residences in connexion with the Houses of Parliament, and, in fact, the space has been required long before now, and many outstanding offices are in use, at heavy rentals, to supply the defect of space in the Westminster Palace. Mr. C. Barry calculates that the money thus expended annually is considerably greater than the interest on the outlay which would be necessary to erect the new buildings as here shown; an argument which, to our remarkably economical Government, will probably be stronger than anything that could be urged in regard to architectural effect or completeness, and from our point of view also that is in one sense the strongest or at all events the most unanswerable argument in favour of at least giving full consideration to this scheme at the present moment. Other things apart, we should not desire to shut Westminster Hall out from sight; but seeing that so much more room is really wanted (and that want will go on increasing) it is surely more in accordance with reason and common-sense to provide for this by completing the great building according to its architect's intentions, than to provide a few paltry rooms between the buttresses of Westminster Hall, and leave the rest to be found on the system of rabbit-burrowing in offices about

the neighbourhood. To carry out this scheme will be doing the thing once and for all, in a way worthy of the nation, and, if Mr. Barry's calculation is right, at an ultimate saving of money. If there is difficulty about the immediate expenditure, or if it is concluded that it gives more room than is wanted at present, the completion would be quite capable of being carried out in two instalments; half now, and when ultimately required.

The First Commissioner of Works suggests lately that some of the present buildings now used as residences might be taken for Committee-rooms, and residences provided elsewhere. In that case, the block fronting St. Margaret-street could very well be made a residential portion, and would be very suitably situated for that purpose.

The view is taken from the end of Great George-street, and shows as the prominent foreground feature the great gateway at the angle of new Palace-yard, which would form a grand entry to the precinct of Parliament. Sir Charles Barry proposed (and his son seconded the proposal) that this tower-like mass of building containing the gateway, with its octagonal lantern rising above, should be named "The Albert Tower."

DESIGN FOR A GATE-HOUSE AND BRIDGE.

WE give the design by Mr. E. Guy Dawkins for this subject, which obtained the 101. prize at the Royal Academy. It is a good "Medieval" bridge, and as such does credit to its author, but we would rather have seen an attempt to deal in a picturesque manner with a bridge built more upon the lines of modern engineering.

BAPTISTERY AND FONT, ST. MATTHEW'S CHURCH, BAYSWATER.

THE baptistery, font, and cover were given by the late Archdeacon Hunter to the new church erected on the site of the old one in St. Peter's-burg-place.* The baptistery is formed by a apsidal extension to one bay of the nave, and vaulted in stone, the moulded ribs being supported by detached shafts. The font is of Caen stone, with shafts of polished Devonshire marble. The cover is of American walnut suspended by chains from the central boss of the vaulting; the weight, of globular form, rests just under the gas corona. The work was executed from the designs of the architect, Mr. John Johnson, Queen Victoria-street, Mansion House, by Messrs. Dove Bros.; the carving being by Mr. Lawlor and Mr. Baird. The windows are filled with stained glass by Messrs. A. L. Moore & Co.

COMPETITIONS.

Newbury District Hospital.—No fewer than 120 sets of plans were sent in this competition. Mr. Waterhouse, A.R.A., spent some time in examining them, and has selected eight from which to give his final judgment. The following is the list of the eight designs so selected (mottos were optional), viz., those sent in by Messrs. Webb & Tubbs, of Reading; Mr. W. E. Woodroffe, of London; Messrs. Gordon & Taylor, Mr. H. G. Turner, Mr. J. B. Phillips, and those bearing the mottoes "Sunshine," "Economy," and "Plan" in red.

Upper Bourne Estate, Bourne-mouth.—The competition for laying out the Upper Bourne Estate near Bourne-mouth, for the Poole Town Council has been decided. The design "Spero," by Mr. Barnes, architect, of Poole, is placed first; and those hearing the mottoes "Au Bon Droit," by Messrs. Habershon & Fawcoker, architects, of London, and "Quod Petis Elic Est," by Messrs. Kemp-Welch & Pinder, architects, of Bourne-mouth, are bracketed second, and considered to be of nearly equal merit with the first.

Nottingham.—Mr. W. H. Radford, Assoc. M. Inst. C.E., &c., has resigned his appointment as assistant engineer to the Nottingham Corporation, and has commenced private practice at Pelham-chambers, Nottingham, as a civil and sanitary engineer and architect.

* A view, plan, and description of the church were given in the *Builder* for April 7, 1883. We regret that our present illustration the title is misprinted "St. Matthias's Church."

ROYAL ACADEMY OF ARTS £10 PREMIUM, 1884.

THE FIREPROOF CLOSING OF OPENINGS IN PARTY-WALLS.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

THE ordinary meeting of the Institute was held on Monday evening, Mr. Ewan Christian, resident, in the chair.

The Chairman referred in feeling terms to the loss the Institute had sustained by the decease of Mr. John Whichcord and Mr. R. M. Gibson. Remembering the interest taken by Mr. Whichcord in the success of the Architects' benevolent Society, it seemed to him that nothing would so well tend to keep his memory near as the founding of a Whichcord Fund in connexion with the Society. In this memorial both young and old might unite, as the fulfilment of the object Mr. Whichcord had had so deeply at heart, viz., of increasing the funds of the Society over which he presided.

Professor Kerr said that two of the professional papers in referring to Mr. Whichcord's decease had suggested that his presidency of the Institute was in some sense unpopular. It would be a great mistake if that statement were permitted to go uncontradicted. It was the fate of Mr. Whichcord, as President, to be, as it were, the first of a new dynasty. Circumstances had caused some difference of opinion, but beyond that Mr. Whichcord's presidency was highly esteemed by the Institute. Mr. Whichcord was a man of cultivated mind, of remarkably powerful intelligence, and of great experience of the world. It was his destiny in his profession to assume the position identified with the name of a purely practical man, and he came before them, as the recipient of their honour, in that light rather than as an artist and scientific man, which he might with a good grace have pretended to be. No one understood better the functions of a chairman,—to promote freedom of debate, and to arrive at the real sense of the meeting.

Mr. Hansard remarked that Mr. Whichcord was one of that band of brethren, of which Professor Kerr was another, who met at Mr. Asphiel's somewhere about 1857, and who propounded the first idea of a diploma for the Institute.

Mr. J. Macvicar Anderson (Hon. Secretary) also bore testimony to the value of Mr. Whichcord's opinion and judgment in difficult and intricate matters.

Mr. W. H. White (the Secretary) announced that the Council had awarded the sum granted under the Pugin Studentship for last year to Mr. Sankey. An examination of the sketches displayed on the walls would show that the Council had been justified in the course they had taken. It was further intimated that the sketches would remain on the walls for a few days.

Mr. Wm. White, F.S.A., then read a paper on "The Fireproof Closing of Openings in relation to the Metropolitan Buildings Act." After some brief preliminary observations, Mr. White came to the discussion of the main subject, consisting of three essential parts, the arrangement of the door; its fittings; and the arrangement of the opening. (1) For the material of the door, iron still held its own. It was not altogether free from perils of its own, but on the whole it was the safest. Mr. Braucon's concrete doors on iron wire lattice frames were admirably suited for fireproof purposes. Wood itself was one of the best non-conductors, and when thoroughly encased in plaster or sheet iron its resistance was remarkable. An oak door, double planked with metal or asbestos, would be very safe. A solid oak door of 3 in. or 4 in. plank, even without extraneous protection, was said to resist almost any fire, provided its edges were well protected. He did not know whether the merits of cyanite or asbestos paint on deal doors had been duly tested. But the door prescribed by the Act was of wrought iron, the thinnest panel of which was not to be less than 1/4 in. thick; hence it was commonly a sheet of iron riveted on to a skeleton framing of the same thickness, dividing it into two or more panels. The possible perils incident to this construction were pointed out, but it was owned that in many serious cases the thickness of iron provided by the Act had sufficed; still, it might often be well if the metallic shield were thickened out. Something might also be done by a contrivance for automatic closing of doors on the outbreak of a fire. Whether iron were the best material or not, it was at present the only one required or allowed

by the Act. (2) The Act required the iron doors to be fitted into a rebated frame. There must not merely be a rebated frame for the door to be hung in, but it must be so fitted that no space must be left anywhere round the edges; thus no draught must be able to pass, and no heat, save by conduction and radiation. The first effect of the great heat upon the iron would be to so expand it as to fix it in its framework and make it still more impermeable. Mr. White said he had been told by Mr. Aston Webb that on two occasions of a fierce fire in the smutting-room of a mill at Deptford, which was thoroughly burned out, the ordinary iron doors fitted in this manner effectually resisted the communication of the fire to the adjoining division of the building, although in each case one of the doors was found to be warped out of its rebate. This, doubtless, took place in cooling, when the worst of the danger was passed. As a construction exactly answering to one not meeting the requirements of the Act, and one not more satisfying the wants of those who on their own account might naturally be thought to wish to adopt a reasonably fireproof system, were introduced the doors separating the different buildings lately destroyed by the great fire in the Queen's-road, Bayswater. (3) Coming now to the third point, Mr. White remarked that the facilities afforded for the spread of fire were largely and dangerously increased by the great and improper number of openings in each divisional wall. By means of these openings each story became practically a huge horizontal warehouse, without any fireproof separation in its height, and accordingly with a succession of seven distinct risks, arising from the seven portions into which the building was nominally separated. On each of the five stories were two openings in each party-wall dividing the several structures. Thus in each party-wall there were ten openings instead of one, and they were told that nobody was responsible for this state of things except the luckless depositors, who ought to have made a personal inspection of the premises, or possibly obtained a professional opinion on their construction before risking their property there. It was not for him, said Mr. White, to give an opinion as to who was responsible for so scandalous a state of things, but he was very greatly astonished to be told there is a serious question as to the number of openings allowed by the Act in any one party-wall; he was told that District Surveyors generally take it for granted there is no restriction. He knew that some who had studied the Act very carefully were of the same opinion. Against this laxity of interpretation he argued very earnestly and at considerable length. After all, however, it seemed to be undeniable that there were really no means of enforcing these provisions of the Act. No penalties were attached to its evasion in these respects. There was no Government Commission, and no system of inspectors to watch over its enforcement, as in the case of the Factory Acts. Again, the Act merely spoke of a building "used,"—not "hereafter to be used,"—and so the condition could not be enforced till after its occupation, the restriction would not apply till after the granting of the District Surveyor's certificate, leaving the owner or occupier free to use it in any way he might see fit. If this should be so, indeed, it was a case for immediate legislation, or, at any rate, for administrative reform. It would be well if in the case of these huge warehouses matters could be put on a better footing for the protection of the public. In respect to dwelling-houses, care was really taken, the District Surveyor having power to get a magistrate's order to stop or even to take down improper work. In theatres, personal safety had not yet been really secured by the compulsory provision of due means of exit in the event of panic. He, however, had done his duty in calling attention to necessary reforms.

Mr. Woodthorpe, in opening the discussion, said that there were many defects in the Act, as in all Acts of Parliament. There was a difficulty with regard to the definition of the term "public building," and the question of the construction of the doors was capable of improvement. At the same time, they had to thank Mr. White for bringing the matter before them so ably. The Act in its present form had succeeded well in many instances where the fire was moderate, but in cases where the fire was great, it was difficult to find anything that would help to stop it. The flames generally spread, not

through the door, but by attacking the roofs. One very weak point in the Act was the fact that there were no means for compelling the closing of the doors. If this were done in the early part of the fire, it would be found very effective, and a heavy penalty should compel this to be done. In the present state of the law, the District Surveyors did the best they could, and in the face of divided opinion there was great difficulty in carrying out the terms of the Act. He agreed that the Act could easily be amended, and considered that amongst other things, the party-walls between warehouses should be carried higher.

Mr. Jennings remarked that Mr. White seemed to imply that District Surveyors had not done their duty. The District Surveyor had no positive power in himself, except to take a case before the magistrate. With respect to the question of the iron doors, the Act did not say how they should be hung. It said that they should be the distance of the party-wall, unless they were thickened as now required by the Fire Offices. Therefore as far as the Act was concerned, it was not requisite to put the door in the exact way Mr. White spoke of. As regards double doors, these had been successful in almost every case. He was present at the fire in Duke-street, when one of a pair of iron doors was opened to have a look at the other, which was found to be perfectly efficient. The requirement of double-doors was most essential for the prevention of fire spreading from one building to another, but, as Mr. Woodthorpe had said, there was no provision for their being kept closed. Indeed, in order to compel this to be done, they would require the services of a police force to examine the doors. In his experience of fifty years he had never met a single instance in which the fire had passed through a properly-built 9-inch wall. The great cause of the spread of fire was the putting of timber into the wall, the heat being sufficient to burn the ends of the timber and so communicate the fire. At the present time a large number of additions and alterations are made by persons cutting into the party-wall, sometimes without knowing they have gone through the wall. He did not think the Metropolitan Board of Works had much power to interfere. They considered they had the power of disapproving of public buildings not built in accordance with the Act, and yet he found they had allowed a wooden staircase in a church where 20,000*l.* had been spent on decoration. He hoped architects generally would take some steps to provide for further security against fire. The public had not much ground of complaint, as they could always insure their goods.

Mr. Robert Walker considered that Mr. White had been severe, not only on architects and District Surveyors, but also on the progress of modern improvement. He did not suppose that Mr. White meant to say anything derogatory to the practice of his profession, or to the high principle of modern architects in doing the best they could for their clients. But he protested, as a District Surveyor and an architect, that any gentleman guilty of direct infringement of an Act of Parliament. He had had a good deal of experience lately in connexion with the iron-door question, and he would join issue with Mr. White when that gentleman said that the fire-proof doors recently constructed had been inefficient. On the contrary, he would contend that the modern system of using fire-proof doors had been a grand and great success, and this had been recognised by the insurance offices. The Stores in the Haymarket, with the greater part of their contents, had been absolutely saved by their fire-proof doors. The same remark applied to Messrs. Crosse & Blackwell's factory, and to the painting-room at the Alhambra, with its most inflammable contents. His experience differed entirely from that of Mr. White. Fire, as a rule, did not spread laterally, but ascended vertically. He had received many applications to allow the employment of concrete fireproof doors, but he did not consider them fitted for their purpose. Every engineer knew that in fitting furnace-work it was a mistake to use Portland cement, and all the best chimneys and furnace-work were constructed with mortar, as heat made the concrete fly. He did not know that, on the whole, the sliding-door

was not the best. There had been a talk about shutting the door, but the necessity for this often did not arise until the fire occurred. In the case of the Haymarket fire the sliding-doors were closed after the fire originated, and yet they answered their purpose. If a door was made to open outwards it was a common custom to allow bulky materials to lie in the gangway, and it was generally in warehouses where these doors were, that they could not be closed in case of fire. The Act stated that stone lintels were necessary, and yet this was the worst substance that could be used. The late Mr. Whichford, however, built the whole interior of the National Safe Deposit Company's building of fire-brick. It had been said that there should be only one door in a party-wall, but hitherto they had always considered that if a person wanted an opening on each floor he should have it, and there could be no objection to iron doors if made of proper material and constructed in a proper manner.

Mr. Tavenor Perry said that when folding doors were used, they frequently opened in the middle, leaving a considerable orifice, which was not the case with sliding-doors. At the Alhambra the sliding-doors effectually stopped the fire, although a quantity of scenery was stored against the other side of the doors.

Mr. J. H. Heathman believed the cause of the spread of the fire at Westbourne-grove was due not to the manner in which the doors were hung or closed, but through a door becoming heated. The heat radiated from that to the other door, and the timber took fire. He was of opinion that doors allowed to swing had full liberty to expand without warping, and if these were closely fitted, and hung in a proper manner, they would answer far better than a door which could not expand without burning. The Act of Parliament did not prohibit the placing of goods in close contact with the door. There should also be some limit to the distance at which timber was fitted near to a door. No timber either in the floor, on the walls, or at the top of the door, should be nearer than 18 in. to any ironwork composing the door.

A visitor, who did not give his name, but who said he had attended as a representative of the Fire Offices Committee, next spoke. As a matter of fact, he said, the Offices had lost faith in the Metropolitan Building Act as far as the doors went. They had suffered so much from the construction of the doors that they had endeavoured to help themselves in this matter. They had, therefore, found it useful in the case of some of the larger docks and warehouses to establish a door of their own, and they had special surveyors engaged to go about and insist that the doors should be built in a certain form. The Offices required that the door should be a hinged one of wrought iron, not less than $\frac{1}{2}$ in. thick in the panels, hung in a cast or wrought iron rebate, and firmly bolted to the wall; such door not to be more than 5 ft. wide and 7 ft. high, and to be in two leaves, not exceeding 2 ft. 6 in. each, fastened with bolts into the frame at the top and bottom. The intention was to prevent backing when the pressure came upon the doors. The term double-iron doors was taken to mean a pair of iron doors similarly hung placed on each side of the opening in the wall so as to be distant from each other the full thickness of the wall.

Mr. Hansard believed that the Fire Offices were entirely wrong in insisting on folding-doors. The sliding-door, not too large in its dimensions, properly sunk into the floor, and with iron guides, was the best form. The top should be 1 ft. 6 in. or 1 ft. higher than the opening, and if such double doors were properly hung on sliding iron rails and wheels, he believed that no fire could possibly penetrate through the sides. According to present circumstances, a rebate was simply allowed to be sunk 2 in. in the wall. If it were insecurely fastened, directly the fire played upon it it passed round the 2-in. rebate, and the danger was immediate.

Mr. H. H. Collins thought it was perfectly futile for any insurance office to lay down rules as to how these doors should be constructed, inasmuch as they had to be made according to the Act of Parliament, whether they liked it or not. He had applied on various occasions to the Board of Works for permission to vary the method of construction as defined in the Act, but it had met with an invariable refusal. Sliding doors, sliding shutters, doors sunk in the floors, and other matters, had invariably, and he believed, rightly, been refused by the

Board of Works, who had no power to vary that part of the Act. If District Surveyors had allowed this, they must have done so in contravention of the Act. After all, the regulations laid down by the Fire Committee seemed to be almost in accordance with what the Act indicated. Many of the doors, no doubt, were never touched from the time they were fixed, and the insurance company might insist upon this being done, or charging an increased premium where it was omitted. They, as officials, could only carry out the provisions of the Act, and the insurance offices should assist them in doing so, rather than lay down rules for the construction of doors. Match-boarding was a very fertile source of fire, and there was no reason why fire-resisting plaster should not be applied to walls. Iron doors were a source not only of anxiety, but were a great nuisance to District Surveyors, and more particularly in the City of London. As Mr. White had said, if these questions were brought before the magistrates, they were simply ignored, or a decision was given totally adverse to what might be desired.

Professor Korr agreed with the last speaker that it was for the fire offices to remedy whatever faults were complained of; the District Surveyors were absolutely powerless. Some people seemed to be unaware of the course that supplementary legislation would take. He happened to be present a good many years ago at a Committee of the House of Commons to consider the Bill brought in by the Metropolitan Board of Works for amending the Building Act. It was found, in dealing with it, that the Committee were going to throw overboard the restrictions with regard to the limitation of areas. Mr. Walter, of the *Times*, for instance, could not understand why the office of that paper should be divided by party-walls; and others, representing businesses on a large scale, were very much disposed to throw the buildings entirely open. As a District Surveyor, he found people extremely reluctant to have iron doors under any circumstances, and it became really a matter of persuasion. As to going to the Police Court, that was out of the question. It was true that the District Surveyor was more or less a policeman, but, if he took the offender before the magistrate, failure was the inevitable result, and he might have his feelings outraged and himself insulted. The magistrate was really sitting for the protection of the public against unnecessary official interference, and could not be got to understand the reason for the precautions in the Building Act. The fire offices should combine together, bearing in mind that this is a commercial and free country, and that draughting will not be submitted to, except as a matter of contract. The offices had the power of contract with the public, and if they laid down ascertained rules, insisting on their performance, without doubt great good might be effected. Parliament had simply meant to advise the public what they ought to do, leaving the fire offices to bring their contracts to bear upon the matter.

The gentleman representing the Fire Offices Committee here referred to a case in which they had a warrant that the doors should be closed; but, when a fire happened in the night, it was discovered that the doors had been left open. Payment was resisted by the insurance companies, on this ground, but eventually they were advised not to plead that. Then, as to area, the limitation was often ignored, and he could point to a large building in Ludgate-hill, the dimensions of which were far in excess of the limits, and without provision for a division. They had felt bound to call the attention of the Board of Works to this matter, but were informed that the Act did not apply.

Mr. Wyatt Papworth thought it was important that the doors should be properly fixed. He had seen iron sliding doors where considerable space was left between the doors and the cement work.

A cordial vote of thanks was then passed to Mr. White for his paper.

Mr. White, in replying, remarked that, there being no means to compel the closing of the doors, he knew perfectly well the great difficulty that would exist supposing there was any compulsion. This seemed a main reason why the number of doors should be limited. If there was no limit, it could hardly be called consistent with what had been laid down in the Act of Parliament if it should be so strict in its limitations in a few details, leaving the rest

wholly uncaared for. It would be well to have sliding doors if they could be made to slide into closed fire-proof frames, but not where the door was on the face of the wall with nothing to protect it. Folding doors should not open more than to the square of the opening. He thought he had guarded against making any insinuations upon District Surveyors.

We have received the following letter from Mr. Banister Fletcher:—

"It seems to me clear that Mr. White is entirely wrong in reading the Act, because if we refer to Section XX., Sub-section XIV., we see 'no flue shall be,' &c. Clearly, therefore, no opening is to be limited to one opening, only one flue is to be built against a party structure, —which I think even Mr. White will agree, the Act never contemplated.

I might also cite Sub-section XV., but it appears to me, as it does to all those to whom I have spoken, that the meaning of the Act is clear, namely that there may be more than one opening, but that no opening shall be made except subject to certain restrictions.

The District Surveyors must interpret the Act in its legal manner, for, as Mr. Jennings pointed out, all our decisions are subject to the review of the court.

With regard to the statement made by the gentleman from the Insurance Offices as to the requirements by the Fire Offices, I venture to point out the defects.

It is well known that many fireproof-doors have been shut after a fire has commenced, as was mentioned in the discussion by Mr. R. Walker; and if they are swing doors they may have become so heated and have consequently expanded that they cannot be shut. Another drawback is that all such doors must have spaces at the top, at the bottom, and at the sides, through which the air can pass, and, of course, fire; whilst sliding-doors, which can be and are made several inches wider and higher than the opening, prevent more effectually the fire circulating; and at the bottom, as the door may and should go into a groove (as mentioned by Mr. Octavius Hansard), the draught cannot get under the door with nearly the same ease as it can with the swing door. The further objection to the swing door that it is much in the way seems to me to be important.

To show that the Insurance Office officials alter their requirements, I would mention that when I was superintending the building of the Monument Wharf and Bonded Warehouse, in Thames-street, acting as Surveyor to the Dyers' Company, much loss of space was occasioned by the Fire Office insisting that 3 ft. space should be left between the iron doors. I write this to show that the Fire Offices have varied their requirements, which would seem to show that they are not certain as to the best method, although the gentleman seemed to speak with such confidence that they thoroughly understood the subject.

I may mention that the District Surveyors' Association has lately been giving special attention to the subject of fires and fire-proof construction. One of the great causes of the spread of fires is the lift, as to which little was said last night.

I feel sure the result of the discussion will be to show that Mr. White has misread the Act, and to fully acquaint both District Surveyors and architects of the serious charge that they act in defiance of legislative enactment."

The Lambeth Water Company's Extension Works.—For several months past the Lambeth Water Works Company have been engaged in laying down a new and enlarged line of water pipes between their intake at Kingston and their reservoirs at Brixton. This has been found necessary in consequence of the great increase of supply by the company during the last few years, and the inadequacy of the existing pipes to convey the water required. Between the company's works at Kingston and the reservoirs at Brixton the distance is upwards of eleven miles, and from Kingston the pipes are being laid along the main high road, passing through the parishes of Norbiton, Wimbledon, Merton, Tooting, Balham, Clapham, to the works at Brixton. The work has now been carried forward as far as Balham. The pipes, which are 3 ft. in diameter, are being laid down by Mr. Docwra as the contractor. The undertaking includes the construction of additional storage reservoirs at Brixton.

ARCHITECTURAL ASSOCIATION.

The seventh ordinary meeting of the session took place on Friday, the 16th inst., Mr. Cole Adams, President, in the chair.

The following new members were elected:—Messrs. E. C. Macpherson, G. W. Tatit, C. H. Mason, R. W. H. Edis, G. E. Pilkington, and T. Wenhorn.

It was intimated that the first visit of the members would take place on Saturday next, the 24th inst., to St. Marylebone Parish Church, Mr. Harris, architect.

The Chairman referred to the loss sustained by the profession in the death of Mr. John Whichcord.* Those who knew that gentleman knew him as a man of rare attainments and of the strictest integrity, and one who, in his particular line, was second to none. In his younger days Mr. Whichcord, he believed, had devoted himself to the study of architecture and colour decoration, but latterly his practice had led him more into that of a surveyor, entrusted with some of the largest concerns and arbitrations in the City of London and neighbourhood. Mr. Whichcord had the rare distinction of having his name frequently put into contracts as a reference, and the more so of a man having won character for integrity and for the strictest judicial mind was worthy of notice. Mr. Whichcord was buried in Kensal Green on the preceding day, and the Chairman had the melancholy duty of representing the Association at the funeral.

The Chairman also drew the attention of the members to the Architectural Association Sketch book, the plates of which were displayed on the walls. Many of the sketches were of a very high character, being excellently drawn, and evincing much artistic feeling. He hoped the subscription list would be enlarged.

The Chairman, in introducing the lecturer of the evening (Mr. Farrow), said that that gentleman, like Mr. Gale and Mr. McLachlan (both members of the Association), had distinguished himself by winning the Godwin Bursary.

Mr. F. H. Farrow then read a paper on "The Ventilation of Public Buildings." The substance of this we give on preceding pages.

The Chairman, in opening the discussion, rejoiced that Mr. Farrow, one of their most talented members, had taken up the question of the science of ventilation, and gone so thoroughly into it. The more his example was imitated the better it would be for the profession. Mr. Farrow had not called attention to one very important medium for ventilation, viz., the warm-air stove. One of the best stoves was that designed by Mr. D. O. Boyd, the curator of the Museum of Building Appliances. By means of this a large volume of fresh air was brought into the room, and the fire, instead of drawing the air needed to support combustion from leaky doors and draughty windows, kept the room at a comfortable temperature. In his practice he had found the John tubes useful. In some positions there would be a down-draught from them, but with a little care that could be obviated. Mr. Farrow had referred to a down-draught in connexion with the syphon ventilator; but this could be prevented by having a board suspended underneath the down-cast to distribute the air. Then there was the simple plan of the ordinary sash window, with the bottom bead of the lower sash made of sufficient height to allow of the admission of air at the meeting-rails, without draught.

Mr. J. A. Gotch, in proposing a vote of thanks to Mr. Farrow, expressed his satisfaction that the paper had not been loaded with statistics.

Mr. H. G. Turner explained the system of ventilation used in the Houses of Parliament, which was believed to be the best ventilated building in the world, though the cost was very great. He differed from Mr. Farrow as to the best method of extraction. In his opinion heat was the best method, as it could be regulated to a nicety, it being possible in the Houses of Parliament to regulate the temperature to half a degree. One of the best ventilated of the smaller buildings of the metropolis was the Brompton Hospital for Consumption. There the fresh air was brought in at the ground level and warmed by passing over coils. The foul air was extracted in vertical tubes with outlets into these at the floor and ceiling levels. The out-patients' department of a hospital was often most offensive, but in the case of the Brompton

Hospital it was perfectly sweet and pleasant. The general public rather than the architects were to blame for the want of ventilation. To do it well cost money, and the public would not pay for it, while, if it were done, and anything went wrong afterwards, the unlucky architect got the blame. Mr. Turner concluded by seconding the vote of thanks.

Mr. H. W. Pratt remarked that architects frequently erred in not allowing sufficient cubical contents to public buildings, churches, and chapels. The Tobin principle had been designed to improve the ventilation of such buildings, and if the area of the tubes and their position were more studied, they would be found more successful as a simple means of introducing air. Air might be warmed without extra expense by the ordinary heating apparatus used in the buildings. Boyle's system had been designed for the extraction of the vitiated air, but architects made a mistake in enclosing the cows in turrets.

Mr. Stokes did not believe in the great necessity for extraction so long as sufficient air was introduced, for then the foul air must go away. If there was a ventilating grate they must trust to Providence for the removal of the foul air. The down-draught from the Tobins often arose through the tubes being too large, and it was better to have a great many small tubes than too few large ones.

After a few remarks from Mr. Ellison, Mr. Mountford, and Mr. Blagrove, the vote of thanks was passed by acclamation.

Mr. Farrow, in replying, said that he had purposely avoided, as far as possible, any reference to the heating of buildings, because it would have occupied the whole of the time at his disposal to have explained the different methods. He had simply dealt with the ventilation question, and the requisite amount of heat which would have to be provided in some way. The Houses of Parliament were good examples of effective ventilation, but there was no doubt the system was an extremely costly one. Most authorities were of opinion that for any given expenditure a better result would be obtained by the use of rotary fans, together with engines, &c., than by the use of enormous furnaces, and a great consumption of fuel.

SANITARY AID COMMITTEES.

From the *Charity Organisation Review*, a monthly pamphlet issued by the Charity Organisation Society, in lieu of their former weekly *Reporter*, we quote the following information in regard to the working of volunteer sanitary aid committees, given by Miss Gertrude Toynebee, a worker on the Marylebone Committee:—

"Thirty-three of these committees have been formed in London, and about twenty of them are vigorously at work. The results accomplished by the latter are quite sufficient to justify more widespread action, and it is to be hoped that when their first annual report is circulated the less vigorous committees will take heart and set to work. The facts which suggested the movement remain as a justification for its continuance. Illegal insanitary conditions in the homes of the working people are more or less universal; the tenants are not sufficiently independent to be able to protest for themselves; the sanitary officials are too few, and their standard too low, to find out any very great number of nuisances on their own account.

It will be as well to give some detailed experiences of sanitary aid work in one district, e.g., Marylebone. There we have three committees at work, the parish being divided for our purpose into North, East, and West Marylebone. These committees have now between them had about 400 cases, and they have proved to be, with very few exceptions, *bona fide* cases, trivial complaints being rare. Speaking roughly, from sixty to seventy remain on hand, the rest having been dismissed as satisfactorily dealt with. But it must here be noted that the endless amount of time and labour expended by the committees to achieve these results would be almost incredible to outsiders. There are many cases which have been visited and reported on, fortnight after fortnight, for months and months, often for six months, and not infrequently for longer. What happens is this. The sanitary inspectors not only delay their visits of inspection, but delay giving orders to the landlords, and when the orders

are given, delay taking measures to enforce them. Hence the landlords simply play with time. In most cases some trifles will be done at first, and promises of more will be made, but there the matter rests for months, until, by persistent complaints from the Sanitary Aid Committee, the whole nuisance is at last abated.

1. There is no doubt that more inspectors ought to be appointed. Their salaries would not materially increase the expenditure of the Vestry, while the improved sanitation thus obtainable would lessen the amount of ill health among the poor, and so compensate the rate-payers.

2. The present staff of inspectors ought to have their work more thoroughly supervised. At present, owing to apathy and want of system, they get through much less work than they might, and much that they do take in hand is ineffectual. Doubtless what we want is a large body of zealous, disinterested gentlemen on the Vestry, who shall make themselves somewhat responsible for the sanitary condition of their district by becoming personally acquainted with it, and with the work done by the inspectors. Such men would do much to raise the official standard of sanitary reform in their district.

Considering the difficulty the Sanitary Committees have had in getting sanitary laws enforced, it is not surprising that the tenants find that when they do muster up courage and energy to make a complaint to the vestry they cannot get it attended to. The other day one of the usual complaints of had drainage, &c., came before the West Marylebone committee. The tenant had lived twenty years in the house, and had himself complained again and again to the vestry and to the landlord, but he could get nothing done. He had constant ill-health in his family, and the doctor asked repeatedly whether the drains were wrong. When the Sanitary Committee complained to the vestry the drains were taken up and found to be broken and porous; neither the water-closet nor the sink had traps, while the only cistern was uncovered, in an outhouse, from the roof of which blacks and cobwebs fell into the water. A new pipe drain and traps were provided, and the committee hope to secure also a proper cistern. This tenant pays a heavy rent, and pays it regularly; and this is the case with a great number of the tenants with whom the committee have had to deal, so that they feel that in pressing the claims of such people to a sanitary condition in their homes they are but doing a simple act of justice.

The tenants, as a rule, have been most grateful for the interference of our committees, and this in spite of their having received a good deal of rough abuse, not only from the landlords, but, I am sorry to say, from the inspectors as well."

"A CLUB-ROOM AT THE INSTITUTE!"

Sir,—I have not misunderstood Professor Kerr, but that gentleman has misunderstood himself. There can be no cohesion between summer and winter.

What is the use of saying, "Those who are in favour of such a measure might," &c. (*Builder*, p. 118, ante), when many more than half of the members of the Institute have no vote, and whose opinions count for nothing upon a division?

It is childish to talk of "a member having anything on his mind" following any such suggestion as submitted.

If it is desirable to "compare notes," let senior members give lectures of their experiences.

There has been a late proof of a very strong cohesion among the younger members, but the attachment of this to the senior members does not surely depend upon the unsavoury atmosphere of a coffee-room.

I am jealous of the dignity and character of our premises at No. 9, Conduit-street, being preserved; and if Professor Kerr has no better legacy to leave to the Institute, he must know, at any rate, that to this "restaurant" idea must be answered

No!

. We also say "No." The notion seems to us unnecessary, and quite incompatible with the resources of the architects' house in Conduit-street.

Whiston.—A large memorial tablet has just been erected in Whiston Church, Northants, to the memory of the late Lord Boston, by his uncle, the Hon. and Rev. L. Irby, the rector of the parish. It has been executed in alabaster and Turkish marble by Messrs. Farmer & Brindley, from the designs of Messrs. Taylor & Gordon, architects.

* For memoir, see last week's *Builder*, p. 98.

ASBESTOS PAINT.

SIR,—Referring to the preservation from fire of inflammable building materials, in his presidential address at the Institution of Civil Engineers on the 13th inst., Sir F. Bramwell said:—

"The processes, more or less successful, that have been tried are so numerous, that I cannot even pretend to enumerate them. I will, however, just mention one, the asbestos paint, because it is used to coat the wooden structures of the Ironclad Exhibition. To the employment of this, I think it is not too much to say, those buildings owed their escape, in last year's very dry summer, from being consumed by a fire that broke out in an exhibitor's stand, but happily not setting the painted woodwork on fire, although it was charred below the surface. I do not pretend to say that a surface application can enable wood to resist the effects of a continued exposure to fire, but it does appear that it can prevent its ready ignition."

It may prevent misconception if you will allow me to add that there are two kinds of asbestos paint, both equally valuable in their way, viz. —

1. Asbestos paint ground in oil, and mainly used for ironwork. This is not fireproof, but resists to a remarkable extent the action of gases, foul atmospheres, &c., preventing corrosion.

2. Asbestos patent fireproof paint, exclusively for timber-work. In the latter, no oil or other inflammable material is used, and this is, of course, the paint referred to by Sir F. Bramwell, and which we have supplied for the wooden buildings of the three Great Exhibitions at South Kensington.

J. ALFRED FISHER,
General Manager and Secretary.
United Asbestos Co.

THE ROYAL ARMS.

SIR,—In your well-written sketch of these, which supplies the out-of-the-way knowledge not easily got at by the world, you omit (or, may I say, perhaps did not know) the curious fact that in Scotland the supporters, the lion and the unicorn, hold reverse positions to what they hold throughout the rest of the United Kingdom; and this was actually stipulated for in, and I believe, is one of the clauses in the Act of Union (circa 1700-1710, I think) between England and Scotland.

You can see them on the Edinburgh Post Office and Stamp Office, and I think I state a fact that when these two buildings were erected, when the then new Regent Bridge was opened, about 1818 or 1819, the stipulation was not attended to, and the local authorities insisted on its being carried out, which had to be done. I lived in Edinburgh then and can almost remember the circumstance.

EDWARD COCKBURN.

PROVINCIAL NEWS.

Loughborough.—Owing to the increase of nearly 25 per cent. in the population of Loughborough, the water supply has been gradually becoming insufficient, and during the drought of the past summer the store of water in the reservoir was wholly exhausted. So far back as 1878 it was pointed out to the Local Board that the capacity of the existing works had been reached, and that a prolonged summer drought might at any time jeopardise the supply to the town, and in 1880 Mr. George Hodson, C.E., F.S.I., of the firm of Hodson, Price, & Hodson, the then surveyor and waterworks manager, was authorised to devise a scheme of extension, and advised a resort to the Black Brook, a stream on Charnwood Forest, which, at a point about five miles from the existing works, where its watershed was about 2,800 acres, might be intercepted and brought by gravitation into the present reservoir. The minimum dry-weather yield of this stream is 500,000 gallons per day, and the average available supply will be from 800,000 to 1,000,000 gallons per day. Owing to various circumstances the Board at that time declined to commit themselves to the scheme, and consulted Mr. Eaton, of Sheffield, who recommended the construction of a large impounding reservoir on the Wood Brook, C.E., of London, upon the Wood Brook scheme. The experience of last year has, however, satisfied the Board that no sufficient supply can be obtained from the source recommended by Mr. Eaton. They have, therefore, resolved to adopt Mr. Hodson's scheme, and have served notices upon the owners of the water rights of their intention to promote a Bill in Parliament for the execution of the works. As Mr. Hodson is a member of the Board his firm cannot carry out the works, and the Board propose appointing an engineer to undertake their execution. Since this was written we learn that the Local Board have instructed Mr. Herbert Walker, C.E., F.S.I., of Nottingham, to prepare the

requisite Parliamentary plans and estimate for the scheme.

Henley-on-Thames.—A drinking-fountain of some importance is about to be erected in the Market-place, as a memorial to the late reactor, the Rev. Greville Phillimore. It will be built on the site now occupied by an awkward-looking obelisk and an equally uncomely pump which adjoins it, both of which will be removed. Mr. James Forsyth, of Finchley-road, is the sculptor.

Wigan.—A large drill-hall was recently opened in Powell-street, Wigan, by the Earl of Crawford and Balcarres, Lieut.-Col. 4th L.R.V. His lordship, in his address, congratulated the Wigan Volunteers on now possessing one of the finest drill-halls in the country. The cost has been 3,300l. Messrs. Isitt & Verity, of Bradford and Wigan, were the architects.

High Wycombe.—The useful Cottage Hospital of this town has been recently enlarged from affording twelve to sixteen beds, a new ward having been constructed, called the "Augusta" ward, from the gift of 100l. presented by her family in memory of the late Lady Carrington towards the cost. The builder was Mr. J. I. Harris, and the architect was Mr. Arthur Vernon, both of High Wycombe.

SCHOOL-BUILDING NEWS.

Witney.—The Wesleyans of Witney have just completed the erection of new and commodious schools, which were opened on the 5th inst. The building is in Late Gothic style, the walls being of stone and the roof of blue slate. The ventilating is by means of air-trunks laid along the whole length of the ceiling, with Boyle's air-pump ventilators. The building is heated with Bacon's high-pressure hot-water apparatus. The architect was Mr. E. Early Hollis, of London, and the builders were Messrs. Bartlett Brothers, of Witney.

High Wycombe.—New schoolrooms have been erected, and were, on the 11th instant, formally opened, in connexion with the Union Chapel, High Wycombe. The buildings comprise schoolroom, 50 ft. by 24 ft., with lavatories, out-buildings, &c.; and the construction, out of the old school buildings, of six class-rooms, large organ, and choir chamber, at the rear of the pupils platform; the galleries and part of the building have been re-pe-wed, and the whole decorated, the total expense being about 1,200l. The contractor was Mr. G. H. Gibson, High Wycombe, who executed the work under the direction of Mr. Arthur Vernon, architect, of the same place.

Wycombe Marsh (Bucks).—New national schools in connexion with St. Anne's Church have just been completed and opened. They comprise a large room and class-room, and are constructed in the Early Gothic style in red bricks and dark tiles. The outlay (for 100 scholars) has been 350l. Mr. W. R. Loosely, of High Wycombe, was the contractor, and Mr. Arthur Vernon, of the same place, the architect.

Woodburn Green (Bucks).—Considerable additions have just been completed to the National Schools, Woodburn, by the construction of a large class-room of brick, flint, and slate, and an ornamental Early English drinking-fountain for the accommodation both of the children and of passers-by. The builder was Mr. C. H. Hunt, and the architect, Mr. Arthur Vernon, High Wycombe.

STAINED GLASS.

Burgess Hill.—A five-light Munich east window has just been placed in the church at Burgess Hill, illustrating the text "Come unto me all ye that labour and are heavy laden," in memory of Thomas Crunden, of Burgess Hill. The work has been designed and carried out by Messrs. Mayer & Co.

Leamington.—There have been fixed in the nave of St. John's Church three more stained glass windows containing figures of St. Alban, St. Patrick, and St. Dubritius, who was the first and only bishop of Warwick. It is intended to continue the series of English saints in the other windows round the church. Those already placed have been executed by Messrs. F. Holt & Co., of Warwick.

Hampton.—The fifth and remaining window in the chancel of Hampton Church has just been filled in with stained glass representing the "Good Shepherd." The artists are Messrs. Mayer & Co., who also carried out the former windows.

The Student's Column.

LIME, CEMENT, AND THEIR USES.—I

THE strength of a cement mortar compared with a lime mortar is not as yet very clearly defined in fact, it is hardly possible to compare two. Portland cement is so much stronger than lime that the best lime mortar is equal in strength to a mortar made of equal parts good Portland cement and ten parts sand. As a mortar of this consistency can hardly be used in practice, it being what is termed "too short," i.e., not sufficiently plastic, it is clear that a cement mortar must have a greater strength than one made of lime. A cement mortar is, therefore, only used where great structural strength is required, or where it is required to set quickly.

A very good mortar is produced by a mixture of five or six parts of sand to one of cement and is one that has sufficient plasticity to be worked easily. The proportion of the cement and sand is always taken by measure, and should be seen that the sand is dry, because more sand will go into a given measure when it is wet, and it would, therefore, be necessary to use more cement to obtain the same proportion if the sand is measured in this condition. The dry measured sand should be placed on a clean platform, and the measured cement placed on the sand; the two should then be thoroughly mixed, without the addition of any water, by turning them over and over with shovels. From this heap of cement and sand so much only water added to it, once should be taken, and the same time with the trowel or spade until it is reduced to the proper consistency for use. The use of too much water should be avoided, because it reduces the strength of the mortar, and the desired plasticity should be obtained by well working it. As soon as it is properly gauged it should be used at once, and not allowed to partially set on the board and be beaten up again, for this only destroys the cement and renders it of no value whatever. Cement, when it has once commenced to set, cannot advantageously be further worked. Too much importance, therefore, cannot be attached to this detail. In making cement concrete, the same general principle must be carried out. The measured aggregate being put first on the mixing platform and the cement placed on the top of it. It is usual to have four men with shovels to mix this, and the operation is to turn over the whole of the material on to another part of the platform, and then back again to its original position, and it should be turned over at least three times dry. The water is then added from a rose. A jet of water is objectionable because it tends to wash the cement away from the aggregate, and nullifies, to a certain extent, the previous operation of dry mixing. The water should, of course, be directed to the portion of the heap which is being turned over, and the concrete should be turned over at least twice wet. By thus turning it over three times dry and twice wet, a nearly perfect mixture of the aggregate and matrix ought to be obtained, and the concrete is then ready to be removed in barrows or skips to its position on the work.

The caution regarding the use of an excess of water must again be given, for the additional reason, beyond that already stated, that too much water will wash away a considerable quantity of the cement.

It is desirable to have the mixing platform near the position in the works where the concrete is to be laid as possible, not only that the labour of wheeling may be reduced to a minimum, but also that the whole operation of making the concrete and laying it in position may be executed as expeditiously as possible; for it is most important for the production of a good cement mortar or concrete that it should be laid in position and left at rest in as short a time as possible after the water has been added to it, and that it should not be afterwards disturbed. The concrete should be laid gently in position, and then shovelled and beaten level. The practice of tipping it in from a height, except in exceptional cases, is to be avoided, as it tends to separate the larger and smaller aggregate and the matrix.

The manner of using lime is somewhat different, because, unlike cement, it is not sold in a condition fit for use, i.e., it is in a condition of pure or quick lime, which, on the addition of water, heats and swells to a greater

extent, according to whether it is a rich hydraulic lime. A rich lime expands on addition of water to twice its bulk, and, more, and then quickly falls to r, while an hydraulic lime expands but in the addition of water, and is some-it may be days,—before it falls to r. Adding water to quick lime is called slaking it, and by this process it is converted into hydrate of lime. In this condition it is used, and theoretically the best results are obtained by using a lime immediately that all of it are perfectly hydrated, and before hydrate has absorbed any carbonic acid from the atmosphere.

It should be slacked by breaking it into sized pieces, and spreading it out in a layer, and then sprinkling it with water a rose. By this means it is ensured that all portions of it have been wetted. It should be shovelled up into a heap and covered with sand, so that it may retain the heat produced by the hydration. When it has fallen to r, it should be sifted in order to remove lumps. It is then in a condition to be used into mortar by mixing it with water to the desired consistency by working it with rakes or trowels. A better mortar is made by finding it in a mortar-mill, but on small works mortar-mills are not always available. Packing lime care should be taken only to so much water as is sufficient to wet the lumps of it. If too much water is used, the slacks into a pasty mass, instead of falling powder. At the first sign of any water being away from the lime and accumulating on the floor is observed, no more water should be added, for it is an indication that the lime has absorbed all it can, and it should then be shovelled into a heap as described above. It may be made into what is called putty by adding water to it when it has fallen into powder, and making it into a thick slip; in condition it is run into a trench in the ground, where it may remain for several weeks if required for use. In this form it is usually used for internal work; but it may be used into mortar with the addition of sand. It, however, not produce so strong a mortar when made in the usual way. Lump lime generally used for mortar, and ground lime concrete. It is only the poor and hydraulic limes that are ground, as rich limes disintegrate so easily on hydration that there would be no object in grinding them. Ground hydraulic lime may be used for concrete without previous grinding.

Unlike cement, lime mortar may be worked again without serious detriment to its strength by the addition of more water, and a concrete cannot be rammed and beaten much. With these few differences, the points requiring care are the same whether using lime cement, and the same precautions and modes of manipulation are common to both. The quantity of sand which any particular lime requires to enable it to give the best results can only be determined by experiment; and the only guide for the determination of the amount of sand to use is by the plasticity of the compound. When too much sand is added the mortar works "short," and in that condition it is not economical to use,—from two to four parts of sand to one of lime is the proportion usually adopted. The proportion of sand to lime is always measured by so many struck measures of dry sand to one fair measure of mp unslacked lime.

A few words of caution are, perhaps, necessary respecting the bricks and other materials which are to be united by the mortar. It is assumed that the mortar, whether it be of lime or cement, has been made of good materials and with proper care. Now, if in this perfect condition it is laid on to dry bricks or stones as whole of the water in it is immediately absorbed by the hot porous surface; the lime cement is thus deprived of the water necessary to ensure a perfect set, and the mortar is reduced to a friable consistency of no adhesion or strength. It is, therefore, most important that all surfaces, more especially in hot dry weather, should be well wetted or even soaked with water before the mortar is put on to them. In stucco work all brick joints should be raked out to a good depth and the surface of the bricks well cleaned before the stucco is laid on in the same way when using old materials all

old mortar should be removed from the bricks before they are re-used, for new mortar will not adhere well to such friable and imperfect surfaces, added to which the strength of the structure would, in the event of the old mortar being left on the bricks, be reduced to the strength of the old mortar instead of, as it should be, the new.

In concluding these remarks the necessity of care in the choice of materials and in their manipulation cannot be too strongly enforced. The strength of the structure depends on the strength with which its parts are held together, and it is the mortar which has to exert this strength. Smeaton, when building the Eddystone Lighthouse, spent more time and trouble in the selection of the materials for his mortar than in selecting the stone, and with the satisfactory result that his work stood a strain which is seldom put on any building. While Smeaton was working here Vicat and others were working in France, and to these two must be given the honour of laying the foundation of all now known respecting the behaviour and proper treatment of limes, cements, and mortars. The works of Viruvius show the importance attached to the strength of limes and mortars two thousand years ago. In this century General Pasley spent half his life in making experiments having a similar object, the results of which are of the greatest value. When men like these thought it wise to make research into the nature of the materials they were using, it is surely worth the while of those who may have to use mortar every day of their life to make themselves, at all events, slightly acquainted with the materials of which it should be compounded and the best manner of its manufacture, and disabuse themselves of the opinion that road scrapings and other similar dirty materials make adequate mortars.

RECENT PATENTS.

ABSTRACTS OF SPECIFICATIONS.

11. Fire-resisting Compound. W. Graham.

A refractory composition is used, either alone or mixed with other fire-resisting materials. With this the backs of stoves, furnaces, boilers, &c. are lined. The ingredients are four parts silica, one part siliceous calcinated clay, and one and two-thirds parts clay, which proportions may be varied according to requirements.

1,690. Sash-bars or Astragals. J. D. Mackenzie.

A development of a former invention. According to this method of glazing, the metal astragals are of a semicircular form, and are enclosed in a thin strip of some non-oxidisable metal. A strip of lead or other metal is bent over the top of the astragal to which it is secured by screws or bolts, to keep the sheets of glass in place. A strip of vulcanite, papier maché, or similar material, being sometimes interposed.

2,653. Chimney Tops. C. Riley.

These are formed with openings in the sides near the base. Flanges or ribs inclined upwards, and provided with slits to facilitate sweating, are connected with these openings, and project within the chimney-shaft: thus currents of air are deflected upwards, and draw out any smoke or foul air with them.

4,098. Ornamental Moulds and Frames. S. Alld.

Strips of velvet or plush are glued upon the bending of mouldings or picture-frames, rods being laid upon the strips until the glue has set. The juxtaposition of the velvet or plush with the gold mouldings of the frames gives a rich effect.

5,014. Venetian Blinds. J. Querre.

The laths are counterbalanced by weights. Two chains are fastened to the bottom lath, passing upward through slots in the laths turning over pulleys, and fixed to weights at the side. It is so arranged that some little force is required to pull the blind down, where it is kept in position by cords fastening at the sides of the frame.

13,841. Closet and Dust-bin combined. J. Ennals.

This structure resembles the ordinary privy without a cesspool. It is all above the ground-line, preventing any soakage, which is often the seat of much soil. The floor is raised one step. The bottom of the receptacle is 3 in. of concrete coated with cement, with a slight incline towards the front to encourage the moisture to draw where the dust falls, thus the urine is absorbed and the excreta deodorised. The seat forms a lid for the dust-bin, being hung with hutt hinges, and is firm as a fixed seat when closed. At the back is a door or flap hung on hinges to admit of its being easily emptied, as the contents (it is claimed) being quite innocuous can be taken out with a shovel and removed in a basket

or barrow. Over the door are louvre-boards, which, with a small opening above the plate at back between the rafters, will cause a free circulation of air overhead, and always keep the place perfectly sweet.

4,614. Improved Devices for Opening and Closing Window-sashes and Fan-lights. Tosh & Preston.

The improvements comprise a long screwed spindle, which is pivoted to the fixed framing of the window, near the opening edge of the movable sash, and a grooved pulley fitted to turn thereon as a nut. A cord is passed over the pulley by which it is turned on the screwed rod or spindle. The pulley in turning travels along the edge of the screw spindle, drawing with it the edge of the window-frame to which it is secured, thus opening the window or fan-light to any extent desired.

APPLICATIONS FOR LETTERS PATENT.

Jan. 9.—314, J. Lee, Improvements in the Intermediate or Junction Parts of Trowels, Spades, &c.—324, W. Stehbs, Construction of Kitchen-ranges and Cooking-stoves.—325, W. Beck, Instrument for Sotting-out Curtes.—331, M. Ismay, Latch or Device for retaining Doors in their Closed Position.—333, W. Heelis, Combination Cupboard, Wardrobe, or Bookcase.

Jan. 10.—339, J. Lorrain, Heating, Cooling, and Ventilating.—340, R. Roseborough, Manufacture of Faced or Coated Bricks, and Apparatus for same.—363, A. Reddie, Improvements in Bakers Ovens.—375, A. M. Lake, Improvements in Excavators.—375, A. M. Clark, Improved Process of Manufacturing Tools of Steel.

Jan. 12.—382, J. Snowdon and S. Swallow, Panelling and Pressing Bricks.—384, F. Silk, Fastening Windows and Casements.—387, J. Lucas and C. Hall, Combination Fliers.—389, D. Dickinson, Device for Preventing the Over-sliding of Drawers, Shelves, Sliding-doors, &c.—390, F. Kellow, Improvements in Bricks.—400, A. Andrews, Mouth-pieces and Dies used in the Manufacture of Clay Bricks, Earthen Pipes, &c.—406, M. Macleod, Laying Asphalte Pavements, Roofs, &c.—425, W. Wegner, Improved Staircase.

Jan. 13.—472, J. Imray, Air-Gas Apparatus.—488, J. Hancock, Producing Ornamental and other Devices in or between Sheets of Glass.

PROVISIONAL SPECIFICATIONS ACCEPTED.

15,009, J. Hopkinson and R. Lapage, Improvements in Roller Blinds.—15,525, W. R. Lake, Water-closet Apparatus.—15,745, E. Reese, Decoration of Chimney-pieces, &c.—15,749, H. Whitaker, Fitting Wash Stands and Lavatories.—15,751, J. Howie, Improvements in Drain Traps.—15,750, T. Durran, Gully Traps.—15,857, H. Gardner, Surfacing Compound for Coating Buildings, &c.—15,871, W. Withington, Improvements in Water-closets.—16,111, J. Edwards, Unpickable Lock.—16,103, J. Dinmore, Band-saw Machines.—16,431, A. Myall, Grates and Stoves.—16,432, F. Knott, Apparatus for Drawing Ellipses.—16,523, R. Holmes, Fire Grates.—16,740, J. Bloomfield, Method and Material for Joining Earthenware Pipes.—16,889, H. Britton, Machine or Apparatus for Painting Walls or other Surfaces.—15,846 H. Besson and E. Kent, Locks or Fastenings.—15,993, W. R. Lake, Refractory Compound for the Manufacture of Bricks, &c.—16,225, J. Loftus and S. Baker, Locks for Fastening Hinged Lids and other Hinged Parts.—16,458, J. Dann, Construction of Step Ladders.—16,582, F. Stolze and E. Morgenroth, Apparatus for Cooking and Heating.—16,667, H. Bridge, Apparatus for Facilitating the Sharpening of Files, Irons, Chisels, &c.—16,821, J. Herbert and T. Colley, Sash-bar Cramp.—16,851, A. Emley, Cooking Ranges.

COMPLETE SPECIFICATIONS ACCEPTED.

Open to opposition for two months.

2,368, H. Hargreaves, W. Beckett, and W. Cliff, Kilns and Ovens for Burning Bricks, Pipes, &c.—2,871, J. Duckett, Signal-indicating Letter Box and Door Bell.—4,631, T. Waller, Constructing and Ventilating Urinals.—4,561, A. Martin, Machines for Embossing Wood and other Surfaces.—4,569, S. Slater, Weather Strips for Doors and Windows.—5,327, J. Sibbald and W. Kinnes, Regulating the Supply of Water to Closets and Cisterns.—8,125, J. Smeaton, Heating, Cooling, and Ventilating Dwelling-houses and other Buildings.—13,391, J. Waller and P. Farrington, Bell Levers and Bell Pulls.—16,066, C. Clarke and A. Parsons, Sash-fasteners.—16,251, E. Brady, Substitute for Wood, Stone, or Iron.—4,286, F. Candy, Lavatories and Closets.—4,607, S. Guinery, Sash-frame Pulley.—4,855, W. J. Cornell, Ornamenting Bricks, Blocks, &c.—6,619, J. Kerr, Construction of Pavements.—7,899, S. Belham and J. Belham, Chimney Pot or Terminal.—16,530, W. Gwynn, Folding Steps.

RECENT SALES OF PROPERTY.
ESTATE EXCHANGE REPORT.

JANUARY 15.	
By NEWBON & HARDING.

MEETINGS.

SATURDAY, JAN. 24.
Architectural Association. — Visit to St. Marylebone Parish Church. 3 p.m.

MONDAY, JAN. 26.
Surveyors' Institution. — (1) Discussion on Mr. R. W. Mann's paper on "The Enfranchisement of Urban Leases" (2) Mr. H. Martin on "Recent Proposals for Leasehold Enfranchisement." 8 p.m.
Leeds and Yorkshire Architectural Society. — Mr. Samuel Vyle on "Lighting Conductors."
Edinburgh Architectural Association. — Mr. H. H. Gunn on "Geology in its Relation to Architecture." 8.30 p.m.
Society of Arts (Lecturer Lectures). — Dr. G. V. Poore on "Climate and its Relation to Health." (III.) "The Chief Sources of Atmospheric Impurities." 8 p.m.
Inventors' Institute. 8 p.m.

TUESDAY, JAN. 27.
Institution of Civil Engineers. — (1) Discussion on Mr. Hamilton-Smythe's paper on "A Comparison of British and Metric Measures for Engineering Purposes." (2) Mr. D. S. Smart on "The Modern Practice in the Design and Construction of Steam Boilers." 8 p.m.

WEDNESDAY, JAN. 28.
Society of Arts. — Mr. F. Brindell Carter, F.R.C.S., on "The Influence of Civilization upon Eyesight." 8 p.m.
Civil and Mechanical Engineers' Society. — Mr. R. Nelson Boyd on "The Petroleum Fields of Europe." 7.30 p.m.

THURSDAY, JAN. 29.
Institution of Mechanical Engineers. — Annual Meeting. Five papers to be read, including one by Mr. George Richards "On Recent Improvements in Wood-Cutting Machinery." 7 p.m.
Society of Antiquaries. — 8.30 p.m.
Parkes Museum. — Mr. James Cantle, F.R.C.S., on "Degeneration amongst Londoners." 8 p.m.
Society of Arts (Howard Lectures). — Mr. W. Anderson on "The Conversion of Heat into Useful Work." 7.30 p.m.
York Arts Guild. — Mr. B. Priestley Shires on "The Domestic Life of the Edwardian Period, as shown by its Architecture." 7.30 p.m.

FRIDAY, JAN. 30.
Institution of Civil Engineers. — (Students' Meeting). — Mr. F. W. Stokes on "The Iron Bridges on the Hull, Barnsley, and West Riding Junction Railway." 7.30 p.m.
Institution of Mechanical Engineers. — Annual Meeting continued. 7 p.m.

Miscellaneous.

The Cause of Soot-Clouds.—Stripped of its technicalities, and reduced to the common-sense level of average human brain-power, the discussion about soot and fuel economisers amounts to this: We want less of force and rapidity and more of volume in the air passing through our domestic fireplaces. They ought not to be so much like small blast-furnaces as they too generally are. The fuel, whatever it be, should burn quietly, consuming the combustible part of the fuel, allowing the gases, which are partly waste, unfortunately, and partly consumed,—to rise slowly and passively, and escape up the chimney without blowing up the residue of the carbon with them. A strong and rapid current of air through a fire must mean waste, and most probably will also mean soot or smoke. The air which supplies oxygen to a fire should be wafted gently between and over the coals in the grate, not blown with a rush from below through them. If this simple fact be mastered, it will be easy to secure the object with almost any grate and any fuel. If it be not understood, the search for a special apparatus and particularly good fuel must be futile. Let us begin by first learning and then teaching the A B C of the process, which is really very simple if it be only understood. As it is, the cloud of words is becoming almost as great a nuisance as the soot-cloud itself.—*Lancet.*

New Peabody Buildings at the West End.—The Peabody Trustees have just erected another range of buildings for the industrial classes, which are intended to be thrown open for occupation during the ensuing week. The buildings are situated on the west side of Little Cornam-street, and have been erected on the Foundling estate, covering an area of about 15,000 superficial feet. They consist of eight double blocks, and have been built on the east, west, north, and south sides of the site respectively, around a spacious open area and recreation-ground, about 220 ft. in length and 120 ft. in width. Each block has its separate entrance in the open area, the whole of the blocks being approached through two gateways in the Little Cornam-street frontage, which is upwards of 300 ft. long, occupying nearly the whole of the west side of the street. The several blocks contain five floors, at the top of each of which there are washhouses, fitted with coppers and every other requisite for their intended purpose. There are kitchen-ranges and register stoves in the different rooms in each block, with convenient fittings for domestic purposes. On each landing there are two water-closets, two main water-taps, and dust-hin. Like the rest of the buildings belonging to the Peabody Trustees, they are faced with stock brick, and stone facings, dressings, and entrances. They have been erected under the superintendence of Mr. H. A. Darbishire, architect to the trustees, Messrs. Cubitt & Co. being the contractors. The apartments on the different floors are arranged in one, two, and three rooms, according to the requirements of families. Six of the blocks are arranged to accommodate twenty-six families each, and the remaining two blocks twenty-four and twenty-five families each, the whole of the blocks being estimated to accommodate a population of about 1,000 persons.

The Continued Enlargement of the Waterloo Station.—During the present week another step has been taken in connexion with the enlargement of the London and South-Western Railway Company's Waterloo terminus, which has been in progress for upwards of four years, and which is now the largest passenger railway station in the metropolis, covering an area of something like twenty-five acres. The new roof to the station, as enlarged on the north side for the Windsor traffic, has just been completed, and this portion of the extended station is shortly to be opened for traffic. The enlargement is, however, about to be effected to a considerable length further northwards, extending to the York-road boundary; and with this view Messrs. Perry & Co., the company's contractors, are at present engaged in the construction of a series of arches on the large area of vacant land extending westward from the recently-erected offices off York-road, to Griffin-street, and northward from the new Windsor Station, just completed, to York-road, along which a retaining-wall, has just been erected. Parallel with this retaining wall, in the direction of Waterloo-road, a number of houses and shops, which the company purchased some time ago, are this week being taken down and on the site thus cleared a new block of offices will shortly be erected, in continuation of those which were recently built, the lower portion of which is now occupied by the Government for Parcels Post purposes, and the upper floors for the engineer's and other departments in the company's service.

"Climate in its Relation to Health."—Dr. Poore delivered his second lecture on this subject at the Society of Arts, on Monday evening. He began by alluding to the fact that the crew of the *Eira* enjoyed excellent health in the Arctic regions under conditions which, in this country, or still more in the tropical countries, would be considered most that in the Arctic regions putrefaction and allied changes were impossible, owing to the cold and dryness, and the diseases dependent on putrefaction were also impossible. Attention was drawn to the fact that most of the diseases which were fatal in tropical countries were connected with putrefaction and decay, and as instances of this, malarious diseases, yellow fever, and cholera, were brought forward. Since putrefaction depended upon the access of minute organisms to the putrescible matter, and since these organisms were found in the atmosphere as well as in the soil and water, a study of the floating matter in the air became most important.

Royal Meteorological Society.—annual general meeting of this Society held on Wednesday evening, the 21st inst. at the Institution of Civil Engineers, Mr. J. Scott, F.R.S., President, in the chair. The secretary read the report of the Council, which showed the Society to be in a very satisfactory condition. The council have appointed a committee to investigate the subjects of brilliant sunrises and sunsets of 1853-4, the local phenomenon known as Helm Wind of Cross Fell, Cumberland, observing stations of the Society now number eighty-five, the results from which are printed in the *Meteorological Record*. The whole of the stations in the south of England have been inspected during the year and found to be generally in a satisfactory state. The number of Fellows on the roll of the Society is 552, of whom 37 were elected in 1884. The President, Mr. H. Scott, then delivered his address, in which he treated of the general state of the science of meteorology over the globe, as compared with the programme sketched out by Prof. Forbes in the Report of the British Association, 1840. He said there were now six meteorological societies publishing journals, and in addition six periodicals almost exclusively devoted to the science. He went on to say, "all this wealth of literature there is very particular in which, in this country at least, science labours under a great disadvantage. So far as he was aware, no instruction is given in it, except at the Royal Naval College, Greenwich. The officers and council for the ensuing year were then elected, Mr. R. H. Scott being re-elected president.

Labour and Wages in America.—This was the subject of a paper read by Mr. W. Pidgeon before the Society of Arts on Wednesday evening last. The author first directed attention to the radical differences which a singular native American from alien labour, exemplifying the high condition of the factory by the Lowell of forty years ago, as described by Dickens, Miss Martineau, and others. Then sketched the social life of certain existing industrial towns, the "fastnesses" to which native American labour has, so to speak, been driven by immigrant operatives, who have imported into the States the lower conditions exhibited by their class in Europe. After considering the efforts which are now being made in America by the State, and by individuals, to raise the status of alien labour to the levels of the past, he concluded that it was doubtful whether or not it is now rising, sinking in the social balance. Passing next to economic considerations, he stated what was now being paid to factory operatives in the States, their relation to the cost of subsistence and to wages and cost of subsistence in this country, concluding that while an English mechanic might vastly better his social condition by residence in the States, he would probably find himself little richer, in money after paying the enhanced prices for subsistence, and conforming to the higher standard of life prevalent in America.

Ventilation of the Law Courts.—The following paragraph appeared in some of the daily papers on Wednesday:—"Mr. Baron Huddleston, while trying a case in one of the courts of the Queen's Bench Division yesterday, complained seriously of the defective ventilation of the draughts, in consequence of which his Lordship and others were suffering. The learned Judge requested that the engineer should be called before him, and when the engineer presented himself, ordered, by way of protest against the now-fangled system of ventilation, that the gratings through which the draughts came should at once be pasted up, remarking that if the consequence was to throw the whole system out of gear he should be very glad, as there was something in it that was radically wrong and must be remedied. The engineer promised to carry the order into effect, and at once proceeded to do so." The learned Judge may have been right; but it seems rather a questionable precedent that the efficacy of a system of ventilation of a court should be thus decided on according to the feelings of the presiding judge at the moment.

Liverpool Engineering Society.—At the ordinary meeting of this society, held on the 14th inst., at the Royal Institution, Colquhoun street, a paper was read by Mr. Ludwig Benjamin, M.I.N.A., on "The Different rules in use for ships' calculations."

Rochester Architectural Association.—One of this association, on Tuesday, January 20th, in the old Town-hall, King-street, John Brooke, A.R.I.B.A., read an interesting account of a ten days' tour in Belgium, illustrated by a number of drawings and slides. Having described the most interesting features of Antwerp, he observed that the architecture was remarkable for its old houses, with gables and dormer windows executed in fifteenth and sixteenth centuries. After his remarks on Brussels and Louvain, Mr. Brooke said he particularly noted the thorough construction and honest building of the modern style at Liège. He thought the colour effect of stone and brick at Bruges remarkable; this contained many interesting churches, and an excellent domestic work. Finally, he mentioned Ghent. He thought that quaint spires, gables, and flat façades formed the chief characteristics of the Belgian towns. Mr. T. H. Wick, A.R.I.B.A., thought that the study of Belgian architecture had already produced good results on buildings designed by many young English architects of the day, and would be more so in the future.

Obituary.—We announce with regret the death of Mr. Stephen Hayworth, builder and contractor, at his residence, No. 108, High-street, Kingsland, on the 11th inst., in his fifty-first year. He was well known in the north-east of London, where he had the control over some important estates. He had been actively employed by the Governors of the new Victuallers' Asylum, in maintaining repairs of their Institution, covering six acres of land, and consisting of 170 houses and 10 buildings in the Old Kent-road, for the fifteen years. Mr. Hayworth was, at the time of his demise, Churchwarden of West-kney Church, and on Saturday last, the 17th inst., a choral service was performed there on the occasion of the funeral, after which the body was conveyed to Abney Park Cemetery for interment. Many of the foremen and workmen of the deceased attended and paid a last tribute of respect at the grave.

Lectures on Sculpture and Architecture at the Royal Academy.—The following lectures are arranged for delivery.—Sculpture: "The School of Praxiteles," by Prof. C. T. Wilson, Feb. 16 and Feb. 23; "Medals," by Mr. R. Stuart Poole, Feb. 18; "Pisano as a Medalist," by Mr. R. S. Poole, Feb. 25; "Imitation as the Means, not the End of Art," by Hamo Thornycroft, A.R.A., Feb. 19; "Bronze Casting as Applied to Sculpture," by J. E. Boehm, R.A., Feb. 26.—Architecture: "The Cairo House," by Mr. R. Stuart Poole, Feb. 27; "Some Principles of Ancient Architecture and their Application to the Modern Practice of Art," by Mr. G. F. Bodley, A.R.A., Feb. 20; "Greek Architecture," by Mr. F. C. Penrose, Feb. 27; "Staircases," by Mr. G. Atchinson, A.R.A., March 2 and March 6; "Westminster Abbey," by Mr. A. Waterhouse, A.R.A., March 4.

School and Church Furniture.—Messrs. G. & Dean, who have been established in the north-west since the commencement of the present century, have lately opened a show-room at London-road, adjoining their steam factory at Barking. The "Southward" Convertible Bench, capable of being used (1) as a desk and seat for school use, (2) as a backed seat, and (3) as a table and seat, is a very good thing of its kind, and may be to some extent inferred from the statement that over 100,000 of them have been sold.

"Borough" School Board Dual Desks, tables and tables for Kindergarten teaching, and masters' and mistresses' desks and tables, special design and construction, are among many other school appliances exhibited in variety in the show-room, all characterised by excellence of material and workmanship.

The Bicycle Show on the Thames Embankment.—Messrs. Piggott Bros., of Finsbury, are erecting a large marquee on the vacant ground adjoining the Thames Embankment, until lately belonging to the Corporation, for the Bicycle and Tricycle Show which is to be held during the ensuing week, commencing on Wednesday next and continuing until Saturday. The marquee is 400 ft. long, ending from Tudor-street, southwards, to the embankment boundary. It is 40 ft. in width, and contains a ground area of 16,000 ft. The contractors are laying down a strong boarded floor, and providing facilities for bicycle and tricycle displays during the time of the exhibition.

The Ancient Church of St. Helen, Cliffe-at-Hoo, near Rochester, one of the most interesting in England, as the scene of the seven Saxon Councils of Cloveshoe, between A.D. 742 and 824, was re-opened, after restoration, on January 7th. The contract has been divided into six sections, the first of which is now complete. The flat roofs and plaster ceilings have been removed and replaced by high-pitched roofs. The portion over the chancel is of English oak, elaborately carved. In taking down the semicircular brick east window of 1732, sufficient remains were discovered to reproduce the magnificent Decorated window, erected in 1350 whilst Archbishop Whitlesey was rector of Cliffe. Many of the old members have been re-used, and the entire east gable has been rebuilt of coursed hands of flint and stone. From the old material found in the débris. The new roof to the north aisle forms the second contract, and is now in course of erection. Mr. Alderman Naylor, of Rochester, is the contractor, and Mr. V. Hibbins clerk of the works. The carving has been executed by Mr. Thomas Earp. The whole of the work is being carried out from the designs and under the superintendence of the architects, Messrs. Romaine-Walker & Tanner, of 19, Buckingham-street, Adelphi, W.C.

Provident Institution of Builders' Foremen and Clerks of Works.—The annual meeting for the election of officers, &c., was held at the Office, 9, Conduit-street, on Wednesday evening last, Mr. Cockrane in the chair. Among the other members present were Messrs. Court, Groom, Welch, Heathcote, Fraser, Brodie, Perrott, Lister, Brown, Elder, Bennett, Merfield, Goodwin, Mead, Hailes, Tooke, West, Ross, Turner, and Stapleton. The minutes of the previous meeting having been read, the decease was announced of Mrs. Bunnell, who had been a pensioner (as the widow of a deceased member) for the long period of

twenty-nine years. Among the letters read by the corresponding secretary (Mr. J. W. H. Bedford), was one from Messrs. Wilcocke & Co., of Burnantofts, Leeds, enclosing a cheque for 5l. as a donation to the funds of the Institution. The meeting then proceeded to the election of officers, Mr. George Plucknett, J.P., being unanimously re-elected as Governor. The retiring Directors were Messrs. Bunn, Heathcote, and Stapleton. Mr. Stapleton was re-elected, and Messrs. Mead & Fraser were appointed to fill the other vacancies. The following officers were re-elected, viz., Mr. J. Welch, Treasurer; Mr. G. Ross, Librarian; Mr. J. Derry, Financial Secretary; and Mr. J. W. H. Bedford, Corresponding Secretary. Mr. Thomas Lister was elected Vice-President; and Mr. T. H. Court, President. Mr. Derry, the Financial Secretary, presented a statement showing that during the past year the sum of 236l. had been paid in pensions to the widows or orphans of deceased members and towards the relief of afflicted members. It has been arranged to hold the annual dinner at the Holborn Restaurant on Saturday, Feb. 28. The Institution was established in 1842, and has done much useful work.

Society for the Encouragement of the Fine Arts.—At the first *conversazione* of this society, held in the new art-galleries in Piccadilly, on the 15th inst., a handsomely illuminated testimonial, signed by Sir John Ellis, Bart., and the Council, was presented to the Chairman, Mr. James Edmonstone, in recognition of his services in promoting the objects of the Society. Mr. Cave Thomas, the deputy-chairman, presented the address, accompanying the presentation by some remarks on the duties which the City of London, as a great commercial centre, owed to art, and the benefit which it should derive from the promotion of art, especially of monumental painting.

TENDERS.

Table with 2 columns: Item description and Amount. Includes 'For rebuilding bank for Messrs. Cox & Co., Craig's court, Charing-cross, S.W.', 'Nightingale', 'Dove Bros', 'Patrick & Son', 'Manley', 'Bird', 'Bywaters', 'G. Shaw', 'L. & R. Roberts', 'Holland & Hannen', 'Ashby Bros', 'Pete Bros', 'Brass & Son'.

Table with 2 columns: Item description and Amount. Includes 'For alterations and additions at the Red Lion public-house, Waltham-green, S.W.', 'Lambie', 'Gadden', 'Cook', 'Walker', 'Burman & Son', 'Gibbs & Flew (accepted)'.

For additional reservoir, filter-beds, &c., at Bedford, for the Bedford Town Council, acting as the Bedford Urban Sanitary Authority. Mr. John Lund, engineer. Quantities supplied:—

Table with 2 columns: Item description and Amount. Includes 'S. Foster, Kempston', 'T. Laughlin, Bedford', 'Holtoms Bros, Battersca', 'Ambrose & Son, Bath', 'Cowdery & Sons, Newent, Gloucestershire', 'J. Dickson, St. Alban's', 'Cook & Co., Battersca', 'Clayson & Sons, Cooknoe, near Northampton', 'Pilling & Co., Manchester', 'B. Ward, Leicester', 'E. Twelvetrees, Biggleswade', 'J. P. Waite, Bedford'.

Table with 2 columns: Item description and Amount. Includes 'For house in Fowler-road, Forest Gate, Essex, for Mr. J. Sharp. Mr. H. F. Simmonds, architect, Cambridge Heath', 'Lipscomb', 'Wood', 'Beale', 'Barton', 'Noble', 'Hughes', 'Pollard', 'Preston', 'Edwards', 'Ling & Needham (accepted)'.

Table with 2 columns: Item description and Amount. Includes 'For the erection of small villa, for Mr. W. H. Higgins, in Castle street, Luton. Mr. John R. Brown, architect, Luton', 'D. Dunham, Luton', 'A. Eaton, Luton', 'S. Redhouse, Stafford', 'Joseph Robinson, Dunstable', 'T. Neville, Luton'.

Table with 2 columns: Item description and Amount. Includes 'For the erection of six shops in Chesapeake, Luton, for Mr. Wiseman. Mr. John R. Brown, architect, Luton', 'S. Redhouse, Stafford', 'T. Neville, Luton', 'D. Dunham, Luton', 'J. Robinson, Dunstable', 'Smart Bros, Luton (accepted)'.

Table with 2 columns: Item description and Amount. Includes 'For additions to ironmonger's shop, &c., High-street, Hounslow, for Mr. Ellalay. Mr. J. R. Morgan, architect. No quantities', 'Sawyer, Cranford', 'Hopkin, Hounslow', 'Daniels, Hounslow (accepted)', 'Billis, Hounslow', '[Architect's estimate, 175s.]'.

Table with 2 columns: Item description and Amount. Includes 'For converting three houses at Boves Park, Wood-green, into shops, for Mr. Geo. Sessile. Mr. D. Taylor, architect and surveyor, New Southgate', 'F. Yoller', 'Kirby & Chase', 'T. Scarborough (accepted)', '[Surveyor's estimate, 109s.]'.

For the construction of roads and sewers, Pegge, for the London and Suburban Land Company, Limited. Messrs. Hammaek & Lambert, architects and surveyors:— F. & P. J. Wood, J. G. Marsh, J. Cardus, J. Bloomfield, P. G. Pound, R. Mayo.

For the erection of an Out-patients' Department and Nurses' Home, for the Victoria Hospital for Children, Queen's-road, Chelsea. Messrs. H. Saxon Snell & Son, architects:— Carcase, Finishings, Total. Nightingale, Massey & Co., Mowlem & Co., Chas. Well.

For general alterations to 7, Newington Butts, and 6, Walworth-road, S.E., for Messrs. Freeman & Winthrop. Mr. Wm. Whiddington, architect, Finsbury-pavement, London, E.C.:— General Works, Plumbing and Gasfitting, Total. Emery, Fritchard, Wood, Harris & Co., Clapham-road.

For additional works in constructing new road and sewers, at the Regent's Park-road Estate, for the Directors of the Birkbeck Freehold Land Society. Mr. Sydney B. Grosvenor, surveyor:— P. Pound (accepted).

SPECIAL NOTICE.— Lists of Tenders frequently reach us too late for insertion. They should be delivered at our Office, 46, Catherine-street, W.C., not later than Four p.m. on THURSDAYS.

TO CORRESPONDENTS. E. H.—C. R. M. (received).—T. L. P. (should send amount).—A. P. (ditto). All statements of facts lists of tenders, &c., must be accompanied by the name and address of the sender, not necessarily for publication. We are compelled to decline pointing out books and giving addresses. The responsibility of signed articles, and papers read at public meetings, rests, of course, with the authors. We cannot undertake to return rejected communications. Letters or communications (beyond news-items) which have been duplicated for other journals, are NOT DESIRED. All communications regarding literary and artistic matters should be addressed to THE EDITOR; all communications relating to advertisements and other exclusively business matters should be addressed to THE PUBLISHER, and not to the Editor.

PUBLISHER'S NOTICES.

CHARGES FOR ADVERTISEMENTS. SITUATIONS VACANT, PARTNERSHIPS, ADVERTISEMENTS, TRADE, AND GENERAL ADVERTISEMENTS. Six lines (about fifty words) or under, 4s. 6d. Each additional line (about ten words) 9s. 6d. Terms for Series of Trade Advertisements, also for Special Advertisements on front page, Competitive, Contract, Sales by Auction, &c., may be obtained on application to the Publisher. SITUATIONS WANTED. FOUR Lines (about thirty words) or under, 5s. 6d. Each additional line (about ten words) 9s. 6d. PREPAYMENT IS ABSOLUTELY NECESSARY. * * * Stamp must not be sent, but all small sums should be remitted by Cash in Registered Letter or by Money Order, payable at the Post-office, Covent-garden, W.C. to DOUGLAS FOURDRINER, Publisher. Addressed to No. 46, Catherine-street, W.C. Advertisements for the current week's issue must reach the Office before THREE o'clock p.m. on THURSDAY. The Publisher cannot be responsible for DRAWINGS, TESTS, MONIALS, &c. left at the Office in reply to Advertisements, and strongly recommends that of the latter COPIES ONLY should be sent. SPECIAL.—ALTERATIONS IN STANDING ADVERTISEMENTS OR ORDERS TO DISCONTINUE must reach the Office before TEN o'clock on WEDNESDAY morning. PERSONS Advertising in "The Builder," may have Replies addressed to the Office, 46, Catherine-street, Covent-garden, W.C. free of charge. Letters will be forwarded if addressed envelope are sent, together with sufficient stamps to cover the postage.

TERMS OF SUBSCRIPTION.

"THE BUILDER" is supplied by post from the Office to readers in any part of the United Kingdom at the rate of 12s. per annum in advance. To countries within the Postal Union, see post and Remittances payable to DOUGLAS FOURDRINER, Publisher, No. 46, Catherine-street, W.C.

Best Bath Stone. WESTWOOD GROUND, Box Ground, Combe Down, Corsham Down, And Farleigh Down. BANDELL, SAUNDERS, & CO., Limited, Corsham, Wilts. Dry Corsham Stone. 150,000 FEET CUBE. PICTOR & SONS, BOX, WILTS.

Douling Freestone and Ham Hill Stone of best quality, in blocks, or prepared ready for fixing. An inspection of the Douling Quarries is respectfully solicited; and Architects & others are CAUTIONED against inferior stone. Prices, delivered to any part of the United Kingdom, given on application to CHARLES TRASK & SONS, Norton-sub-Hamdon, Ilminster, Somerset.—Agent, Mr. E. WILLIAMS, No. 16, Craven-street, Strand, W.C.

Douling Free Stone For prices, &c., apply to dress S. & J. STAPLEHAM HILL STONE, Quarry Owners, Stone, W.C. BLUE LIAS LIME and Lime Merchants, Stoke-under-Ham (Ground or Lump), Ilminster.

Asphalte.—The Seyssel and Metallic Limes Asphalte Company (Mr. H. Glenn), Office, 46, Poultry, E.C.—The best and cheapest material for damp courses, railway arches, warehouse floors, flat roofs, stables, cow-sheds, and mill rooms, granaries, tun-rooms, and terraces.

Asphalte. Seyssel, Patent Metallic Lava, and White Asphaltes. M. STODART & CO. Office: No. 30, Cannon-street, E.C.

EVERY DESCRIPTION OF SEASONED WOODS AND VENEERS IN EXTENSIVE QUANTITIES.

B. J. HUDSON & SONS, Whitfield-street, W. Store-street, W.C., and Great Peter-street, S.W., London. Telephone No. 3,654, and Private Wire connecting Business Premises.

MICHELMORE & REAP, Manufacturers of

COLLINGE'S PATENT HINGE LEVER, SCREW, & BARREL BOLT. Self-acting "FALL-DOWN" GATE STOPS, and IMPROVED GATE FITTINGS of every Description. 36A, BOROUGH ROAD. DISCOUNT TO BUILDERS. LONDON, S.E.

BRABY'S PATENT GLAZING. GLASS SET FREE, ALLOWING EXPANSION AND CONTRACTION, AND PRECLUDING BREAKAGE. ABSOLUTELY WATERTIGHT. PAINTING AND PUTTY SUPERSEDED OVER ONE MILLION FEET FIXED. DRAWINGS AND PRICES ON APPLICATION. — MODELS AND SECTIONS ON VIEW. — LONDON: 356 to 362, EUSTON ROAD. LIVERPOOL: 6 and 8, HATTON GARDEN. GLASGOW: 335, ARGYLE STREET.

Our Timber Supplies: Present and Future.

VERY able and exhaustive paper was recently read before the Society of Arts, on the "Present and Prospective Sources of the Timber Supplies of Great Britain," by Mr. P. L. Simmonds,

whose great technical knowledge of all industrial resources renders him thoroughly qualified to deal with the subject. Dependent as we are for our timber supplies from sources outside the country, and especially in our own particular needs for building industries, a résumé of the principal points indicated by Mr. Simmonds can hardly fail to be useful to the readers of the *Builder*. The magnitude of the timber imports into Great Britain is shown by the fact that for the last ten years they have exceeded 18,000,000*l.*, exclusive of some 4,000,000*l.* more for the imports of forest products, such as harks, dyewoods, pulp, rosin, fibres, vegetable ivory, &c. Our dependence, therefore, on foreign supplies is a very serious matter, which is emphasised by the knowledge that other countries, as well as ourselves, have very heavy calls upon their timber resources, and that it is only of late years that a general disposition has been shown to husband those resources, and control the reckless waste of wood that has been so prevalent. The railway interests alone have made deep inroads into the forests of the globe. Over 290,000 miles of railway are now in operation, and are being added to at the rate of 10,000 miles a year; for it must be remembered that railroad ties have to be periodically renewed. The American lines alone must have consumed over ninety million trees for this requisite, and one-seventh at least of the original number has to be renewed annually. As Mr. Simmonds correctly says, the consumption of timber in all densely-populated countries is out of all proportion to the natural growth of indigenous forests, and this disproportion must infallibly increase with the population, when denser settlements will be formed in those countries whence we obtain our supplies. We are living on our capital, as it were, and it becomes all the more necessary, not only that extreme care should be used, but that every available system of forest conservation and renewal be rigorously adopted.

Roughly speaking, the available forest ground of Europe may be placed at about 728 million acres, of which Russia counts for 527 millions (by far the largest proportion) and Great

Britain 2½ millions (the smallest except Belgium and Holland). Canada outstrips all Europe put together with 1,000 million acres, and the United States with a little less than that. Africa, Asia, South America, and Australasia are almost impossible to estimate with even approximate exactness, but their value can scarcely be over-rated, when we recollect that while Europe and North America are the forest supplies of what may be called the ordinary building woods,—pine, beech, fir, oak, &c.,—the other countries furnish us with inexhaustible quantities of the more decorative woods. Even in countries under the former category, such as Canada, those who are interested in forest growth are seriously alarmed at the condition to which it has been already brought by want of proper precautions. The timber industry there has for long been depressed and overstocked, while in New Brunswick it is considered that in from ten to fifteen years all the large and soft-wood timber will be exhausted, and the manufacturers will have to fall back on second growth and small woods. The principal woods shipped from Canada to Great Britain are oak, elm, ash, birch, maple, tamarac, white and red pine, the deals being both pine and spruce. The supply of foreign woods may be briefly summed up under four heads.

1. Ordinary soft woods of construction, chiefly pine and fir, furnished by North America and North Europe.
2. Shipbuilding woods, principally oak and teak, with small quantities of greenheart and mora from British Guiana, and a few Australian woods.
3. Hardwoods and furniture woods, which are at present very limited in number, although they might be largely increased by a little enterprise and judgment on the part of cabinet-makers and dealers.
4. Dyewoods, of less importance than they used to be, owing to the introduction of aniline dyes and chemical improvements.

Even amongst the shipbuilding woods we have a great deal to learn and much experimentalising to go through. Some Australian hardwoods, such as ironbark, are admitted by Lloyd's only into the ten years' classification of woods suitable for the timbering of ships, whilst mora is placed in the twelve years' grade; and yet reliable tests give to the former as good a character as the latter for shipbuilding. Jarrah, another valuable Australian shipbuilding wood, is ignored. These are examples of many instances where scientific inquiry and prolonged experience are essentially necessary.

To the third category, viz., the hard and furniture woods, we will now devote a little more attention, the rather since great and undeserved

neglect has hitherto been their fate. The chief timber exports from India are teak and sandal wood; the revenue derived from the latter in the State forests of Mysore being very large. The demand for sandal-wood in Europe is inexhaustible, but it is chiefly sent from Bombay to China, where it is used for ornamental work of all kinds. Another Indian furniture-wood, though not much in demand, is the Indian black-wood (*Dalbergia latifolia*), generally called rosewood amongst timber merchants and workmen. It is sound and runs large, so that excellent slabs and planks can be got from it. What is known as Moulmein cedar is the tonewood of India (*Cedrela toona*), a furniture-wood in great request, which fetches about 6*l.* per ton in Burnah. If sent in well-squared hewn logs, about 15 in. square, and 12 ft. and upwards in length, it would fetch nearly 3*s.* a cubic foot, as a substitute for mahogany. In Bengal, Assam, and Burnah it grows to a very large size, trees of 20 ft. girth, and from 80 ft. to 140 ft. of clear stem, being not uncommon in forests that have been little worked, like those in Dumsory and part of the Chittagong hill districts. The Sal timber (*Shorea robusta*), for which Bengal was so famous, still exists largely in some of the forests, though there have been unnecessary destruction and irreparable waste. The Soondri trees (*Heritiera*) of the Soonderbun furnish the best wood for boat-building. The Ceylon woods consist chiefly of ebony, sappan, satin, and sandal woods. The Cinglese forests are very extensive, and as yet practically untouched in the central province, and a proper system of conservation ought to render them permanent sources of income to the colony.

The approximated area occupied by forest trees in Victoria (Australia) is about 40,000 square miles, exclusive of 14,000 covered with Mallee "scrub," such as tea-tree and dwarf eucalypti. The principal forest trees are the large white and red gums (*Eucalyptus amygdalina* and *rostrata*) and stringy bark (*E. obliqua*). At present, however, Victoria is rather an importer than an exporter, and principally of soft woods, in which the colony is deficient. No country has been more favoured by nature than New South Wales in the variety and quality of its timber, there being twenty-seven species of the eucalyptus alone; and the durability is such that the vessels built in the colony never seem to grow old. Some descriptions of wood placed in wells and buried in the ground have been taken up after fifty years' time as sound as on the day when they were first put there. The reason why Australian timber has not met with the favour that it deserves is owing to the fact that it is so frequently felled at improper seasons, whilst the sap-vessels are full; still, moreover, sufficient

care is not exercised in sending the best sorts, or withdrawing faulty pieces from shipment. This is very much to be regretted, for a testing of seventy specimens of New South Wales woods in 1861 showed that for strength, durability, and elasticity, many of them were superior to English ash and oak. The black ironbark (*Eucalyptus eucozylon*) is a wood remarkable for its strength, very hard, and of good colour, but enormously heavy. It is principally used by wheelwrights and coach-makers, and for many purposes in shipbuilding. The black wood (*Acacia entanozylon*) is an exquisite cabinet wood, having a richly-marked grain, and taking polish freely. It is of high value in all cases where lightness, combined with strength and flexibility, are required. Tulip-wood (*Harpullia pendula*) is a large tree, from 50 ft. to 60 ft. high, with a strong timber, beautifully marked with different shades, from black to yellow, and in high esteem for cabinet work. Honeysuckle (*Banksia serrata*) is a wood of a dark red colour, taking a good polish, and is useful for boat-building, and also for veneers, and generally for furniture purposes.

Queensland possesses extensive districts of red cedar (*Cedria toana*), though of late years there has been such a wholesale destruction that the Government has passed a law with respect to the conservation of the forest. It is certainly singular that more logs of Australian cedar tree are not imported, for it is a most valuable wood, easily worked, and in dry situations very durable. Some trees have been cut on the Richmond river yielding 30,000 ft. of saleable timber. The junctions of the branches with the stem furnish those beautiful curled pieces of which the choicest veneers are made, while the root stock is also much valued by cabinet-makers for the same purpose. The market value in Queensland is from 20s. per 100 superficial feet, according to colour and size. The wood can be obtained in considerable quantities, but will soon become scarce, as it can only be procured from the open forest bushes on the coast of New South Wales, and on the Richmond, Bellinger, and Tweed rivers. In 1881-2 a few logs were received in London, and being sound and of good size, realised high prices, 4d. to 6d. per foot.

The cypress pine (*Frenela rhomboida*) is another Queensland wood from 50 ft. to 70 ft. high, with a diameter of 20 in. to 40 in. The timber is durable, fine-grained, fragrant, and capable of a high polish, being much used for wharfs and sheathing boats, as it resists the attacks of *Teredo navalis* and *Termites*. The market value in the colony is 10s. per 100 superficial feet. The brush, or bastard box (*Tristania conferta*), has a peculiar value from its immunity from attacks of white ants. The beef wood and swamp oak (*Casuarina torulosa* and *C. equisetifolia*) give close-grained woods and make handsome veneers, while rosewood (*Diospyros Fraxanum*) is much in favour for turning. Myall (*Acacia homalophylla*) is well adapted for cabinet-making, but is not large. The timber of the bastard sandal (*Eremophila Mitchellii*) is very fragrant and makes good veneers; but the fact is that cabinet-makers are so accustomed to mahogany and a few other woods, that they are reluctant to try any new ones.

Tasmania has not much to send us except small lots of musk-wood and the beautifully-marked Huon pine; and South Australia has so far destroyed the indigenous forests as to be obliged to plant largely. Western Australia, however, is rich in woods, particularly the white gum, eucalyptus, and jarrah, the toart, the red gum, and the sandal wood, a scentless variety of which, called *manitoh*, might be useful for wood engraving from the fineness of the grain. The indigenous forest of New Zealand is evergreen, and contains a large variety of valuable woods, though they are harder and more difficult to work than the European timber. The manuka (*Leptospermum ericoides*) has fine dark-coloured markings, and is very durable; and the birch totara (*Podocarpus totara*) is like cedar, and works with the same freedom. It is useful for piles and ship-building, and the Maoris make their largest canoes from it. The kamri is the finest forest tree in New Zealand,

though it only grows in the North Island. It forms the bulk of the timber exported, and is remarkable for its durability, some of the old mission-houses, built fifty years ago, being as sound now as then. It is a rich and valuable wood for house finishing and furniture, having beautifully-mottled shading. The principal trees in ordinary use are the tawhai or black birch, very strong but tough and hard to cut; the kowhai, a red wood, used chiefly for piles but good for furniture; the matai, of yellowish hue, largely used for bridge-building; the kawaka cypress, a noble tree, with fine-grained, reddish, and heavy wood; the rimu, marked like rosewood, greatly liked by cabinet-makers; the monono, or yellow pine, the most durable timber in the colony, posts made of it having been in use amongst the Maoris for over 100 years; the tankaha, the wood of which resists decay in moist situations most remarkably; the rata, or ironwood, dark red, splits freely, and would probably answer well for cogs and spur wheels; the pohutukawa, of which nearly all the ship frames in Auckland are built.

Quitting the subject of heavy building woods, we must now briefly note Mr. Simmonds's remarks on the furniture woods, the principal of which, of course, are mahogany (the average consumption of which in Great Britain is about 50,000 tons), walnut, boxwood, cedar, ebony, rosewood, maple, and satin: while of minor importance are zebra-wood, ziricote, snake or letter wood, partridge, and tulip. After 1870, veneers were summarised by the Board of Trade with the furniture woods. In the United States, the chief veneering woods are curled and bird's-eye maple, beech, birch, cherry, ash, and oak. The first and most costly is what is known as French walnut, but which, in reality, does not come from France, but from Asia Minor and Persia. The tree is crooked and dwarfed, and is solely valuable for the burr that can be obtained from it. In these large tough excrecences, the grain is twisted into the most singular and complicated figures, and the symmetry and intricacy of these is one of the elements determining the value of a burr. Formerly walnut burrs were in good demand, fetching from 100l. to 200l., but now they are in much less request, the competition being limited to pianoforte-makers. Occasionally burrs are met with in rosewood and mahogany, but they are of little value. Burrs which used to fetch from 10l. to 45l. are now only worth from 9l. to 30l.

Boxwood is chiefly used by the turner and wood-engraver, and is getting very scarce, so that continued efforts are being made to find a substitute. Rosewood is a term as generally applied as boxwood, and to as great a variety of trees in different countries, sometimes from the smell, and sometimes from the colour, of the wood. The cabinet rosewood imported from Brazil is the product of *Tacarcanda Braziliensis*, and the 3,000 planks or so that come annually to Liverpool seem amply sufficient for the demand. About 4,400 logs of cedar were imported in 1884 into Liverpool from Havana, Surinam, Mexico, and Honduras. Next to walnut, ebony is the most valuable of the cabinet woods, and for a particularly fine piece 20s. per lb. has been paid, the main difficulty being to get large pieces that can be used without cutting. Prime large logs from Ceylon readily fetch 14l. per ton and upwards. The ebony wood of commerce, so much used for inlaying, is the duramen of several species of *Diospyros*, natives of Africa and Asia. From its hardness, colour, durability, and susceptibility of polish, it has always been held in high estimation. The commercial descriptions are generally ranged under three kinds, of which the Mauritius is the finest-grained and the blackest, though it is the most costly and unsound. The East Indian is of inferior colour and coarser grained, while the African is the least wasteful, but the most porous.

The cabinet woods of Jamaica are of extreme beauty, and there is no doubt but that they would come into great demand if the difficulty of procuring them from the forests could be reduced. There are many close-grained woods,

suitable for small articles, such as the blood wood (*Laplacea hamatozylon*), of a deep red colour; the fiddle wood (*Citharexylum surretum*); the maboe (*Paritium datum*) of a blackish green colour, which makes a pretty contrast with lighter woods; the yellow sanders (*Bucida capitata*) of a light yellow with satin graining, which takes a high polish; the Brazil letto, of a bright red, and much in request for ornamental work; the Yacca, also very much prized and a denizen of the Blue Mountains, where it is crooked and magnificently cross-grained. Brazil is very rich in furniture woods, as may be imagined from the fact that Prof. Agassiz counted 117 different varieties, of which the most valuable is the tortoise-shell wood (*Omphalobium Lamberti*), found in large quantities on the Upper Amazon. Then there are the Pao Santo or holy-wood and the Saboarana, rivals of the most beautiful walnut, and of which enough is found on the Amazon to veneer all the palaces in Europe. Brazil also abounds in timber for construction, as durable as teak, and of splendid proportions. Dining-tables are often to be seen, 6 ft. in width, all made of one piece.

To sum up, it will be seen that the main sources from which we draw our main supplies of timber are the Northern States of Europe and the Dominion of Canada. From the United States and our colonial possessions we can only import in very limited quantities; and it behoves, therefore, all timber-producing countries to husband their resources, and by judicious forestry regulations to prepare increased supplies for the future demands of the world.

ARAB ART OR COPTIC?

BY REGINALD STUART POOLE, LL.D.

THE history of the art we call Arab is to be learned in its great centre Cairo.* There, and there alone, can we trace its growth, its maturity, and its decay, seeing how foreign elements came in from time to time, and were adopted and modified to suit the purposes of the Cairene architects and decorators. Its source is not to be looked for at Byzantium or in Persia, but in the ancient capitals of Egypt herself. Domestic, not religious architecture, supplies a ready proof. The models and pictures of old houses show the features of the Cairene style, which still flourished in the early years of this century. In one ancient fresco we see the stone doorway, the belvedere, the lattice-windows, the ventilators with their sloping roofs, and the inner court planted with trees, the characteristics of the modern Egyptian house, never complete without all of them. We need not, then, wonder if we find the art of Cairo to be the latest phase of the art of Egypt, which we may trace through a long series of developments, influenced in turn by Greece, by Rome, by Byzantium, by the Italy of the Renaissance, but always preserving that strong individuality which is almost as little disguised by outer forms as is the old Egyptian type of the modern Copt, although he wear the turban and ample robe of the Arab; being, indeed, far more the same man in religious conservatism, and in the subtle qualities of the official scribe.

It may be said that though the Cairo house is truly Egyptian, the mosque presents a new type. The usual ground-plan contradicts this view. The typical mosque so far is like the court of an Egyptian temple. The dome and the minaret are new features, and the constant use of the arch is a deviation, but the frequency of the arch in antiquity is to be noted, as the perishable buildings for which it was usually employed have rarely survived, and the dome is but its development. Moreover, closely connected with arch and dome are those beautiful pendentives which have their stiff prototype in the ancient "arch of approaching stones." The bell-towers of the Coptic desert-churches are not far removed from the type of the Egyptian propylea, and the oldest minaret links them with

* Cairo is here the city, with its environs, together including the early capitals: it has survived, and of which in and around it notable edifices yet stand.

Fig. 4.

the later form. It is, however, a mistake to lay great stress upon structure, and even upon structural skill, when the essential quality of the ancient and modern art lies not in structure. That quality, so strong as to be its very character, is decorative felicity, in a harmonious use of the primitive colours for forms due to wood-carving and joiners' work, whatever the material. This is evident alike in the patterned ceilings of Theban tombs and Cairene houses, alike in the oldest and newest panelling. The ancient work, however rich in decoration, is far inferior to the modern in variety. Yet its root is the same. In the later style the lavish use of wood is as striking as its absence in what time has spared of the older, those great edifices whose very lattices were carved in stone. Yet these lattices represent woodwork. In ornament the stone panels represent wooden panels, and the stone walls of one of the earliest tombs were cased with wainscot. To trace the very patterns through the course of centuries may not be possible, and many are no doubt foreign; but any one who will compare the stone patterns of the oldest tombs with the wooden screens of Cairene mosques cannot fail to recognise certain leading outlines which have survived all internal changes.

Turning from theory to history, we note that the decorator of Cairo has always been a Copt; the architect, so far as we know, a Greek or a Copt. By the Copt the turner's work and the carving in wood and ivory have been made for generation after generation, the peculiar types fixed in the age between the fall of paganism and the Arab conquest.

To trace the history of Cairene art from the last great mosque, that of Mohammad Bey, a little more than a century old, and the fine series of houses closing fifty years later, is an easy and delightful work, which no one has yet been at the pains to do. All that is needed is to select a series of types and work back to the mosque of Ahmad ibn Tuloun, in the middle of the ninth century, taking care to find dated specimens of the obscure periods,

avoiding the exotic art of Constantinople and the far more interesting Tatar type of mosque architecture which appears about the beginning of the fourteenth century. The history of each building should be carefully studied, and the exotic elements again eliminated from a native work, or the native elements rescued from one of foreign type. Thus the fine Gothic door in the main street of the old city is not Cairene work, but the spoil of a church at Acre, carried away when the last stronghold of the Crusaders fell, and set up here as a trophy ("Modern Egyptians," fifth edition, p. 590. E. Stanley Poole's Essay on Arabian Architecture). The great dome of the mosque of Sultan Hasan, the one blemish in the magnificent Cairene sequence of domes, is distinctly Turkish. It was built by a Turkish Pasha, who replaced the original dome when it fell, adopting his national shape for structural purposes, whereas his fellow-countrymen have usually combined the finer Cairene type with their own unshapely minarets. Having thus carefully selected our typical buildings, we find in the eastern branch of Medieval art the law

of progress which the Westerns followed. We see the parallel to our own Norman, Early English, Decorated, Perpendicular, and Tudor or Jacobean, separated by times of transition. The periods are usually earlier in their beginnings, and many differ in length, yet the same law is obeyed. Until this is recognised the study of the art of Cairo or of any other Muslim centre must be not merely useless, but mischievous.

In the study of decoration we must be even more careful, first to fix the dates of later additions and next not to be misled by apparent resemblances. The floral arabesques of the mosque of Kalaoun have a strange air of the Classical Renaissance, and that at the close of the thirteenth century. This is a mere accident, just as the battlements of the same mosque repeat in modified form a well-known Assyrian type. The difference from Italian work is to be seen in the composition both as a whole and in its fineness of line. The true Renaissance influence is detected in the lack of purpose of later architectural forms, especially windows and ceilings, and in the want of

necessary fitness in the details of decoration.

It is a long step from the date of the Mosque of Tooloon, A.D. 879, to the age of the security and mostly not very characteristic Roman remains of Egypt. This earliest mosque was held to offer the last foothold in the journey into past time, unless, indeed, we could rest for a moment in 840 at the Nilometer of Roda, but beyond, all was darkness out of which the theorists evolved the birth of art, each according to his cosmogonic fancy.

An opportune book, Mr. Butler's "Ancient Coptic Churches of Egypt," has, by the natural but as yet unthought-of process of serious inquiry, filled up the chasm and discovered the links between the Pagan and the Arab periods.* It enables us to determine the sequence of Coptic architecture and the immediate origin of Cairene decoration. The first matter needs a very careful study before we can venture on positive conclusions. The dates of all Coptic art are hard to fix, partly because of the confusion caused by the use of the Era of the Martyrs three centuries later than ours, partly because of the absolute newness of the subject. Mr. Butler has clearly shown the presence in the churches of Byzantine elements which are unknown in the mosques, or only known like the semi-dome in Turkish mosques of Byzantine parentage. When these elements are of the essence of the structure, the architectural origin of the building is, without doubt, very early, though it may be historically of later construction. The churches of peculiarly Coptic style are next in date, but their distinctness in type from the mosques again marks an earlier origin. For instance, wagon-vaulting is neither Byzantine nor so-called Arab. It is, indeed, to be seen in Persia, where it may be a survival or an accident due to the abundant use of the arch and dome. This may be observed in the very curious view of Koom in M. Dicalafoy's "L'Art de la Perse," pt. ii., pl. 1, where wagon-vaulting is combined with domes. Thus in origin the Coptic style precedes that of the mosques, and springs from Byzantine-Coptic, itself derived from the art of the basilica-churches, well but scantily represented in Egypt. How far the Coptic period overlapped the so-called Arab is hard to determine. It is probable that nothing important was executed by the Copts in church architecture after the tenth or eleventh century. That they found a wide field for their genius in mosque architecture, however rivalled by the Greeks, we cannot doubt; but it does not follow that they showed the like activity in building for their own rite. This was not necessary; more than this, it was not possible. Persecution upon persecution narrowed their resources and limited their congregations. Thus they had no chance of raising any splendid works for themselves, and the instinct of the persecuted would make them cling to the old ecclesiastical types. The great building age of the Coptic rite was the age of its comparative freedom. Their largest churches were then built, and lavishly adorned. All later work was, in architecture, not restoration so much as the more wholesome reparation. Whatever is truly of these times is decoration; the new screens and other triumphs of carved and turned work which then appear are of distinctly late development.

In ornament the difficulty of finding the true date is yet greater than in architecture. Before the time of Tooloon we are in the dark as to the movement of decorative art. But a comparison of church with mosque decoration settles the question in favour of the prior antiquity of the church style. To determine this we need not go to the earliest examples, but may compare Coptic work of churches and of mosques of any period. It must be remembered that the decorators, simple craftsmen, worked with equal skill in church or mosque. Their art went on developing to its latest phase, when their work was but little touched by the corruption of the Classical Renaissance, even to its close in our own days, the

days of such of us as are old enough to have seen Cairo when she was still the most beautiful city of the East, to have lived in houses so decorated as to have needed no furniture but for use, fully furnished by the triumphs of the craftsman's skill.

Looking at Muslim decoration, whether geometric or floral, we are often struck by a want of purpose, as in the meaningless character of the centres of geometric work, even descending to a suggestion of engine-turning, and in the floral patterns, by the endless repetition of the fleur-de-lis, very charming on occasion. Sometimes the centre of a geometric pattern is a mere boss, sometimes it is empty, sometimes heavy. If we turn for a moment to church decoration, we see the centre of the geometric patterns to be the equal-armed Greek cross, and that the floral patterns spring from a cross flory. We now understand why the best centre of the mosque work is really a salient cross, and why we can perceive in delicate floral tracery the shadow of an almost effaced cross. The variety of the floral patterns in which the fleur-de-lis appears is now interpreted: they are the disconnected limbs of a cross. In the ivory-inlaid lectern at the cathedral of Cairo, reproduced in Mr. Butler's illustration (fig. 1), we note the admirable manner in which on the front, and not so strikingly on the side, the crosses form the central motives of the pattern, and render the surroundings necessary, instead of what we frequently note in work for Muslims, a severity of the centre to the surroundings in which the motive rather lies. In the portion of a carved floral pattern in ivory (fig. 2), exhibiting the decoration of the centre and one limb of a cross, everything springs from the cross which permits the use of the fleur-de-lis in a natural manner. Two other ivory carvings may be cited from the same work, one a delightful floral pattern (fig. 3), and the other a combination of geometric and floral (fig. 4), defective only in some of the minor details which are perfunctorily thrown in. If we thus find that in comparatively late times, perhaps about the fourteenth century, the ecclesiastical work shows the Christian origin of the mosque work, we cannot hesitate in concluding that the decoration of the mosques was not only by Coptic hands, but that it was of distinctly Coptic origin.

The great mosques of Cairo, the rarer private houses, and those of the kindred phase of the Delta, almost unknown, yet full of delightful hints, are fast perishing. Very soon it will be impossible to restore the history of the purest style of one half of Mediaeval art. All is handed over to the destroyer, or perishes for lack of love and care. Again and again I have pressed this subject as not unworthy, nay, most worthy, of the enterprise of our young architects and the generosity of our wealthy men. To the one, I would say, Do not be content with half a grammar, but learn all, and maybe out of your knowledge shall spring an art not unworthy of our great dominion; to the others, It lies with you to furnish our students with larger knowledge, if not with a greater career. Should you send an expedition to Cairo the results will amply reward the little outlay that is needed. The treasures of the past will be saved to make the future yet more rich.

NOTES.

THE wicked attempts at the destruction of public buildings which will make Saturday last a memorable day in the annals of such crimes in this country, though no doubt failing to create a title of the damage which was intended, have nevertheless been so nearly successful that the House of Commons has been partially wrecked, so far as a great portion of its interior fittings are concerned, while Westminster Hall itself has had a narrow escape of being blown up, and so disposing of some of the controversies of which it has been the subject within the last few months. Much of the costly woodwork of the House of Commons has been reduced to matchwood, but arrangements are in progress for temporarily repairing

the damage, so that the House may meet on the 19th prox. as appointed. The fine roof of Westminster Hall has not, we hope and believe, suffered any serious injury. That the damage done in the Hall was not greater is probably mainly due to the intrepid conduct of the policeman who carried the explosive from the vicinity of St. Stephen's Crypt up the steps into the hall, though unhappily he suffered severely for his bravery. We are glad to hear that his courage has met with recognition in high quarters, her Majesty having signified her intention of conferring upon him the Albert Medal.

WITH regard to the Tower, the damage done by the explosion there, though serious enough in itself, and though subsequently added to by fire and water, has happily had no material effect on the structure as a whole, and the White Tower still continues to stand "four-square to all the winds that blow." The explosion took place on the floor of what is still called the Banqueting-hall, near the north wall of St. John's Chapel, and close to the doorway leading from the hall into the chapel. A large hole was rent in the floor of the hall, and several stacks of rifles were thrown down and scattered in great confusion, some of the arms being twisted and broken in a remarkable manner. The force of the explosion raised the floor of the Council Chamber (which is the chamber immediately above the Banqueting-hall), and did much damage to the glass cases which contained specimens of ancient Oriental armour. The force of the explosion seems to have passed through the doorway before mentioned into St. John's Chapel, for it has blown out the whole of the lead-lights of the windows, though the iron cross-bars or stays for the lead-lights were violently forced *inwards*, carrying small masses of broken masonry with them, the explanation of this being that it was due to the violent rebelling of the vacuum caused by the explosion inside the building. Mr. John Taylor, of the Office of Works, informs us that, in the course of the minute examination which has been made of the walls since the perpetration of the outrage, a few slight cracks have been discovered in the masonry, but it is not certain that they did not exist before the explosion. It is earnestly to be hoped that the authors and instigators of these abominable deeds may be speedily brought to justice. In the meanwhile it is satisfactory to be assured that increased vigilance will be exercised by the guardians of our public buildings and historic monuments.

THE correspondence in the *Times* between Lord Bury and the solicitors for the Metropolitan District Railway Company, in regard to the subway under Prince's-gate, is amusing as an example of both parties putting themselves in the wrong. The subway is being made in order to facilitate access to the Exhibition building from the railway. Its effect will be to remove the crowd of persons streaming to the doors, from aboveground to underground, and thus to do away with a great nuisance to dwellers in Prince's-gate or "Exhibition-road" during Exhibition time. Yet Lord Bury writes as if the whole were a scheme for adding to the nuisance, instead of one which will do much towards reducing it. He compares the ventilators which the company are opening in the middle of the road to the "blowholes" which have caused such a nuisance in other places, quite forgetting that this is not a railway tunnel, whence the steam and smoke of locomotives would be given off, but merely a footway for passengers who want to breathe; and he talks of one of the widest streets in London as "our narrow thoroughfare." There could not be a more typical example of the unreasonableness which possesses English householders who fancy they have a grievance. On the other, the reply of the solicitors to the company, which is perfectly reasonable in itself, is obviously open to the objection of claiming a legal right (to deviate from the intended line of the subway, under the footwalk, to one under the centre of the road) which they have not. Lord Bury is

* "The Ancient Coptic Churches of Egypt." By Alfred J. Butler, M.A., F.S.A. Oxford: Clarendon Press, 1884.

right in law, but unreasonable in opinion; the company are wrong in law, but they are in this instance, at least, doing what will be a public benefit, and what among other advantages will probably put a natural stop to that congregation of low hawkers on the edge of the footway, to which we have before referred, and which ought to have been stopped by police interference in any case.

FROM a communication kindly sent to us by the Dean of Winchester we learn that it is proposed to restore the celebrated screen, as a memorial to the late Archdeacon Jacob. The work proposed to be done is grouped under three heads:—(1) The restoration of the stone-work throughout; (2) The restoration of the cross on the existing base; (3) The placing of statues in the niches. The first item comes, we presume, really under the head of what might properly be called "repair," the two latter are restoration. It is to be hoped that the work will be carried out so as to preserve all the ancient work that is in at all an intelligible state as intact as possible. The removal of West's picture from the centre of the screen is spoken of as a possibility, not yet decided on. West was not, from the present point of view, a very powerful artist, but he marks a phase in the history of art, and his aims at least were high. We should hardly advocate the removal of his work without better reason than we have heard yet. About 5,000*l.* is needed for the work. It is not stated what architect and sculptor are to be employed.

IN his second lecture at the Royal Institution last Saturday afternoon, Dr. Waldstein did not after all get as far as Praxiteles, a considerable portion of the time being occupied in an attempt to define the origin and nature of that peculiar state of feeling constantly recurring in the history of all art and literature, and vaguely termed "romanticism." Dr. Waldstein represents it as consisting in an attempt to escape from actuality to a sentimental ideal, an ideal based on sentiment, on what might be rather than on what is. The definition hardly seems quite to cover the ground as far as sculpture is concerned; some of the works which are recognised as of the romantic school, such as the "Apollo Sauroctonos," being in fact more realistic than the sculpture of the period of Pheidias. We doubt if any one ever will define "romanticism" in a logical and satisfactory manner. Those who have studied and compared the art of different epochs feel instinctively the difference, but it is so subtle that it would be difficult for those who felt it most strongly to lay their hands on the special qualities which constitute it. In architecture we should be inclined to say it is that which departs from rule and symmetry, and aims at effect somewhat independently of structural fact. Some of the comparisons which the lecturer instituted between the casts exhibited brought out the distinction plainly enough for those who have eyes to see. A very significant contrast was between the single figure in the Sala Chiamonti of the Vatican, believed to be either the original or a direct copy of one of the figures in the Niobe pediment of Skopas, and part of the drapery of the corresponding figure in the Græco-Roman reproduction of the Niobe group as familiar to us. The distinction is almost startling when the two are brought to juxtaposition; the later drapery is a regular piece of sculptor's "bravura." Dr. Waldstein made no allusion to Mr. Wood's sculptured column from Ephesus in the British Museum, so we presume he does not regard that as probably the work of Skopas, who is said to have sculptured some of the columns.* Dr. Waldstein concluded with an exhortation to breadth of sympathy in regard to various schools of art; difference did not necessarily imply inferiority. His third and concluding lecture takes place to-day (Saturday).

* Dr. Waldstein has since written to us to say that he considers the sculpture of the Ephesus drum to show at least the influence of Skopas, whether it be actually from his chisel or not.

A NEW danger threatens York House Water Gate at the bottom of Buckingham-street, Strand. A railway is proposed to be constructed from Charing Cross to Euston Station, which is to be carried, for the greater portion of its length, beneath the surface of the ground in the line of the proposed new street from Trafalgar-square to Oxford-street. In connexion with the railway a short street is proposed to be formed from St. Martin's-place to the Victoria Embankment, terminating near the Metropolitan District Railway Station at Charing Cross. The centre line of this street passes York Gate at a distance of about 30 ft. to the northward, and there is great reason to fear that if the street is carried out as proposed, York Gate will be destroyed. Several proposals have been recently made for the purpose of preserving the gate, and it is to be hoped that the railway company may not be permitted to sacrifice it to their zeal for increased dividends. The same railway proposes to take a portion of the disused burial-ground adjoining Whitefield's Chapel, Tottenham Court-road, and a portion of St. James's burial ground, St. Pancras.

THE Hôtel Salé, an interesting specimen of seventeenth-century work, at the corner of Rue de Thorigny, Paris, and until recently occupied by the Central School of Arts and Manufactures, is offered for sale, and it appears, runs some danger of being demolished. The staircase is engraved in "L'Encyclopédie d'Architecture," first series, 1855, and is a very charming composition. From an archaeological point of view the mansion is not without interest. The site formed a portion of the ancient *cultures*, or spade farms, of the Hospital St. Gervais, and was the last portion of the marshes of the Temple built over by Henry IV. The ground formerly belonged to the Convent of St. Anastasia, by whom it was sold, in 1656, to Aubert de Fontenay, a wealthy farmer of taxes, who built the present mansion. The arns of the founder may be seen in the balusters of the principal staircase. As the enormous wealth of the owner of the house was chiefly derived from a tax upon salt, the people nicknamed his residence the Hôtel Salé, by which name it is known to the present day. The Society of Friends of Parisian Monuments recently inspected the building, and recommended that it should be utilised as a museum, a library, or a school of art, for any of which purposes it appears to be adapted.

IT is to be feared that the ventilation of the Law Courts will never be satisfactory if each judge is to direct that his particular court is to be hotter or colder as he likes. We mentioned last week Baron Huddleston's remarks, and subsequently, as it appears, when Mr. Justice Grove joined his learned colleague there was a difference of opinion on the bench, Mr. Justice Grove complaining of the heat of the court and saying he preferred draughts to suffocation. The fact is that it is not so much the actual low temperature which vexes many of the judges as the draughts. These are a constant source of complaint, and if they were removed we should hear less of these judicial grievances. But raising a court to a very high temperature, as Baron Huddleston has done in the case of that in which he sits, is simply flying from the frying-pan into the fire. The consequence of such a high temperature is the liability to subsequent chills. If each court were kept at a certain stated temperature, as fixed by competent medical authorities, the judges and the public could not complain.

A COMMITTEE of the Glasgow Town Council appointed to revise the regulations for the construction of theatres, music-halls, and public buildings generally, have prepared a draft code of regulations which are under consideration. The regulations are loosely drawn, and are defective in an important particular, as no provision appears to have been made with a view to prevent a recurrence of the disaster which occurred at the Star Music Hall, Glasgow, by which several persons lost their lives. The loss of life was occasioned by the audience from two different

levels meeting together on one of the landings of the gallery staircase during a panic. The remedy for this would be to require that separate means of egress, conducting directly into the open air, should be provided from every tier or level, and that no emergency doors should be suffered to be formed between any one tier and the intermediate landings of a staircase. By these regulations it is proposed that no place of amusement capable of containing 1,000 persons and upwards shall be allowed to be built unless sufficient access can be obtained to it from at least two streets or lanes, and this rule is proposed to be made applicable to existing buildings. In this latter respect the Glasgow regulations go beyond the regulations in force in France and Russia with regard to theatres and music-halls. The Paris regulations permit a theatre to be built as a detached or an attached building; the St. Petersburg regulations require new theatres only to have an open space upon every side with doors and windows upon each of the four sides, and in neither case are the rules with regard to site made retrospective.

THE City of Paris recently resolved to demolish a number of houses in the Rue des Filles-Dieu and the vicinity, situated in one of the most unhealthy neighbourhoods of Paris, inhabited chiefly by rag-pickers and mendicants. The owners of the property claimed upwards of 9,000,000 francs (360,000*l.*) for their interest. The City offered nearly 3,000,000 francs (120,000*l.*), and the jury awarded a sum of 213,000*l.* One of the owners received as much as 15,500*l.* as compensation, from which we may infer that the owning of unwholesome houses is not less profitable in Paris than it is in London.

THE February number of the *Art Journal*, which at its now reduced price of 1*s.* 6*d.* is a wonderful "monthly" for the money, contains an interesting and well-illustrated article on "Grotesques," by Mr. Lewis F. Day. An article on "Art-Teaching at Rugby School" gives a pleasant idea of what is being done there to stimulate a taste for and knowledge of art among the boys. The schoolboys of this generation at Rugby, at all events, need not grow up in such entire artistic darkness as that which used to enclose the mind of the British schoolboy.

SEVERAL architects have sent us, with various indignant or sarcastic comments, the following circular, sent round by a firm of contractors:—

"Dear Sir,—We shall be pleased to tender for construction, alterations, joinery, and high-class decorations.

When unusual trouble is taken, we shall be pleased to remunerate.—We are, dear sir, your obedient servants,
W. B. & Co."

Such a circular is simply an insult to those to whom it is addressed, and we hope that the authors of it will have got a good many unmistakable "hack-handers" from those members of the profession whom they have taken the liberty to address in that fashion. The communication is marked "private," a sufficient indication that those who issued it knew very well they were doing what they, and any one who should accept their obliging offer, ought to be ashamed of.

Blackburn.—The new wing attached to the Blackburn and East Lancashire Infirmary was opened for the reception of patients a short time ago, without any formal ceremony. The Board of Management at their last meeting expressed themselves well pleased with the special features in ventilation and the sanitary arrangements generally. The cost of the new wing has been 3,950*l.*, inclusive of drainage and re-forming the ground, and the cost of the entrance-lodges, 350*l.* each. The architect for the work was Mr. A. W. R. Simpson, Blackburn; the builders being Messrs. Thomas Higson & Sons, also of Blackburn. The new wing gives additional accommodation for twenty patients, and sleeping accommodation for six nurses.

THE TOPOGRAPHICAL SOCIETY, AND AN OLD MAP OF LONDON.

"Μάψ, ἀνάφ' οὐ κατὰ εὐθυσίαν." Πόλις, Η., v. 759.

For the earliest recorded view of London taken as a whole, we must look, if happily indeed it might be found, in the Cathedral Library at Seville. Ferdinand, nephew to Christopher Columbus visited England with Charles V., and was at Winchester in the year 1521. Travelling through Europe during the period 1518-1525 he had leisure and means to exercise his tastes as a collector and bibliographer. Some of the books and maps he acquired, together with a catalogue in his own handwriting, are preserved in the Cathedral Library. One item in the catalogue reads thus: "Bought a map of London engraved on copper dated 1407." Until that map be recovered we have to accept as the oldest of its kind the freehand drawing which, whilst neither signed nor dated, is popularly attributed to Antony Van den Wynegaerde. That Flemish artist made several pen sketches, folio size, of notable buildings in Rome, Spain, and the Netherlands, and principally in England, when attached to the suite of Philip II. of Spain. His collected drawings first came into England about sixty years ago, to the care of Messrs. Harding, Triphook, & Lepard, the well-known booksellers, and subsequently passed to the Bodleian trustees. N. Whitlock made a reduced and finished copy of the London view, but sullied his work by introducing details at variance with the received date of the original.* Wynegaerde's work, when fully displayed, extends to more than 10 ft. in length, and is about 17 in. wide. The execution is not careful, whilst the very nature of the subject forbids accuracy of perspective or of relative distance. At the same time we there have a valuable presentment of London, ranging from Placentia (Greenwich Palace) to the King's Palace at Westminster, as it stood temp. Edward VI. Its most prominent features are the White Tower, the four angle turrets already capped with the incongruous cupolas retained by Wren; and the glorious spire of old St. Paul's, which as yet unstruck by the lightning of 1561, rises from the four-pinnacled tower and lifts its vane to an elevation exceeding that of any other Christian church. By the courtesy of the authorities at the Bodleian, the London Topographical Society was lately enabled to present its subscribers with a replica, in two parts, of Wynegaerde's view.

In the Crace collection at the British Museum may be found an uncoloured copy of the "Λονδίνιον Περαισιμί Ἀγγλικῆς Ἐβνῆς Μετροπόλις," taken from the "Civitates Orbis Terrarum," which George Braun and Francis Hogenburch dedicated in 1572 to Maximilian II., nephew of the Emperor Charles V. Within the same portfolio are filed a few later editions, one of them, a French issue, being cut out of Bellefleur's "Cosmography." Since these differ from the first, and from one another, it should be observed that the original, in dimensions 19½ in. by 13½ in., carries its title in a top central panel placed between the armorial bearings of the City and of Queen Elizabeth. At the sides are two tablets, containing descriptive matter in Latin, mainly relating to the Stillards, or Steelyard,† and below stand two male with two female figures. Remarking to its theme after an interval of repose, the Society, whose labours, by the way, seem to be devoted exclusively to a remote past, has just published a reprint of the Braun and Hogenburch, again availing itself of the process employed by the Typographic Etching Company.

Though the river's bend as it flows between Westminster and Lambeth Marshes is incorrectly set out, the bird's-eye view of 1572 can be regarded as generally authentic in essential particulars. The inhabited ground comprises Lambeth, Bankside, and Southwark along the south, forming a chord to the arc which is bounded by Westminster, St. Giles in the Fields,—we reproduce the names as they appear,—Clarkeuwell, Spitel fields, the Myrcories, and the Towne precincts. Through the open fields lying beyond run such main thoroughfares as Howle's hurne (the modern High Holborn), Bushoppe's gate strete, the Barres from near to the Gowne founders h^o (houses)

without Aldgate, and what at this day is known as the Borough. The Strand is shown as a continuous line of dwellings, but nearly all of London proper lies within the City wall. At the south-eastern corner of the map by the waterside is marked a "Beere howse." This is situated (a little below the later Pickle-herring stairs), exactly over against another house, also so named, upon the opposite bank of the river Thames just outside the Tower Iron Gate. In the corresponding corner to the west appear Lamberth and the Slawghter howse, this latter being the abattoir appertaining to the royal palace of Westminster, at the outlet of the former ditch or race, which, serving the Abbot's Mill, is now represented by an affluent of the Aye Bourne running in a sewer beneath Great Collego-street. A short distance down the Thames are marked the Queen's bridge (or stairs), Stehar Chamber, Chanoy row, the Corte, and another Beere howse. The last-named undoubtedly corresponds with the Battery at Whitehall, to whose dismantled remains we recently directed attention.* Barnard's Castle is styled Benam's Castle; in fact the whole nomenclature of this map is well worthy of study.

We have alluded to the comparatively small space covered by the ordinary dwellings. Not yet has begun that rapid outgrowth of buildings, principally to the northern and western quarters, against whose increase Queen Elizabeth herself and her successor on the throne issue their neglected edicts. Looking at Braun's and Hogenburch's picture one is forcibly reminded of the greatest crisis in the history, topographically speaking, of London. We at once see more graphically than mere words could demonstrate how, had the Great Fire then raged, very little of the town would have escaped. For laying waste a portion which is equal to the joint areas of the Green and Hyde Parks the conflagration consumed the whole heart of the city which is delineated in the picture under review. Again, we see at a glance how, with one or two notable exceptions,† poorly provided were the parish and conventual churches with towers or steeples. But with the Great Fire Sir Christopher Wren found an opportunity such as no architect had ever enjoyed before. What he might have done, unfettered and uncontrolled, it were idle to conjecture. What has been done since it were as painful to recall, but one thing is certain, that to him and him alone the City owes a charm and a beauty so distinctive and yet so varied that even the most vaunted of all other European capitals must acknowledge their inferiority.

Of other and even older views it will be sufficient to mention the illustrations in MS. copies of Matthew Paris's work, dated 1230, at the British Museum and at Corpus Christi, Cambridge; as well as the miniature painting (1418) which represents the Duke of Orleans as a captive in the Tower. These three views were produced in facsimile by J. West. There is also the co-eval painting at Lord Egmont's monastic seat of Cowdray, in Sussex, wherein is delineated the procession of King Edward VI. from the Tower to Westminster, on the 10th of February, 1547, previously to his coronation. That painting, 50½ in. by 22 in. in dimension, J. Basire engraved for the Society of Antiquaries in 1787. To them may be added the diminutive foreign map, only 4½ in. by 3½ in., by Francis Velazio, from a book entitled "The Cities of the World," formerly in the Wellesley Collection and now in the British Museum. These, however, are valuable rather by reason of their antiquity and intrinsic excellence than for the trustworthiness of their details.

British Museum Lectures.—Professor Hodgetts, whose lectures in the Anglo-Saxon room last year were noticed in our pages, will commence shortly a course of six lectures in the British Museum, on the following subjects:—"The Normans," "The English," "The Monk," "Armour," "Civil Dress," and "Sports and Pastimes." The lectures will be given at two p.m. on successive Friday afternoons, commencing February 20th.

* The Builder (Aug. 9th, 1881), vol. xvii., pp. 187-8.
 † For instance, the towers and spires of St. Lawrence Pountney and St. Dunstons-in-the-East, with the towers of St. Mary Somerset, St. Mary-le-Bow, St. Mary Spital, St. Mary Aldemary, and St. Michael Cornhill. These are still more conspicuous in Agge's map and in Hollar's delightful little etchings from the fields about New River Head.

ROYAL BADGES.

SECOND only in importance to the Royal Arms (of which we gave a slight sketch in a former number, p. 115, ante), come the personal emblems or crests and devices which each one adopted as his or she thought fit, as to any amount,—a liberty that some of our sovereigns freely availed themselves of taking a round dozen to their aid.

The derivation of the word "badge" is a moot point, and Mr. Lower has given the precedence in dispute in his "Curiosities of Heraldry" to which we cannot further refer.

The badge is at least as ancient as the shield of arms, and was borne on the breasts of retainers as the more simple device, and it furnished many a public-house sign; to wit, it is "White Hart" of Richard II.

In this brief article it would be impossible to enumerate all the royal badges, and we can only glance at a few of the more celebrated ones: those of York and Lancaster alone form two chapters in "Planché's Pursuivant," and are of great interest.

The "Plantagenista" is about one of the earliest that we are acquainted with, and, at the same time, one of the best known as a punning device of the Plantagenet kings, in our language it is the broom plant.

Richard I. used a star rising from a half-moon or crescent, to typify the triumph of the cross over the infidel, and this was retained by King John, his most unworthy brother.

The far-famed and most familiar Prince of Wales plume was first borne by the Black Prince but its origin is doubtful.

Richard II., in his better days, bore the "sun in splendour,"—too soon to be charged for the light of day behind a cloud; he also bore the well-known white hart, with several others.

The white swan of Henry IV. is equally familiar to us in its present use as a public-house sign. The bear of Richard III. is a notorious royal badge.

We now come to the portcullis of Henry VII. derived from the Beauforts, and perhaps no royal badge will be more familiar to an architect than this one, and, in our judgment, none seems better adapted as an ornament to a building, and it has certainly been made the most of in his chapel at Westminster, in conjunction with the Tudor rose. So profusely do the Tudor badges adorn the architecture of this period, that one writer claims for it the title of "the Heraldic period," instead of the Perpendicular style.

Henry VIII. appears to have continued to use his father's badges, and his numerous wives adopted their own devices, the pomegranate of Catherine of Arragon being the most familiar.

The next three sovereigns bore Tudor roses, to which Elizabeth added a crowned falcon and sceptre, with the motto, "Semper Eadem," and a most inappropriate one it was.

James I. introduced the Scottish thistle, and sometimes bore it in conjunction with a rose-crowned, and this appears to have been the last original badge borne by English monarchs, if we except the rose-branch and thistle (growing from one branch) of Queen Anne, and with this last of the Stuarts personal badges ceased to be used by the reigning monarchs, and the plume of the Princes of Wales is all that is left to us of the numerous tribe.

Some fine examples of this ostrich plume are to be met with at Peterborough, Worcester, Ludlow, Exeter, and St. Albans.

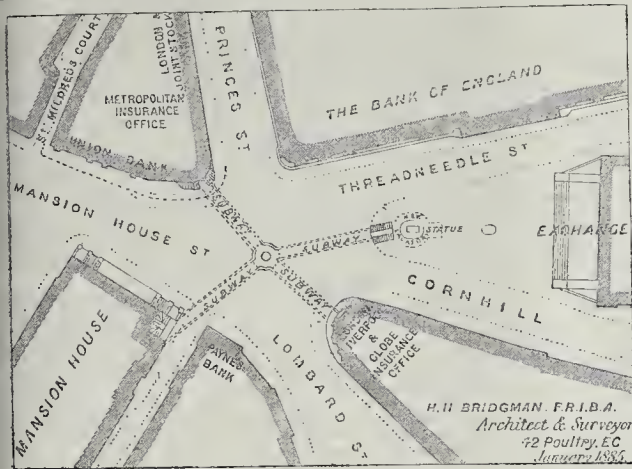

The "collar of essee," so constantly met with on the effigies in our old churches and cathedrals, is a badge of the house of Lancaster, and the origin of the S is a matter of dispute, but it is generally supposed to represent the word "Soveraygne," the favourite motto of Henry IV.

The corresponding collar of the House of York is made up of suns and roses alternate, but, perhaps, it is not so familiar as its rival.

With the extinction of the feudal system the bearing of badges has gone out, and with it a most important landmark in our country's history has disappeared, and the means of fixing the age of a building, and in many cases the determining the founder of it.

Liverpool.—The offices of the Toxteth Park Local Board, Liverpool, are being altered, from plans prepared by their surveyor, Mr. John Price, Assoc. M. Inst. C.E., the tender of Mr. John Carruthers, of Lucerne-street, Toxteth Park, having been accepted.

* Circa 1550. It distinguishes the Protector Somerset's mansion.
 † A corruption of Stalhof or Sta'thof, i.e., staple-house. Its site is covered by the Cannon-street terminus of the South-Eastern Railway.

Plan of Proposed Subways in the City.

PROPOSED SUBWAYS AT THE MANSION HOUSE.

The annexed cut shows the lines of the subways for foot-passengers which were proposed recently to the City Commissioners of Sewers, and which were referred to the Streets Committee for a report and estimate. The plan is devised by Mr. H. H. Bridgman. In regard to the advisability of the scheme it may be observed that for many years past it has been a very difficult matter for pedestrians to make progress at all in that immediate locality in consequence of the very large concentration of vehicular traffic from all directions, and where the pedestrian traffic is greater than at any other point in the metropolis. In 1860, during nine busy hours of the day, 56,235 people crossed over on foot between the vehicles and under horses' heads, a rather trying task for the strongest and bravest, but for a considerable number a matter of great difficulty and danger. King William-street, by the statue, comes next in this respect, where 42,935 crossed over. During the twenty-four hours of the day, however, a total number of 84,352 persons crossed over at the Mansion House intersection, and 63,592 at King William-street, which is equal to totals of 27,279,416 and 20,565,632 respectively, and the greater part of these enormous crowds have to cross over between the vehicular traffic, which is stopped every few minutes to let a stream of pedestrians across, and so on throughout the day. This necessarily causes considerable delay in the traffic, while at the same time foot-passengers are waiting in groups at every corner to cross when an opportunity occurs. There has been a general increase in the pedestrian traffic of the City during the past twenty-five years of 29 per cent., so that at the present time there is crossing over daily in the manner previously described at the Mansion House 108,814 people, or a total of 34,080,515 during the year, allowing for one-fifth of the traffic on Sundays. The vehicular traffic in the principal streets of the City has increased far more rapidly. From 1850 to 1865 it increased at the rate of 50 per cent., but the increase has not been so great in recent years. In the year 1873, 9,225 vehicles passed into and from the Bank through the Poultry alone, and at the present rate of increase 1,106 vehicles pass the Poultry daily. The total number of vehicles, however, passing the Mansion House and Bank centre daily is estimated at 51,989 or 17,222,555 per annum. It is difficult to understand figures without comparisons. In 1866, of vehicles passing along Oxford-street, over two-thirds of the same number (6,500) passed along Princes-street by the Bank daily, and whilst over Westminster Bridge (where there is a larger traffic than at any other point outside the City boundary) there passed 11,609 vehicles daily; yet the number passing along Cheap-side, by Milk-street, every day was 13,016. These figures speak volumes in favour of the urgent necessity of some greater facility for crossing

at that point. The proposal is to construct underground, in the centre of the several roadways in a line with Princes-street, a circular chamber, about 20 ft. in diameter, with an 8 ft. skylight at the top, for light and ventilation. Around such skylight, at the street level, would be a footway left, 6 ft. wide, as a refuge, protected by a kerb and posts, in lieu of the inadequate small refuges. From the circular chamber beneath would radiate subways (1) to the Union Bank corner, by Princes-street (the projecting property having been recently bought by the Commissioners of sewers, for the purpose of widening and improving Mansion House-street; (2) to the north-east corner of the Mansion House basement; (3) to the open space in front of the Exchange, by the Wellington statue; and (4) to the Globe Insurance Office corner. At each of these points access by means of a flight of steps would be gained to the several subways, all of which would be lined with white glazed bricks, with name-plates fixed to the walls at the central chamber, indicating where the subways lead to. The subways would be amply ventilated, and lighted by means of the electric light, a preliminary contract having been just entered into with one of the electric light companies for the purpose of lighting the immediate locality, so that the cost would not be great. Policemen would be stationed beneath, and gates be placed at the entrances, which would be closed at night.

The last suggestion does away with one objection to subways, the liability of their becoming lurking-places for dangerous or disreputable characters. The practical difficulty will be with regard to sewers and gas and water mains, and this is matter for special examination and report. That such an underground crossing would be an immense convenience, and remove what is to a certain extent a source of danger, there can be no doubt; and the removal of the pedestrian traffic from the surface would lead to some little acceleration of the vehicular traffic, as vehicles are stopped at intervals now by the police to allow of pedestrians crossing.

THE PARISH CHURCH OF ST. MARYLEBONE.

VISIT OF THE ARCHITECTURAL ASSOCIATION.

ST. MARYLEBONE (like St. Pancras) possesses two parish churches, the old and the new. When Tyburn Church was rebuilt in 1741 on the site of the former edifice, it was dedicated to the Virgin by the name of St. Mary-le-Bonne, now Marylebone. It is situated in the High-street, and is the mother church of the manor and parish. St. Mary-le-bone New Church is situated a little to the north of the old church, on the south side of the Marylebone-road, opposite York Gate, Regent's Park, and was designed by Mr. Thomas Hardwick, a pupil of Sir William Chambers, and father of Mr. Philip Hardwick, R.A. This was the church selected by the members of the Architectural Association

for their first Saturday afternoon's visit this session, on Saturday last, the 24th inst. The portico faces the north, "a peculiarity," says Peter Cunningham, "in some measure forced upon the architect by the nature of the ground selected for its erection." The first stone was laid July 5th, 1813, and the building consecrated February 4th, 1817. The total cost was about 60,000l. The altar-piece of the "Holy Family" was presented by the painter, Benjamin West, P.R.A.

The members assembled in the nave of the church at three p.m., and were received by Mr. Thomas Harris, architect, of Gray's Inn, who has been superintending the execution of very extensive alterations and additions, and also by Mr. G. Constantine, who has been officiating as clerk of the works. After explaining the drawings, Mr. Harris proceeded to show the members what is being done to the building. Some lithographic sketches of the interior were handed round, entitled "St. Marylebone Parish Church, as it appeared, May, 1883." At that time a contract was entered into with Mr. Edward Conder, builder, for 11,353l., who is executing the work; the contract for heating apparatus in the basement being completed by Mr. Stainton, of 26, Liverpool-street, King's cross. The whole of the stained glass and decorations are by Messrs. Campbell, Smith, & Campbell; and all the marble and mosaic work is by Messrs. Burke & Co., the wood carving being by Messrs. Daymond & Co. Altogether the several contracts and extra works when completed would, Mr. Harris said, cost about 24,000l. The principal alteration consists in taking down the south wall of the church, usually occupying the east end, and throwing out a large circular apse, at once giving the interior a bold and imposing effect. The old pews and seats have been removed, and new ones of Honduras mahogany substituted, French polished.

The sedilia and choir-stalls have been executed by Mr. Walden, of Maiden-lane, Covent-garden, and the reseating of the nave by Messrs. Lascelles & Co., of Bunhill-row, who have also executed the external concrete facings. The organ is by Messrs. Gray & Davison, of Enston-road; the carton-pierre work by Messrs. Jackson & Sons; and the lectern, gas-standards, and gas-fittings generally by Messrs. Richardson & Co., of Brownlow-street. The cushions and mats for the use of the sacarium have been embroidered in colours by ladies of the congregation from designs by the architect. Besides the addition of the semi-circular apse at the end of the nave, a new clergy vestry and a strong-room have been added. These works, Mr. Harris said, have been designed to harmonise with the old structure, and are so planned as not to alter or interfere with any of its main external features.

The whole of the upper side galleries have been removed. The old altar piece by Benjamin West is now placed in the new clergy vestry. The body of the church has been repaired with Comblanchien and Rouge Royal marbles in chequers, the old marble font being fixed in its former position. The iron columns supporting the lower galleries have been cased with wood, as Ionic columns on bases level with top of benches.

The new screen walls have a podium up to the gallery ceiling level; these are enriched with fluted Corinthian pilasters, and are pierced with openings into the wings. The large arched opening on the left contains the organ front and screen. An enriched Corinthian entablature, surmounting the pilasters of screen walls is carried all round the church in place of the old unsightly cove.

The ceiling has been enriched with moulded ribs. That portion over the choir and a wide border round the main ceiling being panelled, and the portion over the choir and elsewhere slightly relieved with carton-pierre enrichments. Adjustable flaps are arranged in the roof, in connexion with the pierced moulding round the large central space, to assist the ventilation.

In the left-hand wing the alteration consists of a rearrangement of the stairs from the vestibule to the gallery and to the vaults, and the formation of a verger's room.

The marbles used in the pulpit and screen are,—Pulpit, rouge royal, Siena, Joinville, Comblanchien, and alabaster; Screen, rouge royal and alabaster, circular panels, Joinville, inlaid with white marble.

The stalls are panelled and enriched with

carving, four of the ends having angels with musical instruments. The sacarium occupies the whole of the apse, and is raised two steps above the level of the choir, from which it is separated by a marble balustrade. The floor of the sacarium and choir is paved with mosaic, the altar-space being two steps higher than the adjoining floor level, and 2 ft. 4 in. higher than the floor of the nave. There are four windows to the apse, two on either side of the reredos. A domical roof surmounts the whole, ceiled with fibrous plaster, and divided into five compartments by moulded ribs.

A plumb and surface of marble lines the walls 5 ft. high, above and up to the window-sills being filled with marble mosaic, representing emblems of the four Evangelists, angels, cherub-heads, &c. The credence-table is of carved marble, and the sedilia panelled and carved. A prie-dieu is placed in front of the sedilia. The altar-table is of wood, having a mosaic frontal in marble frame. The subjects in the panels are connected with the Passover.

The reredos embraces the whole of the middle bay. The front plasters are carved in low relief, with arabesques symbolical of the Resurrection. The marble entablature continues round over the reredos with a carved pediment, the tympanum being enriched with cherub heads.

The four windows of the apse are filled with painted glass, forming, with the Crucifixion, a series of five subjects connected with our Lord's life on earth. The windows of the apse were presented by Mrs. Waller; six of the painted subjects between the nave windows by Mr. E. Armitage, R.A.

There was another meeting at the church on Wednesday last, when many members of the committee and the architect attended to point out to those invited the chief points in the alterations.

The reconsecration of the church will take place this day (Saturday, Jan. 31st) by the Bishop of Bedford.

Illustrations.

DESIGN FOR THE DECORATION OF THE DOME OF ST. PAUL'S CATHEDRAL.

BY JOHN P. SEDDON, ARCHITECT.

MR. SEDDON, in the course of the recent discussion upon the paper read about the decoration of the Dome of St. Paul's by Mr. Stannus, at the Royal Institute of British Architects, contended that all the designs yet brought before the public, being based upon an old-division of the dome by vertical ribs or circular panels, involving more or less sham architectural details beyond the real ones provided by Sir Christopher Wren, were wrong in principle. Such features, in themselves inadmissible, disturbed the serenity of the surface of the dome which Wren had not broken up; and, in the case of the vertical ribs, they introduced a Gothic aspiring tendency instead of the repose appropriate to the Classic architecture of St. Paul's, and, in the case of the circular panels, they produce a *petite* and confused effect. He called attention to the picture by Sandro Botticelli in the National Gallery as affording an example of fit and proper treatment for the decoration of such a dome by means of subdividing it by horizontal zones alone.

The accompanying drawing was made from Mr. Seddon's sketches and directions during the fortnight that had elapsed between the date of the reading of Mr. Stannus's paper and the adjourned discussion thereon, by Mr. H. G. Murray, an artist in the employ of Messrs. Bolham, of 155, Buckingham Palace-road, who had been his (Mr. Seddon's) pupil in decorative art.

In this design the surface of the dome is subdivided horizontally into three zones of figures representing seated saints, prophets, and martyrs, with attendant angels standing behind them. The disposition of these figures is in accord with the spacing of the architectural supports below, with groups of angels concentrated over the eight principal piers, so as to emphasise them and avoid monotony in the arrangement. This treatment would be further accentuated by colour; the figures above the piers being clad in white to render them more prominent than the rest.

In tone of colouring Botticelli's picture would afford much help, as in the lustrous subdued

golden hue of the cloud-background of the figures, from and upon which the stars and rays in brighter gold would detach themselves, while the several zones would be separated from each other and from the cornice below by the quiet greyish-blue which would be the proper contrast to the rest of the ground; the wings of the angels and dresses of the figures would supply the stronger colouring needed. In the upper zones the heavenly host and angelic choirs would be represented, and around the central circle or eye of the dome, symbolising light or the sun, golden rays would stream downwards towards the several groups below.

Of course the treatment thus somewhat hastily elaborated is open to modification and improvement; but as regards the general principles of design, and the predominance of horizontal zonal divisions which Mr. Seddon maintains to be appropriate, ample scope would be afforded for the talents of the able artists who have been engaged.

The question, at any rate, is one that must not be looked upon only from a painter's point of view, and certainly not from a false architectural one. It demands that proper combination of the arts which constitutes true decorative art, which, from the long severance of Architecture, Painting, and Sculpture, seems to have been lost sight of.

The illustration is reproduced from the coloured drawing by Messrs. Boussoad & Valadon's (late Goupil & Co.) phototype process.

THE HOLBORN RESTAURANT.

WE illustrate this week two views of this restaurant.

One view shows the front towards Holborn of the block which has now for some time been erected; the interior arrangement of which is so well known that we need not now describe it.

The other view shows the front towards Little Queen-street of the block now to be erected, forming as it does the eastern annex of the restaurant. The ground-floor will contain the new grill-room, 70 ft. by 60 ft., and the upper stories will be devoted to private dining-rooms to accommodate parties of from twenty to fifty persons. The upper part of this front has been set back to avoid litigation with the owners of property on the opposite side of Little Queen-street.

It will be seen that, to carry out the entire scheme of the promoters of this restaurant, the eastern corner of Little Queen-street must be taken in, and, as soon as the leases of that block fall in, the premises will be pulled down and the new work proceeded with, thus completing the building.

The buildings now illustrated have been and will be carried out from the designs of Messrs. Archer & Green, Mr. Holloway acting as the superintendent of works.

THREE SUFFOLK ROOFS.

THE three roofs illustrated in this week's issue were sketched during the Architectural Association's visit to Bury St. Edmunds and neighbourhood last August, and are certainly among the most interesting examples seen on the excursion. They all three have the alternating trusses varied, but with that single feature their similarity ends.

The roof at Ixworth is over the chancel, and the main truss is of a collar-braced construction, the arched brace coming down on to a small hammer-beam, the hammer-brace resting upon a small octagonal shaft with moulded cap and hase worked out of the wall-piece, and carried by a moulded and foliated stone corbel. The intermediate is collar-braced also, but has the hammer-beam omitted, the arched brace finishing directly on to the octagonal shaft and corbel. The spandrels, filled with delicate tracery, have a very rich and pleasing effect. The cornice has the usual square four-leaved flower in a hollow, and is embattled, but above that again is some effective pierced work. The ridges, purlin, and truss appear to be well moulded, but the rafters are left square.

Hawstead nave roof is of a flatter pitch, and has heavier timbers, giving it a much more substantial appearance. The main truss has a four-centre arched brace resting on a hammer-beam, carved as an angel, with wings slightly spread, and the hammer-brace finished on a stone corbel, moulded and carved as a head or mask. The intermediate has a larger four-centre arched brace coming down directly on to

a similar stone corbel. A curious feature in this truss is that, at the same level as the hammer-beam of the main truss, there is a row of hammer-beam carved on the arch brace, but not projecting beyond it. The cornice is unusually deep. At the bottom is a row of small shields separated by a continuous overlapping and zig-zag label or band; above this a row of quatrefoil and traaced pierced edged above and below with the strawberry-leaf enrichment, and above that again large four-leaved flowers in a hollow, these ornaments separated with moulding, and the wide crowned with the strawberry-leaf enrichment. The spandrels above the hammer-beam are filled with tracery. There are two purlins between the ridge and cornice, and all the large timbers are richly moulded.

If there were nothing but the roofs to see, the church of St. Andrew, Mildenhall, it would be worth the exertion of a long day's journey to pay it a visit. Those to the aisles are remarkable, if not altogether beautiful, that on the north for its bold and vigorous carving dragons and grotesques, that on the south for its richly-moulded timbers, traaced spandrels and carved angels, but the feature of the church is its glorious nave-roof. In this the alternating arrangement of the trusses is particularly happy, as the appearance of crowding, so noticeable in some of those elaborate roofs where the trusses are not far distant from each other, is here entirely absent; there is richness, but there is repose also, for, where the intermediates finish at the cornice spring out large and beautifully carved angels, "hovering" as it were, the wings outspreading and catching the play of light here and there from the windows which are directly under them. The roof itself rather flat-pitched, and the beam of the main truss cambered beneath it is a deep four-centre arched brace lying into the wall-piece and resting on a stone cap, the shaft coming down to the ground; over the centre of the beam and springing directly from it is an arch, the spandrels on either side being filled with tracery, as are those below also. The beam and cornice are similarly enriched with the square flower embattlements, small angels alternating with large carved paterae and the strawberry-leaf running all round as the crowning member. The lower edge of the intermediate and of the curved brace has a square flower in a flat hollow and all the larger timbers are well moulded. Neither sketch nor description expresses the beauty of this roof, but perhaps they may tempt one or another to make the long day's journey as opportunity occurs.

THOMAS GARRATT.

HÔTEL DE VILLE, DINANT.

THE Hôtel de Ville was erected in the commencement of the seventeenth century, on part of the walls and a turret which had escaped demolition in the sixteenth century when Dinant was taken by the French under the Duc de Noers. The bow-window, &c., and roof are evidently of later date, and were probably added after the unfortunate town was again taken by the French in 1673, when no doubt it again suffered partial demolition. The building is now entirely yellow-washed over.

R. A. BRIGGS.

THE SURVEYORS' INSTITUTION.

PRELIMINARY EXAMINATION, 1885.

Of the Candidates who presented themselves at the Preliminary Examination of the Institution, held on the 20th and 21st inst., the following satisfied the Examiners:—

Archibald, C. F.	Lumley, J. A.
Beard, E. T.	Mann, J. B.
Bensley, O. E.	Mann, R. B.
Brown, W. E.	Mathews, J. M.
Buss, F. G. W.	Newton, F. J. C.
Champion, L. C.	Nicholson, E.
Crew, T. J.	Nockolds, M. C. P.
Coates, H. G.	Parry, R. E.
Crokat, E. A.	Patonson, H.
Eves, W. L.	Pratt, P.
Fitzhugh, W. R.	Rand, J.
Goodman, P.	Robinson, A. W.
Gough, G. S.	Solby, F.
Green, T. J.	Sauntwaite, W. J.
Harding, R. B.	Varley, R. E.
Jenkins, H. L.	Yankey, E. B.
Jonas, S. M.	Webb, F. N.
Jonas, F. H.	Wilkinson, G. H.
Lloyd, W. R.	

Passed at head of list.

QUEEN STREET.

Diagram explanatory of Mr. Fergusson's Proposed Method of Treating the West Front of Westminster Hall.

WESTMINSTER HALL.

SIR,—The evidence already collected by the Committee of the House of Commons, together with the correspondence on the subject in the Times and other papers, have, at all events, made it quite clear that the west side of Westminster Hall was never seen or meant to be seen from without. It formed one side of the court, or series of courts, in which the domestic offices of the palace were situated; it, in fact, formed a good strong blank wall, which was, at all times, from its erection, utilised to support buildings or lean-tos of one or two stories, with sloping or flat roofs as convenience may have required. There is, however, absolutely no proof, either historical or material, that a cloister, or anything of the sort, ever existed there. The remains of traces of the external walls of the Hall of Rufus being still found *in situ* in itself is sufficient to prove that it never was intended to be seen. The architects of the time of Richard II. considered the Norman style as barbarous and exploded, and never would have allowed any fragments of it to remain had they not been covered up and concealed by some subsequent exertions. This, therefore, is a case in which archaeology may, for once, be safely thrown overboard. It is in vain and absurd to look at the wall of the Hall when it formed the unseen side of a private inner court for any hints as to the mode of treating it, when, by the recent demolitions, it has become the most prominent and important external feature of one of the most ornate buildings in Europe.

This being so, the one question that now remains to be solved is to try to ascertain how, under these altered circumstances, a Medieval architect would have treated the west flank of the Hall, and we may certainly answer, in the

first place,—Notas Mr. Pearson proposes to treat it. The great defect of the west wall as at present exposed, and it is a serious one, is that it is too low when seen in conjunction with the noble but colossal roof it was built to support. By cutting the height into two or three low stories, by dividing it into walls in two planes, and by strongly accentuating the horizontal lines, Mr. Pearson's design tends in every way to exaggerate this defect and to destroy the dignity that would result from a simpler treatment. What I, on the contrary, conceive a Medieval architect would have done under the circumstances would have been to accentuate the vertical lines of his design at the expense of the horizontal, and to introduce no prominent feature between the base and the coping. This could easily be effected by introducing an attached buttress between each of the flying ones, and crowning them all by pinnacles of appropriate height. Whether exactly as shown in the annexed woodcut or in any other form we need not now stop to discuss. It would certainly be on that principle. The woodcut, however, must not be considered as pretending to be a design fit for execution; it is in reality a diagram intended to illustrate two among the many modes which could be adopted for that purpose, but the details of which must be left to be designed by whoever is entrusted with the execution of the work. The special merit of the proposal shown in the woodcut, for the present purpose, is that its thirteen buttresses and pinnacles reproduce the thirteen trusses of the roof internally, and so bring the exterior and the interior into that harmony which is one of the important elements of all good architecture.

There are in England probably 100 halls of various sizes attached to palaces, colleges, or other public buildings, not one of which, I venture to assert, has its principal front encumbered by low mean buildings, such as it is proposed to add to this the greatest and most important of them all. In every one, so far as I know, the front wall rises from the ground and continues unbroken to the coping, and a battlement of more or less

importance is added with pinnacles and other ornaments to give it greater height and dignity.

Neither Mr. Pearson nor any of the architects consulted by the Government seem to have realised the glorious opportunity the recent demolitions afford of completing one of the most beautiful architectural combinations anywhere to be seen. The Hall, as a secular building, is the exact counterpart of the nave of the Abbey, as an ecclesiastical one, and the two seen together form a group, in combination with the Parliament Houses, which one might challenge the world to rival. On the whole, I am inclined to believe that the Hall,—if properly treated,—is the finest and grandest of the two, and to deform it, as it is proposed to do, by mean and incongruous adjuncts, would be,—to use the mildest form of expression applicable,—an unpardonable mistake.

The design by the late Sir Charles Barry, represented in your last issue, is too grandiose, and on too expensive a scale to be thought of, in these days of economy. If the Government want a building to accommodate commissions and committees, or residences for officers of the House, they can obtain it nearly as conveniently, and far more cheaply, by erecting a plainer building at the south end of the garden facing the Victoria Tower. It could easily be connected with the Houses by a corridor along the Embankment, and might be made a far more valuable metropolitan improvement than any building in New Palace-yard.

The great objection, however, to Sir Charles Barry's scheme, to my mind, is that it again covers up and hides the Hall. My impression is that if he had lived to see the Hall in the dignified position it now holds, he would have seized on its exterior, and made it the central and most important feature of his new buildings, in the same manner as he has made its interior the appropriate vestibule to the Houses, which thus forms the noblest feature in his design. With his taste and skill he could very easily have accomplished this. It remains to be seen whether his mantle has fallen on any of his successors, and if they are capable of making it externally, as it is avowedly internally, the most beautiful Hall in Europe.

JAS. FERGUSSON.

20, Langham-place, Jan. 27, 1885.

SURVEYORSHIP ITEMS.

Accrington.—Mr. E. Knowles, Borough Engineer and Surveyor of Accrington, has been appointed by the Accrington and Church Joint Sewerage Board as their Engineer, at a salary of 200*l.* per annum, in addition to his salary as Engineer to the Corporation.

Lynn.—The Lynn Town Council, at a special meeting on the 16th inst. convened for the consideration of the Borough Surveyor's duties and emoluments, unanimously resolved to employ Mr. E. G. Mawbey (the Borough Surveyor) to design their engineering and architectural works, and for such work, in addition to his salary for ordinary duties, to pay him 4*l.* per cent. if the works are carried out and if approved, but if not carried out, 2*l.* per cent. The architectural work now in hand consists of the restoration of the Town-hall, new Fire Brigade Station, stabling, stores, and cart-sheds. The latter are now being erected. The engineering work includes an iron bridge over the river Nar. The salary is 300*l.* a year, with house, rates, and coal free, for the appointments of borough surveyor, waterworks manager, chief officer of the fire brigade, and estate agent. The Corporation are the principal land and property owners in the borough, and own extensive estates beyond its boundaries.

Schools and Mission Church, Blackburn.—In response to an invitation from the Building Committee of St. Michael's Parish Schools, Blackburn, ten sets of drawings have been received in competition for the proposed Branch Schools and Mission Church at Little Harwood, Blackburn. After an examination by the committee, it was resolved that the whole of the drawings be submitted to an independent architect for adjudication (no one, excepting the vicar, the Rev. S. F. Harris, M.A., to become acquainted with the name of the referee). The four designs selected by the referee are two sets with the motto "Knowledge is Power," one each "Design by Study," and "Self-Help."

PETERBOROUGH CATHEDRAL TOWER.

SIR,—During the correspondence on this subject in the *Times*, reference was made by Professor Freeman to the new steeple of Chichester Cathedral, as "preserving the actual touch of the old building." This, though on the whole correct, seems to imply that the rebuilding was carried out *exactly* as before the fall in 1561. There was, however, an important alteration then made, in order to get over an ancient defect, much like that which existed at Peterborough.

At Chichester the roofs and clearstory walls of the body of the church had all been raised in the fourteenth century, and the pitch of the roofs slightly increased above that of the roofs of the preceding century, which were co-eval with the tower belfry stage then reconstructed on the Norman arches. The result was that the roofs, as raised, ran up against and covered the bases and lower part of the shafts of the belfry windows.

When the plans for the rebuilding of the steeple were prepared (from drawings of the old one) it was decided by the architects, the late Sir G. G. Scott and the late Mr. W. Slater, that this manifest defect should not be reproduced, and therefore they raised the lower arcaded stage sufficiently high to keep the string-course above the roofs, giving thereby an increased height to the tower of about 5 ft.

At the same time the window piers were constructed of sufficient strength to support the weight of the spire, thus making it unnecessary to reproduce the filling in (of the fourteenth century) of the belfry lancets.

Such judicious alterations are surely allowable in a nineteenth-century rebuilding, and may be cited as an example in the proposed reproduction of the Norman arcaded stage at Peterborough, and the consequent lifting of the fourteenth-century belfry stage above it.

I may add that the pinnacles and spire lights at Chichester had been repaired and altered by Sir Christopher Wren. The new ones are copies of these, as no other detail could be discovered. They had been repaired in Portland stone instead of in Beer stone, like the spire.

R. HERBERT CARPENTER.

THE LATE MR. SAMUEL HUGGINS.

SIR,—To your brief notice of the late Mr. Samuel Huggins [p. 129, *ante*] may be added that on one occasion, at least, he tried for success in the field of active professional work in the competition for the Liverpool Free Public Library and Museum. His design remains in my remembrance as one characterised by refinement and elegance.* During the last months of his life his mind was much occupied by the Liverpool Cathedral project, and I had several letters from him on the subject. In one dated October 4th he wrote,—"I was not one of the ninety-nine (original competitors), but I have made a design for a Protestant cathedral (Classic), which I intend to publish somehow or other, if possible." I strongly urged him to fulfil his intention in a sufficiently adequate manner, and cited for example Wordsworth's publishing of the "White Doe of Rylstone" in quarto, to show the world, as the poet said, his own opinion of it.

Besides the Chart of Architectural History you refer to, Mr. Huggins compiled a manuscript Chart of Philosophy, which is now in the Liverpool Reference Library.

JAMES HIBBERT.

FIREPROOF CLOSING OF OPENINGS IN PARTY-WALLS.

SIR,—In my paper at the Institute I spoke, it is true, of persons "acting in defiance of legislative enactment." This referred, however, not to the number of the openings (as implied by the first published abstract), but to the use of over-lapping sliding doors instead of doors fitted into a rebate.

I must confess that I had not, until after the reading of my paper, the very slightest notion that this deviation from the lines of the statute was accepted and acted upon by architects, by District Surveyors, or by members of the Metropolitan Board of Works as an improvement.

* I remember the design, which was a good one. An incident in it was the introduction of two colossal lions flanking the steps to the main entrance, which were put in by the architect's brother, the eminent animal painter, who was great in lions.—Ed.

ment upon the Act, justified by the necessities of the case and by the supposed impossibility of complying always with the letter of what is laid down. But even then no explanation was given, or in any way attempted, as to the mode in which this interpretation was supposed to be reconcilable with the Act. And what I pleaded was that, if the Act practically could not be followed or enforced, there was at least a call for immediate legislation, whether by altering it or by making it more clear and obligatory. It is most undesirable that a professedly stringent Act, the provisions of which are admittedly difficult of enforcement, should be set at naught in the daily practice of those who are bound to work in accordance with these provisions. It can only make other equally-important provisions all the more burdensome and impossible of observance. Still more so will this be the case if the Act is to be considered as "intended as a sort of advice rather than a dictation of what should be done."

As to the number of openings, I certainly expressed myself strongly upon the Act being capable of the interpretation of their strict limitation, though I could not insist upon it, especially as the interpretations of the authorities quoted by me were on the other side. But what I insisted upon was, that if no limitation were laid down in the Act, it ought to be laid down.

I have certainly no wish to make unbecoming charges against District Surveyors or others of my brethren. It may be better to leave admitted and prevalent abuses to be raked up by some valiant Saint Edmund, who can deal with them incisively, and without such offence. At the same time it may be, upon the whole, better that we should do what we can to reform our own abuses by a frank acknowledgment of them. And if, from the absence of all definition of a "rebate," the Act is so obscure that the magistrate in his density cannot penetrate the gloom, it is time that a little light should be admitted from some direction or other.

WILLIAM WHITE, F.R.A.

No. 30, Wimpole-street, W.

SIR,—The paper read on the above subject at the Royal Institute of British Architects, and the discussion arising therefrom, as reported by you on the 24th of January [p. 149], afford sufficient evidence that, as a rule, the provisions of the Metropolitan Buildings Act are inadequate to secure the protection desired. The reasons of failure are not difficult to trace. In the instances mentioned, the doors made merely according to the Act which are reported to have been successful, the success has arisen from the comparatively slight test to which they have been subjected. Whenever the full weight of the fire has been directed against the door by the direction of air-currents, there can be little doubt that in a fire of any magnitude they have invariably failed. The immediate causes of failure are these:—

1. The intense heat causes expansion and buckling of the door-plate.
2. The occasional openings between the door-plate and frame, and, in the case of sliding doors, between the door-plate and wall.
3. This, again, allows the fire to penetrate to the door fixed to the other side of the wall, which, in its turn, similarly succumbs, and allows the fire free passage from one compartment of the building to the other.
4. But in the case of sliding-doors, even without expansion and buckling by heat, a considerable space exists between the door and the face of the wall at the top, bottom, and sides of the door, as mentioned by Mr. Wyatt Papworth in the course of the discussion.

It follows, then, from these facts, that there can be no security in such doors (whether hinged or sliding) unless they be so firmly held in position all round their edges that no amount of expansion or buckling shall be able to draw their edges out of their rebates. This we claim to have effectually provided for by our patent of 1883.

In 1883 we were applied to by the late Mr. Thomas Chamberlain, architect, to design and supply, for Messrs. Faudel & Co.'s new premises in Newgate-street, a number of sliding iron doors, which, while complying with the terms of the Buildings Act, would also be really effective against a fire of the greatest magnitude, even when subjected by great wind-pressure carrying it directly against the door. In compliance with these instructions, doors were manufactured by us for four distinct openings. The efficiency of these doors was fully proved in the disastrous fire which occurred in April, 1884. On the rebuilding of the shop to supply doors throughout, constructed on the same principle as those which had been thus thoroughly tested.

HOBBS, HART, & CO.

SIR,—In your account of the debate upon Mr. White's paper, read at the Institute of British Architects, you refer [p. 150, *ante*] to statements made "by a visitor who did not give his name, but who said he had attended as a representative of the Fire Offices Committee." I beg to state that this is not correct. Not only did I give my name, but added that, "although a member of the Fire Office Committee, I did not attend there as a delegate from that body." G. W. COOKER, London Manager of West of England Fire and Life Office.

THE ROYAL ARMS.

SIR,—Your correspondent in to-day's issue has given an interesting fact in connexion with "supporters" being reversed north of the Tweed, and I venture to say, a fact very little known.

I have somewhere read that the quarterings are also reversed in Scotland, that is to say, the lion rampant occupies the first and fourth quarters (the "Lions of England" do with us), while the harp of Ireland take the second and third quarters respectively, but at this moment I cannot call to mind the authority for this assertion, and I write this in the hope that it may meet your correspondent's eye and induce him to say whether it is a fact or not. I should be most glad to have any information on the "supporters" would be almost sure to note the alteration in the quarterings, and this question is also of interest.

J. B.

SIR,—In the interesting article on this subject in your issue of the 17th inst. [p. 115], you inquire "Where is the beginning?" The following passage from Kobrasse's "History of Germany" may be information to some of your readers, as was to me:—"In 1235, Frederick II. of Germany held a Diet. Before the Diet assembled, he celebrated at Worms his espousal with his second consort, the English Princess Isabella. At the marriage feast, King, Queen, and thirty counts and many knights were present. The king made the most costly presents to the English ambassadors, among the rest he sent rich gifts of curiosities from the East to the king of England, as well as three leopards, the leopards being included in the English coat of arms." W. G.

SIR,—Permit me to supplement the concise and interesting notice that appeared in your pages of January 17th, by stating, firstly, that the shield of Richard I. bore two lions combatant before the *Crescent*. Secondly, the motto "Dieu et mon droit," was first adopted by the same monarch (Cour-de-Lion) after the battle of Gisors, A.D. 1198, it being his parole on that memorable day.

EDWD. A. HEPFER.

"ARCHITECTS' CLUB."

SIR,—I quite approve of Professor Kerr's proposal for the establishment of a club-room at the Institute and entirely agree with "No. 1" [p. 151, *ante*], that there is anything derogatory in the idea. The want of such a rendezvous has long been felt, and often talked about. It would be a great convenience to many town and country members, especially the latter, who would then have a recognised headquarters where they could make appointments, write and receive letters, and meet other members of their profession with whom they might be desirous of comparing notes on the many questions that are constantly cropping up in the architectural world.

The Institute premises are quite large enough in the meantime; there is a good library and reading room,—to the latter might be added a larger and more varied supply of papers; and the present arbitration-room would make a capital club-room *per se*.

The question of refreshments, and the hours during which the club would be open, may be safely left to a representative committee, every member of which would doubtless be as jealous of the dignity of the Institute as "No. 1" can possibly be.

I, for one, am quite ready to give Professor Kerr any assistance that may be in my power if he will take the matter up, as, if properly managed, I feel sure it will prove a success.

J. M. BRYDON.

SEWER VENTILATION.

SIR,—Some local authorities are urging,—and would, if they had the power, compel,—architects and builders to ventilate main sewers by running up the sides of houses pipes connected with the main sewer outside of the trap that separates the main from the house drains. I am neither an architect nor a builder, but as a layman I have a practical interest in this question. Where can I find the most recent and best arguments for and against this plan of ventilating main sewers? At present my mind is inclined to object to the plan as likely to fill the air round the upper windows not only with sewer gases, but also with disease germs. Most sewer gases become innocuous as soon as they are oxygenised by contact with the air; but the disease germs are not thus killed. The best argument in my sense of the importance of having the main sewers properly ventilated, but the above does not appear to me to be the proper plan. I ask for instruction.

LAITUS.

RIGHT OF WAY.

SIR,—In reply to "A. B." [p. 118, ante] I do not think there is any legal width for such a road as described by him. The width, if it came to trial or arbitration, would be decided by what users of such roads said on both sides was necessary.

I have just finished laying out a road for the conveyance of agricultural produce through a field to and from a farm-house and a main road, and, by consultation with the user, I made the metalling 8 ft. wide, commencing the metalling 5 ft. from the stools of the fence; there was no ditch. I may say the road skirted along one side of the field close to the fence, the object being to take as little a width of the field for the road as possible, the user of the road being also the occupier of the field. I should think if 3 ft. were also allowed on the side of the metalling farthest from the fence you would then get the minimum width for such a road,—namely, 16 ft. 6 in.

It should be borne in mind by "A. B." that if loads specially large,—the largest loads I ever saw were in London,—have to come along the road he asks about, 3 ft. more in width at least should be given; and if provision must be made for carts and wagons jacking each other, the metalling should be doubled in width, making total width 24 ft. 6 in.

W.

VENTILATORS.

SIR,—In your issue of January 24th [p. 129], you publish a paper on Ventilation, read by Mr. F. R. Farrow at the Architectural Association. We notice that Mr. Farrow spoke most favourably of our ventilating cowl, although in a qualified manner; for, whilst admitting that "nothing could be simpler, and nothing more effectual," he intimated that he personally preferred a fixed or stationary ventilator with no moving parts. Now, as we are makers of fixed or stationary ventilators, patented by us in 1877, which are made on the same principle as our movable cowl (the only difference being that in the fixed ventilator the action of the wind is utilised in a vertical direction instead of horizontally), we must ask your permission to call Mr. Farrow's and your numerous readers' attention to this fact.

Mr. Farrow's paper is a most interesting and sensible one, but we must ask you to insert this in your valuable publication, in order to remove what is evidently an erroneous impression on his part as well as some of the public.

BANNER BROS. & Co.

Builder-square, E.C.

NEW STREETS.

SIR,—It appears that at last some progress has been made with the new street in Piccadilly to Oxford-street, and your advertising columns show that the ground will soon be cleared; but what is intended as to St. Andrew's-reet and St. Martin's-lane,—a matter of great moment, and calling for immediate action!

You some little time ago gave an interesting account of the noted houses in the latter, but nothing seems in progress as to its improvement. Homing's-row, also, and the way to Leicester-square, much requires widening, the traffic being very great.

Perhaps you can furnish information, and give a sketch map of the alterations proposed.

ST. MARTIN'S.

NON-ACCEPTANCE OF LOWEST TENDER.

SIR,—After wading through plans and specification for the purpose of giving a *bona fide* tender, one naturally expects that if he is the lowest he will have the work, especially when he is asked to tender, and does not get his information through an advertisement. This, however, is not always the case, and in a recent instance a tender 20s. above mine was selected.

I consider this absolutely unfair, and calculated to prevent genuine tenders; but anyhow, some one should be responsible for the trouble and expense to which one has to go.

FAIRPLAY.

PAINT ON FRONT DOOR.

SIR,—Two or three weeks ago I asked if any of your readers could tell me how to stop the running of gum, or whatever it is, from a front door that has been hung about ten years. It causes the paint to peel off as soon as ever the sun has any power on it, though the paint has been burned off and the parts knocked and painted four or six more than once.

In asking this question I fear I have given a poser, but I should be very glad to get a reply. Will any of your practical readers kindly tackle it?

H. G.

The City Law Courts.—According to the *City Press*, the old law courts in Guildhall-yard are to be arranged for the use of the Chamberlain and the officers in his department.

ST. MATTHEW'S, BAYSWATER.

SIR,—In your impression of the 24th inst. [p. 132] I find a notice of the Baptistery of St. Matthew's Church, Bayswater, in which the carvings are attributed solely to Mr. Lawlor and Mr. Baird. Please allow me to request a correction of that statement, as the walnut font-cover, so prominent in your engraving, was executed by me, also the oak carvings in the chancel.

WILLIAM HAWES.

THE CONNEXION OF HOUSE DRAINS WITH SEWERS.

WHAT IS A "PAVEMENT"?

A CASE of some importance to builders interested in the development of building sites in new districts came before Mr. Mansfield at the Marylebone Police-court on Wednesday, when Mr. William Hooper, builder, of 17, Victoria-villas, Kilburn, appeared to answer two summonses, issued at the instance of the Vestry of St. John, Hampstead. The first summons was taken out under the Act 18 & 19 Vict., c. 20, s. 78, for that on the 26th of December the defendant did neglect and refuse to pay to the said Vestry the sum of 11l. 7s. 7d., being the expenses incurred by the Vestry in making and branching out in drains from four houses into the public sewer in D'Eresby-road, West Hampstead, it being necessary to open part of the pavement of the street for the purpose of doing the work. The other summons was taken out under the Act 25 & 26 Vict., c. 102, s. 61, that on the 12th of December last the defendant did unlawfully make an opening into the sewer in D'Eresby-road (which sewer is vested in the Vestry) without the consent of the Vestry.

Mr. Ricketts and Mr. Moore, solicitors, were for the Vestry; and Mr. E. B. Dennis, barrister, instructed by Mr. S. Tiley, appeared for the defendant. The case for the complainants was that a sewer constructed in any road within the metropolitan area became vested in the Vestry or District Board, and that any one entering it without proper consent was, according to act of Parliament, committing an offence for which he was liable to a 50l. penalty. The Act also gave the Vestry the right to claim to make all connexions of drains to the sewer, the expense to be charged to the owner. The defendant in this case had been refused permission to make the drains to his houses and connect them with the sewer, and the Vestry having carried out the work now claimed the cost of the work. In regard to the second summons, it was urged Mr. Hooper had clearly committed an offence by breaking into the sewer.

Mr. Chas. Harlow Lowe, Chief Surveyor to the Vestry of St. John, Hampstead, and Mr. F. Thompson, his assistant, gave evidence to the effect that prior to the Act of 1884, the Vestry had permitted builders, after having got proper sanction, to make the drains to their houses upon the payment of certain fees. The Vestry then adopted a new regulation, by which they claimed to do the work themselves and charge the owner with the costs. On the 12th of December, Mr. Thompson found a man putting in an "eye," connecting the drain of the defendant's houses with the sewer, and reported the matter. Under his supervision the parish workmen had made the drains to four of the defendant's houses, and a charge of 11l. 7s. 7d. for the work was made, which account the defendant refused to pay. In cross-examination, Mr. Lowe admitted that the roadway in the thoroughfare in question was what was known as a "builder's road." It lay between a street and a "builder's road," the footpath being of hogging and burnt ballast, and having a stone kerbing. The account was made up of time and material, and an addition of five per cent. for supervision. It was not denied that the defendant had tendered to the Vestry two sums of 14s. 8d. when asking permission to make the drains, and that they were refused.

Mr. Dennis, for the defence, asked the magistrate to dismiss the first summonses, as the complainants had not made out their case. First of all, they had not proved that any "pavement" had been removed, according to the wording of the summons, to carry out the work; and next he should contend that this D'Eresby-road was not a "street" within the meaning of the Act, and that what had been done was, in fact, an interference with private property; further that this was an attempt to set up a right, which, if well founded, had been possessed by the Vestry for the last twenty-nine years, and had never been assented unto now. The sewer, which defendant's predecessor had constructed, was, no doubt, by the Act, vested in the Vestry, and his claim did not rest on breaking into it. But it had been the practice of the Hampstead Vestry to allow Mr. Hooper to make the drains of his houses, and however much the Vestry might have control over the making of the drains of houses in roads vested in the parish, this was a private piece of land, and did not come within the meaning of the word "street" as defined by the Act.

Mr. Ricketts urged that the term "pavement" did not necessarily mean York stone, but any material used in the formation of a pavement. The sewer was clearly vested in the parish authorities, and it was equally clear that if the sewer needed to be repaired, the Vestry would have the right to take

up the road to do the work. He should submit that the formation of the pavement must be held to be the pavement.

Mr. Dennis quoted a case promoted by the Corporation of Manchester, in which it was held that a pavement must consist of stone, asphalt, or some material of a permanent character, not of the nature of gravel; also a decision of the late Sir Geo. Jessell, who ruled that no local authorities could take over a road which had not been paved, kerbed, channelled, and lighted.

Mr. Mansfield said that the action of the Vestry might involve a hardship upon the defendant, but as a matter of public policy he thought the Vestries should make the drains to all houses, and that would put a stop to the state of things often found in houses not properly constructed. The sections of the Act referring to the word "pavement" were very difficult to understand in the absence of any definitions, but he was inclined to absolve the construction put forward by the counsel for the defendant. As at present advised, he should decide against the Vestry as regards the claim of the cost of making the four drains, but against the defendant for breaking into the sewer, and should order him to pay a nominal penalty of 40s., with 2s. costs. He should give no decision as to the term "street."

Mr. Ricketts asked that a case might be stated for a Superior Court, and the application was granted.

LIGHT AND AIR CASE.

BIGNOLD T. MITCHELL AND OTHERS.

The plaintiff in this action (tried at the Norfolk and Norwich Assizes, before Lord Chief Justice Coleridge), Mr. E. S. Bignold, solicitor, brought an action against the defendants, Messrs. Mitchell, Burtou, & Barnes, trustees of the Norwich Medical Institute, for raising a building which interfered with and obstructed the ancient lights of his house. Defendants denied they were ancient lights, and claimed that if they were, the light had not been materially obstructed.

Mr. Balwer, Q.C., M.P., and Mr. Blefield appeared for the plaintiff, and Mr. Grantham, Q.C., M.P., and Mr. S. Reeves for the defendants.

The plaintiff complained that in front of the house occupied by the Medical Institute in Lady's-lane, a building 11 ft. 5 in. high had been erected as a dispensary at a distance of 25 ft. from plaintiff's dining-room windows. This building was 4 ft. or 5 ft. higher than the old ivy-covered wall which formerly existed. Plaintiff made no objection to the old wall being raised 1 ft. 6 in.; but when he saw the work was progressing higher he applied for an injunction. The Court of Chancery directed that a jury at these Assizes should try the case. The plaintiff, with others, gave evidence that his dining-room was much darkened by this wall, and Mr. E. Preston Willis, architect and surveyor, produced a model of the buildings in dispute, and deposed as to the loss of superficial light formerly enjoyed, and also as to how the building could have been constructed so as to avoid this difficulty.

The defendants called the builder of the place, and Mr. E. Boardman and Mr. J. H. Brown, architects, and Mr. Barnard, surveyor, who relied upon the angle of 45°, which the Judge directed the special jury was an exploded theory.

A verdict was given for the plaintiff for 40s., to carry costs; and the Lord Chief Justice granted an injunction in the terms prayed for,—that is, to pull down the whole of the wall in dispute.

The Wages of the Working Classes.—

It is satisfactory to be told by so good an authority as Professor Leone Levi that the earnings of the working classes amount to 521,000,000l. per annum, or, exclusive of food, &c., 470,000,000l.; yielding an average of 32s. per week per family, assuming each family to have 2 1/2 earners. Comparing the earnings of the working classes for the year 1867 with those of 1884, there is an increase from 38l. to 42l. 14s. With good health and good thrift the case of our working classes should not be so bad as it is. We may well believe with Professor Levi that in no other country are the working classes so well off. The next most important question is, How are the wages spent? It is useless to maintain that the answer to this question is satisfactory. Part of the untrifled is to be lightly condemned, but much of it is really culpable. The enormous amount spent on drink is not denied by any authority. It is said that while we as a nation spend on bread 70,000,000l., on milk 30,000,000l., on butter and cheese 25,000,000l., on house rent 70,000,000l., and on the rent of farms 60,000,000l., we spend on alcoholic liquors 136,000,000l. We want improvements in cooking for the working classes, so as to make the most of their food supplies. This is to be done partly by educating girls more practically, and partly by public arrangements.—*Lancet*.

The Student's Column.

LESSONS IN PERSPECTIVE.—No. 3.

PARALLEL PERSPECTIVE AND BIRD'S-EYE VIEWS.

IN the former lessons, the object to be drawn was placed at an angle to the spectator, and was represented by the process known as *angular perspective*.

The same process may be applied to the representation of an object, such as the interior of a rectangular room, as seen by a spectator standing at one end of the room and looking straight at the other end, so that the central visual ray will be parallel to the side walls. He will next fix his picture-plane at a convenient place across the room.

The vanishing-point of these side walls will then, of course, be on the central visual ray, as any one will find by laying down the plan and vanishing-points,*

* There are refinements upon this rule to meet the distortion or exaggerated appearance of length sometimes produced by it; but it will be found to answer most purposes if the usual care be taken not to comprise too wide an angle of vision.

This one vanishing-point will serve for all the cornices, floor-boards, and all other lines that are parallel to the side walls, and when they are connected across from the end corners of the room, these connecting lines, representing the end of the floor and ceiling, will be found to be parallel to each other. In other words, all such lines will be horizontal.

Such a representation is said to be drawn in *parallel perspective*.

Now, some benefactor to the human race, or those members of it who make perspective this same result could be produced by simpler means, and that, instead of having to crowd a plan with an infinity of visual rays, the distance of any object beyond the picture-plane may be itself without touching the plan.

Indeed, the plan need not even be pinned down on a board, nor any preparation be made beyond laying down a sheet of paper for the perspective view, and setting up thereon a transverse section of the room (fig. 1).

Across this section draw a horizontal line at about 6 ft. above the floor, and draw a vertical

line to represent the central visual ray. This need not be in the centre of the room, as it is better to show a little more of one side of the room than of the other.

The point where these two lines intersect will be our old friend the *vanishing-point*, sometimes called the *point of sight*, and towards it all the lines of the side walls, &c., will converge.

Reverting to our first lesson (vol. xvii., p. 443) we will suppose that a huge sheet of glass is placed across the room and that we have to represent thereon what we see through it.

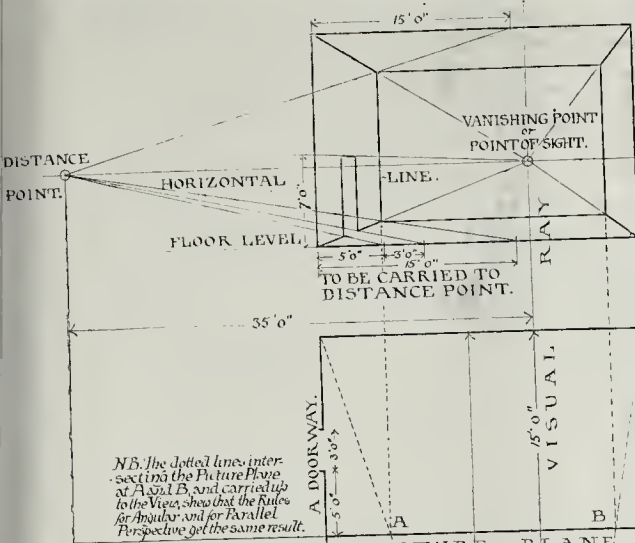

How far down the room shall we set up the imaginary sheet of glass?

This will be decided by the distance that we can stand back from it, so as to look through it comfortably.

Suppose the room to be 50 ft. long and 24 ft. wide. If we stand near one end wall and set up the glass 35 ft. down the room, we should see the remaining 15 ft. through it, which would form our perspective view.

Now, the transverse section that we have set up, as above described, is to correspond in position with the imaginary sheet of glass, or picture-plane.

THE VIEW.

N.B. The dotted lines intersecting the Picture Plane at A and B, and carried up to the View, show that the Rules for Angular and for Parallel Perspective get the same result.

We have next to see how far the lines representing the side walls, &c., travel towards the vanishing-point (or point of sight) before they are stopped or cut off by the end of the room.

In angular perspective this is done on a plan, by bringing visual rays from the corners of the room back to the picture-plane, and so also can be position of every object in the picture be found.

But the multiplicity of lines would be confusing and the picture-plane would bristle with them like quills upon the fretful porcupine, and the fretfulness might be conveyed to the draughtsman.

Here the angel and minister of light who sits upon the use of distance-points comes to our relief. We have settled the station-point to be 35 ft. distant from the picture-plane.

Now mark on the section of the room a distance of 35 ft., right or left, along the horizontal line from the vanishing-point (or point of sight), and the trick is done.

We want to find how far the left hand corner of the room appears in the picture at the floor level.

We know that it is 15 ft. beyond the picture-plane, and we have only to mark 15 ft. to the right of its position on the picture-plane at the floor level. A line drawn from this point to the left hand distance-point gives the required intersection.

In this manner the whole of the floor can be represented, and the best practice to begin with will be to divide the floor into squares, like a chess-board. Then repeat the same process on the ceiling.

As to the walls, if a doorway occur, say 5 ft. beyond the picture-plane, and be 3 ft. wide, its position can be similarly found, and its height also, by marking, say 7 ft., up the side of the picture-plane. The intersection of height and position completes the doorway.

Now, what is true of the floor of a room is equally true of a field or tract of land, and the first time that the writer had occasion to draw a bird's-eye view of an estate, many years ago, it occurred to him to cover the plan with squares which could be easily put into parallel perspective, and that the perspective position of each object could then be readily ascertained (fig. 2).

The accompanying diagrams will explain this. One of them represents the plan of some recreation grounds that the writer has recently laid out. It is divided out into as many squares as will cover it. These are then distinguished by letters along the top and bottom, and by numbers along the sides.

A corresponding "chess-board," to any scale that may be convenient, is then put into perspective and duly lettered and numbered (fig. 3).

All that one has to do is to find, as it were, the latitude and longitude of each object on the plan and transfer the same to the perspective.

THE PLAN.

Fig. 1.

By continuing any line, such as the drive in front of the lawn tennis pavilion, up to the horizontal line, a vanishing-point is found for that and all lines parallel to it; and a little practice will soon enable one to find every position accurately.

The ground, in this case, is level, and the squares from 1 to 17 are found by cutting the lines from B to R, with one line from R to the distance-point. This saves the trouble of repeating the process for each square.

If the ground be undulating, the measurement of the hills and valleys can be set up above or below the proper points on the picture-plane and be carried into the picture.

It is not even necessary to disfigure the plan with a network of squares. A sheet of tracing paper so divided has simply to be pinned down over it in order to observe the positions.

In this manner the most tortuous and irregular plans of land and the buildings thereon may be put into very correct perspective.

* * * We are much obliged to our correspondents, "Alacius" and "Riser" for suggestions as to subjects to be treated in the "Student's Column"; their suggestions are duly noted for future attention. At present the "Student's Column" is filled up for some little time in advance.

Books.

The Abbeys of Arbroath, Balmerino, and Lindores, illustrated and described by GEORGE SHAW AITKEN, F.S.A. Scot., Architect. Dundee: John Leung & Co. 1884.

THE information we possess about the monastic buildings north of the Tweed is, if not more scanty, at any rate less accessible, than that which attaches to English foundations, and the interest felt in them is proportionately inferior. Of the thousands of tourists who yearly cross the Scottish border "in search of the picturesque" very few concern themselves with aught but the natural scenery, and we should doubt whether a score of them in any single season turn aside to look at the three abbeys which form the subject of Mr. Aitken's volume. With Melrose and Dryburgh, Holyrood and Jedburgh, most persons are, in some sense, familiar, but Arbroath, Balmerino, and Lindores are unknown names to the ordinary traveller, and the two latter are not even mentioned in the edition of *Black's Guide* which lies before us.

Mr. Aitken has, therefore, done good service in directing attention to these almost forgotten relics of an eventful past. He writes, however, as an architect rather than as an antiquary. The history of each house is, indeed, briefly given, but as no authorities are cited for the statements made, we cannot determine their precise value. Grose, Pennant, Sibbald, Turnbull, and others are mentioned in general terms, and the author tells us that he is under special obligations to Dr. Laing and Dr. Campbell for particular information. It would, we think, have been better if Mr. Aitken had added to his thirty-three pages of letterpress some references to original and other authorities in support of what he tells us.

Arhrath, the most important of the three abbeys described, was founded by William the Lion in 1178, and was one of the wealthiest religious houses north of the Tweed. It was dedicated to St. Thomas à Becket, and corresponded in width of nave and number of bays with his cathedral at Canterbury. Of course, the difference of arrangement was considerable, and the choir at Canterbury soon outstripped in magnificence that of the Northern house, though the fragments of moulding and carving which have been discovered proclaim the latter to have been no mean structure. Unfortunately these fragments have suffered greatly from exposure and neglect. The situation of the abbey, open alike to maritime attack and to the blasts that sweep across the Northern sea, must have rendered the maintenance of the fabric always a costly and difficult matter. Added to this, there was injury done by lightning and fire in three successive centuries, the second, occurring in 1380, having destroyed the roofs of choir, nave, and transept.

Mr. Aitken, however, has (so to speak) rebuilt the abbey, and by his ground-plans and careful drawings enabled us to realise its general character and main features. The style is partly Norman and partly Early English, and the unbroken continuity of the work shows itself in the conspicuous unity of design and uniform standard of excellence displayed by the abbey. The choir, nave, and transepts are represented by Mr. Aitken as unusually lofty and well lighted, the clearstory being double lancets. The central tower (which fell with destructive force in the eighteenth century) is low and massive, and of the two western towers one only is carried above the roof-line. Mr. Aitken says, "The first authentic [sic] change on the original structure appears to have been the addition of a story to the north-west tower, which, with the south-west, was probably intended to have been crowned with a spire. Uncertain foundations may have caused the abandonment of this idea, and the substitution of a safer, but less ambitious lantern, which, though aesthetically doubtful, would be available for a beacon-light in the event of approaching English or Norse invaders." We do not know all that may be meant by "aesthetically doubtful," but we have instances of spires being pulled down, e.g., at Southampton, because they served to attract pirates and other pillagers. The western front of the abbey, as reproduced by Mr. Aitken, may be regarded as a faithful representation of the original, for the recessed doorway,—a graceful

combination of Norman and Early English work,—yet remains, and there are sufficient traces of the noble circular window which filled the gable above it. The sacristy is in fair preservation, and within it are some interesting edifices well worth examining. Mr. Aitken has devoted no less than fifteen plates (executed in photo-lithography by Sprague & Co.) to the illustration of Arbroath, and they bear ample witness to his skill and taste.

Of Balmerino, which gave its name to the unhappy peer who took part in the Pretender's rising, and lost his head upon the scaffold in 1746, the remains are very scanty. The situation of the abbey, in the middle of the Carse of Gowrie, is the very opposite to that of Arbroath. Deep in the recesses of a dell, and overshadowed by lofty trees, the site suggested itself to Queen Elizabeth as a fit abode for religious recluses. To this sequestered spot her son, Alexander II., transported some Cistercian monks from Melrose in 1229. Here they erected a church, of which sufficient vestiges still remain to indicate that it followed the outline of a Latin Cross, with two or more aisles. But the road-maker having for centuries regarded the ruins as his most convenient quarry, has left little of the masonry untouched. The secular buildings have been more fortunate. The chapter-house, on the east side of the principal cloister, has survived through its adaptation to modern domestic uses, and the ancient granary required no changes to secure its preservation. Mr. Aitken is, perhaps, a little rash in attempting to make a ground-plan of the abbey out of the slender materials that have been left; he would certainly have done better had he omitted the drawing of the Balmerino Spanish chestnut, where he is obviously *ultra precipitum*.

Lindores is as rich in historic associations as it is poor in architectural remains. The abbey, founded in 1178 by David, Earl of Huntingdon, brother of William the Lion, was a richly-dowered house, and stood in the fertile plain east of the town of Newburgh. It was built in the form of a Greek cross, and the design may perhaps have been suggested to the founder by some church he had visited during the Third Crusade. Within its walls Wallace sought repose after the battle of Earnside, and the stone coffin which have been exhumed enclosed, it is thought, the remains of David, Duke of Rothesay, who was murdered in Falkland Palace, and of one whom Mr. Aitken rather vaguely terms "the monastic Brother and Peer of the realm, Earl Douglas." The walls themselves are too ruinous to exhibit any details of architectural interest, and the only part of the fabric in any state of preservation is the vaulted slype between the south transept and the chapter-house.

We hope Mr. Aitken will be encouraged to prosecute his labours in other quarters, and give the results to the world in a volume equal in interest and in other respects to that we have described.

French Pottery. By PAUL GASNAULT and E. GARNIER. London: Chapman & Hall.

This little handbook is one of a series published under the auspices of the Committee of Council on Education, and refers to specimens in the South Kensington Museum. It is in the main a chronological account of the manufacture of faience and porcelain in France, well written and admirably translated. We are a little surprised to find in the account of the Parisian manufactories no mention of Jacob Petit (1750—), whose modelling of fruit and flowers was certainly of distinctive excellence. And we think a word of gentle deprecation might have tempered the encomium on Lanfrey, the director of the Niederwittler manufactory, who certainly did not show good taste in inaugurating the "style of decoration which consisted in painting the whole surface to be decorated in imitation of veined pine-wood, upon which was figured an engraving fixed on the wood by a pin. In order to make the illusion more complete, one angle of the engraving is sometimes turned in, and projects a shadow on the wood." Surely the force of foolishness can do further good. The *amende* is, however, made by the authors of the book, in general terms, on p. 175, and we hope readers will not overlook it. The illustrations to this little book are both numerous and good, and the copious lists of "marks" are very serviceable, and, with the one exception above noted, so far as we know, complete.

VARIORUM.

In the third edition of "Hydropathy at Home," by Joseph Constantine (London: Simpkin, Marshall, & Co.; Manchester: John Heywood), there is a chapter on "Hydropathy for Horses," which will be read with interest by keepers of horses. The use of the Turkish bath for horses appears to have been found very satisfactory, during a period of eleven or twelve years, by Messrs. Pickford & Co., the well-known carriers, in their hospital for horses at Finchley. Encouraged by this success, the Great Northern Railway Company have fitted up a Turkish Bath at their new hospital for horses at Totteridge. A plan and description of this bath were given in the *Builder* for May 31st, 1881. The bath was fitted up by the author of the book now under notice. Mr. Constantine will be well known to many of our readers as the patentee of the Convoluted Stove, which is used for the heating. The work also includes a chapter on the ventilation of stables and cattle-sheds.—The tenth volume of "Proceedings of the Association of Municipal and Sanitary Engineers and Surveyors," edited by Mr. Thomas Cole, Secretary of the Association (London: E. & F. N. Spon), contains several important papers on subjects of great practical value to all concerned in town improvements and sanitation, including street-cleaning and maintenance. The Association includes among its members the borough engineers and surveyors of all the principal towns in the kingdom, and the value and usefulness of the Association in affording means for an interchange of their experiences is shown by this volume of "Transactions"; still more so by the Index which it contains to the previous nine volumes. This Index has been prepared by Mr. S. S. Platt, Assoc.-M.Inst. C.E., Borough Surveyor of Rochdale, and will be found very useful by those in search of practical information on any of the subjects which come within the purview of a borough surveyor.

RECENT SALES OF PROPERTY.

ESTATE EXCHANGE REPORT.

Table with columns for property location, agent, and price. Includes entries for Enfield Highway, St. Pancras, Highgate, and various other properties.

New Buildings for Gibraltar.—We understand that Messrs. W. H. Lascelles & Co., of Bunhill-row, are about to erect a large building at Gibraltar. The work will be carried out under the direction of the architect, Mr. C. H. Driver, of 5, Victoria-street, Westminster. A list of tenders for the work will be found in another column.

MEETINGS.

- SATURDAY, JAN. 31. Royal Institution.—Dr. Walsby on "Greek Art from Phidias to the Roman Era." 8 p.m. St. Paul's Bœtological Society.—Annual Meeting. 2.30 p.m. MONDAY, FEB. 2. Society of Engineers.—Address by the President, Charles Gordon. 7.3 p.m. Royal Institute of British Architects.—Mr. Adams on "Architectural Drawing." 8 p.m. Clerks of Works' Association (31), Spring Gardens.—Monthly Meeting. 7 p.m. Parkes Museum.—Meeting of Members only. Society of Arts (Lecturer Lectures).—Professor Forley on "The Distribution of Electricity." 10 p.m. TUESDAY, FEB. 3. Society of Biblical Archaeology.—(1) "Notes on Antiquities from Babylonia in the collection of Mr. Hilton Price, F.S.A." (2) Professor A. H. Sayce on "Kassian Inscriptions." 8 p.m. Institution of Civil Engineers.—Mr. D. S. Scott on "The Design and Construction of Steam Boilers." 8 p.m. WEDNESDAY, FEB. 4. Leland on "Lion in Industrial Art." 8 p.m. Ordinary meeting. 8.30 p.m. THURSDAY, FEB. 5. Royal Archaeological Institute.—(1) "Pierres de Balby by Adnair Fremitt." (2) "Notes on Screen of St. Andrew's Church, Herts." by Mr. Somers Clarke. 8 p.m. London Institution.—Sir John Lubbock on "Lion in Industry." 8.30 p.m. Society of Antiquaries.—8.30 p.m. St. Paul's Bœtological Society.—A paper by H. Roussee Gough. 7.30 p.m. Society of Arts (Lecturer Lectures).—Mr. W. Andrews on "The Conversion of Heat into Useful Work." 8 p.m. FRIDAY, FEB. 6. Architectural Association.—Mr. A. Young on "Buildings." 7.30 p.m. University College.—Professor C. T. Newton on "Cassian Inscriptions." 11.15 a.m. SATURDAY, FEB. 7. Association of Public Sanitary Inspectors.—Capt. Douglas Galton on "The Purity of Air in Towns." 6 p.m.

Miscellaneous.

Fresco Paintings at Fingringhoe.

Charles Golding writes to the Essex Standard.—Upon examination of the interior of Parish Church of St. Andrew, Fingringhoe since the earthquake, with the intention of re-seating and benching it, it has been found that the walls in many parts have been richly ornamented. I endeavoured last week to make a careful survey of them, and find that there in some instances at least three or four courses of Churchwarden's whitewash have been used to cover them up, yet by removing the same slowly and carefully much may be observed. Near the South Porch entrance, on each side of the arch from the south aisle to the nave, and exact in juxtaposition to where the font stands, at which formerly was probably the baptistery, the west arch is a full-length figure, apparently of the Blessed Virgin, with nimbus on head and holding an orb and cross in her hand. Above appears an angel or cherub, having two wings and holding above the Virgin's head a scroll bearing a sentence upon it, now partially indistinct, but evidently extending the width of the fresco. The letters are in some instances picked off. However, as near as I could read it is,—

"Thy... rous... ap... pit... ralo... fins."

But I would not undertake to say this is literally correct. Directly opposite, on the north arch is another fresco, apparently of St. John the Baptist,—evidently a person arising from what may be termed a pool or basin of water. In the centre aisle, immediately at entering is a rich and highly embellished fresco (or at least has been), the background bearing diaper-work of green and gold, interspersed alternately with spangles, stars, and initials "H" and this figure has been the representation of some saint, and on part of the scroll yet remaining I thought I could discern "LUCY," possibly for Saint Lucy the Virgin. Over the chancel arch, and in other parts of the church, is to be seen much decoration of the Jacobean period.

The Sanitary Assurance Association.

At a special meeting of the Executive Council of the Association, at the office, 5, Argyll-place, W., on Monday last, Sir Joseph Fayer, F.R.S., in the chair, a vote of condolence with the family and friends of the late Mr. John Whichcord, F.R.I.B.A., who was one of the earliest members of the Honorary Council of the Association, was passed.

Proportion in Theory and Proportion in Practice.

ENOUGH has probably been said in some previous articles in illustration of the thesis that proportion is as essential an element in the convenience and the beauty of works of

architecture as in the structure of the natural organisms to which these works have such direct analogy. But when we proceed to develop this principle as a matter of practical application, the very first question which presents itself is, to what degree of strictness are we bound. Proportion in general science, and also in some of the arts, we are well aware is fatally vitiated by disregard of even minute exactness. But is beauty in architecture dependent on conditions so exacting? In a broad sense, of course, and constructionally, proportion is not to be trifled with; the strength of supports must be duly responsive to weights, resistance to thrust, toughness to strain, and so forth. A daring architect at Beauvais, Amiens, or Salisbury may seem to adjust proportions to so strict a nicety as to approach the very ultimate margin consistent with stability. But this adventurousness is exceptional, and the vast majority of noble and beautiful effects are manifestly independent of it.

The engineer, with whom beauty is a secondary consideration,—if, indeed, he condescends to consider it at all,—only makes calculations of proportions for the sake of a limit in one direction, and then doubles them without hesitation in the direction of security, makes pier or arches twice as strong as any weight that they will ever have to bear could require, and chains capable of bearing double the strain they can ever be exposed to. The architect may likewise make a study of the strictly necessary proportions of the parts of his structure, but when he proceeds to modify these in practice he finds himself under obligations to which the engineer is a stranger. For him it is not sufficient that stability is real,—it must be manifest; and it must not only be manifest, but distinguished by some definite typical expression. The gradations of such expressions are infinite, but they tend in the direction of one or other cardinal type; they are varieties of an elegance which seems to avoid most carefully any suspicion of superfluous material, or of a solidity which has a semblance of tending in preference to display

a free employment and mastery control of abundant material.

All these varieties ultimately depend for consistent appropriateness upon certain pervading proportions, but the recognition of this fact and principle only brings us still again, and still closer, face to face with the problem,—how far are such proportions even in the best examples only loose and general, matters of there or thereabouts, or how far contingent on numerically accurate relative dimensions. Vitruvius lays down the rule that the height of the capital of a Corinthian capital, including its abacus, should be exactly equal to the lower diameter of the shaft. This is one of his rules which, unlike many others that he lays down with equal positiveness, is found to have been pretty generally observed in practice, and certainly with a successful result in effect. The effect is, of course, quite independent of any power in the eye to determine, by scanning the column as executed, that these two dimensions are in agreement, but the question is whether the fact of such exact agreement does or does not tell although unrecognised,—has it anything to do with the value of an impression of satisfaction which we may receive without knowing the cause? Some will say, Of course not, and why entertain such a question? But this, as we shall say, is to fly in the face of some authorities which it were presumption utterly to disregard.

Let us take the case, again, of the diminution of the shaft of a column. It is proved to be both appropriate and agreeable that the shaft should taper, and the question of proportion comes in to arbitrate between the too little and too much. Experience also proves that the difference of the *poco piu* and the *poco meno* may be very delicate indeed. Here, again, the Greeks of the best age observed very exact proportions, and such as were capable of being expressed in simple terms. By what necessity, we inquire, and with what justification? It is not easy to understand how a satisfactory proportionate diminution for a column of a certain lower diameter and given height could be discovered otherwise than by critical comparison of executed works as more or less approximately successful, or by experiment on full-sized models; mere drawing on the flat, or even resort to small-sized models, would be deceptive or nugatory. Let us say that we make such a variety of comparisons or changes, and, at last, arrive in a particular case at a certain degree of diminution which approves itself as decisively pleasing. In such a proceeding there is something analogous to that of a musician who, with two similar monochords before him, should strike a note upon one with the full string while he went on striking the other succes-

sively as he gradually shortened it till he arrived at a note which should give his ear assurance of consonance. We know that if he now measured the two sounding strings their lengths would be found to have a perfectly exact and very simple proportion. But will this or anything like this be the case, otherwise than accidentally, with the compared upper and lower diameters of our satisfactorily tapering column? There is every reason to believe that the Greek architects of the best age thought so, and that, having this conviction, if they proceeded in the experimental fashion they would have tried, not dimensions at random, but one proportion of low numbers after another between the upper and lower diameters, in full confidence that somewhere among these the truly satisfactory difference must certainly be included.

Experiments thus conducted have at least a limit assigned to them, and yet would be sufficiently numerous to cover the required solution of the problem. But for moderns they involve a principle which would be felt as a serious inconvenience; the dimensions brought out would be liable to involve fractional parts not coincident with the usual subdivisions of the foot-rule. So we are thrown again upon the question, Is such nicety of any practical value? Some differences of dimension have to be adopted, and some reason is required for adopting one rather than another, but it occurs to us to ask, Can it be necessary to have regard in regulating the relative height of two stories to the difference between the whole or the half thickness of a brick? Let all dimensions be determined by the uniform divisions of a certain standard measure, and then you have facility of execution combined with the aptness of different parts to coincide with each other.

This seems to disperse all speculations as to the value of minutely accurate architectural proportion to the winds. And the difficulties of the theory seem to increase with increase of scale. We have seen that the heights of the horizontal divisions of the nave bays are regulated by very simple serial proportion, and the beauty of the result is recognised with enthusiastic admiration; yet how are we to understand that these more or less accurate halves, thirds, and sixths, of the total height can, in truth, contribute to the admirable impression on the spectator? When his station point is in front of a bay, the dimensions come under view unequally modified by perspective. The upper half is seen under an angle much more acute than the lower, and the reduction of visible proportion is accordingly greater; as he looks down the nave obliquely this difference varies with every bay; for it to vanish entirely it would be necessary for him to be at a greater distance than the dimensions and plan of the abbey allow him to retire to.

Such perspective differences, whether of proportions of plan or elevation, will always be greater as the position of the spectator is nearer at hand, and near at hand comparatively he must be in the most important cases. The plan of an apartment may be a double square, but, whether it be exactly or only very nearly so will hardly be appreciable by the keenest sight from any position within it. The vibrations which produce musical notes that are in consonance travel at the same rate and strike the auditory organs together; the rays of light from the lines which define the length and breadth of an apartment also travel at the same rate, but are neither parallel nor convergent under equal angles, and, so far, the analogy entirely fails us. Nor can it, apparently, be fairly argued that precise proportions may affect us delightfully, though the secret of the charm escapes us, inasmuch as this is the case with the harmony of colours. The analogy is direct between harmony of colour and harmonies of sound; the relation of the stimulative excitement to the sensitive organ is much the same in both cases, and that colour harmonies have hitherto defied endeavour to reduce them, like vocal harmonies, to numerical estimates, experimentally does not alter the case. The sense of harmony in a combination of colours may safely be assumed to prove that it is due to some certain, however unknown, proportionate relations among the particular tints harmonised, and which affect the sense proportionately; but when we are concerned with impressions produced by comparative height, length, and breadth of an apartment, the senses are affected by these in proportions which vary with every change of position, and which in no one case accurately correspond with the proportions of the dimensions as executed.

There is something more in favour, it would seem, of the importance of exact proportions when exteriors are in question,—such exteriors, at least, as are exposed to favourable view from a considerable distance. The further we remove the more do the projecting rays approach parallelism, and the more nearly are different equal parts seen under the same angle. When Lichfield or Salisbury Cathedral is seen from a distance, the spire tells for its true height relatively to the height of the nave or tower below. But the distant views which tend to reduce differences of perspective projection to zero, are far less important than those aspects presented to spectators in the very precincts when such differences are at their maximum.

Perspective modification from the more important points of view near at hand has the special claim to be taken into account by the architect in the first instance, and neglect of it has serious consequences. As we approach St. Peter's, the stupendous cupola, its special glory, retires out of sight, and whatever of grandeur the approach possesses is due to the prolonged portico, and the fine open space with the majestic obelisk and perpetual fountains which they embrace. Wren, at whatever cost in some other respects, raised his cupola upon a plain drum to such a height that it composes beautifully with campaniles and portico as we approach the western front. It is possible, of course, that while his design was controlled by this as a leading consideration, he regulated the height of his structure at least in consistency with some simple and accurately respected proportion. But the question which is here mooted and discussed,—on which information and instruction are honestly desiderated,—is how far care for regulation on this principle had any value.

Perhaps it may be asked why, considering the objections and complications which seem to beset any such assumption, is it worth while beginning to bring forward the subject for discussion at all? The answer to this, on the broad principle, is not that merely connoisseurs, but the world at large, of those who have displayed a general sensitiveness to the impressions of fine art, have always been wont to recognise, as if intuitively, that Music and Architecture are as naturally to be associated as Painting and Sculpture. And, beyond this, to come to something more practical, if not on

that account necessarily more cogent, it is certain that the Greeks did study architecture very deeply and thoughtfully, and that their best masters held firmly and consistently to the importance of carefully-selected and exactly-executed proportions. This is not only recorded historically, but is to be certified most absolutely by examination of the remains of their finest works: they adhered to the principle at the cost of extraordinary enhancement of labour, and applied it as seriously to numerous subordinate members, as well as to the more comprehensive dimensions.

These observations are intended to open and provoke consideration of an important subject rather than to make a pretence of deciding upon it.

It will be in the remembrance of many that it came up in discussion, a year or two since, in connexion with a theory that the dimensions of the Parthenon were so designed as to tell as proportionate when seen from one particular point of view. The predominant feeling at the time seemed to be that not very much was to be made of this.

But if the elucidation of the question, which involves many collateral considerations of interest, is to make any progress at all, it cannot but be advantageous to follow up,—what has been attempted here,—a fair statement of its difficulties, with some illustrations of the system which, as can be proved from their works, was, at least, well thought out and systematically brought into practice by some of the greatest geniuses in architecture the world has known.

EXPERIMENTAL RESEARCHES INTO THE STRENGTH OF BUILDING MATERIALS.

BY E. WYNDHAM TARN, M.A.

WHEN we examine the construction of ancient buildings we find but little trace of the designers possessing any accurate knowledge of the amount of strain that could be safely borne by the materials used; for example, the strength of the columns of the Parthenon is out of all proportion to the load they have to support. From recent experiments, the crushing strength of white marble has been shown to be about 800 tons per square foot, so that each of the columns of the Parthenon would require a load of 14,000 tons to crush it. The actual load on each column would probably never exceed 100 tons, or about $\frac{1}{14}$ of the crushing strength. Taking the safe load at one-tenth of the crushing weight, we find that the actual strength of each column was 14 times greater than the circumstances required, or the quantity of material used was so much more than was necessary for the work to be done. Had the Greek architects been acquainted with the strength of materials, it seems probable that they would not have wasted so much valuable material unnecessarily.* With our present knowledge, however, there is no excuse for modern architects employing heavy masses of stone in order to carry trifling loads, merely because they find that the Greeks were in the habit of doing so.

Coming down to more modern times, we find in the timber roofs of the Middle Ages the same exaggerated massiveness in the beams used in their construction. The rafters also were generally laid with their thinner side vertical, and broader side horizontal, thereby diminishing in a great degree their power of resisting transverse strain, and causing them to sag under the heavy covering of lead which they had to support: whereas if they had been placed the other way their strength would have been ample for the purpose. Heavy balks of timber were often placed across to form tie-beams, their scantling being sufficient to carry the floor of a warehouse for heavy goods.

The accurate determination of the strength

* Of course this is leaving the æsthetic of architecture entirely on one side. Probably the Greeks did not regard such a work as the Parthenon from an engineering point of view at all.—Ed.

of materials by experiments and scientific deductions therefrom is a subject that has attracted the attention of modern architects and engineers, and it may be interesting to give a kind of summary or general view of the results which have been obtained; and the methods by which the probable strength of beam, column, or other important structural feature can be determined before-hand.

When we come to compare the results given by different experimentalists on the strength of various kinds of wood, we find an amount of variation that seems almost unaccountable. To some extent this may have arisen from the specimens having been cut from trees at different stages of growth, and also from some having been better seasoned than others. The size of the specimens also has something to do with the discrepancies, as large pieces generally exhibit less strength in proportion than small ones do. To take the crushing strength of wood, that of well-seasoned English oak was found by Professor Eaton Hodgkinson to be $4\frac{1}{2}$ tons per square inch, the specimens being cylinders 1 in. diameter and 2 in. long; while Mr. Laslett's experiments at Woolwich on 1-in. cubes, the strength was only 3.56 tons, the ratio being that of 5 to 4. For that of well-seasoned red pine the former finds the crushing strength to be $3\frac{1}{2}$ tons, and the latter $3\frac{1}{4}$ tons for 1-in. cubes and only $2\frac{1}{2}$ tons for 4-in. cubes. For yellow pine the results obtained on small cubes by both experimentalists agree in giving $2\frac{1}{2}$ tons per inch, but with 4-in. cubes Mr. Laslett obtained less than $1\frac{1}{2}$ tons. With pitch-pine the crushing strength is nearly 3 tons per inch from both experimentalists, while with English elm the divergence is very great, Mr. Hodgkinson giving 5 tons per inch, and Mr. Laslett little more than $2\frac{1}{2}$ tons. For the former obtains a crushing strength of nearly $5\frac{1}{2}$ tons, while the latter obtains less than 3 tons. The experiments of George Rennie gave much lower results than the above, while those of Rondelet nearly agree with Mr. Laslett's experiments.

As regards the tensile strength of wood, its resistance to a force pulling it asunder in the direction of the fibres, there is also a considerable difference in the results obtained by independent experimentalists, that of Riga having been found by the late Prof. Barlow of Woolwich, to be nearly $5\frac{1}{2}$ tons per square inch, while Mr. Laslett gives it as less than 2 tons. For English oak the former gives the tensile strength of $4\frac{1}{2}$ tons per inch, while the latter found it to be only $3\frac{1}{2}$ tons. Barlow found the strength of pitch pine to be over $3\frac{1}{2}$ tons, but Laslett obtained little more than 2 tons per square inch. The former experimentalist gives the strength of teak as $6\frac{1}{2}$ tons per inch, and the latter makes it only $1\frac{1}{2}$ tons. The strength of English elm was found by Barlow to exceed 6 tons per inch, while Laslett makes it only $2\frac{1}{2}$ tons.

The Modulus of Elasticity represents the force required to pull a rod of any material to twice its original length (supposing such a thing to be possible), and is obtained by measuring the extension of the rod when a gradually increasing stretching force is applied to it, as long as the extension increases in the same ratio as the load applied. Suppose, then, that e is the extension of a rod of length l inches for a load w , and that $\frac{w}{e}$ is constant for

any given material, and represented by C , then that E is the value of w when $e=l$, then E represents the modulus of elasticity of the particular material, and we have

$$E = C \times l$$

The modulus of elasticity is therefore the measure of the resistance of the material to stretching force, and in the case of Riga fir was found by Barlow to be $E=1,159,600$ lb., while Laslett's experiments gave $E=3,009,680$ lb. For English oak $E=1,172,000$ lb. according to Barlow, and $E=1,545,600$ lb. according to Laslett. The former also gives $E=1,325,600$ lb. for pitch-pine, and the latter $E=3,020,940$ lb. For Red Canadian pine he has $E=1,840,000$ from Barlow's experiments, $E=2,355,600$ from those of Laslett, and $E=1,102,000$ lb. from those of Lieut. Dennison. The values of E were calcu-

lated by Barlow from the deflexions observed of beams loaded with a transverse load, while those of Laslett were from experiments on the direct tensile strain upon rods.

When a beam is supported at both ends in a horizontal position and loaded with a weight (W) in the middle, the effect of the load may be considered either as producing or tending to produce rupture, in which case W is called the breaking-weight of the beam; or it may be considered as producing a deflexion or bending of the beam in the middle. The strength of the beam, or its resistance to rupture, follows a very different law to that of its stiffness or resistance to bending. In the former case, if we put W for the breaking-weight in pounds, L the length of hearing in feet, B the breadth, and D the depth in inches, we find from theoretical investigations that for any given material,—

$$\frac{W.L}{B.D^2} = \text{a constant number, say } c.$$

And the value of *c* is determined by experiments on beams of various sizes. For example, in a beam of oak 7½ feet long, having B=4·28 in., and D=4·28 in., Buffon found the breaking weight to be 3,756 lb., so that

$$\frac{W.L}{B.D^2} = \frac{5,756 \times 7.5}{(4.28)^2} = 550 = c.$$

The value of *c* for English oak was found by Tredgold to be 694 when taken from a young tree, and 436 from an old tree. For old oak Fincham gives *c*=547, and Laslett finds *c*=705. The average of several other experiments on English oak gives *c*=773. For Riga fir Tredgold gives *c*=530, Laslett puts it at 525, and Fincham at 593. Tredgold's value of *c* for Norway fir is 792, Fincham's 451. For Christiana deal Tredgold gives *c*=686. The value of *c* for red pine is 483 according to Fincham, and 572 from the experiments of Laslett. The same authorities give 421 and 471 as the values of *c* for yellow pine, and 461 and 769 respectively for pitch-pine. The breaking-weight of beams of any of the above kinds of wood can, therefore, be calculated from the formula,—

$$W = c \frac{B.D^2}{L}$$

when the load is at the centre of the beam; and, if uniformly distributed over its length, the breaking-weight will be double the above. The permanent load on a beam should not exceed one-fifth or one-sixth of the breaking-weight.

We can also determine the scantling of a beam by fixing, from experiment, the amount of strain per square inch of section to which it would be safe to subject any of its fibres. Suppose *f* to represent the resistance or strain per square inch at a distance of 1 inch from the middle of the beam, then

$$f \propto \frac{D}{2}$$

the resistance at the top or bottom edge of the beam per square inch, and we have

$$W = f \times \frac{D}{2} \times \frac{B.D^2}{18L}$$

the load in the middle that will produce this strain. Putting ½ *f* × D = ½ ton, or 1,120 lb. for fir, we have for the safe-load in pounds,—

$$W = 62 \frac{B.D^2}{L}$$

The stiffness of a beam, or its resistance to bending, is a matter of more importance than its strength to resist a strain, as it is necessary that there should be no perceptible bending or deflexion of the beams when used in a building. Tredgold has laid down the rule that the deflexion of a beam at the middle should not exceed ¼ in. for every foot of its length, or ¼ in. in a beam 40 ft. long. Now the deflexion *δ* in inches of a beam with a load W in the middle is

$$\delta = 432 \frac{W.L^3}{E.B.D^3} \text{ or } W = \frac{E.B.D^3}{432L^3} \times \frac{\delta}{L}$$

where E is the "modulus of elasticity," and if $\delta = \frac{1}{40}$ then we have

$$W = \frac{E.B.D^3}{17,280L^3}$$

Taking E = 1,159,600 for fir, we find

$$W = 67 \frac{B.D^3}{L^3}$$

which is the load in the middle (in pounds) that will produce a deflexion of ¼ in. for every foot length of the beam: L being in feet, B and D in inches.

The strength of long pillars of wood is found to be very nearly proportional to the fourth power of the diameter and inversely as the square of the length; so that, if W is the breaking-weight in pounds, we have

$$\frac{W.L^2}{d^4} = \text{some constant } a.$$

The value of *a* is found by experiments; those of Hodgkinson giving *a*=24,542 for oak where the length was at least 30 diameters, while those of Lamandé gave *a*=16,000. For shorter pillars this formula gives too high a result, as the resistance to crushing has to be taken into consideration. The formula which Hodgkinson deduced for shorter pillars was,—

$$W = \frac{c.d^2}{1 + \frac{3c.L^2}{4a.d^2}}$$

where *c* is the crushing strength per square inch of the timber, if short pieces are taken. Taking the load in tons, we may put *a*=9 as the mean of the above, and *c*=4 tons as the crushing strength of oak. Then, for short oak pillars, we have the breaking-weight W in tons,

$$W = \frac{4d^2}{1 + \frac{L^2}{3d^2}}$$

l being in feet and *d* in inches.

Some oak pillars 2½ in. square and 4 ft. 3 in. long, were found by Lamandé to have an average strength of 5·6 tons; the above formula, however, gives 7·7 tons. Another pillar, 3·18 in. square, and the same length as the former, was broken with 16 tons, but by the formula the breaking-weight should be 25 tons. When larger pillars are tested to breaking, there is generally found a still greater falling off in the strength, so that in using these formulae it is necessary to make a considerable allowance, one-tenth of the calculated breaking-weight being the utmost permanent strain to which a pillar should be subjected.

Iron is used for constructional purposes in three distinct forms, namely, cast iron, wrought or malleable iron, and steel. The first of these is a comparatively modern invention, and it differs very much in character from the second, having a high resistance to crushing combined with a low tensile strength. It is, therefore, more suitable for columns, stanchions, or other supports, which have to sustain a heavy compressive load, the crushing strength of short pieces varying from 25 up to 50 tons per square inch, while the tensile strength is from 6 to 10 tons per square inch. The resistance to crushing is generally greater in specimens of high specific gravity than in those in which it is low: thus Hodgkinson found the resistance to be 33 tons in one whose specific gravity was 6·989, and 43½ tons in another having a specific gravity of 7·119. When the crushing strength is high, the tensile strength is often proportionally low; thus, iron in which the former was 27 tons, had the ratio of crushing to tensile strength as 4·76 to 1; in another, in which it was 30 tons, the ratio was 4·8 to 1; and another, whose crushing strength was 40 tons, had the ratio 5·6 to 1; and where it was 43 tons, the ratio was 6·73 to 1.

The amount of extension and compression which is produced in cast-iron bars by heavy strains is very small as compared with that in wrought iron; cast-bars, 10 ft. long and 1 in. square, enclosed in an iron frame to prevent them from bending, were compressed ·0187 in. by 2,065 lb., and similar bars extended ·019 in. by 2,117 lb.; 4,130 lb. produced a compression of ·0388 in.; and 4,234 lb. an extension of ·0397 in.; 6,194 lb. a compression of ·0598 in., and 6,352 lb. an extension of ·0623 in.; 8,239 lb. a compression of ·0788 in., and 8,469 lb. an extension of ·0871 in. From which it appears that with a strain of less than 3½ tons per square inch the resistances to com-

pression and extension are nearly equal in cast iron. The total amount that cast-iron bars were stretched before fracture ensued varied from ⅓ to ⅔ of the length of the bar. The ratio of load to extension, as long as the latter increased in proportion to the former, or *w*:*e*, was found in Low Moor iron to be 110,301; putting *e* equal to 120 in., or the length of the bar, then *w*=*E*=the "modulus of elasticity," or *E*=110,301 × 120 = 13,236,120 lb. For Blaenavon iron, *w*:*e* was 110,651, or *E*=13,278,110 lb. In Gartsherrie iron, *w*:*e* was 110,251, and *E*=13,230,120 lb. In other Scotch irons, *w*:*e* was 111,109, and *E*=13,333,080 lb.

The experiments of Hodgkinson on wrought-iron bars give a tensile strength of nearly 24 tons per square inch. Some qualities of iron will stretch more than others under the same amount of strain. Taking bars 10 ft. long and 1 in. square, one was found to stretch ·022 in. with 2½ tons, the same extension being produced in another by 2½ tons; 4½ tons produced an extension of ·045 in. in the former, and 4½ tons stretched the latter ·043 in.; 9½ tons stretched the first bar ·092 in., and 9 tons stretched the second one ·087 in.; 12 tons produced an extension of ·122 in. in the first, and 11½ tons an extension of ·112 in. in the second; 14½ tons stretched the first bar ·283 in., and 13½ tons stretched the second one ·205 in., showing that the amount of extension is very nearly proportional to the load up to one-half the breaking-weight, beyond which it increased more rapidly. In the first case, *w*:*e* is 232,223, therefore *E*=232,223 × 120 = 27,866,760 lb.; in the second *w*:*e* is 230,760, and we have *E*=27,691,200 lb. The permanent set or elongation after the load is removed is an important point to be noticed in these experiments. In the first bar this was ·0004 in. with a strain of 4½ tons, ·0006 in. with 7½ tons, ·0008 in. with 8½, but with 9½ tons it amounted to ·0015 in., or nearly double that produced by 8½ tons. From this we gather that the iron might safely be strained with one-third its breaking-weight without injury to its elasticity. In the second bar the "set" was ·0006 in. with 2½ tons, ·0007 in. with 5½ tons, ·0013 in. with 8 tons, and ·0027 in. with 9 tons; so that this iron could not safely be strained with more than one-fourth its breaking-weight. One of these bars stretched ⅓ of its length before breaking.

Let us now consider the bearing that the above experiments have upon the proper form of iron beams subjected to transverse strains. It is well known that when a beam is supported in a horizontal position and loaded in the middle, a certain amount of deflexion is produced, so that the upper portion of the beam is compressed while the lower one is in a state of tension. It was argued by Hodgkinson that because the ultimate crushing strength of cast iron was about six times as great as the tensile strength, the parts in tension should be made six times the size of those in compression in order to equalise the strength of the beam and to utilise the metal to the greatest advantage. He also showed by numerous experiments with beams of equal depth and sectional area, that those in which the bottom flange was nearly six times the sectional area of the top flange required a greater weight to break them than those in which the flanges were more nearly equal. This form of beam, having the section like an inverted I, was consequently adopted for several years, the formula for its breaking-weight in tons being

$$W = \frac{2.166 a.D}{L}$$

where *a* is the sectional area of the bottom flange at the centre, and D the depth in inches, L being the bearing in feet.

It has been argued by other authorities that as we find by experiment the resistances to extension and compression to be nearly equal in cast iron, so long as the elasticity remains practically uninjured, that is to say, up to a strain of 3 tons per square inch; and the proper form of beam is the one in which the top and bottom flanges are nearly equal, having, as it is called, an I section. For in practice we do not allow the load to approach anything near

to the breaking-weight, and it should never be allowed to produce any injury to the elasticity of the metal. If we call f the resistance per square inch of section at a distance of 1 in. from the centre of the beam, B the breadth of the flanges in inches, b their breadth less the thickness of the vertical part of the web, D the total depth, d that between the flanges, L the length in feet, then the weight, W , which produces a given strain per square inch at top and bottom is

$$W = \frac{f}{36L} (B \cdot D^2 - b \cdot d^2)$$

If we put $f \times \frac{D}{2} = 3$ tons, as the strain at top and bottom which it is safe to put on the beam, then $f = \frac{6}{D}$, and

$$W = \frac{6 \cdot D^2 - b \cdot d^2}{6 \cdot D \cdot L}, \text{ in tons.}$$

A beam of this form, having $D = 5 \cdot 125$, $d = 4 \cdot 315$, $B = 1 \cdot 76$, $b = 1 \cdot 47$, $L = 4 \cdot 5$, was broken with a load at the centre of nearly 3 tons; the above formula gives $W = 77$ ton, or about one-fourth the breaking-weight, as the safe load that might be used. If we apply Hodgkinson's formula to a beam of the same sectional area and depth, but having two-thirds of the area in the bottom flange, we find 4.63 tons is the load that would produce fracture; but in this case, as the whole is supposed to be in tension, we ought not to use more than one-sixth of the breaking-weight for a safe load, which will, therefore, make the two beams equally strong for practical purposes. The difficulty of making perfect castings in beams having one part so much thicker than the others has led to the use of cast-iron beams having the flanges nearly equal.

The resistance to compression of wrought-iron bars, 10 ft. long and 1 in. square, which were kept from bending by being held in an iron frame, has been determined by several experiments. The average compression of two such bars was .0275 in. with a load of 2½ tons; .0495 in. with 4½ tons; .07 in. with 6½ tons; .0925 in. with 8½ tons; and .1035 in. with 9 tons. Comparing these results with those previously given for tensile strain we find that the resistance to extension is to that to compression as 6 : 5, as long as the elasticity remains uninjured, although the ultimate resistance to extension is to the ultimate resistance to compression nearly as 3 : 2. As the ratio of 6 : 5 does not materially differ from one of equality, we may make the top and bottom flanges equal in a beam of I section, and the same formula can be used as was given above for cast-iron beams, namely,

$$W = \frac{f}{36L} (B \cdot D^2 - b \cdot d^2)$$

With wrought iron, however, we may take $f \times \frac{D}{2} = 4$ tons as the safe strain at top and bottom, or $f = \frac{8}{D}$; therefore

$$W = \frac{8 \cdot D^2 - b \cdot d^2}{9 \cdot D \cdot L},$$

as the safe load at the middle in tons.

The tensile strength of iron plates appears to be less than that of bars, experiments by Kirkaldy on boiler-plate made by Krupp at Essen giving 26,190 lb. per square inch as the tensile strain when the elasticity begins to be impaired, and 27,477 lb. for the harder Yorkshire iron or about 9 per cent. more. The ultimate stress, however, of the Essen plates was 48,028 lb., while that of the Yorkshire plates was only 43,515 lb., or 5 per cent. less. The ultimate strength was, therefore, 21.8 and 20.3 tons, or an average of 21 tons, which is one-eighth less than the strength of bars.

In order to determine the laws which regulated the strength of long cast-iron columns, numerous experiments were made by Hodgkinson. To determine the power n of the diameter according to which the strength varies, we have 11,204 lb. as the breaking-weight of a pillar 10 ft. long and 1.53 in. diameter, while for one of the same length, but with 2.511 in. diameter,

the breaking-weight was 63,499 lb. Now, $2 \cdot 511 : 1 \cdot 53 :: 1 \cdot 64 : 1$; therefore

$$1^n : 1 \cdot 64^n :: 11,204 : 63,499, \text{ or } 1 \cdot 64^n = 5 \cdot 67.$$

Taking the logarithms of both sides, we have

$$n = \frac{\log. 5 \cdot 67}{\log. 1 \cdot 64} = 3 \cdot 5, \text{ very nearly.}$$

To find the power x of the length according to which the strength varies inversely, a comparison of ten pillars 2½ in. diameter, with lengths of 10 ft. and 7 ft. 6 in., gives $x = 1 \cdot 63$. Therefore the breaking-weight w is

$$w = m \frac{D^{3 \cdot 5}}{L^{1 \cdot 63}}$$

And to find the value of m , experiments give the strength of a pillar 10 ft. long and 1 in. diameter as 2,223 lb., which, multiplied by $10^{1 \cdot 63}$ gives that of a pillar 1 ft. long, namely, 94,858 lb., or 42.247 tons, for the value of m . Therefore the strength of a hollow pillar in which D is the external and d the internal diameter is

$$w = 42 \cdot 247 \frac{D^{3 \cdot 5} - d^{3 \cdot 5}}{L^{1 \cdot 63}}, \text{ in tons.}$$

For a solid pillar, $d = 0$. This formula only applies to columns whose length is at least thirty times the diameter, but gives too high a result for shorter ones; for, in long pillars, the resistance to crushing is not considered, while in short ones this is of more importance. If, then, w is the breaking-weight, as obtained from the above formula, and c is the crushing strength per square inch of a short piece of cast iron, a the area of section, we have for the correct breaking-weight of a short pillar,—

$$W = \frac{w \cdot c \cdot a}{w + \frac{2}{3} c \cdot a}$$

The value of c varies from 25 tons up to 49 tons, the mean being about 37 tons, so that in a solid round pillar we shall have $c \cdot a = 29 \cdot D^2$, which gives

$$W = \frac{29 \cdot D^2}{1 + 514 \frac{L^{1 \cdot 63}}{D^{3 \cdot 5}}}$$

$D^{1 \cdot 63}$ being the same as the square-root of the cube of D .

The law of the strength of long pillars of wrought iron appears to be somewhat different to that of cast, being

$$w = a \frac{D^{2 \cdot 55}}{L^2}$$

and to determine the value of the constant a , we find that a pillar, 7 ft. 6½ in. long, and 1.02 in. diameter, broke with 5,280 lb., which gives $a = 281,475$; and another, whose length was 5.0423 ft., and diameter 1.03 in., broke with 12,990 lb., giving $a = 307,850$; the mean of the two values of a being 294,662 if w is in pounds, and 131.5 if in tons. The strength of short pillars of wrought iron is found in the same way as those of cast iron, except that the value of c will be 16 tons instead of 37, as in the latter.

The effect of great heat upon iron is to reduce its strength very appreciably, iron losing half its strength when heated to redness, as is often the case when a building in which it is used takes fire. Consequently it should always be protected by some non-conducting and non-combustible material.

Steel is a material which is beginning to supersede both cast and wrought iron for many constructional purposes. The tensile strength of Swedish steel was found by Kirkaldy to average 25½ tons per square inch for elastic stress, and 40 tons for ultimate stress. Taking the average of a large number of specimens of English steel, the ultimate tensile strength was 44 tons for bars, and 38½ tons for plates per square inch.

The compressive strength of short pieces of Swedish steel was found to average 25 tons for elastic stress and 70 tons for ultimate stress per square inch; while for pieces whose length was four diameters the ultimate stress averaged only 37 tons per square inch. From which it appears that when steel beams are strained so as not to impair their elasticity the resistances to compression and extension are nearly equal, so that the same formula as was

used for iron beams will apply to steel beam of I section having equal flanges, namely,

$$W = \frac{f}{36L} (B \cdot D^2 - b \cdot d^2)$$

Putting $f \times \frac{D}{2} = 12$ tons, or rather less than

half the elastic stress, we have $f = \frac{24}{D}$

$$\therefore W = \frac{2 \cdot B \cdot D^2 - b \cdot d^2}{3 \cdot D \cdot L}$$

is the safe load on a steel beam in tons.

For long pillars of steel, Hodgkinson gives the breaking-weight as

$$W = a \frac{D^4}{L^2}$$

and as a pillar .87 in. in diameter, and 2.5 ft. long broke with 26,059 lb., we get $a = 281,863$ lb. or 126 tons. For short pillars the same rules will apply as in the case of short iron ones, only the value of c must be taken a 70 tons.

The modulus of elasticity (E) for steel can be found by experiments on its extension under tensile strain. Kirkaldy's experiments on unannealed plates of Swedish steel, 100 in. long, give $w = 335,518$, where w is the load in pounds producing the extension e in inches so that $w = E$ when $e = 100$, or $E = 33,551,800$. The ultimate tensile strength, however, averaged only 23 tons per square inch. The same steel, when annealed, gives $E = 32,014,800$ the tensile strength being only 21.3 tons.

The resistance of various building stones to crushing has been tested by numerous experiments, and it is generally found that the strength is greater in those of a high specific gravity than in the lighter stones. The Cornish granite, whose specific gravity is 2.6 has a crushing strength of 2.9 tons per inch and that of Aberdeen, with a specific gravity of 2.7, has a crushing strength of from 4 to 5 tons. The "grits" of Yorkshire are strong and heavy stones, the crushing strength being from 2 to 3 tons, and the specific gravity about 2.4. Red Mansfield stone, whose specific gravity is 2.38, has a crushing strength of 3 tons per square inch. Portland stone, with a specific gravity of 2.2, has a crushing strength of 1½ ton; while that of Bath stone, whose specific gravity is 2.0, is only ¾ ton per inch.

Very few experiments have been made either on the cohesive strength of stone when subjected to a pulling stress, or upon their strength when used as beams and strained transversely, as in lintels, brackets, corbels, steps, landings, &c. This is the direction in which all stones offer the least resistance; thus Chilmark limestone, which has a crushing strength of 2½ tons per inch, has a cohesive strength of only 500 lb. when subjected to tensile strain, and the red Mansfield, which requires 3½ tons per inch to crush it, is torn asunder by a tensile strain of only ½ ton per square inch. It is this low cohesive strength that makes stone very liable to crack across when subjected to a transverse strain.

The transverse strength of red Mansfield stone, when used as a beam with a load at the middle, has been determined by Kirkaldy's testing-machine. A piece, 1 ft. long, 5.7 in. broad, and 5.97 in. deep, broke with 110.4 cwt. at the middle; so that if we assume the formula

$$W = S \frac{B \cdot D^2}{L}$$

to hold good in the case of stone, then we find $S = 544$. Another specimen, whose breadth was 5.91 in., and depth 5.9 in., broke with 93.6 cwt., which gives $S = 455$; and another whose breadth was 5.66, and depth 6 in., broke with 93 cwt., which gives $S = 456$. The average value from these three specimens is $S = 485$, when W is the breaking-weight at the centre in cwt. In Riga fir we find $S = 5$, or ten times as much.

Similar experiments were tried on beams of Carrara marble 6 in. square, two kinds of marble being used, one of a bluish tint, and the other white. With a span of 4 ft. the bluish broke with 447 cwt., and the white with 37½ cwt., giving $S = 83$, and $S = 106$ respectively. With a span of 3 ft., the blue broke

with 67 cwt., and the white with 80 cwt., giving $S=9.44$ and $S=1.11$. With a span of 2 ft. the blue broke with 99.3 cwt., and the white with 117.3 cwt., from which we get $S=92$ and $S=109$. The mean value for blue marble is $S=898$, and for white $S=1087$. The crushing strength of the blue was $5\frac{1}{2}$ tons per square inch, and of the white 5 tons, where the height did not exceed four times the diameter.

Beams of Yorkshire paving stone, 10 in. span, 1 in. deep, and $2\frac{1}{2}$ in. wide, were broken by Mr. G. Rennie with 3 cwt. at the middle, from which we get $S=1$. A similar beam of Caithness stone broke with 7.65 cwt., giving $S=2.55$. Stock bricks laid horizontally on two supports, 8 in. apart, and having a depth of $2\frac{1}{2}$ in., and breadth 4 in., broke with 4 cwt. at the centre, which gives $S=107$. The crushing strength of ordinary brick is from 5 to 7 cwt. per square inch.

The cohesive strength of the best Portland cement is found to increase with the length of time it has been mixed; neat cement weighing 123 lb. per bushel being found by Mr. Henry Reid to have a cohesion of 3.7 cwt. per square inch at the end of a month and of $5\frac{1}{2}$ cwt. at the end of two years. If mixed with an equal quantity of sand, the strength at the end of a month was 1.8 cwt., and 3.13 cwt. at the end of two years. The crushing strength also increases with age, bricks made of neat cement being crushed with 1.7 ton per square inch at the end of three months, 2.4 tons at the end of six months, and with three tons at the end of nine months. The strength of cement also depends very much on its weight per bushel, that with a weight of 106 lb. having little more than half the cohesive strength of that which weighs 130 lb. to the bushel, the light cement setting more rapidly than the heavy. Cement which weighs about 1 cwt. per bushel is generally preferred for building purposes.

The late Professor Rankine gave the following ratios of ultimate to working stress as usually adopted in different materials: steel and wrought iron, 3 to 1; cast iron, 3 or 4 to 1; timber, 10 to 1; stone and brick, 8 to 1. Having found the breaking-weight in any case, divide by the numbers given above and you have the safe-load to be laid on the material.

NOTES.

THE meeting in Albermarle-street, on Monday last, of the general committee and subscribers for the promotion of the proposed British School of Archaeology at Athens, marks, we hope, an epoch in the history of modern English archaeological study. As we have before mentioned, the Greek Government have presented a site for the proposed building, — a site, on the southern slope of Mount Lycabettus, commanding a view of Mount Hymettus in front and of the Bay of Phaleron and the Island of Ægina on the right, names in themselves enough to stir the imagination and vivify the ardour of students eager, in Herbert's words, to

"Copy fair what time hath blurr'd,"

and penetrate further into the remains, and through them into the spirit, of Greek art and Greek history. The funds subscribed or promised only amount as yet, however, to something over 4,000l. This will suffice, however, to provide the building required for the school, for which Mr. Penrose, who unlocked for us the most interesting secrets of the Parthenon architecture, is appropriately to be the architect. What the committee now want, as the Chairman (the Bishop of Durham) informed the meeting was a regular income of 600l. a year, or a capital sum of 15,000l., for the establishment and support of the school. Ought it, he asked, to be very difficult to collect that sum? We hope not; it seems to us extraordinary and discreditable that there should be any doubt of it, in a country containing so much culture and so much wealth at once as this. Yet when we see the first Greek archaeologist among us giving lectures on Greek inscriptions, to audiences which may

pretty nearly be counted on the fingers, the prospect from English enthusiasm, apart from that of the small band of "those who know," does not seem very bright.

"WHY should we raise subscriptions for the study of Greek archaeology?" Well, to put it briefly, because among the Greeks the union of beautiful life with bright and beautiful art was more complete and full than with any other people who have left a record on the globe; because their architecture is the foundation of all architecture which has been evolved since; their literature the highest and purest in form which has been achieved; their language the most finished and artistic form in which thought has been crystallised into speech; their sculpture the most noble and complete that has ever existed; their decorative art presenting the highest combination of execution with intellectual perception of the fitness of things. These be reasons enough, surely, for saving all that can be saved from decay, for unearthing what has never yet seen the light, for learning all we can know further about a people and a period so full of interest to all who do not, like Sir Andrew Agnecheek, regard life as consisting of eating and drinking. Others at least think so, if we do not. The announcement of the formation of an English school has been received, we are assured, with great interest and enthusiasm in Athens and throughout Greece, and it was remarked by the Chairman that when he wanted his difficulties solved in any question of classical archaeology he had to go, not to any English source, but to a monograph in German, or French, or sometimes Italian. When a new "find" turns up anywhere on Grecian soil, it is from the archaeological schools of Germany, France, or America, established in Athens, that delegates go to investigate, measure, and produce materials for restoration and for monographs. Let us hope it will not be much longer thus, and that our own hand of students at Athens will ere long be actively engaged in this competition of research and intellect on the elucidation of so fascinating a subject.

THE objects of the school were thus stated in a resolution moved by Mr. C. T. Newton at the meeting:—

1. The first aim of the school shall be to promote the study of Greek archaeology in all its departments. Among these shall be (1) the study of Greek art and architecture in their remains of every period; (2) the study of inscriptions; (3) the exploration of ancient sites; (4) the tracing of ancient roads and routes of traffic.
2. Besides being a school of archaeology, it shall be also, in the most comprehensive sense, a school of classical studies. Every period of the Greek language and literature, from the earliest age to the present day, shall be considered as coming within the province of the school.
3. The school shall be under the care of a director, whose primary duties shall be (1) to guide the studies of the members, and to exercise a general supervision over the researches undertaken by them; (2) to report at least once a year on the work of the school, to record from time to time for the information of scholars at home any important discoveries which may come to his knowledge, and to edit any publications of the school.
4. It shall further be the duty of the director to afford information and advice to all properly accredited British travellers in Greece who may apply to him."

In advertising to the amount of archaeological work still to be done, Professor Newton remarked that there was still room for many more workers. "One single ancient city would take years to explore thoroughly. It would be a regret to him for the rest of his life that he had been called away from Cnidus after considerable exploration, but without having explored a tenth part of the city. At Halicarnassus, again, he had made what he might call a house-to-house visitation to see where there might be any inscriptions, and yet since he had left inscriptions of the highest value had been discovered."

THE Industrial Remuneration Conference, which has just been held, was chiefly remarkable for the flood of contradictory statements and inconsistent proposals, and has, we suspect, left matters very much in the same

position as they were before. The fact is that real usefulness in such subjects as these is not to be attained by bringing together the crude and undigested theories of every enthusiastic dreamer, but rather by carefully getting together the retrospective conditions of past years from which practical results may be deduced. As an instance of such, a paper recently read before the Manchester Statistical Society by Mr. Montgomery is worth a ton of theories, for it proves beyond doubt that the average wages of the working classes in Manchester have increased at least 40 per cent. in fifty years, the increase showing most markedly in the case of women and boys, though it was in varying proportions through all the trades in the following scale:—

Trade.	Increase per cent.	Trade.	Increase per cent.
Spinning	63	Mechanical Engineer- ing	18
Weaving	33	Glass Making	40
Dyeing	16	Silk Trade	37
Calico Printing	48	Building Trades	46
Calendering	47	Tailoring	53
Bleaching	32	Police	46

Not only have the wages increased, but the purchasing power of the money has likewise increased, at about the rate of 18 per cent. If persons would study dispassionately the condition of industrial and social matters in "the good old times," they would probably modify the frantic denunciations which appear to find such favour at the present day.

AMONG the papers which were at least suggestive in matter and elevated in tone, may be mentioned that by Professor Beesley. His views, stated on behalf of the Positivist Society, may be Utopian as regarded our present position, but it is a Utopianism to which it is to be hoped every generation will come a step nearer as time goes on. He has no ready-made panacea for distributing wealth equally. He looks to the progress of public opinion and of religion (in the widest sense of the word) in developing the feeling which, without actually interfering between the capitalist and his gains when made by his own energy and ability, will regard those gains more and more as a fund held in trust to be exercised for the general good of society. There have already been individuals who rose to that height; Professor Beesley hopes that what is now the exception may some day be the rule. It is a high aspiration: but "aim high and you strike high." Mr. Sedley Taylor advocated strongly the principle of co-operation of the workman in the profits of the employer, as we have often done; but some troublesome facts were brought forward on the other side. It was said that in some cases the employes had been very willing to receive a percentage on their wages when times were prosperous, but objected to a percentage the other way when times were bad: "Heads I win, tails you lose," in fact. Possibly the employes in such an instance were not taken sufficiently into the confidence of the firm. Some wonderful things were to be heard at the Conference. We predicted that a good deal of nonsense would be talked, but hardly expected it to go so far as to have a speaker getting up and gravely observing that "all private property in things must be done away with!"

FIGURES, we find from the Annual Report of Captain Shaw, are on the increase in London. It is hard to see what else to expect. There are now rather more than six fires per day in the metropolis. The population of Inner London, which in 1881 was 3,815,000 persons, increased by 17.2 per cent. between 1871 and 1881. If this rate of increase has been continued, the numbers cannot now be less than 4,080,000 individuals; so that 2,000 fires in a year would only be at the rate of one fire-causing piece of carelessness among 2,000 persons in a year. Considering how easy are the oversights which, even in the most careful families, may wrap a house in flames, this is not a high fire-rate. It is only at the rate of one fire in 260 houses in a year. Apart from the growth of actual numbers of population and of houses, there are other causes that tend, from time to time, to increase or to diminish the danger of accident

from fire. It will be beyond the remembrance of most of our readers to rank among the latter causes the disuse of thatch. But we can well remember, years ago, the alarm caused by the outbreak of fire in a country town, where most of the houses were thatched. The effect of the disuse of wood in house-building, again, which must long have been appreciable, is now possibly reversed. There is now much more visible wood in our house-fronts than was the case twenty years ago. Then the experience and prompt courage of the Fire Brigade are constantly increasing. The facility of warming supplied by telegraphic appliances is of the utmost value when safety is a question of seconds; and both the steam fire-engines, and the hydrants that yield water for their supply, are steadily undergoing improvement, decade after decade. On the other hand, the increasing size of warehouses tends to make a fire, when it occurs, more destructive to property; and it is said that insurance rates are rising, not alone in London, but also in Manchester, and elsewhere. The question is now to the fore, whether it is not desirable to organise a special branch of the Fire Brigade for the daily watch of London. A cost of 500*l.* a week, which this would require, would probably be an economical and remunerative outlay.

RECENT advices from Pittsburg, in the United States, inform us that by a new arrangement the use of coal is about to be, — indeed, has been, — superseded by the utilisation of the natural coal-gas with which the earth in that region abounds. A severe competition of long duration has set the iron and steel makers on the *qui vive*, and they have for a long time past turned their attention to the use of gas, and now at last their efforts are crowned with success. The gas is obtained by digging artesian wells deep enough to tap the stratum, and tubes convey it from these wells to the furnaces. In one case reported the tube is twenty miles long. It is not only cheaper than the cheapest bituminous coal, but in large iron works saves the labour of 100 men. The supply is believed to be practically inexhaustible. Its effect upon our own iron and steel manufacture in England will probably be to still further reduce prices, which are now too low to yield any but the barest profit.

IT was hardly to be expected that the railway companies should passively allow the attacks of the various trade associations upon their Bills to pass unnoticed, and we have now heard a little of the other side of the question. The *Times* and the *Standard* have published several letters condemning the Bills, and, through the medium of the first-named journal, the companies have made their reply. The letter published on January 31 from Mr. Oakley, the able secretary of the Railway Companies' Association, is an emphatic denial of the traders' allegation that the companies have combined to raise rates all round, thus aggravating the already depressed commerce of the country. He contends that their motives and objects are entirely misunderstood, and says, — "The companies disclaim emphatically any intention of acting adversely to the general interests of trade and agriculture. They recognise that their own well-being is dependent upon the national prosperity, and they claim from Parliament and from their opponents a counter-recognition of the public advantage of settling upon a fair and equitable basis the conditions upon which the railway service of the country may be best conducted." He deals with the objections to the Bills under four heads, viz. — 1. That the companies are seeking a general increase of their rates. 2. That the proposed classification is unjust to traders. 3. That preferential rates for foreign produce will be legalised and extended. 4. That the right of the companies to charge "station terminals" will be recognised. These are all replied to *seriatim*, and forcible arguments used in favour of the measures. We have previously remarked upon the immense amount of labour which must have been involved in the compilation of the Bills. Mr.

Oakley also makes a brief reference to this, and pleads for a fair and full discussion in Parliament of all the points involved.

WE hear on good authority that Lord Bramwell will, early in the session, introduce the Code of Arbitration Law Bill which was read a first time last session. Various changes and alterations have been made in this Bill since last year, and it is much to be hoped it may become law before the expiration of the present year. So much of the litigation in connexion with buildings takes the form of arbitration, that an Act such as this will be of value to a large number of our readers. We hope to comment on the Bill as soon as it is laid on the table of the House of Lords.

THE recent decision by Mr. Justice Kay in the case of Lord Jersey v. The Uxbridge Rural Sanitary Authority is one that should be taken to heart by other similar public bodies. It appears that Lord Jersey complained that the Uxbridge authorities were polluting Osterley stream and lake, by means of a sewer which drained a considerable number of houses and communicated directly with the stream, the property on the banks of which belong to his lordship. Associated in the action with the Sanitary Authority was a Mr. Woodward, who had made a communication between his house and the sewer, but as this had been done before the commencement of the action, it was dismissed, as against him, with costs. Not so, however, in the case of the Sanitary Authority, for the Judge has granted a perpetual injunction (with costs), restraining them from making further connexions with the sewer. All houses at present unconnected must remain so, and no connexion can be made with the existing sewer from houses now being built or which may hereafter be built, so long as the sewage continues to pollute the Osterley stream and lake. Although this decision must act as a considerable deadlock to those who have house property in this position, and will, at all events, check house-building for a time, it cannot but be regarded as a wholesome proceeding if it tends, as it must do, to force on the development of a general system of drainage.

AT the annual meeting of the Institution of Mechanical Engineers a paper, by Mr. George Richards, of Manchester, on wood-working machinery, was read on the second day (Friday, January 30th) of the meeting, being, in fact, the last paper dealt with. In consequence of the late hour, the discussion was postponed until the next meeting. A large number of specimens were, however, exhibited, showing the work the machines described in the paper would turn out. Some shavings several feet in length, and some as much as 10 in. and 12 in. wide, taken off by the scraping-machine described, were especially noticeable. Specimens representing parts of founders' patterns and other articles of a like nature were likewise shown. Some of these were of a very intricate description, and it was difficult at first to believe, — what, however, was an undoubted fact, — that they were entirely formed by machine tools without being finished by hand. The usefulness of the saw-setting apparatus was well illustrated by the beautiful surface of the specimens cut, which had the appearance of being highly finished by hand.

THE first number of the *Manx Note Book*, published at Douglas, Isle of Man, should not go unnoticed. These local publications do good service by preserving local traditions and facts, which often prove of great value in later years. The Isle of Man is especially a place where such a journal as this is of value, retaining as it does so many marked and unique characteristics of a semi-independence which has lasted for centuries. Already traces are visible of a nearer approach to English systems, for the insular Courts have now been amalgamated into a High Court of Justice, with a Common Law and a Chancery Division, as in England. Something more picturesque and characteristic of this sea-girt island might, indeed, have been found for a frontispiece than the old chapel in the Market-place,

Douglas, as unsightly a building as can well be seen. Castle Rushen, or the ruins of the cathedral at Peel, would have been a better beginning for this journal than a building in the worst style of the eighteenth century.

THE series of engravings illustrative of eighteenth-century art, to be seen at the rooms of the Fine Art Society, is of great interest, both historical and artistic. Some of the engravings, as engravings, are exquisite; among these may be noticed especially the first in the catalogue, Watteau's "Bosquet de Bacchus," engraved by Cochin. The scenes by Watteau, Lancret, Saint Aubin, Lavreince, and others are almost pathetically interesting in their portrayal of the life of artificial yet graceful luxury which belonged to the period. Fragonard's figure, again, of a young girl engraving a name on the trunk of a tree, "Le Chiffre d'Amour" (43), shows an exquisite combination of Nature and Art in this artificially dressed, but not by any means artificial, young personage. Fragonard's more *risqué* subjects, of which there were plenty and very clever, are not represented. Chardin strikes a more serious note than the rest in such things as "Etude de Dessen" (23) and others, which are more distinctly governed by an artistic ideal. The engraving of the "Coronnement de Voltaire," by Gaucher, after Moreau, is a masterpiece of minute engraving, but the head of Voltaire wants character, and is not thin enough for representation of the "inspired skelton."

WE understand that the Council of the Royal Institute of British Architects intend to recommend that the Gold Medal for this year should be given to Dr. Schliehmann in recognition of his remarkable archaeological work. This is an award about which we may presume there will be absolutely no difference of opinion. It may be thought by some that it comes rather late in the day; but the medal is only available for awards to foreigners once in three years, and the two last foreign recipients, the Marquis de Vogüé and Baron von Ferstel, had both prior claims to Dr. Schliehmann in point of time; besides that their distinction was gained in work more distinctly and specially architectural.

LETTER FROM PARIS.

THE artistic and literary world of France has suffered cruel losses of late. The record of death closed our last letter, and it is with the record of a death not less unexpected that we commence this one. Just after Bastien-Lepage, the earnest and picturesque painter, we have lost Idrac, the nervous and talented sculptor; — both dead in the prime of life and in the possession of powers which had given promise of still more brilliant future.

Jean Idrac, son-in-law of M. Ballu, the eminent architect, was the son of a poor mason of Tonlouse. A pupil of MM. Cavalier, Falguière, and Guillaume, he gained the *prix de Rome* in 1873. Two statues, "L'Amour piqué," and "Salambo," had placed him quickly in the foremost rank, and death came upon him, at the age of thirty-nine, at the moment when he had finished, for the Hôtel de Ville, the equestrian statue of Étienne Marcel, of which we spoke in our letter of January 3rd.

After Idrac, we have lost Edmund About, a firm and delicate genius who unhappily got astray in the field of political conflict. We speak here only of his success as a romance-writer and a art-critic. His last will shortly be executed by the sculptor Crank, who is at present engaged in completing, for the Rue de Rivoli, the monument of Admiral Coligny.

Another well-known sculptor, M. Franceschi has nearly completed the bust of a gifted man of letters whose tragic end in a distant country painfully impressed the Parisian public last year. We allude to Commandant Henry Rivière, killed at Tonkin; who, as far as his leisure time allowed, was a distinguished *littérateur*. The monument erected to his memory in the cemetery of Montmartre, by the "Société des Gens de Lettres," was inaugurated last week.

This obituary subject leads us to mention also the exhibition of the works of Ev. Gonzales, a young artist also taken away prematurely in the height of her talent. Mme

Gouzaïe, whose works have been collected in "Salons de la Vie moderne," Place St. Georges, was successively the pupil of Chaplin and of Manet. Among the eighty-eight pastels and oil-paintings there exhibited are some very remarkable works, revealing in piquant fashion the strife between the influence of the easy and rather affected execution of her first master, and the strange tones and often intentional exaggerations of the second; but all corrected by her own strongly-marked individual taste.

We are just entering on the period of private gallery exhibitions, which in Paris succeed each other almost uninterruptedly till the opening of the *Salon*. The Artistic and Literary Club of the Rue Volney opened first. Some works of great merit are there, drowned among a crowd of mediocrities. This exhibition, which closed on the 4th, will be, we believe, advantageously replaced, from the artistic point of view, by that of the "Union Artistique" (Place Vendôme), known under the eccentric name of the "Cercle des Mirilitons," and which will remain open till March 9th. We will speak again of this exhibition, which constitutes every year an event in the world of higher aestheticism. The same may be said of the exhibition of the Society of French Water-Colour Artists, which opened on the 2nd, in the Galerie Georges Petit, Rue de Sèze. The names of such exhibitors as Eugène Lami, Eugène Isabey, Heilbuth, Le Blanc, John Lewis Brown, Cazin, Vibert, Detaille, and De Neuville, gave great attraction to the opening *soirée*, which was a gathering of the whole fashionable, literary, and artistic world of Paris, and where even politicians met without distinction of parties.

Another exhibition of exceptional interest, already announced, is that of the works of Delacroix, which are to be collected at the École des Beaux Arts from the 1st of March to the 30th of April, by the exertions of M. Georges Petit. If, as the committee hope, the French and foreign collectors consent to lend the works which they possess, one may predict the success of the exhibition, the proceeds of which are to be expended in raising a monument to the illustrious master. In reference to this subject, we may add that, thanks to the Conseil Municipal of Paris, one of the finest works of Delacroix,—the "Pieta," a fresco in the church of St. Denis du Sacrament in the Rue du Turenne,—which was lost in the darkness of a chapel, is to be placed, by the opening of new windows for the purpose, in the full light of day.

To complete the information given in our last in regard to the removal of the collections of the Luxembourg in the ancient Orangerie, we may add that the new Museum, which is nearly completed, will include an immense sculpture-gallery in which the marbles will be arranged in four ranks. The bronzes will be placed on an exterior terrace. A large *salon d'honneur* of 210 square metres in extent, and ten smaller rooms, will be devoted to paintings, water-colours, and drawings. Lastly, a special space will be reserved for engraving, which is not represented in the existing museum. Speaking of the Luxembourg, we must bestow a word also on its neighbour, the new École de Pharmacie, the artistic decoration of which has been entrusted to M. Besnard. This includes two new compositions of great originality, which will figure in the next *Salon*.

The general stagnation of business continues, and the absence of any large works in progress gives little promise of any amelioration of the crisis in the building trades, which the severity of the season has caused to be the more keenly felt. The distress in Paris is unhappily very great, and seems to be lying idle instead of putting in motion any private enterprise. There is more and more talk of a loan to be negotiated by the Municipality, in order to furnish work to those who are out of work. While we are waiting for the International Exhibition, large workshops might be thus opened, especially if the Government consent at last to suppress the fortifications of Paris, now become completely useless, if not dangerous. The project of the Government would consist, in the first place, in demolishing all that portion of the fortified *ceinture* which extends from the Porte St. Cloud to the Porte de Clichy, which would offer an immense site for private buildings, and would give opportunity for an experiment in the project of cheap dwelling-houses (*logements à bon marché*), which the Municipal Council is still desiring to realise. This great operation would

put in direct communication with the capital the Communes of Boulogne, Neuilly, and Levallois-Perret; that is to say, the most elegant, populous, and richest suburbs. Another operation which suggests itself strongly, in view of the approaching Exposition Universelle, is the construction of a metropolitan railway. There would be occupation for thousands of workmen for some time in such a project. But the question does not seem likely to settle itself soon, although the Municipal Council has given its approval to the principle of that great subterranean work.

In regard to the Exposition Universelle, it may be added that according to the plans approved by the committee of organisation at their last sitting, the buildings will consist of two palaces placed at the entrance of the Champ-de-Mars, immediately adjoining the square of the Ville de Paris; the one intended for the Arts and placed on the side next to Avenue Labroulaye; the other, for the Sciences, adjoining the Avenue Sauffren. These two portions of the palace will communicate by a gallery. These palaces, which will each cover a space of 24,000 metres, will be placed in communication with temporary structures ranging over an extent of 228,000 metres. An avenue 60 metres wide will be left through the midst of these constructions and the axis of the Ecole Militaire. The Commission has decided that the exhibition must have an entrance at the Champs Élysées to the Palais d'Industrie, partly in view of a grand industrial and commercial congress. The constructions will encroach also on a part of the Cours la Reine; the Seine will be crossed opposite the front of the Invalides, by the aid of a covered bridge; the esplanade of the Invalides will be reserved for the Colonial exhibits; a space of 70,000 metres on the Quai will be given up to Agriculture; and, lastly, the garden of the Trocadéro will be in part utilised for an exhibition of horticulture.

This perspective of the Exhibition of 1889, and yet brought so near by the vast scale of the preparations to be made for it, has already excited a crowd of projects more or less realisable. We have already referred in a "Note" to that of the well-known builder, M. Eiffel, who proposes a monumental tower 300 metres in height. He has charged M. Sauvestre, the architect, with the plans of this colossal annexe to the Exhibition.

M. Bourdais, the architect of the Trocadéro, on his part, is spurred to emulation, and in a paper which he is to read to the Société Centrale des Architectes, he has developed a project for the construction of a tower of the same height, but in which masonry will be associated with metal. At the summit will be a lantern measuring more than 17 square metres, and enclosing a lighting apparatus of the power of more than two million gas-burners. For the site of this tower, M. Bourdais proposes the esplanade of the Invalides, whence he would easily light not only all Paris, but the Bois de Boulogne, Neuilly, and Le Vallois. We mention this as a record of a project which seems likely to be classed in the category Utopian; and which, at the best, can only be regarded as a *tour de force* supplying no seriously demonstrated need.

We cannot say so of the very interesting Museum of Casts which the Minister of Public Instruction has formed at the Palace of the Trocadéro, and which is at the same time an object of interest for strangers, and a precious centre of study for sculptors and architects. This museum is about to be enriched by a new collection of bas-reliefs intended to form a kind of history of antique art. The two first rooms will be open to the public in April.

Let us close this rather long letter by announcing that there is at last some question of putting the Palace of the Popes at Avignon to a use more conformable to its origin and its great historic and artistic interest. It is given out, in fact, that the Department de Vaucluse and the town of Avignon, in order to re-enter on the possession of that ancient abode which has been so long occupied as a garrison, have offered to construct new barracks at their own expense. If the Ministry of War accepts this combination, the municipality of Avignon, with some financial assistance from the State, will restore the Papal palace in accordance with a project formerly prepared by Viollet-le-Duc, and will install there its archives, a school of art, and its museum. There is a fine piece of news for all tourists who have visited our fair

Provence, and admired that marvellous specimen of the military architecture of the Middle Ages.

IPSWICH AND BIRMINGHAM SHIP CANAL.

It was observed in a recent issue of the *Builder* that symptoms were not wanting of public dissatisfaction with the railway policy in the matter of tariffs, and of a growing conviction on the part of the trading community of the necessity for re-establishing the ancient water routes of this country on an improved basis. The most recent instance of such a conviction is a pamphlet by Mr. Joseph Robinson, of Ipswich, addressed "to the Traders, Manufacturers, and Shippers of England," in which he advocates a scheme for "a steam-ship route from Harwich to Liverpool by means of a canal 200 miles long, at an estimated cost of fifty millions of pounds. The arguments he advances in support of his scheme are plainly and tersely put, and, though familiar to those who have studied the relative possibilities and merits of rail and water carriage, are probably known to but a very small section of those most interested in the question, viz., the trading community.

Quoting from the Board of Trade Returns, Mr. Robinson states that during the year 1883 the English railways carried 184,485,600 tons of minerals and 76,897,356 tons of goods and merchandise, and that their receipts on all accounts were as follow:—

For goods and merchandise.....	£38,701,319
Miscellaneous receipts.....	2,852,218
Passengers.....	29,609,733
Total receipts.....	71,063,270
Deduct working expenses.....	37,368,562
Balance of profit.....	33,694,708

Assuming that one-half of the goods and minerals moved in 1883 might and would be carried by canal at a charge of one-third the present railway rates, he asserts that there would be a total annual national saving of 12,900,440*l.*, which large sum, he observes, is at present "lost to the country for want of the adoption of the most economical method of heavy goods transport." This is a clear way of stating his case, and is possibly quite within the mark; but, of course, it is open to the reply that it is based on an assumption of the relative quantity of goods which would be diverted from the railway. The matter simply resolves itself into a question of economy, not only of actual transport between two given places, but of the various additional charges involved in the collection and delivery of goods from dépôt to dépôt, or between warehouse and warehouse. But Mr. Robinson's case is strengthened by a fact which he has omitted to notice, and that is, that a number of articles of bulk and low value, which now cannot be moved at all, owing to the high cost of carriage, would, by the provision of cheap water transit, be immediately set in motion. That "the mixing up of express and slow traffic on railways is nothing short of a public calamity as being the cause, direct or indirect, of a large amount of delay, and a number of railway accidents involving loss of life," is certainly true, and has been practically acknowledged by such of our practical lines as have provided an additional track for the separate conveyance of minerals and goods; but even with this arrangement it has not been found possible to reduce the mileage charge for goods, while the Railway Bills, of which notice has been given in Parliament, indicate an increase rather than a diminution of charges, and have led to the recent conferences of the Traders' Associations for protesting against them. At the meeting held at the Cannon-street Hotel, presided over by Lord Henniker, Mr. Adamson, the chairman of the Manchester Ship Canal, pointed out "That the protection of traders and agriculturists lay not so much in fighting the railway companies as in the development of the waterways of the country which had done so much service before the former were invented; also, that water was the cheapest transport in the world, and its economy might be greatly increased by the use of steam." The development of the existing canals in England is, however, a different measure to the scheme put forth by Mr. Robinson. A costly project like that of a ship canal across England, estimated at fifty millions, can scarcely be said to be one of the pressing needs of the day, or to be capable by itself of

attaining the object advocated by Mr. Adamson, which, according to the evidence laid before the Select Committee on Canals in 1883, could probably be accomplished for one-fourth of that sum. Nevertheless Mr. Robinson has done good service in bringing the advantages of water carriage so prominently and clearly before the traders and manufacturers of this country, as, without doubt, the foreign competition from which they are now suffering is aggravated by the high cost of internal transit which the railway companies apparently are unable, even if willing, to reduce.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.
THE GOLD MEDAL FOR 1885.

The ordinary meeting of the Institute was held on Monday evening last, Mr. Ewan Christian, President, in the chair.

The Chairman announced that the Council had awarded the Pugin Travelling Studentship for the current year to Mr. William Henry Bidlake, B.A., Leicester; and a medal of merit to Mr. Herbert Osborn Cresswell, 10, Queen Anne's Gate, Westminster. The Chairman further announced that the Council had awarded the Godwin Bursary to Mr. John Bradshaw Gass, of Silverstreet, Bolton, who purposed visiting certain cities in Canada and the United States of America. Mr. Gass's written application for the Bursary showed evidence of unusual industry and variety of professional study, and we have no doubt he will bring some solid results from his expedition.

With regard to the Royal Gold Medal, the Chairman said that the Council proposed to submit to her Majesty the Queen, as the recipient of the Royal Gold Medal for the current year, the name of Dr. Henry Schliemann, Honorary Corresponding Member (Athens), Hon. D.C.L. Oxon, Hon. Fellow of Queen's College, Oxford, for his excavations at Hissarlik, Mycenae, Orchomeus, and Tiryns, and for his various works describing his discoveries.

Professor Kerr said that the drawings for the Pugin Studentship were this year of exceedingly high character, and he was gratified to find that the Council had awarded a special medal to the second in order of merit. He was going to ask the Council to award another medal to the author of the drawings which were third in merit, who was a Scotchman, and therefore laboured under disadvantage as compared with his fellows in London. It would be only fair to award this medal, as Mr. MacLaren came so very near to the second in merit.

Mr. R. Phené Spiers seconded Professor Kerr's proposition.

Mr. Charles Barry thought the better course would be not to put it to the meeting in the form of a resolution, but to leave it as a recommendation to the Council.

Professor Kerr said he would be quite satisfied with that.

Mr. Henry Curry remarked that as a member of the Committee he might say that Mr. MacLaren's drawings were included in the three sets selected for further inspection. They had the greatest difficulty in deciding which should be second and third.

Obituary.—Mr. Henry Rydon, well known for his building and brick-making operations at Highbury and in adjacent localities, died on the 14th ult. at Brighton, where he had resided of late years. He had acquired a handsome fortune.—Mr. Edmund Reddin, the well-known contractor, of Bankside and the Grove, Southwark, and of Shot Tower Wharf, Lambeth, died at his residence, Albury House, Clapham Rise, on the 28th ult., of bronchitis, in his seventy-fourth year. He commenced his successful career in partnership with his brother Michael at Bankside, nearly fifty years ago. On the death of Mr. Michael Reddin, in 1847, he largely increased his business, which was still further extended on the death of his father, Mr. Daniel Reddin, of Castle-yard and the Grove, Southwark, in the year 1854. For several years after this date a great many of the large excavation and sewer jobs in London, as well as a large number of parish contracts for dusting, slopping, &c., were executed by him. He is spoken of in high terms by those who knew him. The funeral obsequies took place on Tuesday last, when a requiem was sung at St. George's (R.C.) Cathedral, Southwark. The interment took place at Norwood Cemetery.

"ENGLISH ARCHITECTURE THIRTY YEARS HENCE."

ARCHITECTURAL ASSOCIATION.

A discussion upon the paper bearing this title, read by Professor Kerr at the Architectural Conference last year,* took place at the meeting of the Architectural Association on Friday, the 30th ult.

The Chairman (Mr. Hampden W. Pratt, Vice-President) said that most of the members had either heard or read Professor Kerr's lecture, which was to be the subject of the evening's discussion. The Professor had favoured them with his presence, and had kindly undertaken to offer some introductory remarks.

Professor Kerr said he had great pleasure in being present to hear a discussion on the paper read by him at last year's Architectural Conference. Not that he wished to interfere in the slightest degree with that perfect freedom of debate which he admired in all societies, and particularly in a society composed of young men who had the world all before them, and who need not be afraid of expressing their opinions; but he wished to avail himself of the opportunity of making a few preliminary remarks, inasmuch as some of the criticisms which had been passed on his paper seemed to have missed the mark intended by him. He would tell them, in the first place, how it came about that his paper was written and read. Some of his critics had spoken as if he had come forward almost presumptuously with prognostications which promised much and fulfilled little. That was scarcely fair, however. When arrangements were being made for the Conference, the Committee conceived the idea that it might be well to include in the programme a discussion on the immediate future of the profession, and a gentleman well known to them all, but whose name he would not mention, asked him whether he would undertake to open a discussion on the subject. He replied that he believed he could do so. For many years, in the leading articles of one of the journals, he had taken a peculiar view of the position of art in England. He had altogether discontinued the idea of our being backward, nationally or essentially, in any way. He had, of course, admitted our backwardness in certain points and our inferiority generally in genius to the French, but he contended that we were advancing now, by some means, no matter what, in a certain course which was highly honourable to the nation; and he saw no reason to doubt that in a future generation, perhaps the next or the one following, England, instead of being behind-hand, might take the lead in the world of art. His doctrine involved the assertion of the abandonment of Academicism, the adoption of great freedom of thought, and what would be called universalism in art—perfect liberty and equality of all the arts, perfect magnanimity and generosity of all artists towards each other. Upon this basis he had contended, and was still prepared to contend, that England had now assumed a very noble position in the face of the whole world, which it was well for every member of a society like the Association to understand, and to speculate upon for his own advantage, and for the advantage of his art. Looking at our country as compared with other European nations, they might safely acknowledge that it was too plain to be disputed that we are not a sentimental race, but prefer practical views of everything, and a substantial outcome rather than anything that might be called visionary, transcendental, or illusive. The French, on the other hand, were a different race, actuated by a universal sentiment of artistic feeling, which in this country it would be difficult to appreciate, but which was patent to all who understood what art was, and who could enjoy art in its finest and most elegant forms. Germany, again, was like England, liable to be considered an inartistic nation. We were both Teutonic peoples, and devoid of the *esprit* which is characteristic of the French. In Italy the position of art was entirely traditional. There was not much genius of a novel kind, but there was an inheritance of the forms and the works of genius that have come down from past ages. Turning, then, from Europe to America, one of the most promising nationalities of modern times, they found art, as it were, in a condition of adolescence, imitating and aspiring to succeed Europe when

Europe should be effete, and to represent all the conditions of Europe, perhaps many centuries hence, in a more brilliant development of civilisation. Those who had not beyond fifty years of age knew it was idle to dispute that during the last thirty-five years a very remarkable change had come over the minds of the people of this country in regard to art. The sluggish intelligence of the period before the Exhibition of 1851 must, to most of the members of the Association, be a thing not to be intensely understood. Indeed, there was no much to be read about it, because it was not commented on as it ought to be, but those who could remember what it really was from their own experience could testify that the state of things at the present day, regarded the arts universally, was as different from the state of things at that time as one thing could reasonably be different from another. It seemed as if the English intelligence were now acquiring a national purpose peculiar to itself in the domains of art; a purpose essentially identified with that broad basis upon which English operations in modern times are universally performed, and which was recognised in the allusion contained in the phrase that "England is the workshop of the world." Thus, industrial art in its widest sense was the thing which particularly commended itself to the minds of Englishmen, and what he contended for was the probability that this industrial art in the hands of Englishmen would, and must, in course of time, develop into art of altogether a different kind from anything exhibited in modern or in ancient times, and in such a form that we or our successors might expect to take the lead in it. He would ask those who could carry their minds back for a few years,—ten years would be sufficient,—to observe how what used to be called the sacred circle of the academical artists had been losing its virtue. When he was at their age he was told there were three arts for their recognition,—painting, sculpture, architecture, and no more. To some the enunciation of that proposition might seem somewhat strange, so different had the public view of the matter already become, and this circumstance was what he spoke of when he said that art was becoming non-academical. The exclusiveness of the Royal Academy was gradually beginning to be undermined, and the time had come, and could not be avoided, when the Royal Academicians, or whoever might take their place, would no longer be mere painters, and sculptors, and architects, with a few engravers thrown in, one knew not why, but would be the representatives of all that that was the true art of the nation. Now, in those circumstances, architecture came to the front, and it was remarkable how it had done so in this country within the last ten or twenty years. The reason was not far to seek; it was in the rise of the minor arts into a position of public recognition, whereby they now formed a galaxy around architecture. He ought to say that architecture as a demonstrative art was in this position,—that it combined, as no other profession did, three elements seldom found to be combined at all. The first was art, meaning artistic design; the second, science, meaning the mathematical contrivance of construction; and the third element was trade, or commerce. Painters and sculptors might profess to repudiate connexion with trade and commerce; architecture never did. Every house built by the architect, however carefully designed, was never considered in such a light as to be forgetful of commercial considerations; and in these times it was commercial considerations which must to a great and paramount extent be the ultimate effect of the industrial arts. Now, the question which had been dictated to them for discussion was this, what was coming? There was one way of discerning what was coming better than by any other course. When as little boys at school, they wanted to take a leap forward, they went backward a little, took a run, and by getting momentum they were carried forward with an acquired force. Now, if they wished to foretell the future in such a matter as the progress of art in England, the best course was to go back for a sufficient distance to get a run, to keep steadily on the course which public taste and policy had been taking, and having acquired as much momentum as possible, to let it carry them forward where it would, which was likely to be the course which the future would take. It was in that view of the case that he adopted a line of retrospection, which he

* For full text of the paper, and for a report of the discussion on it at the Conference, see *Builder*, May 17, 1884, pp. 713, 726-731.

had plainly enough pointed out to be adopted for the mere purpose he had now explained. What, then, was coming? Young men were apt in answering this question to consider what ought to be coming. But that was of no use, because what ought to be coming was matter of opinion; what was to be was matter of fact. In this way the idea of what ought to be was generally a mere individual fancy, often what was called a crocheted, very often delusive in one form or another, but what would be was a matter of calculation, calm and dispassionate, upon sufficient data and by sufficient means. The question, then, of what was coming within the next few years might, in the matter of architecture, be put in another form. What direction was the general national taste now taking; what might they, as young men, gather for their own sake and profit out of a studious contemplation of the course pursued for so many years past; and what was the probability of its being pursued in a certain direction for many years to come? There was an expression of his which he had made use of for a good many years, and which some had thought was a laughable expression,—“the Modern European style of architecture.” When they considered what modern Europe was, and reflected on the history of architecture and the other arts, through every development of civilisation, during many centuries, it must be perfectly plain in the minds of judgmental men, that the idea of modern Europe, existing without its own style of architecture, was, on the face of it, impossible. What, then, was the modern style of European architecture? Modern Europe had its rise in the fifteenth century in Italy, and they all knew that a style of architecture had its rise at the same time. Modern Europe had pursued a course devious, but still persistent, from that time to the present; and, for good or ill, in examples which might be admired, and in others which could not be admired, that style of architecture had been continuously practised throughout the length and breadth of Europe. This was what was called the Modern Classic, and whatever might be said of its merits, do not let them pretend to mystify the matter by denying the fact that Modern Classic architecture so-called,—Italian Classic if they chose to call it so,—was the modern European style. Now in that they had a basis on which to stand, and, having mastered that fact, he would refer to another remarkable incident, which many of them appreciated with great force, viz., the Gothic Revival. Without entering into the merits of the Gothic Revival, which was quite unnecessary in this particular connexion, it was enough to understand that, regarding it as an episode, more particularly in this country, among those whose minds were calculated to accept the idea, cherish it, and carry it forward, it introduced the element of vigour. It was said that the modern European style, pure and simple, had become effete; that it lacked muscularity and manliness. The Gothic style in this revival, on the other hand, in the form in which Englishmen took it up, was characterised by vigour, truthfulness, straightforwardness, determination to deviate neither to the right hand nor to the left; and this idea getting thoroughly into their minds was what he signified by the term “vigour.” He would next turn to another incident,—the Exhibition of 1851. Some people were accustomed to sneer at that Exhibition, but it was a vain and futile sneer. Like all other human enterprises, it had its misadventures, and its weak sides; but no enterprise in the whole history of art had, in his humble judgment, produced, in so short a time, such marvellous effects as that simple act of English enterprise had produced in England. As far as they were concerned, what did it produce? It brought into prominence the universality of the minor arts, and the Academicism of Royal Academies was swept away. He need not go into any description of what he meant by the minor arts; they were rising into greater distinction and eminence in England every day. Another term used was “the industrial arts,” but the meaning was pretty much the same, though the latter term might be the more expressive. Liberty now became established as the right of artists, and he could speak from his own recollection of how criticism had changed from what it was thirty or forty years ago,—how much more respectful it was even in this country, where a disregard for art seemed

to be the deliberate pastime of penny-a-liners; how much more respectful criticism on even small efforts of art now was compared to what it used to be. A new gospel had sprung up within his recollection. They were no longer confined to the hallucinations of dignitaries. Small men, of small minds, could discuss in their small way small efforts of art. With this popularity of universal art, there had come to attach itself to the liberty of artists that equality which he had mentioned,—that fraternity which time must develop in a common-sense country like this, and in the development of which, he contended, the future of England lay along a path of great distinction. This being so, they had been taking their walk back and their run forward; but had they acquired sufficient momentum to carry them a little into the future? He thought they had. Was it likely that a course of intellectual development such as he had been endeavouring to describe, was to suddenly stop there, or take another direction? Certainly not. What, then, were the young men encouraged to look forward to as the probabilities of the immediate future? They had been taught,—and he did not disapprove of the teaching, for what it was worth,—that in Mediæval art generally was to be found the sole field of meritorious design. He would ask them to dismiss that from their minds altogether, as a contracted and narrow opinion quite unworthy of Englishmen. Everything which constituted a development of human intellect was like the tree,—first the seed, then vigour of growth, ripeness, decay, and disappearance; and when the Gothic revival finally disappeared, as all things must, it would have to be acknowledged that it had done good service to this country, and that was enough. Then if they wished to look a little into the future they should not allow their minds to be distracted from the facts of the case, by any undue appreciation of this episode of local architectural development, but should bear in mind that the Modern European style not only survived, but must be, until the end of its own age, paramount. The one element which the modern or Italian style endeavoured to encourage and to rely upon was grace; not that the Mediæval artists were lacking in grace, but vigour had been the leading feature of the Gothic revival. The popular idiosyncrasy of the people of this country encouraged him to expect that they might combine grace with vigour in a way which should be more or less successful. If they pursued this line, remembering the universality of art, and the dogma of the equality of artists, while looking strictly at the peculiarity of the English character, the prospects of architecture in this country were as follows:—Pursuing the current style belonging to the age and to the whole of Europe, adding to that style the peculiar elements which had come to the front in the Gothic episode, and hearing in mind also the elements of universality, equality, and perfect liberty, he believed that the progress of architecture in England during the next generation was a thing of great promise. Painting and sculpture, as old academical allies of architecture, were descending from the high pinnacle on which they had been set of old. Their high position was pronounced to savour much of affectation and assumption. And while these were descending, all the industrial arts were ascending and meeting on the level of architecture, the first and greatest of all industrial arts! Let every one of them then consider, for his own sake, that where there was this universality of art recognised, there would also be an increasing competition, and that he who understood the future best, contemplating it most calmly in the right direction, would have the advantage over his brethren.

The Chairman said that Professor Kerr had laid great stress upon the modern European architecture, but would only lead them to look upon the Gothic Revival as a mere episode. Now the Gothic Revival was surely to be regarded as something more than a mere episode, as it had taken such deep root in the architecture of this country. It would be long before ecclesiastical architecture would be transformed from the Gothic work to any other style or development. In a few instances Wren's work had been taken as a model or style which might be developed in churches, but he believed that Gothic was so deeply rooted in the minds of the English people that it would die a very hard death, if it died at all.

He believed that the architecture of the next thirty years would principally depend upon what leaders they might have in the profession, and, of course, within the last few years they had lost their leaders amongst the Gothicists. Materials had a good deal to do with style; much would doubtless be done with iron and concrete in the next thirty years, and architects would follow in the direction of using manufactured materials.

Mr. A. B. Pite did not think they were yet out of the wood. The question was, what sort of work should they be doing thirty years hence? and would it be different to what it had always been? They could hardly be expected to answer this, although Professor Kerr had so brilliantly drawn their minds back to the rise of the Italian Renaissance, telling them they must run back, run forward, and then jump,—and see where they were. Had they done this a century ago would any such jump have brought them to the Gothic Revival? Or had they jumped fifty years ago, would it have landed them in the present state of Queen Anneism? Experience did not give truth to the doctrine, for architecture did not go forward in jumps. They seemed to be entirely at the disposal of genius, and art was really at the mercy of a few minds strong enough to take the lead, influenced, of course, by surrounding circumstances. He had no fear as to the position which the nineteenth century would hold in future. Since the opening of the century there had been a number of revivals, the Greek, the Gothic, and the Queen Anne. This would stand out in centuries to come as a most eccentric age, and yet one as powerful in the history of art as the fifteenth and sixteenth centuries. He was inclined to think that Classic art as the national art of England had been worked to death at the end of the last century. There was little to be proud of in the modern London streets. Moorgate and King William streets were works of the Greek Revival, and did not belong to the line of design termed by the Professor the architecture of the future. Suppose they had a town-hall to design next week, how should it be done? Classic work was said to be dead or antiquated; “Queen Anne” work was ignominious for a public building; and Gothic also was said to have died. One of our greatest ecclesiastical architects had been advocating a return to the Renaissance, but this must be an “artistic gambol!” Their attention should be turned to the study of plain building without archaeological style, seeing what could be done simply by the use of pure sculpture, or by the application of colour. Mr. Pite concluded by proposing a vote of thanks to Professor Kerr.

Mr. G. H. Blagrove contended that no living style had been developed from its predecessor since the Elizabethan era. In the future there should be one style for all buildings, which might be so modified as to meet all requirements. The question was what the style should be. The construction of the present day was essentially iron construction, and everything else was secondary in all our greatest buildings. The leading feature in iron construction was the lintel, and the style of the future must depend for its main features upon horizontal or Classic, rather than on vertical or Gothic. He seconded the vote of thanks.

Mr. Thomas Blashill remarked that even after his long run and jump, the Professor was not able to go so far as they might have wished. If he were firing at a mark without anything to consider but the direction of the barrel, the thing would be extremely simple, and this was about as far as analogy could go between the line of argument taken by the Professor and the act of firing at a mark. But other things had to be considered, such as the earth's attraction, wind, and the resistance of the atmosphere, which had to be calculated before-hand. The things necessary to take into consideration in completing the Professor's argument were things which were to take place in the future. There lay the difficulty, and it was not to be imputed to the Professor that he was unsuccessful because he had not got over it. Professor Kerr considered that the style with which long experience had made him familiar, and which was most to his taste, was the most likely to be followed in the future. The Professor seemed to forget that the Renaissance was the result of an art movement in a great measure artificial. The question had been treated too much as if it were a matter of designing the

outside of buildings. They should find out what their clients desired, and be able to tell them if they did not know, the height of the stories, the shape and size of the openings, and the best kind of roof. By combining this with a knowledge of the materials at their disposal, they would arrive at the best forms and composition generally. He was not prepared to say that anything like the pure Italian would get the better of everything else; in fact, he was decidedly of opinion that it would not. At the same time, looking at the works perpetrated nowadays under the name of "Queen Anne," which was a debased form of architecture, the more the students could get to Italy, and enliven their minds by the study of the great Italian works, the better it would be for them, and the less would people be satisfied with crude and unsatisfactory forms, and wretched mouldings.

Mr. Hooper said that as wet blankets had been thrown upon the youngsters of the profession by the addresses of the President and Mr. Sedding,* it was pleasant to find that Mr. Aitchison had given them some encouragement,† and that Professor Kerr had lent his eloquence in the same direction.

Mr. H. D. Appleton (hon. secretary) remarked that nearly all the movements in art had been preceded by movements in literature. The Gothic revival had been generally referred to the romantic school started by Sir Walter Scott, and he believed the "Queen Anne" revival had some beginning among the aesthetes at Oxford before it was translated into brick and mortar.

Mr. W. H. Wood thought the Professor had not gone back far enough. If they went back to ancient Greece they found a learned democracy in vogue, with every one taking an interest in public affairs, and knowing something of art, so that it was impossible to have bad architectural works. The Romans, again, although not themselves artists, yet employed them, and their organisation was perfect; while in Mediaeval times the religious fervour was the great and ruling power. In our own times there was nothing to compare with this, unless it were the fervour at the time of the Gothic revival. Since then there had been a rise of scepticism; the public were split into sections, and public buildings did not please the whole people as in the old Greek times. The industrial arts were now much before the people, and would become more and more generally adopted. There would be a desire on the part of the public to have something which was logical in style,—not mere affectations, but the outcome of the times.

After a few remarks from Mr. T. Ellison, Mr. Johnson said there was a tendency nowadays towards too much fussiness and elaboration of detail, while many lost sight of the grand principles which should be prominently borne in mind. Generalism was a mistake; and it would be much better to devote originality in one's favourite style, than to look up the past volumes of the professional journals before commencing to design. By working out their own ideas in the most suitable form they would arrive at much better results. The architect was too apt to pander to the craze of the moment, instead of having a preconceived set of ideas, and working them out as best he could, according to the subject placed before him.

The vote of thanks was then carried by acclamation.

Professor Kerr, without replying, complimented the members on the discussion which had taken place.

St. Paul's Ecclesiological Society.—The sixth annual report of this society, presented by the council to the annual meeting of members on Saturday last, states that the position and prospects of the society are highly satisfactory. During the past year ten meetings have been held at the Chapter House, and visits were made during the season to various churches in Town and country. A day was spent in Winchester, Mr. Somers Clarke conducting the members over the Cathedral and the Hospital of St. Cross. There are now 322 names on the register of members, twenty-nine having been elected and eight having resigned during the year.

Illustrations.

STAINED-GLASS WINDOWS, EAST-HAMPSTEAD CHURCH.

THIS three-light design, representing the Resurrection, was carried out by Messrs. Morris & Co., from the designs of Mr. E. Burne Jones.

ST. PADARN CHURCH, LLANBERIS.

The present Church of St. Padarn affords a striking and melancholy instance of cheap church building. Only erected eleven years ago, it was found to be not only too small, but in such a sad state of dilapidation as to be beyond repair, its walls being cracked and porous, the roof leaking and spreading, and the Bath stone dressings in a crumbling state.

To take the place of the ruinous structure the church we now illustrate was designed by Mr. Arthur Baker, and the first section,—consisting of the chancel, transepts, central tower, and a part of the nave, seating 500 persons in chairs,—will be completed by Easter.

The church stands on the rock, and the walls are built and faced, inside and out, with the local green stone quarried near the site. The dressings are of Rancorn stone.

Owing to the exposed position, extraordinary precautions, involving a cost of 500*l.*, have been taken to keep the walls watertight. The cost of the first section of the church, exclusive of the chancel, fittings, and heating, will be about 5,800*l.* The work is being executed by Mr. R. R. Williams, of Carnarvon.

BEER-BOTTLING STORES, KENTISH TOWN.

THESE premises have been erected for Messrs. Read Bros., upon an extensive site adjoining the Midland Railway, and have been arranged so that each department has an entrance from the railway siding as well as from the roadway.

The architects were instructed to design a building in the early Scottish baronial style, and the materials originally proposed were bright red Leicestershire bricks and buff terra-cotta dressings.

The whole of the basement, having an area of 13,000 square feet, is arranged as a cool cellage, and has about a quarter of a mile of raised staging for the 2,400 bblts of beer usually kept to season. It is entirely covered with a concrete floor on iron columns. Behind the main building is the store for cleaning and storing bottles, with an area of 7,900 ft.

The stock of bottles kept is over 70,000. The high-pressure washing-apparatus is supplied from a tank in the main tower.

The greater part of the upper floor is used for labelling and packing. It is well lighted by continuous skylights facing the north. It communicates with the stores below by a lift worked by a gas-engine. The entrance from the road is under the central gable.

The remainder of this floor is occupied by the offices, laboratory, &c., which are fitted up with pitch-pine ceilings, dados, &c. The private office in the tower has oriel windows overlooking all the entrances.

The greater portion of the work was executed by Mr. W. Brass. The terra-cotta work is by Messrs. Donlton; the ironwork by Messrs. Homan & Rodgers; the office-fittings by Mr. Avis of Putney; and the mosaic floor by Mr. Burke. The quantities were prepared by Mr. D. Campbell, and the whole was erected from the designs and under the superintendence of Messrs. T. K. Green & Son, architects.

No. 321, STRAND.

THESE premises are now being rebuilt for an old-established business of confectioner, &c.

The basement contains bakeries with three ovens, bread-lift, flour and other stores, ice-well, coal-cellars, &c. The bakeries are to be paved with cement concrete, the walls lined with glazed bricks, the lower 3 ft., in brown glazed bricks, and the upper white. The ceilings are to be in Keene's cement, each bake-house to have a large air-shaft with gas-tight ventilators. On the ground-floor will be the shop, luncheon-room, kitchen, and offices, the men in the rear. There is to be a refreshment-room on the first floor, with a water-closet, lavatory, and lift. The upper

part of the house will be occupied privately by the proprietress, and contains dining and drawing rooms, seven bedrooms, bath-lavatory and water-closet. There will be a dinner-lift from the second floor to the first floor, on which is the private kitchen, ventilated and lighted by large skylight, with scull, larder, coals, &c. The back part of building will be roofed in by a fireproof flat roof with asphalt, enclosed by iron railings; convenience of shaking mats, &c., and to serve as a fire-escape.

The front will be built of concrete mould blocks, coloured red by the incorporation of pounded red bricks, the ornaments being cast with the blocks.

The tender of Messrs. Ashby Bros. for 32 was accepted for the erection of the building. The quantities were by Messrs. Batterbury, Maxley, 29, John-street, Bedford-row, V. The architect is Mr. T. E. Knightley.

DESIGN FOR A BLOCK OF THREE HOUSES.

THIS design has gained for its author, F. M. Simpson, the R.A. travelling students at the last distribution of prizes at the Academy, as already mentioned by us (p. 755, vol. xlv). Mr. Simpson has shown much spirit and freedom in his varied treatment of the separate houses, though, when regarded as a block of three, there is perhaps not quite sufficient unity and connexion in the design. It looks rather like the commencement of a series which might be indefinitely continued. The separate buildings shown to a larger scale is effectively and consistently treated in the main. As a matter of detail, we should object to the manner in which the rather oddly-shaped crockets (if they may be so called) are placed on the gable coping. They look too much as if liable to be easily knocked off. Such features should appear rather to grow from the coping than to be stuck on to it, as these appear.

In regard to the plan, Mr. Simpson takes exception to a sentence in our former notice that the newly-arrived guests would have to deposit their hats and cloaks. He points out that there is a hat closet adjoining the entrance (this is shown in only one of the three plans) and we presume he regards the vestibule as "neutral ground" for guests who have not yet prepared themselves for the "reception-room." The position of the door between this and the vestibule is not the best that could be desired. On the whole, however, the plan makes good use of the available space.

IMPROVEMENTS AT THE WIMBLEDOY SEWAGE FARM.

THE Wimbledon sewage farm has recently been extended and improved to a considerable extent, so much so that in giving judgment recently in the action against the Local Board, Mr. Justice Denman observed, that with the appliances now possessed by the Board the need be no nuisance in future, if proper care be exercised in disposing of the sewage. The most important improvement, however, has been the construction of filter-presses for the reduction of the sludge. This most offensive material, used formerly to run into drying-pits, which necessarily were situated close to the main road and also close to habitations. In hot weather, therefore, complaints of foul smells were often heard. In March, 1884, the surveyor to the Board, Mr. Santo Crimp, recommended the adoption of filter presses for the treatment of the sludge. His plans have been carried out at a cost of 1,600*l.*, and the presses are now in successful operation. The daily production of wet sludge, with 90 per cent. of moisture, amounts to about 16 tons, and this is at once reduced to 3½ tons of sludge cake, containing 50 per cent. of moisture, and in an inoffensive condition. The working expenses amount to about 3s. 9d. per ton of cake, or 9d. per ton of wet sludge. The old sludge-pits, which formerly occupied nearly an acre of ground, are being rapidly filled in. The presses and other machinery are by Johnson & Co., of Stratford. The two machines at Wimbledon have each twenty-four chambers and are fully capable of dealing with 40 tons of wet sludge per working-day. We hear that the whole arrangement has proved to be most satisfactory so far.

The contractors for all the works were Messrs. Cooke & Co., of Battersea.

WEST LONDON SCHOOL OF ART.

The annual distribution of prizes to the students of this school took place on the 30th in the Steinway Hall, Lower Seymour-street, Mr. George A. Thrupp in the chair. After an introductory address from the Chairman, Mr. John S. Rawle, the Head Master, read an annual report, from which it appears that, during the year 1884, 420 students attended the school. The Government grant on results was £1,858 7s. 7d., which is the highest sum ever yet received by this school. In April last the school was taken up to South Kensington, for examination, an unprecedented number of 5,700 works, which had been executed during the previous twelve months. In the National Art Competition the school gained one Gold Medal, five Bronze Medals, and thirteen Queen's Prizes; total nineteen awards. The Gold Medal was gained by Alfred C. Weatherstone, for a set of designs for decorative treatment of a room. The remaining awards were for studies from the life, the antique, modelling, design, &c. The school obtained nearly 26 per cent. of the entire number of national awards, gained by the nineteen Metropolitan District Schools of Art in London. In the highest, or Government Third-class Examinations in drawing from the living, design, anatomy, and still-life painting, the school obtained ten successes, including two Queen's Prizes. In the Government Second-class Examinations the school had 139 successes, including sixty-two prizes. Thirty-one students also obtained full second-grade certificates, for having passed in all the subjects of the second-grade. The school also obtained eight Government Free Studentships; and in the Entrance Examinations, in building construction, there were four candidates, all of whom were successful.* A National Scholarship, worth £21 a annum, which may be increased in value to £40, was gained by W. Kellock Brown. He is now devoting his whole time, at South Kensington, to the study of modelling as applied to decorative purposes. He was the only London student, among fifteen candidates, who succeeded in obtaining one of the five vacant scholarships. In the Owen Jones Competition, the Council of the Society of Arts awarded a gold medal and a bronze medal to Alfred C. Weatherstone, for his designs, which obtained the Gold Medal at South Kensington; and the travelling studentship, of the value of 50*l.*, so generously conferred for competition in this school by Mr. George Menace-Smith, through the Painters' Company of London, has also been gained by Alfred Weatherstone, who is now in Italy, engaged in the study of decorative art. The West London Etching Club, composed of past and present students of the school, and numbering ninety members, continues to make satisfactory progress. The Royal Institute of Painters in Water Colours has established schools, to be conducted on a similar principle to those of the Royal Academy, but for the teaching of water-colour painting only. Five out of the twenty-five successful candidates for admission were West London students. In conclusion, Mr. Rawle expresses his consciousness that much of the success of the school is due to the friendly and constant support he has always received from his colleagues, especial mention being made of Mr. Thompson, for his assistance in the general work of the school, and of Mr. Townroe and Mr. Wilson.

Before presenting the prizes, Mr. Owen Roberts, F.S.A., addressed a few words to the students, expressing the hope that the time was not at hand when drawing would be taught in connexion with the three Rs. in all our elementary schools. Such was the case in France, and several members of the School Board for London were determined to cultivate it in this country. Reviewing his twenty-five years' anxiety with educational measures, he said he was surprised to note the great progress which our schools had made. At the end of the last century the art productions of England received due check, owing to the Peninsular wars. At the commencement of the reign of Victoria came a period of renaissance, but it was not till the Exhibition of 1851, through the exertions of the Prince Consort, that the proper position of schools of art was duly recognised. Since then there had been an annual progress, mainly due to the art influence of South Kensington, and

of this the West London School was one of the most conspicuous instances.

Mr. J. S. Rawle, F.S.A., the Head Master, in the course of some remarks upon architecture, sculpture, &c., said we saw how the architect, with the rough and uncouth stones from the quarry, erected edifices which, under the inspiration of his genius, oft became the pride and glory of his time, and which proved to after ages "a thing of beauty" and "a joy for ever." Again, the sculptor had before him a rude, shapeless piece of marble, which by his genius he converted into an almost living being, and which aroused the admiration of men thousands of years after the sculptor had rested in his tomb. The painter, again, with a piece of canvas and a few simple colours, could create a scene of the most vivid beauty; and, with powers such as these, who could refuse to admit that artists were priests and priestesses in the temple of humanity?

Votes of thanks were passed to the headmaster and Mr. Owen Roberts for distributing the prizes, and to the chairman, and the meeting terminated with the announcement that the students' works would be on exhibition at the school premises, 155, Great Titchfield-street, on Friday and Saturday, February 6th and 7th.

SOCIETY OF ENGINEERS.

PRESIDENT'S ADDRESS.

The first ordinary meeting, for the present year, of the members of the Society of Engineers was held on Monday evening last, at the Town-hall, Westminster.

The statement of accounts for 1884 was read, after which the President for the past year, Mr. Arthur Rigg, presented the premiums of books awarded for papers read during that year. These were to Mr. A. C. Engert, for his paper on "Defects in Steam Boilers and their Remedy," and to Mr. J. Corry Fell, for his paper on "Hard v. Soft Water for Manufacturing Purposes."

Mr. Charles Gandon, M.Inst. C.E., &c., the President for 1885, then delivered his inaugural address. After referring to the papers read at the meetings of the society during the last session, and the summer visits to the Midland Railway Company's Locomotive Works at Derby, the South Metropolitan Gas Company's new Works at East Greenwich, and Messrs. Siemens Brothers' Works at Charlton, the President reviewed the present position of the profession, especially referring to the increasing use of steel in place of iron for structural and other purposes, as well as for heavy ordnance and armour-plating. Mention was then made of the Severn and Mersey Tunnels, the completion of the Inner Circle of the Metropolitan Railway, the Forth and Tay Bridges, and also of improvements in the steam engine. The address then dealt with water engineering, and pointed out that quantity is not the only essential of a good water-supply, but that quality and pressure are also important elements. Rivers are, as a rule, objectionable as a source of supply, on account of the danger of pollution, unless the supply can be drawn from or near the source. Water from the chalk formation, such as underlies London, is preferable, although recent authorities have stated that such water is not always free from pollution. One important advantage of a good supply of water at high pressure is the protection it affords against fire; high-level reservoirs supplying by gravitation being preferred for this. Reference was also made to the assessment of water-rates on the rental value of house property, and its merits considered as compared with sale by measure, which would necessitate an expensive system of meters, increasing the cost of distribution and collection, and inducing the poor to exercise undue economy in the use of water. On the vexed question of the monopoly of gas and water supply, it was contended that it is doubtful whether any advantage arises from its being undertaken by local authorities. Water being a necessary of life, there is, perhaps, less to be argued against its being so supplied; but in the case of gas, it was thought there was no more reason for the supply being in the hands of local authorities, than for such bodies to acquire railways, or to undertake the exclusive supply of bread or meat. Some statistics were then given of the capital employed in the United Kingdom on gas supply, as well as the consumption of coal, the quantity of gas supplied,

and the rental derived from it. Great economies have been effected in the details of gas manufacture, resulting in considerable reductions in prices, although great differences still exist between various gas undertakings, both in cost of plant and manufacture. Sanitary engineering was referred to as another branch of the profession belonging comparatively to recent times, and, if taken to comprise sewerage, drainage, and the warming and ventilating of buildings, still requiring much attention; the state of the Thames and other large rivers being a reflection on the failure to utilise what should be a valuable fertiliser, instead of allowing it to become a nuisance. It was pointed out how frequently ventilation was a failure in large buildings, while in ordinary dwellings the defects were still more apparent. Defects also exist in house drainage in most cases, and no general improvement can be looked for without legislative supervision. The pollution of air in towns was also alluded to, as the engineer may largely aid in preventing it by the abatement of smoke. In this connexion the experiments made by Dr. H. J. Russell on the atmosphere of London were referred to, as including other evils besides those arising from visible impurities of the air. Mr. Lowthian Bell's estimates of the coal output of Great Britain in 1882 were quoted to show that, with the exception of iron and steel works, the greatest consumption of coal is for domestic purposes, and it is, consequently, in this direction that reform is most urgently needed. The last subject touched upon by the address was electrical engineering, both in its application to telegraphy and its further development to electric lighting. That the electric light is at present somewhat under a cloud is due to unprincipled speculations of company-mongers and inventors, but there can be no doubt that there is a vast field for its use. In referring to telegraphy, attention was called to the great increase in the speed of transmission, and it was said that, by a system in use in Canada, as many as three thousand words had been transmitted per minute.

ARCHITECTURAL SOCIETIES.

Birmingham Architectural Association.—The fourth ordinary meeting of the current session was held at Queen's College on Tuesday evening last. The Vice-President, Mr. W. H. Kendrick, was in the chair. Mr. J. Goodman was elected as an ordinary member. The secretary read a letter he had received from Mr. A. M. Mowbray concerning "an Architectural Diploma," and asking the assistance of the Birmingham Architectural Association in endeavouring to obtain a compulsory examination for architects, and embodying the same in the new charter of the Royal Institute of British Architects. A paper was then read by Mr. Victor Scruton (hon. sec.) on the "Necessity and Use of Architectural Associations," in which the lecturer dealt somewhat fully with the systems of architectural education abroad as compared with those of our own country. A discussion ensued, in which the Vice-President remarked that he intended dealing with several of the points treated by Mr. Scruton in his annual address to be given on February 17th. A hearty vote of thanks, proposed by Mr. H. H. McConnal, and seconded by Mr. W. G. Mantle, was accorded to the author for his paper.

Manchester Architectural Association.—At a meeting held at the Old Town Hall, Manchester, on the 3rd inst., Mr. J. Spencer Hodgson, in the chair, Mr. T. L. Worthington read a paper on "Aspects of Old Manchester," illustrated by drawings, sketches, and engravings. Having described the extent and aspects of Manchester during the British, Roman, and Saxon rules, he depicted and commented upon the appearance and progress of the town during the 11th, 12th, 13th, 14th, 15th, and 16th centuries, and gave a history of the Cathedral Church and Cbatham College. Speaking of Manchester in the seventeenth century he described the few remnants of the old half-timbered houses of that time. A discussion followed, in which Messrs. Chadwick, Hodgson, Mee, Harrison, and Woodhouse took part.

Edinburgh Architectural Association.—At the meeting of this Association on the 26th ult., Mr. Henry H. Gunn delivered an interesting lecture on "Geology in its Relation to Architecture." Mr. J. Washington Brown, President of the Association, was in the chair.

* Their names are Alexander Ford and Frederick A. Mills, who take first-class certificates; and Frank Mesler and John F. Wetherell, second-class certificates.

NATIONAL ASSOCIATION OF MASTER BUILDERS.

The National Association of Master Builders of Great Britain held its half-yearly meeting on the 28th ult., at the Saracen's Head Hotel, Lincoln, and local Associations at London, Manchester and Salford, Liverpool, Birmingham, Bristol, Bradford, Hull, Lancaster, Doncaster, Bolton, Walsall, Northampton, Lincoln, Warrington, Ashton-under-Lyne, and Stalybridge, were represented.

The report and accounts for the past half-year were read and adopted. Mr. W. H. Cowlin, junr., of Manchester, and Mr. J. Howard Colls, of London, were elected Vice-Presidents. Mr. Stanley G. Bird, of London, was re-elected Vice-President, Mr. J. C. White was re-elected Treasurer, and Mr. Joseph Stevenson Jones, of Liverpool, was elected Hon. Auditor and Representatives of the local Associations of Birmingham, Bolton, Bradford, Edinburgh, Huddersfield, Hull, Lancaster, Leeds, Lincoln, Liverpool, London, Manchester and Salford, Northampton, Nottingham, St. Helen's, Wigan, and Wolverhampton.

The Chairman explained the various clauses in the form of contract suggested by the special committee, to be laid before the Committee of the Royal Institute of British Architects, and it was resolved to leave the matter in the hands of the special committee appointed.

The Secretary was instructed to obtain statistics from the members of the local Association, as to the fires they have had upon their premises and buildings in course of erection, and what damage has been done during the last five years.

It was resolved that the best thanks of the Association be embodied in an illuminated address, and presented to Mr. Stanley G. Bird, for his valuable services as President during the last four years.

The Association decided to hold its next half-yearly meeting at Bristol.

COMPETITIONS.

Independent Church, Stand.—Four architects having been invited to submit designs for the new Stand Independent Church, near Manchester, the committee have selected that sent in by Mr. J. P. Pritchett, of Darlington, who is to carry it out at once.

Ventnor Pier.—The committee appointed to examine the twenty-seven plans sent in, in the first place selected the seven sent by the following gentlemen, viz. Messrs. J. Forrest Branton, F. E. Robinson, E. G. Stead and J. J. Potts (joint design), H. O. Baldry, H. E. Wallis, G. N. Abernethy, and Dawson & Fyson. These were again reduced to three, viz., those by Mr. G. N. Abernethy, C.E., Delahay-street, Westminster, Mr. F. E. Robinson, A.M.I.C.E., 7, Westminster Chambers, Victoria-street, S.W., and Mr. H. E. Wallis, M.I.C.E., 9, Bridge-street, Westminster. Eventually Mr. Wallis's design was selected, and the Board have retained him to carry out the works.

ARCHITECTS' COMMISSION.

BELL v. MOSS.

The plaintiff in this action, which was tried before Mr. Justice Day and a special jury at the Manchester Assizes on the 28th ult., was Mr. Asahel P. Bell, an architect practising his profession in Manchester. He sued the Rev. R. Moss, D.D., Vicar of Christ Church, Blackburn, and the owner of certain property at Bowdon, to recover 157l. 2s. balance of an account for professional services, damages for a wrongful termination of a contract, and, in the alternative, to recover payment for work and labour done.

Mr. Addison, Q.C., and Mr. Sutton appeared for the plaintiff, and Mr. Ambrose, Q.C., and Mr. Rotch, for the defendant, who set up a counter-claim for moneys which he alleged the plaintiff had received on his behalf and failed to account for.

Mr. Addison, in opening the case for the plaintiff, said it was not disputed that the plaintiff did the work for which he charged, but the defendant sought to defeat the claim by raising a series of the most unseemly defences which were ever laid before a jury. First of all he charged the plaintiff with fraud, but some of these charges were subsequently withdrawn and others not persisted in, but he still put forward a number of sordid and preposterous claims in order to defeat Mr. Bell's just claim.

The jury returned a verdict for the plaintiff upon the claim and counter-claim; damages, 175l.

The Judge refused an application from Mr. Rotch to withhold payment of costs.

MITCHELL V. FIELDING.

This was an action (tried at the Manchester Assizes on the 30th ult., before Mr. Justice Day and a common jury) to recover commission for work and services rendered to the defendants in connexion with the erection of the Winter Gardens, Blackpool.

Mr. Bradbury was for the plaintiff; Mr. Yates for the defendants.

Mr. Bradbury said the plaintiff was an architect, and designed the Blackpool Winter Gardens. The defendants were the contractors for the masonry work, and carried on business in Blackpool. Two contracts were entered into by them,—one for the basement, and one for the story above, and it was with regard to the second contract that the present action related. They were to have 3,939l. for the work, with the usual clause as to additions and reductions. The work was completed, and the plaintiff took the measurements. By custom he was entitled to 5 per cent. commission on architect's work, and, if he measured and adjusted the accounts, to a further commission of 1 1/2 per cent. Two and a half per cent. was the usual charge, and was so in this case, one half being charged to the employer and a half to the contractor. The defendants had paid the charge on the first contract without demur. There had been additions and deductions in the contract, and it was in the measuring up of these that the present action arose. In cross-examination plaintiff said his agreement with the company, which specified "adjustment of accounts," did not include the measurement of defendants' work.

Mr. James Murgatroyd, architect, Manchester, said an architect who measured up variations and additions on a contract charged 2 1/2 per cent., which was borne equally by the builder and proprietor.

Mr. George Clay, builder, Manchester, corroborated the statement as to the custom of dividing the 2 1/2 per cent. commission for measuring up variations between the contractor and the proprietor, though, he said, it was a great hardship upon a contractor, and the cost ought to be borne by the employer.

Mr. Dawes, architect, Manchester, gave like testimony, and further corroborative evidence was given.

Mr. Yates, for the defendants, said the Winter Gardens were completed in 1875. The defendants' original contract was 5,900l. Deductions and additions were made to it, amounting to a considerable sum, and he contended that the alleged custom was absurd, and further, that it was not the universal custom.

Mr. Fielding, one of the defendants, said he had never done work outside the Blackpool district, and denied that there was such a custom as alleged by plaintiff and his witnesses. His firm assisted plaintiff in the measurement of the work, but he had never heard of such a custom.

Mr. Benjamin Sykes, architect, Preston, said there was no such universal custom.

The learned Judge said the material question was whether the custom as alleged by the plaintiff and his witnesses, had been made out. Was it plaintiff employed by the defendants? If so, then it would certainly have to pay him. There was conflicting testimony as to the custom, upon which the jury would have to decide.

The jury gave a verdict for 1 1/2 per cent. on alterations amounting to 488l.

Judgment for plaintiff for 5l.

WESTMINSTER HALL.

Sir,—I have read Mr. Fergusson's letter in your last number [p. 181] with all the respect due to any communication coming from him.

If the problem were simply how best to treat the west front of Westminster Hall on the assumption that it was henceforth to be exposed to view, I think Mr. Fergusson's proposed treatment more satisfactory than that proposed by Mr. Pearson, but I strongly insist that this is not the question.

Any treatment of Westminster Hall of the severe simplicity which is demanded must be incongruous with the style of the great building of which it now forms a part, and therefore in my opinion it should not be exposed to view. Mr. Fergusson is convinced, as most people are who have studied the subject, that it was never intended to be so seen, and was, in fact, not so seen. Thus, the original design and its actual condition for many years thoroughly justify my father's scheme, to interpose a structure between it and St. Margaret's-street which should be in harmony with his great work, and enable us to obtain a land front as river front, and as fine architecturally, as his river front.

Mr. Fergusson gives, as he says, not a studied design, but only a suggestive diagram; and he does not touch at all the important question

how such diagram design would take up St. Stephen's porch, nor the still more important one of how to deal with the space at the north adjacent to the entrance front of Westminster Hall as seen from New Palace-yard.

He terms my father's design "too grand and too costly"; quite overlooking the fact (a) That my father's plan would utilise a valuable building area now wasted; (b) That the interest on 500,000l., which my father's complete design (including enclosing New Palace-yard with buildings) would cost, would at the per cent. be only 15,000l. a year, and would accommodate public departments now inconveniently located in private houses, for which rental estimated at about 40,000l. a year paid; so that a public saving of 25,000l. a year would appear to result, which, in these economical days, is surely a matter worthy of the fullest consideration, to say nothing of the convenience of having these departments concentrated and under one control instead of being dispersed as at present.

Without for one moment denying the interest and importance of such an historical building as Westminster Hall, I do think that it is fairly urged that the importance of the larger and grander building of the New Palace at Westminster claims the primary consideration, and that its due completion (as its architect would have had it done) is a matter which the English public may be expected to take more interest than the precise mode of restoration or alteration of one side of Westminster Hall considered by itself.

The drawing in the *Builder* of the 17th January is evidence of what would be lost to the world unless the present opportunity were taken to fittingly complete this important building, of which, by common consent, the nineteenth century may well be proud, and in which nature take most intense interest.

CHARLES BARRY.

Sir,—It seems to be agreed on all sides that the "west front" (or flank) of Westminster Hall was never intended to be seen, except from some small courtyards, and Sir Charles Barry, in his design for the completion of the Houses of Parliament, published in your issue of January 24th, conceals this flank.

Now, surely, in face of the two facts, that the original builders of the Hall, and the architect of the modern palace, both agreed in this treatment, there ought to be no question about the matter. They were certainly the best judges as to how their works ought to be seen. The original builders of the Hall never contemplated this portion of the Hall being seen, and Sir Charles Barry considered the complete "land front" to his building as a necessary portion of his design, yet the proposed schemes for the "Restoration of Westminster Hall" simply ignore both the original builders of the Hall and Sir Charles Barry.

I do not think that any one has yet called attention to the fact that the Great Hall at the Hague, which bears such a remarkable resemblance to that of Westminster, has always had its flanks concealed by buildings. The same treatment may be noticed at the "Ladisscheschen saal" in the Palace of the Hradschine in Prague, and has been repeated in the case of the Grand Hall of the New Law Courts in London. The argument that Sir Charles Barry's design ought to be set aside "because of its expense" should not be allowed to pass, because there is no necessity for carrying it out just at present; and, however much we may be wedded to economical schemes, we ought not to condemn future ages to an incomplete or mutilated design. Why could not Westminster Hall be simply "repaired" without the addition of new features? and, if extra accommodation be necessary, why could not as much of Sir Charles Barry's design be carried out as is absolutely required, so as to leave to future ages the possibility of completing the noblest building of the nineteenth century?

H. W. BREWER.

Building Partnership.—Mr. William Brass, the well-known builder, of 47, Old-street, St. Luke's, and 18, Silver-street, Wood-street, City, has taken his son, Mr. William Brass, junr., who for several years has taken an active part in the management of the business, into partnership, and henceforth the business will be carried on in the name of "William Brass & Son."

THE DOME OF ST. PAUL'S.

Sir,—Having received the accompanying letter, I called to see the engraving, which Mr. Blake describes it. All I can remark on subject is that it is so much the worse for it. It records, as I take it, with Thorne's paintings, and the architectural features, these are only painted ones.

JOHN P. SEDDON.

"New River Office, Clerkenwell, E.C., January 30th, 1885.

John P. Seddon, esq., Dear Sir,—In this day's issue of the Builder, with reference to your remarks at the Royal Institute of British Architects, on the decoration of the dome of St. Paul's, I notice the following:—"Mr. Seddon . . . contended that all the signs yet brought before the public, being based on the subdivision of the dome by vertical ribs and circular panels. . . were wrong in principle, and that the panels themselves inadmissible, disturbed the serenity of the surface of the dome, which when not broken up; and in the case of vertical ribs, they introduced a Gothic aspiring tendency, instead of the repose appropriate to the Classic architecture of St. Paul's, &c.

Now I have in my possession an engraving of an entire section (north to south) of St. Paul's, bearing the following inscription:—"To his Royal Highness George, Prince of Wales, his section of St. Paul's Cathedral, decorated exactly to the original intention of Sir Christopher Wren, is with all humility inscribed by his Royal Highness's most devoted and most obedient humble servants,

SAM'L WALE, } Proprietors. JNO. GWIN, }

(Size of sheet, 34 in. by 25 in.) Published May 27th, 1755.

This design shows the dome to be divided into eight panels, by double pilasters, each pair of which is divided by a recess, and surmounted by an abuttable; these carry a series of arches round the upper part of the dome. The recesses between the pilasters are filled in with a conventional ornament, while the panels themselves are decorated with paintings of various subjects. I cannot reconcile the existence of this engraving with your remarks, as the design appears to me to combine the very two defects you most strongly denounce, and of which you hold Wren altogether innocent. It has occurred to me that you might possibly like to see the engraving; if so, and you will favour me with a call, I shall be most happy to show it you.

I am, dear Sir, yours faithfully, WALTER EDWARD BLAKE, Surveyor, New River Company."

COMPETITIONS COMMITTEE, R.I.B.A. BOROUGH OF CROYDON STREET IMPROVEMENTS COMPETITION.

Sir,—We have been asked by some architects who signed the agreement not to compete unless an assessor was appointed, as to whether the above competition came under the terms of that agreement.

After careful consideration of the published conditions, we are of opinion that it is architectural in character, and that architects who signed the said agreement cannot, consistently with the terms of it, compete in this one, as we are officially informed that no assessor will be appointed.

(Signed) HENRY CURREY, Chairman. COLE A. ADAMS } Hon. Secs. ASTON WEBB }

FIREPROOF CLOSING OF OPENINGS IN PARTY WALLS.

Sir,—I have only just been able to read Mr. White's paper, and the discussion thereon [p. 14, ante]. Permit me to state that in 1865, when I further altered and enlarged No. 119, Cannon-street, E.C. (a building consisting about 300 offices), I adopted a double revolving wrought-iron shutters, in wrought-iron rebated frames, to the corridors on each floor. These shutters are placed above the openings, and by a few turns of a lever handle they are both immediately pulled down and closed at the same time.

Folding doors are frequently in the way, and unfortunately sliding doors will not always slide, and require too many parts.

I forgot who made these shutters, but Messrs. Bywaters, of King-street, Regent-street, carried out the additions under my directions. I may add all the floors are all fireproof.

It is not much use, however, to put any kind of doors, unless they are frequently examined and kept in working order, and the insurance companies should insert a clause in their policies that periodical inspection will be made by their surveyor, and if the doors are not found in a proper state, the insurer is to pay the surveyor's fee, and to at once remedy the defect. PHILIP B. LEE.

SEWER VENTILATION.

Sir,—In reply to "Laicus" [p. 182, ante], I think he will find this matter discussed in the back pages of the Builder. If the sewer blow-off pipes are placed high enough, I think it is safer to have the sewer air above the houses than in the middle of the streets and close to the edge of the pavements, below our noses and mouths. In many cases it would be just as easy or easier for the sewer air to blow in at open windows from the gutter gratings as from the mouth of the proposed pipes. Generally speaking it should not be difficult to so put up the sewer blow-off pipes as that the sewer air could not easily get in through windows; while at a high level the disease germs have greater chance of being carried away by the wind. The pipes should be of iron, and at least 1/2 in. thick, and red-leaded or coated inside to prevent rusting up, otherwise they would be useless in a short time. I have advocated the high-level system of sewer ventilation for many years. W. F. BUCHAN.

CARELESS NOMENCLATURE.

Sir,—In a description of some Northampton churches published in Church Bells, the spire of St. Sepulchre's is described as a "pyramidal spire," and the roof of the round nave is called a "cupola." The spire is hexagonal, and the roof of the nave is similar to those on many of our cathedral chapter-houses.

The description appears to me to be neither lucid nor architecturally correct. The term "pyramidal" is usually applied to short spires with four sides, and then they are generally called a "capping." All spires may, of course, be defined as pyramids, but it is not usual thus to describe them. A cupola must surely be curvilinear. N. M. Medway, Feb. 3, 1885.

NON-ACCEPTANCE OF LOWEST TENDER.

Sir,—"Fairplay" [p. 183, ante] may be glad to know that he has a case for damages if he has been invited to tender for a work and another tender, higher than his, has been accepted. I cannot quote the case, for it was tried many years ago. In several cases where this has been attempted by a committee, I have refused to sanction it, offering rather to throw up the work. I should not expect to get respectable men to tender for my work if this were done. But committees often are not ashamed of doing what private individuals would be afraid to attempt.

WILLIAM WHITE, F.S.A.

DRAWINGS IN LAMBETH PALACE LIBRARY.

Sir,—As a matter of interest to architects, I should like to state that the working drawings of Lambeth Palace made by Mr. Blore are preserved in the Archiepiscopal Library, which is open daily, Saturdays excepted. There are also two fine water-colours by Paul Sandby, R.A., of the old gates of Canterbury, among the Kentish collection of prints and drawings to which notice is invited.

As an example of the unexpected whereabouts of art, there is here, in the margin of MS. 1166, a pen-and-ink sketch of the west end of St. Paul's Cathedral in the fourteenth century.

S. W. KERSHAW, F.S.A.

PAINT ON FRONT DOOR.

Sir,—Did "H. G." [p. 183] try the usual plan of covering the places where the gum runs with gold leaf? If so, and this did not answer, I should recommend covering the panels with tinfoil. It should be put on with a mixture of white-lead and oil run through a painter's sieve to take away all lumps, &c. I have seen panels of front doors formed with rubbed slate, 1/2 in. thick.

On referring to "H. G.'s" previous letter [p. 876, vol. xviii.], I see he speaks of the sun bringing up blisters. White paint blisters less than any.

Of course, "H. G." is aware that one coat of paint should not be put upon another till the underneath coat is quite hard. Any paint would blister if so. Doors which I have found blister when painted green, even although the greatest care was taken in the work, have not blistered when painted with good white-lead and oil. C. F. M.

Sir,—In reply to "H. G." the following is the method in such cases:—Burn off all paint, then heat your salamander or hot iron, and burn out the heart of the knots to a depth of 1/2 in. below the surface of the door, until you have extracted all the resinous matter, knot, and fill up as usual, with spirit stopping, keeping all coats sharp to finish. S. W.

Sir,—I would advise "H. G." to give the door a coating of gold leaf (if he does not mind the expense). I have used this with success when other plans have failed. THOMAS DUCKETT.

* Unquestionably.—Ed.

CHURCH-BUILDING NEWS.

Mistley.—The chancel of St. Mary's Church, Mistley, Essex, has been reopened, after decoration. The roof is divided into panels by curved ribs. These panels are richly gilded, and bear on the gold surface various sacred emblems, painted in a warm chocolate tint, while the ribs and cornice are coloured to match. The space beneath the windows is covered with a diapered pattern in olive-green, surmounted by a broad gold band, on which is inscribed in red letters,—"Sanctus, Sanctus, Sanctus, Dominus Deus Sabaoth," room being left for a reredos, which will complete the whole. The walls of the chancel above the string-course running under the windows are painted with a subdued red tint, and ornamented with conventional foliage. Five of the seven lancet windows with which the walls of the apse are pierced are filled with stained glass by Messrs. Clayton & Bell, two having been recently inserted in memory of Mr. Thomas G. Kensit and his wife. In the nave, the space over the chancel arch, which in so many churches is now left bare since the times when the lion and unicorn disappeared, is filled with figures representing angels, with instruments of music, rising towards the Lamb of God, encircled with the emblematical vesica over the crown of the arch. These are on a dull blue ground. The spandrel spaces between the arches are ornamented with twelve medallions, bearing busts of the twelve Apostles, each accompanied by his appropriate emblem. The large window at the west end is intended ere long to be filled with stained glass, a design having been prepared for the same by Messrs. Clayton & Bell. The decorative work has been executed by Messrs. Simpson & Sons, St. Martin's-lane, London, from the designs and under the direction of Messrs. Wadmore & Baker, architects, of London. A brass eagle has been presented to the church by members of the Kensit and Norman families. It was supplied by Messrs. Jones & Willis. The cost of the decoration of the church has been defrayed by the Rev. C. F. Norman.

Moseley.—A font has been presented to the new church of St. Agnes, Moseley, near Birmingham. It is of Caen stone, with quatrefoil marble columns, the carving of the capitals and that round the bowl being in the Early English style, in harmony with the architecture of the church. The work has been carried out by Messrs. Jones & Willis, of Birmingham and London, who also supplied the choir stalls, chancel rails, and gas standards.

Ventilation Abolished Altogether.—Mr. Baron Huddleston is trying a great sanitary experiment at the Royal Courts of Justice. It is one which will interest everybody, and we hope to be duly kept informed of the results obtained; indeed, we shall look for information with considerable impatience. The late Lord Derby is reported to have said in reference to some wine recommended to him as a preventive against the gout, that he preferred that disease to the beverage that promised immunity. Mr. Baron Huddleston prefers to be unventilated rather than have cool air blown on him from every quarter under pretence of purifying the chamber in which he is doomed to sit. The engineer is enjoined, on peril of contempt of court, not to ventilate Mr. Baron Huddleston's court any more. It will be curious to note whether the strictly local death-rate of that particular court rises or falls. We should like to receive a weekly bulletin of health and mortality, countersigned by the Judge himself. Will he oblige us? It is a pity the idea is not to be carried a little further, and that a portion of the Royal Courts of Justice cannot be freed from the nuisance of drains, artificial water-supply, artificial lighting appliances, and so on. At the Health Exhibition insanitary houses were exhibited for comparison with the sanitary buildings and appliances which the public were to be incited to emulate. In olden times wise men made their slaves drink to excess as a warning to their sons. It has, however, been left to Mr. Baron Huddleston to exhibit a court of law in the Royal Courts of Justice in which "ventilation is to be altogether abolished."—Lancet.

Royal Architectural Museum and School of Art.—The annual public distribution of medals and prizes will take place at the Museum on Monday, the 16th inst., when Mr. Philip R. Morris, A.R.A., will preside.

The Student's Column.

DESCRIPTIVE GEOMETRY.—I.

REPRESENTATION OF OBJECTS, INTERSECTION OF SURFACES, DELINEATION OF SHADOWS, STEREO-TOMY OR THE SETTING OUT OF MASONRY, CARPENTRY, AND JOINERS' WORK.

IN treating of this subject, our object is to endeavour to open the eyes of architectural students to the great advantages they would gain by a scientific knowledge of the system of drawing they use. There are buildings for which designs, harmonious in every part, have been mutilated by architects or builders not possessing the knowledge to set out the work thereof.

When a man is quite insensible to beauty of form and is utterly ignorant of anything beyond the everyday routine of building with bricks and mortar, he is called a *practical man*. An experience a friend of ours had many years ago will show you which is really the more practical: science or ignorance.

"I had for the first time," said he, "entered an architect's office after finishing my studies at a foreign polytechnic school. I was crammed with many sciences, including differential and integral calculus, but I had never seen a four-panel door put together. My principal was completing a large hall with a gallery running round it according to the section here given (Fig. 1), and having in plan three straight lines connected by quadrants. Our builder, emphatically a *practical man*, came to the office one day in an agony of despair. He had succeeded, without trouble, in nailing the boards on the straight parts of the gallery, but when he came to the quadrants he found it utterly impossible to get the boards to fit in. He had been trying to get them down by bending them with steam and powerful presses for more than three days, but all to no purpose. Time was pressing, the hall was wanted in a great hurry; what should he do? My principal was absent on business for two or three weeks, and it was not possible to take upon ourselves to change such an important feature of the design as replacing the quadrants by straight pieces; besides, the floor and the ribs of the gallery were all fixed. Happily I saw at once where the shoe pinched. In the quadrant each board was evidently but a zone or ring of a cone, such as the one which has its apex at *a'*, very much like a lamp-shade turned upside down. I had only to develop for each board the cone to which it belonged and I could draw the pattern of the boards. I did so; the builder cut out his planks according to my drawings, and they fell in their places without the slightest effort. Thus the raw student pulled the practical man out of the mire."

It would be absurd to conclude from this story that science can dispense with practical experience, but we mean to say that science renders the acquirement of practical knowledge much easier and much surer. The well-trained student has his eyes donly open to everything he sees, either in his master's office or on the works; he critically examines the parts of the structure, and sees whether they are justified by the requirements or whether they are only the outcome of routine, and by the intelligent questions he will put to his master he will learn more in a few days than the ordinary run of pupils in a year. Besides, you must remember that if a builder or a workman can rest contented with doing what he has seen done before, the architect is often called upon to solve new problems; *novens volens* he must invent, sometimes on the spur of the moment; this he can only do by applying general principles to each special case. Moreover, the architect must be able to set out the work in full-size details when the routine knowledge of the foreman proves insufficient, otherwise he may find himself obliged to cripple his designs to suit the workmen's ignorance, and his own.

In architecture, all questions of style, art, or taste are debatable, they rest on nothing absolute; but not so the sciences which bear on construction, and especially descriptive geometry, which must be learned somehow; for it is the method of drawing used by architects and engineers,—in fact, it is their language. The study of descriptive geometry should be the backbone of an architect's education: the more thoroughly he is trained in this science, the more thoroughly he will master his business, both as a constructor and an artist.

There is a kind of drawing we seldom employ in this country, or, at least, seldom well. We allude to *correctly-shaded drawings* such as the French architects make. Now, mathematically shaded drawings have the great *practical* advantage over line drawings of giving correctly the projections and recesses of a building,—a very important element of architecture. We make, it is true, perspective drawings, but we do not get thereby the exact amount in feet and inches

and find out at the same time, in a complete diagram, lines and points which have not been sought both in elevation and in plan. In this paper we only wish to introduce the subject to architectural students, and will, therefore, as much as possible any complicated problem, but try to solve only such questions as can arise in the practice of building.

We recommend students to draw on a scale the diagrams accompanying this paper.

of the projections and recesses; besides which, to make a *correct* perspective drawing is always a long job, whereas to shade a drawing with mathematical exactness is relatively a very short affair, and, therefore, can be done on the roughest sketches as well as on the finished drawings.

By far the easiest way of learning descriptive geometry is to follow the lessons of a lecturer; the problems are worked out before your eyes, and the word of the master accompanies his pencil. In a book it is very hard to keep the thread of the explanation in your mind

We shall define descriptive geometry as the methods of representing objects in space, and solving all questions appertaining thereto.

In maps and land surveys the objects are projected on to a horizontal picture-plane, and the height of each object above that plane is given in figures.

In architectural drawings, two picture-planes are used at right angles with one another: the one is horizontal, and is called the *plan*; the other is vertical, and is called the *elevation*.

DESCRIPTIVE GEOMETRY.

accompanying diagram (fig. 2) will give a clear notion of the convention on which architectural drawing is based.

A is a model of a house at a given scale: on a sheet of paper B we have its plan; on the vertical sheet C its elevation: such are the relative positions plans and elevations are assumed to occupy, although, for convenience sake, they are often drawn on the same sheet of paper; in which case the sheet C is supposed to have been turned down on the table, as shown in C.

We call ground line the line X Y, where the two picture-planes of plan and elevation meet. The plan of the point, m, is the foot m' of a perpendicular line drawn through the point m in the horizontal plane of the plan.

The elevation of the point m is the foot m'' of a perpendicular line drawn through the point m to the vertical plane of the elevation.

The plan of a line is the line formed by the plans of all the points of that line. The elevation of a line is the line formed by the elevations of all the points of that line.

A plane can be given by three of its points, or by two straight lines thereof intersecting one another, or by two parallel lines, or by one horizontal line belonging to the plane and by the inclination of the plane; that is, the angle which the plane forms with the horizontal picture plane or plan. For instance, the surface of a roof is determined by its ridge and hip, or by its ridge and eaves, or by its eaves and its inclination, given either by a section or in degrees. For working out many problems in setting out masonry and carpentry it is found convenient to determine planes by their traces, these are the lines where the planes intersect the two picture surfaces of elevation and plan.

Signs used in making Working Drawings.

Points are indicated in these diagrams by small letters; their projections are marked by the signs 'a' or 'b' tacked on, meaning horizontal or vertical projection, that is, plan or elevation of.

- m is a point in space.
m' is the plan of m.
m'' is the elevation of m.
A line is indicated by a capital letter taken from the beginning of the alphabet:—
B is a line in space.
B' is the plan of B.
B'' is the elevation of B.

Note.—If a right line be perpendicular to either of the picture planes, its projection on that plane, that is, either its elevation or its plan, will be only a point; but we shall still mark it by a capital letter, as the projection of a line. A straight line may be defined also by two of its points, say, m, n. We shall use either way, according to which is most convenient in each special case.

A plane is indicated by a capital letter taken from the end of the alphabet.

- P is a plane in space.
P' is the trace of P on the plan.
P'' is the trace of P on the elevation.

Full lines and dotted lines are used for both the lines given, and the results of the problem; the dotted lines are supposed to be hidden.

Lines formed of strokes refer only to the construction of the diagrams.

Lines formed of strokes and dots represent real lines in space, used as auxiliaries for the working out of the problem.

The ground-line is marked by L T for lines terre.

“Education in Industrial Art.”—This was the title of an interesting paper read by Mr. C. G. Leland at the meeting of the Society of Arts on Wednesday evening last. Mr. Leland, in the course of his lecture, said the principle on which he would base instruction was that a child not as yet capable of learning a trade, or a serious or severe branch of industry, could easily master all branches of decorative art, and that these formed a fit introduction to more practical work. In his native city of Philadelphia he laid his theory of industrial art education before the School Board, and ultimately he was given a suite of large, well-lighted rooms, properly furnished, and began with 150 children, which number soon increased to 200. There were two classes of 100 in each, to which every public grammar school had the privilege,—which was greatly prized,—of sending two or more pupils.

RECENT PATENTS.

ABSTRACTS OF SPECIFICATIONS.

1,371, Brick Moulds. J. T. Bower.
Plain sheet metal head-pieces are riveted to inside flanges of cast metal sides. The sides between the outside top and bottom flanges are cased with wood attached to screws, and are replaceable without taking the mould to pieces. Angle-iron may be used instead of the form of flanges prescribed, but this is not recommended.

1,379, Pumps. J. Keogh.
The object is to save power in pumping. From the upper part of the barrel of a force-pump is carried a vertical pipe, with an outlet preferably half-way between the discharge level and the suction level. On opposite sides of the piston there are valves, which are connected together, so that when one is open, the other is shut: hence at every stroke a small quantity of water passes to the upper side of the piston, and a column of water half the height of the discharge column is thereby retained to balance the pump.

1,736, Refractory Material for Lining Furnaces, &c. E. Brooke.
This material, intended for use in furnace linings, or for fire-bricks, blocks, tuyeres, pipes, &c., is made by mixing ganister, quartz, or other siliceous stone with fire-clay, boiled tar and oil, and water, in suitable proportions, and ground in a mortar-mill.

2,571, Valves. J. Pritchard.
This improvement is adapted for sluice and similar valves, and the object is to avoid the loss of time occupied in surfacing the faces of such valves and the liability of the same to be spoiled by grit. This is effected by the employment of leather or asbestos set into a groove in the valve seat. The lower edge of the valve face is hvelled to prevent it from cutting the packing.

3,006, Glazing Roofs, &c. G. Deacon.
The sheets of glass are laid upon flat astragals and are fixed by means of indiarubber washers tightened down by bolts of galvanised iron or brass. The washers are placed at the corners of the plates, which are rounded off to allow the bolts to pass. There is a drip channel down the centre of the astragals.

3,725, Ventilating Drains. G. Crapper.
An air-heating chamber is fixed in the flue at the back of the kitchen-range or other fireplace, and is connected by a pipe with the drain. A ventilating or upcast pipe is carried from the air-heating chamber through the flue and out above the eaves of the roof. The usual system of soil-pipes is retained, but the cowl at the top is dispensed with, the soil-pipe is utilised as a downcast pipe. The inspection-chamber of the syphon-trap between the drain and the sewer is fitted with a mica valve for inlet for fresh air. For ventilating apartments an air-heating chamber is connected by a pipe with the open air, and a constant stream of pure air is delivered by it into any apartment, the vitiated air passing out by an outlet-pipe.

394, Improvements in Bricks for Preventing Wet from Penetrating Walls. Wm. Parry.

This invention has for its object a brick that will shed the rain, and that will catch the percolating water, and deliver it to the outside. The front of the brick projects, and is cut at an angle, and is 1/4 in. longer than the bedding portion of the brick. A vertical cut or groove is made in each brick, forming together a tunnel or hole that intercepts and detours off the water. In laying the bricks, mortar is only used for the bedding portion of the bricks, but not for the outside joints. Any rain that falls on the brick will drain off, as it cannot run up the sloping part; any that falls on the vertical crack can get no farther than the cut or groove, but runs down that, and out into the sloping portion of the brick below. The front portion being from 1/4 in. to 1/2 in. long, and thicker than the body of the brick, will lie close together, even when there is a good bed of mortar between the bricks, while if the mortar squeezes into the grooves, and fills it, no harm is done, as it cannot do that without making a good joint at the back of the groove.

2,816, Improvements in Fire-places. E. Taylor.

A hot air-box of metal is made with a top opening into the flue. This box is placed at the chimney bottom, over the back part of the fireplace. Into the front side of this box are fixed a number of tubes of metal or other material, which project across the chimney flue till they nearly reach the opposite or front of the chimney, nearly level with the bottom of the chimney-piece. The object of this range of tubes, which are open at both ends, is to draw up any foul air as the tubes get heated, and a greater draught is created. If the draught is too strong, a metal trap closes the tubes. Another part of the invention is the fixing of a metal plate in a diagonal position at the back of the fire. This radiates the heat, and serves also for letting down the fire when wanted for cooking.

APPLICATIONS FOR LETTERS PATENT.

JONES, LANG, & CO.	
Commercial-road, E.—31-49 even, Taring-street, and 39, Spencer-street, 7 years, ground-rent 32l. 19s.	200

MEETINGS.

SATURDAY, FEB. 7.	
Association of Public Sanitary Inspectors.—Captain Douglas Galton on "The Purity of Air in Towns." 6 p.m.	
MONDAY, FEB. 9.	
Surveyors' Institution.—Mr. H. Robinson on "Some Recent Phases of the Sewage Question." 8 p.m.	
Leeds and Yorkshire Architectural Society.—Mr. G. Beaumont on "An American Frame House."	
Edinburgh Architectural Association.—Professor G. Baldwin Brown on "Gottfried Semper and his Theory of Architecture." 8.30 p.m.	
Society of Arts (Lecture Lectures).—Professor George Forbes on "The Distribution of Electricity." 11. 8 p.m.	
TUESDAY, FEB. 10.	
Institution of Civil Engineers.—(1) Discussion on Mr. Smart's paper on "The Construction of Steam Boilers" and (line permitting) Mr. B. Baker on "The Metropolitan and Metropolitan District Railways," and Mr. J. W. Barry on "The City Lines and Extensions of the Metropolitan and District Railways." 8 p.m.	
London and Middlesex Archaeological Society.—(1) Mr. Charles Roach Smith on "The Late Discoveries in the Wall of London." (2) Mr. E. Walford on "Thomas Park, and his History of Hampstead." 8 p.m.	
WEDNESDAY, FEB. 11.	
Corporation's Hall, London Wall (Free Lectures to Artisans).—Professor Kerr on "The Comparative Anatomy of Beams, Trusses, and Arches." 8 p.m.	
Royal Academy.—Mr. R. Stuart Poole on "The Cairene House." 8 p.m.	
Society of Arts.—Captain Douglas Galton on "The Report of the Royal Commission on Metropolitan Sewage." 8 p.m.	
Civil and Mechanical Engineers' Society.—Mr. B. Haughton on "Indian Railway Network, 1851." 7.30 p.m.	
THURSDAY, FEB. 12.	
Society for the Encouragement of the Fine Arts.—Mr. G. C. Hallé on "Wall-papers and their Manufacture." 8 p.m.	
Parkes Museum.—Dr. Perry Frankland, F.R.S., on "The Selection of Water for Domestic Supply." 8 p.m.	
Society of Telegraph-Engineers and Electricians.—(1) Captain H. R. Sankey, R.E., on "Some Recent Experiments in Electroplying with a Dynamo-Electric Machine." (2) Mr. J. A. Timmins on "The Working of Railway Signals and Points by Electro-Magnets." 8 p.m.	
FRIDAY, FEB. 13.	
Royal Institution.—Sir John Lubbock on "The Forms of Leaves." 8 p.m.	
Institution of Civil Engineers.—(Students Meeting).—Mr. Gilbert Hunter on "The Maybole Waterworks." 7.30 p.m.	
SATURDAY, FEB. 14.	
Architectural Association.—Visit to 16, Carlton House-terrace. 3 p.m.	

Miscellaneous.

Greek Epigraphy.—Professor C. T. Newton, C.B., is now delivering an interesting course of lectures on ancient Greek inscriptions. In his first lecture he observed that in the present state of our knowledge of Greek epigraphy we may confidently assert that inscribed monuments of equal interest to those of Athens, and Hellenic city of any political importance, and there is good ground for supposing that a considerable salvage of their remains will be accomplished as systematic excavations on ancient sites are carried on on a more extended scale. In his second lecture he traced the descent of the Greek alphabet from that of the Phœnicians, and pointed out the local varieties of the characters or letters in early inscriptions.

A Floating Breakwater for the Sussex Coast.

According to the *Sussex Advertiser*, a floating breakwater of an altogether novel type is shortly to be put up experimentally on the Sussex coast. The greater part of the funds required are already subscribed. There is no harbour of refuge between Dover and Portsmouth, and notwithstanding many official recommendations,—some of them urgent,—in favour of the construction of such, nothing has yet been done in this direction except the works now in progress at Newhaven. According to the old principle of solid stone walls carried down to the bottom, the expense of erecting breakwaters is very considerable. At Dover, where there is exceptionally deep water, the cost is 415l. per lineal foot, at Plymouth 300l., at Alderney 284l. Even at Portsmouth the employment of convict labour has reduced it only to 120l. By the adoption of the modern system of building upon huge months of concrete,—thus far applied only at Aberdeen and Newhaven,—the cost has been reduced to 72l. at Aberdeen and 52l. at Newhaven. For the system now advocated it is claimed by its inventors, Messrs. A. E. Carey and E. Latham, that the initial cost will amount to only 18l. per lineal foot. The construction of the new breakwater was fully explained by Mr. Carey at a public meeting held at Eastbourne the other day. Messrs. Carey & Latham's contrivance consists of a double row of empty iron boxes (to be possibly filled with cork to maintain buoyancy in case of damage by accidental collision or hostile acts in war) running out into sea in parallel lines. The front facing the sea tide-walls has a wedge-like shape, presenting to the oncoming waves its tolerably sharp edge, which is intended to divide the mass of water the underwave is first to be broken by a lattice framing carried 12 ft. below the pontoon (a depth sufficiently for all practical purposes), which will,—especially when overgrown with seaweed,—help to render the pontoon as heavy and steady as a waterlogged vessel. At the back of the wedge-shaped pontoon is another pontoon, also constructed of an iron box composed of water-tight compartments, which acts simply as a wall. The intervening space is to serve as a "wave trap," in which the waves passing the wedge will spend their force. The breakwater is to be moored, by means of an endless cable made of non-corrodible phosphor-bronze.

Steam-worked Tramways in London.

The long-cherished hope of advanced practical minds of seeing tramways within the metropolitan area worked by steam is about to be realised after a protracted struggle, and the North London Tramways system will have the credit of inaugurating the reign of common sense in this connexion. Seventeen engines have been built by Messrs. Merryweather & Sons for that system, and one of these made its first run on the line on Wednesday evening, January 28. This engine has 7½-in. cylinders, and is fitted with all the requirements as directed to those by the same firm which are in work on the Stockton and the Batley lines, where it has been shown that steam haulage costs but 3d. per mile as compared with horse traction previously employed on the same routes, and costing as nearly as possible 6d. per mile. The condenser, with which the engine is fitted, is so arranged that it is impossible for the exhaust steam to show in the least degree; this being collected in a feed cistern is sufficiently cool to be returned to the boiler by the feed-pump or injector. Within the next three weeks the line from Stamford-hill to Edmonton will be fully worked by these improved motors, a circumstance upon which we congratulate all parties concerned.—*Iron.*

The Improved Industrial Dwellings Company.

The half-yearly report of the Improved Industrial Dwellings Company, Limited, has been issued. The Company now possesses thirty-four estates in various parts of the metropolis, on which 4,586 dwellings have been built and are in occupation, and 355 are in course of erection and completion, making a total of 4,971 tenements. When these are completed, the number of persons residing on the Company's estates will be upwards of 25,000. The expenditure on capital account has reached 899,157l. The usual dividend of 5 per cent. is recommended for payment, after carrying 1,000l. to the reserve fund for the equalisation of dividends.

The "Chelsea" Centre-bit Moulding Lock.

The "Chelsea" patent reversible centre-bit mortise lock, which has been introduced by Messrs. Broughton & Co., of 169, Q. Victoria-street, has been already briefly noticed by us with commendation when shown in one of the numerous exhibitions of the past year, and it is so good a thing that some of our readers who have not yet seen it may thank us for calling attention to its merits. The leading feature of its construction is that its working parts are so arranged that the lock can be fixed in ordinary centre-bit borings, in a very short time, and without any knocking about of door with mallet and chisel. The mortise-hole is cut by a centre-bit (Jennings's 1-in. screw pointed centre-bit being used), the spindle key-holes being made with a ½-in. bit. W inserted into the mortise-holes, the lock can be withdrawn from the door by simply unscrewing the fixing screw, which pulls the lock out of the door. The furniture "roses" can be secured by screws which go nearly through the door and by the side of the barrel of the lock.

Clock at Kintbury Church, Berks.

The tower of this church has been recently fitted with a new clock by Mr. J. W. Benson, of Luton. The dial is 4 ft. 6 in. in diameter, copper painted black, with figures and hands of gold, well displayed. All the wheels are of hard brass, the teeth being divided, cut, and polished by steam machinery, which gives accuracy and immunity from the corrosion and rust inseparable from iron are secured. The escapement is "Graham's" dead beat, with special improvements introduced. For striking part the rack repeating principle used instead of the old-fashioned and unreliable locking plate, much given to strike the wrong hours.

Surveyors of Ecclesiastical Dilapidations, Diocese of Norwich.

A meeting of the Archdeacons and Rural Deans, under the presidency of the Bishop of the Diocese, was held on the 31st of January, for the purpose of electing a surveyor for Ecclesiastical Dilapidations in the place of the late Mr. R. M. Phipson, F.S.A. It was unanimously decided to have two surveyors in the place of one, Mr. Herbert Green, of Norwich, and Mr. E. F. Bishopp, of Ipswich, being elected, Mr. Gree obtaining twenty-five votes and Mr. Bishopp eleven votes. There were seven other candidates.

Exhibition of Meteorological Instruments.

The Council of the Royal Meteorological Society have arranged to hold, at 25, Great George-street, S.W. (by permission of the President and Council of the Institution of Civil Engineers), on the evenings of March 18th and 19th next, an exhibition of sunshine recorders and solar and terrestrial radiating instruments. The committee will also be glad to show any new meteorological apparatus invented or first constructed since last March as well as photographs and drawings possessing meteorological interest.

Alfreton Sewerage.

The Belper Rural Sanitary Authority have approved the recommendation of the Alfreton Sanitary Parochial Committee that Mr. W. H. Radford, Assoc. M.Inst.C.E. (late Assistant Engineer to the Nottingham Corporation), should be engaged to report on the present Sewage Works at Swanwick Delves, and advise as to the future disposal of the sewage, and as to the adaptability to that purpose of certain land now owned by the Local Authority.

London and County Banking Company.

The report adopted at the annual general meeting, held on the 5th inst., will be found in our advertisement columns. The net profits for the half-year ending 31st of December last amounted to 185,000l. This sum, added to 33,000l. balance brought forward from last account, produces a total of 218,000l. A dividend of 10 per cent. for the half-year has been declared, making 21 per cent. for the year 1884.

Dispensary and Relief Offices, Wandsworth Union.

The Guardians of the Wandsworth and Clapham Union have instructed their architect, Mr. Thos. W. Aldwinckle, to prepare plans for new Dispensary and Relief Offices, together with separate residences for two relieving Officers, to be built upon a piece of land acquired for that purpose at Battersea.

Deptford District Surveyorship.

Mr. Hugh MacLachlan, who obtained the Godwin Bursary in 1883, and thereby proved himself to have devoted considerable study to the practical side of building, is a candidate for the vacant post of Surveyor for the Deptford District.

The National Health Society.—The annual meeting of the members of this society was held on the 3rd inst., Mr. Ernest Hart in the chair. The annual report showed that 100,000 copies of the second report had been issued during the year to large audiences of working people and others in London and the provinces; and that the committee for investigating venereal and other poisons had been actively at work; that about 35,000 of the society's useful publications had been sold at the International Exhibition, where a successful conference school hygiene had been held under its auspices, and that several new pamphlets and leaflets had been issued, including one entitled "How to avoid and prevent the cholera," of which 10,000 copies had been sold and distributed. The chairman urged the members to make the fulfilment of the society known among their friends, increased funds being much needed to carry it on.

The Metropolitan Sewage Question.—The meeting of the Society of Arts, on Wednesday next, there will be a discussion on the recent Report of the Royal Commission on Metropolitan Sewage. It will be commenced by a paper by Captain Douglas Galton, F.R.S. Mr. Frederick Abel will be in the chair.

"Illicit Commissions."—In reference to a "Note" in our issue of last week [p. 161, ante], referring to a circular signed "W. B. — & Co.," we are asked to state that the circular was not issued by the well-known firm of William Bangs & Co., builders and contractors, Bow.

Ewerby.—Mr. W. F. Dixon, of University-street, London, has just erected a large five-light stained-glass window in Ewerby parish church as a memorial to the late Earl Winchelsea, of Nottingham. The work is the gift of the Hon. Finch Hatton, M.P., and his family.

Rainford Hall, near Liverpool. is undergoing alteration and enlargement, at a cost of about 11,000*l.*, from the designs and under the direction of Mr. Medland Taylor, architect, Manchester.

Royal Cambrian Academy of Arts.—At a general meeting of members of the Royal Cambrian Academy of Arts, Mr. Henry Clarence White, R.W.S., was selected their first president.

Great Barr.—A two-light Munich window has lately been placed in Great Barr Church, near Birmingham, representing the delivery of St. Peter from prison. The artists are Messrs. Mayer & Co.

For roughing-out a road and removing part of a hill on the Beulah Park Estate, Norwood. Mr. Newton Dunn, surveyor, Beckenbury, E.C. —

Phœnician Art.

TO write the history of the art of Phœnicia is, at the present date, no easy task. About the arts of Egypt and Assyria, which, in his two preceding volumes, M. Perrot has so

ably treated, there exists, and has long existed, a vast store of indisputable facts, and a body of received opinion which has become canonical; but with respect to Phœnicia the material is but of yesterday, and opinion still in flux. M. Perrot's third volume* has, therefore, been eagerly looked for; he, if any one, would bring, we feel sure, order into this chaos,—would utter, if it were possible, some "clear disposing word" which should at least point out the way to some future conclusive theory. Nor does he disappoint us. In his usual luminous convincing way he states the difficulties of the case in such simple straightforward fashion that they seem at the outset half cleared away. His mind is of that delightful constructive sort that his material seems only to exist as part of the theory he is building. There is no lumber of useless detail; each fact falls into its fitting place. He is also such a finished workman that he never lets us see the process of his work; he is not all tools and scaffolding, as is the too common fashion of learned writers; he sweeps up all his chips, leaving behind no litter of useless learning; and, best of all, the walls of his theory rise up, as though Apollo built them, to the music of a perfect style.

We are haunted by a feeling of what a terrible book this history of Phœnicia might have been had it fallen into hands less capable. What dreary and puzzle-headed wanderings among scattered material,—what accumulation and comparison of fruitless theory,—what doubt, what learned and exhaustive weariness, what caution, and what fencing, to avoid the uttering of an opinion. Of all this M. Perrot knows nothing. His method for Phœnicia is as clear and sure as for Egypt and Assyria, though it has to be modified to suit the altered character of the material. He begins, as before in the case of Egypt and Assyria, with a sketch of the civilisation of the Phœnicians, and first with the topography of the mother country itself. Phœnicia was predestined to be the intermediary between the East and the West, between the old civilisations of Egypt and

Assyria on the one hand, and the young land of Hellas struggling into existence in the West. Egypt was no country to spread her influence by sea, rigid, conservative, monotonous, as the ebb and flow of her Nile river; she shrank from trusting herself to the perilous Mediterranean and to the still more perilous intercourse with foreign nations beyond the sea. Assyria was far distant, removed from Greece by thousands of miles of desert and mountain country. But between those two stable and hoary civilisations lay the narrow strip of sea-coast land we know as Phœnicia, a link between the two, trading from early times with both, and destined to carry their influence to the far-off West. And why destined? For the simple reason that the peculiar configuration of their country, where land-communication is difficult and often impossible, drove them to a coast trade, and that coast trade predestined them to commerce. "Partout et toujours, le cabotage a été l'école où se sont préparés et formés par degrés les peuples de commerçants," in Tsidon (Sidon) the "fishery," and Tsor (Tyre) the rock-promontory, were upreared the nation of sea-faring folk who were to be the traders of the world. Trade is the secret of the politics of Phœnicia, and trade, as we shall see, the main impulse to her art. "Anything, everything that will sell," was the motto of her artists. We cannot, of course, follow M. Perrot in his delightful voyage in the wake of Phœnician traders, "mariners renowned," as Homer calls them, "greedy merchantmen with all manner of gauds in a black ship," who passed from the mainland to Cyprus, from Cyprus to Rhodes, step by step from island to island, till they touched the coast of Hellas. Once they carried with them a goodly mixing-bowl for Achilles, the son of Peleus, and he set it for a racing prize at the funeral games of Patroklos. "Six measures it held, and in beauty it was far the best in all the earth, for artificers of Sidon wrought it cunningly and men of the Phœnicians brought it over the misty sea and landed it in harbour." Perhaps the secret of the fascination of this Phœnician art, the otherwise dull art of copyists and tradesmen, is that it was the art of Homer's days, that his heroes did about them Phœnician armour when they went forth to war, and clasped their mantles at home with brooches of Phœnician workmanship.

To the nature of this work it is time to pass. In his chapter on the method of study in dealing with Phœnician art, M. Perrot clearly states his plan of procedure. From the outset we have to understand that we must look for our materials far beyond the limits of Phœnicia itself. In studying Egyptian art we had but to transport ourselves to the valley of the Nile; all was clear and compact. The

same with Assyria. In studying Phœnician art, it is far otherwise; owing to Phœnicia's extensive trade, we are, so to speak, turned loose on the whole basin of the Mediterranean, from Tyre to Tarshish,—nay, even to Egypt and Assyria. It was in a Phœnician ship bound for Tarshish that the prophet Jonah sought to fly from the presence of the Lord, and that ship was no doubt carrying a cargo of rich stuffs, carved ivories, bronze bowls, amber beads, anything and everything that might cultivate the fancy of the half-savage dweller in distant Spain. Indeed, it is in the colonies and factories and trading-posts of Phœnicia, far more than in the mother country itself, that monuments of her art are to be found, in Carthage and Sardinia and Cyprus, in Thera and Melos, rather than in Tyre and Sidon, Aradus and Berytus. Of Phœnician inscriptions now known, nine only came from Syria; Athens and the Piræus have yielded seven; Cyprus alone eighty-four; Malta and Gaul, twelve; Sardinia, twenty-four; Carthage counts her thousands. "L'Antiquité Phœnicienne," says M. Rénan, "est de toutes les antiquités la plus émietlée," and the reason, he adds, is that the country has also been densely populated; successive waves of peoples have passed over it, each doing their share in the work of destruction, Greeks, Romans, Byzantines, Crusaders, Mussulmans. The coast trade of Phœnicia, so advantageous to her development, has also favoured her destruction, and finally her monuments have been exposed to centuries of Christian iconoclastic zeal. When the geographical distribution of monuments is so wide, naturally the doubt as to their authenticity is perplexing. How do we know that this or that object found in Cyprus, in Sardinia, at Præneste, is or is not Phœnician. It is almost entirely a question of style, not of provenance.* Happily as regards style we have a few certain criteria to go by, and these M. Perrot is careful to indicate. We have a few signed monuments with unmistakable, decipherable inscriptions in the Phœnician language, and these form a standard by which to judge of others; noticeably we have the famous bronze bowl found at Pales-trina with the inscription Esmunjaur-ben Asto. In the same tomb were found a number of other objects, vases, diadems, jewelry, all decorated in the same style. Here, then, as M. Perrot notes, we have a whole "find" of monuments which bear, so to speak, the stamp or label of Phœnicia, or rather,—for we know them to have been exported from Africa,—of Carthage. In judging, then, of Phœnician

* Histoire de l'Art dans l'Antiquité. Par Georges Perrot et Charles Chipiez. Tome III. Phœnicie Cypre.

* Recent archaeologists have adopted from the French the word "provenance" as signifying the identification of objects in regard to site or "whereabouts," as it might be expressed. The word is a convenient bit of shorthand for avoiding roundabout phrase.

monuments, what we must demand of them is, not that they should be found in Phœnicia proper, but that they should bear the stamp of what, from a few inscribed specimens, we know to be Phœnician style.

Having thus established and explained his method, M. Perrot turns to the subdivisions of his subject. He treats in succession of the following:—Architecture under the three heads of material and construction, forms and decoration, then certain special subdivisions, architecture of the tomb, of the temple, and of civil monuments, such as hydraulic arrangements and the fortification of seaports. To a nation so utilitarian as the Phœnicians this civil architecture was naturally a matter of paramount importance. From architecture, M. Perrot turns to sculpture, dividing it into the two main branches of the sculpture of Phœnicia proper and Cypriote sculpture. The history of Phœnician sculpture labours under the serious disadvantage that there are no works of the first rank preserved, and, indeed, probably none such ever existed,—works that might strike the imagination of the reader when presented to him and leave in his mind some clear impression of a national style. From the first the Phœnician artist himself was at a disadvantage; he had wretched material in which to work; nothing with the compact, close grain of the stone of Egypt to compel a careful, laborious, and finished style; nor yet the yielding material of Assyria, which tempted facility, still less the magnificent marbles of Paros or Pentelicus, only a coarse tufa-stone which favoured a mean and slipshod, rough and ready, manner. Further, the Phœnician sculptor suffered, in common with the Assyrian, from the absence of the nude model, without which there can be no truth in dealing with the human body, and, therefore, no dignity and simplicity, and, of course, no organic harmony of limb with limb, head with body. The Phœnicians, like the Assyrians, were a nation of clothes, of externalism, of ritual, of vestments; the human body was to them a mere peg on which to hang a certain amount of decoration. This is the curse that rests on all purely Semitic art, and from which the Egyptians and the Greeks were wholly exempt. A nation of artists who look at nature only in this disguised and distorted fashion will never advance so far as to distinguish in sculpture the individual, nor yet even the race. They are debarred for ever from a healthy naturalism. From Phœnician sculpture we cannot reconstruct the peculiarities of the Phœnician race. The type is always fluctuating, vague, confused; in fact, they were, as we shall see more clearly later, always eclectic, never original. Not caring to see nature at first hand, they took her at second-hand from the types of Egypt and Assyria, and later from Greece.

From sculpture, M. Perrot passes to the glyptic art, to painting, and to the industrial arts, including in these last pottery, glass, metal-work and jewelry, furniture and toilette apparatus, armour and woven stuffs. We have no hesitation in saying that the most fascinating part of M. Perrot's book is that in which he deals with metal-work in general, and in particular with the long famous bronze and silver bowls. These it was that first drew attention to Phœnician art, and these it is that give the key to the whole situation. Of all the works of art attributable to Phœnicia these are at once the most authentic and the most instructive. M. Perrot has engraved a goodly series of these bowls, and his remarks on the system of decoration common to all are so valuable that we must summarise them shortly. The elements of decoration observable on these bowls are drawn, as has long been known, from Egypt and Assyria, with, on the whole, a preference for Assyria. In sculpture and architecture, as well as the decorative arts, the eclectic tendency of Phœnicia is clearly seen; but it is in these bowls, and in them only, that the utterly mechanical and unintelligent nature of their borrowing appears. By far the largest element in their system of decoration are what M. Perrot calls "empty forms" (*formes vides*); that is, designs which have not only been bor-

rowed, but which have been ignorantly borrowed, and have in the process utterly lost their old meaning, and received no new one from the borrowers. These designs amuse the eye, "as the ear may be charmed by the sound of a language not understood," but they say nothing to the mind. Even the human figure becomes in such a system mere ornamental motive. Side by side with this borrowed phraseology rigidly stereotyped and constantly recurring, this repetition of mere artistic formulae, these heraldic sphinxes and griffins, these schematic Egyptian combats, these copied but unintelligent hieroglyphs, there runs also a vein of realism, an attempt to depict in the terms of actual life a lion hunt, a siege of a city, a ritual scene of offering, a choral dance, and the like. But even when this realism is attempted, it is a confused and unintelligent realism, a *pile-môle* mingling of, as in one instance, Greek hoplites, Assyrian archers, Cypriot horsemen, light-armed Africans, anything and everything that came to hand to fill the space. The instinct of the Phœnician craftsman, for we cannot call him artist, is not for expression,—he has no thought to express,—but for decoration; eclectic, unmeaning, but for all that, saleable decoration. When we have analysed Phœnician art, as M. Perrot trenchantly says, into its component parts, and separated off the borrowed elements, nothing is left at the bottom for the Phœnicians to claim as their own but the receipt for the mixture. And yet to this people, so mechanical, so uninventive, the ancient world owes a deep debt of gratitude; they were the art missionaries of the whole basin of the Mediterranean, only they brought a gospel they themselves did not understand,—they preached a dead letter. They had no desire to teach, and yet they left behind them everywhere lessons of priceless worth to a nation that was keen to learn. They stole from the Greeks, they cheated them, but they left in exchange not only the alphabet of letters, but the alphabet of art, so swiftly to develop into the full and perfect utterance of a Pheidias and a Praxiteles. Those "empty forms" which were to the Phœnicians themselves mere vacant patterns, became to the Greeks the vehicles of new and living thought. Devices charged with sacred meaning and doubly hallowed by long usage in Egypt and Assyria were, in their original meaning, as little understood in Greece as in Phœnicia, but the Greek mind did not gladly suffer the unintelligible; it was too clear, too incisive, too,—in the fullest sense,—classical. If the old meaning was lost, a new one could be found. A fascinating chapter in Greek art (and a chapter, we may say, which has yet to be written) will hereafter deal with this subject of "iconology," the form that suggests the thought. M. Clermont Ganneau has indicated the first lines of the study in his "Inauguration Phœnicienne," and we look eagerly to see what development of the matter M. Perrot may attain when he comes to treat of archaic Greek art. May he come soon, but, alas! he has first to dispose of Asia Minor and—the Hittites!

THE CATHEDRAL SITE FOR LIVERPOOL.

BY JOHN P. SEDDON.

THE proposed cathedral for Liverpool is a matter of almost universal interest, and the world may be said to be awaiting with anxiety to see whether that wealthy city, which ranks but second to the metropolis, will or will not approach the task in a spirit worthy of the occasion.

Such an opportunity occurs now but seldom in a generation, and there is a consequent absence of the emulative enthusiasm which, under like circumstances in Medieval times, led to magnificent results. The majesty of York Minster, around which that city is grouped, is followed at a very St. Mary at Edinburgh, which seems as if it could hardly claim the title of a cathedral at all, and which is stowed away, as it were, in

a suburb. It is earnestly to be hoped that the opportunity now afforded at Liverpool may be met rather in the manner of the builders of the former of these precedents than in that of this latter.

It is to be feared that in the preliminary selection of a site, this has not yet been the case. The choice already made of St. John's Churchyard for the purpose is, it must be owned, most unfortunate. Cheapness is its sole claim to consideration, and this in reality only from the most superficial point of view for the cost of another, in every way more advantageous, could be recouped by the increased value of surrounding property.

Liverpool happens to have this vacant space in its centre,—a space of inestimable value as such, both in an æsthetic and practical sense—a vital lung which it would be positive treason to obliterate, even with a cathedral. It possesses around it a series of noble municipal buildings, to which it affords means for being viewed from a sufficient distance as a whole, which would be lost were it occupied by any structure whatever. This site is so much below that on which St. George's Hall stands, that any building erected upon it would be dominated by that, and comparatively dwarfed. It is so small that, though an exaggerated parish church, a cathedral built in name, might be crowded into it, it would have none of the surroundings that are essential to such a structure. Ingenious schemes have been devised for raising its level somewhat, but these would entail the virtual destruction of the adjoining streets (which would be reduced to mere sunk lanes) and almost the extinction of the surrounding buildings. Surely, under such circumstances, cheapness (were it demonstrable, which is far from being the case, if all circumstances be considered) could not justify the persistence in such a site as this.

Mr. Robson, who was so long the town surveyor of Liverpool, and whose authority on such a subject is indisputable, has designated as "the foolish site" the one that has been chosen. In face of this judgment it is hardly conceivable that it can be longer maintained.*

It has been suggested that an appropriate site for a cathedral for Liverpool would be on the banks of the Mersey, and were it simply a matter of effect or sentiment there is much that might be alleged for such. It would be prominent at the entrance to the city from that splendid waterway, and it would be seen to advantage from the opposite side of the river.

There are, however, certain conditions for the position of a cathedral in a city which are attainable in one place and nowhere else. It should be central; in connexion with other fine municipal buildings; elevated, so that it might dominate, and not be dominated over a temple, not only for a cathedral, but for a tree-planted area around it, and other appurtenances appropriate to such ecclesiastical establishment.

Such a site exists in that known as that of Commutation-row, with the space eastward thereof. This is nearly 150 ft. higher than the river, and 50 ft. higher than St. John's Churchyard. It is in a line with the noble North-Western Hotel, and a cathedral built on it would complete, and not destroy, the splendid range of buildings formed by the Walter Art Museum, the Picton Library, &c.

It would also compose well with the surrounding structures in whatever style it were erected; for the strong predominance of horizontal lines in the Classical St. George's Hall, and its neighbours would form a good base even for an aspiring cathedral of Gothic architecture, or a dome, if preferred, would fitly crown the whole group.

Here is the best site Liverpool can find for its cathedral; the question is, will it give of its best for such a purpose? If it be not prepared to do so I do not hesitate to say it had better abandon the project for the present and leave it to posterity, who may be richer or more generously disposed; or, if more com-

* We are not, of course, responsible for the opinions expressed under the writer's own name, though we think Mr. Seddon's proposal deserves very careful consideration.
—E.

mercial views must have the first consideration, even from such this, the best site, will be found the cheapest in the end, for the following reasons:—

The property it would displace is already for the most part owned by the Corporation of Liverpool, and much of it is of a bad, and even of a disgraceful, character, needing to be pulled down and rebuilt.

The adjacent streets and buildings here, unlike those of St. John's Churchyard, would be immensely improved by the erection of a cathedral in their midst; and if advantage were taken to acquire sufficient ground in its vicinity, I have it upon good authority that the profit would more than recoup the value of the land appropriated as the site of the cathedral itself.

In order to show how a really fine cathedral would grace this splendid site, I have obtained from the skilled pencil of Mr. Brewer a drawing representing that of Notre Dame of Paris, as given by M. Viollet-le-Duc, with the spires which were intended to complete it. I have chosen this particular example, because the unusually strong horizontality of the main lines of its façade cause it to harmonise with those of St. George's Hall on the right, and the museum and libraries on the left. These, therefore, would form the base of a composition that if realised would be unequalled in the world, since the veritable Notre Dame of Paris cannot boast of a site to compare with this which is at the disposal of Liverpool for the purpose.

M. Viollet-le-Duc, writing of this western façade of Notre Dame, remarks that it is hardly possible to conceive a design more imposing as a whole, more sound in construction, or more skilfully executed in its details. Every one, he says, knows the front of this cathedral, but few, perhaps, realise the amount of knowledge, care, resolution, and experience implied by the erection of that colossal pile within the space of, at most, ten or twelve years. Still it is, as we see it in Paris, an unfinished work; the two towers were to have been terminated by spires in stone, which would have completed and rendered intelligible the admirably-designed tower masses. "Here, indeed, we have Art, and art of the noblest kind."

I have thought that it would be a useful thing to show how this restoration of the façade of Notre Dame by M. Viollet-le-Duc with the spires added to the towers would appear in perspective, and therefore have obtained the able services of Mr. Brewer for that purpose. The accompanying drawing has been carefully set up by him from the geometrical illustration given in plate xiv. of the "Lectures on Architecture," by that accomplished deceased architect, upon the site known as Commutation-row, in Liverpool, taken from the Ordnance plans and data of levels, and with those portions of the adjoining buildings which would come into view therewith. I feel that I need say no more on the subject, but trust that this ocular demonstration may press home my previous arguments.

I will conclude by summarising the criticisms of M. Viollet-le-Duc upon this magnificent façade in order to call attention to its principal features and excellences. The divisions of the front by grand horizontal lines form resting-places for the eye. Each division has its purpose; that in the massive basement provides for the three wide and rich portals, connected by the four canopies and colossal statues, which relieve what would be the hardness in the lines of the buttresses.

The gravity and strength of this basement is emphasised by the continuous belt of ornament formed by the splendid gallery of kings which surmounts it; and the parapet above it, adapted to the scale of the human figure, marks the colossal size of these statues. The great rose-window in the centre and the couplets of the towers on each side repeat and continue the character of the basement story, as also does the loftier traceried gallery above them form, as it were, an echo to that with the range of royal statues below, and its comparative lightness seems to be the preparation for the aspiring part of the composition, which commences therefrom. Up to this point the façade

has a stern and massive character, which would harmonise perfectly with the horizontality of the buildings which would form its foreground.

Now the towers disengage themselves and spring upwards with their lofty belfry openings and the shafted buttresses, but so vigorously that they call out for something adequate to support, otherwise it must be owned that they would seem superfluously strong. Every part of the composition appears designed to support and lead up gradually to spires, which should then soar heavenwards unrestrainedly.

One other point is noticeable in this western façade of Notre Dame at Paris: this, as M. Viollet-le-Duc puts it, is "variety in unity." Though at first sight the portals appear symmetrical, the left doorway differs from that on the right. The left tower is larger than the other, and the arcading of its great gallery is the more severe and solid of the two. Thence he concludes that the spires would have been varied, and in his restoration he has accordingly made them different in many points. This diversity is still more observable in the details when examined, and certainly gives an extraordinary feeling of life to the composition.

Of course, it must be understood that I am not suggesting the repetition of this particular design for the cathedral of Liverpool. No doubt it is possible,—would it were probable,—that as grand and glorious an ideal could be incorporated with the doubtless different practical requirements of a cathedral for this age. The able architects engaged to design one may be trusted to work out the problem in a manner that will sustain their high reputation. All that I contend is that they may be allowed to employ their talents in connexion with a site worthy of them and of the noble purpose which Liverpool is contemplating.

NOTES.

WHAT has been rumoured for some time is now officially announced, that Lord Rosebery has accepted, in addition to the office of Lord Privy Seal, that of First Commissioner of Works, in place of the Right Hon. G. Shaw-Lefevre, who has succeeded Mr. Fawcett as Postmaster-General. The outgoing First Commissioner has left his mark on the administration of his late office more distinctly than most First Commissioners for some time past, and we should be the last to refuse acknowledgment of his energy and determination in carrying out improvements from what he regarded as the right point of view. We felt bound, however, to oppose much of his work, regarding it as entirely mistaken from an architectural point of view, and the small minority of Englishmen who understand at all what architecture means will be the most disposed to concur in our opinion, and to regard with satisfaction the translation of the late First Commissioner to a sphere in which his remarkable administrative ability and his energy for reform will be devoted to a class of work which he probably understands much better than architecture and aesthetics. The evidence which Lord Rosebery has given, in some of his speeches on matters other than political, of the possession of wide culture and critical sense, promises well for his ability in dealing with the class of subjects which come under the decision of a First Commissioner of Works. One can hardly avoid, however, the expression of a feeling that the treatment of works and buildings is likely at the present juncture to be a very secondary consideration in the minds of most Englishmen, and that many of our readers who have more than merely professional interests at heart will consider the accession of Lord Rosebery to a seat in the Cabinet at the present moment a more important matter than his presidency over the Office of Works.

WE print, in another column, a letter from a professional correspondent of standing and experience, who shrouds himself behind the *nom-de-plume* of "Excelsior," in regard to the subject of specifications and the alleged

neglect of specification-writing, by London architects more especially, and the frequent execution of this important branch of practical literature by proxy. We publish the letter as a statement in regard to an important branch of professional work, which, if (as we hope) it is overstated, had better be openly refuted; if it is true, should receive serious consideration. In the latter case it is, perhaps, open to those who may feel themselves to be implicated, to argue that architecture is a branch of art, that specification is a piece of dry business routine best executed by the business-man who has given himself to that special branch of work; and such an argument may claim consideration for what it is worth. To our thinking an architect who commits the specifying entirely to other hands cannot possibly know as much about his building as he ought to know. We should be glad to hear the opinions of others, both as to what is the extent of the practice in London of turning over specifications to a specialist, and how far it is desirable or justifiable.

NOTWITHSTANDING Mr. Oakley's assurance that the railway companies have no sinister designs upon the British public, the opposition to their Rates Bills is increasing daily. Condemnatory resolutions are being passed, and memorials drawn up for presentation to Parliament, from one end of the land to the other. The Canterbury Chamber of Trade is co-operating with the East Kent Chamber of Agriculture to wage war against the measures; the Midland hardware trades and the Cardiff steel industries are equally hostile; while, to turn northwards, the Highland Agricultural Society of Scotland is preparing to memorialise Parliament, and is sending circulars to the Scottish members, asking them to use their best endeavours to prevent the passing of the obnoxious Bills. The agitation is not confined to manufacturers and agriculturists, for the Worshipful Company of Butchers find that the provisions of the Bills are calculated seriously to interfere with the cost of the food supply of London, and have decided to petition Parliament against them. This brings the question home to the people, and it is rapidly pushing its way to the front as an important public question. Numerous letters have appeared in the *Times* and other journals from influential and practical men commenting upon Mr. Oakley's defence of the measures,—some disputing his statements and others supporting them. All accept the points laid down by him as forming the principal grounds of the contention, and the views expressed upon them vary considerably. The question is looked at both from a legal and practical point of view, and Members of Parliament and others interested will find that there are many different points to be considered. All this, however, goes to show that the question is one of national interest, and not, as it was at first looked upon, a matter affecting the trader and agriculturist only.

SOME interesting facts bearing upon the building trades, are published *cum multis aliis* by the *Statist* in its financial *resumé* of the past year. The demand for wood was less than in either 1882 or 1883, while the decline in value of the importation was still greater, being only 14,464,743*l.* in 1884, against 16,647,606*l.* in 1883. Prices steadily went down from the commencement to the end of the year, and although no great losses were made during the year, profits were so meagre that they represented little more than bare commission. The extreme cheapness of production, combined with the lowest freights ever known, has just enabled the trade to pay its way, but without having regained any of the strength or credit lost in the preceding years. In the iron trade, values have been most dishearteningly low for the makers, and the depression is naturally felt very keenly by the engineering community, especially those members who are dependant on the great industries of agriculture, sugar manufacture, and shipbuilding. Steel for structures in large sections is as cheap as iron, while bridges, roofs, and all structural ironwork, have not been

so low-priced for many years. There has been a great absence of railway extension, though this has been in some degree compensated by the numerous widenings and enlargement of stations on the part of the companies. The price for copper, as the result of the year's trading, is not only about 12 per cent. below the lowest price ever known, but some 30 per cent. below what is usually considered moderate and safe, and nearly the same story has to be told of tin, lead, and spelter. It would seem, looking merely at the value of materials, that never could a house be built as cheaply as now; but, unfortunately, the decline has been correspondingly rapid in the demand for houses, and also, except in favoured localities, in the value of rents.

THE contrast presented by the declining dividends of some of the most important railway companies to the cheering reports of those minor associations, the omnibus and tramway companies, has extreme significance. It demands the very serious attention of men of business. Of course an explanation is forthcoming as to the former result. In one instance it is the decline in manufacturing industry, in another the falling-off in passengers going abroad, and so on. And in so far as these excuses go to show that care, skill, and other good qualities are as characteristic of the staff of each several line, as has always been the case, we heartily agree with them. But improvement of property is better than the best explanations why the reverse is going on; especially when that reverse has been long-predicted, unless certain steps were taken to avoid it. Thus the 10 per cent. dividend, with 1l. 5s. bonus, free of income-tax, of the London General Omnibus Company, shows a prosperity like that which attended the London and Birmingham Railway in 1844. The Tramways of the United Kingdom paid 5½ per cent. all round on their capital last year, and 6, 8, and 10 per cent. dividends are being announced for the last six months. And yet the tramways have to spend 80 per cent., and the omnibus companies more than 90 per cent., of their receipts for the conduct of their traffic.

THE reason for this difference is to be found in the fact that the smaller companies have concentrated their energies on one description of traffic. Of that they keep a complete debtor and creditor account. They work with their eyes open. They content their customers and they pay. The railways that act on the same way prosper also,—as in the case of the Taff Vale,—with its 16 per cent. dividend. But the railways that attempt incompatible traffic, that run slow mineral trains and fast passenger trains, necessarily interfering with one another, and actually so doing to the extent of reducing the capacity of the lines for traffic by 40 per cent., are going backwards, as they have been doing for some time. It does not seem likely that the attempt to raise the freights by the Bills now deposited will succeed. Indeed, in some cases, such as the carriage of hops, it would be cheaper to revert to wagons and horses than to pay the proposed tariff. If the managers of the English railways would take a leaf out of the book of the French Railway Companies they might expect, in a few years, to earn as good dividends. By carrying, at a fair and ascertained profit, all such freight as can afford to pay for speed; and by remitting to water carriage all such traffic as can not afford so to pay, trade and commerce would be relieved from a heavy burden, industry would be stimulated, and railway dividends would become as good as omnibus and tramway dividends in this country, and as railway dividends in France, actually are.

IN regard to the proposal mentioned in our Paris letter last week to erect a lofty iron tower of 300 metres (984 ft.) high, at the Paris Exhibition of 1889, it may be further observed that this is not dictated altogether by a desire to possess some great novelty, for it is claimed that the scheme will have certain scientific advantages. One of these will be that strategic observations can be made, having

a radius of 60 kilomètres, and thus military telegraphy may have a good deal of additional light shed upon it by experiments, such as communicating with Ronen, and other distant towns, in case of a repetition of an invasion and siege. As incidental observations, meteorology and the condition of atmospheric currents, astronomy, and experiments on electric lighting at this vast height, would all come under consideration. Comparing the Exhibition tower at 300 metres, we find that the tower of Cologne Cathedral is 159; the Flèche at Ronen, 150; the Pyramids, 146; Strasburg Cathedral, 142; St. Stephen's Dom at Vienna, 138; St. Peter's, Rome, 132; the Invalides, Paris, 105; the Pantheon, 79; and Notre Dame, 66 metres.

NEW YORK appears to be by no means free from the reproach of overcrowding, seeing that in the early part of last year it contained 101,735 separate buildings of all kinds, of which 17,615, or more than three-eighths, were exclusively of wood, or some other inflammable material. Only about 49,000 of the New York buildings are used exclusively for dwellings, 29,000 being used partly for habitation and partly for business purposes. The whole population of New York is located in 77,000 buildings, many of which are employed also for business or manufactures, and this makes an average of sixteen persons to a house. The outlook is not improved by the fact, that a large portion of the city is filled with small and inferior houses.

THE paper which was read by Captain Douglas Galton at the meeting of the Society of Arts on Wednesday evening, on the question of dealing with the sewage of the metropolis, contained a concise historical sketch of the subject, as well as a *résumé* of "The Report of the Royal Commission on Metropolitan Sewage." The question has been a "burning" one during the greater part of the last forty years, and its present condition is undoubtedly, as Captain Galton observed, due to the hap-hazard way in which the metropolitan drainage system came into existence. Captain Galton recounts the circumstances which operated to prevent the main-drainage system being rendered more perfect than it is, and concluded his paper with the following paragraph:—

"The importance of the report of the Royal Commission lies not so much in what it recommends for the metropolis, as in the valuable information which it has collected on the present state of the general question of sewage disposal,—information which is applicable to the wants of the whole country. The comprehensive manner in which the subject has been treated is of especial value at the present time, because the country is becoming too closely built over for this question to be allowed to remain any longer in the *laissez-faire* condition which it has hitherto occupied, if regard is to be had to the purity of the air, the purity of the soil, or the purity of the rivers and watercourses."

A MEETING was arranged at the Mansion House for Friday this week, at three p.m. under the presidency of the Lord Mayor, to obtain more extended support for the Parkes Museum, so that it may be firmly established on a permanent basis. We sincerely hope this substantial guarantee will be raised for the continued existence and prosperity of an institution which has been such a useful and important centre of sanitary work and study. In connexion with the subject, we may mention that the large and valuable collection of books in the Health Section of the Library of the International Health Exhibition, consisting of about 1,500 volumes, has been presented to the Library of the Parkes Museum, thus adding materially to a sanitary library which was already of considerable value.

THE recently-reported case of Mitchell v. The Darley Main Colliery Company, though in itself a decision as to the subsidence of land from mining, in principle has a very wide application. In effect it decides that if there has been some kind of underground working and a subsidence occurs in consequence so that damage is done to a person's property, the subsidence is the cause of action.

This is followed by the further development of the principle that if there ensues a second subsidence several years after the first in consequence of the old working, an action will still lie for any damage which may occur, and it is not barred by the Statute of Limitations. The second subsidence is, in fact, a new and wholly independent injury if damage result from it. It is unnecessary here to enter into a discussion of the general legal principles which underlie this important decision: the effect of it, whether damage be caused to buildings by mining or by excavations of other sort, is very visible.

WE recently commented on the noise occasioned in the Law Courts by the machinery beneath the central hall, which is used for the purpose of the electric light. To noise is now added a strong and offensive smell, which pervades the hall and the adjoining passages. It may or may not be unhealthy, being apparently produced by the oil or grease on the machinery. Be this as it may, it is not creditable to the public department which superintends this building that our metropolitan law courts should reek with offensive smells.

ON Monday, February 9th, the obsequies of the late M. dn Sommerard were celebrated at the Church of St. Severin and at the cemetery of Père-la-Chaise, with the pomp and ceremony suitable to the memory of one who held the important offices of Director of the Musée de Cluny, Vice-President of the "Commission des Monuments Historiques," President of the "Association des Artistes" (including painters, sculptors, and architects), and who was a "Grand Officier" of the Legion of Honour and a member of the Institute of France, besides being the holder of many foreign orders and honorary decorations. The pall-bearers were M. Kaempfen, Directeur des Beaux-Arts, representing the French Government; M. Bouguereau, President of the Académie des Beaux-Arts; M. Antonin Proust, Deputy-President of the Commission des Monuments Historiques; and M. Sahatier, Senior Vice-President of the Association des Artistes; all of whom, in the name of the various bodies which they represented, spoke in commemoration of the professional career of the deceased, referring also more especially to the important part which, as Commissaire-Général of France, he had taken in the International Exhibitions at London in 1872 and Vienna in 1874, to the dutiful and artistic care which he had taken in the conservation and increase of the treasures of the Musée de Cluny, and to his active collaboration in the recent formation of the Comparative Museum of Sculpture and Casts in the Palace of the Trocadéro.

ARCHITECTS who desire to turn an easy, if not an honest, penny are certainly not left without their opportunities and suggestions in that direction. A fortnight since we noticed the circular of a building firm, offering commissions on work introduced. We have now before us a circular of a more ambitious description, on larger paper, and with more pomp and circumstance; the appeal of a Land and Building Company "To Architects and Surveyors," indicating that the directors are prepared to erect private houses, schools, hotels, churches, or public buildings on the following terms:—"The Directors will erect any of the above class of properties at a profit of 10 per cent. on the moneys expended on the works in materials, labour, and hire of plant, and will allow the architects or surveyors introducing business (that is accepted by the Directors) half the Company's profit, viz., 5 per cent. The Commission is payable on receipt of all monies by the Company." The directors must surely be aware that architects and surveyors are supposed to be the impartial advisers of their clients, yet they are offering the profession the direct inducement to advise clients for their own, the architects', private interests in an indirect and underhand way. In both these cases the circulars in question were sent to us by architects, requesting our reputation, on the part of the profession, of any co-operation in such dealings. We shall

be happy to deal with any more literature of the same sort that may be going about.

THE following little story throws an interesting light on the spirit in which some of the so-called sculpture in connexion with ecclesiastical architecture is carried out by the carving firms who supply statues of the proper saints at so much a head. A dignitary of the church, looking on at the work of a carver on a restored church front, wished to inform himself of the cost of such work. "Why, that depends," was the reply; "you see they are so different; now, one like that David there runs into a heap of money,—arps and that like makes 'em ever so dear." The questioner tried again with, "Well, then, what do you suppose those angels would come to?" "Oh! we don't think nothing of angels; we turn them out by the dozen!"

PROVISION FOR HOUSING THE WORKING CLASSES IN ITALY.

THE urgency of the question of housing the workman is by no means felt only within the shores of the United Kingdom. In Italy, where the climate allows so many of the occupations of daily life to be carried on out of doors, the cubic volume of house-room required per individual is much less than is the case with us. Yet so great is the pressure as to call for the interference of the Government in the case of their most important arsenal. In Italy, it should be remembered, the problem of housing the greatest number of persons on a given area has been twice solved, and that under two distinct forms of civilisation. In Imperial times, as we know from the structural remains of Pompeii, the sleeping-apartments for working folk, as well as for domestic servants, were but little larger than would hold a bed or mattress. The *cubicula* were often without doors, shut off from court or corridor only by a curtain, and in keeping with the little open-fronted dens occupied as shops. It was before, rather than in, these apartments that the wares for sale were displayed to attract attention, and that, as in the present day in Naples, the owners were wont to carry on their handicraft *al fresco*. It is desirable to bear this question of accommodation in mind when any question arises as to the comparative cost of Italian and English buildings. Material, over the greater part of Italy, is cheaply furnished by tufa, which is as easy to quarry and to dress as our own chalk, or by other building stones, some of them of great excellence and heavy. Lime almost everywhere is excellent, and the *lapilli*, or white gritty volcanic ashes, or, rather, cinders, form an admirable ingredient for cement, for stucco, and for scagliola. The men, in many instances, are born masons; constructing, with the utmost readiness, out of a few stones, a little mortar, and perhaps a coating or cushion of mud, those temporary appliances for which we are accustomed to call in the aid of the carpenter; as, for example, the centering of an arch. On the other hand, the solidity of the buildings and the thickness of the walls throughout Italy, intended as they are to resist the force of earthquakes, are incomparably greater than with ourselves. Thus when we set the quantity of walling required for a given content of cubic space in Italy, against the cheapness of the material and of the workmanship, we still find that it is only by the reduction to the minimum size of the accommodation per head, as in the cells of the large monasteries, that cost is kept from becoming excessive.

Around the great arsenal of Spezia the working population has been housed, or has housed itself, in so small a space of house-room, that the result has been to intensify the recent ravages of cholera, which is said to have raged more fiercely there than even in Naples. The Minister of Marine has called on the Municipality of Spezia to aid in removing the source of mischief, in so far as it is attributable to overcrowding. Dwellings to accommodate 1,000 families are at once to be commenced, and to be completed within three years. The buildings will be somewhat on the ordinary plan of the monasteries, but of three floors only; a quadrangular edifice surrounding an interior court or garden of 200 metres on a side. A hospital, with 200 beds, an infant asylum, a public school, a washhouse, and an establishment of warm

baths, will also be erected; as well as a sort of *hospitium* or accommodation for the nightly lodging of 200 workmen. The charges proposed are extremely moderate. For each room the rent is fixed at 4 francs a month, which is as nearly as possible 1*l.* 18*s.* 4*d.* per year. For a kitchen the rent is 3 francs a month; for the temporary lodging, 2*d.* per night; for a warm bath, 1*d.*

It is proposed to meet the expenditure by a loan of 64 millions of francs at 5 per cent., which rate of interest is to cover a sinking fund to extinguish the debt in twenty-five years. By comparing this amount of capital and rate of interest with the charges for rent, we find that the cost of accommodation will be about 35*s.* 2*d.* per room, about 25*s.* 7*d.* per kitchen,—the kitchens will probably be in the basement,—and they are usually, in Italian houses, what we should consider disproportionately small,—and about 60*s.* for each bed of temporary accommodation. In the latter case, therefore, the use of such furniture as is indispensable must be included in the nightly charge. As the interest on the proposed capital will amount to 13,000*l.* a year, it is evident that the provision to be made is for more than the thousand families mentioned in the first instance. It will be matter of great interest to watch the mode in which this project is carried out. Working plans of the buildings may, perhaps, be obtained and communicated by some of our travelling architectural students; and the balance-sheet of the establishment, which the careful and accurate book-keeping of the Italian statisticians will, no doubt, provide in exact detail, will be full of instruction for ourselves.

The water supply, in buildings of somewhat the same kind as those described, in many parts of Italy, is usually given by wells sunk in the court; and a little crane, fixed on the topmost story, enables any occupant of a floor in a vertical line below to draw water by a rope passing over the pulley of the crane. Of course this method depends on the geological character of the site. If large quantities of water are required this hand-work comes to an appreciable cost of labour; but as it may be said to economise time that would otherwise be lost, it is likely to be generally preferred to the laying on of water through pipes, even at the lowest cost yet known in any of the great American cities.

In the calculations which have from time to time been made, by ourselves and by others, as to the feasibility of erecting in London or other great centres of population large *cenobia*, or buildings for the occupation of a considerable body of workpeople, the cost has usually come out at such a figure as to be prohibitive. It has been said that the habits and prejudices of the English people are such as to limit our cheap house-architecture to the mean and paltry aspect of such places as the outskirts of Birmingham. We suspect, however, that prejudices of this kind would disappear before the offer of cheap accommodation in a commodious barrack or *hospitium* like a great Italian monastery. The real question is, Can this be cheaply given? The subject will well repay a large amount of study. We fear that the exigencies of our climate are such as to demand a cubic volume of space, per head of the residents, which, at our prices for land, for materials, and for workmanship, render very cheap housing impracticable. Whether this be so or not, it will be doing good service to the profession and to the public to have the matter thoroughly threshed out.

It is clear that in all the inquiries and discussions that are now going on as to the housing of the working classes, such a statement of the practical cost per head, or per 100 ft. of space, as might be taken to be normal, is a primary requisite. This would, of course, involve the adoption, at all events for purposes of calculation, of a normal plan of dwelling-house, whether composite, as in the case of a large building to contain a number of families, or simple, as in the case of rows of small houses. We anticipate that the ground-rent (which should be calculated separately) would be lowest for the large house, but that the cost of building would be lowest for the row. That, however, is a matter that would soon come into daylight. Provided with a scheme of this kind, distinguishing the cost for site; for buildings; and for rates, gas and water supply; on either plan, our municipal authorities, or any persons interested in the provision of accommodation for the working classes, would have given ground from which to start. To provide a

normal plan and estimate would be beginning at the beginning; and this work of the Italian Government may well aid us in the task.

THE CAIRENE HOUSE.

ON Wednesday last Mr. R. S. Poole, LL.D., delivered a lecture to the students of the Royal Academy on "Cairene Domestic Architecture." The lecturer said that the subject he had chosen was large but yet obscure,—large in point of its far-reaching architectural scope, and obscure in the little which is known about it in the present day. This house architecture had not had its chance, it was fast dying out, and the number of those few but earnest enthusiasts who strove to save its few records was indeed small: among this number were Mr. Frank Dillon and Mr. James Wild, to the former of whom Mr. Poole expressed his great indebtedness for a series of beautiful water-colour drawings unexampled in point of completeness and fidelity,—the only series of the kind extant. The great art of the Middle Ages had two sides,—its eastern side and its western side. The names we assign to these two great sister arts are Gothic and Arab, both strangely wrong when taken in their literal sense. These two arts are in many respects so nearly akin to one another, and the one bears such remarkable and unmistakable traces of the same movements as the other, that, in order to study either in any complete manner, due consideration must be paid to its sister art. In the latest great mosque, for instance, a century old, distinct traces of the Renaissance style may be observed which are so prominent, and carry so much conviction with them that one can no longer doubt the distinct affinity between these two branches.

Where did this Arab art originate, and who were its makers? To answer those questions we must turn our steps back to the distant period of 3,000 years ago: we have an old Theban fresco representing all the particulars of what domestic architecture then was. Here we see the belvedere looking northward, and the same sloping ventilators open in the same direction, covering the terraces of the upper stories, as are now to be seen in the Cairene house of the present century. The reason, perhaps, that there have been so few radical changes is that the style of architecture which is peculiar to Egypt, and especially to Cairo, is thoroughly suited to the climate of the country.

It is somewhat astonishing to find so large a proportion of the interior of the houses built of wood, which must have been expensive in a country where very few trees are to be found; but this circumstance shows the infinite trouble which the working architect would take in order to vary the monotony of the appearance of his work, and to render it thereby as pleasing to the eye as possible. And the mention of the word architect brings us to the question as to who were the designers of these beautiful buildings. Regarding those of very ancient date, history is silent; but when we come to those which are comparatively more modern, we can say with certainty that the decorators were *Christian* Copts. When we say that they were Copts, we must not forget that though the art-workmen were undoubtedly all Copts, the architects of greater buildings were both Copts and Greeks.

So many circumstances have combined to prove the truth of this theory, that one or two instances may suffice to do away with any doubts on the subject. Remembering the essentially decorative character of Cairene art, in comparing the ornament of the Coptic church with that of the Mohammedan mosque, we find designs of a precisely similar nature, and one of the most remarkable proofs of the theory comes from the fact that the finest Coptic geometrical and florid patterns spring from a central cross, and that this cross-pattern, modified so as to conceal or obliterate the cross itself, is found in the Mohammedan mosques, where a cross could not possibly be introduced, as a symbol contrary to all the religious feelings of the Muslim. One has only to compare the Coptic type with the cross with the Coptic type used for Mohammedan without to see the far greater beauty of the Christian pattern. The cross suggests its surroundings, patterns without it are either heavy in the centre from the superposition of the saltire on the cross, so as practically to erase it,

or they present an appearance suggestive of vacancy and meaninglessness,—the want of a true centre. In any case, whichever way we look at it, the force of the Mohammedan pattern is in the surroundings, that of the Christian pattern in the centre; it is almost unnecessary to state which is the more beautiful, nay, which is the only beautiful one; and this fact does away with the sentiment of those who maintain that this Eastern art is no Christian art; and it is surely well to remove a feeling which, if true, would deserve our entire respect. It is, then, to the Copts and to their religion that we owe a debt of gratitude for the beautiful work they have left behind them, and which it is the duty of all artists to strive to maintain.

Cairo is, and, practically, for centuries has been, the capital of Egypt, and it is here that we are to look for the best specimens of our subject. The art of Cairo in the Middle Ages must stand before Spanish and Indian, or even Sicilian, but in domestic work it is an art of within rather than of without. Its beauty is, so to speak, indoors. The outside of the Cairo house is comparatively plain, with the exception, of course, of a handsome door, and sometimes a latticed window, usually belonging to the inferior apartments, the Oriental habits precluding any unnecessary views upon the street. The house architecture of Cairo is all that really survives of fine Medieval work of this kind, and is now on the eve of perishing. The examples still remaining are of the sixteenth, seventeenth, and eighteenth centuries. Even so short a time as forty years ago there were a multitude of specimens of houses which were marvels of decorative skill. A few efforts, it is true, have been made to rescue them from hopeless obliteration, notably that of Mr. Frank Dillon, who, in his splendid water-colour drawings referred to above, has given us what he actually saw before him on the spot, and not artistic efforts straining after effect. Mr. Stanley Lane-Poole also, by dint of untiring energy, has succeeded, not in transplanting a whole Cairene house to England, but in reproducing, with the original materials, an Egyptian room, which, though somewhat diminutive in point of size, is still an accurate representation, and which is to be seen now at the South Kensington Museum.

The plan of the Cairene house is intricate in details, the principles being, however, simple. One must not be led into taking one house as a general example and type of all the rest. By so doing we should narrow ourselves into forming an idea that these houses were all built alike, on hard and fast rules, a notion entirely contrary to that which the architect had in view. His great idea was variety, and his chief care to avoid monotony in appearance and construction; hence it is that all houses differ in their details. The Cairene house was built round three, or sometimes four, sides of a central court, in the which was planted a fine tree. When the house itself only took up three sides of the court, the fourth was usually occupied by a partition wall, separating it from another house. When there are more courts than one the house is made up of so many different houses, corresponding in number to that of the courts. The principal side in point of decorative beauty, that, in fact, on which the artist lavished all his skill, was the side which looked towards the north, and the reason for this was twofold, first because the belvedere or open room with arches was built to face in that direction, and secondly in order that the cool breezes thence might penetrate the latticed windows of the principal rooms of the house. This belvedere was a sort of open gallery with pillars in front,* which formed an agreeable lounge in the hot weather, and which almost always was reserved to the use of the men; in some cases, however, we find it latticed up to a sufficient height for the use of the women. The horror which the Coptic artist and architect had of monotony alike in construction and design is eminently exemplified by the arrangement of the stories and rooms, which present great irregularity. Thus the chief room or men's saloon on the ground floor often reaches to the roof, as also does the chief room on the second floor or women's saloon, and again we have an intermediate story or mezzanine built over a lower ground-floor. The ground-floor, and usually the greater portion of the north side, is generally built of stone, and painted in alternate

* See illustration in this number.

courses of red ochre and white; the higher part plastered with the fine white gypsum of the country. Throughout the building great constructive skill is shown, and, as in all architecture, wherever the construction is good it is sure to be shown prominently. So it is with our Cairene house. The beams which support the ceiling are plainly visible to the eye, and are supported at the ends by elongated corbels ending in perfect stalagmic patterns. Nothing is hidden away; everything is fair and above ground; there is no insincere work, and, unlike our modern edifices, the process of building would have stood the minutest and most critical inspection. The principal rooms in the house were the belvederes mentioned above, the men's saloon, and the women's saloon. One of the beauties of these rooms is the extensive use of wood and the rare use of stucco, which is, indeed, a testimonial to the sterling value of the architect's work, since he preferred to go out of his way to employ wood for his purpose, when he might have got a far easier but more perishable material at home. The men's saloon and the women's saloon were much the same, as far as their design was concerned, the women's being, if anything, the finer of the two; the Orientals showing that they, too, as much as other people, had the right feeling as to the magnificence of the reception apartment of the chief lady of the house. The room itself had a depressed centre, at each extremity of which was a deep bay or dais raised slightly above the central level. Round each of these bays ran divans, and in the extremities of the recesses were the latticed windows,* known as Meshraheeyehs, unequalled for their perfect harmony of designs in wood. Above the depressed centre rises a clerestory, which is usually lighted by a lantern or dome. Round the walls runs a high dado, made of light-coloured marbles, inlaid in simple geometrical patterns, or rich blue tiles of floral patterns, and in this simplicity the Copts showed their excellent taste. Our Oriental artist never forced a complicated pattern before people's faces so as to constantly bewilder them and tire their eyes. But when we bring a piece of lattice-work to England, and put it in a wrong place, we may say, because others do, that it is very charming, but in our heart of hearts we put it down as too complicated, and, therefore, trying to the eyes. But when the Egyptian sat in his room or saloon he was not obliged to be for ever staring at lattices and elaborately intricate patterns. The meshraheeyeh was behind him, and the reposeful dado on his level. The general surface, besides the dado, was usually painted in bluish grey distemper, or the white gypsum of the country was left. The only breaks in the wall were those which were absolutely necessary, such as cupboards and recesses for pottery, porcelain, &c. The only furniture, and that of the simplest kind, consisted in a small table for meals, and on the daises few coloured mats, a prayer carpet or two, and divans. What we should call the furniture in our sense in reality did not exist, the house being furnished by the architect and not by the upholsterer. Stained glass was used sometimes in the upper part of the meshraheeyeh, and constantly in the complete stained-glass windows higher up the wall. In the centre of the depressed centre, in a tessellated marble pavement, a fountain played. There was also a niche in the wall, originally for the purpose of the direction of prayer. As regards colour, and this is about the last point for our consideration, the Copts used what we should call decidedly primitive colours. The red stands for vermilion, the yellow gold, the blue lapis lazuli or ultramarine, the green emerald (sulphate of copper), the black ebony, and the white ivory; and, in their colour, the workmen had due regard for their earlier predecessors' example, and, although they might have made use of the Persian mixed tints, they preferred to employ the above primitive colours, which in no case, in the good period, grate on one's sense of harmony or offend the eye. Towards the close of the age of domestic art, which is known by examples, mixed tints came in. The possibility of adapting an art such as this to our country and climate is a question which has met with ridicule from those who are ignorant of the way to set about the work. It is not an undertaking to be finished in a day, or a work to be treated lightly. The only way to set about it is to acquire a complete knowledge

* See second illustration.

of the grammar of the art, so as to be able to speak its language, instead of, parrot-like, repeating unintelligible phrases. This truth was illustrated by meshraheeyehs, which we usually imagine as being closely latticed, but which here showed large open arches, as well as by instances of the open lattices commonly used in men's apartments. The lecturer, in conclusion, urged upon his audience the necessity of sending students to Cairo to study on the spot this noble art,—an art which, in house architecture, has no rival, and yet which is fast dying away.

FARM BUILDINGS.*

The question of satisfactorily planning and constructing buildings for agricultural purposes is likely in the immediate future to become a pressing one, and although we architects may not be called in as often as we should wish, so much work of this class falls into the hands of land agents and managers of estates, still it is worth our while to study the question as closely as we can, and to give it more attention than the subject has hitherto received, particularly keeping in view the all-important point of economy, as, with decreased rents and the uncertainty that must for many years to come overhang the agricultural interest, owners will be loth to spend the sums that even of late years have been spent upon this class of property; and although the different companies for advancing money for the improvement of lauded estates have helped many landlords to improve their holdings and replace the old and dilapidated buildings with more modern ones, and on estates under good agents and wealthy landlords much has been tried in the way of experiment, and so-called model buildings have been erected, still the great question will always be, what is the least expense that can be entered into properly to house the various farm stock and implements, and to construct the necessary dwellings for the farmer and his labourers?

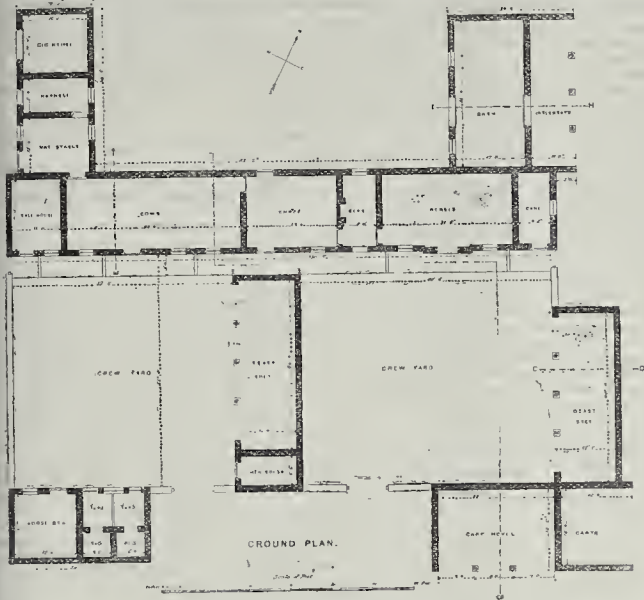

There seems little doubt also that one of the next experiments of the present rulers of our destinies will be to try and develop more largely that class of farmers known as peasant proprietors, and this will of necessity give a certain amount of impetus to agricultural building; but as the greater part of the capital required to be spent will in all probability be provided by the State in the form of mortgage loans, only carefully-planned buildings, useful for their several purposes and economical in construction, should be erected, and I purpose to give here the information bearing upon this question I have managed to gather during the last few years.

I shall not attempt to take you into the higher fields of theory, or to go into the vexed questions of silos, covered yards, or any of the elaborate details of so-called model premises, but will describe the various buildings requisite for an average-sized mixed husbandry farm; and have selected as examples three sets of buildings in the Midland counties, as being fair specimens of the ordinary requirements. I have had no experience of specially-arranged dairy farms, or of the buildings requisite in the hop-growing districts of the southern counties; nor have any of the people with whom I have come into connexion yet entered largely into the manufacture of jam,—which industry, I understand, is to rescue the impoverished British farmer from his present Slough of Despond.

The first point to consider in fixing the site of almost any building in a country district is the water supply, and for farming purposes it is most important that a plentiful supply should be obtainable close at hand. In theory, also, it is best that the buildings should be as nearly as possible in the centre of the holding; but in practice I find that the farmers as a rule prefer to have their house and home buildings as near to a village as they can be got. On any holding above 100 acres, the stock-yards, &c., then, should at any rate be on the farm itself, and a foreman's cottage should be built close at hand. The position of the main roads must be carefully studied, and the easiest access to railway stations considered, the cost of transport being one of the largest items of expenditure in outlying districts.

Having satisfactorily settled the site, the next point to consider is, whether there shall be one, two, or more stock-yards. For holdings

* A paper by Mr. Arthur Young, read before the Architectural Association on the 6th inst.

Threave's Farm Buildings.—Plan.

up to 500 acres two yards will as a rule suffice; but it is best, if the funds at the architect's disposal will allow of it, always to give two, and as far as possible to separate the yards thoroughly. The plan of Threave's Farm shows a simple way of doing this.* Having arranged the yards, the next point to take into consideration is the aspect; and it is most essential to place the buildings so in relation to the crew-yards that the stock fattening shall get the benefit of all the sun that can be obtained, and also should be sheltered from the cold winds by the buildings. The buildings should, therefore, be on the northern and eastern sides of the yards, and the sides to the south and west left open. The level of the yard should be about 2 ft. below the level of the stable pavement, and should be made as impervious as possible by well ramming and clay puddling so as to keep the straw-bedding, &c., in the yard as "good" as possible. In the yards provision should be made for drinking-water for the stock, and if this can be running water so much the better; and an overflow-pipe to keep the yard sufficiently drained is a necessity.

In disposing the various buildings round the yards, it is best to place the following within easy distance of the farmer's house or bailiff's cottage: the wag stable, gig-house, and harness-room, the calf-house, and the infirmary box. The first for convenience by day, and the latter by night, as occasion may arise when it will be important to watch a cow or mare, or to feed the calves by hand, and a dry way of access to them is a good thing. It is a fault on the right side to make both the gig-house and harness-room larger than the uses indicated by their names would imply, as the gig-house becomes generally a storage place for all sorts of odds and ends, and in the harness-room the odd boy about the place cleans the boots, oils the gun, and reads the local weekly paper on Sunday afternoon. About 18 ft. by 14 ft. is a good average size for the gig-house, and about half that width for the harness-room. A small loft is usually arranged over in which a small supply of corn is kept, along with apples.

Taking the buildings in the rotation of the plan before us, we next come to the calf-house, which, in an ordinary way, is simply a large box, about 18 ft. square, with a low manger on three sides divided up by wooden palings into pens of about 4 ft. square. In larger buildings it will sometimes form a detached building with, perhaps, a tramway running down the centre for convenience of feeding, with the pens on each side,

* See also sections and elevations on separate plate in this week's illustrations.

and a gangway all round of about 4 ft. With this arrangement the floor is sometimes sunk about 2 ft. 6 in., and I have seen a very simple and ingenious contrivance for altering the height of the manger daily as the bedding gradually becomes raised, so that the calves can get at their food without difficulty, but an ordinary iron trough answers all practical purposes.

The internal temperature of the calf-house should be kept as even as possible, and it is better to build them with hollow walls. I need not add that no loft for hay or any other fodder should be placed over any cow-shed or similar building, as the hay is not by any means improved by the exhalations of the cattle, and the risk of fire is intensified.

The most impervious floor is the best, and I advise any of the many forms of Portland cement concrete, whether called Granolithic, Imperial stone, or Wilkinson's patent concrete, is immaterial, so long as the cement is really good and the granite chips and shingle clean. I can speak in high terms of Wilkinson's work from practical experience.

The cowhouse may next be described. It is a great point here, as well as in the calf-house and stable, to ensure an equal temperature and perfect ventilation. Where the buildings are of brick, hollow walls will be of great assistance, care being taken to have a thoroughly effectual damp-course of slates in cement, and two or three courses of brickwork, also cemented under, to keep out the mice and rats, great enemies of the farmer as far as his buildings are concerned. The usual width of a cowhouse is about 18 ft.; this allows of a feeding-passage at the back of the mangers of 4 ft. The floor should slope very slightly towards the heels of the cows, and there should then be a drop of 2 in. into a surface-gutter about 1 ft. 6 in. wide, and the remainder will form the usual gangway. It is not necessary to divide the building up into stalls, but it is better to do so at the manger. This is done in the simplest way with oak paling. The mangers should be constructed of some hard and impervious material. There are very good purposely-made glazed terra-cotta bricks for this purpose. Hard blue Staffordshire bricks also do very well, but one of the simplest and best mangers is formed by using the large-sized half pipes, of glazed stoneware used for drainage works, bedded on concrete, and having an oak capping. The joints are fewer and easier made than with the other materials mentioned. I am now referring more particularly to what one may call home-made fittings, in contradistinction to the iron fittings manufactured by those firms who devote their energies to stable fittings. The cost of these would be more than

the ordinary buildings would carry; although for dairy farms, and in those establishments of a more or less show character, they are very effective.

But the strongest fittings, and those which are least likely to cost money in repairs or to need repairs, are those best suited for the farmer.

Again, the simplest methods of ventilation are the best, and the system I recommend is to carry up a large trough of wood, about 2 ft. 6 in. broad at the base, gradually decreasing to about 1 ft. 3 in. at the outlet, and having a plain cap at the top. The sides should be formed in two thicknesses, and the spaces between filled with sawdust. Sufficient air will find its way in by the door and windows to thoroughly change the air in a very short time. One ventilator in about every 15 ft. of length will suffice.

The doors of a cow-house should always open outwards, and should not be less than 4 ft. wide; 4 ft. 6 in. is a better width, and sliding doors are best. But here again the question of cost will probably intervene. I may say here that it is better, if possible, to use nothing in the way of hinges or bolts, &c., except the strongest, and those only that can be made or repaired, if necessary, by the village smith. Avoid complicated patents. The windows should be placed at such a height that if the upper portion is glazed it cannot be reached by the horns of the stock in the yards. The old-fashioned hit-and-miss window, strongly made in wood is as good as anything, and if with a small quantity of glass over will answer every purpose. Where the glass is omitted in the windows, a few glass slates or tiles in the roof will be of use. Cast-iron hit-and-miss windows can be obtained from many foundries. The cost of one, 3 ft. 6 in. by 2 ft. 6 in., will be about 25s., list price.

We next take in hand the stable. There is little to say about it that has not already been mentioned in describing the cow-house. The stall divisions, which should be about 9 ft. deep, should be about 6 ft. 3 in. apart centre to centre, and should be thoroughly strong; the mangers should be much as described for the cow-house, but one must bear in mind that the horse is rather a dainty feeder and has a very strong objection to dirt. Therefore, to avoid waste it is a good thing to have the mangers of some materials easily kept clean, and here, again, any strong glazed ware will be found the best. A cart-horse stable should be, at least, 18 ft. wide, and that dimension is quite sufficient. But it must be borne in mind that the harness, &c., is frequently kept in the stable (although this is a bad thing to do), and provision should be made for, at any rate, temporarily placing the saddles, &c., on rests until they can be put away in the gear-house.

Marking back to the dainty ways of a horse: as regards his feeding, I have been told that if one was to place a pin amongst a feed of corn in the manger, a horse would in all probability pick up every grain and leave the pin. I have not tried the experiment, but I quite believe I should do the same myself. As regards ventilation, the same as I described previously for the cow-house will answer admirably. But avoid if possible any cross draughts, and if you are obliged, as may sometimes happen, to put either windows or ventilators in the same side as the mangers, keep them as high as possible.

The horses are usually brought into the stables reeking hot from ploughing or other work in the winter, and would then be particularly susceptible to cold. I do not think, even in the best stables, it is a good thing to lay on water to the drinking-pot forming part of some iron mangers. A horse will drink with much greater zest from a freshly-drawn bucket of clear water than from a slimy trough that may have been standing for days, and it is more natural for a horse to drink from the ground-level and not from a raised trough; he can get his nose much better into the bucket. If you are compelled, from motives of economy or want of space, to place lofts for hay or corn over the stable (only do so when you are absolutely obliged) be sure and have the loft-floor of cement. The old plaster floors cannot be beaten for this purpose as they are rather warmer than a Portland cement concrete; but in ordinary farm buildings it will rarely happen that you will have to place lofts over any of the buildings, but in hunting-stables and those attached to country houses the architect is obliged to put his lofts on the upper floor, and this

arrangement has many conveniences; but, wherever possible, put lofts over coach-houses, harness-rooms, &c., and only put a passage for service over the stable. I fancy, as a rough rule in large stables, about half of the superficial area of the stable would give the requisite amount of floor-space for the lofts. Mice are troublesome amongst the corn. It is a good thing, where they are very destructive, to cover the floor and line the walls with thin zinc.

The harness and gear-house should be placed as near to the stable as possible, and should be about 8 ft. wide, and should have a fire-opening and flue, as here the farm labourers who are not boarded occasionally sit to take their "hit on the thumb," and it is frequently useful to be able to make up a fire quickly to heat a bran-mash or boil food for the pigs; and a fireplace here saves a journey to, and gossip in, the farm-kitchen. Harness fittings should be of the strongest and rudest description; there is nothing better than strong oak pegs, built well into the wall. The gear-house should have a good-sized window.

A small space should also be provided for storing, under lock and key, artificial manures and oil-cake. The floor of this department should be of wood, with about half an inch between each board, and plenty of ventilation under, as oilcake very quickly gets mouldy, and requires to be kept in a dry and well-ventilated place. Between the stable and the cow-house is the best situation for the root and chaff-cutting place; in small farms an area about 12 ft. by 18 ft. will do, but in larger ones these dimensions should be increased. As the roots will probably be stacked and bedded on the opposite side of the stable range to the crew-yard, it is necessary to have a door at both ends of the building. In the ordinary way, of course, the machines will be worked by hand, but on large farms, and in other cases where steam power is used for other purposes, the chaff-cutting, mulling, &c., will be done by steam power. In the large set of buildings the same engine, one of about 10-horse power, drives, works the sawing-machine, and also does the chaff and root cutting, &c., the gearing being interchangeable.

The barn, partly I suppose by the greater facility with which farmers now dispose of their produce, and partly also from the fact that much that was formerly placed in the barn is now kept in separate places, is generally built very much smaller than used to be the case. Many of us have no doubt wondered at the tremendous stocks that must have been accumulated in the tithe-barns of bygone days. Unfortunately in recent years the farmer has been only too anxious to get his corn thrashed and sold, and there has been little use made of the barn for long storing,—35 ft. to 50 ft. by 20 ft. will nowadays be considered a good barn. It is usual to put the doors of such size that a wagon can be driven through it, and about a third of the barn has a sort of loft over. Cement makes the best floor, and it is a good thing to render the walls in cement for about 5 ft. in height all round. Sufficient ventilation is gained by putting a few air-slits, which should be covered with bird-netting to keep out intrusive sparrows.

I have now taken you round most of the buildings, and there remain only to describe the open sheds for various purposes, and the piggeries. Open sheds are required firstly in the crew-yards, for the protection of the fattening stock, and next for the covering of the various implements, wagons, and carts. The construction of them all is similar on three sides, enclosed by walls, and open on the fourth. On the open sides the roof should be supported by story-posts of wood or iron, and these should be placed on stone bases. The top of the stone base should be about 1 ft. above the level of the paving of the yard, to keep the wood or iron post away from the damp bedding laid down for the beasts. Great care should be taken with the principal trusses of the sheds, as, indeed, throughout farm buildings, and I think that on the whole the queen-post truss is the best one to adopt; and it is a good point to make the tie-beam deeper and stronger than usual, as the principals will most likely be called upon to carry the ladders, sheep-trays, and all sorts of poles, &c., that are wanted out of the way.

I think I have previously mentioned that the sheds should get all the sun possible, so the south-east is the best aspect for them; but

with the cart and implement shed the reverse is the case, as they should be sheltered as much as possible from the sun, and also from the rainy quarter, which in most English districts is the south-west; so that the best position for the cart-shed is facing north-east. It should also be on the main farm road if possible. About 15 ft. is a good depth for these sheds. In many cases an additional useful room could be obtained for standing implements by bringing down the eaves of the barn to take anything not finding sufficient length of room in the cart-shed. This would be cheaper than increasing the width of the shed throughout.

An important point is to get a good isolated infirmary box. This should be about 14 ft. square, and be as much apart from the other stables, &c., as the yard will allow, but should be within easy reach of the farm-house.

Ordinarily in England we do not give very much thought to the housing of the pigs; but upon the plan of the Swiss buildings upon the wall you will see that very great attention is given to "interesting little animals."

Over the infirmary-box in the buildings shown on the wall I have arranged the pigeon-cot, or dove-house, as it is called in Northamptonshire. The great point in arranging a dove-house or columbarium is to provide plenty of nests, and in building with brick this is easily done. A table in the centre, a looking-glass, and a good lump of salt, complete the furniture of the most improved pigeon-cot. It is a good thing to put an external door, as pigeons are easily stolen by putting a net over the pigeon-hole and then rattling the doors which startles the birds, driving them into the nets. Of course, this applies more particularly to those detached buildings at some little distance from the house.

I am afraid that I have already exhausted your patience, or I should have wished to have gone into the question of labourers' cottages and the working portions of farm-houses. But the time at our disposal will not allow this. The question of cost is the great one that requires attention, and the points for us, as architects, to consider how best we can build the most durable buildings, leaving to the farmer and land agent to give us in each case the particular requirements, and having obtained from them the number of horses likely to be required on the farm, and the number of cattle kept, then to give them the necessary accommodation, and to do this always with the materials ready to our hand.

I am having continually impressed upon me that the cost of buildings erected recently is really greater than the land can bear, and that we ought to turn our attention to devising, if it be possible, cheaper modes of construction. And I shall be glad to hear if any of the gentlemen present can give us any information as to the cost of concrete buildings. I am of opinion that farm premises might be erected more cheaply in this material in many districts.

Then the question of roofing material is also a most important one. Galvanised iron is recommended by many as the coming material. I cannot say that I have yet seen it introduced in an architectural manner; and it seems to me lacking in the first essential for roofing material,—durability. It will do admirably for open barns and in similar positions, but how long will it last, watertight, without painting? Not quite long enough to repay the first cost, I am afraid. We have a difficult problem to work out. Let us do it well,—with beauty, if possible,—but always with truth.

For a few notes of the discussion which followed, see next column.

Endless Wire Saw.—A French engineer, M. Viallette, has invented a new saw for stone-cutting, consisting of an endless metallic cord, composed of one or more soft steel wires twisted together, and subjected to a continuous movement in a uniform direction. It is fed with silicious sand or grit, mixed with water, as in ordinary stone-sawing, in order to facilitate its penetration to the bottom of the crevice, and to prevent heating. The apparatus can be easily set up, taken down, or transported from place to place, one of its great advantages being the readiness with which it can be used in quarries, so as to avoid superfluous transportation. M. Tisaandrier, the editor of *La Nature*, speaks of it as "the butter-cutting wire used for sawing stones."

ARCHITECTURAL ASSOCIATION.

At the ordinary meeting, held on Friday, 14th inst., Mr. Colo A. Adams, President, in the chair, it was intimated that the second Saturday afternoon visit will be made this Saturday, 14th, to 16, Carlton House-terrace, Waterloo place.

Mr. Arthur Young then read a paper on "Farm Buildings," which will be found in another column.

The Chairman, in opening the discussion, said that any special subject brought before the Association by a man who had devoted his attention to mastering its details must be professionally interesting. Mr. Young had evidently gone into the subject *con amore* as was seen from a professional point of view, and had given them a most useful lecture for reference hereafter. An important question for the architect and engineer was the necessity of seeing how the greatest amount of accommodation could be brought into the smallest space how the health of the stock could best be preserved; and instead of rule-of-thumb, there should be a *raison d'être* for everything. Considering the rise in the cost of building, and the great depression in agriculture, the necessity for arriving at the lowest cost, in the most scientific manner, became at once apparent. With reference to damp-courses, it was necessary in wet climates to have these to the chimneys.

Mr. H. W. Pratt said he should be sorry if the cutting up of the land into small holdings resulted in farm buildings being too much of one pattern. Architects, if consulted in reference to such buildings, should study what was most suitable, in conjunction with the landscape, as a model farm set down amongst beautiful scenery would mar it to a great extent. He had much pleasure in proposing a vote of thanks to Mr. Young.

Mr. C. H. Brodie remarked that in the matter of plaster floors he knew of an instance in which a manure-tank was tried in the yard, but was finally filled up. It was found that liquid manure did not get to the tank, but that only water from a neighbouring stream got there. The reason so much trouble was taken in Switzerland in regard to manure was its utilisation in the vineyards. He seconded the vote of thanks.

Mr. H. G. Turner had always found that the great difficulty lay in the question of cost. The general idea was to have good buildings, but the expense must be kept down, and, as Mr. Young had remarked, this question would become more difficult in future. If large farms and a considerable amount of capital could not afford good buildings, what could be done by peasant proprietors? He could hardly imagine that the system of ventilation mentioned by Mr. Young would answer well; but he found that Kite's or Boyle's ventilators answered in stables. His experience was that concrete was the best flooring for stables, giving a good foothold for the horses, and being the cheapest floor that could be laid down. He had always heard the plaster floors called "Nott's floors," but he could not understand their being warm. He was born in a house with such floors, and it was no joke to get out of bed and step on them in cold weather. As to the cost of concrete farm buildings, they might be economical where several farms of one shape and in one district had to be built, but not otherwise. He was afraid that picturesqueness in farm buildings would have to be given up, especially where it interfered with economy, and that the picturesqueness would have to be resorted to.

Mr. Ellison questioned whether corrugated iron roofs would come into use in farm buildings. They stood very well about three years, after which the only thing to be done was to tar or paint them every year. The question of paving was often a matter of choice, one man preferring blue Staffordshire bricks, and another Dntch clinkers.

The Chairman then put the vote of thanks, which was carried by acclamation. He also referred to the picturesqueness and simplicity with which Mr. Young had treated some of these buildings. He (the Chairman) had used a good deal of concrete pavement; he believed it was the best; and if channelled out there was not the slightest fear of the horses slipping. The drainage should be in straight lines, with an eyelet at every junction.

Mr. Young, in replying, advised the members to get the Swiss book on agricultural construction to which he had referred. With

regard to simplicity, nothing in that way was so picturesque as a group of Sussex farm buildings, while there could be no greater blot on a landscape than a set of new farm buildings built of new bricks and slated.

THE PUGIN TRAVELLING STUDENT-SHIP.

DURING a part of last week there were exhibited, in the "Arbitration" room of the Royal Institute of British Architects in Conduit-street, the drawings and sketches submitted in competition for this fine ribbon of the architectural sketched, which this year has attracted no less than twelve knights of the pencil; in strong contrast with the Godwin Bursary, for which we are sorry to see there were but two competitors,—a very regrettable fact, and one which is a little surprising when we recollect the complaint in some quarters that our young men are becoming too practical, to the neglect of the artistic side of the profession. Some of the sketches exhibited are certainly very excellent, and in at least one instance of quite exceptional quality. We say this in all sincerity, and recalling, as well as we may, former competitions for the same prize, we think that the general level of execution is up to the average of other years.

It seems to be understood by the judges and most of the competitors that the claims of applicants who submit specimens of both measured drawings in ink and of freehand, pencil or water-colour sketches, will be considered before those of students who produce the one or the other alone. This is only right and reasonable, since both are necessary to the proper study of architecture; and it is to be regretted that some very beautiful work in either section was unaccompanied by any effort in the other, and was, probably, more or less put out of court on that account.

The choice of the judges has this year fallen upon Mr. W. H. Bidlake, who has already distinguished himself by winning the Institute Silver Medal for his measured drawings of St. Mary's Church, Leicester, and by obtaining honourable mention in the last competition for the Architectural Association Travelling Studentship. We think that few will question the wisdom or justice of the decision. The drawings of St. Mary's Church, just mentioned, are themselves marvels of conscientious draughtsmanship, but are surpassed by those of Prior Crauden's Chapel, now shown for the first time, and of which it is hardly too much to say that they leave nothing to be desired in the way of beautiful execution.

Mr. Bidlake's pencil sketches* show a wonderful delicacy of touch and a painstaking determination to be true as well as effective, which is most delightful and refreshing after some of the dashing scribbles that seem fashionable just now. We would offer one criticism, and that is, that the author seems to have, either consciously or unconsciously, a little too great love for the effect of pretty pencil work for its own sake, and apart from consideration of the objects represented; such a feeling, though creditable in itself, is likely to hamper its possessor unless fully recognised and kept in its place.

Mr. H. O. Cresswell, to whom has been awarded a medal of merit and the second place, showed careful measured drawings of the tomb and shrine of Henry VII. in his chapel in Westminster Abbey. Of these it is no disparagement to say that they are only a little less beautiful than the drawings of the same shrine made by Mr. Pither in 1874, and which obtained for him the Silver Medal of the Royal Academy. Mr. Cresswell submitted also a large number of pencil sketches, some strong water-colours, and two drawings of a design for a theological college, which were awarded a medal of merit in the competition for the Soane Medal last year.

Mr. T. MacLaren, who, at the instance of Professor Kerr, was recommended to the prize committee as deserving a second medal, exhibited some fine measured drawings of the cloisters of Westminster Abbey, and some careful ones of the south transept, which are also good, but being executed some time back show by comparison the very decided progress of their author in draughtsmanship. The pencil sketches of this competitor are numerous, and

particularly interesting as representing rather unfamiliar objects with great force and feeling. We heartily applaud the wish to recognise the merit of Mr. MacLaren's work. Such sketches as those of St. George's Chapel at Windsor, the east window of Malrose Abbey, and that grand old fellow the Florentine Boar, should not go unnoticed.

Mr. Reginald Barratt sent some truly delightful sketches of Italian buildings and church furniture,—and other less architectural objects,—sketches which are certainly above the common level of architectural students' work. It was obviously no lack of merit that failed to gain them recognition, but probably the absence of studies of English work, and, indeed, of any important ones of a purely architectural character. We noticed with particular pleasure the sketches of the market-place at Verona, of the font in the Frari Church at Venice, some lamp-pendants, and some Byzantine capitals, as well as one of a shrine in St. Mark's.*

Mr. E. Guy Dawher had a number of good sketches in portfolios on the table, but, owing to the absence of larger drawings, they may have attracted less notice than their merit entitled them to. Mr. Littlewood had a goodly show of measured work. Mr. J. R. Sutton exhibited the drawings of Terrington St. Clements Church, which gained him a medal of merit in another competition last year. Among the other competitors there was, we believe, one from the United States, but his work was not up to the level of what we have lately seen of American students' sketches,—for instance, in the Sketch Book of the Boston Architectural Association,—and failed to gain recognition. We hope and believe that this will not in any way tend to deter others of our consins from the opposite side of "the puddle" from competing for architectural honours in the old country; it is obvious, from remarks made in the course of the discussion at the Institute last Monday week, that if any notice at all were taken by the judges of the nationality of competitors—and we do not for a moment believe such a thing possible—it would rather tend to take the form of considering the disadvantages under which these students labour who have none of the fostering care of our London societies, the inspiring influence of our London buildings, and the other advantages of a residence in the English metropolis.

MR. C. ROACH SMITH, F.S.A., ON THE ROMAN WALL OF LONDON.

LONDON AND MIDDLESEX ARCHAEOLOGICAL SOCIETY.

THE usual monthly meeting of the members of this society was held on Tuesday evening last, at King's College, Somerset House, Mr. J. G. Waller in the chair, when a paper written by Mr. Charles Roach Smith, F.S.A., vice-president of the society, was read, in the unavoidable absence of that gentleman, by Mr. E. W. Brabrook, F.S.A. The paper was entitled, "On the late discoveries in the Roman Wall at Bevis Marks, and at other parts of the northern mural boundary of London," and in it the author said:—

The London and Middlesex Archaeological Society has recently contributed materials of the most important kind for the history of Roman London, thanks to the energy and perseverance of a few of its more active members. Written records are but scanty; they are but little beyond a blank for centuries. They do not amount to as much as the newspapers of our time tell us in a day. Yet the metropolis of Roman Britain, the central focus of the province to which converged the great highways, crowded with military bodies, with travellers, merchants, and merchandise, through the very heart of Britain, must have had a history of its own which, had there been chronicles of it, would have stirred our souls far beyond what is effected by the disjointed and loose annals of the ages immediately subsequent. Deprived of written narratives which would have revealed the mental life of the great city, we are supplied only with a few disintegrated fragments of tangible memorials to help the formation of some idea of the architectural constructiveness, of the artistic skill, and of the social condition of the inhabitants. In these, however, there is something, and

it is the duty and province of the antiquary to make the most of them. When bronze heads, arms, and legs are dug up in different places, in imagination we restore the bodies. We justly conclude that they were public monuments, and that no city but one of importance could have afforded such costly adornments. The same with the remains of villas, of sculptures, and the examples of the elegant and industrial arts preserved in our public museums, or engraved in publications. It is not difficult to point out here and there the sites of public buildings, of a temple, and of villas, but nothing more; who erected them, or at what precise time, there is nothing to show. The genius of destruction is swift and relentless; almost before the lapidary record which indicated the site of a temple to the personified province could be copied, it was snatched from us, and the resurrection of thousands of historical monuments has been more perpetually fatal to them than the grave in which they had so long been buried.

I need not here describe the sculptures which of late years have been recovered from the foundations of the Roman wall on the north of the city of London. The Society has rendered it unnecessary by its engravings and descriptions. Added to these must be the statue from Bevis Marks, engraved as the frontispiece to the catalogue of my London Collections,* and also the fragments of sculptures engraved or described in the same volume. I see that I remarked, "They prove a violent destruction of at least considerable portions of Roman London, at a comparatively early time," &c.

Especially connected with the discoveries now before the Society are those made at Tower-hill, in 1852, described in my "Illustrations of Roman London," taken, I make no doubt, from the foundations of a Roman bastion; but I had no opportunity of witnessing this disinterment. With them were mill-stones in Andernach lava so large that they must have been worked with horses or mules. These remains were all from the foundations of bastions; but the equally-important sculptured stones, which I have repeatedly referred to in former years, excavated in Thames-street, were in the foundations of the curtain wall, at the depth of some 14 or 15 feet. They were mostly of very large size, sculptured, with Lewis holes; and must have originally belonged to edifices of great public importance. They had been found, I was told, by hundreds, and were carted away forthwith to be used again for building materials. There were some dozens on the ground when I saw and sketched a few. It must be remembered that the existence of a wall on the river-side had been denied,—denied because no trace of it could be seen!

Now come the questions, when and for what cause or causes were these sculptures placed in the foundations of the wall? It is probable I may at the outset be at variance in my opinion with some of my friends and colleagues in saying "the wall." They may consider that the bastions do not properly constitute a part of the wall, and that they may have been built later. I look upon them as co-eval, and I have shown that, so far as regards the river mural boundary, at least, sculptured stones were used in the foundations of the curtain wall.

Many years ago, I laid before the Society of Antiquaries of London reasons for believing that the great Roman circumvallation known as "London Wall" was built at some time posterior to the time of Severus, and that the limits of the earlier wall did not extend northwards so far as the site of the Royal Exchange.

Unfortunately, none of the inscriptions found in the wall afford the means of fixing a date. But, made and rough as some of the sculptures are, taken altogether they suggest a comparatively early and not a late date; they are quite unmixt with any characteristics of the style of art or of the sentiment of the times after the Constantines; and, I need scarcely add, they show no trace of Christian influence. Among the inscriptions found in the walls of Bordeaux, to which I am about to refer, was one of the time of Posthumus, A.D. 258, proving the wall to have been built subsequently to that epoch. Had opportunities been afforded in past years, no doubt some decided evidence of date might have been gathered from other parts of the London Wall, for I believe that in its construction throughout these monuments were

* A drawing of the pulpit in S. Lorenzo, at Rome, which Mr. Barratt also submitted, was reproduced in the *Builder* for July 12, 1884.

* Also in "Illustrations of Roman London," Pl. V. *Ibid.*, Pl. VI.

* We propose to reproduce two of these next week.

used. Why were they employed in such abundance? They indicate violence in each case, whether they are from public buildings or from cemeteries.

When the city was enlarged, large portions of the latter must have been included within the walls, where, it is probable, they would no longer be tolerated; and, moreover, generations had passed away and the memorials of tributary affection had become disregarded. Human nature is the same in all ages. What has become of the thousands upon thousands of the sepulchral monuments of our ancestors? Search the graveyards, and it is rare to find any anterior to the sixteenth century. Search the churches, and perhaps not one in a hundred is to be found. From the absence of historical evidence it is difficult, if not impossible, to point to any national calamity to which the destruction of public buildings in Londinium can be inferred, yet such there may have been, and extensions of the city may have immediately followed it. We shall gain something by comparison. It will be seen that numerous other Roman towns and cities exhibit in their walls precisely similar revelations as those of London. Most of the extremely interesting monuments which (chiefly by aid of the artistic skill of Mr. Waller) I have published* from Bordeaux, Sens, Dijon, &c., are from the foundations of the walls of those towns. At Sens, upwards of 300 sculptures, all more or less important,† have been collected from the destroyed walls; at Bordeaux and many other places, probably as many more. At Bordeaux the wall was found to be built to a height of about 12 ft., and to the thickness of about 15 ft., with large worked stones from the violent destruction of ancient monuments, such as temples, palaces, triumphal arches, fountains, tombs, &c.; these stones were carefully laid without mortar, one upon another. Above this thick substructure, mortar was used for the usual materials, the facing being of small squared stones regularly laid, with hands of tiles at intervals. It is remarkable that the Roman masons, in using these ancient monumental stones, had, almost always, taken care to avoid useless mutilation, and had evidently laid them in a spirit of religious conservatism. But, whatever may have been the degree of veneration for these remains, it was obvious that the monuments had been destroyed by violence. The walls had been built, especially on the south side, upon the ruins of burnt houses, and the vicinity was entirely composed of the debris of ancient edifices destroyed by fire; many of the largest stones were calcined, and almost all bore traces of intentional and brutal mutilation. In 1826 another excavation at Bordeaux,‡ brought to light similar sculptures, with a like respect for their preservation; for they had been carefully arranged without mortar, in the interior of the wall, and guarded on the exterior by layers of enormous stones, placed without cement. I noticed the same construction of the wall of Tours. Such is the indestructible tenacity of the mortar, that while in the lower part fragments of large monuments and inscriptions are to be seen in place, the corps of the wall is yet well preserved. The extensive lapidary museum at Narbonne has been supplied almost wholly from the destroyed walls of the town. I only refer to a few out of numerous instances, and I have not referred to the castra, in some of which ancient monuments have been used for the foundations of the walls, as, for instance, at Larzac, near Tours, where large columns, sawn horizontally, are disposed exactly as those were which I saw in a bastion at Bevis Marks. M. H. Schnermaus, of Liège, in an almost exhaustive article on the Ramparts of Arlon and Tongres,§ has discussed this subject in all its bearings with great judgment and success. Arlon, *Orolanium*, has furnished from its walls, which showed a construction similar to those of Bordeaux and other towns, a large number of sculptures and inscriptions. M. Schuermaus has reviewed comprehensively the remains I have referred to and those of other places, and he concludes, with M. de Camont, that the building of these walls with ancient monumental remains must be assigned to the end of the third century. He denies the possibility of any such erections (as has been in one

instance suggested) in the interval between the fourth and ninth century.

To return to our own country, I can see that these discoveries in London will tend to promote inquiry as to what similar facts have occurred in towns and castra in England. Some can certainly be shown.

A discussion ensued, in which Messrs. Alfred White, F.S.A.; J. E. Price, Hon. Sec.; and the Chairman took part, and a vote of thanks was accorded unanimously to Mr. Roach Smith for his paper.

ARCHITECTURAL SOCIETIES.

York Architectural Association.—On the 5th inst., in the saloon of the Victoria Hall, Mr. K. A. Parkin completed a course of three lectures on graphic strains, principally referring to buildings. A good attendance at each meeting has been the rule. Mr. Wm. Hepper, vice-president, proposed a hearty vote of thanks to the lecturer, which was ably seconded by Mr. Norman R. Yeomans. Mr. Parkin, in responding, offered a few encouraging words as to the value in the future of the subjects he had attempted to demonstrate.

Edinburgh Architectural Association.—The usual fortnightly meeting of this Association was held on Monday evening last in the Professional Hall, George-street. The President, Mr. G. Washington Brown, occupied the chair. After some preliminary business, the Chairman called on Professor Baldwin Brown, B.A., to read his paper entitled "Gottfried Semper and his Theory of Architecture." The lecturer described Semper as one of the most distinguished of modern German architects, and as a writer famous for his contributions to the history and theory of the art he practised. His career was especially interesting to natives of this country, as part of it was passed in London, where he worked for some years in connexion with the Science and Art Department. The leading events of Semper's life were briefly summarised. His last practical work as an architect was in connexion with the colossal buildings erected on the "Ring" at Vienna, where he finished designs for the Opera House and the new Museums. He died in Italy in 1879. Referring to Semper's contributions to the literature of his art, Professor Baldwin Brown gave a short account of Semper's book on "Style," which contained, he said, in the first place, a full and admirable discussion on the industrial arts, the materials employed in them, and the style of treatment which the artist should adopt in dealing with different purposes. In the second place, there might be found in the work the materials for a history of the constructive and ornamental arts of antiquity, which should do for ancient times what Jules Lahorte has done for Byzantine and Medieval in his "Histoire des Arts Industriels," while there were dispersed through the volumes profound and suggestive remarks, which might form bases for a philosophy of art. As a specimen of Semper's treatment of the industrial arts, a *resumé* was given of the first few chapters of his book, which deal with the materials of the textile art, and the principles to be followed in the decoration of walls and floors. Semper's general theory of architecture was next referred to. Architecture as a fine art did not, in his view, begin with the shelter or fortress of primitive man, but in structures raised for purposes of religious or patriotic commemoration. Early monuments of architecture were in many cases, like the Temple of Solomon, merely copies in permanent materials of festal structures formed of wooden framing, and covered with rich hangings and garlands. A few words on the bearing of this theory on the history of architecture up to the time of the Romans concluded the paper.

The Improved Wood Pavement Company (Limited).—The report and balance-sheet presented to the shareholders at the thirteenth ordinary general meeting held on Monday last show a net profit of 11,700*l.* 19*s.* 1*d.*, from which, on the recommendation of the Directors, it was resolved to pay a dividend of ten per cent., which will absorb 8,221*l.*, and to credit the account of the "vendors" with the sum of 1,622*l.* 16*s.*, as shown year by year in the balance-sheet, carrying the balance 1,851*l.* 8*s.* 1*d.* to "Reserve Fund," which will then stand at 11,991*l.* 1*s.* 3*d.* The Directors state that in face of the very severe competition, the company has still held its own successfully.

Illustrations.

CARVED WOODEN PANEL (RENAISSANCE).

THIS panel, the original of which in the Louvre, may be described as a conglomerate of details very executed, though having so much Renaissance ornament with no logical connexion or character of detail. The foliage of the lower portion is naturalistic, as well as that in the cornucopia; the foliage which the arms of the torso ramify, is conventional and of very fine type. It cannot be recommended, therefore, as a study of ornamental art in the abstract ought to be, there is a holdness and freedom about it which one must admire while condemning its esthetic principle, or want of principle. Work of this kind often furnishes admirable hints for designs which could be worked out in a more homogeneous style of detail.

REREDOS, ST. ANDREW'S CHURCH, ABERDEEN.

THE reredos has been erected as a memorial to the late Bishop Suther. It is in Caen stone with the shafts of the columns of polished Devonshire marble, and was executed by Harry Hems, Exeter. The inscription above the base runs, "In memoria viri reverendissimi Thomæ Georgii Suther, D.C.L., qui xxv annos (1857-1883) Dioceseos Aberdoniæ Episcopatum, simulque per xxv annos (1855-1879) hujus etiam Ecclesiæ curam pastoralem gessit. Hoc sacrosanctum monumentum pietatis, desiderii, testimonium Natus 1814. Obiit 1883."

PROPOSED CATHEDRAL SITE FOR LIVERPOOL.

FOR description of Mr. H. W. Brewer's design of the Cathedral of Notre Dame, Paris, restored with its spires by M. Viollet-le-Duc and arranged upon the site for a cathedral at Liverpool, see Mr. J. P. Scaddon's article, p. 224.

HOUSES IN CAIRO.

THE two photolithographs entitled "Front House on Court, showing Mak'ad" (after Prisse), and "Barber's Shop" (after Coste) formed part of the illustrations used by Mr. Stuart Poole in his lecture at the Royal Academy on "The Cairene House," for report of which see p. 227.

TOYNBEE HALL.

THE University Settlement, Commercial-street, Whitechapel, has just been completed from designs by Mr. E. Hoole, F.R.I.B.A., 104, Great Russell-street, W.C. Accommodation is provided for twenty resident University men, for whom bedrooms, private sitting-room, and common room are provided. On the ground-floor are lecture-hall, dining-hall, drawing-room, and offices. The buildings have been executed by Messrs. Lathey Bros., in brick and Box stone.

The object of the institution, it may be mentioned, is to provide for and encourage the residence of educated men in the midst of the East End population, and it is one of the machines which have been promoted by the Rev. S. A. Barnett, of Whitechapel,—whose name will be known to all in London who are interested in the good of the people,—for enabling various classes of society to meet more, and know each other better, and for giving increased facilities to the poor for gaining culture and raising the standard of life. A large number of classes and lectures are already in progress in the hall to which all are admitted at merely nominal fees.

FARM BUILDINGS.

FOR details of these see Mr. Arthur Young's paper on p. 228.

The Hospitals Association.—The first annual meeting of this Association is to be held on the 11th of March, when Sir Andrew Clark, Bart., M.D., will preside.

WILLEY CHURCH, WARWICKSHIRE.

WILLEY CHURCH, WARWICKSHIRE.

This small but interesting church, which lies in the neighbourhood of Lutterworth, where Wycliffe ministered, is at present undergoing thorough restoration, together with several important additions.

The building previously to restoration consisted of a plain but effective Late Decorated tower and nave, with a semi-Classic chancel and porch of red brick and stone dressings, added in the early part of this century.

The tower not being square on plan has a curious oblong appearance, and is heavily buttressed at the angles. It has good gargoyles and parapets, and is connected with the nave inside by a boldly-moulded arch.

The nave has been overhauled in Perpendicular times, when a flat roof of the period was substituted for the old high-pitched Decorated roof, the rake of which is shown by the stone string on the tower; at the same period two large three-light windows were inserted. The present existing roof is a later one still, and is very curious and interesting, having been added at an age not particularly famous for church restoration. At the first glance the principals appear to be Perpendicular, but the date 1678, carved upon them, and the character of the initials I O and E R, and carving generally, show its undoubted age. A curious "end" was made when the architect was examining the building: over the chancel arch (which only remains to the spring) there was discovered, partly covered up with plaster and timber work, a well-carved principal of Perpendicular work; no doubt one of the beams of the earlier roof which appears to have been destroyed by fire, and which served as a model for the principals put up in the repairs of 1678.

In these explorations a very good square-headed doorway, with an internal arch, was found on the north side of the nave leading into the octagonal stair-turret, which shows on the north side of the nave outside; above this was found another door, narrower and arch-headed, at the level of the roof-loft, all traces of which are gone.

There were also found the remains of a very beautiful thirteenth-century tomb, built as a lintel over the south door, probably in the repairs of 1678. It represents the recumbent and nearly-

perfect figure of a woman with her hands clasped in prayer, resting behind three well-moulded quatrefoil panels cut in stone of a very red colour, apparently so by the action of fire.

On removing the plaster from the north wall of the nave the whole wall was found to be covered with paintings in distemper arranged in panels, and a dado with a stencilled running pattern on the top representing I.H.S. monograms interchanged with scroll-work and birds; the doorways to the rood-screen stair and chancel arch were also stencilled with very good ornament. The paintings were all too much defaced to make a restoration possible.

The outside of the nave roof was roughly covered with lead, lapping over the walls at the eaves, all traces of the parapet being gone. It is intended to relay the roof, and to place a crenellated parapet, with mask gargoyles and lead spouts, on both sides of the nave.

The new additions to the church in course of erection are a Decorated chancel and porch, a new chancel arch, and a vestry opening into the chancel by a stone arch filled up to the spring with a wooden screen.

The old gallery at the west end of the nave and the old seating will be removed, and new seating substituted upon wood flooring.

Every care is being taken in these restorations to preserve the ancient character of the old work, and nothing will be removed or touched which is not absolutely necessary.

The work is being done by the rector, the Rev. F. Morgan Payler, from designs by Mr. Walter F. Lyon, of 50, Lincoln's Inn-fields; the builders being Messrs. Law & King, of Lutterworth, who carried out the restoration of Bitteswell Church in the same neighbourhood in a very satisfactory manner for the same architect a year or two ago.

The Cheshire Lines Extension Contract.

Owing to the failure of Mr. Walter Smith, the contract for the Cheshire Lines Extension to Southport fell through, but was subsequently tendered for by Messrs. R. Neill & Sons, of Manchester. That firm will complete the work, with several additions. The contract on the whole will amount to upwards of 20,000.—*Liverpool Journal of Commerce.*

THE PURITY OF AIR IN TOWNS.

CAPTAIN DOUGLAS GALTON, C.B., read a paper on this subject on the 7th inst., at a meeting of the Association of Public Sanitary Inspectors, held in the rooms of the Social Science Association, Adam-street, Adelphi, Mr. Jerram being in the chair.

Captain Galton said he had selected a subject which had a most important bearing on the profession of his auditors. All air, and especially town air, was full of floating matter or dust. The experiments of Mr. Aitken, of Edinburgh, showed that it was owing to the presence of foreign matter, such as dust or smoke, that aqueous vapour became visible as fog. If there was no dust in the air there would be no fog, no cloud, no mist, and probably no rain. Dust was not, therefore, necessarily an evil except when present in excess, which was generally the case in large towns. In manufacturing districts and in towns which approached the size of London, the evils arising from smoke and dust became greatly intensified. The experiments of Dr. Russell on London air, of Angus Smith on the air of the Scottish hills, and of M. Marie Davy of Paris, had proved that air in the centre of large towns was more laden with bacteria and similar organisms, which are forms of dust, than air in more open and elevated places. These organisms were of immense use in the economy of nature, but they were also causes of certain forms of disease: and the question of how to diminish the impurity of air in large towns, therefore, became one of the utmost importance. The smoke of factories, the dust from street sweepings, organic matter from stable-yards, and defective sanitary arrangements in the home, were the principal causes of the pollution of town air. Dr. Morgan's statistics showed that the mortality of persons under fifteen was 40.7 per 1,000 in certain enumerated towns as compared with 22 per 1,000 in the country districts.

The removal of the children of the London Orphan Asylum from Clapton to Watford had resulted in a large diminution in the death-rate. The deaths in the ten years previous to removal from Clapton amounted to forty, and in the subsequent ten years at Watford to only fourteen. It was an undoubted fact that the populations of large towns deteriorated, and that the stamina of these populations was mainly

kept up by immigration from the country. The importance of the removal, and as far as possible of the prevention, of smoke would be evident in comparing the population of London at different periods. At the beginning of the present century it was 960,000, at the present time 4,000,000, and it was estimated that, at its present rate of increase, in 1920 it would be 8,000,000. Simple machinery for the uniform distribution of fuel over the bars of grates would prevent black smoke; bakers' ovens could be worked by gas, though not profitably at the present price of gas; steam, hot-water, hot-air, and gas might be much more largely introduced into the household for heating purposes, and in other ways the evil of smoke might be almost entirely got rid of. An increasingly-important question in London in respect to purity of air was that of the disposal of the dead. The universal use of the inhumation should be insisted upon.

An interesting discussion followed, in which Mr. E. C. Robins, F.R.I.B.A., and Messrs. Middleverick (South Kensington), Mr. Rains (St. George's-in-the-East), Mr. Stace (Limehouse), Mr. Fisher (Camberwell), Mr. Alexander (Shoreditch), and other inspectors took part.

TEMPORARY OR MOVABLE WOODEN STRUCTURES.

By Section 13 of 45 Vic., c. 14, it is provided that it shall not be lawful for any person to erect or set up any wooden structure or erection of the above character, unless the same be exempt from the first part of the Metropolitan Building Act, 1855, which exemption, so far as is necessary for the consideration of this section, is as follows:—

"All buildings not exceeding in height 30 ft., as measured from the footings of the walls, and not exceeding in extent 125,000 cubic feet, and not being public buildings wholly in one occupation, and distant at least 8 ft. from the nearest street or alley, whether public or private, and at the least 30 ft. from the nearest buildings and from the ground of any adjoining owner."

And further,—

"All buildings not exceeding in extent 210,000 cubic feet and not being public buildings, and distant at least 30 ft. from the nearest street or alley, whether public or private, and at least 60 ft. from the nearest buildings and from the ground of any adjoining owner."

And in case any person erects or sets up any such structure or erection without the licence first had and obtained from the Metropolitan Board of Works, a penalty not exceeding 5l. and a further penalty of 40s. for each day during the continuance of the same, may be proceeded for. Wooden structures erected by builders for use during the construction, alteration, or repair of any building, are exempted.

This is a very important section to keep in mind, as a great number of temporary erections, such as mission-halls, temporary chapels, meeting-houses, &c., are being erected in the metropolis, and as it has been held in a recent case that the penalties are continuous, and may be sued for at any time, a builder or other person may find himself, after some time has elapsed, mulcted in a very heavy amount; and in all cases it would be well before erecting structures of the above character to first obtain the licence of the Board.

The Powers of Water Companies.—In a special report which has been submitted to the Kensington Vestry, Dr. Dudfield draws attention to a case in which twenty separate business premises in a mews in his district were suddenly deprived of their water-supply by the action of the Grand Junction Waterworks Company, who severed the service-pipes to the several premises because the landlord had failed to pay the water-rates. In this case the landlord's default to make the proper payment seems to have been inexcusable; but Dr. Dudfield refers to the case mainly with a view of showing how needlessly extensive and arbitrary are the powers with which water companies are vested in this matter. Not only can groups of houses be thus suddenly deprived of one of the necessities of health and life, but if any neighbours or friends were to give those persons whose water has been cut off a supply from their own service-pipes, or were to allow them to take enough for their needs, they would render themselves liable to penalties of 10l. and 5l. respectively; whereas the company could, without resorting to so extreme a measure, recover the rent for water by an ordinary legal process.—*Lancet.*

HOUSE DECORATORS' CLUB AND INSTITUTE.

The fourth annual general meeting of the shareholders of the House Decorators' Club and Institute Company, Limited, was held in the large room of the Club, 19, Howland-street, on Thursday, the 5th inst., Mr. J. H. Donaldson in the chair. After the minutes of the last meeting had been read and adopted,

The report and balance-sheet were carefully discussed. It appeared from these that the number of shares had been increased by 104, making the subscribed capital upwards of 1,000l. Owing to the delay caused by the completion of the necessary legal arrangements with adjoining owners and others, only a portion of the alterations and improvements referred to in a previous report had been commenced, but it was hoped the remainder would be proceeded with shortly. The decreased income derived from the Club was considered to be sufficiently accounted for by the very depressed state of trade during the past year.

After the passing of the balance-sheet and report, and the re-election of the secretary and treasurer, six directors were elected to complete the board. A suggestion from the chairman to secure the services of a public accountant as auditor was unanimously adopted, the usual remuneration being voted to the retiring auditors.

Replying to the cordial vote of thanks which closed the business of the meeting, Mr. Donaldson said that in the face of the state of trade in the past year their report must not be looked on as discouraging. Business is often sick, but never dies, and he hoped that a revival of trade during the ensuing year would bring greater prosperity to the company. He would venture to suggest that the greater attention should be paid to the library of the Club, the book-shelves of which he regretted to see so sparsely filled. Mr. J. F. Pascock, their solicitor, had just authorised him to promise them a parcel of books at once. In addition, he (the chairman) recommended that each one should give a small sum specially for this object; and if he succeeded in collecting by their next meeting the sum of 100l., he would himself give a similar amount. The 20l. to be entrusted to a specially appointed book committee to expend on the books most suitable for a library principally used by house decorators.

LIGHT AND AIR CASE.

BULLER v. DICKINSON.

This was a case (High Court of Justice, Chancery Division) in which it was contended that there had been a loss or abandonment of an ancient right

under the following circumstances:—The light in question was originally derived from a window in a room on the ground-floor of an old wooden toll-house three stories high, the line of frontage of which projected forward into a street, 4 ft. at one end and 7 ft. at the other. Nine years before the action the old house was pulled down by the then owners, who sold the projecting part of the site to the Vestry of the parish for the purpose of widening and straightening the street, and further without any interval erected a brick building of one story on the rest of the site. In so doing, he carried back the frontage to the line of the rest of the street, and he placed in the front wall a window which, according to the evidence, occupied a portion of the corresponding space of the ancient light in the old house, but was situated in a wall not built in the same plane as or parallel to the old wall, but set further back 4 ft. at one end and 7 ft. on the other. The ground-floor room which this window lighted was an extremely small room, and was used for the storage of iron.

Mr. Justice Kay, in giving judgment, held that the ancient light had neither been lost nor abandoned.

WIDTH OF STREETS.

FELIX BELL, of 5, Lansdowne-road, Old Charlton, appeared to a summons taken out by the Metropolitan Board of Works, at the Woolwich Police Court, for unlawfully (after committing a breach of the Metropolis Management Act, 1856 and 1862, and 41 & 42 Vic., c. 32, and By-laws), continuing a certain house or building in such a manner that the external wall or fence was at a less distance than 20 ft. from the centre of West-street, Charlton; and for allowing the same to remain after conviction for a period of 172 days.

Mr. Thomas Burton appeared for the Board, and the defendant appeared in person.

Mr. Burton, in opening the case, stated that this was the third application against the defendant, who was first convicted on the 27th of November last, and fined 20s. and 2s. costs. As defendant had done nothing to remedy the offence, a second summons was taken out, which, after several adjournments, was heard on February 6th, 1885, when defendant was fined 10l. and costs. He now applied for the balance of the penalties at 20s. a day for the breach of the by-law.

The defendant said it was impossible to remedy the defect, and that he had the consent of the Vestry to the erection as it now stood.

Mr. Marsham said he should again convict the defendant, and fined him 20l. and costs.

WHO WRITES THE SPECIFICATIONS?

Sir,—The Institute is fortunate in its present President, for many reasons. Amongst others because he believes in specifications as an important part of a true architect's work and duties. Witness his address a few years ago to the Architectural Association.

In the rules of the Institute, the specification (for estimate and contract) is described as one of the items of an architect's work to be covered by the 5 per cent.

I should like to know how many of the "leading" architects practising in London write their own specifications, or have them, a rule, written in their own offices, under their own immediate direction, by their own clerks? The specification is, or should be, an important part of the design. It sets forth, for the information of the client and of the builder, the architect's mind and purpose as to innumerable matters, or it should so set it forth.

When I entered a London office, many years ago, I found it the practice to let the quantity surveyor write even the more important specifications. Now, again, in 1885, I am told by an architect's assistant (working for me), and who was articulated in one of the leading London offices, that after seven years' experience in London, the greater part of the time under architects of eminence, he never had a chance at specification writing. He does "not think it was done in the office." "The quantity surveyor used to do it" (just as they used in experience, over a quarter of a century ago). I should like to ask also if those architects who do not write (or pay for the composition of "their" specifications, make a corresponding deduction from the 5 per cent. commission.

Nothing has done, nothing is doing, our profession more harm than the action of those architects,—many of them deservedly eminent—who undertake a great deal more work than they can possibly duly design or see to in detail; which they cannot (for want of time) duly describe in a proper artistic specification and which they cannot, for the same reason, properly supervise as the buildings go on. Trouble comes surely enough,—on the builder or on the client, or on the architect, or on a three. Cases crowd on my memory as I write of defective foundations, undrained basements, costly apartments unusable, pillars of arcade giving way, stone shafts chipping and flying with unskillful construction, decay of timber (and within a few years) too-flat tiled roofs letting water in like a sieve, bad flanking omitted, masonry and brickwork with little or no mortar, dangerous steps, scamped builder's work undetected, drains letting sewage soak into foundations, or acting as conduits of sewage to dwellings.

These are the things that defile our profession. There is one sort of architect who, when he gets work, spares neither time, nor trouble, nor money in order that everything may be the best that he can make it under the instructions received,—a man who shows his "genius in an infinite capacity for taking pains." There is another sort, whose chief anxiety and effort is to get work, and when once the client is committed to him, his next point is to carry on the work at the least pecuniary cost to himself, and at the least trouble.

Nowadays any number of people can draw and draw well. A very large number can design well too, and of these a large proportion can make good details. I fear that comparatively few can see a building well through to the end, and deliver it up to its proprietor in all respects what it should be and is understood to be; and of these last I fear there are still fewer who do it. EXCELSIOR.

ÆSTHETIC PROPORTION.

Sir,—If I rightly interpret your leader in the *Builder* of the 7th, headed, "Proportion in Theory, and Proportion in Practice," it is an invitation to discuss the subject. I cannot just at present, say all that I would wish because I have to give a lecture in April,—not on the 1st,—on the Foundations of my new Science of Æsthetics, in which I propose to show why the subject of proportion is so important a study in the fine arts. With moderns it would appear to be a foregone conclusion that the Greeks possessed a science of æsthetic proportion. I myself believe that this was the case, but we have to recollect that belief is not certainty, and that not until we

shall have worked out and formulated a science of proportion by a rigorously scientific method, and are able to test Grecian work by his science, shall we be able confidently to assert that the Greeks had also worked out this self-same science. It would appear to be thought that the Greeks were in possession of some occult science of proportion never to be revealed to meaner mortals. That such a notion should obtain in this scientific age is somewhat anomalous. It is clearly absurd to suppose that the Greeks could, by any possibility, have been acquainted with the correct principles of proportion, had they not obtained them by careful investigation, by a scientific method. It is true that the instinct of a perfectly constituted optic sense may have been their monitor, and kept them near the truth, or it is on the evidence of the perfectly constituted optic sense that the principles of correct proportion are founded, or, at all events, verified. Instinct, however, is not knowledge. We should not forget that although the Greeks had not traversed the whole circle of the sciences as we moderns, they, nevertheless, had their one pre-eminently exact science, the mathematics, and we may reasonably suppose that possessing but this one, they may have made much of it, and have even applied it to express the principles of art. This art, about which persons without the slightest understanding of it are so fond of chattering, is a product of the human nature; it is in the constitution of this that its principles are to be sought. Art is not an entity of the outer world to be observed and measured like the planets and their orbits. Art is, as we have said, a human product, resulting from the adaptation, of whatever may for the nonce be its theme, — either to human taste, or to the human understanding. Strange to say, however, that when we push our investigations on this subject to their ultimate issues, we find that the principles of proportion, oppositely to the human nature, coincide with those which obtain in the Cosmos. That is to say, there is but one science of proportion.

W. CAVE THOMAS.

THAMES SEWAGE NUISANCE.

SIR,—With respect to the Thames River nuisance frequently discussed in your journal, may mention that I had occasion to pass up and down the river four times, in the course of travelling, last autumn; I venture, therefore, to add my testimony to confirm the statements therein as to the noxious emanations both from the banks and waters of the river. If one considers the hydraulic action of river estuaries, it will be seen that they may be unsuitable pools for the discharge into them of outfalls of sewage. Any one may observe the phenomena of discharge and entrance of the waters of a river at a seaport provided with a river flowing out between two jetties into the sea, as at Ostend. The sea-water on the flood tide will be found creeping along the bottom of the channel, and flung up the fresh water flowing down on its back. When the tide of salt water recedes it will be seen that it creeps down again the same way it came up, leaving the fresh water on top. This physical condition is effected by virtue of the heavier specific gravity of the sea-water (1025.30) over the fresh water, compelling it always to tend to lie underneath it, and not to mix with the other above, unless by violence.

The sewage and drainage matters and fluids will consequently tend to remain generally on the surface of the water of the river estuary, except the mineral ingredients, whose specific gravities will be greater than that of the sea-water. Further, when the tide is running up on the flood, the level of the water will be an inclined plane sloping downwards from the mouth of the river to the town above. This will tend to prevent the river water flowing out to sea, and drive it back again to the town.

When the sea-tide is running out, the inclined plane will be reversed, and the fresh water will tend to run down to the mouth of the river. This reversal, however, will take place, not at the point of the backed fresh water at the town, but will commence first at the river's mouth, and gradually ascend to the relief of the imprisoned water above.

It may, however, in long rivers arrive too late to be of much service in letting out the

whole of the impounded fresh water down stream for an exit to the sea. Consequently before this can be done, owing to want of time and great distance, back comes the fresh water on the back of the rising flood, with all its impurities, to discharge afresh decomposing vapours over the riverine areas.

Viewing the sewage fluid as an organic infusion, like tanning or dyeing solutions, the ultimate destination of it on arrival at and discharge into the sea will, no doubt, be to float on the surface and spread out as a film, owing to its superior lightness and lower specific gravity than that of pure salt water. It will then be probably carried off by the prevailing winds in different directions, assisted by the tidal currents.

Its final dissipation will likely be due more to their natural action than to that of the sea-water underneath, which already has dissolved in it nearly as much as it can carry, viz., from three to four per cent. by weight of solid matter.

In the summer weather the evils of the floating sewage will necessarily be intensified, as its light specific gravity will be made lighter still by the sun's heat, and decomposing interstitial gases will be easier liberated by virtue of increased elasticity imparted to them.

In the winter the only mitigation must come from the aerial coldness diminishing evaporation and gaseous elimination, as the condensation of bulk owing to this cause in the sewage fluid can scarcely attain the superior original density of the sea-water. It would become of much interest in this view of the matter that experiments might be made in the river to find the temperature and density at different depths, and at different places along its course a chemical investigation at the same spots might also lead to determining the different ratios that subsist between the organic and saline matters present in each sample taken.

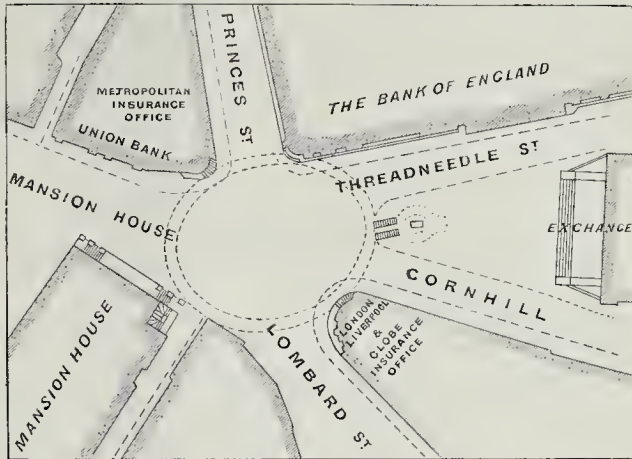

If sewage were found to float off on the surface of the river and not become mixed or dissolved in it, then this would explain why the banks get fouled with blackened deposits.

If the fluid really did mix with the sea-water, then it would be borne down by the ebb tide in the centre of the chief current in the middle of the river, out to the open month.

The phenomenal appearance there of fish in the river would be explained by their swimming in their real native element below the film of sewage fluid above, which no sooner they by chance would enter than they would get poisoned.

TRAVELLER.

Hydraulic Power.—Mr. J. Stannah, of Southwark Bridge-road, has just completed new hydraulic cylinders for working a very powerful crane, and a passenger-lift, at Messrs. Page, Draper, & Co.'s warehouse, Weston-street, Bermondsey. They are working by the high-pressure water supplied from the General Hydraulic Power Company's mains.

Mr. E. Gregg's Plan for a Subway at the Mansion House.

MANSION-HOUSE SUBWAY.

SIR,—I beg leave to point out a defect in the proposed scheme [*Builder*, p. 163, ante], and to offer the suggestion of an alternative route. It is well known that a large number of persons cross the space from the corner of the Bank of England, and by the scheme this corner is excluded from the proposed benefit; the alternative route is shown on the enclosed sketch, and consists of an irregular oval subway touching the six points, Bank of England, Union Bank, Mansion House, Smith Payne's Bank, Liverpool London and Globe Office, and, finally, the Wellington Statue. This particular form could easily be ventilated by means of the six approaches, and would obviate the necessity of the central circular obstruction 20 ft. in diameter, which must seriously interfere with the vehicular traffic. The space could be left entirely free, or the present refuges could be retained for such persons as would not avail themselves of the subway. I make this suggestion solely on the assumption that a subway is a necessity. I am not by any means sure that it is.

E. GREGG.

VENTILATION AND VENTILATORS.

SIR,—The paper upon this subject, read before the Architectural Association by Mr. F. R. Farrow, as reported in your issue of the 24th of January [p. 123], is one of the best I remember reading.

I was particularly struck with the sensible remarks of the author upon the diffusion of gases. Many people believe because carbonic acid gas, in comparison with the atmosphere generally, is much heavier, that therefore it inclines to collect at the bottom of the room. Mr. Farrow very ably corrects that mistake; and if further proof be wanted, it will be got in the interesting experiment made by Count Berthollet (as explained in Part I., p. 151, of Deschamps's "Natural Philosophy"), who filled two globes respectively with hydrogen and carbonic acid, and placed them above each other at some distance apart and communicating by a very small pipe. Notwithstanding the carbonic acid being in the lowest globe, it would not stay there, but went up and mixed with the hydrogen, which latter came down and mixed with the carbonic acid, all while the two globes were at rest.

I agree with Mr. Farrow that a good fixed ventilator is better than a moving one.

W. P. BUCHAN.

Glasgow.

KINNAIRD CASTLE.

SIR,—In the Dictionary of the "Architectural Publication Society," it is stated that W. H. Playfair, of Edinburgh, was the architect of Kinnaird Castle, Forfarshire (the mansion preceding the present one by Bryce); and the authority for this appears to be a work entitled "Forsyth's Beauties of Scotland," 1805-8, but this statement is clearly inaccurate, as Playfair was at the date not more than seventeen or eighteen years of age.

A recent writer on the mansions of Scotland also associates W. H. Playfair with the erection of the castle, but states that it was completed by the year 1790.

This seems rather to point to James Playfair, the father of W. H., as the author of the design. He was living in London till 1792, and was esteemed an architect of eminence in his day. Can Mr. Papworth or any of your readers kindly throw any light upon this?

G. S. AITKEN.

Dundee.

GOVERNMENT TENDERS.

SIR,—I observe that your paper contains almost every week numerous advertisements of the Commissioners of her Majesty's Works and Public Buildings soliciting tenders for various works in London and other towns, but my experience is that in no case will the Department give the slightest information concerning the result, except as to the acceptance or non-acceptance of a tender.

As your readers are aware, this is totally opposed to the usual practice of architects, who generally open tenders in the presence of the competitors, or at least furnish them with a detailed list.

Even the London School Board is considerate enough to post up such lists in their lobby for general inspection, and the Poor Law Department tenders are usually made known, while the Office of Works will not even give the name and amount of the accepted tender.

It therefore seems quite time, in this age of competition and publicity, that this secret practice of her Majesty's Office of Works should be given up, as no one knows whether the lowest tender is usually accepted, or the grossest favoritism shown.

It is hard, too, on the firms who tender, as, if the lists were shown to them, they would see their relative position, and be saved the annoyance and loss of repeatedly tendering when it is all to no purpose, either through their prices being too high or their tender being passed over in favour of some one else's.

I do not suggest that there is actual unfairness in the selections that are made; but if none exists there can be no good reason for such impenetrable secrecy.

Could not the Builders' Society or the National Association of Master Builders induce the architects of the Department to conform to the general practice? Or, must we try and get some Members of Parliament, before another election, to obtain a relaxation of the present rules?

Even if publication were prohibited, I think those who expend time and trouble in the preparation of *bona fide* tenders should be allowed to know how they stand.

H. S.

"NON-ACCEPTANCE OF LOWEST TENDER."

SIR,—I can fully endorse the opinion expressed by Mr. Wm. White in last week's *Builder* [p. 217], that if "Fairplay" has been asked to tender for work, and his tender, being the lowest, is not accepted, he can charge the person inviting him to tender with the cost of preparing his estimate. If he has simply applied, in answer to an advertisement, for the quantities, &c., he has no ground for action.

To prevent the possibility of any misunderstanding on this point, I always print on the endorsement of my quantities the following words:—"The lowest or any tender not necessarily accepted, and no allowance made for tenders."

W. HOFFMAN WOOD, F.G.S.

Leeds, February 9.

DAMP DWELLINGS.

SIR,—Could any of your readers kindly give me some information or advice on the following case? About two years ago I built a large dwelling-house in a somewhat exposed situation, the outer walls of which are 1 ft. 6 in. thick, built of mountain limestone, with "diamond rock-work" facing in close joints and Beer stone dressings, and lined inside with bricks (no air-space). After occupation, one angle of the building (north-west aspect) showed signs of excessive damp, which has continued to the present time, the plaster crumbling and the wall-papers rotting and dropping off. This is in the drawing-room, and, curious to say, in no other part of the building is there the least sign of damp. For some time it was thought to be the natural effect of the new walls, and would dry out; but it has now been occupied twenty-one months, and is no hotter than at first. Nothing has been done externally; but a year ago the walls inside were coated with silicate, and tar-paper put under the wall-paper, but with no good result. Can any one suggest a remedy?

JOSEPH BIRD.

CAUTION TO ARCHITECTS, SURVEYORS, AND OTHERS.

SIR,—Let me warn you and other members of our profession against a circular recently issued by "The Orphans," five in number, of a highly respectable practitioner (P.S.A. and F.R.I.B.A.), who died in September last, and who before his death received a considerable sum of money subscribed for him by friends and several professional colleagues.

It has come to my knowledge that money has been and is being obtained, ostensibly for the family of this deceased architect, by a person who has signed their names without, I am told, their authority. One pretence under which small amounts have been thus obtained from two well-known London architects is that one of the orphans (the second in age) required a certain sum to enable him to defray the cost of a passage to Australia; another is, that the Architects' Benevolent Society, having made a grant to these orphans, is unable to pay it for a

week, a fortnight, or so on,—a statement made with profit some weeks after the whole amount of the said grant had been paid to the eldest of them.

This letter may, perhaps, be in time to save many from being victimised, and if the few who have already suffered will communicate with me, or send me any of the numerous letters written by, or in the name of, these orphans, some good may yet result from the too-indiscriminate almsgiving which has taken place in this instance.

WILLIAM H. WHITE,
Hon. Sec. Architects' Benevolent Society.

IMPERMEABLE SURFACE.

SIR,—Would any of your readers be so good as to inform me, through your paper, of an inexpensive way of rendering the surface of a few rods of ground nearly, or quite, impermeable to water, in order to collect rainfall to fill a tank?

T. T.

The Student's Column.

DESCRIPTIVE GEOMETRY.—II.

HERE are cases when it is exceedingly easy to draw the projections of an object, and work out any problem relating thereto; for instance, a wall parallel to the plane of the picture allows one to measure its dimensions on the elevation, both widths and heights, but the elevation of the roof will not allow you to measure direct the distance from the ridge to the eaves. If there be a wall on the skew relatively to the elevation, such as the sides of a bow-window, you cannot get at its width from the elevation only, you must then use the plan.

The whole science of descriptive geometry consists in various methods of bringing back the objects represented to such positions relatively to the planes of elevation and plan, that the problems relating thereto should be easily solved.

This is achieved by two different methods. 1. Rotations.—You can turn about an object and bring it to any position you like by two rotations, which are very easy to draw. In the first, the object rotates round a vertical axle; in the second, round a horizontal axle. In the rotation round a vertical axle, Δ , the elevation of the point m^* travels along a horizontal line from m^* to m^v , whereas the plan of the point m travels along an arc of a circle from m^h to m^h . See fig. 3.

Fig. 3.

In the rotation round a horizontal axle, A^h , it is the elevation of the point m which travels along an arc of a circle from m^* to m^v ; whereas

Fig. 4.

* The point is sp. ken of as m simply, when no immediate reference is made to its relative positions on the diagram; it is m^h or m^v when the special positions thus designated are referred to.

now the plan of the point m travels from m^h along a line parallel to $L T$. See fig. 4.

It is often convenient to be able to rotate plane, P , round one of its traces, P^h , and lay flat against one of the picture planes, say on $plan$. In this case the plan m^h of a point m move on a line perpendicular to the trace P^h of the plane, which serves as axle or hinge to rotation. See fig. 5.

Fig. 5.

Practical Application of Rotations.

We want the real length and the real inclination of the hip of a roof given in plan and elevation.

We can make it rotate until it be parallel to the elevation plane. In fig. 6 the vertical

Fig. 6.

Fig. 7.

rotation axle is taken at the lower end of the hip; $a^v b^v$ is the real length of the hip, $a^h b^h$ angle a of $a^v b^v$ with the horizon, is its inclination.

Fig. 8.

If you want to mark out a certain length of the hip,—to draw, for instance, a given zinc lead ornament thereon,—all you have to do is first bring the hip parallel to the elevation

mark thereon the dimension $b^1 m^1 r^1$ red, and rotate back the point m to $m^1 m^1$. There are many ways of carrying out this item which the student may try simply as a way of exercising himself in geometrical drawing. It can be brought by rotation the hip parallel to the horizontal plane. See fig. 7. It can be rotated the hip round its horizontal projection, and lay it down flat upon the plane having marked the length, $b^1 m^1$, he wishes to draw, he rotates the hip line back in its former position. See fig. 8.

Fig. 8.

It can rotate the hip round its vertical projection and lay it down flat upon the elevation. See fig. 9.

Fig. 9.

But all these processes are, in practice, not carried out to the following figure. You make a right-

Fig. 10.

angle triangle, of which the horizontal projection $a^1 b^1$ is the base; the height, $b^1 m^1$, of the triangle over the eaves forms the other side; the perpendicular, $a^1 m^1$, on the third side is the real height of the hip; and the angle, a , is its inclination.

VARIORUM.

MR. EDWARD STANFORD, of Charing-cross, has sent us his annual map showing the proposed new metropolitan railways, tramways, and miscellaneous improvements for which plans were deposited at the Private Bill Office in November last with a view to legislative sanction in the coming Session of Parliament. It is very clearly arranged, and provided with adequate "references." Mr. Stanford has also issued another map of much interest at the present time, viz., "A Map of the New London Boroughs as proposed in 'The Redistribution of Seats Act, 1885.'" The map shows at a glance the extent of the several new boroughs, their population, and the number of members to be allotted to each. The proposed divisions of the new boroughs are not shown, no doubt because the Boundary Commissioners have only just held their inquiries in the metropolis. An examination of the boundaries of the boroughs as proposed to be constituted shows several anomalies, — or, at any rate, the lack of a "scientific frontier" in more than one place. For instance, the new borough of Chelsea (the major part of which consists of Chelsea proper), has a minor part far to the north, between Kensington and Willesden; thus the proposed new borough of Kensington will intervene (in the direction of its greatest length) between the two parts of the new borough of Chelsea. Two or three similar cases are to be noted south of the Thames, where a small portion of the new borough of Wandsworth is completely detached and wedged in between the new borough of Lambeth and Camberwell, this minor portion of Wandsworth being to the east of Lambeth, while the major portion is to the westward. Another instance south of the Thames is in Southwark, where the districts known as St. Saviour's, St. Olave's, and Horselydown are, as at present proposed, not to form any part of the suggested new borough of Southwark, but are to be thrown together and form a completely detached portion of the new borough of Rotherhithe, with the new borough of Bermondsey between them! No wonder that the inhabitants of St. Saviour's and the other districts are protesting against this arrangement. The inconvenience and confusion caused by calling the district of which St. Saviour's Church (St. Mary Overy's) is the centre by the name of a district some distance further down the river, and not even adjoining it, will be great. The proposed new borough of Southwark is to be formed of the districts of Christ Church and St. George-the-Martyr, and will be one of the oddest and most awkwardly-shaped of any of the boroughs. Bounded on the north by the Thames in the vicinity of Blackfriars Bridge, and on the west and south by Lambeth, the new borough of Southwark will be bounded on the east by the detached part (St. Saviour's) of the proposed borough of Rotherhithe and by the proposed borough of Newington, but will have an awkward tongue or isthmus running out in a south-easterly direction for about a mile between the boroughs of Bermondsey and Newington. This strip mainly follows the line of the Old Kent-road, and is for a great part only an eighth of a mile wide, and in no part apparently more than a quarter of a mile wide. Such anomalies are due, of course, to adherence to the parochial boundaries, which in London are sometimes "fearfully and wonderfully made." How this comes about we will not stop to inquire, nor shall we venture to suggest any re-arrangement of the districts on lines which should partially ignore existing boundaries. With the political aspect of the subject we have nothing to do; we have merely pointed out certain anomalous boundaries because we think that the constitution of the proposed new Parliamentary boroughs cannot but have some bearing on the municipal government of the metropolis, its efficacy or its inefficiency in the promotion of the public health. We should add that the map showing the proposed new borough boundaries forms a supplement to Mr. Stanford's series of London Government maps, which we noticed in the *Builder* for June 21 last, p. 912. — Messrs. Cassell & Company (Limited) send us a parcel of their magazines for February. In the *Quiver* there is an article on church steeples and towers, illustrated by views of the Norman tower at Bury St. Edmunds and the tower of St. Mary's, Hull. Knight's "Practical Dictionary of Me-

chanics," part 98, contains a great deal of information, concisely put, as to Electricity and Electric Lighting. Part 12 of the new and revised edition of Cassell's "Technical Educator," contains, among others, papers on mining and quarrying, the art of glass-painting, perspective, drawing for stonemasons, and principles of design. — The *Leisure Hour* for February (56, Paternoster-row) contains an article entitled "Hints for the Improvement of the Dwellings of Artisans and Labourers," addressed "not to speculating builders, but to the wealthy, and especially to proprietors of land and extensive manufactories and mines." — Part 3 of Ward & Lock's "Technical Journal and Industrial Self-Instructor" (Ward, Lock, & Co.) contains papers on draughtsmanship for the building and engineering trades, wood-working and cabinet-making, "The Stonemason as a Technical Worker," and other subjects. With this work is being issued a "cyclopaedic dictionary of terms in technical science and industrial art," with French and German equivalents. The section now being issued deals with "architectural design and building construction."

RECENT SALES OF PROPERTY.

ESTATE EXCHANGE REPORT.	
FEBRUARY 2.	
By G. A. WILKINSON.	
City—15, Fish-street-hill, freehold, area 954 ft.	£4,500
Walworth—Ground-rent of 40l. a year, reversion in 38 years	1,000
Victoria Docks—25, Custom House-terrace, freehold	2,630
21, Custom House-terrace, freehold	800
Shoreditch—10, Church-street, freehold	855
By H. C. NEWSON.	
Lavender-hill—20, Ficke-road, 85 years, ground-rent 6l. 5s.	330
Upper Holloway—84, Elthorne-road, freehold	465
Hoxton—11, Bristow-street, 22 years, ground-rent 6l. 4s.	215
14, Wimbourne-street, 19 years, ground-rent 4l.	230
81 and 82, Shaftesbury-road, 17 years, ground-rent 7l.	430
By W. B. HALLETT.	
Hampstead Heath—The Lease of Windmill Hill House, term 10 years	40
FEBRUARY 3.	
By FURBER, PRICE, & FURBER.	
Marylebone, 25, St. Mary's-terrace, 53 years, ground-rent 12l. 12s.	680
Knightbridge—33, Trevor-square, 32 years, ground-rent 3l.	560
FEBRUARY 4.	
By MARK LIEBL.	
Poplar—9, Dull-street, freehold	270
Milwall—183, Westferry-road, and a Plot of Land, 27 years, ground-rent 3l. 16s.	405
By S. WALKER & RUNTZ.	
Wood Green, Neas-road—Four Residences, 93 years, ground-rent 25l. 4s.	639
Southgate-road—Two Villas, 24 years, ground-rent 16l.	620
Station-road—Three plots of freehold land	220
Southgate—1 to 4, Cyprus Cottages, 92 years, ground-rent 12l. 12s.	410
Glebeon Cottage, and a plot of land, freehold	160
FEBRUARY 5.	
By TOWERS, WILLIAMSON, & ELLIS.	
Paddington—30 and 32, Prad-street, 36 years, ground-rent 24l.	1,610
By MARSH, MILNER, & LANGTON.	
Lewisham—130 and 132, Lewisham-road, 31 years, ground-rent 10l. 15s.	855
FEBRUARY 6.	
By MITCHELL & SCODDLE.	
Clapham-road—14 and 20, Lingham-street, freehold	730

MEETINGS.

SATURDAY, FEB. 14.	
Architectural Association.—Visit to 18, Carlton House-terrace. 3 p.m.	
MONDAY, FEB. 16.	
Royal Institute of British Architects.—Mr. Ralph Nevill, F.S.A., on "Roof Coverings." 8 p.m.	
Royal Academy.—Professor C. F. Newton on Sculpture: "The School of Praxiteles." 1. 8 p.m.	
Royal Architectural Museum and School of Art.—Distribution of Prizes by Mr. F. H. Morris, A.R.A. 8 p.m.	
Statistical Society of Glasgow (Architectural Section).—(1) Mr. R. A. McIlvray on "Plaster Work." (2) Mr. H. Morrison on "Slates."—Professor George Forbes on "The Distribution of Electricity." III, 8 p.m.	
Victoria Institute.—8 p.m.	
TUESDAY, FEB. 17.	
Institution of Civil Engineers.—(1) Mr. B. Baker on "The Metropolitan and Metropolitan District Railways." (2) Mr. J. Wolfe Barry on "The City Lines and Extensions (Inner Circle Completion) of the Metropolitan and District Railways." 8 p.m.	
Royal Institution.—Prof. Sidney Colvin on "Museums and National Education." I. 3 p.m.	
Birmingham Architectural Association.—Address by the Vice-President, Mr. W. H. Kendrick, 7.30 p.m.	
Statistical Society.—Sir Richard Tempe on "Population Statistics of China." 7.45 p.m.	
WEDNESDAY, FEB. 18.	
Royal Academy.—Lectures on Sculpture: Mr. R. Stuart Cook, LL.D., on "Medals." 8 p.m.	
Carpenters' Hall, London Wall (Free Lectures to Artisans).—Professor Corfield on "House Sanitation." 8 p.m.	
British Archaeological Association.—(1) Mr. Thomas Morgan on "The Roman Baths of Bath." (2) The Rev. G. F. Browne on "The Ancient Cross in Leeds Church." 8 p.m.	

Erratum.—In the list of "Complete Specifications Accepted," on p. 219 of our last, No. 15,139, Piggott, should have been described as relating private or domestic fire-escapes, not fireplaces.

Builders' Foremen and Clerks of Works' Institution.—Ordinary meeting, 8.30 p.m.
Douglas Institute of Architecture.—Professor Carnelley on "Some Chemical Facts connected with Plumbers' Work." *Royal Meteorological Society.*—7 p.m.

THURSDAY, FEB. 13.

Royal Academy.—Lectures on Sculpture: Mr. Hamo Thornycroft, A.R.A., on "Imitation the Means, not the End of Art." 8 p.m.
Institution of Civil Engineers.—(Special Meeting).—Mr. W. Pole, F.R.S., on "The Theory and Practice of Hydro-Mechanics." II. Water Supply. 8 p.m.
Society of Antiquaries.—8.30 p.m.
York Architectural Association.—Mr. W. H. Thorpe on "Colour Decoration." 7.30 p.m.

FRIDAY, FEB. 20.

Royal Academy.—Mr. G. F. Bodley, A.R.A., on "Some Principles of Ancient Architecture, and their Application to the Modern Practice of the Art." 8 p.m.
Architectural Association.—Mr. H. A. Gribble on "The Human Renaissance." 7.30 p.m.
Society of Arts (Indian Section).—Mr. P. L. Simmonds on "The Teak Forests of India and the East, and our British Imports of Teak." 8 p.m.
British Museum.—Professor J. F. Hodgkiss on "Medieval English Remains." I.—The Normans. 2 p.m.
University College.—Professor C. T. Newton on "Greek Inscriptions." IV. 4 p.m.

SATURDAY, FEB. 21.

Edinburgh Architectural Association.—Visit to Calton Jail.

Miscellaneous.

Hygienic Comparisons between Gas and Electric Light.—Some interesting experiments have been recently made at the Royal Theatre, Munich, in order to determine the elevation of temperature and amount of carbonic acid generated under illumination by gas and the electric light respectively. Before the performance commenced, the curtain was raised, and all the lamps allowed to burn for an hour, at the end of which time the temperature was observed at intervals of five minutes simultaneously in the parquet, balcony, and third gallery. During the performance, when from 500 to 600 persons were in the theatre, the thermometer was observed every two minutes. The experiments showed that the electric light greatly diminishes the increase of temperature. It does not render ventilation superfluous, but it requires a less active ventilation than gas, since it does not, like gas, contribute to the increase of heat and carbonic acid.

Durrans's Patent Disconnecting Valve for Soil-pipes.—Mr. Thos. Durrans, A.R.I.B.A., has recently patented a new arrangement for disconnecting water-closets, and bath, lavatory, and other "wastes," from direct communication with the main soil-pipe. The water-closet outlet or bath or lavatory waste-pipe discharges into a globular receptacle which is supported on, and forms an enlargement of, an arm or branch soil-pipe connected with the main soil-pipe. In this arm or branch soil-pipe is an air-tight valve below the globular chamber, so arranged as to shut without any mechanism, and not needing any packing. It is claimed for this valve that "it opens with the slightest flush of water, at the same time allowing every drop to drain away." On the top of the globular chamber before mentioned is fitted an air-tight access door for inspection. The arrangement (one merit of which is that one down-pipe only is needed for all requirements) may be seen in action on the premises of the manufacturer, Mr. F. Botting, 6, Baker-street, Portman-square.

A mural Tablet is to be erected in the church of Overstone, near Northampton, as a memorial of the late Baron Overstone. It is of Dove marble, nearly 5 ft. long, 4 ft. high, and 3 in. thick, with a hollow moulding round the outside edges. The corners are square, and project $\frac{1}{4}$ in. beyond the general line of the design, with a semicircular centre at the top. There are eleven inlaid panels of pure black marble, the four corner ones being cross-shaped, the centre top one circular, with long narrow ones extending from corner to corner and surrounding the large centre panel, which is 3 ft. 3 in. long and 2 ft. 3 in. high, and upon which the inscription is engraved in gilt letters. All the marble-work is highly polished. The whole of the mouldings are of bronze, and surround each panel, that round the centre one being surmounted by the baron's coronet, while within and upon the black marble is his monogram. The tablet has been executed by Messrs. J. W. Bird & Co., Marble Masons, of 147, Easton-road, where it is on view up to Monday evening next.

The Sanitary Assurance Association.

The fourth annual meeting of the members of the Sanitary Assurance Association was held at the Offices, 5, Argyl-place, Regent-street, W., on Monday last. Professor F. de Chaumont, M.D., F.R.S., in the chair. The secretary, Mr. Joseph Hadley, F.S.S., read the annual report and financial statement for the year 1884, from which it appeared that the work of sanitary inspection and issue of sanitary certificates had been continued on the plan initiated by the Association in 1881. The properties inspected during the year had been of the most varied character, including residences of every class in London and the country, also mercantile offices, dairies, and other trading premises, and institutions of a public character. In every case, save one, the sanitary arrangements had been found to be more or less defective. In order to encourage good workmanship, certificates had been given to builders and plumbers who had satisfactorily executed sanitary works under the supervision of the Association. A reduced and inclusive scale of fees had been issued, with the result that the demand for the services of the Association had so much increased that, in spite of the reduced charges, the financial statement for the year showed a greater income than in 1883. The Chairman, in proposing the adoption of the report and balance-sheet, expressed his satisfaction at the steady progress which had been made during the fourth year, and he looked forward to this progress being continued so long as the Association maintained its present high standard of sanitary work. Lieut.-General Burne seconded the adoption of the report, which, after some discussion, was carried unanimously. Mr. Barrington Kennet and Dr. Danford Thomas were re-elected members of the executive council. Sir Joseph Fayer, K.C.S.I., F.R.S., was re-elected President, and Professor Roger Smith, F.R.I.B.A., was elected Vice-president.

British Archaeological Association.—At the meeting of this society on Wednesday, the 3rd inst., Mr. S. Tucker, Somerset Herald, in the chair, the Rev. Prohemary Scarth reported the discovery of the base of a pedestal at Park Farm, Tockington, Gloucester, with some fragments of tessellated pavements of Roman date. It was ornamental, with a star pattern, and an adaptation of an egg-and-tongue moulding. Mr. Earle Way described a large find of Roman pottery and glass at St. Saviour's, Southwark, among which was the head of a remarkably large Amphora. Mr. C. Lynam described two plaster casts of portions of the Runic cross, at St. Michael's, Isle of Man, worked in slate. Mr. Loftus Brock, F.S.A., drew attention to the mode of execution of the figures represented, which had evidently been cut by a chisel, although some authorities believe that all old work was executed by a pick or axe. The date is that of the ninth or tenth century. The first paper was by Mr. J. W. Grover, F.S.A., on the registers of the Old Clapham parish. These are fairly complete from 1551, except that those from 1691 to 1701 are missing. In course of an animated discussion, in which Mr. Walford, Mr. Wright, F.S.A., Mr. Brock, and the Chairman took part, the lecturer stated that the recent excavation of Mount Nod, Clapham, has only revealed that the mound was artificial, but nothing was met with to determine its date, although, contrary to expectation, it was probably no older than the large mansion which formerly stood on the site of the Cedars-terrace. A portion of a paper was then read by the Rev. G. F. Browne on the remarkable cross now preserved in Leeds Church, found during the rebuilding. The remainder of the paper was deferred until the next meeting.

Henley-on-Thames.—By the liberality of Col. Mains, M.P., the Town-hall at this well-known riverside resort has been presented with an illuminated clock, visible at night from a long distance, manufactured by Messrs. Benson, Ladzate-hill, and fitted with all recent improvements. All the pinions are of steel and the wheels of gun metal, and made by machinery. The pendulum is compensated to counteract the variations of temperature, and to cause the clock to keep a uniform rate of time in all weathers, the lighting and extinguishing are performed by the clock itself by means of an automatic machine, specially designed for that purpose.

"Thomas Park and his 'History of Hampstead.'"—At the meeting of the London and Middlesex Archaeological Society on Tuesday evening last, Mr. E. Walford, M.A., reporter entitled "Thomas Park and his 'History of Hampstead.'" This work, Mr. Walford said, had been regarded as a valuable contribution to topographical literature. It was out of print soon after its publication in 1814, and he (the lecturer) was now commencing its reissue. Its author was a native of Hampstead, and died commencing to study law though not until he had been elected to the chair of English Law and Jurisprudence in King's College. Mr. Park's father, Thos. Park, F.S.A., the editor of Horace Walpole's catalogue of Royal and Noble Authors of the Harleian Miscellany, and of a long series of reprints of old English poetry, had long been resident in Church-row. As a child he was searched over and over again through the parish records, and had pored over the registers and charters in the keeping of the Dean of the Chapter of Westminster, to whom nearly all of Hampstead had once belonged, and this he had done with such good effect that when he was only twenty years old he produced a work equal in merit to Robinson's History of Tottenham and Hackney, and superior to Prichard's History of Highgate. A discussion followed, and a cordial vote of thanks was accorded Mr. Walford.

Lectures at Carpenters' Hall.—The first of a series of free lectures to artisans, inaugurated by the Carpenters' Company, was delivered on Wednesday evening to a large and attentive audience at Carpenters' Hall, London wall. Professor Kerr was the lecturer, and chose as his subject the "Comparative Anatomy of Beams, Trusses, and Arches." Mr. Alfred Preston, a Past-Master of the Company, presided, and was supported by Professor T. R. Smith, Mr. T. Blashill, F.R.I.B.A., Mr. J. Kennard, Mr. Simpson, and others. The Chairman, in introducing the lecturer, referred to the desire of the Carpenters' Company to do use to the craft, as was shown by the exhibition they held last year, and by the course of lectures now inaugurated. What they wish to impress upon the workman is a desire to do their work conscientiously and honourably, whether it was visible or hidden from the eye of experts and professional men. We desire a report of the lecture until next week.

The National Freehold Land Society.—The thirty-fifth annual report, submitted to the members at the annual meeting, held on the 5th inst., states that the subscriptions during the year were 503,914*l.*, the withdrawal, 537,416*l.*, and the members' capital at the end of the year was 1,830,933*l.* The freehold leasehold securities and properties have been increased to 1,677,033*l.*, and the convertible securities reduced to 236,384*l.* The rate of profit on uncompleted shares was 3 per cent. throughout the year. The interest on completed shares was 4 per cent., from the 1st November, 1883, to the 31st of July, 1884, in which date it was reduced to 3½ per cent. The directors, with much reluctance, felt it necessary to adopt this course in consequence of the difficulty of obtaining suitable investments sufficiently remunerative rates of interest to enable them with safety to maintain the rate of 4 per cent. The gross profit of the year was 87,009*l.*

Messrs. William Brass & Son, the well-known firm of builders, carrying on business 47, Old-street, St. Luke's, and 18, Silver-street, Wood-street, write to say (as all who know them will be aware) that they have no connection with the firm who issued the circular condemned by us in a "Note" a fortnight ago (see p. 161, ante). They point out that the disclaimer is the more necessary in consequence of the recent alteration (referred to by us on p. 215) in the style under which their established business is being carried on.

Ilkeston.—The new Church of Holy Trinity, Ilkeston, which was opened some four weeks since, has been supplied with a pulpit and font by Messrs. Jones & Willis, of Birmingham. The font is of Caen stone, octagonal in form, supported by a marble shaft, the panels of the bowl being carved with emblems of the Trinity &c. The body of the pulpit is of oak, upon a stone base, and consists of carved figure panels representing respectively the Sermon on the Mount, St. Paul, and St. Peter.

COMPETITIONS, CONTRACTS, & PUBLIC APPOINTMENTS.

Epitome of Advertisements in this Number.

COMPETITIONS.

Table with columns: Nature of Work, By whom required, Premium, Designs to be delivered, Page. Includes entries for Asylum at Hartwood, Colchester Hotel, etc.

CONTRACTS.

Table with columns: Nature of Work, By whom required, Architect, Surveyor, or Engineer, Tenders to be delivered, Page. Includes entries for Scavenging, Widening a Bridge, New Engine House, etc.

PUBLIC APPOINTMENTS.

Table with columns: Nature of Appointment, By whom Advertised, Salary, Applications to be in, Page. Includes entries for Storekeeper, Surveyor, etc.

TENDERS.

Table listing tenders for construction of Queen's road, Dalston Sewer, Maidenstone, etc., with names and amounts.

For alterations and additions to Girls' and Infant Schools, Red Lion Yard, Watford, for the Watford School Board. Mr. W. H. Syms, architect, Watford. Turner 1,829 8 0; Longman 1,474 0 0; Waterman 1,299 5 0; Chadwick 1,314 0 0; Judge & Fames (accepted) 1,237 10 0; Neal (withdrawn) 1,137 0 0.

Table listing tenders for new business premises, warehouses, &c., South Eastern-road, Canterbury, for Messrs. Cox & Elliott. Mr. J. Cowell, architect: Schofield 27,980 0 0; Newby Brok 5,726 0 0; Mills 5,317 0 0; Slade 5,240 0 0; Woolgar & Son 5,168 0 0; Hayward & Farmer 5,145 0 0; Richardson 5,065 0 0; Snow 5,040 0 0; Knock 5,000 0 0; Brooks 4,958 0 0; Cozens 4,957 0 0; Lovell 4,928 0 0; White 4,741 0 0; Bingham 4,543 0 0; Whiting 4,318 0 0; Cornelius 4,267 0 0; Adcock 4,288 0 0; Wallis & Clements 4,784 0 0; Stiff 4,734 0 0; Shrubsole 4,724 0 0; Amos & Ead. 4,724 0 0; Guskie 4,719 0 0; W. & T. Denue 4,685 0 0; Martin 4,684 0 0; Wins 4,674 0 0; Howell 4,670 0 0; De uo & Son 4,688 0 0; Greenwood 4,560 0 0; Terry 4,983 0 0.

For the erection of a residence, boarding-house, and school preparatory to the King's school, Sherborne, Dorset, for Mr. W. Hoildland Blake. Messrs. Thomas Farrall & Edmunds, architects, Sherborne. Quantities supplied by the architects: Phillips, Exeter 21,450 0 0; Jeakins & Son, Bournemouth 4,746 0 0; George, Bournemouth 4,225 0 0; sievel & Son, Bristol 3,993 0 0; Young Bros., Salisbury (accepted) 3,800 0 0.

For six four roomed cottages at Winkfield, for Mr. W. J. McCloskie. Messrs. Byrne & Wilnot, architects, Loudon and Windsor. Quantities by the architects: Hicks, Egham 11,020 0 0; Norris, Ascot 955 0 0; Akery, Windsor 895 0 0; Watson, Ascot 876 0 0; Wiliam, Windsor 815 0 0; Snell, Maidenhead 810 0 0; Charman, Ascot 796 0 0; Baker, Slough 732 0 0; Bishop, Windsor 735 0 0; Hann & Co., Windsor (accepted) 735 0 0.

For proposed boat-houses at the King's Arms, Thames side, Windsor, for Messrs. Burgess & Co., Victoria Brewery, W.C.: J. L. Hollis, Windsor 4,934 0 0; H. Foreman, Windsor 340 0 0; W. P. Reevell, Windsor 298 0 0; Hann & Co., Windsor 288 0 0.

For Croydon Union New Infirmary, roads and paths, and tar asphaltting. Messrs. Berney & Monday, architects: W. Carter, Anerley 23,915 0 0; Adam Bull, Croydon 3,128 0 0; H. Lake, Croydon 3,068 0 0; B. Cooke & Co., Battersea 2,908 0 0; Wm. Williams, Wimbledon 2,653 0 0; H. Streeter, Croydon 2,635 0 0; Fathing, Lorrimer, & Co., Wandsworth 2,432 13 9.

For the erection of stabling at Hurlingham-lane, Fulham, for the London General Omnibus Company, under the superintendence of Mr. G. T. Lanham. Quantities by Mr. A. J. Bolton: Collier 21,655 0 0; Howell & Son 1,372 0 0; Dearing & Son 1,460 0 0; Parker 1,410 0 0; Knight 1,429 14 0; Bolding 1,437 0 0; Jackson & Field 1,414 0 0; Haynes 1,375 0 0; Aldridge & Jenvey 1,368 0 0; G-rud 1,394 15 0; Huut 1,341 0 0; Evans 1,335 0 0; Richens & Mount 1,274 0 0; Scherren & Williams 1,312 0 0.

For alterations and repairs to the Pied Bull, St. Margara's, Herts, for Mr. B. Young, Brewer, Hertford. Mr. C. Legg, architect. Quantities by W. Hawker: Chudney 2,825 2 6; Huggins 706 7 6; Fisher 585 0 0; Nichol 794 0 0; Vint 759 0 0; Saunders 709 0 0; Norris 4,561 14 0; S. W. Hawkings 689 0 0.

For section I of the Working Lads' Institute, White-chapel, Mr. George Baines, architect, Great Winchester-street, E.C.: Wm. Bangs & Co. 25,453 0 0; G. & J. Green 5,491 0 0; Atherton & Latta 5,154 0 0; James Morter 5,119 0 0; Wm. Brass & Son 5,148 0 0; G. H. & A. Bywaters 4,699 0 0; Ashby Broe 4,282 0 0; Patman & Fotheringham 4,973 0 0; Laurence & So 4,968 0 0; B. E. Nightingale 4,839 0 0; J. H. Johnson 4,733 0 0; Kilby & Grayford 4,734 0 0; Staines & Son 4,543 0 0; Thos. Boyce 4,451 0 0; Shurmer 4,419 0 0; Jackson & Todd 4,375 0 0; Wm. Gregar, Stratford (accepted) 4,128 0 0; A. Reed, stratford 3,500 0 0.

For engineering works at the Baths and Wash-houses, Bermondsey. Messrs. George Elkington & Son, architects.—

Table with columns for contractor name, amount, and status. Includes Bradford & Co., Cockburn & Co., Thomas & Taylor, George Pratt & Co., Badham & Co., J. Season, T. & J. Hosking, J. Knight, E. Richmond & Co., E. Thompson, J. & E. May (accepted).

For proposed boundary-wall, entrance gates, &c., at Burfield, Old Windsor, for Lieutenant-Colonel Hon. Wm. H. P. Carleton, M.P. Messrs. Edgington & Summerhill, architects, Park-street, Windsor.—

Table with columns for contractor name, amount, and status. Includes Bowyer, Slough, Halley, Slough, Oades & Son, Egham, Hann & Co., Windsor (accepted).

For stables, &c., at Hackney, for Mr. T. Wood, Mr. Batten, architect. Batstone Brothers, surveyors.—

Table with columns for contractor name, amount, and status. Includes Wyatt, Roberts, Forrest, Thomerson & Son, Hawkins, Coulson, T. G. Green, S. Babey & Son, Hughes.

For the erection of male lunatic wards at the Work-house, Poland-street, Oxford-street, W., for the Guardians of the Westminster Union. Messrs. H. Sutton Snell & Son, architects, Southampton Buildings, W.C.—

Table with columns for contractor name, amount, and status. Includes Johnson & Manners, W. Bamford, F. R. Tozer, M. Fenley, G. Howard, W. J. Hack, H. & E. Lee, E. Cook, Wall Bros., C. Tyford, W. Holt, Howell & Sons, Newell & Co.

Table with columns for contractor name, amount, and status. Includes Messrs. Down & Kennedy, Messrs. Hargreave & Bolton, Messrs. Bull & Co., Mr. S. Atkins, Mr. H. Minnett.

SPECIAL NOTICE.—Lists of Tenders frequently reach us too late for insertion. They should be delivered at our Office, 46, Catherine-street, W.C., not later than Four p.m. on THURSDAYS.

TO CORRESPONDENTS.

E. W. W.—T. B.—C. L., Paris (thanks)—J. B.—E. C. R.—"Doctor Wain" (the words "Boy" and "Bay" are used quite indiscriminately)—H. B. and B. (thanks)—H. B. (please send correct address: a note directed to the address on years has been returned through the post-office)—V. de M. (shall appear)—A. M. C. (consult a solicitor)—J. B. (below our mark). All statements of facts lists of tenders, &c., must be accompanied by the name and address of the sender, not necessarily for publication. We are compelled to decline pointing out books and giving addresses. Letters or communications beyond mere news items which have been duplicated for other journals, are NOT DESIRED. We cannot undertake to return rejected communications. Letters or communications (not news items) which have been duplicated for other journals, are NOT DESIRED. All communications regarding literary and artistic matters should be addressed to THE EDITOR; all communications relating to advertisements and other exclusively business matters should be addressed to THE PUBLISHER, and not to the Editor.

PUBLISHER'S NOTICES.

CHARGES FOR ADVERTISEMENTS. SITUATIONS VACANT, PARTNERSHIPS, APPRENTICESHIPS, TRADE, AND GENERAL ADVERTISEMENTS. Six lines (about fifty words) or under. Each additional line (about ten words) or under. Terms for Series of Trade Advertisements, also for Special Advertisements on front page. Compositions, Contracts, Sales by Auction, &c. may be obtained on application to the Publisher. SITUATIONS WANTED. FOUR Lines (about THIRTY words) or under. Each additional line (about ten words) or under. PREPAYMENT IS ABSOLUTELY NECESSARY. * * * Stamps must not be sent, but all small sums should be remitted by Cash in Registered Letter or by Money Order, payable at the Post-office, Government, W.C. DOUGLAS FOURDRINER, Publisher. Addressed to No. 46, Catherine-street, W.C. Advertisements for the current week's issue must reach the Office before THREE o'clock p.m. on THURSDAY. The Publisher cannot be responsible for DRAWINGS, TESTIMONIALS, &c. left at the Office in reply to Advertisements, and strongly recommends that of the latter COPIES ONLY should be sent. SPECIAL.—ALTERATIONS IN STANDING ADVERTISEMENTS or ORDERS TO DISCONTINUE same, must reach our Office before TEN o'clock on WEDNESDAY mornings. PERSONS Advertising in "The Builder," may have Engraving addressed to the Office, 46, Catherine-street, Covent-garden, W.C. Free of charge. Letters will be forwarded if addressed envelopes are sent, together with sufficient stamps to cover the postage. TERMS OF SUBSCRIPTION. "THE BUILDER" is supplied direct from the Office to residents in every part of the United Kingdom at the rate of 10s. per annum. FREIGHT to countries within the Postal Union, 25s. per annum. Remittances payable to DOUGLAS FOURDRINER, Publisher, No. 46, Catherine-street, W.C.

Still on Sale.—A few COPIES of the NEW YEAR'S NUMBER of "THE BUILDER," containing the following ILLUSTRATIONS, THE CHAPEL, KEBLE COLLEGE (Mr. W. Butterfield, Architect), Interior and Exterior Views. THE TOWERS OF LONDON IN THE REIGN OF ELIZABETH. Drawn by H. W. Brewer. NEW PICTURE BRIDGES, Working Drawings. ST. STEPHEN'S, WALBROOK. Measured and Drawn by E. H. ST. JOHN. Additions: Royal Academy Prize Drawings. PART OF STAINED-GLASS WINDOW, Salisbury Cathedral. Designed by E. Burne Jones. WEST FRONT OF TWYCKENBURY ABBEY. Drawn by H. E. Stubbins. CALENDAR HOUSE. Plan of CIRCULAR WAHD HOSPITAL for Egypt. By Lady Stanfield. 44, by post 44d. Publishing Office, 46, Catherine-street, W.C.

JUST PUBLISHED.

The Craft of the Carpenter.

CARPENTRY may be briefly defined as the art of framing timbers for various purposes of support; but much more is implied in this definition than is apparent on the face of it, for just as the strength of a chain is only that of its weakest link, so however carefully an assemblage of pieces of timber may be framed together, if they are so arranged that the weakest point of the framing is where the strain on it is greatest, no mere skill in adjusting the parts will prevent failure. Hence it is necessary, as Professor Robison remarked, that a skilled carpenter should know the mathematical and mechanical laws according to which strains are propagated on the one hand, and the material fibres of timber are exerted in resistance to them on the other. For the designer who is, or ought to be, the architect, something more is required, and that is a knowledge of the geometrical rules according to which graphic delineations of various forms are drawn,—in other words, of stereotomy. We are afraid that these very essential branches of an architect's education have been too much neglected, and, in fact, almost ignored in this country. In France and Germany much greater importance is attached to these subjects, and various papers have been read recently at the architectural societies' meetings, which we hope will have the effect of drawing attention to the methods of education adopted in those countries. Old Nicholson, who is always interesting and instructive, though not always accurate, says that "no man may pretend to be an architect who is not well acquainted with the principles and practice of carpentry"; and Tredgold, writing in 1820, laments the fact that "in consequence of the neglect by architects of the principles of construction, works requiring any considerable skill are given to the members of a new profession,—civil engineers."

Although carpentry must necessarily have been one of the first arts practised by man in an early state of civilisation, it would advance but slowly in consequence of the slender resources of the early builders, and the probability is that timbers would at first be joined by ligatures and not by mortises and tenons; but the use of iron for cutting-tools was very early, and we know, from Wilkinson's researches, that the Egyptians were very expert carpenters and used a most complicated system of dove-tailing. The buildings of the Romans show them to have been great car-

penters, and their mantle, probably, descended on such men as Serlio and Palladio, whose works are the earliest treating of the subject at all fully. We get an occasional glimpse from old travellers' records of skill in carpentry in most unexpected places; for example, Pyrrard de la Val, a Frenchman who was wrecked on the Maldivic Islands in 1601 and wrote an account of his voyage, states that the carpentry and joinery there was of the finest and most beautiful kind, no iron being used. Mediaeval carpentry depended upon large and heavy scantlings, but was always good, simple, and well proportioned. It attained its highest development in the sixteenth century, and depended almost entirely on skilful framing without iron straps. Viollet-le-Duc says of it: "Le fer ne vient pas, comme dans les charpentes modernes, suppléer à l'insuffisance ou à la faiblesse des assemblages." There can be no doubt that the extended use of iron has led to the decadence of carpentry proper, and, if we want to find the technical skill of the old carpenters, we shall have to look for it in some of the more secluded English villages.

We have still no work in English equal in completeness to Colonel Emy's "Traité de l'Art de la Charpenterie," published in Paris in 1841, and in fact there have been very few English works on carpentry of any importance, the earliest that we are acquainted with being Richards's translation of the first book of Palladio, published in 1676, the phraseology of which is very quaint and instructive, because all the old terms of carpentry such as *summer*, *interbrace*, *wind-beam*, and others, show the original purpose of many parts of a building which have quite lost their former meaning. The ablest treatises on carpentry up to a recent date are buried away in obscure places; for instance, Nicholson's article on "Carpentry" is in Rees's "Cyclopaedia," and Professor Robison's article, which really forms the basis of all that has since been written, is in the "Encyc. Brit.," edit. 4. The first edition of Tredgold was published in 1820, and it has been the standard work ever since, and the sixth edition is now before us.*

The earlier editions of this work are so well known that we do not propose to allude particularly to the original matter, but we are chiefly interested in the additions. In the earlier editions of the work no attempt was made to give the mathematical investigation of the various formulae for strength, stiffness, &c.; but reference was made to other works where this information could be obtained. We think, however, it is a great gain to the

* Elementary Principles of Carpentry. By Thomas Tredgold, C.E. Sixth edition, thoroughly revised and considerably enlarged by E. Wynham Tarn, M.A., architect. London: Crosby Lockwood & Co.

student to have these investigations, where the higher mathematics are not involved, ready to his hand, with an explanation of the method of practically applying them; and we hold, therefore, that the present editor has acted wisely in embodying these in the new edition. The mathematical investigations of the formulae for calculating the strains upon timber in different positions, and framed in various ways, do not, with few exceptions, involve the higher mathematics, and a splendid opportunity was open to the editor, by a careful revision of the old work and the addition of new matter, to make the new edition the standard work on carpentry in the English language. In a work of this kind special care is requisite to avoid errors, and the closest possible scrutiny of the proofs is needful in order to detect mistakes, which may prove most perplexing and misleading to the student, and we are very sorry to have to notice many signs of haste or carelessness in this respect. We are not disposed to criticise too severely such slips as *verticle* line, and the statement that "timber is wrought into various forms according to the *principal* of geometry," though we think with a little care they might have been avoided.

We notice in the discussion of the question of the best form for lock-gates that the radius of the curve of equilibrium is given as $\frac{x^2 \times y^2}{2x}$, where x represents the sally of the gate, and y the half breadth of the lock: this ought to be $\frac{x^2 + y^2}{2x}$, and we cannot help thinking that a diagram showing the curve of equilibrium should have been added, as in the diagram given the above expression will not hold good.

The strain upon beams when laid in a horizontal position, and loaded, is one of the most important subjects of investigation in practical carpentry, and a considerable amount of attention is paid to it in the new edition, but as the principle of the lever is so intimately connected with the subject, we should have been glad if Mr. Tarn had devoted a few paragraphs to a clearer explanation of its action, as this would have rendered many of the subsequent paragraphs easier to the student. We also think it would have been desirable to give a diagram, with a few words of explanation, showing how to calculate the moment of rupture at any point in a beam loaded by a weight placed at any other point. This is of considerable practical importance when considering the strains on girders supporting binding joists.

The strains upon beams are, on the whole, well treated, but here, again, we are quite sure,—judging from what Mr. Tarn has done in previous works,—that a little more care would

have rendered the investigations more lucid. For instance, on p. 39 the diagram is carelessly drawn, and a very slight alteration would have rendered the steps of the reasoning much clearer. Again, throughout these investigations L is supposed to represent the length in feet, l the length in inches, so that $12 L = l$, yet on p. 47 in ascertaining the deflection of a beam uniformly loaded L and l are used indiscriminately to represent the same thing. This may seem a very small point, but we are strongly of opinion that these errors ought not to occur in a work of this importance.

Several examples involving the use of the integral calculus are given. Now, we think Mr. Tarn might have drawn the line at the calculus, as very few would be able to follow him; but if he does use it, at least he should be correct. But there is an equation worked out on p. 50, of which the first integration is correct, but the second is wrong, as it is based on an assumption inconsistent with one made in the first integration; and it is the more curious that this error should not have been noticed, as the result as printed is a fraction in terms of l and x , which can only equal zero when $l = x$, whereas the proper solution is something quite different. Now, it is scarcely kind of the editor thus to befog the student who attempts to follow him. It may be said that if the results are given correctly these errors are not of very material consequence, but we assume the editor would not have given the steps of the calculations unless he thought they would be useful to some one. It is, however, when we come to the tables of scantlings that we find ourselves most hopelessly perplexed. In the earlier editions of this work it was stated that the table of scantlings for girders in a framed floor was calculated from experimental data, and there is no doubt that the scantlings there given were inadequate for the longer bearings. There is a considerable amount of new matter in this section, and the strains are estimated upon girders in accordance with the number of points at which the weight rests on the girder: 120 lb. per foot super. is taken as the load of the floor, the girders being supposed to be 10 ft. apart. Now, let W represent the entire weight of that portion of the floor extending 5 ft. on each side of the centre of the girder; then, if the latter be about 12 ft. long, it will have but one hindering-joint resting on it, and the load on the girder will be $\frac{W}{2}$ at the centre. The longer the

girder the greater will be the number of binders resting on it, and the more nearly will the load on the girder approach to W, but also the more nearly will it be a distributed load, which would be equivalent to $\frac{W}{2}$ at the centre, so that the strain on the girder varies very slightly whatever the number of the binders may be. The mathematical investigation is, however, interesting from the fact that it shows clearly that how many soever the binders may be the strains is always a maximum when one of them rests on the centre of the girder, and this shows the great desirability of leaving the centre of any timber beam free from load whenever possible. When the weight is taken at 120 lb. per foot super., the familiar formula $B D^2 = a W L^2$ becomes $B D^2 = 6 L^2$, or very near it, and from this formula the scantlings in the new table are professedly calculated. This table interested us considerably, as it differs from Tredgold's *total* *rule*; but we are very sorry to say it is not reliable for the longer bearings when tested by Mr. Tarn's own formulae. For instance, a girder 30 ft. long and 18 in. deep is given 21 in. wide; in reality, according to the formula, it should be 27 in. wide, and it is actually stated that the dimensions of a timber girder 36 ft. long may be 17 in. deep and 37 in. wide. A girder of this depth and bearing ought to be, according to the formula, 57 in. wide. We do not wonder that Mr. Tarn recoiled from this dimension. But even the scantling given in the tables is rather startling, and such a girder would be somewhat of a curiosity. We have calculated the deflection of such a girder when

loaded, and we find it would be 1½ in. instead of ¾ in. as it ought to be. Now what is the practical use of giving tables of this kind? No one nowadays would think of using timber for such bearings as this, and if Mr. Tarn had said that iron was always used now for long bearings, but that if on an emergency timber had to be used for a 36 ft. bearing, it should be a built-up beam, 26 in. deep and 15½ in. broad, this would have been a piece of useful information, and would also have had the merit of being correct, and the same plan might have been adopted with all girders over 24 ft. bearing. The method of building up beams by holding and keying two pieces together is described on pp. 90 and 91; but here, again, we must complain of the carelessness of the revision of the work, as we find in the letter-press references to figs. 42, 43, 44, and 45 on Plate IV., but when we turn to Plate IV. we find no figures at all thus numbered, the illustrations referred to being numbered 5, 6, 7, and 8; and this is by no means the only instance where illustrations are wrongly indicated,—the reader has to hunt them out on the plates for himself. The tables for binding joists and for single joists also differ from Tredgold's, and here, again, we find they are not accurately calculated according to Mr. Tarn's own formula; for instance, a single joist 20 ft. long and 3 in. wide is given as 1½ in. deep, whereas the rule makes it 1½ in. deep; and, in the same way, a joist of similar bearing of 2 in. breadth is given as 13 in. deep, when it should be over 14 in.; and we are disposed to ask whether 19 in. by 1½ in. is a practical dimension for a joist of 25 ft. bearing. Moreover, according to this table, a joist 8 in. by ¾ in. is of the same stiffness as one 8 in. by ¾ in., and several similar cases could be pointed out. We find it to be the same with the table for binding-joists; for instance, a binder 20 ft. long and 12 in. deep is given as 17 in. wide; if tested by the rule it ought to be 20½ in. wide. The table gives the breadth of a binder 14 in. deep for a 17 ft. bearing as 7 in., the rule makes it over 8 in.

Now, for one person who will read the work throughout probably a hundred will consult the tables, and the least the editor could have done, after deciding to alter tables which have been accepted for so many years, would have been to take care that the calculations are accurate and the dimensions practical. We are not saying that timbers of the scantlings given would break when loaded in the ordinary way, but these tables are professedly calculated for *stiffness* and not for *strength*, and the necessity of distinguishing between these two properties is frequently alluded to, as the comparative stiffness of timbers is of much more importance than the comparative strength; a girder, for instance, carrying both floor joists and ceiling joists would defect enough to utterly ruin a ceiling, while there would be no danger of its breaking.

When we come to the section on roofs, we find that the useful remarks of Tredgold on roofs, domes, &c., are reproduced, together with new matter, which, in some cases, is very valuable; but we are continually being pulled up by annoying errors which a little care would have avoided. Here, again, the tables of scantlings are altered, new rules for calculating them are given, but in many instances the figures given are not those obtained by the rule.

We will take two instances: first, that of a tie-beam. Tredgold's old rule is, "Take the length of the longest unsupported part in feet and divide it by the cube root of the breadth in inches, multiply the quotient by 1.47, and the result will be the depth," and on this calculation his tables are based, and we have always found them reliable. Mr. Tarn gives the rule as above, with the omission of the words in italics, but he does not act upon his rule. Take the case of a roof 50 ft. span of the design shown on Plate IX, the longest unsupported part of this tie-beam would certainly not exceed 15 ft. Taking L to represent this length, and B and D the breadth and depth of the beam, the rule says $D = \frac{L}{\sqrt[3]{B}}$, which when $B = 6 = \frac{15}{\sqrt[3]{6}}$, or just

over 8 in. for the depth; but the table gives 10 in. as the depth of this tie-beam, and we should be glad if this discrepancy had been accounted for. The old table give 12 in. as the depth, and we must say we should prefer to use this. Secondly, the principal rafters. The new rule is very simple, and says:—"Find a queen-post roof, multiply the cube of the span by .0125, and the square root of the product will give the area of the principal i inches. If this be worked out for a span of 46 ft., the area of the principal would be 34.8 sq ft. The area as given in the tables is 41.25 sq ft. We have dwelt upon this matter of the table at some length, because we do think it a most important matter that these should be accurate. Mr. Tarn appears to us to be in this dilemma: he has altered the old tables and gives new rules for calculating them; either these rules are reliable or they are not; if not, why are they given? if they are reliable, why does he not act upon them? No one can retain in his memory a number of tables, whereas simple rules can be learned by heart and applied wherever wanted; but it scarcely inspires confidence in these rules to find their author departing from them so frequently without a word of explanation.

The latter part of the work comprises a great deal of very useful and interesting information on the nature and properties of timber, in which advantage has been taken of the investigations made on this branch of the subject subsequently to Tredgold's time by Rhind, Lasset, and Fitcham; but we must most strongly protest against the manner in which the references to the works consulted are given. In this section of the work there are not less than between seventy and eighty references to other works, and in no single instance is the page of the work referred to given. The utility of giving such a reference, for instance, as Beckman's "History of Inventions," vol. ii., is practically nil, as no one can spare the time to hunt through the volume to find out the exact passage. And these omissions are the less excusable as in the earlier editions the pages of the references are all given, and any new ones introduced could have been verified by a couple of hours' work.

It is in no captious spirit of fault-finding that we have noticed this work. We took it up with great expectations, and we finished its perusal with feelings of deep disappointment. We hold that the editor of such a standard work as this takes upon himself great responsibilities, and ought to exercise special care to send the work out as free from errors as the closest scrutiny can render it, and we can only hope that the present edition is not a large one, and that care will be taken to revise the revision before another edition is issued.

THE ROMAN BRIDGE OVER THE TRENT AT SOUTH COLLINGHAM.

BY E. P. LOFTUS BROCK, F.S.A.

THE discovery of ancient Roman remains is always a matter of interest, even when the objects found are only sufficient to gratify ordinary curiosity, or when they are but similar to those ordinarily met with. When the discovery reveals some object out of the common we feel that a fresh page, so to speak, of the history of bygone times is being turned over for our inspection; and feelings of curiosity give place to the more real work of practical study.

Such an event has recently occurred at South Collingham, Nottinghamshire, where sufficient of the fabric of a large Roman bridge has been found to enable us to reconstruct the structure theoretically, so completely has the design been recovered.

During recent months works have been undertaken along the course of the river Trent to improve its navigable powers, the importance of which will be rightly estimated when it is remembered that the navigation along this river connects Hull, Grimsby, and Goole with the whole Midland canal system, including Birmingham and all its district. These works are in progress by the Trent Navigation Company, under the direction of

Mr. H. Rope, C.E., engineer-in-chief of the company, and consist of, among others, of a large amount of dredging to deepen the bed of the river.

When the works had reached to a point between the villages of Cromwell on the north bank of the river and South Collingham on its southern, the workmen found a mass of timber framing and stonework in the bed of the river, resting on the undisturbed gravel formation. On examination, it was found that this unexpected obstruction was, in fact, the massive pier of a bridge. About 20 ft. nearer to the northern bank a second pier was found, precisely similar. Subsequent observation enabled the system of construction to be entirely recovered, and the details are so curious as to merit exact description. The piers were constructed of masonry, tied together by a framework of solid oak timbering, resting upon a carefully-framed base acutely diamond-shaped on plan. This latter was naturally set

still carried four piles to support the superstructure, which were driven about 3 ft. into the gravel through the sill, by means of neatly worked rectangular holes cut through it for the purpose. These piles were set slightly diagonally, being inclined at an angle from each end respectively to afford a wider base, and thus giving a lesser width for the roadway above. The angle of the supports was clearly shown by the marks in the sills, and a portion of one of them was in position. The oak was still solid and hard, and the whole bore evidence of having been skillfully framed and put together in a very workmanlike way.

Masses of masonry found in the stream during the dredging operations, as well as by the weather-worn surfaces on some of them, indicated that the piles were encased in piers of stonework, the mortar-heds and jointings still remaining on some of the stones, while rebates, as if to fit over the timbers, were also visible, some of the stones being 2 ft. high.

with its pointed ends to the stream. The extreme length from west to east was 30 ft. 9 in., the width being 10 ft., while the roadway was 20 ft. in the clear from pier to pier. The diamond shape was not an exact figure, for the bridge having crossed the river diagonally, the shape of the piers was set out to afford the proper course to the superstructure. A solid central sleeper, about 18 in. by 18 in., formed the backbone, so to speak, of the framing, the diamond forms being made up by waling pieces about 18 in. by 4 in., carried to the extreme points and neatly mitred. These were secured into the sill by stout ties mortised through both waling and sill in each case, ending outside the latter in large octagonal headings worked out of the solid. Square holes were sunk through these heads, and also through the opposite ends of the ties after having passed through the sills, for the insertion of stout wedges, whereby the whole of the framed structure was kept in place and rigid. Extra solidity was given to the varying position of the lateral angles marking the outline of the diamond form by struts, also laid horizontally to the main sill, and four tapering piles, two on each side, driven into the solid river bed, kept the whole in position.

This system of framing was found to be the same, or nearly so, in both of the piers met with, and it was solid and firm after the lapse of so many centuries. Indeed, when it was found necessary to remove the piers as obstructions to the deepened river bed, it was deemed advisable to use dynamite for the purpose. Eight charges of dynamite were requisite before the solid mass could be removed, and the fragments of framing recovered were still so well tied together that it was not a difficult task on shore to place them again in position, when a very interesting photograph was taken. It was evident, on observation, that the framework had been put together on the land, and simply lowered down into position afterwards, and then the spaces of the framing filled in with rubble masonry, solidly hedged in the well-known hard setting mortar, which the Romans so well knew how to make. The main

The stone is similar to Ancaster, and the mass of it still remaining, built up into the walls of the oldest of the cottages and barns in the locality, on both sides of the river, is sufficient to show to how great an extent the material of the old piers was utilised at a period, it may be, long subsequently to the destruction of the bridge. No arch stones having been found, it is reasonable to conclude that the roadway was carried on a horizontal framing of oak resting on the masonry and oak piers. The width of the roadway, as determined by the rake of the piles, must have been about 20 ft. or 22 ft. It is not likely to have exceeded the latter width. The width of the Trent at the point of crossing is about 240 ft., and, making allowance for the two abutments at the river banks, seven piers would have been necessary to form the bridge. Only two have been met with and destroyed; a third one was not found, and it is probable that it was removed on some former occasion, and, since the river has receded from the southern bank (to encroach upon the old line of the northern) it is a matter almost of certainty that the traces of the remaining piers are still safe, to be revealed, it may be, to some future generation. No traces of the abutments are visible, and indeed, nothing is very apparent of the course of the road itself, which crossed the river by this bridge. The diagonal position of the piers gives us exactly the direction of the roadway, and it may be here remarked, as evidence of the direct course taken in Roman constructions, that an obstacle such as the River Trent was not considered sufficient to cause the direct line to be diverted even to the small extent necessary to cross the river at right angles to its course.

Considerable interest has been taken in this remarkable discovery, not only by Mr. Rope, but by others, and a very careful set of plans indicating the construction has been prepared by Mr. J. H. Whieldon, Surveyor to the Company, while both these gentlemen have obligingly rendered me particulars on every point, and shown me copies of the drawings which were exhibited publicly at a recent

meeting of the British Archaeological Association. But for the painstaking care and attention of the engineers named, the discovery would, perhaps, have passed unnoticed, and certainly it would not have been possible for the system of construction of this important work to have been recovered.

The capabilities of oak for preservation under water during so lengthened a period, demonstrated by this discovery, as well as some others, help us to estimate the age of some similar discoveries which were passed by at the time, somewhat unnoticed. Thus the removal of old Rochester Bridge, and the construction of the present one, revealed the existence of a mass of wooden piling which we may very reasonably conclude to have been of Roman date, and a part of an ancient wooden bridge to carry the Watling-street across the Medway. In like manner, the removal of old London Bridge revealed similar evidences, while much of the Thames River bank along Billingsgate was piled at some remote period, doubtless to render the waterway secure. Close to Lanercost Priory, in Cumberland, the oak-framed base of a small Roman bridge can still be seen partly lying in the bed of the little river, the Irthing, partly raised above the water-line, it having been disturbed by some flood. It is framed in a very similar manner to what has now been described, and one work will serve to illustrate the other. The mode of construction of the upper part of the bridge spoken of, namely, a series of piers supporting horizontal bearers to carry the superstructure, had its counterpart in the fine Roman work, the North Tyne Bridge, erected on the line of the Picts' wall, to carry it across that river, where it seems to be a matter of certainty that the massive abutments, one of which is now entirely excavated for observation, were not to receive the thrust of masonry arches, but only to take, it may be, massive lintels of oak, upon which the wall across the river was built.

It is just possible that at Collingham the timber framing was erected first and the masonry filling in subsequently. Be this as may, we may reasonably conclude that some system was adopted by which air could have circulated around the timbers to prevent their decay, for such good constructors as the Romans would hardly have carried them up solidly in the mass of masonry. Examples have been met with elsewhere showing the care taken by these old builders to prevent the decay of their timber constructions, when they were even less exposed than here to the danger of being covered up. Notably, the process of charring has been met with, although not observable here. Mediaeval builders were not so careful in this respect, and it not infrequently happens that when an old wall has been examined, where bond timbering or anything of an analogous nature has been used and the air excluded, nothing has been found except the void space occupied by the wood. A noteworthy instance of this occurs at Plympton Earls. The Norman walls of the shell keep were constructed with a chain bond of timber of fairly large scantling. It has completely decayed, leaving only a curious passage in the mass of masonry, to which many and various uses have been assigned. The modern west front of St. David's Cathedral, erected by Nash at the close of the last century, had two flying buttresses springing from detached piers. These have recently been removed for the rebuilding of the front in better taste. They were found to contain wooden shores evidently erected as a support to the original front prior to its rebuilding, and retained within the mass of the masonry. Although so few years, comparatively, had elapsed, the woodwork was found to be badly decayed. Many other examples derived from old buildings might be cited, but these may suffice to show the bad results of excluding the air from any timber work. Our modern works, however, themselves teach the same lesson.

The framing at Collingham was wedged together, and neither pinned with oak nor bolted with iron,—at least, so far as the foundations were concerned; there was not sufficient evidence remaining to indicate the construc-

tion of the upper portions. The expansion of the timbers under the action of the water had made the framing very rigid and solid.

The peculiarity of the roadway not having crossed the river at right angles has already been referred to. It can scarcely be doubted but that this was arranged for to preserve exactly the straight course of the roadway, however unnecessary for practical purposes the arrangement may have been. Taking the line formed by the axis of the bridge, which is an angle of 79 degrees to the river's south bank, we find that if prolonged to the south-east it falls in with the straight course of a modern road for two miles or so, indicating most probably that this latter is on the site of the old one. If prolonged further, it would join the main Roman road, the foss-way, at a distance of about six miles and a quarter from the bridge. The foss-way was undoubtedly the principal road in this part of Nottinghamshire, and it is but reasonable to conclude that the adjacent roads must have had some relation to it. Following its course, the distance from Lincoln to the bridge would be fifteen modern miles. Taking up the line of the roadway on the other side of the river, we find that, if extended to the north-west, still going perfectly straight, it would fall in with the Roman road, Spring-lane going westward across Sherwood Forest, on the high ground, into Derlyshire, while the point of junction would be very close to the ancient encampment marked on the maps as existing just to the north-west of Kirklington. This line is but a theoretical one, based on the angle given by the bridge itself; but whatever its direction may have been, it is evident that the object of the bridge was to afford a way from Lincoln along Spring-lane. The fact that a portion of this was along the foss-way indicates that the latter road was the older of the two.

This course avoids Southwell entirely, where it is more than probable that a Roman station existed. This station would probably be reached by a road branching out of the foss-way over a bridge crossing the Trent near Winthrop, where some foundations were discovered about ninety years ago. It would then most probably be continued to the north-west to join the course of the road already referred to at Kirklington. It is also very probable that a third road started from the foss-way at East Bridgeford, going northwards up to Spring-lane.

This most remarkable discovery has naturally caused a great deal of local comment and attention, especially with respect to any evidence it may afford as to the undecided positions of the stations named in the Itineraries. These are Margidunum, Ad Pontem, and Croccalana, the latter being twelve Roman miles from Lindum (Lincoln), the others being stated as being seven miles apart from each other. The finding of the bridge not unreasonably points to Ad Pontem being somewhere in its locality, although it would apply equally well to the position of the bridge near Winthrop or to East Bridgeford. It must, however, be borne in mind that the name of this missing station does not occur in the Itinerary of Antoninus, but in the forged history, said to be the work of Richard of Cirencester, who, tracing the well-known course of the foss-way, probably found in the name East Bridgeford, where there was a Roman station, a plausible opportunity for its interpolation. The bridge at Winthrop had not been found in the days of the arch-impostor referred to. The two other stations named were doubtless along the course of the foss-way, and therefore, wherever their true positions may have been, the discovery at Collingham does not afford additional evidence of their position, except, perhaps, to call attention to the point where the axis of the bridge would cut the foss-way.

It is a matter of congratulation that this discovery has been in such good hands, and that such careful attention should have been bestowed upon the details of the discovery. Still more will thank be due to Mr. Rope, since he has the intention of having the exact position of the bridge marked for all time by a stone set in the bank of the river.

NOTES.

THE meeting at the Mansion House last week in furtherance of the better support of the Parkes Museum was at least a success in regard to the reception of the speakers who moved and supported the principal resolutions. The Duke of Cambridge moved that the Parkes Museum is meeting a great educational want, and is worthy of increased public support. Mr. Erichsen seconded the resolution, and Mr. G. Godwin, speaking in support of it, rightly urged that the premises in which the Museum was now situated were too small for the work which the institution might accomplish, and that more room was wanted for extending the instruction which could then be given to those qualifying themselves for sanitary inspectors, and for builders, plumbers, and others connected with the building trades. Lord Temple moved that it is essential to the permanent efficiency of the Parkes Museum that the number of annual subscribers be increased. Mr. Ernest Hart, in support of this resolution, observed that the Parkes Museum had served as the model for similar institutions at Washington, Paris, Turin, and Yokohama, but these museums had been subsidised by the Governments of their respective countries, while no such recognition had been bestowed on the Parkes Museum. It is surely time that this example of other Governments should be followed by our own. Some considerable donations were announced at the close of the meeting,—sufficient to meet pressing requirements, but far from what is needed to put the museum on the footing which its importance and value demand. The resolutions were passed unanimously.

THE Swedish Government are making an effort to provide a museum building at Stockholm, to be called the "Nordiska" Museum (Museum of the North), for a collection of which the nucleus will be formed by the valuable assortment of Scandinavian antiquities brought together by the energy, and at the cost, of Dr. Arthur Hazelius, and at present distributed in various rooms in Stockholm. In 1880, Dr. Hazelius, who had already designed to hand over his museum to the country as a permanent national possession, formed a committee of trustees, consisting of five persons, to co-operate with himself in carrying out his scheme, and to share with him the heavy burden of management. King Oscar, who is president of the committee, having given a suitable site in the Djurgården, a noble park in the eastern suburbs of the city, an open competition of designs for a great museum was invited in 1883, and was mentioned in our columns. Plans were sent in last year by fifteen architects of different nationalities, to seven of which prizes were awarded, but a final decision has not yet been made. It is determined, however, that the building must be of ample dimensions to meet the requirements of the present, and to provide for the growth of the collections. It is to be of brick on a deep substructure of granite, and the estimated cost of construction and fitting up is about 165,000*l.* Towards this about 7,000*l.* has been contributed, and decorative materials (originally designed for a palace) to the value of upwards of 3,000*l.* have been given by members of the Royal Family. The Committee will not commence building till 30,000*l.* is in hand, and towards raising this sum they intend to hold a lottery at the close of the present year, to consist of three million tickets at one krona (1*s.* 2*d.*) each, and they appeal for help in the way of articles for the lottery, or of money, "to art-loving English men and women." We fear the method adopted will not much commend itself to the English mind. Those, however, who think the end sanctifies the means, or who are superior to insular prejudices, have thus the opportunity of assisting. Contributions of any kind will be received by the Swedish Minister, 47, Charles-street, Berkeley-square; or by Sir Philip Cunliffe-Owen, at the South Kensington Museum.

THE offer of the Ecclesiastical Commissioners, made through Lord Stanhope to the last meeting of the Court of Common Council, "to appropriate for the perpetual use and enjoyment of the inhabitants of the metropolis sixty-nine acres of wood at Highgate and thirty acres of land at Kilburn," was unanimously referred to the Coal, Corn, and Finance Committee for consideration, but with every symptom of approval. The growing need of the vast population of London for open spaces, secured in perpetuity for recreation and fresh air, and saved from the inroads of the speculative builder, cannot be too strongly insisted upon, and the gift is a wise and well-timed one. It is available subject to the sanction of Parliament to the proceeding, and the undertaking of the Corporation to maintain these two spaces as parks in perpetuity. The latter condition we have no doubt the Corporation will be willing to fulfil. About the former there may be a contest, possibly. Clerical writers in the daily papers appear to think that the scheme involves an alienation of their rights. "This would be scanned," of course; but the consideration of the greatest happiness of the greatest number points in the other direction, and those who may be eventually in full enjoyment of the Highgate woods and their health-giving influence will, perhaps, be apt to dismiss the clerical claims as shortly as the man in one of Leech's old hunting scenes: "Who's that come to grief in the ditch?" "The Parson." "Never mind, we shan't want him till Sunday."

THE returns relating to all authorised gas undertakings in the United Kingdom, which have been recently printed, enable us to take a bird's-eye view of an industry which, for its magnitude, is unquestionably the most prosperous of any carried on within our shores. Nor is the magnitude contemptible. Of that sixty-nine millions sterling authorised, fifty-two millions have been actually raised in shares and loans, of which 18 millions come under the control of local authorities, and thirty-four millions under that of companies. The sums paid as interest or dividend are not included in the returns; but the receipts of the local authorities amount to 4,252,296*l.*, and their expenditure to 2,877,732. As to the companies, ten per cent. is in most cases fixed as the maximum rate of dividend, but eleven and twelve per cent. have been not unfrequently divided. The total tonnage of coal carbonised is 7,631,304 tons; a quantity almost exactly equal one-third of the total quantity exported in 1883. Ten thousand cubic feet of gas have been produced from each ton of coal, on the average. The consumers of gas are returned at 2,019,846, which we may take to represent rather more than 10,000,000 individuals, as the number approaches very closely to that of the houses in Parliamentary boroughs, which were 2,096,497 in 1881. At this rate gas capital is rather more than 5*l.* per head for our urban population, each member of which will have been furnished with the gaseous product of 15 cwt. of coal, at an average cost, probably, of from seven to eight shillings a year, including public as well as private lights. The annual value of the property assessed to income tax, in gas works, in 1882, was 4,640,363*l.*, but it is not apparent whether the returns of the local authorities are included in that amount.

THE Revenue Report of the Irrigation Branch of the Public Works Department in the Government of Bengal has just been issued. From it we take the following figures. The total area irrigated during the years 1883-84 was 497,293 acres, of which 350,614 acres are situated in the province of Behar, within the limits of the system comprising the Sone Delta scheme; 48,760 acres in Orissa proper, and 97,919 acres in the Midnapore series. The irrigated area in the Sone system was double that in the previous year, while Orissa shows only one-half, and Midnapore about 4,000 acres less than in 1882-83. The diminution in Orissa is ascribed to the fact of the greater portion of the five-year leases having fallen in, and an expectation on the

art of the cultivators that by holding aloof they would be able to obtain lower rates from the Government. The receipts aggregated early 117,000*l.*, of which about 72,700*l.* were paid for water, and 37,820*l.* were navigation bills. The working expenses were 107,000*l.* The Lieut.-Governor considers the results of the year, in a financial point of view, unsatisfactory. A commission has lately been appointed to inquire into the administration of the Orissa canals, and to report on the actual profits derived from the works, independent of the share received by Government, and their inquiries will afford grounds for coming to a conclusion as to the propriety of endeavouring to secure for the State a larger share of the benefits reaped.

SEVEN of our principal railways there has been a decline in both gross and net revenue for the year 1884. On three there has been a fractional increase; and on two, namely, the London, Brighton, and South Coast and the Great Eastern, there has been an increase of respectively 14,500*l.* and 37,000*l.* in net revenue. The diminution in the aggregate receipts of the twelve lines has been $\frac{1}{2}$ per cent. The working expenses have been reduced by rather less than $\frac{1}{2}$ per cent.; and the result is a decrease of $\frac{1}{3}$ per cent. in the net profit for the year. To that has to be added the charge for additional capital, which as yet to be shown. With a declining revenue the proportion between increase and expenditure has been very fairly maintained, the proportion of working expenses to gross revenue having been 51.44 per cent. in 1884, against 51.29 per cent. in 1883. The result is the more discouraging, as the increase in gross revenue has hitherto been steady since 1879, the amount for 1883 being 9 $\frac{1}{2}$ millions sterling more than that for 1879. The net receipts were not advanced *pari passu*, having been 9,000*l.* less in 1882 than 1881; but they were more by 5 $\frac{1}{2}$ millions in 1883 than in 1879. The proportion (over the whole of the railways of the United Kingdom) of net revenue to capital in the last five years has been:—1879, 15 per cent.; 1880, 4.33 per cent.; 1881, 2.6 per cent.; 1882, 4.32 per cent.; 1883, 2.9 per cent.

AN interesting letter from Athens in last week's *Athenæum*, by Mr. S. P. Lambros, deals with the question of the demolition of some of the Turkish buildings on the Acropolis, in order to bring to light portions of ancient Athenian structure which have been hidden by these late additions. Mr. Lambros specially refers to the demolition of the Byzantine bastions which abutted on the eastern side of the Propylæa. The removal of these has brought to light various fragments containing reliefs and inscriptions, one of the latter being of great interest. Mr. Freeman has, it appears, written strongly against this and other demolitions of Turkish work on the Acropolis as interfering with and obliterating historical records. This is, of course, in itself to be deplored, but we must consider the matter with due regard to the relative value of the remains. We cannot think that Turkish utilitarian structures of the seventeenth century are in any way comparable in value to ancient Athenian remains, and their demolition, if it gives place for a fuller study of the latter, is gain both to history and archaeology. Mr. Lambros, who argues in this sense, has, we think, quite made out his case.

SOME interesting discoveries have just been made at that remarkable building, the Great Yarmouth Tolhouse, now in process of repair under the supervision of the architects, Mr. E. P. Loftus Brock, F.S.A., of London, and Messrs. Bottle & Olley, of Yarmouth. The whole of the rough-cast which has for many years covered the old walls, giving to the building a very modern appearance, is being removed, thus opening out to view the ancient walling. A series of pretty arches of early fourteenth-century work, supported upon neatly-cut corbels, has been found, hidden hitherto by the plastering, just below the open

porch from which proclamations and addresses used to be made. Below this, again, has been found and opened up the arched opening which once let light and air into the "Hold," a dreary prison, partly underground, into which offenders of all sorts and ages were thrust in former times, and chained to a central beam. The opening had been enlarged roughly at the expense of the arcading, much of which had been cut away for the purpose and walled up at a much later period. This very interesting feature of the fabric will be carefully repaired. Indeed, the effect generally of the works in progress will be to make this curious building appear more ancient than it did at their commencement. The old roof has been opened out, and it is intended to fill the side windows with amorphous glass of the old local families.

FROM the *Gazette des Architectes* we learn that the following gentlemen have been appointed as officers and council of the "Société des Amis des Monuments Parisiens":—President, M. Albert Lenoir, Member of the Institute of France; Vice-Presidents, M. Cernisson, architect, former President of the Municipal Council; M. Franklin, Chief Administrator of the Bibliothèque Mazarine; and M. de Montaignon, President of the "Société de l'Histoire de l'Art Français"; General Secretary, M. Chas. Normand, architect; Assistant Secretaries, M. Alfred Lenoir, sculptor; M. Maignan, painter; and M. Mareuse, Secretary of the "Commission des Inscriptions Parisiennes"; "Archiviste," M. Muntz, Keeper of the Museum and Library of the "Ecole des Beaux Arts." The Society has its quarters at 215, Boulevard St. Germain.

THE current number of the *Antiquary* contains the second instalment of an interesting series of articles by Mr. W. Carew Hazlitt on "Venice before the Stones." The author has collected much interesting information as to the original condition and the artificial formation of the ground from which the city of the sea was to rise. "The true foundations of Venice," he observes, "were laid by men who ate and slept like the beasts of the field, and whose wages were their daily bread and the grace of life.* The free work we see, but the other lies beneath us, wherever we move: a gigantic task of preparation by such as knew not for what they were making ready, nor cared." Repeated entries on the proceedings of the General Council, particularly in 1303 and 1305, show that the directing authorities, however, spared no trouble in securing a firm bottom everywhere, and that "a considerable part of the capital and the adjacent islands rests on made ground of a date much posterior to the natural uprise of the lagoons; and this may be taken to be the true interpretation of the term *fundamentum* or *fondamento*, which we find so frequently applied in documents to established routes as well as to prepared sites for building, and which survives in the modern nomenclature."

ACCORDING to the *Courier de l'Art*, M. Amboise Tardieu has discovered, over a confessional in the little church of Herment, a small town about thirty miles from Clermont, a painting, which he believes to be a hitherto unknown work by Guido Reni.

WE do not know to whom we are indebted for the trees with which the southern end of Gray's Inn-road is planted, whether it be to the Metropolitan Board or the Holborn District Board, but we would like to call the attention of the authority responsible for their planting to the extremely ugly supports which have been placed around these trees. The supports are of wood and are unnecessarily thick and clumsy, and are certain to be destroyed in a short time. A light iron guard of a simple character should be substituted, and the galvanised iron netting which at present protects the trees should be replaced by something of a more permanent character.

* Hardly so much "grace," in Falstaff's phrase, "as would be prologue to an egg and butter," one may suppose.

OUR readers may remember that a short time back we made note of a case of building with bad mortar, which took place at Hackney. In August, 1882, proceedings were taken by Mr. A. Payne, the District Surveyor of East Hackney (South) and North Bow, against Simeon Muncey, the builder of two houses, who was fined 3*l.* and costs for not using proper mortar. As he made no alteration to the structures, the Metropolitan Board of Works proceeded still further against him, and the Magistrate made an order that the houses should be taken down. The defendant then appealed to the High Court of Justice, having in the meantime mortgaged the property. The Magistrate's ruling, however, was confirmed, and judgment was given for the Board, and, after great delay, by an arrangement with the mortgagees, all the parts built with bad mortar have been taken down. In the interest of the public, there is no doubt that houses built with bad mortar should be levelled to the ground. It is to be regretted, however, that under the present system of building the mortgagees may, in such cases, chiefly suffer, while the builder, who certainly deserves punishment, escapes practically free. But it is also true that there are other cases in which the builder is a mere dummy to shield some real owner, who carefully keeps his name and ownership out of sight so as to escape the penalties of the Building Acts.

IN view of the proposed change in reckoning the hours of the day, from 1 to 24, instead of by two twelves (which we are inclined to believe will be tacitly adopted before very long), Mr. T. R. Weston has taken out a provisional patent for affixing to any watch or clock face, divided on the present system, a ring of thin enamelled card, bearing in red numerals the hours from 13 to 24; the ring falling within the outer circle of hours as at present marked. This will render the renumbering a matter of easy application to any watch or clock face of ordinary size.

THE respective Mayors of Birkenhead and Liverpool formally shook hands, on Friday, the 13th, in the middle of the Mersey Tunnel, signalling by this ceremony the completion of this valuable and successful piece of engineering. We gave a detailed account some time ago of the method and progress of the operations, and will shortly illustrate the new stations which are being erected over the two ends of the tunnel, from the designs of Mr. Grayson. The tunnel will not be actually open for railway traffic for some little time yet.

RECENT DISCOVERIES IN LYCIA.

A FULL account of the splendid and costly work, in which is embodied the official report of the first Austrian expedition to Lycia, has already appeared in the pages of the *Builder*.* We are glad to be able to point out that a small popular volume† has appeared almost simultaneously, which deals with such aspects of the expedition as struck the non-professional mind. This small octavo, with its abundant excellent illustrations, may be obtained for as many shillings as the official folio costs pounds, and it should be in the hands of all who care to study both sculpture and architecture in their relation to topography. Baron Warsberg is already known by his "Odysseeische Landschaften" (including Cofu, Epirus, Ithaka, Cephalonia, Zante), and he promises us forthcoming books of a similar description, with views of Thracian, Mysian, and Bithynian landscapes. He feels very rightly that all students are too apt to take the *musæum* view of the remains of ancient art, to think habitually of fragments of sculpture and architecture as they now lie in dark museums, rather than to picture them in their original tectonic and topographical surroundings. A little effort is needed to think back the old circumstances, and the effort is gladly shirked. We have ourselves met with students of Greek art who were well versed in the many and conflicting theories as to the

* See p. 127, *ante*.

† "Homerische Landschaften." Von Alexander Freiherr von Warsberg. Erster Band. I. Das Reich des Sarpedon. II. Rhodos. III. Im Ägäer Meer. Wien: Carl Graeser, 1884.

interpretation of the sculptures (to take a Lycian example) of the so-called Harry tomb in the British Museum, who yet had formed no image, however shadowy, of the beautiful Xanthos valley where they once stood, nor even of the height and shape of the pillar-like tomb from which they were rent. The Berlin Cast Museum has found it possible to surround the walls of each different "Saal" with paintings of the surroundings of the sculptures arranged below, the landscape of valley or mountain, and sometimes when possible the reconstruction of the monument. Till something of this sort is possible in England we must welcome the more eagerly illustrated books of topography. It is not the least our purpose even to summarise the contents of Baron Warsberg's book; he writes in a pleasant chatty style, telling always as much of the history of the place as is necessary for the understanding of its monuments; he was one of the few eager enthusiasts (would there were more of the same sort) who met in Dr. Bendorff's drawing-room on that memorable evening of the 24th of March, just before the expedition started, and he tells in German fashion how eager was the enthusiasm then kindled in his heart, and how indomitable the vitality of the good "seed then sown." Wherever Dr. Bendorff went, he went with Homeric associations ever present in his mind; and in the twenty-one plates interspersed in the book he has left us the landscape background to many a Homeric action. Some of these plates we recognise as the same as those in the large work of Dr. Bendorff, and we are glad they should thereby obtain a wider circulation. Three relate to the Djölascher Heroon, as yet left untouched by the official account. They give the entrance to the Heroon, the frizes on the inside of one wall, and the magnificent view seen from the hill on which the monument stands.

Naturally Baron Warsberg is strong on the method by which the expedition was set on foot; it was, as we have already had occasion to note, a private enterprise, not a Government undertaking; the Austrians are, as opposed to the Prussians, strong on the subject of self-government. Like the English, they are apt to reduce the functions of State government to the lowest practical minimum. For archaeological, and, indeed, all scientific enterprise, Baron Warsberg thinks the private system is preferable, but, then, he is an Austrian. For ourselves, with the Prussian excavations of Olympia and Pergamos before our minds, and the inertia of England as a contrast, we are not so sure. Anyhow, there is room for all.

ROOF COVERINGS.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

At the ordinary meeting of the Institute, held on Monday evening last, Mr. Alfred Waterhouse, A.R.A., presiding, the death of Mr. John Middleton, Cheltenham, Fellow, was announced.

Mr. Ralph Nevill, F.S.A., read a paper on "Roof Coverings." After stating that it was very difficult to obtain from the older members of the profession, who were in full working, long and exhaustive papers on any subject, Mr. Nevill expressed his conviction that considerable benefit would result from the discussion of subjects of practical interest, introduced in short papers requiring little preparation. He could not attempt to deal exhaustively with so large a subject, and would confine himself to what he could speak of from practical experience. Nearly all roofs in rural districts were constructed either of tiles or slates, the former being superior from the point of view of pictorialness and non-conduction of heat; the latter from that of cheapness and closeness of fit. In the great snowstorm of 1882 there was scarcely a single tile roof which kept out the snow, and this had caused him to endeavour to find some easy method of meeting the difficulty.

After alluding to the general plan of securing tiles to laths, and showing how liable the laths were to split, reference was made to the old plan of bedding tiles on hay, and its objections were pointed out, as also the serious drawbacks to bedding in mortar. The various ways of laying felt under tiles were next described, and the objections to its use noted, viz., its liability to stretch, the likelihood of its causing the rafters to rot, and its short durability. Mr. Nevill then described the plan

adopted by himself. He advocated covering the backs of the rafters with 1 in. of concrete or plaster, in which the pins for the tiles could be fixed, the plaster being laid on the laths in the ordinary way, 3-in. rose-nails being first driven into the backs of the rafters, standing out 1 in., care being taken to keep these nails out of the line of the tile-pins. The plaster or concrete should be made of seolemic lime, mixed with coke breeze and sand, and it was essential it should set quickly, and it should be trowelled to a smooth and hard face. Before the plaster had quite set, the tiles should be laid, the pins being pressed into the plaster, and it was important that the pins should not be more than 1½ in. long. Should the plaster have become too hard, the pins must be driven in with the hammer. The eaves-lath should be 1½ in. thicker than usual, in order to stop the plaster; the valleys should be carefully trowelled, and the hips would require a raised rail. No practical difficulty occurred in the case of chimney-stacks. It would be apparent from this description that there would be a coat of concrete all over the roof, which would throw off any damp that might penetrate through the tiles, and would make the rooms underneath much more equal in temperature. Specimens of concrete plaster that had been used were exhibited, and the advantage of such a roof in preventing the spread of fire was pointed out. Objections might be raised on the score of increased weight, but Mr. Nevill had not found it necessary to increase the scantling of roof timbers. It might also be thought that the timbers would decay for lack of ventilation, but hitherto no signs of such decay had appeared in roofs thus treated. The cost, as a rule, would not be more than 14s. per square above ordinary tiling, and several tables of comparison had been prepared. Mr. Nevill concluded by referring to the advantages of this system of laying tiles in the case of the larger tiles, such as pastiles, Phillips's, &c.

Mr. W. G. Coldwell next read a paper on the same subject. He said that after an inspection of the districts in Essex affected by the earthquake in April last, he was profoundly impressed with the want of security of the plain tile roofing. The tile roofs had come down almost en masse, and it was evidently most desirable to adopt some system of laying tiles different from that now in vogue. With reference to lead, no more important subject for discussion could he suggested than the deterioration in the quality of lead as now supplied. In the case of the lead-covered roofs over an important building, which was examined some few years ago, it was found that on the underside of the lead, which was laid on boarding, a film of white powder existed, in lines corresponding with the joints of the boarding, thus indicating that injurious action had taken place below. Dr. Frankland, who examined this lead, found that the white powder was white lead, and it was probable that the modern de-silvering process really rendered the lead more liable to injury from acidulative vapours, than the other process which did not remove so much silver from the ore. Various methods of covering iron roofs were alluded to by Mr. Coldwell.

Mr. McLachlan gave some extracts from a report he had made when holder of the Godwin Barony. The roofing materials used in North Germany were tiles—plain and ornamental; slates of English and German fashion; corrugated iron, galvanised zinc, copper, lead, asphalt, roofing paper, felt, and wood-cement. In the case of tiles, the effect of some of the German roofs was very good. The laths were laid from course to course, and on each lath was hung a double row of tiles, the upper being supported by the lower course. There was always a thickness of two tiles, and, in parts, even of four tiles. The heavily-weighted laths were from 1½ in. to 2½ in. wide, care being taken in the selection of the wood. The church of St. John, Altona, was roofed with plain tiles, and some of the German churches had colours laid in patterns. German tiles were 4 in. or 5 in. longer than English tiles. Slates had only been introduced as a roofing material in many of the North German towns during the last fifty years. In several cases Welsh slates were now used; the German mode of laying slates being in oblique courses, similar to what could be seen at the Law Courts. Copper appeared to have been chiefly used for public and municipal buildings of the first class, especially spires and domes. Zinc was now perhaps the material most extensively used for

covering buildings, where it was a matter of great moment that there should be an equal temperature beneath. Forty years ago it was unknown in Berlin for roofing purposes, but it was now used there to a very great extent. Galvanised corrugated iron was extensively used for the roof coverings of the new prison buildings in Hamburg. He had not seen a single instance of the use of lead for roofing in Germany, and he was told that it had been superseded by zinc and copper. Roofing paper was largely used for buildings where great economy was desired; it was necessary, however, to re-tar it every two or three years. Wood-cement was one of the most important roofing materials in North Germany, and appeared to be in a fair way of superseding other materials.

Mr. John Slater said he had had some experience of the roofing-paper and the wood cement. He had superintended the erection of a brewery built by a German contractor, who had used it in great quantities. He was afraid it would not last, but it had lasted well and produced an equal temperature underneath. They had worked out the idea of sowing seeds on the *hals-cement*; but the gravel was washed away and the gutters and pipes became clogged. He could have wished that Mr. Nevill had had a larger experience of the roofs described by him. That they were very impervious went without saying, but they must be extremely heavy. Through differences of temperature and the variations of the wind, roofs had a certain amount of spring, and it would be curious to ascertain whether this affected Mr. Nevill's roofs. If it did, it probably was that the cement would crack in a great many places. It was interesting to notice how closely alike in form and character some of the new patent tiles were to the Roman and Medieval tiles. Tiles were doubtless used for roof-covering at an early period, and the probability was that the early Roman tiles were made with a ridge on one side and a notch on the other, so that the ridge fitted in the notch vertically. They also ran up a series of hollow tiles which overlapped and covered the vertical joints. He believed an improvement of the principle was made by having tiles of a trapezoidal shape, fitting closely to the underneath. With regard to Medieval tiles, a better had been made than those used in Champagne for buildings of the thirteenth and fourteenth centuries. Some which could be seen in the neighbourhood of Troyes were very carefully made, and the exposed parts were sometimes slightly vitrified. One thing in connection with the Medieval tiles might be adopted in modern ones, viz., the chaufuring off of the end of the tile, which largely diminished the risk of the roof being stripped off by wind-pressure. The question of wind-pressure on roofs was an interesting one and deserved an evening of itself. He proposed a vote of thanks to Mr. Nevill for introducing the subject.

Mr. W. H. White (Secretary) said that reference had been made to the French system of using books for slates instead of nails. It was usual in English specifications to stipulate for copper nails, but, during the last twenty-five years, in all French buildings of any importance slates had been hooked and not nailed. A copper hook was used, so that when the wind played against the side of the roof it simply blew under the slates, and rattled, without destroying them. M. Viollet-le-Duc was, he believed, the first to introduce these books. Even twenty years ago he (Mr. White) had the advantage of seeing them at Cherbourg, a town which was very much exposed. There he had seen part of the roof of a chateau destroyed by the wind when the slates were simply nailed, but, when books were substituted, the wind had no injurious effect whatever. With regard to Mr. Coldwell's remark as to the effect of the lead on timber, he could recall a visit which Mr. Roger Smith and he had made to the dome of the Invalides when it was being repaired, seventeen years ago. The lead was then being taken off and they found half an inch of the greyish powder referred to between the lead and the oak battening of the dome. Mr. Nevill had suggested that our roof should be concreted, but he might say that the French had adopted this plan for a considerable time.

Mr. E. G. Paley referred to the danger of using felt under the slates. On one occasion he found the common inodorous felt had been fired by sparks from a chimney. Mr. Nevill's suggestion of using concrete was a most important one, and unless the weight and expense were serious

certainly seemed to be the right thing. Mr. Nevill appeared to be wrong in one respect, in regard to slating. If well fastened with copper nails on good battens, and afterwards pointed, slatted slates were perfectly impervious to the finest drizzle or snow. A slate well put on and pointed would really last for ever, and in that respect was perhaps the best possible roofing.

Mr. Brodie asked Mr. Nevill what was the best of repairing his roofs?
 Mr. Alexander Payne had prepared the following paper on the subject:—I was only asked on Saturday last by the Secretary to write a short paper on the "Employment of Concrete for Roofs and Roof Coverings" as a corollary to Mr. R. Nevill's paper. I may be allowed briefly to recapitulate what I have already said in this room on this subject. In the volume of the Transactions for session 1874-75, p. 183, is an appendix to Mr. C. H. Driver's paper on Iron as a Constructive Material, which will be found some remarks accompanied by an illustration on concrete combined with iron as applied to the construction of vaults and domes, and I believe I am correct in saying that the most important fireproof domes of large span which have been constructed in this country since that date have been constructed on the system therein indicated, viz., of concrete with an ties embedded to resist the tendency to spread. Perhaps the largest is the dome over the Oratory at Brompton, by Mr. Herbert Turnbull. I believe the dome over the Greek church, in Bayswater, is constructed of concrete in the same way, but I am obliged to refer to memory here, as I cannot find my notes on its construction. In 1876 I had the honour of reading a paper before the Institute on concrete as a building material, which dealt chiefly with walls and ornamentation, but roofs and vaults were also alluded to, and illustrated by some examples. In treating of concrete as a material for roofs and roof-coverings, it may be well to limit the subject at once to those instances in which the employment of such a material would be of practical advantage. For an ordinary pitched roof of the general run of buildings we are not likely to see concrete much employed, except in the form of concrete slabs or slates, on account of its great weight, and the consequent expense of both the roof itself and its supports. We may also, I think, lay it down as a rule that concrete, if employed, should be not only used as a covering, but would itself form part of the construction of the roof. The following appear to me to be cases in which concrete may be advantageously employed in roofs:—1. For flat roofs. 2. For all kinds of fireproof roofs. 3. For all kinds of domes and vaults. 4. For the roofs of all buildings of a monumental character in which great strength or durability is required. As an example of the first kind, viz., flat roofs, may mention one which has come under my notice as District Surveyor in my district at Hackney, where Mr. H. M. Millar, builder, is erecting some small houses in which several ingenious applications of concrete are adopted. The top story is covered by joists 8 in. by 3 in. at one end and 3 in. by 3 in. at the other, made by putting through a 11 in. by 3 in. joist diagonally so as to get fall without waste, placed about 21 in. apart; these are covered by boarding 2 1/2 in. widths and 3/4 in. thick, each board being 1/4 in. distant from the next one (a very important point, as if laid close they swell with wet, spring up and break the roof). On this, as centering, is added 2 in. of Portland cement concrete as a roof-covering; the concrete is made of brick rubbish, ground to powder in a mill; one quarter in bulk of Portland cement is added, thoroughly mixed dry, and then wetted and brought to the consistency of a thick paste; it is laid on the boarding, smoothed over with a trowel, and the roof is complete,—a coat of tar is sometimes added, but is not absolutely necessary. Mr. Millar says he has had about eight years' experience with roofs of this kind, has made about fifty, and has never had a failure, except in the case of some which were done during a frost. More frequently the centering boards are put under the joists, embedding them in, and thus making the roof practically fireproof. I believe this is a method frequently adopted in the roofs of artisans' dwellings in the East End and elsewhere. It is quite obvious that in buildings of greater importance the same system might be adopted with iron joists instead of wood; or

any of the numerous methods in use for the construction of fireproof floors in concrete would come in also with slight variation as useful flat roofs, and no doubt many of the members present could give examples of such application. 2. The same reasons that make concrete available for fireproof floors make it also available for fireproof roofs of all kinds. Suppose a fireproof roof be required, and it is determined to cover the building with a roof on the Mansard principle. Let all the principals be formed of iron trusses, the front and back walls of the attic story being framed of suitable iron uprights, instead of the usual wooden quarterings, and let the common rafters be of iron; put boarding on each side of these rafters and quarterings to form a mould, and fill in with fireproof concrete, so arranged as to cover and protect the iron, and you then have a complete fireproof roof without thrust on the walls, which is neutralised by the trusses. I have noticed in houses in the course of construction in Paris that all the roof framing and common rafters are frequently of iron, and it would be interesting if our secretary, or some other gentleman equally well acquainted with French construction, could tell us in the discussion if this iron framework ever has a concrete filling-in like the fireproof floors which are so general in Paris; [The Secretary: Always.] and also some member may possibly be able to inform us if this mode of construction has been adopted in America. 3. On the subject of domes and vaults, I think I have little to add to what I have already said in the former papers above alluded to, so that I will not take up the time of the meeting by going into it, except to allude to the immense importance of the subject and its bearing upon the whole question of style and construction in architecture. To realise this, one has only to turn to a work like M. Viollet-le-Duc's Dictionary, and glance at the chapter on vaults in the article on "Construction," where he shows, in that lucid, analytical style which is peculiarly his own, how the whole fabric of the Gothic cathedral rose up step by step from the repeated attempts after many failures to cover in those large buildings in a fireproof manner with stone vaulting. We know how the Gothic architects ultimately succeeded by an ingenious collection of the various thrusts of the vaults in given points, and opposing these by buttresses. Wonderfully ingenious and skillful as this method is, I think it must be admitted that it carries with it the elements of unrest and of comparatively early dissolution; in most instances, if one pier or one buttress gives way, the rest will follow at no distant date, like houses built of cards; it is to be doubted if buildings on this system, unless constantly watched and repaired, will ever attain the ages of those of Egypt and Greece, constructed on the principle of the upright support and horizontal lintel; and, is it not quite possible that if the ingenious and practical designers of the Middle Ages had had at their disposal iron in large bulk, worked with the ease and facility that it is in modern times, and a strong and plastic material like Portland cement concrete to use in conjunction with it, that the problem of roofing in large buildings in a fireproof manner might have taken a totally different direction to the buttress system of equilibrium between thrusts and dead weight which so characterises Gothic vaulted buildings? I am now trenching on my fourth heading, viz., the suitability of the employment of concrete for roofs of buildings of a monumental character where durability and fire-proof construction are required, and in proof of this, I think I need only refer to the examples of splendid buildings erected in India, both in ancient and modern times, some of which have been described and illustrated in the Transactions of the Institute, and in which concrete figures certainly as the chief material in the construction both of roofs, vaults, and domes.

Mr. Blagrove mentioned that there were no iron ribs in the dome of the Oratory at Brompton, concrete only being used throughout.

Mr. T. Blashill remarked that he much preferred good large fillets to flashings, where the roof came against the wall or chimney, for with the most carefully put-on flashings the water would come into the house. It was not so easy to put soakers under the edge of the tiles as it was to put them on the slates; but if a good fillet were put upon the edge of the plain tile roofing, it generally held well.

Mr. J. Macvicar Anderson (Hon. Secretary) considered that, instead of using ordinary tile fillets, the better course was to cut a small chase in the brick-work, to let the tiles into the chase, and to make any slight settlement afterwards good with cement. Lead flashings on a tile roof were an abomination.

The Chairman, having seconded the vote of thanks to Mr. Nevill, was carried.

Mr. Nevill, in replying, said that he had tested a great number of buildings with these roofs, but in no case had he found the least sign of any sagging. As to repairs he had found no difficulty, because, if a tile snapped in the middle, it could be taken out and replaced in cement. He had not meant to say that slates were pervious to snow; on the contrary, he gave them the advantage over tiles in that respect.

MEDALS.

ON Wednesday evening last, Mr. R. S. Poole, LL.D., delivered a lecture to the students of the Royal Academy on the "Art of Medals." The lecturer said that medals were commemorative, and should therefore hold a great place in art. They commemorated the deeds and faces of great men, and were much more generally diffused than statues or pictures. Medals may either be produced by the process of striking or that of casting. We may at once reject the struck medal from its mechanical character, and select the cast as the one to be described. We give this preference to the cast medal from the possibility and scope it affords the artist for skillful and true work, owing to the process it undergoes in its production. It is also a far cheaper method than the other, costing one-third or one-half as much. In a struck medal the expense is owing to the mechanical part of the work, and in a cast the honorarium for the artist's labour is the main outlay. This art is not taught at any of our great artistic schools except the Slade, and Professor Legros and Miss Hallé are perhaps the only teachers of the art of medal-working. The production of a medal can be performed in either of the two following ways:—First, you may model your medal in wax; from this wax you may get a succession of plaster moulds and proofs, and from the last plaster essay the final mould itself; otherwise you may make the wax model your final work, and the mould may be produced from it, or it may be converted into a medal by the process *à la pertuis*. The tools generally used in making a medal vary in their material as the substance worked upon. For work in plaster steel tools are used; for wax, wood; but, as often as not, in the finishing work of the wax medal, steel should also be used. The shape of the tool used is really a matter of taste, and provided that the worker used something with which to work the right curves, a blunt needle or penknife answered the purpose as well as anything else. The method adopted by the Greeks is remarkable, as they made dies of hard steel, and worked them, like gems, with the wheel. And now, leaving the mechanical side, and turning our attention to the artistic, we find that relief is necessarily adopted, and it is this feature that enables us to place the medal as a sort of connecting link between the picture and the statue. Thus we find that in ages when painting was the leading art, relief, and in consequence the medal in all its principal features, showed its relationship to the picture, and when sculpture predominated medals followed the lines of sculpture. For the three kinds of relief, bas-relief, high, and mezzo, we cannot do better than accept Sir Charles Eastlake's definition. He says that bas or low relief is used where there is a bad light. It therefore requires strongly-marked and clearly-defined drawing for its principal outlines. High or alto relief is generally to be seen in the open air, and has its own shadows as well as those cast upon it; it must, accordingly, be treated largely and very simply. Mezzo-relief was used by the Greeks for objects near the eye and in a good light, an instance in point being the choroi frieze of the Mausoleum. The metals used by the Greeks for the purpose of making medals were four in number; gold, silver, electrum, and bronze. Of course, it is not possible to command an unlimited supply of gold for purposes of working now, but it should be remembered that when bronze is used for this purpose, as it almost invariably is, due regard should be paid to the character and substance of the metal in the nature of the

production. As regards the shape of a medal, it should, above all things, be natural, and not mechanical: it should bear evidence in all its details of the presence of the human hand. In Italian medals, we can almost see the gradual formation of the rim, which was not clearly defined in the first instance by a pair of compasses. The surface should not be a dead surface; in Greek work we find the obverse convex and the reverse slightly concave. The importance of this relief in the surface is due to the fact that from the shades of light cast we practically get air, and even colour. The two sides of the medal should be harmonious; and this was a fact recognised largely by the Roman and Greek artists: thus we find the head of a divinity on one side and something relating to his myth on the reverse. In order to understand as nearly as possible this harmony of the two sides, it is better to note the obverse and reverse side by side. There are two positions in which the head is depicted on a medal, either three-quarter face or in profile; the former belonging to the purest age of Greek art, namely, from B.C. 420-330, or, roughly, from the age of Pheidias to that of Lysippus. The finest period of Italian medal work is also characterised by the three-quarter face. The profile is easier than the three-quarter face, and presents less difficulty. The great point of difference between the Greek medal and the Italian is that, while the Greek sought to represent heauty in as perfect a form as possible, the Italian's aim was to give us man as he was and could be: he could depict all the stages of existence. Thus the Greek sought to represent measure and the elimination of all that was disagreeable to him; the Italian was absolutely true and natural. The lecturer then briefly criticised the Greek and Italian diagrams, drawing particular attention to the simplicity of the head-dresses and the accessories, which, he said, should not be thrown in vaguely and without discrimination, but should be typical. The border might be either of the fillet type or a wreath. With respect to the inscription, the letters should carry dignity, be bold, and slightly rounded, as though the limbs were of cylindrical shape. In conclusion, the lecturer drew attention to the importance of combining work from the model with a due observation of the antique, and of producing work from memory rather than by trusting to a mere system of copying.

LECTURES TO ARTISANS AT CARPENTERS' HALL.

THE COMPARATIVE ANATOMY OF BEAMS, TRUSSES, AND ARCHES.

As we briefly announced last week (p. 254, ante), Professor Kerr on the 11th inst. gave the first of a series of free lectures to artisans, in the great hall of the Carpenters' Company, taking the above-named subject as the theme of his discourse.

The lecturer commenced by asking his audience to suppose that the carpenter's rule he held in his hand was a beam loaded so heavily on the middle as to be overstrained. They all knew what happened: it began to deflect more and more until it opened at the soffit and became fractured. At the same time it became buckled at the upper surface. If he took a bar of iron instead of a carpenter's rule, and supposed it to be overloaded, it would deflect very considerably, the material being highly elastic, and while the under side became extended, the upper side became perceptibly crumpled. This showed that the lower part of the beam was in tension, and the upper part in compression. The strength of a beam was in direct proportion to its breadth, because two beams put together would carry twice the weight. But it was as the square of the depth, so that the depth was of the principal value. In considering these facts they would find all kinds of materials tabulated in respect of strength, and they would get into the system of adjusting sectional areas at the top and bottom of a beam so that it should be equally strained in the two capacities of compression and tension. The resistances of timber against compression and tension did not vary sufficiently to induce them to interfere with the simplicity of the square or rectangular section. But cast iron resisted tension with only one-sixth of the force with which it resisted compression. Thus they required a very different section from the rectangular one, and they had the utmost

strength that the material could offer in a complicated section, based on the relative strengths of this particular material as against compression and tension. If, on the other hand, they were dealing with a wrought-iron joist, the top and bottom flanges were equal, because the strengths were as nearly as possible the same. The web had only one function; it had nothing to do but to maintain the element of depth. With regard to stone, as long ago as the time of the Romans, when large stones were used as lintels, they made use of discharging arches. Concrete was a better material, and here he would mention a proposition he was accustomed to lay before his students at King's College. It was this: Nature did not undertake to find us in building materials. Building is a highly artificial performance, and nature expects us to improve on the raw materials in order to make them suit our artificial purposes. Thus concrete ought not to be looked upon as an inferior makeshift for stone, but as a superior artificial material. The cementing medium was stronger, while the bonding of the particles was also better, giving a sort of fibrous character to concrete which stone could not possess. The Professor then referred to tubular iron bridges as exhibiting the perfection of scientific design, returning to the primitive form of a plain rectangular beam, with its upper surface all in compression, its lower surface all in tension, and the walls serving only to maintain the d -square against cross-strain. He then showed how the plain timber beam in side elevation became converted into the form of a truss, by cutting out superfluous material, leaving the equivalent of a pair of rafters in compression, and of a tie in tension, with the same d as before, maintained no matter how, but the former cross-strain being now abolished, that is, converted into the more favourable strains of tension and compression. Out of this the regulation king-post and queen-post roof-trusses of timber, and the same in iron, were easily developed, the d being always the chief element of strength. The unscientific roof-trusses of the Medieval period were also illustrated, and the origin of true trussing in the sixteenth century shown by drawings. Braced and latticed girders, and the simple Warren girder, were here again returned to the primitive form of a solid timber beam, with the d in simplicity. Thus it was manifest that the truss, of whatever kind, was only a beam after all, with the top portion in compression, the bottom portion in tension, and the depth made the most of for the sake of the strength being as the square of it. The lecturer proceeded next to show how a scientifically perfect truss is made by two pieces of cane spreading asunder at the foot, and restrained by a piece of string; and then converted this at once into an arch, by substituting a single piece of cane, brought up to a curve by the same piece of string. In the first case the depth was measured from the string to the apex of the truss; in the second, from the same string to the crown of the arch. The next step was to get rid of the tie in the arch by applying at each end an immovable abutment, and then we had in effect just the same beam as at first, with an upper portion, the voussoirs, in compression; an imaginary lower portion, the tie, in tension; and the d preserved by the resistance of the abutments: that is to say, a beam with the superfluous cut out, and the cross strain all converted as in the truss. The history of the arch was then referred to. Although the old Egyptians and Assyrians were said to be ignorant of the arch, they even better than the Romans. What the Romans did was to introduce the use of the arch extensively, by making a characteristic feature of it, and thus it was that the semicircular arch became a matter of every-day construction throughout the world. In the twelfth century a new arch was introduced from the East, viz., the pointed arch, which was stronger than the semicircular arch. The reason for the introduction of this arch might be that the European builders had got into the habit of building less substantially than their predecessors, so that a great many of their buildings gave way. There could be little doubt that the pointed arch was introduced, not for show, but for a sufficient reason, which must have been a question of strength. The lecturer next touched on bridge equilibration, referring to Southwark Bridge as a special example, and finally dealt with flying buttresses. What he

had wished to impress upon his hearers throughout the whole was the development of a beam, in the first place, into the truss; and the second place, into the arch; and being identified from the beginning to the end with the d , the most important element in the formula of calculation. Whatever might be form of any construction which had to carry a load from one support to another, it was always looked at in that light. There was something equivalent to the upper surface or flange of a beam which was in compression, and something equivalent to the lower flange or tie-rod which was in tension, and between these two was the element of depth. This he termed a comparative anatomy of beams, trusses, and arches, their comparison resulting in a certain identification of philosophical or constructive principle, most important to understand a most interesting to study. The only consideration to be borne in mind was, that whatever forms of construction or contrivance whatever new, strange, or apparently hazardous forms, were developed or designed, the section areas must be adjusted,—that which was compression being adjusted to that which was in tension, thus giving the full force of the d -square to carry the load. He had desired to lay before them, in the first place, an intellectual exercise of a strictly practical and common-sense character, and, in the second place, a proposition full, at all events, of suggestiveness to practical men, and of considerations which might be developed in a discussion offered into sound, substantial, and serviceable knowledge.

The lecturer, after complimenting his numerous hearers upon the close attention which they had followed his discourse, resumed his seat amidst loud applause, and a vote of thanks was passed to him, on the motion of Mr. Kennard, seconded by one of the artists in the body of the hall.

HOUSE SANITATION.

The second lecture of the course was delivered on Wednesday evening, to a large audience at the artisan class. The lecturer was Professor Corfield, M.A., who treated of "House Sanitation."

Professor Corfield dealt first with permeable and impervious soils and the diseases attaching to them. To plaster the outside walls of a house was to render it permanently unwholesome, and the way to cure damp was to put a damp-proof course in the walls when the house was built. This course would be of tar, asphalt or tiles set with cement, or better still of stone ware. This was a matter of the greatest importance, and was the only way of preventing decay in timbers. The sub-soil or ground-water varied very much in different localities, and at different times. The nearer this water was to the basement the more unhealthy would the house be, and it had been generally shown that wherever means had been taken to lower the level of the ground water, the death-rate from consumption had been lessened. Ground air, again, which made its way into the house, contained foul organic matter, and its entrance should be prevented by having an impervious basement floor made of cement concrete, or of York paving set in cement or asphalt. In houses where this precaution had not been taken the inmates were usually unhealthy. The air of over-crowded places contained foul organic matter, with little less oxygen and a little more carbonic acid than the ordinary air. It was, therefore, of the utmost importance that it should be changed, each individual requiring about 3,000 cubic feet of air per hour. The wind by perflation and aspiration was an important agent in changing the air in houses. If a hole were made in the wall of a room in which a fire was burning, the outside air would flow in like water; but the incoming air should be given an upward direction in the form of an air fountain, and be thus distributed over the room. A piece of wood placed in front of an inlet ventilator would prevent the air falling down, the opening should be such as to give the air an upward direction, but should not be too near the ceiling. In the case of a door one of the top panels might be cut out and a kind of hopper fastened to it. The well-known Sheringham valve worked on this principle, although it was movable. Louvres formed good inlets, and Venetian blinds in front of a window made excellent inlet ventilators. There was also the system

known as Tobin's tubes. One objection to all inlet ventilators in towns was that soot and blacks came in with the air, but there were a variety of devices to prevent this. Passing on to the water supply, the Professor pointed out the danger arising from shallow wells in the soil, dealing also with the questions of constant and intermittent services, and the necessity for a thorough periodical cleansing out of cisterns. The waste-pipe of the cistern should always discharge into the open air, and the cistern supplying the drinking water should not connect directly with the water-closet. In regard to the disposal of waste matter, dust-bins built against the walls of houses were very unwholesome. The proper way to collect dust was in movable receptacles, like galvanised iron boxes, which could be lifted by one or two men, and emptied into a cart. In the matter of drainage, the old brick house-drains were very bad, being pervious, and allowing rats to work their way through them. One rat in a house would do an immense amount of mischief. The Professor here exhibited part of the waste-pipe of a sink with a hole about 3 in. long made by a rat. House-drains should be impervious, and made of glazed stoneware or iron pipes, the former being better suited for the purpose. After being laid and properly joined the drains should be tested to see that they were watertight. House-drains should be self-cleansing, and the size generally used should be 6 in., the pipes being laid at a fall of 3 in. or 4 in. in 10 ft. A water-trap of some sort ought to be put on the house-drain before it joined the main sewer. The dip-trap commonly used in brick drains was bad, as it was not self-cleansing. The water passing through it could not prevent an accumulation of filth, and it was, in fact, a small cesspool. A much better form of trap was that commonly called a syphon, but which might be termed a U-trap. This was self-cleansing, and no deposit would take place if a sufficient amount of water passed through it. In spite of the traps in the drains, a certain amount of foul air would pass through them, and they therefore required to be ventilated. The ventilating pipe carried above the roof was not sufficient; there should be an inlet for fresh air, the trap having a pipe leading up to the level of the ground, with a grating over it. The air would then come in at the inlet, and leave at the outlet, and if it did not do this it was the fault of the arrangement, not of the system. The water-closet should be of as simple a form as possible, one of the best forms being the short hopper or "Artisan's" water-closet, provided with a flushing rim. A basin of this kind with a small bend underneath it, might be perfectly self-cleansing if supplied with sufficient water by means of a 1½-inch lead pipe. The syphon action water-waste preventer held about two gallons, and might be filled from the drinking-water cistern. In houses where the water-closet was upstairs the descent-pipe should be outside. It should be made of 7 lb. lead or galvanised cast-iron; if not ventilated the foul air would sometimes eat holes in these pipes. The D-trap was generally used upstairs in houses; it was not a self-cleansing trap, but in course of time became foul. The waste-pipe of the sink should not be connected directly with the drain, and underneath the sink a syphon trap should be fixed to prevent the entry of air fouled by matter adhering to the sides of the pipe. Rain-water pipes also should not connect with the drains, but should discharge into the yard over gullies. The bell-trap was one of the worst possible contrivances; it was not self-cleansing, and when the trap was off the foul air could make its way into the house. The trap which should be used in the yard was the syphon gully. The Professor concluded by remarking that he had said enough to show that the principles of sanitation as applied to houses were exceedingly simple.

The following are the remaining lectures of the series:—On the 25th inst., Professor Church, M.A., will lecture on "Black, White, and Red Lead"; on March 4th, Mr. Blashill, F.R.I.B.A., on "The Shoring of Buildings"; on March 11th, Professor A. B. W. Kennedy, M.Inst.C.E., on "A Piece of Steel"; on March 18th, Professor Bonney, F.R.S., on "Flint"; on March 25th, Mr. J. Slater, B.A., on "Roof Coverings"; and on April 1st, Professor T. R. Smith, F.R.I.B.A., on "Some Celebrated Timber Roofs."

NO. 16, CARLTON HOUSE TERRACE. VISIT OF THE ARCHITECTURAL ASSOCIATION.

CARLTON House-terrace occupies a part of the site of Carlton House, the exact position of which is the opening between the York Column and the foot of Regent-street. The original Carlton House was built by Henry Boyle, Baron Carlton, on a piece of ground leased to him by Queen Anne in 1709. He died without issue in 1725, and his house and grounds descended to his nephew, Robert Boyle, Lord Burlington, the well-known architectural amateur. When in 1783 the Prince of Wales, afterwards George IV., was allowed a separate establishment, Carlton House was assigned for his residence, and Henry Holland, the architect, was appointed to execute the necessary alterations; he added the chief features of the House,—the Ionic screen and the Corinthian portico. Carlton House was taken down in 1826, and the columns of the portico transferred to the National Gallery. No. 16, Carlton House-terrace is the town residence of Mr. Alfred Morrison, and, by permission of that gentleman, was the place selected for the second afternoon visit this session by the members of the Architectural Association, which took place last Saturday. The members assembled at the house at three p.m., and were headed by Mr. Cole A. Adams, the president, and Mr. H. D. Appleton, hon. secretary, who conducted them through the various rooms and apartments.

This visit was one of much interest to the members of the Association, the object being to study and examine the decorations of the house by the late Mr. Owen Jones; this design being, we believe, one of his latest works, executed and completed just prior to his decease, April 19th, 1874. The designs and drawings for the decorations and furniture of this house had been previously exhibited in the Vienna Exhibition. They have been more than once described and commented on in the pages of the *Builder*, and at the time of the lamented death of Mr. Jones we published a long memoir of him in this journal, and alluded especially to these decorations as among his best works.*

The cabinet inlays, tables, couches, chimney-pieces, chairs, &c., are generally in that semi-Saracenic style which Owen Jones had made his own. They were carried out very ably by Messrs. Jackson & Graham.

The members dispersed soon after four o'clock, having had a most agreeable hour's study of Owen Jones's decorative work.

THE SOUTH WINDOW, WESTMINSTER HALL.

THE large south window of Westminster Hall, which was executed by Messrs. John Hardman & Co. between the years 1847 and 1851, and erected in the year of the Great Exhibition, is now placed in the hands of the same firm, under the First Commissioner of Works, for restoration, since the destructive effects of the explosion of the 24th ult. The window represents the arms of all the kings and queens, and founders of reigning houses of England from some time before the Conquest downwards. Fortunately it has been found that all the authorities and drawings prepared by Messrs. Hardman with much labour and care some thirty-seven years ago, from which the work was executed, are safely preserved in their possession, and will be of course invaluable in the work of restoration.

The window in its present damaged state exhibits a remarkable and interesting evidence of the power of suction peculiar to dynamite in explosion. The panels of leaded glass, nearly 100 in number, much torn and distorted by the force of the explosion, are nearly, without exception, bulged *inwards*; the plain diamond-shaped glazing which formed an outer guard or protection to the stained glass, is bulged outwards at every point, but the inner window hears unmistakable evidence of a sudden and violent contraction of air immediately subsequent to the first expansion recorded by the state of the outer glass. It would seem that the same force would account for the fact of the two constables and Mr. Green being found drawn into the hole which the explosion itself had made.

Messrs. John Hardman & Co., who designed and executed all the stained glass in the new

Palace of Westminster, under the late Sir Chas. Barry, are commissioned to restore all that is destroyed or damaged, comprising a number of windows in the House of Commons, Division Lobbies, and St. Stephen's Hall. Except to the great south window in Westminster Hall, the greatest damage is to the series of windows in St. Stephen's crypt. The total cost of Messrs. Hardman's restorations will amount to some 2,000l.

ARCHITECTURAL SOCIETIES.

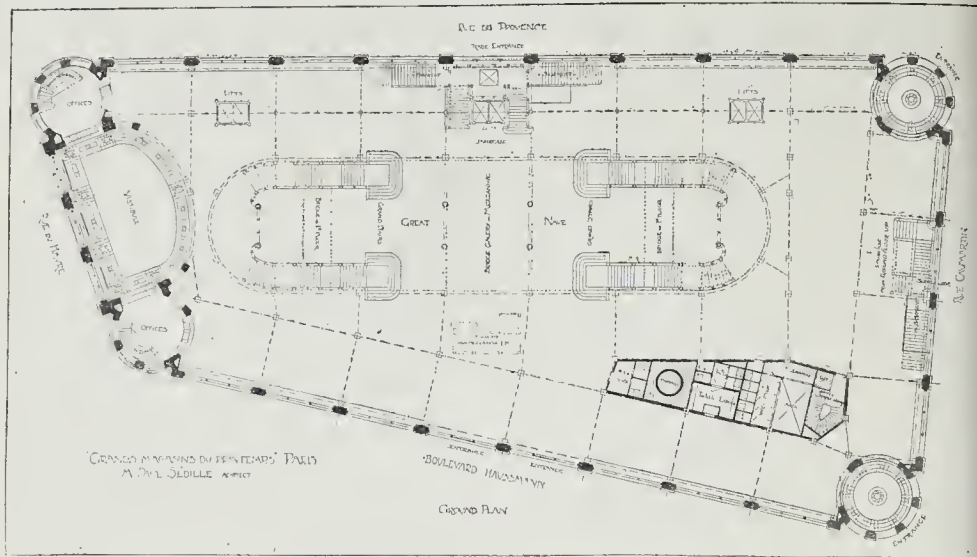

Birmingham Architectural Association.—The fifth ordinary meeting was held at Queen's College, on Tuesday evening last, when the Vice-President (Mr. W. H. Kendrick) delivered an address. He first of all dealt with the affairs of the Association, and inferred that, judging from the present and increasing success of its classes, &c., prosperity in the future was assured. The connexion now existing between them and the London Architectural Association was commended, as serving to mutually strengthen each other for the promotion of the interests of the profession. The lecturer then gave his views upon the education of architects, and recommended the pupilage system, supplemented by technical study, as by this method the vigorous individuality of British design would be sustained. He desired also a greater appreciation of art workmen, and as a means for their improvement he desired the establishment of a technical museum in Birmingham. This should contain a completely arranged collection of specimens of every period of architecture and sculpture. He believed that if this were accomplished the art work of the town would be raised in tone, and the workman, by the study of good examples, would be dissatisfied with his present meaningless productions. On the proposition of Mr. H. H. McConnell, supported by Messrs. R. B. Morgan and Victor Scruton (hon. sec.), a hearty vote of thanks was accorded to the lecturer.

Architectural Section of the Glasgow Philosophical Society.—On Monday evening last a meeting of the members of the Architectural Section of the Glasgow Philosophical Society was held in their Hall, 207, Bath-street. Mr. Landless, architect, presided. Mr. E. A. McGilvray read a paper on "Plaster Work." He confined himself to the plain branches, and said he hoped at some future time to say something of the ornamental branches. Mr. Henry Morrison subsequently read a paper on "Slates." He traced the growth of slate rock, and pointed out the localities of the principal slate ranges in this country. He also referred to some of the more important slate quarries, to slates as a covering for roofs and as articles of commerce.

British Museum Lectures.—On Wednesday next Mr. W. St. Chad Boscawen will commence a second series of six afternoon lectures on the "History and Antiquities of the Assyrian and Babylonian Empires." The unexpected success which attended the former course has enabled the authorities of the British Museum to arrange a new and commodious lecture-room in the new east wing of the Museum, where the lectures will be given each Wednesday at 2.30. The subjects selected for the present course are, February 25th: "The Chaldean Temple: its Construction, Symbolism, and Services"; March 4th, "The Creation Legends"; March 11th, "The Palace: its Architecture and Ornament"; March 18th, "The Deluge Legend"; March 25th, "Chaldean and Assyrian Libraries"; April 1st, "The Legends of the War in Heaven." The lectures will be fully illustrated by maps, plans, and diagrams, and casts of antiquities from other museums. In order that students attending the course may become familiar with the monuments in the British Museum, Mr. Boscawen has arranged a series of morning tours of demonstration, to which the lecture-tickets will admit. Tickets and full syllabus of the lectures may be obtained from Mr. W. B. Cutler, 35, Great Russell-street, Bloomsbury, W.C.; or on application by letter to Mr. W. Boscawen, at the British Museum.

International Inventions Exhibition.—We understand that the Wilkes' Metallic Flooring Company, of 17, Devonshire-square, Bishopsgate, have received instructions to pave the Old London Street at the International Inventions Exhibition.

Illustrations.

THE "MAGASINS DU PRINTEMPS," PARIS.

THE vast "Magasins du Printemps," of which two-thirds only are reconstruction, occupy, including the new building and the rebuilt portions, the large trapezium-shaped site bounded by the Rue du Havre, the Boulevard Haussmann, the Rue Neuve des Mathurins, and the Rue de Provence, between the new Opera and St. Lazare Railway Station. These buildings are noteworthy as much for their internal arrangements as for their external architecture; and their architect, M. Paul Sédille, has distinguished himself in the threefold capacity of engineer, architect, and decorative artist. It may be added that the company, of which M. Jaluzot is the director, has placed immense sums at his disposal, both to insure the solidity of the foundations (which are partly laid across or in a subterranean pool of water), to give full scope for costly decoration, architectural and sculptural, and to bring the latest mechanical improvements to bear on the full ventilation, warming, and lighting of this vast hall of stone, iron, and glass.

Our illustration of the building, which is engraved by Mr. Cooper from a photograph, shows only the principal and most ornate front; the long flank of the building, of which a small portion only is seen in the view, is a good deal shut in by trees, and is more utilitarian in character.

SCULPTURE.

We give separate illustrations, to a large scale, of the principal sculptures, representing the Four Seasons, by M. Chapu, which are in themselves fine works of art. In England we see decorative architectural sculpture of this class, even on a large scale, so frequently given over to mere carvers, and marked by nothing better than respectable mediocrity, that it is desirable to emphasise the fact that, in some cases at all events, they "manage these matters better in France." Why are not our sculptors given similar opportunities?

HÔTEL BOURGTHÉROULDE, ROUEN.

THIS extremely interesting building may be easily overlooked. It is reached through a low archway leading from the Place de la Pucelle. The façade, of which our illustration shows one bay, forms one side of a courtyard. An adjoining side is of late Gothic work, and is well illustrated in Pugin's work on Normandy. The remaining sides are mostly modern, and of little interest.

G. G. WOODWARD.

A BIT OF OLD FRENCH RENAISSANCE.

THE sketch of a portion of the Francis I. part of the Chateau of Blois reproduced, from a sepia sketch by Mr. A. B. Pite, by Messrs. Boussoad & Valadon. It was originally made to afford a sample of this method of reproduction through the agency of photography, of which another example was given in the first number of the *Builder* of this year (Callender House).

The process, which results in what is practically an engraving on metal in very low relief, is satisfactory as a reproduction of monochrome brush drawing, and can be used in any other cases where contributors prefer it to other processes. In the case of coloured drawings it is open only to the objection which affects all photographic reproductions from colour,—the balance of light and dark is not preserved in the case of certain colours.

The bit of architecture represented exhibits well the admirable qualities of that school of French Renaissance, forcible yet refined, which Viollet-le-Duc characterises as the best modern application of Classical materials in architecture. A great deal of Medieval feeling still pervades this type of French Renaissance.

OBITUARY.

Mr. John Middleton, F.R.I.B.A., of Cheltenham, died on the 13th inst., at Adpar House, Newcastle Emlyn. He was elected a Fellow of the Institute in 1876. At the meeting of the Institute on Monday evening last, Mr. Alexander Payne said that Mr. Middleton had been in business as an architect for at least thirty years. He practised successfully at Darlington, then spent some years in travelling, especially in Italy, and finally settled in Cheltenham, there. A year or two afterwards, however, he gratuitously made the design for All Saints Church, Cheltenham, which was so much admired that he was induced to commence practice again, and carried out the Ladies' College, Cheltenham, and a great many other works in the neighbourhood, having especially a large connexion amongst the clergy in Wales. Whilst on a business round, through Wales, a week ago, Mr. Middleton was struck down by paralysis. He was devoted to his profession, and several well-known men were brought forward by him, amongst others Mr. Boniton, the architectural sculptor.

Mr. Colin Minton Campbell, of Stoke-on-Trent, died on the 8th inst. He was the grandson of the founder of the extensive china works at Stoke, which were commenced in 1788. He was born in 1827, and at the early age of fifteen years he was inducted into the pottery business by his uncle, Mr. Herbert Minton, who, having no children of his own, seems to have taken a

special interest in his nephews. Under his watchful supervision, Mr. Campbell became a good practical potter, and was also made acquainted with the commercial department of the business. Upon attaining his majority Mr. Campbell was taken into partnership with his uncle.

THE DRAINAGE OF GREATER LONDON.

AN important report was to be presented to the Metropolitan Board of Works at its meeting yesterday (Friday), by the Works and General Purposes Committee, who recommend,—

"That, in reply to their communications, the Home Secretary and the Local Government Board be informed that this Board has had under consideration the suggestion that the parish of Tottenham should be annexed to the metropolis pursuant to section 249 of the 18 & 19 Vict., c. 120, especially with reference to the main-drainage system, but that the Board is advised that financial and other arrangements would be involved in such a proceeding to which legal effect could only be given by special legislation, and that, in considering the question of the drainage of Tottenham, it would further be necessary to have regard to the possible expediency of taking the sewage from other localities in the Valley of the Lee, which could not, as the Board is advised, be dealt with under the 249th section.

That, even if it could be so dealt with, there would still remain the question whether it would be expedient to deal with that portion of the outlying districts of the metropolis otherwise than as part of a measure for the general extension of the drainage to the whole of the districts round London.

That, at the same time, should her Majesty's Government decide to promote legislation with a view to bringing outlying districts within the metropolitan area,—which measure would, however, as above mentioned, necessitate the consideration of very important financial and other matters,—the Board would not be unwilling to have the duty cast upon it of dealing with the sewage of the lower valley of the Lee, as well as that of other outlying districts."

New Buildings at Westminster Workhouse.

—For some time past the Guardians of the Westminster Union have been alive to the fact that the accommodation for pauper lunatics of the male sex has been very inadequate, and the result was an application to the Local Government Board for permission to erect a building affording the requisite accommodation. That permission having been obtained, the plan of Messrs. Saxon Snell & Son, of Southampton-buildings, was decided upon, and the contract for the execution of the works has just been entrusted to Messrs. Mowlem, Barr, & Freeman. The building will be erected within the precincts of the workhouse in Poland-street, and will occupy part of the space which is at present an open quadrangle bounded by the workhouse buildings. The structure, which is intended for the accommodation of about a dozen patients, will be one story high.

Michele's Automatic Cement-Testing Machine.

MICHELE'S PATENT AUTOMATIC CEMENT-TESTING MACHINE.

We illustrate above a new and improved machine for testing cement, lately patented and brought out by Mr. V. De Michele, of 14, Delahay-street, Westminster. As will be seen, differs considerably from the machine which has been hitherto associated with his name, and which has been so extensively adopted by the principal cement manufacturers and users for many years past.

The old machine is so well known as hardly need description here, but we may remind our readers that the cement briquette was broken by exerting a pull through the briquette at the short end of a weighted lever, by means of a handle and worm, and wheel.

In the new machine, as will be seen by our illustration, the strain is applied by the slightest lever on the right-hand side of the machine falling, and as it does so, raising through the medium of the briquette, the other eighted lever, the motion being governed by a handle regulating the resistance of oil to the piston of a cataraet. In this way the motion of the machine is most completely under control, and is, moreover, very uniform and steady. It can be handled can be set so as to break a briquette slowly or as quickly as may be desired, but the standard test is that the strain should be applied at the rate of 100 lb. per second on the pure inch. At any period of the stroke the machine can be stopped for any desired interval, and when re-started, applies the strain at the same rate as it did before the stop. The machine is also made in a non-automatic form. In this case the weighted levers are in equilibrium at all portions of the stroke, and the briquette is broken by lowering the right-hand lever by hand pressure.

The Strains on the Forth Bridge.—At a meeting of the Royal Scottish Society of Arts, held last week, Dr. Edward Sang read the second part of his paper giving "An Elementary view of the Strains on the Forth Bridge due to the Shifting Load." This part of the paper was devoted to the geometry of the cantilever truss, and in the course of his remarks Dr. Sang used the laws of trussed structures and the method of lessening strains, and referred to the fitness of the structure in question, and the determination of the distance between the piers. Regarding the structure of the truss, he said he was at variance with the designers of the bridge, who crossed bracings introduced new points, each of which must have its three determinants; that as the bracings were in pairs, and as no collection of even numbers could ever make an odd number, there must always be either deficiency or redundancy. Solely from a geometric point of view, the construction was inadmissible. Mr. Westland said no one could say anything against what Dr. Sang had said, and that the theory was perfectly correct, and he said that the double bracing of the pier was just one fault he could see with design of the bridge. Mr. Reid said that, after the experience of the Tay Bridge, he would be inclined to doubt the accuracy of the calculations of some of the people who had to do with the Forth Bridge.

ROYAL ARCHITECTURAL MUSEUM AND SCHOOL OF ART.

PRIZE DISTRIBUTION.

On Monday evening last, Mr. P. R. Morris, A.R.A., presided at the annual distribution of prizes to the students of the Art School at this Museum, situate in Tufton-street, Westminster.

The curator, Mr. Randall Bruce, presented a report which stated that the school had earned last year a Government grant of nearly 100*l.*, the highest yet gained. The Saturday "Life Class" numbered 38 students, with frequently 20 in attendance; while the evening class for drawing from the life, though only started last March, had outgrown the accommodation provided for it. The class for Modelling in Clay numbered about 12, and that for Drawing from the Antique 42 students. The Elementary Class had 60 members. Lectures on Architecture, and on Design and Building Construction, had also been given during the year, the exceedingly valuable collections stored in the Museum being thus well utilised. Among the principal prize-winners was Mr. G. Wilson, who gained the silver medal and first prize offered by the Plasterers' Company for a design in mastic for a panel. For Building Construction first-class certificates were gained by Messrs. T. Morgan, J. Jackson, W. King, and E. Bird; and in the Class for Architecture prizes were gained by Mr. Ernest Poole for a design for a cathedral, and by Mr. W. Ferguson. The attendance prize given by the President, Mr. A. J. B. Beresford-Hops, M.P., was won by Mr. W. Kirk.

Mr. Morris having distributed the prizes, delivered an address, in which he observed that the training of the artist must be thorough, and not a training in one branch or speciality of art only, but a training on a very much broader basis. The professor of the pictorial art should know something of architecture, the architect should know something of modelling, and the sculptor should be able to paint. Without such a varied training, it was useless for the artist to think of achieving success in life. Pretentious was the besetting sin of modern art. The sculptor's whole endeavour was too often not to produce a good work, but to make it pretty; but he was, perhaps, not altogether to be blamed,—he only produced what was demanded. Though England was a century later than Continental countries in beginning to recognise the national importance of artistic knowledge, it had a great future before it. We had been too long the Cheap Jacks of the world, but there were signs that the artistic education being given to so many hundreds of thousands of students in our art-schools throughout the country would yet acquire for us a foremost reputation for artistic superiority. Already he had been informed we had obtained a leading position in the export of wall-papers through the superiority of our designs. He looked forward to the time when every man, woman, and child in the Kingdom would feel something of that great art-movement and benefit by the influence of such schools as that. We should raise up a race of architects who would rescue our towns and villages from the squalor which seemed to be inevitable at the present day. To drive through London from St. Pancras to Charing-cross and to see the black houses weeping with soot was most depressing. The taste of the rich required to be educated quite as much as that of the poor. In proof of this he had had only to call attention to the mania for chocolate colour. Chocolate as a colour did not exist, except in chocolate; and even if it were a colour it was worse than all others for this London of ours. It was a horrible invention. The inventor of chocolate and the inventor of stone colour should have niches all to themselves in the Aquarium.

The Charity and Endowed Schools Commissioners of England and Wales have appointed Mr. Joseph Clarke, F.S.A., their architect.

"WHO WRITES THE SPECIFICATIONS?"

STR,—If you will permit me to offer a word of comment on your editorial note [p. 225] on my letter [p. 250] in your issue of the 14th inst., I would say that I have always considered a proper specification to be a work that gives ample exercise both to the inventive and to the imaginative faculties. One describes much of one's design that one cannot well draw. One describes ways of doing things, not necessarily routine ways, helping out one's words by abundant marginal sketches. I contend that a specification that can be at all correctly described as "a piece of dry business routine" is signally fails in its scope and purpose. It would be possible to make such numerous drawings, so covered with descriptive notes and memoranda, as would to a great extent supersede such a specification as I speak of. But then this is merely putting part of one's specification on drawing-paper instead of on specification paper. It does not affect my argument. You do not want invention and imagination in quantity-taking. You want a man to measure off accurately, and with knowledge of trade technicalities, what an architect shows on his drawings and describes in his specification. The qualities that would make a man a good quantity-taker are very different from those required in writing a good specification. There are dry technicalities and routine in a set of artistic drawings, as there are in a specification; but a good specification is an interesting document on the whole, and will be read with real interest by the intelligent client. I know accomplished quantity-takers, but I do not happen to know one who is also a good specification writer. A quantity-taker has to deal with facts presented to, and prepared for, him. An architect (one after my heart) delights as much in his specification as in his drawings, all being a portion of his one design. An architect who does not write, or have written under his own direction, his specifications, is apt to be the kind of man (whom I have known in the flesh too often) who "leaves all that sort of thing to the builder," or, it may be, to the clerk of works. A quantity-taker may write the specification to oblige the architect who finds him work; but he does not, and cannot, write it as the author of the design should do it. It is one thing to depute work to the man who can do it better than one's self, but quite another to shirk one's own proper work that one ought to be able to do better than any one else. EXCELSIOR.

FARM BUILDINGS.

STR,—Will you permit one who has had some experience in farm buildings, and who looks at the question of designing them from a different standpoint to that generally adopted by architects, to make a few observations re Mr. Young's paper and plans as given in the *Builder* of the 14th inst.? Principally, I find fault with him for evidently looking at the question as though, while it is important that they serve their purpose as farm buildings, it is more important that, in their elevation, they shall show that an "architect" had a hand in it. Now, although in the designing of most buildings, whether public or private, questions of style, precedent, taste, &c., are of some importance, they need scarcely at all be considered when planning farm buildings,—not, in fact, to any greater extent than would be required say in designing a set of ironworks. And, if in designing the furnace box were to be influenced in his ideas of proportion (say) by his previous studies of public buildings or private dwellings, instead of by the question of how to make or smelt the iron at the least expense, it would be rather unfortunate for the owner of the works, particularly if he had to meet with much competition. Now this is something like what happens when an architect is asked to design a set of farm buildings. He does not look upon it as a question of how to manufacture meat, or milk, or corn at the most profit,—or perhaps I might say at the least loss,—but how to make a set of buildings that, while they shall in some measure answer the purpose for which they were intended, they at the same time *must* exhibit in the elevations something that, for want of a better name, I will call style, but which in substance is something no more connected with, or necessary for, the manufacture of meat, &c.,

* We did not call it so; we only said that some other people might.—Ed.

than it would be for any other business quite foreign to that in hand. And as in the supposed case of building an iron furnace, any other consideration than that of how to make iron in the cheapest and best manner would, if indulged in, be at the cost of the iron made, so similar indulgences in the designing of farm buildings will be at the cost of the articles manufactured in them, and the early probability of "the works being shut up," &c., the farm being unutilized.

A detail in Mr. Young's plans which I think is open to improvement, is the unnecessary high pitch and consequent expense of the roofing. I presume they are of tiles, and, if so, I should only have had the roofing of a square pitch, which is ample. Not only is money wasted in this, but the factory is less suited for the manufacture of its goods. Cattle-sheds should be warm, and, for this purpose, should be kept as low as possible. High roofs do not favour warmth. If a desire or study for appearance has prompted these high roofs, a satisfactory result might have been better attained by overhanging the eaves and gables, which would also have protected the walls very much from the rain.

I should have liked to have made a remark or two on some other details, but my main object has been to enter a strong protest against the designing of these buildings being entered upon in any other spirit than that which should actuate a man when designing, say, a furnace for smelting iron or a steam saw for sawing wood.

It is probably news to most members of the profession that it is in consequence largely of this adherence to details suitable only for very different buildings, combined with a want of knowledge of the requirements of farm-buildings, they are so little employed in this branch. To those who do make it a study it is an unworked and profitable mine. H. G.

THE ROYAL ARMS.

SIR,—“J. R.,” in your issue of the 31st of January [p. 182], referring to my letter of the preceding week [p. 152], as to the place of honour as supporter being held on the Scottish shield by the unicorn instead of the lion, asks if I can tell whether the quarterings on the shield are also reversed in Scotland.

This point I could not answer of my own knowledge, so I wrote to a friend in Edinburgh who was likely to be able to give the information, which he supplies quite to the point in the following words:—“You are quite right in your heraldry of the royal arms of Scotland. If you consult Chambers's ‘Encyclopædia,’ under the head of ‘Scotland, Royal Arms,’ you will find a short account of the matter. The arms of the two countries came to be quartered at the time of the union of the crowns in 1603, and since then in Scotland precedence has always been given, not only to the unicorn, &c., as supporter, but to the Scottish lion on the quarterings occupying the first and fourth quarters, while England and Ireland hold the second and third quarters respectively; on all judicial seals and public buildings in Scotland the rule prevails. The Act and Treaty of Union, sec. 24, sanctions the ancient Scottish seals. The question of the proper marshalling of the Royal arms within Scotland was raised in 1853 by a petition to the Queen from the magistrates of Brechin; a reference was made by the Home Office to Garter King of Arms, and to the Lord Lyon, who considered Scotland entitled to precedence on the judicial seals of the country, and his views have since continued to be acted on.”

EDWD. COCKBURN.

CLOSET AND DUST-BIN.

SIR,—Allow me to call the attention of architects and others interested in sanitary matters to the description of a recent patent, which appeared in your issue of the 24th ult. [p. 153], the one numbered 13,841, entitled a “Closet and Dust-bin” combined, by J. Ennals. I maintain there is nothing new in his arrangement, substantially the same thing having been in use for years. Attached to my house is one where a modification (I might say a great improvement) of the same idea is in use. Instead of the moisture being encouraged to draw to the front, and become mixed with the soil and dust, and so become a great nuisance (it is generally admitted that the nuisance of ordinary privies lies in the collection and retention of moisture), it is drawn to the back of the receptacle and drained off, and connected with a sewer, leaving the rest of the “contents innocuous.” I am afraid under Mr. Ennals's arrangement it would hardly be so, owing to its being so sloppy, and more readily giving off an offensive odour.

I think under these circumstances, Mr. Ennals

will have some difficulty in proving his right to the patent if it should be disputed.

It seems to me a pity the Patent Office authorities should grant a patent for any such arrangements. Why not patent the planning of rooms? W. J. S.

* * We give the patents, of course, simply as information; not as endorsing or recommending them in any way.

“NON-ACCEPTANCE OF LOWEST TENDER.”

SIR,—I shall be obliged if “Mr. W. Hoffman Wood, F.G.S.,” Leeds, will kindly give me his authority for the statement he so confidently makes in his letter on the above subject in your issue of Feb. 14th, p. 252, viz.:

“That if he [the contractor] has simply applied, in answer to an advertisement, for the quantities, &c., (and his tender being the lowest is not accepted), he has no ground for action.”

Is Mr. Wood aware that there is an important action pending, on this particular point, against a wealthy Corporation in the West? The result of this action is looked forward to with great interest, and will seriously affect every responsible contractor in the kingdom who devotes his energies, experience, and valuable time to the preparation of *bona-fide* tenders for the execution of works or the supply of goods.

I should like Mr. Wood to say what is the object of advertising for tenders, unless it is to obtain the lowest possible estimate from a substantial contractor. BONA FIDES.

GREY FRIARS CHURCH, ABERDEEN.

SIR.—The authorities of Marischal College, Aberdeen, contemplate an extension of their buildings, and it is rumoured that in the event of the scheme being carried out they seriously propose removing the old Grey Friars Church which stands on the site; but as this fine old building can easily be converted into a College Hall there is no justification whatever for such an act of Vandalism. It will be a source of lasting regret if anything of the sort takes place. G. S. A.

STOCKHOLM TAR.

SIR.—Last summer I had the weather-boarding of some new farm buildings tarred with two coats of Stockholm tar, which, after about a month or so, became the colour of mud. Could any reader tell me the cause of this? Soon after the tar had been put on we had some very wet weather, and I also find now that the men used paraffin with the tar to make it work on easy. Would this cause it? E. B.

PROVINCIAL NEWS.

Chester.—The foundation-stone of the new Museum and School of Art for Chester was laid a few days ago. The style of the building is an adaptation of the Anglicised Renaissance which was in vogue during the seventeenth century. The accommodation for the various purposes is comprised on three floors, besides a basement, which would be available for stores, &c. The ground-floor is about 4 ft. above the level of Grosvenor-street, the main entrance being through a corridor leading to a large open staircase-hall, whence access is gained to each department. On entering the building there is a joint library and reading-room, 21 ft. by 19 ft., on the left, and an apartment on the right, 36 ft. by 25 ft., intended as a natural history museum; beyond this is the lecture-theatre, 44 ft. 6 in. by 30 ft., having two distinct entrances from the staircase-halls, beside platform-entrance and preparation-room at the other end; this room is specially arranged so that all present may have an uninterrupted view of the platform and the lecturer's table, and, in connexion with the preparation-room, a lift is provided to the chemical laboratory on the first floor. The room to be devoted to the archaeological specimens, and also to an art-gallery, is 60 ft. by 25 ft., with top light suitable for pictures, &c. The first floor comprises joint committee-rooms 20 ft. by 19 ft., two science-class rooms having an area of 1,170 square feet, and a chemical laboratory 30 ft. wide, having an area of 520 square feet, and there is a room devoted to the school of art on this floor 320 ft. in area. The second floor is devoted entirely to the school of art, being upwards of 66 ft. in length and 25 ft. 6 in. in width, amply lighted from the northwards; besides this there is a master's room 14 ft. 6 in. by 12 ft., so situated as to overlook the whole of the teaching space. The whole of the floors of the main building will be fireproof, with

wrought-iron beams and light Dennett arcing which would also prevent the transmission of sand between the various floors. The materials for the decorative facing of the exterior consist of red Ruabon bricks, with dressings of Grinshill stone. The architect for the building is Mr. Thomas M. Lockwood, of Chester, and the work will be carried out by Mr. Edmund Gabbatt, of Liverpool, whose tender of 8,150 has been accepted by the committee; the clerk of works is Mr. E. Muspratt.

Liverpool.—Some eight years ago the Liverpool Union Bank opened a branch in Bold-street, and they have now removed the business to new and spacious premises in the same street, which were opened on the 9th inst. The building is of the Italian style of architecture. The lower portion is of polished Scotch granite, and the entrance to the bank is of stone ornamented by a carved representation of the arms of the bank. There is an outer and an inner vestibule, and the bank proper is situated in the centre of the building. It is one story high, apical, and is lighted by a cupola and other lights high up next to the ceiling, all of which are filled in with coloured glass. The walls of the vestibules are lined with marble and falcene glazed tiles and the floors are covered with mosaic. The fittings throughout, door casings, &c., are also of American walnut, and the counters are made of the same wood. There is a keeper's residence at the back, and the front portion over the shops adjoining the bank is to be used as showrooms and workrooms. The cost of the new building is about 9,000l. The granite has been supplied by Messrs. Newall, of Dalbeattie; the decorative and tile work by Messrs. Simpson & Son, of London; Messrs. Jones & Sons, of Pleasant-street, Liverpool, were the contractors and the architect is Mr. G. E. Grayson, of James-street.

Rotherham.—At a Council meeting of the Rotherham Corporation, held last week, Mr. H. L. Tacon, of Rotherham, was appointed architect for the proposed new baths and free library, which are to be erected at a cost of 6,000l.

Richmond (Yorkshire).—At the meeting of the Richmond (Yorkshire) Town Council held on the 4th inst., it was decided to proceed with the new Cemetery, and Messrs. Clark & Moscrop, architects, of Darlington, have been instructed to prepare plans for laying out the ground and for the erection of chapel and lodge.

Darlington.—On the 6th inst. the new Hospital and Dispensary at Darlington was formally opened by Mr. J. B. Hodgkin, the Mayor, of which occasion his worship was presented with a silver key by the architect, Mr. G. G. Hosking, F.R.I.B.A. The key, which has been specially designed by the architect, and manufactured at his expense by Messrs. Harrison & Son, silver smiths, Darlington, is of solid sterling silver weighing 4 ounces. The several contractors have been:—For excavating, brickwork, and mason's work, Messrs. J. W. & M. McKenzie; Darlington; carpenter and joiner's work, Mr. R. T. Smith, Darlington; plasterer's work, Mr. R. M. Ormerod, Carlisle; slating, Messrs. G. Pattison & Son, Darlington; plumber and glazier's work, Mr. Emmerson Smith, Darlington and painting, Mr. John Law, Darlington. The heating arrangements are by Messrs. Haden & Son, of Manchester. Mr. Joseph Hindmarsh was the clerk of the works.

Colchester.—The Board of Guardians have decided to appoint Mr. J. W. Start, architect (of Colchester), to inspect the traps' war and make suggestions as to structural alterations for the better accommodation of vagrants.

Torquay.—The construction of a new reservoir, filter beds, &c., in connexion with the above works has been carried out to meet increasing requirements. They are situated a Kennick, near Christow, Devon, in close proximity to the company's existing reservoir at Tottilford. The first sod was cut some two years since, but on account of the fissures in rock, &c., that have been met with, the work has been carried out under very great engineering difficulties. They are now complete and Torquay will have a plentiful supply of water for the future. The two reservoirs have a superficial area of a hundred acres, and are capable of containing 300,000,000 gallons of water when full, or a supply for 300 days for the whole of the district supplied. The engineer is Mr. H. M. Brunel, of Dolabey-street Westminster, and the works have been carried out by Mr. A. Krauss, of Bristol.

The Student's Column.

DESCRIPTIVE GEOMETRY. — III.

THE second method of solving problems is by changes of projection planes. This means, an object being drawn on given planes of elevation and plan, and redrawn on other planes of elevation and plan which suit your purpose better. For instance, a bow-window being drawn in your general elevation, if you want to show exactly the sides of the bow-window, you must make a special elevation of the side on an elevation plane parallel to that side. This is quite elementary, but there are numerous cases where the process is not so obvious, such as, for instance, as to find the exact shape of the sides of an octagonal roof over a bow-window.

PROBLEMS ON PLANES.

If a plane P be given by its traces P^h and P^v , as in accompanying figs. 11 and 12, any line, A, belonging to the plane P will, if prolonged, intersect the picture planes in points m and n on the traces P^h and P^v of the plane P.

Fig. 11.—View of Plane P, and its Traces, P^h and P^v .

Fig. 12.—Geometrical Representation of the above.

The slope of the plane P is given by a straight line, A, thereof, perpendicular to the horizontal trace P^h of that plane, as in fig. 13.

Fig. 13.

The inclination of line A is to be found by rotation as shown before. The slope of a roof will be given by a line perpendicular to the eaves.

Any horizontal line A belonging to a plane P will be parallel to its horizontal trace P^h (in a roof to its eaves). If a point belongs to a

Fig. 14.

Fig. 15.

Fig. 16.

plane it will be on a line belonging to the same plane; as the point m in fig. 14.

Intersection of two planes, P and Q, given by their traces.

We know that the points m and n , where the traces of the planes meet, are points of the intersection I; by connecting the plans and the elevations of m and n we have I^h and I^v as in fig. 15.

If the planes have parallel traces, such as P^h and Q^h in fig. 16, or P^v and Q^v in fig. 17, then the projection of the intersection, I, will be parallel to the traces.

Fig. 17.

Intersection of two planes, P and Q, given by their traces, when their traces do not intersect within the limits of the drawing-paper.

This is accomplished by the use of auxiliary planes. You cut the two planes P and Q by a horizontal auxiliary plane R; the intersections of plane R with planes P and Q are the lines A and B, of which A^h and B^h are the plans, the point m where A and B cut one another is a point in the line formed by the intersection of the planes P and Q. By operating in the same way by the means of an auxiliary plane, S, parallel to the elevation, we find another point n , which also belongs to the intersection of the planes P and Q; the line m and n is therefore the intersection required. (See fig. 18.)

Fig. 18.

Fig. 19.

Intersection of two planes given each by three points belonging to their respective surfaces.

This is the case most likely to occur in practice, as, in architectural drawings, we have not to do with unlimited planes given by their traces, but with planes defined by lines or points belonging to them. Let the points 1, 2, 3 given in plan and elevation belong to the first plane, the points 4, 5, 6 belong to the second plane.

We use, in this case, the very same method as in the preceding one; that is, we select auxiliary planes, the intersection of which with the planes given can be readily determined, and we get thereby two points which we have only to join to get the intersection required.

In fig. 19 the auxiliary planes selected are vertical, and their horizontal traces are on the lines 1^a, 2^a, 3^a and 4^a, 5^a, 6^a is the line A, which is found by joining the intersections m and n of the auxiliary plane with the lines 4, 5 and 4, 6. A^a is of course on the line 2, 3. The intersection of the same auxiliary plane (2, 3) with the given plane (1, 2, 3) is the line 2, 3 itself; the point of intersection x of the lines A and 2, 3, belongs to the intersection of the two planes given. By means of the auxiliary plane 1, 3, we find the line B and the point y, and by joining x and y we have the intersection of the two planes as required. (Students are particularly advised to re-draw this diagram on a large scale, many times varying the disposition of the planes.)

Books.

Diocesan Histories: Winchester. By WILLIAM BENHAM, B.D., F.S.A. Society for Promoting Christian Knowledge.

THIS is the latest volume in the useful series of Diocesan Handbooks issued by the venerable Society above named, which now conducts a great publishing business. Mr. Benham deals chiefly with historical matters, but, of course, he finds it impossible to give biographies of such prelates as Henry de Blois, Godfrey de Lucy, and William of Wykeham, without saying a good deal about their architectural works. St. Cross Hospital, founded by the first of these bishops, though it naturally falls short of the noble cathedral of Winchester in grandeur and dignity, possesses some features of unique interest. Nowhere else does the atmosphere of antiquity cling more closely about the relics of the past,—nowhere else can

one realise so well the character of a Mediaeval religious house. Its restoration within the last few years has been singularly happy, having extended from the material fabric to its sometimes notorious administration. Bishop Godfrey's work, in which is included all the east end of the cathedral from the hack of the apse (excepting the Lady-chapel), is specially interesting, not merely on account of its architectural beauty, but from the fact that its date, 1202-1207, is accurately known. Wykeham is best known in connexion with the two colleges which he built and endowed, but he also left his mark upon the cathedral. Bishop Edjngdon, his predecessor, had begun the restoration of the nave; Wykeham pursued it, but in a very different way. Edjngdon pulled down the old Norman work to make room for his own improvements; Wykeham, on the other hand, retained Walkeyn's structure, but transformed it from Norman to Perpendicular by altering the mouldings of the undisturbed stones, or else by entirely encasing the Norman piers with new work. This singular treatment is shown with great care by Professor Willis, and is worthy of close examination.

Of the ecclesiastical buildings within the diocese of Winchester we must not speak at length. Romsey Abbey is an excellent example of Norman work, and Christchurch Abbey, though marred by later additions and mutilations, almost rivals it. Gilbert White says that, "Norfolk excepted, Hampshire and Sussex are as meanly furnished with churches as any counties in the kingdom"; but few persons will be found nowadays to accept this dictum. Mr. Benham, indeed, goes so far as to assert that "the most exquisite modern church in the diocese, if not in England," is that of the little parish of Privett. It was built only seven years ago, and has not yet attracted general attention. Mr. Benham has written a book of some little value, but has been too often content with second-hand authorities for many of his statements.

Sketches in Holland and Scandinavia. By AUGUSTUS J. C. HARE. London: Smith, Elder, & Co.; 1885.

We might call this pretty little book "Holland and Scandinavia in Vignette," for the sketches, whether in pen or pencil, are upon a very small scale. Norway has less than thirty pages allotted to it, and Denmark and Sweden are treated with even greater brevity. But Mr. Hare knows how to use his tools efficiently, and is able to convey to his readers, by means of a few graphic touches, very distinct impressions

of the places he has visited. His book will be of service to those who follow the author's steps, and of interest to those who are obliged to stay at home. Only we would recommend tourists to select the spring and not the autumn for their visit to Holland. If Mr. Hare had chosen the former season, he would have had far less occasion for groaning over the dulness and drabness of the country and the mildewed stagnation of the towns. That the latter are not without features attractive to the artist and suggestive to the architect, Mr. Hare's sketches abundantly prove. The town gateways at Kampon and Zwolle are noble examples of Mediaeval brickwork. The great church at Haarlem is, at any rate, externally, a striking edifice. At Utrecht there are quaint gabled houses, picturesque in their decay; and the same may be said of Breda, Dordrecht, and Alkmaar. Picture-lovers may spend pleasant hours at the Hague, Amsterdam, and Rotterdam, while at Delft and Leyden the antiquary may live in the past without an effort. We are glad to find that Mr. Hare, in his notice of Denmark, draws attention to Lübeck, which has been strangely neglected by tourists, though almost rivalling Nuremberg in interest. With Copenhagen he was charmed, and of the great Castle of Frederikshorg he says,—"Each view is more picturesque than the last. It is a dream of architectural beauty." Sweden he describes as pretty, but never rising to absolute beauty. A good sketch is given of the Church of Old Upsala, with its detached wooden helvy and apse, "built out of the Pagan sanctuary." Of course, in Norway he visited and sketched "the date-forgotten old wooden church" of Hitterdal, which resembles a Chinese pagoda more than anything in occidental architecture, and he is warm in his admiration of St. Olaf's Cathedral at Throndhjem, or, as we prefer to call it, Drontheim. But it is the natural scenery which attracts people to Norway, and there takes them captive. For such as desire to taste the sweets of that captivity, Mr. Hare's little volume will be found very useful.

RECENT PATENTS.

ABSTRACTS OF SPECIFICATIONS.

1,034, Cold-water Tap. R. Hallimond.

The valve of the tap is an indiarubber ball mounted on a spindle, which, in the upper part of the casing, is provided with indiarubber rings. The pressure of the water from the main keeps the valve closed, and it is opened by screwing down a small milled head-screw which is the top part of the spindle. When the tap is open and water has access to the upper part of the tap, the indiarubber packing rings are compressed, and thereby prevent any leakage through the top.

4,143, Pressure Regulator. J. Roff and others, of Melhornrc.

This is a pressure regulator and economiser for gas, steam, water, and other pipes. A short conical tube is inserted in the piping so that the fluid current impinges on the small end and external surface. By properly proportioning the area of this orifice to the area of the pipe it is stated that uniformity of discharge and a consequent economy is insured. In applying the conical tube to piping it may either be made separate and fastened by screwing or otherwise, or it may be cast in one piece with the main pipe.

6,037, Roofing Tiles. J. and H. Grimbleby.

The tiles are formed with wings on one side and fillets or hars on the other, and interlock, forming waterproof joints.

1,322, Improvements in Sliding Sashes, &c. F. Oldfield.

Instead of sash-cords, pulleys, &c., a stationary screw is placed in a groove formed on one side of the sash, and upon this screw is fastened a revolving nut, the outside of which is formed as a toothed pinion gearing into a bevel-wheel. A corresponding bevel wheel geared into this is keyed upon a spindle mounted in suitable bearings, which may be actuated by a winch-handle. By revolving this handle the sashes may be opened or shut as they slide in the frames with an easy movement.

8,172, Improvements in Weather Bars. W. Greenwood and Others.

This invention automatically moves the weather bars or strips attached to the bottom of doors as weather bars or strips. A system of rods and levers is attached to the door-post or lintel and the door, by which, as the door is opened, a rod is moved to the door's outer edge; and, in closing, the reverse motion is imparted to the weather bar until it is finally pressed down when the door is shut.

7,838, Cast-iron Skylight-Frames. H. Steven and J. Walker.

The skylight-frame has two pivots or trunnions

atched to it which fit into and turn in recesses ormed in two lugs. One of these lugs is permanently fixed to a plate on the roof; the other is movable and is kept in place by means of a screw, which engages with a nut inside it. The screw can be inserted or removed from the inside of the house. When the skylight is put on, one pivot is fitted to the fixed lug and the other lug is then put on over the other pivot and screwed down. By this means unaltered entrance is rendered more difficult.

4,607, Improved Sash Frame Pulley. S. Hinery.

The front of this pulley represents three circles, one under the other in a direct line, and slightly intersecting each other. In the centre there is the usual opening for the pulley wheel and cord, and near the bottom there is a frame cast on the back of the front face to receive the wheel. This frame is closed at the bottom, but open at the back and top. The sides form the bearings on which the axle of the wheel revolves; the back portion of these sides is higher than the front, and inclines sharply down towards the front, terminating at the point where the axle works. By this arrangement the wheel put in at the back slides down the incline to its bearings, requiring no fitting, and when fixed on the window-frame, it cannot come out. To fix the pulley on the window-frame, it is slightly larger in front than at the back, it is only necessary to bore three holes of a corresponding size with a centre-bit and drive it tightly in with a mallet; but in order to prevent the possibility of its getting loose, holes for screws are provided just inside the front, and as the wheel will readily recede from the front up the inclined sides, they may be easily inserted.

4,856, Improvements in Ornamented Bricks, &c. W. R. Cornell.

The surface of the brick, block, or such like article is given a thin coat of cement. In this layer is fixed pieces of glass, earthenware, paper, or metal, according to the design or pattern to be formed on either the top or the sides, and the whole is allowed to stand out in relief. The bricks are afterwards baked and the cement hardened.

5,845, Chimney Pots. E. S. Romilly.

A pipe, whose upper part is made conical, is fitted with the smaller end uppermost to the upper end of the chimney. Surrounding this, and extending above it, is a second pipe, slightly conical. The lower end of this pipe either forms part of or is fastened to the first pipe, or it may rest and be fixed upon a ledge or flange round the pipe at or below where the conical part begins. Apertures are made where the annular space between the two pipes commences, such that any air entering through these apertures will be deflected upwards, and induce an upward current through the inner pot.

6,306, Griddle or Gully Trap for Sinks. E. Page.

The trap consists of a glazed stoneware box, rectangular in shape, with a cast-iron cover, which is set in cement. The box is divided by a partition, which does not reach the bottom, but dips below the surface of the water, forming the trap. One compartment is connected with the waste-pipe from the sink, and the other with the drain, and the object is to prevent the grease from the sink passing down the drain. This is effected by a plug, which is placed in the opening of the compartment connected with the sink, and which may be removed for cleaning through a hinged grating in the cast-iron cover.

APPLICATIONS FOR LETTERS PATENT.

Jan. 23.—960, A. Graham, Self-Acting Bolt Fasteners for Cupboard Doors, &c.—988, H. Fletcher, Improvements in Teaspoons.—993, T. Palmer, Clamps or Clamping Presses.—996, J. MEETINGS.

SATURDAY, FEB. 21.
Edinburgh Architectural Association.—Visit to Calton Jail.
MONDAY, FEB. 23.
Royal Academy.—Professor C. T. Newton on Sculpture: "The School of Praxiteles." 11. 8 p.m.
Surrey Art Institute.—Discussion on Messrs. R. W. Mann's and H. Martin's papers on "Leasehold Entrenchment." 8 p.m.
Society of Arts (Cantor Lectures).—Mr. J. M. Thomson on "The Chimney of Eignants." 1. 8 p.m.
Leeds and Yorkshire Architectural Association.—Mr. Cole A. Adams on "Architectural Competitions."
Edinburgh Architectural Association.—Mr. J. C. Watt on "The Poetic Aspects of Architecture." 8:30 p.m.
Lancashire Institute. 8 p.m.
TUESDAY, FEB. 24.
Builders' Clerks' Benevolent Institution.—Eighteenth Annual General Meeting. 7 p.m.
Institution of Civil Engineers.—Discussion on Messrs. B. Baker's and Wolfe Barry's papers on the Metropolitan and District Railways. 8 p.m.
Royal Institution.—Prof. Sidney Colvin on "Museums and National Education." 11. 3 p.m.
St. Paul's Ecclesiastical Society.—Mr. Arthur Taylor on "The History of Stained Glass." 7:30 p.m.
WEDNESDAY, FEB. 25.
Royal Academy.—Lectures on Sculpture: Mr. R. Stuart Poole, LL.D., on "Bianco as a Medalist." 8 p.m.
Surrey Art Institute.—Prof. Charles Hart (Free Lectures to Artists).—Professor Church on "Black, White, and Red Lead." 8 p.m.
British Museum.—Mr. W. St. C. Dawson on "Assyrian and Babylonian Antiquities.—I. The Chaldean Temple, its Construction, Symbolism, and Services." 2:30 p.m.
Civil and Mechanical Engineers' Society.—Mr. R. Nelson Boyd on "The Petroleum Fields of Europe." 8:30 p.m.
Surrey Archaeological Society.—Annual Meeting. 5 p.m.
Society of Arts.—Mr. W. D. Scott Moncrieff on "Methods of Supplying Steam-Bolters with Water." 8 p.m.
THURSDAY, FEB. 26.
Royal Academy.—Mr. J. E. Boehm, R.A., on "Bronze Casting as applied to Sculpture." 8 p.m.
Surrey Art Institute.—Professor H. Robinson on "River Pollution." 8 p.m.
Society of Arts (Applied Chemistry and Physics Section). Dr. Frederick Siemens on "Tempered Glass." 8 p.m.
Society for the Encouragement of the Fine Arts.—Mr. C. Ponsonby on "The Folk-lore and Art of Old Japan." 8 p.m.

Society of Telegraph-Engineers and Electricians.—(1) Discussion on Mr. J. A. Timmis's paper on "The Working of Railway Signals and Points by Electro-Magnets." (2) Sir David Salomon on "Constant Electro-Motive Force in an Electric Light Circuit." 8 p.m.
Society of Antiquaries.—8.30 p.m.

FRIDAY, FEB. 27.

Royal Academy.—Mr. F. C. Penrose on "Greek Architecture." 8 p.m.
Institution of Civil Engineers.—(Students' Meeting).—Mr. H. T. Turner on "The Gauging of Flowing Water." 7.30 p.m.
British Museum.—Professor J. F. Hodgkin on "Medieval English Remains." II.—The English. 2 p.m.

SATURDAY, FEB. 28.

Architectural Association.—Visit to Houses in Collingham-gardens and St. Paul's School, Kensington. Assemble at School at 3 p.m.
Builders' Foremen and Clerks of Works' Institution.—Annual Dinner. Holborn Restaurant. 6.30 p.m.

Miscellaneous.

Society of Antiquaries of Scotland.—At the monthly meeting of this Society, held in Edinburgh last week, the first paper read was a notice of the recent excavation of St. Ninian's Cave, Glasserton, Wigtownshire, by Sir Herbert Enslace Maxwell, bart., M.P. In Sir Herbert's unavoidable absence, the paper was read by Mr. J. R. Findlay, the secretary. Local tradition has long assigned to this cave the honour of having been the retreat chosen by St. Ninian for purposes of prayer and meditation. In 1871 it was visited by the late Dean Stanley, and an incised cross was discovered on the rock near the entrance. Last year some other crosses were discovered on detached stones, one of which was presented to the National Museum by Mr. Johnston Stewart, of Glasserton. This explorations now described were undertaken in June last for the Ayr and Wigtownshire Archaeological Association, and resulted in the discovery of a number of indications of the use of the cave in by-past ages,—first as a simple shelter, and latterly as a chapel and place of pilgrimage. The second paper was a description of the Church of St. Clement at Rowdill, in Harris, by Mr. Alexander Ross, architect, Inverness, F.S.A.Scot. This church, situated at the south-east angle of the island, is cruciform in plan, with a square western tower. At some time it seems to have become ruinous, and the upper part of the walls of the nave and tower have been rebuilt from old materials without much regard to character or design, a number of fragments of old moulded cornices and sculptures having been built into the tower promiscuously, and the figures placed in most unlikely positions. The lower portions of the walls of the nave, the transept arches, and the side and end windows of the chancel end are evidently of early date. The third paper was a notice by Sir Walter Elliot of Wolfelee, F.S.A.Scot., of two very curious masks of bronze, found some time ago about 1 ft. 3 in. under the surface in a coffee plantation at Canajore, in the Province of Mysore, India, and presented to the Museum by Mr. R. C. Saderson.

Gouthorn Cathedral, New South Wales. Messrs. Heaton, Butler, & Bayne, of Garrick-street, London, have just shipped two large stained-glass windows for Gouthorn Cathedral, one for the east end of the chancel and the other for the north transept. The east window consists of seven large lights and elaborate tracery in the Decorated style, and is filled with figure work very richly coloured, illustrating "The Angel's Appearance to the Shepherds," "Christ as a Child in the Temple," "Baptism," "Sermon on the Mount," "Crucifixion" and "Ascension." In the numerous pieces of tracery above the lights are emblems and Christian symbols. The window is to be erected as a memorial of William and Emily Elizabeth Bradley, at the cost of their daughters. The north transept window, consisting of six lights and tracery, contains eighteen figure panels from the Old Testament history, which subjects are arranged in bands of colour across the window, having pattern-work between. This window is in memory of Thomas Sutcliffe Mort, and has been executed under the supervision of Mr. J. D. Grace, of Wigmore-street, on behalf of the Mort family. These windows have cost about 1,000l.

Registration of Titles.—The committees of the Building Societies' Protection Association are about to offer prizes for the best essays on this subject, more especially with reference to dealings with smaller classes of property, such as constituting the main portion of the transactions of building societies.

Combination of Employers and Workmen.—A meeting of the employers and workmen in the net and holt trade was held on Monday night at Darlaston to consider what action shall be taken with regard to underselling by certain firms in the district. Mr. A. Keen, J.P., presided, and there was a large attendance. It was pointed out that some of the employers were selling goods at a price which left little or no profit, and that the men were consequently threatened with a reduction of 10 per cent. in their wages. The meeting represented four-fifths of the trade, and representatives of men and masters spoke against the proposed reduction; after which a resolution was passed to the effect that the time had arrived when there should be complete unity between the employers and workmen engaged in the trade. Another resolution was also agreed to that, as the action of employers and workmen outside the trade association was seriously injuring the prospects of trade, the meeting was of opinion that employers should employ none but associated workmen, and that workmen should only work for associated employers.

New Buildings in Birmingham.—The annual return by Mr. Lloyd, the buildings surveyor, of new buildings for which plans were approved by the Borough Surveyor during the year 1884, has just been published. From this it appears that numerically there has been a slight improvement in number of new buildings, including alterations, upon the two previous years, as follows:—

Houses	1884. 622	1883. 876	1882. 601
Shops	62	62	65
Churches	1	2	2
Chapels	—	2	—
Schools	5	2	1
Manufactories and Warehouses	24	37	64
Miscellaneous	187	—	62
Alterations, &c.	84	158	163
Totals	1,285	1,285	963

947 notices to property-owners and others relating to dangerous structures have also been sent out during the year, as against 767 in 1883.

The Safety of Theatres in Glasgow.—At the meeting of the Glasgow Town Council last week, the special committee charged with the consideration of the matter submitted regulations to be observed in the construction of all buildings intended for theatres or music-halls, as well as drainage. After much discussion, the regulations were again resubmitted to the committee, the general opinion being that they were insufficient. Bailie Richmond, in protesting against delay, remarked that there were music-halls and other halls in Glasgow that were simply in a scandalous condition, and the Council were not doing their duty as representatives of the public if they did not call the attention of the Lord Advocate to the state of matters at once. He added that there were holders of such places who, just because they knew the authorities had not the power to force them, were not using any means to improve matters.

Society for the Encouragement of the Fine Arts.—Mr. George C. Haité, author of "Plant Studies," and member of the Council of the above-named Society, read an interesting paper to members of the Society at the rooms in Conduit-street on February 12. The subject was "Wall-papers and their Manufacture," and to illustrate his discourse the lecturer had provided copper and wooden blocks, arsenical papers, and many non-arsenical papers of the present day, including designs by E. W. Godwin, F.S.A., Walter Crane, Lewis F. Day, and the lecturer himself. Representatives of the leading town and country paper-houses were present. Mr. Cave Thomas, F.S.A., kindly took the chair in the unavoidable absence of Mr. E. W. Godwin.

Free Libraries for Glasgow.—A meeting was held in the City Hall, Glasgow, on Monday evening, under the presidency of ex-Lord Provost Ure, in favour of the adoption of the Public Libraries Acts. The attendance, which was large, included many prominent citizens. Resolutions declaring that the Acts have been of great advantage elsewhere, that further delay in their adoption in Glasgow would be unworthy of the city, that until the Acts were adopted the full benefits of the Mitchell, Stirling, and Glasgow Libraries could not be obtained, and pledging the meeting to support the committee in the matter, were unanimously agreed to.

Civil and Mechanical Engineers' Society. An ordinary meeting was held on the 11th inst. at the President, Mr. Colvile, M.Inst.C.E., in the chair, when Mr. B. Haughton, C.E., read a paper entitled "Indian Railway Network, 1854." The principal points taken up by the author were,—(1) The Physical Geography of India as it applies to the Rivers and Mountain Ranges which in every Country affect its Railway Network; (2) The General Character of the Railway Network; (3) An Indo-European Railway and its connexion with the Indian Lines; (4) The Indian Railway Gauges; (5) Financial Position of the Railways. A discussion followed, and the proceedings terminated with a vote of thanks to Mr. Haughton for his paper. The next meeting will be held on the 25th inst., when Mr. Nelson Boyd, M.Inst.C.E., will read a paper on the "Petroleum Fields of Europe," in lieu of the paper previously announced, by Mr. Barge, M.Inst.C.E.

A New Board School.—On Monday last Mr. Buxton, Chairman of the School Board for London, opened the new school in Surrey-lane, Battersea Bridge-road. The school, which is one of the most imposing buildings of the 307 of a similar character which have been opened in London, will accommodate 480 boys, the same number of girls, and 632 infants,—a total of 1,592. The site, which occupies an area of 74,054 ft. cost, including legal expenses, 3,468l., or 2l. 4s. 8d. per head, and the building 15,068l., or 9l. 12s. 11d. per head, making a total cost of 18,527l. 12s. 6d., or 11l. 17s. 2d. per head. An interesting and novel feature in connexion with the school is a workshop, in which Mr. Toombs, the headmaster, proposes to teach the boys the use of various simple tools, how to execute trivial repairs, and in other ways to make them on leaving school handy and intelligent lads.

Constructional Ironwork.—Messrs. Rowson, Drew, & Co. send us a very well illustrated catalogue of constructional ironwork, beams, trusses, sections of roofs, fire-proof floors, &c., as carried out by them. Their iron tank construction appears very satisfactory; occasional serious failures in such tanks render this an important matter. In the combination of iron beams and concrete we observe that, as in other illustrated catalogues of the same class, the influence of the concrete in resisting compression, and thus rendering possible the reduction of the area of the upper flange of the beam, is not taken into account. So much has been said, and so many experiments made in regard to this, that it is odd that it should be so constantly overlooked.

Sunday Exhibition Opening.—The Council of the Institute of Painters in Oil Colours, Fecundilly, have generously placed their present Exhibition at the disposal of the Sunday Society, and it will accordingly be open next Sunday to the members of the Society and their friends; and on Sunday, March 1st, the Exhibition will be open to the public by tickets, which may be had free by all who make written application to Mr. Mark H. Judge, the Honorary Secretary, No. 8, Park-place, Villas, W., the only condition being that each applicant must send a stamped and addressed envelope for the reply.

Masons' Strike at Cardiff.—Last week the masons employed at the new Roath Dock, now in course of construction by Messrs. Nelson & Co., at Cardiff, to the number of 150, struck work against an infringement of their local rule by which their working hours are regulated. As one result, upwards of 500 other men who were no parties to the dispute have been thrown out of work. By the latest accounts, however, a foreman who had made himself obnoxious to the masons, and whose discharge was demanded by the men, has gone away, and the men were to resume work on Thursday morning last.

Clerks of Works' Reports.—Johnston's registered "Clerk of Work" Report Sheets (published by Morrison Bros., 99, Buchanan-street, Glasgow), of which a specimen has been sent to us, are very compactly arranged, and will be found exceedingly convenient and time-saving. Although published in Scotland, they are applicable for use in all parts of the Kingdom.

Post-Office, Inverness.—According to the Scotsman, it has been definitely arranged that new and more commodious premises will be erected for the Inverness Post-office, on a site fixed upon in a street at present being constructed in a central part of the town. The building will cost not less than 10,000l.

The Proposed Park at Dulwich.—A deputation from the Vestry of St. Luke's has waited on the Charity Commissioners at Whitehall to object to the interference of the commissioners in the proposals of the governors of Dulwich to make a free gift of 72 acres of land to Metropolitan Board for the purpose of a park in South London. The arguments that the property in question was held upon for the joint benefit of four metropolitan parishes—namely, St. Botolph's, Bishopsgate; St. Andrew's, Southwark; St. Luke's, and St. Dunstons, and it should be used for the national purposes for which it was left, were supported by Mr. F. G. Tolson, the Mayor of Dulwich, in reply, said that the commissioners were appointed for a special purpose, and it would be entirely beyond their powers to express an opinion upon a matter of this nature. Mr. Tolson was before Parliament.

Michael's New Schools, Little Harwood.—Mr. Lowe, architect, Manchester, who was called in to adjudicate upon the plans sent to the committee formed for the erection of schools at Little Harwood, in connexion with St. Michael's Church, has chosen those of Mr. Robinson, Derby and Blackburn, as the

first in order of merit, and those of Mr. J. W. Shorrocks and Messrs. Stones & Gradwell as second and third respectively. The design of Mr. Robinson will be carried out. It is only proposed to erect, in the first instance, the infants' school, to be used also as a mission-room on Sundays. The building will be Gothic in style, and is estimated to cost about 1,000l.

Dundee.—At a meeting of the School Committee of the Dundee School Board on the 5th inst., plans of Rosebank and Butterburn Schools, amended in accordance with the suggestions of the architect for the Education Department, were submitted by Mr. MacLaren. The plans for Rosebank showed accommodation for one hundred additional scholars, and those for Butterburn additional accommodation for thirty-four scholars. The committee approved of the plans, and instructed that they should be forwarded to the Education Department for approval.

Swinton.—At a meeting of the Church-building Committee, Swinton, near Rotherham, Mr. H. L. Tacon, of Rotherham, was appointed architect for proposed section of a church to be built at Swinton Bridge.

For rebuilding the Jamaica Coffee House, St. Michael's Alley, Cornhill. Mr. Banister Fletcher, architect:—

	Conduct if Bath stone		
J. Dover	£9,570 0 0	283 0 0

Working Lads' Institute, Whitechapel.—We are asked by Mr. A. Reed, of Stratford, to say that his tender for this job should not have been included with the tenders for above given in our last issue (p. 255), as it was withdrawn on January 23.

SPECIAL NOTICE.—Lists of Tenders frequently reach us too late for insertion. They should be delivered at our Office, 46, Catherine-street, W.C., not later than Four p.m. on THURSDAYS.

TO CORRESPONDENTS.

K. and Co.—W. E. M.—A. K.—E. L. B.—O. C. [we cannot answer such questions].—H. H.—G. A. W. [we cannot print your letter, which is practically an advertisement; but it has been forwarded to our correspondent].—A. H.—O. F. B.—F. W. [thanks, not required].—G. N.—W. G. S.—E. R.

All statements of facts, lists of tenders, &c., must be accompanied by the name and address of the sender, not necessarily for publication.

We are compelled to decline pointing out books and giving addresses.

Notes.—The responsibility of signed articles, and papers read at public meetings, rests, of course, with the authors.

We cannot undertake to return rejected communications. Letters or communications beyond mere news items which have been duplicated for other journals, are NOT DESIRED.

All communications regarding literary and artistic matters should be addressed to THE EDITOR; all communications relating to advertisements and other exclusively business matters should be addressed to THE PUBLISHER, and not to the Editor.

PUBLISHER'S NOTICES.

CHARGES FOR ADVERTISEMENTS. SITUATIONS VACANT, PARTNERSHIPS, APPOINTMENTS, TRADE, AND GENERAL ADVERTISEMENTS. Six lines (about fifty words) or under, 6s. 6d. Each additional line (about ten words) 1s. 6d. Terms for series of Trade Advertisements, also for Special Advertisements on front page, Competitions, Contracts, Sales by Auction, &c., may be obtained on application to the Publisher.

SITUATIONS WANTED. SOUP Lines (about THIRTY words) or under 2s. 6d. Each additional line (about ten words) 1s. 6d. PREPAYMENT IS ABSOLUTELY NECESSARY.

Stamps must not be sent, but all small sums should be remitted by Cash in Registered Letter or by Money Order, payable at the Post-office, Covent-garden, W.C. to ROUGLAS FOURDRINIER, Publisher, Addressed to No. 46, Catherine-street, W.C.

Advertisements for the current week's issue must reach the Office before THREE o'clock p.m. on THURSDAY. The Publisher cannot be responsible for DRAWINGS, TESTS, SCHEMATA, &c. left at the Office in reply to Advertisements, and strongly recommends that of the latter COPIES ONLY should be sent.

SPECIAL.—ALTERATIONS IN STANDING ADVERTISEMENTS or ORDERS TO DISCONTINUE same, must reach the Office before TEN o'clock on WEDNESDAY MORNINGS.

PERSONS Advertising in "The Builder," may have Replies addressed free of charge, to the Office, 46, Catherine-street, Covent-garden, W.C. Letters will be forwarded if addressed envelopes are sent, together with sufficient stamps to cover the postage.

TERMS OF SUBSCRIPTION. "THE BUILDER" is supplied gratis from the Office to residents in any part of the United Kingdom at the rate of 19s. per annum, PREPAID. To countries within the Postal Union, 26s. per annum. Remittances payable to ROUGLAS FOURDRINIER, Publisher, No. 46, Catherine-street, W.C.

Notes on Early Painting and Craftsmen-Painters.

IN speaking of the craft or trade of painting, we have been long accustomed to associate its practice with house-finishings, and, therefore, we call it a building trade. If we go back, however, a

few centuries, we find this craft existing under a different set of conditions than what obtained at a later period, when the revival of art in Western Europe and Great Britain brought a distinct class of practitioners to the front, and when the artist found a special field for his talent without being obliged to combine fine art with handicraft. The brotherhood or guild of painters existed from a very early period to the time of Elizabeth, before it was incorporated. We have in the civic records a very interesting acknowledgment made by a painter in the 12th Edward I. (1284). This entry, which is in Latin, says:—"On Friday, the Eve of St. Botolph, in the twelfth year of the reign of King Edward, Nicholas Bacon, painter, acknowledged that he was bound to Hugh Motun, in the sum of twenty shillings, for cinople, vermilion, and canvas, varnish and verdigris, the same to be paid to the same Hugh or his certain attorney, ten shillings at the Feast of St. Bartholomew, and ten shillings at the Feast of St. Michael, without delay." This very distinct mention of the materials used for varnish painting upon canvas is worthy of particular note, inasmuch as it is more than a century earlier than the time of John Van Eyck, who is reputed to have been its inventor. In our "Notes" some months ago* on "Early Plastering and Plasterers," we alluded to the practice of fresco-painting in the Middle Ages, in connexion with the walls of our ecclesiastical buildings and the state chambers of our chief castles, and no doubt native painters of skill participated in the work as well as foreign artists. In the reign of Elizabeth the painters began to make sore complaint about the decay of their craft by reason of other persons that had not been apprenticed to the calling undertaking painting work, and the house-plasterers among others were accused of intermeddling "in the same science." We are told much slight work was palmed off as pictures of the queen, noblemen, and others. And as John Strype, in his edition of Stow, tells the story,—“People bought the same,

being much deceived, for that such pictures and works were not substantially wrought, a slander to the whole company of painters, and a great decay of all workmanship in the said science, and also a great discouragement to divers forward young men desirous to travel for knowledge in the same.” Complaints were also made from time to time to the Lord Mayor, but without redress: so in 1575-6 the craft of painters addressed Elizabeth, and shortly succeeded in obtaining a charter of incorporation, and became known in future as the Painter-Stainers. The craft or guild, among other exclusive privileges, obtained power to prevent persons following the trade who had not been apprenticed to that mystery for seven years. They had also authority to enter shops, warehouses, or workhouses of men exercising the craft, and to “search, examine, and survey their works, painting, colours, or other stuff.”

In Elizabeth's time we see, as at a much later period, the painters or painter-stainers of London were not merely house-painters, but essayed a little artistic work in picture and sign painting. Queen Elizabeth's Sergeant-painter was one George Gower, and it was his office and that of his deputies to superintend all the painting work required in the service of her Majesty. To enumerate, this included “all colour, oil, varnish, workmen, and labourers, as well free as foreign, and all manner of necessaries and stuff whatsoever, meet for to be employed for that service. And also to take up all manner of carriages, as barges, boats, carts, wagons, horses, with their furniture, necessary for the conveyance of the premises, as well by water as land at reasonable payments and prices to be made on that behalf.” The Sergeant-painter to the Queen had certainly a kind of public department to control, and if he was obliged to express an opinion as to the excellence of certain pictures and statues, like our modern First Commissioner of Public Works, we may suppose that his decision would not give unmixed satisfaction to the artists and artist-craftsmen of his day. In the 1st Edward III. (1327), in the civic records, there is a long agreement drawn up in Latin and Norman French, having relation to the grievances of the painters as well as their brother-crafts, the joiners, and the lorniners in copper and iron, who were assaulted and defrauded by the craft of the saddlers. There was an appearance before the mayor and sheriffs on the part of the offenders and the offended, and certain rules as to the future were agreed to. The saddlers appear to have ridden the high horse for a long time, beating and otherwise maltreating the painters and men of other trades, and repudiating their lawful debts. The painters were owed upwards of 100*l.*, and the other trades lesser sums.

Alleged infringement of the privileges of one trade by another has been an immemorial cause of trade disputes, and notwithstanding that the exclusive privileges of trade guilds have been abolished, trade jealousies still exist to a remarkable extent. The infringement of a trade mark in these days is in the eye of the law an illegal act, and, apart from the litigation ensuing from a flagrant case of fraud, we constantly see what an amount of bad blood is generated even on the suspicion of a colourable imitation. *Appropos* to the early allusion to oil painting above, as also to the crafts of painters and saddlers, there is a passage in the Liber Horn, *temp.* Edward II. (preserved in the Guildhall), of interest,—“Rules as to painting old and new saddles. It is provided that no one put any but good and pure colour upon gold and silver; that is to say, good cynople, good green, good vermilion, or other colour tempered with oil and not brasil or indigo of Baldas or any other bad colour.” The sinople was most likely the green colour mentioned in old French heraldry, the brasil was a coarse red, and the indigo should be from Bagdad instead of “Baldas.”

To skilled and artistic members of the old guilds of painters may be safely attributed sundry paintings and pictures that formerly embellished the walls, wainscots, and ceilings of their old trade-halls in several cities and towns in the three kingdoms as well as in London. The painting of sign-boards and the pictorial representations of men, animals, birds, and mystic personages over the doors of inns and hostleries was, for the most part, the work of members of the painter's craft, though there have been a few artists in modern days, who afterwards became distinguished members of their profession, who did not disdain in their early career painting a pictorial sign for an inn. Large prices have been demanded and paid for some of these signs in our own day, when their author became known. Before the passing of the Irish Municipal Reform Act, which abolished the old trade guilds of Dublin, the craft of the painters or painter-stainers did not exist as a distinct guild among the twenty-five minor corporations of that city, but the trade, nevertheless, was, in its representation, associated with another; indeed, two, three, or more crafts were often represented by a guild which bore no relation in name or affinity of pursuit with those associated with it. In Glasgow, for instance, the craft or ancient guild of Wrights, *i.e.* Carpenters, had associated with them the painters and plasterers. The wrights in Glasgow were originally mated with the masons and coopers; but the latter seeking separation, were disjoined in 1567. Later on the wrights sought disjunction, and obtained from the magistrates and town council a

* See *Builder*, May 31, 1884, p. 774.

separate letter of deaconry or seal of cause, dated the 3rd of May, 1600. It appears then, by this incorporation were included wrights, glazing-wrights, boat-wrights, painters, bowyers, and sawyers. From the minutes of the Glasgow Town Council of October 1st, 1659, we take the following curious entry as to "One painter in Glasgow," his skill, and the work the City Fathers required him to do:—"The said day, in answer to the supplicatione given in be Robert Marschell, pyntor, showing that hes skill in washing and pynting of houses, and given proof thereof in sundrie places within this burgh, and seeing there is but on [one] the lyk within the samyn burgh, and not one vthir in all the Wast of Scotland, desyring therfor license to practise and occupy the samyn peacablie heirafter within the said burgh [that occupation being rather an science nor an craft], quhilk being weighed and considered be the said provost, bailies, and counsell, they, after consideration had thereanent, doe heitry grant licence and libertie to the said Rot. Marschell to wash and pynt houses to any within this burgh or territorie thairof who pleases to employ him for that effect without any impediment to be made be him thairintill." House-painters must have been in a very backward state in Glasgow in the middle of the seventeenth century. Two years earlier than the above entry, one John Colquhoun appears to have been in request by the Glasgow Town Council for making engines for carting water, mending the town clock, painting, and doing other town work. On the 8th of August, 1657, we find the following minute:—"The same day it is concludit and agreed upon be the saide Magistrates and Counsell that James Colquhoun paint and fix the townes armes and zeir of God on everie horologe hrode, and that been done, grantis warrant to James Eornis to pay the said John Colquhoun for the paynting and colouring of the four horologe brodis of the tolbooth, and gilting the letters thairof as they now stand, the summe of four hundreth merks money, out of the money collectit for the bucknats, and quhat the said James does farder to the globis, he is to be satisfied thairfore, be sicht of John Walkinschaw." The regular profession of the architect appears to have been as much under the shade in Glasgow at the end of the seventeenth century as that of the craft of painting. In October, 1678, one Alexander Thom, "archibctor," was granted liberty and licence to reside within the burgh, "and to exercise his employment and calling in architectorie and mesourie." In 1684 we find the said Alexander Thom sending in his account and getting paid in the sum of 405*l.* Scots, in addition to other moneys previously received for work done. His work included, among other details, "cutting the king's armes upon stone, furnishing ane stone thairto,—peynting and gilding thereof, and cutting the king's armes on timber for the king's seat in the High Kirk, contriving the modelles of the frontispiece of the lofts thereof, and for cutting severall thistles and crowns for the use of the said seat, and his hall panes and attendance thairon, and the taking down and putting up the said lofts, and for eight cedar tables and the pertinents belonging thairto, furnished be him for the use of the town, &c."

Some what cognate to our subject is the early craft or art of glass-painting, or staining, in connexion with our Medieval churches, and later on in the houses of the wealthy, where the work of the glass-painter was executed in movable casements and became articles of furniture. The origin and growth of glass-painting would, however, need a paper to itself; but, apart from foreign indebtedness, England in the fifteenth and sixteenth centuries, without going back further, has good reason to feel proud of the work of her craftsmen-artists, although these men were content to be known under the appellation of "glaziers." The names of several of these highly-skilled native craftsmen have reached us, with their agreements or contracts with their patrons. Dallaway and others who have written on the subject are inclined to the opinion that, from the contracts made between the benefactors of ecclesiastical buildings in the middle centuries

after the Conquest, the glaziers furnished the stained glass cut into various shapes and inclosed in lead as the colours were required. It is believed also that the pattern or design from which the windows were composed was first given by the same artists who painted the walls in fresco. John Thornton, of Coventry, executed the great east window at York in the reign of Henry IV., and the art must have been more or less successfully practised by native craftsmen before that time. James Nicolson, a glass-stainer, was in much request in the sixteenth century; and it is recorded of Mark Willens, who died in 1561, that he supplied the glass-stainers and arras-makers of his time with designs for their several works. The city company or guild of glaziers were a long time in existence before they became a chartered body. It was not until the 13th of Charles I. that they appear by the name of "Master Wardens and Commonalty of the Art or Mystery of Glaziers and Painters on Glass of the City of London." At the Reformation glass-painting in connexion with our churches passed under a dark and bursting storm-cloud of Vandalism, but there was a revival in the seventeenth century.

Before concluding our notes, a passing allusion will not be out of place to the ancient craft of writers of text letter commonly called "Limners." This class included the illuminators, painters, and decorators of manuscripts. There is an ordinance of the writers of text-letter and others who bind and sell books dating from the 4th Henry IV. (1403). The representatives of these crafts petitioned the Mayor and Aldermen "to grant unto them that they may elect yearly two respectable men, the one a lymenour the other a text-writer to be wardens of the said trades," &c., so that the crafts might be better governed and conducted in future, and that good work should result. The Limners for the time being were granted what they solicited. Ireland, at least, may feel justly proud of her early illuminated manuscripts, particularly the almost miraculous skill in ornamentation evidenced in the Book of Kells. From the fifth to the end of the eighth century illumination, or the art of ornamenting manuscripts, was practised with great perfection in Ireland in connexion with the Church. Those who wish to know more of the subject will find, in the "Paleographia Sacra Pictoria" of Mr. J. O. Westwood, the English paleographer; in "Illuminations and Fac-Similes from Irish Manuscripts in the Libraries of Switzerland," by the Rev. Dr. Ferdinand Keller, of Zurich; and in the "Handbook to the Byzantine Court" and "Art of Illumination," by Digby Wyatt, food for reflection and just tributes. The influences of this early school of illumination, in the opinion of the last-named writer, extended much further than is generally supposed, Scotland, Wales, Cornwall, the North of England, and Scandinavia adopting its peculiar system of ornament. The matchless illuminators of old have long died out, but in the architecture of the long past their influence may be traced. The history of civilisation is the history of education and science and art combined. Stone-carving in process of time in the British Islands gave birth to sculpture proper and painting as fine arts and painting, as a skilled craft, and other building handicrafts, performed good pioneer service.

NOTES.*

MR. SELLARS'S Bill to amend the system of Private Bill legislation in the United Kingdom is a practical attempt to effect a needed reform. When so much national and public business requires the attention of members of Parliament, it is wholly unreasonable to expect them to sit as judges on the numerous private Bills which require to be investigated. In one word, the object of this Bill is the creation of a court of not more than three judges, which shall be either formed

* In order to report more fully the valuable lectures at the Royal Academy, we omit our usual signed article this week.

of the whole number, or of a single judge, and fulfil the functions of the present private Bill Committees. After taking evidence and investigating the scheme and the views of those who oppose it, the Court is to report to Parliament. It is to have the power of sitting when Parliament is not in session, and of reporting the results of its investigations during the prorogation of Parliament, when it reassembles. There is also provision made for the court to sit in other places than London. Of course, there are further details, but such are the main features of this scheme.

THE advantage of the above scheme would be that it would leave Parliament free to fulfil its larger functions, and that it would allow more time and consideration to private Bills, which would not, as now, be pushed into the few months of a session. In many instances, by taking local inquiries by one member of the Court, such as in tramway and gas Bills, a great deal of expense might be saved, and a more satisfactory result attained than is now the case. Nor would the absurdity of an appeal from a Committee of the Commons to a Committee of the Lords, or the reverse, any longer continue. The scheme, in some interested quarters, and among very Conservative members of Parliament, who are fond of traditional privileges, may meet with opposition, but its main principles can scarcely fail to be approved by the Legislature and the country at large.

THE announcement that the London and North-Western Railway Company are reducing the time in their great workshops at Wolverton by one day in the week, and one hour in each of the remaining five days, is perhaps the most serious indication of bad times that has recently been given. From 1854, when the Board of Trade Railway Returns commence, to the end of 1883, the income of the English railways has shown a steady and continuous increase, the sole exceptions having been in the years 1878 and 1879, in the former of which there was a decline of 600,000*l.* in gross revenues, followed by a further decline of equal amount in the latter. With this exception, advance has been constant. From 1854 to 1877 it amounted to a little over 3*½* percent. per annum, year after year, and it has maintained the same rate on the average from 1877 to 1883. The repairs of engines and vehicles form an accurate gauge of the activity of a line, as they rise or fall in close proportion to the locomotive cost. The indication, therefore, now given that the wear, and thus the use, of vehicles, is falling off by one-sixth on this great line, is of the most serious nature; more especially coming as it does on the heels of the decline already brought to account for the latter half of 1884. When this mark of waning traffic is compared with the decline of fifty-five ships, and 59,000*l.* in receipts, on the Suez Canal, in January, 1885, from January, 1884, it will be seen that the subject is one demanding very serious attention.

THE difficulties that attend the sanitary government of suburban London do not decrease as time goes on, nor are they likely to do so, so long as the great city continues to squeeze out its inhabitants *extra muros*, while, on the other hand, the country districts continue to furnish perpetual relays of persons whom taste or circumstances induce to become town residents. Nowhere is this more clearly illustrated than in the once rural and exclusively Richmond, which, for various reasons, has fallen upon troublous times, that do not tend to make the position of the powers that be a bed of roses. First and foremost, the celebrated deep well in the chalk, about which so much has been written and said within the last year or two, has been summarily extinguished, and the engineer and contractor desired to carry away their plant. But little has been said about it since the final abandonment of the undertaking three weeks or so ago, which is not to be wondered at, as such an ill-considered and costly fiasco is not creditable to those concerned. The well was commenced originally in 1873, and, despite the experience

and ill-success of similar ventures at Kentish Town and Tottenham Court-road, was proceeded with until the great depth of over 1,400 ft. was reached, while from first to last at least 75,000 ft. has been thrown away, with scarce a single favourable item that can be placed to the credit side. The Vestry has another, though comparatively small, difficulty on hand in the shape of the new dust-destroyer, which was erected a few months ago with many laudations all round. It undoubtedly does its work as far as consuming rubbish goes, but so vigorously that the whole neighbourhood complains of it as a nuisance, and the result is that an injunction has been applied for in Chancery. When to the water and the dust troubles is added the formidable expenditure that is looming over the town for the general drainage scheme, it must be admitted that both the authorities and the ratepayers are likely to have anything but a pleasant time before them.

AMONGST other proposals for solving the vexed question of the sewerage of the Lower Thames Valley, a scheme has been submitted to the Local Government Board, based on the Shone hydro-pneumatic system, for collecting and delivering the sewage to Bisleys Moor, where it is believed sufficient land can be acquired for purification purposes by utilization. As some doubts exist as to the possibility of acquiring the land, the alternative is suggested to adopt the tank system for purification by atmospheric oxygenation, on the method patented by Messrs. Shone, Donaldson, & Ault, which consists of clarification in the first instance by settlement, and upward filtration through coke or gravel, and then by discharge through perforated plates, which form the sewage into a fine spray, each perforated plate being separated from the succeeding one by a horizontal conduit, in which the sewage flows from one cascade to the other of sufficient length to allow of the combination of the oxygen absorbed at each cascading with the impurities in the effluent sewage. The estimated cost of collecting and delivering the sewage to Bisleys amounts to 338,054*l.*, and of the tanks and cascades sufficient to deal with a volume of 7,500,000 gallons a day, about 15,000*l.*, besides 9,000*l.* for the land; or, in all, 362,054*l.* The annual charges are estimated at 20,882*l.*, inclusive of interest on capital and redemption fund. If this is intended to be distributed amongst a population of 200,000 persons, it will amount to a rate of 2s. per head of population, in addition to the sum required to meet the charge for the collection and conveyance of the sewage within each district itself. The Shone system has proved an effective one where it has been tried, and the present proposal may be the best solution for a joint scheme, which, under any circumstances, seemingly, cannot but be very costly.

PROFESSOR HENRY ROBINSON gave an address at the Parkes Museum on Thursday evening, on the subject of "River Pollution," in the course of which he observed that the Rivers Pollution Prevention Act of 1876, the result of the various Royal Commissions on the subject, was now seen to be of too optional a character, and to have a fatal defect in leaving it to local authorities (who were often the offenders) to put in force the Act. Various abortive Bills had since that time been brought before Parliament, and there now existed such a general agreement upon main points as to enable further legislation to be shaped. The recent returns obtained by the Duke of Northumberland showed that since the passing of the Rivers Pollution Prevention Act of 1876, only fifty-three cases had arisen under it, and only twenty-four cases had resulted in orders being obtained to desist from pollution. This indicated that the Act was practically a dead letter. The remedy would probably be found in the formation of Conservancy Boards to have control over wide areas, and to have charge of watersheds.

FROM Mr. MacMahon, the Sanitary Inspector for the District of Torquay, we receive a report of "seven years' sanitary progress" in that district (1878 to 1884), printed by order of the Board. In the course of it, the use of terebene oil is mentioned as a successful means of detecting the existence and position of flaws in drainage. We may quote one case as described:—

"In August, 1879, there was some illness and complaint of bad smells at a house on Victoria Parade. At that time, carbolic acid was the test generally used. I tested the drains of the house carefully, and made an examination of the arrangements, but neither succeeded in discovering any cause for the smells, which the occupier was convinced were drain smells. He pointed out a spot in the party-wall between his and the next shop as being where he sometimes found the bad odours. I obtained the adjoining occupier's consent to test his drains, which, however, be maintained was unnecessary, as he was sure they were right, having been recently laid. The result of the test was uncertain, as the smell found in the affected house resembled gas. A late member of this Board (Dr. Campbell) suggested 'terebene' as a testing oil; this was applied, with the result that near the door of the second shop the odour was perceptible, it was unmistakable in the other, and in a cupboard in a direct line with the other places named it was also found. The drain was opened under where the smell was first found, and about 2 ft. of the collar of a pipe was broken off, from which, through earth and party-wall, sewer gas found its hateful way to the house. The unfortunate occupier had suffered illness in his family, and some deaths also occurred, which were to some extent due to the cause thus brought to light. There has been no complaint from that house since. The second case gave even more satisfactory results as an experiment."

THE case of *Ballard v. Tomlinson*, decided on Tuesday, February 17th, by the Court of Appeal, by which the decision of Mr. Justice Pearson was reversed, places the law in regard to the pollution of underground water on a satisfactory footing. The Judge decided that as a person has no right of property in underground water percolating through his soil,—that is to say, that a previous landowner may drain it away if he pleases,—he has no right to any particular quality of water if it reaches his land. The corollary of this proposition naturally is that any person through whose property the underground water percolates may do what he pleases in regard to it, may foul it, and make it as impure as he pleases. It is obvious that such a decision must be injurious in its consequences. A man may not have any reason to take away the water which flows under his land, and therefore it reaches the land of B, who pumps it up. But had Mr. Justice Pearson's decision remained the law, then, as happened in the particular case, A might pollute the underground water before B could get it, so that it may not only be useless, but may actually do injury to any one who uses it. The Court of Appeal have now set the matter, if we may say so, right. They have held that a person, though he may not have a right to underground water, yet if it reaches him, is entitled to have it in a pure condition; that A may not pollute the percolating stream by putting noxious matter into a place where it will contaminate the water which reaches the land of B. It is clear that the decision may have far-reaching consequences: for it may preclude dealing with the surface of lands in a way to prevent water flowing underground therefrom being fouled. It cannot be confined to the pollution of the underground water, as in *Ballard v. Tomlinson*, where an old well was turned into a cesspool so as to pollute the water which the plaintiff drew from his well. But wholesome water is one of the first necessities of life, and a decision which helps to keep it pure is of the highest importance. There are certainly many country villages where pollution, knowingly or unknowingly, is permitted. This recent, clear, and common-sense decision of the Court of Appeal will place the law on this point in such a state that the pollution of underground water can, we hope, now be stopped without litigation.

ANOTHER case, that of *Dawson v. Clementson*, which was tried before Baron Huddleston on Tuesday last, was of some interest in relation to the rights

of tenants to throw up their engagements in consequence of sanitary defects in a house. In a general way, the law is a great deal too favourable to landlords in regard to such questions. In this case the defendant (the landlord) was shown to have gone to some expense in relaying the drains before letting the house to the plaintiff. The latter noticed a disagreeable smell under the kitchen window, and the defendant, on attention being drawn to it, satisfied the plaintiff that it was owing to a bell trap at that spot not having been kept charged with water. The plaintiff, however, left the house abruptly before the termination of the engagement, and repudiated the contract. The defendant's case was that no accusation of breach of contract in regard to the condition of the house was valid until the plaintiff had served defendant with a notice to repair, which he had never done. The jury came to the conclusion that the house was "reasonably fit for habitation" when the plaintiff abandoned it. Judgment for defendant, with costs. We hold that in the abstract no contract should compel a tenant to remain in an unhealthy house; but it seems clear that the plaintiff put himself technically in the wrong, through omitting the proper legal action, and perhaps exaggerated the evils complained of. Part of the moral of the case is,—do not trust to traps that require artificial nursing to be kept in an efficient condition.

THE Water-Colour Exhibition at the Dudley Gallery contains some powerful drawings, and some of the best work is signed by names with which we are not very familiar. Among architectural subjects, the "Exterior of the Church of the Holy Sepulchre" (179), by Mr. N. E. Green, may be mentioned, and Mr. Harry Goodwin's "Verona," seen just as it is described in "Sordello," a dark outline against a long flare of sunset light. Mr. Herbert Marshall's "Sunrise in London, Midwinter" (79), is a very fine view of the side of Westminster Hall and the Victoria Tower behind; but the points of the compass seem to have been a little freely treated to get the light behind the Victoria Tower. Mr. Medleycot's "Westminster, from Lambeth" (66), is a mere travesty of the Houses of Parliament, and shows the painter to have little eye for architecture. Mr. Edwin Ellis's "The Shadow of the Head" (178), a rough sea under the shadow of a great rocky promontory, is the best thing of his that we have seen. Mr. C. Robertson's "Whitby" and "Newcastle" (273, 348) are worth attention, the former especially; and, in a very different style, Mr. G. Marks's "Sunshine and Shadow" (380) is a bold attempt to deal frankly with the bright tone of green verdure in strong light. Mr. Bernard Evans treats "The old Road to Mientwog" (535) in a style slightly reminiscent of David Cox. Miss Helen Thornycroft has one or two admirable flower pieces, and Mr. H. R. Steer has caught the spirit of Dickens in his small but highly-elaborated representation of a scene from "David Copperfield" (491), in the middle of the screen.

THE sale is announced at Christie's, on the 5th of March, of the works of the late Mr. Harry Johnson, the well-known water-colour artist, and formerly a member of the Institute of Painters in Water-Colours. The drawings will be on view on the two previous days, and will comprise, among other things, many interesting sketches of monuments of Classic architecture in Greece and Asia Minor.

MESSRS. DOWDESWELL exhibit, at their rooms in Bond-street, a collection of marine sketches in water colours by Mr. W. Ayerst Ingram, comprising studies of sea water under very various conditions of light and movement, not all equally successful. "Tide Ripple" (28) is one of the best, and "A Drifting Match," where a number of yachts are nearly becalmed, with every inch of canvas set, is very real. But our impression is that the artist is aiming at variety rather than thoroughness of work.

THE *Courier de l'Art* mentions that Madame de Châtillon, a talented lady artist, and Professor of Painting in the Ecole Municipale of Paris, is about to organise a gratuitous course of instruction in drawing for ladies and young girls who wish to perfect themselves in the art. Madame de Châtillon entertains the hope of thus founding a school of design applicable to industries such as are most generally carried on, or may be carried on, by feminine hands, such as the shaping and ornamentation of dresses, the design of curtains and hangings, of lace, the decoration of hooks, painting on panels and on glass, &c. The Department of Public Instruction, we are told, has recognised the value of Madame de Châtillon's endeavours, and is prepared to subsidise the school.

THE Duke of Marlborough's reply to the offer made by Mr. Gladstone to purchase certain of the pictures in the Blenheim Collection, as given in a recently-issued Parliamentary paper, reminds one irresistibly of Mr. Wegg's rejoinder to Mr. Boffin's overtures to that remarkably endowed literary man, "I never 'aggle, Mr. Boffin," said Wegg; "so, done for double the money." Mr. Gladstone informed the Duke that he would be prepared to advise the Treasury to give 100,000*l.* for the "Madonna degli Ansidei," by Raffaele, the full-length equestrian portrait of Charles I., by Vanduyck, and the "Garden of the Hesperides," by Rubens, to which the Duke replied that he would be willing to take 200,000*l.* His Grace, however, ultimately agreed to accept 70,000*l.* for the Raffaele and 17,500*l.* for the Vanduyck; but as it will be necessary for the Treasury to obtain a vote for these amounts, the bargain cannot be regarded as concluded. The memorial sent in by the Royal Academy in favour of the purchase of the pictures is a curious specimen of composition, in which Raffaele's "Madonna" is said to illustrate "that happy period in which the reverent purity and serene grace of the master's earliest work is already mellowing," and more in a similar strain. Let us obtain the pictures by all means if possible, but why "gush" about them?

THE next examination of candidates for the Associateship of the Institute of Architects will commence on the 23rd of March, and the last day for receiving applications is Saturday, the 7th of March. During the present week a provincial examination for Associateship is being held at Manchester under the direction of the Manchester Society of Architects, the oral examination being conducted by the Chairman of the London Board of Examiners, Mr. Cates. The examination renders the admission to membership of the Institute a real guarantee of adequate professional knowledge and training; it is one of the best moves the Institute has ever set on foot, both for its own interests and those of the profession at large, provided the latter accept the situation *en masse*, as they will probably be more and more inclined to do as they recognise the value to themselves of co-operating with a central body which makes examination by competent men a test of admission into its ranks.

New Riverside Fish-market.—The Duke and Duchess of Westminster visited the East-end on Wednesday in order to perform the ceremony of driving the first pile at the works which have been already begun for the erection of a fish-market at Shadwell. The site is on the shores of a deep bay of the river, about one mile and a half below London Bridge, one advantage gained by the choice of this situation being that the vessels bringing up fish to the market will avoid the delays to navigation in the Pool. The market proper, that is for the disposal of fish wholesale, will have a frontage of 224 ft. to the river and an area of nearly 22,000 ft. The semi-wholesale and retail market to be erected hereafter will have an area of over 14,000 ft. Mr. C. Dunch is the architect of the market and works. The market is being erected by a joint-stock company.

ON SOME PRINCIPLES AND CHARACTERISTICS OF ANCIENT ARCHITECTURE, AND THEIR APPLICATION TO THE MODERN PRACTICE OF THE ART.*

I AM to speak to you to-night of some principles and characteristics of architectural design which may, I think, be usefully brought before you for your consideration. My remarks will be but suggestive, and will embody ideas which you may work out for yourselves, at greater length, in your researches into the nature and the history of ancient architecture. They will be, for the most part, principles and characteristics common to all styles, rather than those peculiar to any.

It is no insignificant subject that I would bring before you. Think of the long story of the great works of architecture in the past. What a history it is. Not to look further back, let us think of that marvellous time when Greece, as it were, brought order out of the chaos of barbaric work, and, suddenly, became the land of all that was beautiful in art,—art with its sculptural portraying nature and expressing the life of nature, not only in its highest phase, the portraiture of ideal perfection of the human form, but also in the delicate beauty of carved ornament and artistic detail. Then on to the work of the Romans, massive and sturdy, lacking, indeed, the grace and tenderness of the best Greek work, but eminently impressive and manly, and superior to that of the Greeks, in construction, inasmuch as the round arch was a more noble thing than a straight beam of stone.

Then, the darkness before the dawn,—through the many gloomy centuries of barbaric work; and then, to look only at our own land, the gradually refining and enriching work of the Norman; the effect of the creation of Gothic, and the revolution that its pointed arch brought about,—the almost Greek-like work of the thirteenth century, full of religious feeling, hardly, indeed, seen at its best in England, for it was more advanced and noble in other countries,—nevertheless, replete with growing beauty and interest amongst us. Then, the great time of the fourteenth century, when, for refinement of design and beauty of detail, our English architecture was second to that of no other country.

Then the fifteenth-century work, the very flower of the Gothic manner, with its development of the kindred arts of painting, of sculpture, stained glass, embroidery, and textile fabrics,—works all partaking of an architectural character.

And then the Renaissance, with its great artistic skill and exuberant richness, with almost lawless beauty, with some lack of restraint and a certain impatience of authority.

We may well review the varied images which such a vision calls up.

I shall not weary you by reciting any long list of examples of the great works of the great past, or by pointing out their merits,—you should know them well; but rather speak of some principles of the art that may lead us to see the shortcomings of our modern works, for their possible improvement. For we are not here to recount the great works of the past in our art, but rather to try and learn some lessons to be derived from the principles such examples afford. Before doing so let us, briefly, look at the building of the present day. There is little we can call architecture.

Where in our works, I would ask, are the architectural influences that would tend to educate the people?

Look at any of our new towns where there is not the presence of old buildings to redeem the general aspect of ugliness and vulgarity. It is not that the houses are merely destitute of ornament; there is the presence of vulgar and ugly ornament, so-called, in plenty, sometimes, indeed, in heavy and tiresome profusion.

The shapes and proportions of the houses seem to have come by chance and without design. The ugliest materials have been used, bricks of the poorest colour and of ungainly size, the roofs covered with cold-looking blue slates, also of too large dimensions. The details of the exterior, throughout, without interest, delicacy, or refinement.

But I have sketched enough of the outside of the kind of house which it is a positive pain to enter, so far as one's artistic perceptions are

* A Paper by Mr. G. F. Bodley, A.R.A., F.S.A., read before the Students of the Royal Academy on the 23rd inst.

concerned. Inside we find the same poverty, or vulgarity, of design everywhere. The meanness of stained deal seems to have been delighted in, or, if it could be afforded, that ugliest of all woods "pitch-pine," with its coarse grain and hot colour. In colour, in form, all is without beauty. Nor am I thinking so much of those unhappy new towns amongst us which are devoted, I had almost said doomed, to manufactures and industrial works, where the sky is darkened, and all nature disfigured, where the enjoyment of any art is almost impossible. I am thinking rather of modern watering-places, and the like,—places devoted to leisure and to pleasure, chosen for their brightness of climate and beauty of scenery, but presently made hideous by a very nightmare of badly designed, and worse constructed buildings. In such new towns as I am speaking of, the inhabitants live surrounded by these buildings, to the great detriment of all artistic perception. Or look again at our London houses of a slightly older, and better, period. Our "long, unlovely streets" are without interest or dignity, a uniform dullness, at best, prevails, with but few exceptions. You may pass through many miles of our London streets without seeing one redeeming building, or even a part of any such building. There is a uniformity of dreary ugliness alike in Camden Town and Belgravia. Whitechapel is better, there are some old buildings there. Is not all this a satire on our civilisation and on our culture?

It is easy for you in these days to compare and contrast such modern buildings with ancient ones. If you have not travelled, nor even seen much of old places in England, drawings and photographs will have, broadly, shown you the contrast. And what a contrast it is. Now in what does this contrast principally consist? It is a difference in kind, not one merely of degree; the whole feeling, the animus, is different.

And here I am brought to speak of some of those principles and characteristics of architectural design which I would bring before you to-night.

They are: Refinement, concentration, true use of detail, symmetry, economy of material, contrast, avoidance of extravagance of manner, suitability, harmony, colour, work founded on that of the past, consonance with nature, lastly truth.

Refinement of Design.

Now if there is one principle in the practice of architecture in the present day which is chiefly wanting, it is, I think, the lack of refinement of design.

What is the history of architectural art but the history of refinement in the art? We have briefly glanced at this history in our own land. What was the one principle that led on from century to century, from style to style, but that of a true artistic feeling, the desire for refinement. Nature, our great guide, never stops in her refinement. We cannot gauge the infinite delicacy of nature, nor her redundancy of life and its variety. Now it is in refinement for architectural work, that this expression of life is chiefly shown. According to the material and means at command, there should be the careful expression of artistic power to bring out, to the utmost, the expression of life.

This expression is a great principle of all art, and one to which limits can hardly be assigned. It should animate all your work. Every detail, not only as in the carving of natural ornament, however conventionalised, but in architectural mouldings, and the like, should express this, which is the highest gift of nature,—life. You see it in all good architectural work,—in the branching vault, and the graceful clustered column from which it springs; in the steady, sturdy, but thrusting buttress; in the varied moulding of carved ornament; or even in the mouldings of a cornice or of a string-course. Whatever, in architectural work, is endowed with the expression of death is bad art. Good art, on the contrary, is ever imbued with the expression of life. Look at a bit of decorative carving, it may be of the most conventional kind, as the so-called "boneysuckle" of the Greeks, or carved leafage of one of the great periods of Gothic art, and you will find this expression of life in the nervous curves, in the strength of the sturdy stem, and the delicate, reaching or twisting spray. The whole drawing and modelling, as well as the execution, express life. You may see this even in

the common utensils of daily use. Compare a Greek cup, of the simplest kind, with its subdued, refined, but nervous and animated curves, with the similar vessels we may see amongst us now. The one is instinct with the expression of life, the other is dead, as the metal or the clay out of which it was formed. It is thus that man, into whom was breathed the breath of life, has, God-like, imbued his work with the expression of the Divine attributes.

Now, it is refinement of design that is such a great aid in giving this expression of life. It is not against this principle that much of the best architectural ornament is conventional, for conventional ornament should ever be imbued with the spirit of nature,—with its energy, its repose, its beauty of detail, and its breadth of effect.

You can work out this idea of refinement for yourselves in many interesting details, as in the refinement of curves, so remarkable a feature in our fourteenth-century Gothic; in mouldings, in all the great styles, giving refinement in the effect of delicate shadows; and in many other ways, as in the refinement of decorative colour, where gradations are gentle, and colours are delicately contrasted,—not, however, in any work in a manner indicative of weakness or incapacity; for refined work in no sense denotes weakness, nor vulgarity strength. True refinement rather denotes restrained power.

Nor is it in details only that the principle of refinement is of importance. The whole building, in its lines and mass, should have the same expression,—one rather of reserve and power controlled, than of any ostentation or display.

It is these expressions which give the charm to so many ancient works of architecture. They are the principles of nature.

I have spoken of the advance of refinement in the successive styles of the Gothic period. The same history occurred in the great Classic styles. It would seem that while an art is a living and healthy one it will advance, and, like the intellectual or moral condition of man, it will progress. Alas! that a time should come when it begins to decay, and at length becomes moribund.

The English woodwork of the fourteenth, fifteenth, and sixteenth centuries shows a school of art of a very remarkable character. It showed the utmost refinement of detail in delicacy of moulded work, and in most able carvings. It was hardly equalled by any work of the same character abroad. It is work well worth your close attention and study. Comparing these beautiful works with much modern woodwork, one cannot but miss the element of refinement. In the old work you will find the traceries were more or less elaborately moulded in different orders, while a modern,—and a very crude fashion of the day,—merely pierces certain shapes in a very elementary manner. It is but childish work at best, and is an instance of what one cannot but call the barbarism of much modern work, contrasting with the refinement of the ancient manner.

Let us glance for a moment at the reverse of this element of refinement. Look at what has been called the "Victorian style." I do not mean work designed, in an honest spirit, to meet the requirements of the times, that which tries to catch the true spirit of old work, but that shallow, conceited, and futile attempt to outdo the works of the past by coarseness and what is vulgarly called "go" in design. It is a manner that can have no lasting influence, one would hope, and we may dismiss it as out of count, except to point a moral. It is a manner the very reverse of that which I would lead you to follow,—that of a true and noble refinement in your art; that which you will find, in different degrees, expressed in all noble ancient architecture.

Concentration.

Another principle on which I would touch is that of concentration of ornament, especially for our larger buildings. It is one too much neglected in modern architectural works.

For the enjoyment of richness and beauty of ornament there should be a well-designed concentration of it. The eye wearies of, and the mind fails to be interested with, a monotony of richness.

Design your building in good proportions, that is with the proportion that has an expression, suiting the character you wish to give your work. Then enrich the chief, and most important parts, with carefully-designed orna-

ment, rather than sprinkle the whole with it. Here, of course, the scale of the building dictates the character, and it is no fault for a small one to be enriched all over: it is, as it were, a detail itself. The surrounding buildings may give the necessary effect of contrast. But for large and monumental works, you will find this concentration of ornament a sound and judicious principle. It is one of the characteristics of the best old buildings.

True Use of Detail.

Another principle of which I would speak is that of the true use of detail. Now, the use of detail is not so much in order to show variety, or beauty, of design, but that it may enhance the expression, whatever that may designedly be, that is to be given to the whole building. It is surprising how the use of detail, skilfully dealt with, may add scale to a building and enhance its general effect. It is a great, but manifest, error to suppose that by boldness of detail you make your building look large. The reverse is eminently the case. This is obvious; nevertheless, much modern Gothic work, and not work in that style alone, has been ruined in effect by largeness, if not coarseness, of detail. When your mouldings are large their curves should be especially delicate and subdued. The delicacy of the shadows prevents the effect of any coarseness.

Not that it is only detail which, carefully used, gives scale to a building. The multiplication of parts is an arrangement of much use for this purpose. You know how skilfully this was done in Mediæval and in Renaissance buildings.

The study of the best designed ancient works will make the intention very apparent. It is a point, again, that you can work out for yourselves, in studying such buildings. Compare, for example, Milan Cathedral with our Westminster Abbey, or with York Minster or other great Gothic churches. To give scale by breaking up a wall into stages, as by arcades and the like, is of frequent occurrence, and is of much effect.

Symmetry.

Another principle, on which I would touch, is that of symmetry or balance in design. It is one, for the most part, applicable and of chief use for large buildings and those of monumental character; nevertheless, a house of moderate dimensions, planned on a symmetrical arrangement, may have a repose and a dignity fitting many sites. Our large Elizabethan houses owe much of their effect, externally, to this arrangement. It is not a Gothic idea; nevertheless, even for this style, a forced irregularity is always to be avoided. There is no plan for a large house, standing by itself, more dignified and quiet in effect than one with three sides of a quadrangle,—the entrance with its high porch marking the centre, and hearing, it may be, an enriched panel with shield and other sculptured ornament. The two projecting wings may be of more or less projection, as circumstances dictate.

In these symmetrical designs occasional variation from exact balance may well be brought in, as in the somewhat varied positions or sizes of windows, and the like. The general balance may be kept, but, like an unexpected note in music, the variation in no way destroys the general effect of harmony. Symmetry of design denotes care and pains on the part of the designer. It is a courteous manner and has much to recommend it. Certainly it is a principle founded on nature. It was in constant use in old days.

Another point on which I would briefly touch is that of a nice economy in the use of material. It is again another point of refinement. The almost brutal strength and ponderous use of material of the Egyptian work, especially as in the Pyramids, has an unpleasant sentiment. Contrast this with the great Gothic buildings in which (with no economy of thought, or of skill), through delicate ribs of curved or straight stone, the weight of the hanging vault is held, as if by magic, and passed down into the ground,—all with the nicest economy and without any undue waste. Each member does its work. It is Christian liberty and carefulness, contrasted with Egyptian slavery and its waste of power.

Roman work had some of this Egyptian-like waste. But I must not enlarge on this point, which opens out a large field of observation; one word, nevertheless, I would add, and it is

this. Engineers make their nice calculations, of less and more, and tell us this or that "will stand." But good architecture is not only "built to stand," it is built to last from generation to generation. It is no waste to build in such a manner that the eye and the mind are satisfied, that centuries may see the building as we see it now,—that, if not properly tended, and not cruelly dealt with by the more ruthless hand of man, the gentle, slow, natural decay of time will leave the inheritance well nigh untouched.

Such strength, combined with a nice economy, should be our aim in designing buildings.

Contrast.

Another principle I would speak of is that of well-contrasted work. In all the best architecture you will find a noble simplicity of design, due breadth of surface, contrasted with delicate detail. Neither has it its full value without the other. How well the delicate Gothic traceries and niche work, and the lines of the richly-carved cornices, contrast with the broad surfaces of the massive buttresses and the smooth ashlar of the walls. It is thus in nature you may see the delicate foliage and the fragile flower contrasting with the huzzess-like rocks, smoothed by the hand of time.

Some of the best effects of Gothic work are obtained by the use of thick walls and small detail, as in windows where the broad splay is finished by a slender shaft, giving a fine line of light and a delicate shadow, contrasting with the uniform light on the wide breadth of surface of the splayed jamb. Here, again, you can work out this principle for yourself in many ways, both as shown in examples of the past and in designing new buildings or their details. In many churches in the South of France we see the capitals throughout, both large and small, elaborately and richly carved, while the rest of the building is of the sternest simplicity. The capitals form, as it were, rich bands, contrasting with the plain walls and piers.

Again you will find that the whole practice of mouldings is derived from the sense of contrasted light and shade. Vigorous, at times even harsh, as in some early Gothic work, the system of mouldings became gradually refined to the most gentle gradations of light and shade, the simple roll moulding eventually turning into what is termed the "wave moulding," with the most delicate effect of light and shade on its surface.

Or, again, in carved work of the great times, the delicate lines of light on the ridges and the edges of the ornament, the half-shadows, tender and slight, on which the ornament seems, as it were, to rest, then the sudden deepening and darkening of the background, to throw out, in strongest contrast, the chief points of the ornament into greater light, to rule over the rest. Well considered and ably executed, contrast is seen everywhere, full of tender grace or decided vigour.

The carver has delighted in the effect nature affords everywhere where there is light to see its subtlety. It is our loss that here, in England, our dark days are so frequent. The want of light has, no doubt, a depressing effect on art. Let us the more carefully enlighten our mind's eye with the thoughtful contemplation of the works of other and sunnier countries, and of brighter days of art.

Avoidance of Extravagance of Manner.

Another suggestion that I would make is a negative one,—the avoidance of extravagance of design and manner. For example, avoid extravagant proportions. One has seen too much of this, of late, in Gothic work. A shaft only two or three times its diameter in height is surmounted by a capital out of all proportion to that shaft. It is an ugly affectation, and in no way commendable. It is an exaggeration that becomes a caricature of good art.

There is one kind of strongly-marked proportion, however, that we need hardly fear to carry out in these days. I mean that of considerable height. The controlling exigencies of economy too often prevent our churches, for example, from rising into stately and inspiring proportions.

You know the high proportion of that, perhaps, the most beautiful of all Gothic churches in the world; Westminster Abbey,—the most beautiful as regards the architecture of the interior.

The proportion of Westminster Abbey, that

of three squares, is excellent, and without any undue exaggeration of height.

The extravagance of manner I have spoken of more often lends itself to stumpy proportion, without grace or beauty. It is, like other extravagancies, to be avoided.

Suitability.

Another principle I would bring before you is to suit your design to the place it is meant for, and to the surroundings among which you are to build.

With our old buildings in the country one often sees an instinctive harmony with the sentiment of the aspect of the natural scenery, or, it may be, a wise contrast with it.

It was not apart from this refined feeling that for an old Gothic church, built among hills, you will generally find a low broad tower, with an affinity for the masses of surrounding scenery,—while, on the other hand, on the long, low, level lands the pointing spire will have been lifted in contrast to the horizontal line of the plain,—a point of relief which the traveller's eye may rest on, as he travels through the monotonous level country. In towns you may take pains, in some way, to assimilate your building to those of neighbouring ones of former times, if there be any of sufficient interest to command such respect.

It is to our loss that so many towns, in which we may have to build, are destitute of any character with which we can harmonise our work. Nevertheless it should be done where possible, not only in the use of local material, but in designing in the local manner, and in harmony with the surrounding buildings. One sees examples of what we must call "bad manners" in this way. The surroundings have been ignored.

And here let me say that we need not go abroad to find a style in which to design buildings in England. Let us keep to the *genius loci*.

Both in Gothic and in Renaissance buildings among us there has been too much copying of a foreign manner, unwisely imported from the Continent. Our own English architecture is second to none on the Continent for beauty and poetry of design. If abroad the architect is more grandiose, yet it often lacks the refinement and the poetry of sentiment of our English work. Though "art speaks the tongue of every clime," yet, in a sense, we may have a patriotism in our art. You know how long a list of admirable English works one might enumerate; each county with its hundreds of more or less beautiful churches, and often still more beautiful remains of ruined abbeys; each city with its more or less stately cathedral; our universities of Oxford and Cambridge, places unique in the world for venerable collegiate buildings; our great historical mansions, Haddon, Burleigh, Kirby, Fontaine Hall, Hardwick, Longleat, Bramshill, Montacute, Temple Newsam, and others; lastly, the refined and simple beauty of our old homesteads, and even cottages, on many a country side. Let us be loyal to the traditions of our beautiful English architecture.

Harmony.

Another principle is an obvious one,—that of harmony, not only of style, but of character and feeling throughout a building. No Eclectic School which mingles styles incongruously will ever be long-lived or successful. The result, if not one of continuous discord, affords but occasional harmony. It is true that certain styles, as Gothic, lend themselves to strong construction, while Renaissance may be more consonant with great richness and delicacy of detail; as, for example, in plaster work and the like; but there is a risk of discordant character. It is better not to attempt any such mingling of styles in a complete work, however good the effect of different styles, combined, may be in from time to time. The mind is satisfied with such an historical building, but it is irritated by the needless conceit of combined styles in a new one.

If you look at any complete work of the great periods you will find that they have a unity of feeling, and a breadth of effect, stamped upon them. Look at our abbey of Westminster and Tintern. I mention these, for you know them well. The same character is given to the whole building, in a marvellous degree. Each holding expresses, in its own distinctive manner, the sentiment desired, and there is a true artistic

breadth of effect and of idea. You will find this so in all complete buildings of the great periods. They are interpenetrated with one idea, though there is the utmost variety of detail.

Colour.

Another, and an important part of an architect's work is connected with colour, whether in the use of marble or other constructional colour, or in painting.

A fine eye for colour is a natural gift, as much as a fine ear for music, but the love of good colour may, no doubt, be caught from the teaching of nature and the great schools of painting, chiefly those of the fourteenth century, and later on. That there was a great school of decorative painting in England in the fifteenth and sixteenth centuries is seen by the painted roofs and screens remaining. Those without sufficient knowledge are apt to speak of the colouring of the Middle Ages as crude and inharmonious, or, at best, as of little artistic value. There can be no greater mistake. The wall painting has chiefly perished, but enough remains on woodwork to show how refined and beautiful the works of decorative painting were. In all the great periods of art there was, indeed, the keenest delight in colour. Take alone, for example, the stained glass of the successive centuries of the Middle Ages. It is an important part of architectural decoration, especially of churches, college halls, and similar places. Look at the deep-toned glass of the twelfth and thirteenth centuries, the gradually refining glass of the fourteenth century,—silver setting, as it were, of jewels; the figures rich and splendid in colour. Then the still fairer glass of the fifteenth and sixteenth centuries. Figures, as of painted statuary, of rich, but subdued colour, standing in tabernacle work, of wrought silver touched with gold, the delight of all beholders. Is it for us to think lightly of the colour works of the Middle Ages when we, in these days, have filled nearly every one of our cathedrals in England, and most of our churches, with glass so crude, so harsh in colour, that to see it for a moment is a pain and a shock to all our artistic feelings?

In this beautiful art of glass-painting, however, one begins to see real improvement in the works of some, though but few, artists.

Before I pass on to other matters, I would observe that the history of glass and other painting shows the same story of progress in refinement (pardon the refrain) as we have seen took place in building. The early work was powerful but crude in colour, the latter ever becoming more and more refined; and this so much so, that presently the whole scheme and idea of the decorative treatment of the building was gradually changed. For the early building had its walls white, with but little decoration, and its windows of dark richly-coloured glass.

By the time of the fifteenth century this scheme of colour was completely changed, and a nobler manner prevailed; the walls were painted with figures and subjects in dark rich colour, of the beautiful type of full but harmonious colour that we see in many old German and Flemish pictures, and the windows were, for the most part, of silvery white, with but little and that subdued colour.

It was a complete revolution. It was one towards refinement.

Let us turn for a moment to a very different branch of this subject of colour. However poor the architectural character of our houses may be, beauty of colour may be obtained for our rooms. There is not enough intelligent interest spent on the subject of the decorative effect of our houses. I cannot but express the hope that they may be made more beautiful in colour, and that our rooms may show not only a jumbled collection of old things, however beautiful these may be in themselves, but that intentional design, and harmonious architectural colour, may be given to them. In the modern decorative treatment of rooms, even those of some dignity, one too often sees mistakes of the most evident kind. For example, it is the frequent modern practice to colour the cornice of a room as if it were part of the ceiling; so if the ceiling is white the cornice is white also, though the walls and woodwork be of colour. Now surely the cornice is the crown of the wall, and not a part of the ceiling. The architectural value of a cornice in a room is to soften off the harsh line that we get without

any projecting moulding. This effect is obviously lost if the cornice is coloured like the ceiling, and not like the wall. I would just say before quitting this part of our subject, that while we now often see "dados" introduced, the use of the frieze is too seldom adopted. Yet it is a far better effect to have a well designed frieze and no dado, rather than have a dado and no frieze. The frieze, and not the dado, was the earlier arrangement. Let me say, in passing, that we should do better, in our domestic work, to follow the style of the Renaissance rather than that which is called "Queen Anne," and which is a very inferior manner at best.

Again, there is a fashion for a papered dado. This brings out with undue prominence the poor, thin, line of the dado moulding.

Now this dado moulding or "chair rail" is as it were, the cornice of the dado, and the whole should be of the same colour. Above this dado moulding there may be a wall-paper of good pattern and colour. Such a paper is best when it is of two or three shades of the same colour, and the spotty and unarchitectural effect of a variously-coloured pattern is avoided. Wall-papers were the successors of damask silk hangings, which were usually of one colour, or different shades of the same colour. These silk hangings, it is true, were the successors of tapestry of varied colour, but the pictured scenes of tapestry take one into a higher, and altogether different, kind of decorative effect. There is nothing in common with tapestry in them, except that both are for the clothing of a wall.

Again, one sees other palpable mistakes of colour, such as the use of the "black pointing" of brick work. We need not add to the gloom and dinginess of our buildings by its use.

But what I would chiefly urge on this subject is, that you should not think decorative art in any way beneath your serious attention. Here, again, look at the works of the past, or the great schools of Europe. They will be of more use to you than the imitation of Japanese or Chinese work, the fashion of the day, however ingenious it may be.

Work founded on that of the Past.

Another principle is the founding designs or the works of the past.

Sir Joshua Reynolds said, "The more extensive your acquaintance is with the works of those who have excelled, the more extensive will be your powers of invention, and, what may appear still more like a paradox, the more original will be your conceptions."

This is, I think, eminently true of architectural design. You may well find your design on some previously executed work that has won your respect and admiration, but you make it your own, your mind's eye seeing it, thus or thus, different, wholly altered, from that which produced the idea. It is thus that art hands on, in the tradition of art, the spirit of it, which is immortal.

Consonance with Nature.

Another principle is that of harmony and consonance with nature.

We have incidentally spoken of nature as the guide in all art.

It should be eminently so with the creative art of architecture.

Though our art, like music, is not an imitative one, yet its characteristics should be those of nature, in the spirit, though not in the letter. It is the strength and the delicacy, the refinement and the richness, and the other great attributes of nature, which we should endeavour to embody in our works, rather than any exact imitation.

It is thus that art should be consonant with nature. Wordsworth wrote,—

"To the solid ground
Of nature trusts the mind that builds for eye,
Convinced that there, there only, she can lay
Secure foundations."

In our art, from the rough, rock-like foundations, to the highest and most delicate pinnacle, all should be in harmony with nature and her work. It is the law for all art, at once the law and the Gospel.

Truth.

Time suffices not to speak of other principles of our art, and yet there remains one great and leading principle of this and all art, that which should indeed be first, the principle of truth. Let it have here, as in a procession of state, the

most honoured place, and be the last named of our principles.

Of truth, as expressed in architecture, much has been written, and written well, more especially by Mr. Ruskin, to whose teaching we owe so much in the whole field of art. Truth is an essential element of good art. I need not dwell on this part of our subject; nevertheless, what are many of our new street-fronts in the City and other buildings elsewhere rising around us but examples of most untruthful architecture? Iron columns and iron girders are concealed by stone columns and thin stone friezes, and the like deceptions. It is an unpleasant, and, indeed, a wretched style of building, without truth or dignity. Should a fire try the nature of the work the writhing columns and bending girders will soon show that they are found wanting in that first necessity of good building,—stability,—and the disguise will be manifest.

To conclude, let me say that architecture and all art should be animated by some great and leading principle. Religion is the highest. The noblest buildings in the world have ever been those consecrated to her service. We see this alike in the Pagan temple and in the great churches of Christendom.

After religion, civil or national dignity should call out the expression of high artistic power. Then the domestic feeling, the house, great or small, built for a family, in successive generations, to abide in, the house that should be handed down as the shrine of domestic honour; and, lastly, honour to the departed, as in sculptured monuments and memorial buildings. For art should be delighted in, not for itself alone, but as the expression, in a lasting way, that can perpetuate the feeling expressed.

Art requires, as it were, the salt of noble sentiment to keep it elevated and pure.

How far any revival of a great school of architecture is possible is a question. That there is a strong archeological feeling for the art is certain. It is an age of travel and the great works of former days, combined with their historical associations, have impressed themselves strongly on many minds.

The want of unity of feeling, as compared with other times, is one serious impediment to the formation of any school of the art. Is any such unity possible? Is any such school of architecture possible without such unity?

But consider that it is the "animus" with which you design that is of real import; that whatever style you are led to work in, let your manner be courteous, your expression that of truth, and your aim to do the right thing for the building you are designing.

No doubt our work as architects in these days is one of difficulty. It is an age of science, not of art; architectural tradition has been cut off, or, rather, alas! we inherit a century or more of bad tradition.

We have great facilities, in these days of easy travel, for seeing old buildings. Or, to take the subject of decorative art work generally, our collections and museums are numerous and admirable. Are we to make such use of them as may lead to better designs, and a more intelligent interest in such decorative work?

Such collections ought to bring about a more healthy state of public taste and inspire us all with a desire to do good work, thorough work, both awakening interest and cultivating it.

Let us remember that what we may call the "architectural arts" may have a considerable bearing on the industries of a country. Attempts at artistic manufacture have been brought before the public. Are they to lead to better things, or are they only the fashions of a day?

But I must end with one more word of advice.

Have enthusiasm for your art in all its branches, rather than an ambition for your own success, and better work will be done. There are some signs of the dawn of better things, amidst the general gloom, and we may hope that a more intelligent interest may yet be taken in architecture, and in things that belong to architecture.

Time was when she was the queen and the mistress of all the arts. Is it not for our unfaithfulness that she has abdicated her throne?

Teak.—An interesting paper on "The Teak Forests of India and the East, and our British Imports of Teak," was read by Mr. P. L. Simmonds before the Indian Section of the Society of Arts on the 20th inst.

IMITATION THE MEANS, NOT THE END, OF ART.*

ON more than one occasion we have lately heard it stated within these walls, and on no less an authority than that of our President, that the work of the sculptor-students has shown in recent years a considerable and sustained advance. This opinion, which is confirmed on all sides by current criticism, is one which cannot fail to be extremely gratifying to those who take a real interest in the plastic art.

If we examine the causes of this advance we find it due, I think, to a closer study of nature than was recommended in the last generation and to the increased opportunities for that study which are now open to the student in our public Schools of Art.

This closer study of nature, leading to the production of work of a more realistic character than used to be admired, has, of course, not been confined to the schools of the Royal Academy.

The annual exhibitions of modern work, both here and in most foreign countries, but especially in France, have shown that artists all over the world have been aiming at a closer imitation of nature than was usual fifty years ago.

The pursuit of exactitude, indeed, has been carried so far as sometimes to exceed the bounds within which this imitation should properly be confined. It is this universal tendency towards realism in the most vital school of recent sculpture which has suggested the central idea of my lecture to you this evening.

In the face of this general movement I feel it is necessary for us to ask ourselves what the bounds of imitation are, and how far this devotion to realism is praiseworthy.

We all admit that a complete subjection of our aims to it would result in the production of work worthy only of a waxwork exhibition,—that is to say, ingenious and mechanical reproduction of objects, which might amuse us for a moment, but which would completely fail to satisfy our artistic cravings.

The fact that sculpture, or the formative art, is in one respect essentially imitative is, I think, a source of considerable danger to students of it, and the tendency to which I have referred, which has shown itself of late in all the arts, namely, the search for resemblance to individual forms of nature, although a step in the right direction, may lead to serious evil, and sculpture be degraded by a misconception of the ends of art.

In the history of art there have been epochs which we, who are at a sufficient distance to judge fairly, do consider as debased and bad in various ways.

The character of the work of these epochs has generally been due to the misuse of art in the attempt to make it express what was not within its field, for the extension of this field was evidently considered to show cleverness and originality then, as in our day.

I need, perhaps, only recall to you the work of Bernini, and the sculptors who followed him, to show to what an evil end extravagance can lead sculpture.

The Trevi fountain in Rome, erected from the designs of Niccolò Salvi in 1735, consists of a large florid architectural façade, from the centre of which a colossal figure of Neptune drives his car and horses and attendant Tritons over a mass of rocks and streams of real water, the whole composition covering an area much larger than this lecture-room. This work has been well described as a "pompos confusion of fable and fact, gods and pedlars, aqueducts and sea-monsters." But the most remarkable example is near Naples, and represents the classic fable of Diana and her nymphs discovered bathing by Actæon. This work cannot, of course, be called a group. It is situated in a palace garden, and consists of hundreds of tons of rocks and a flowing stream, and at least ten or twelve marble nymphs scattered about, all of them more or less agitated at being perceived by the shepherd Actæon in the distance.

This is a characteristic example of the use to which sculpture was put during the eighteenth century, in the attempt to make it rival the scenic effect produced by a picture. It was an effort in the direction of realism, in so far as

* A lecture by Mr. Hans Thornycroft, A.R.A., delivered to the students of the Royal Academy on the 15th inst.

the figures were relatively placed as a number of figures in nature might be.

In our own Westminster Abbey we have sad specimens of this utter absence of the sense of what is within the range of sculpture, for even a man of great genius like Roubiliac could not resist the temptation to make his work pictorial, going so far as to carve marble clouds above his statues. The pursuit of novelty, which is also a characteristic of our own time, is no doubt an influence which carries art further and further in new directions, and now especially in the direction of realism. Let us certainly have truth to nature, for art cannot be good without it, but let us not merely aim at the imitation of individual forms without thought or selection merely as opportunities for showing the dexterity with which we can handle our material.

Sir Joshua Reynolds, in one of his admirable discourses, says,—"Imitation is the means, and not the end of art." These are words which it is important to recollect, for they contain the truth of the whole matter, and should be a guide to you at your work, either when studying from nature or designing without it.

In this age of scientific accuracy, the artist has especial need to keep before him the means and end of art; for as yet that vigorous child of our century, modern science, although she ultimately will help him, does little but confuse the artist. She shows him so much in nature that he knows not what to select.

The time was when the artist could impose upon the spectator to a considerable extent, and insist that such and such a representation of nature was true, and did not violate Nature's laws.

He might, in fact, draw on his imagination, and by new combinations construct works that excited amazement. But I need hardly trouble to remind you that matters are now changed; it would be impossible nowadays for a painter to produce works so far removed from realistic forms as were those of Fuseli or Blake.

Science now, with the sun's immediate aid, makes an accurate drawing of an object in the fraction of a second, and any artist who attempts to make a drawing by hand of such an object is brought to task, and the accuracy of his drawing tested by comparison with the work of the unbiassed eye of the camera, which, although it may not give the proper values of tone, is accurate as regards scale and position in its transfer to the picture of the minutest details.

However hard a trial this may be to the artist, it is beneficial, and has its lesson; it teaches him to draw more truthfully, while, on the other hand, it proves to him that art must have an aim of its own, and that that aim cannot be mere copying with scientific exactness.

This was fairly demonstrated in a lecture given in this room just three years ago, when the American photographer, Mr. Muybridge, exhibited a series of instantaneous photographs taken of a horse in rapid movement. There were, I think, about twenty outline pictures taken consecutively during a single stride of the animal when at a gallop, from the commencement of the stride to its completion, so that it was possible to follow the action of any limb through its entire movement, until the same movement or step began again. In each of these twenty silhouettes, for there was no detail within the outline, the action of the limbs at a particular instant was exactly given, yet scarcely one of them gave to an observer the impression of the action of a horse; most of them were quite ludicrously false to the optical effect. The grace and rhythm of movement of a gallop were not in the least expressed.

The fact is that the impression the eye receives of rapid movement is a combination of successive actions, and to give that impression in a motionless form, as in a picture or statue, more than one instant of the action must be rendered, and the different limbs arranged to express those different successive instants.

It is, I think, an acknowledged fact that it is much easier to give apparent movement in making a drawing or statue of a horse, or any quadruped galloping or running, than in attempting the same with a man running. The latter is liable to look as if suspended in the air like a pair of compasses. With two limbs it is possible to express two moments of a stride, but that is a limited power; whereas in the quadruped four movements of the stride can be suggested, and these will more adequately

express the successive positions of the legs during the stride.

The more the student has observed the action of horses the more will he be able to know what moments of action to select in order to give apparent movement.

Science teaches man how to make use of the forces and laws in nature, and shows him their perfect consistency and harmony. But it is by means of art that the ever-changing and evanescent forms and effects in nature, which are constantly before man, and which astonish and perplex him, can alone be arrested and permanently expressed. Art can thus interpret nature to man and teach him to perceive her beauty.

The art of sculpture is a language whose special province is the expression of beauty of form. Its secondary province is the expression of sentiment and character. In order to remind you of the force of this language as an exponent of the beauty of the forms of nature, I will only ask you to call to mind almost any authentic piece of Greek sculpture, but more especially the statues from the pediments of the Parthenon in the British Museum and the Venus of Melos in the Louvre. It is by the imitation of nature's forms that these works speak to us.

The extent to which this imitation can be carried is the great difficulty the sculptor has to meet, and is the subject which I now wish to consider.

The question is, what are the forms in nature which present the best material for the sculptor's language, and how closely is he to imitate them?

The forms which constitute nature's highest organism, man, are, of course, the first and most important; next comes man's raiment, or that which clothes him; and then the forms of the lower animals. Now, how closely we are to imitate the forms in nature is extremely difficult to say; for the reason that the possibility of imitation is almost unlimited by certain mechanical methods, such as by moulding directly from nature and casting. A cast from nature, however, as we admit, is not satisfactory, not altogether because it is a mechanical cast, for a slavish copy made by hand might have a like effect. We should feel this latter to be a wonderful achievement and a feat of skill, yet there would be something wanting. There would be in the work an entire absence of the individual impress of the sculptor or his school, and in its place a preponderance of the individual peculiarities of the particular model cast or copied, scientifically interesting, but not artistically so. Indeed, we should not allow it to rank as a work of art.

At the other extreme it is possible to generalise and to imitate only the structural and essential forms, eliminating the individual and accidental in favour of the usual and typical, and this is the fault to which English sculpture particularly lieth.

So we see that two dangers lie, one on either hand of us,—the temptation to produce an absolute copy of nature, and the tendency to generalise until our work is so conventional as to be devoid of all value and character.

These dangers more especially beset the sculptor in the branches of his work other than portraiture, in which the individual and accidental are obviously essential.

But by what means are we to use the forms of nature to make our language of sculpture most eloquent and intelligible, and to fulfil the high aims which we consider as its province, the expression of beauty and grace, of sentiment and character?

Obviously, we must follow the forms of nature closely in order to interest the spectator, selecting those we think best for the purpose before us, combining them to make a harmonious composition, but never making a combination which would be impossible in nature, unless it be in the case of some well-recognised convention, such as when the wings of birds are attached to human backs to express super-human powers of movement. But for such deviation the artist must always have an intelligent reason.

Sometimes, owing to colour or transparency, the effect of nature is not at all represented by form, as, for instance, in the human eye, to express which the sculptor must flatten the convexity of the eyeball, or, if he wishes to make a realistic portrait of the eye, he must cut a cavity in his model of it in order to form a shadow indicating the dark of the pupil.

A mass of hair which is partially transparent cannot be represented by means of a solid material of the same size. It must necessarily be made less and often thinned down in order to indicate the form beneath.

A sculptor ceases to imitate also, when the form is such as to be unsuitable for reproduction in his material, perhaps impossible to be wrought out in it; or, at any rate, requiring an endless amount of labour to achieve an end, which may again be easily frustrated by accident. It may, indeed, be taken as a rule that we should not attempt in sculpture forms and effects which can be more adequately, and at the same time more permanently, rendered in another art. What may be a wonderful feat of labour and painstaking may prove at last to be an execrable work of art.

I remember, when a boy, being taken to see some famous china-works in Staffordshire, where, in the show-room of the establishment, there were arranged all the sample cups and saucers and prettily-painted dessert-dishes, and such like, but where, in the place of honour, trembling beneath a high glass-shade, sat a perfectly white bird of Paradise, life-size, in porcelain china. This was pointed out as the wonder of the place. The delicacy of the workmanship I can well recollect as extraordinary, for every detail of the elaborate creature had been built up bit by bit, and the long tail hung like a delicate frosted twig, and all in burnt china clay. I was told that it was not quite finished, as the workman had died before he could complete it, and that to do so had been the one idea of his life. The story seemed sad to me then, but it seems sadder now. Only a few months ago I was in a little china-shop in Hammersmith, looking over some odd pieces of ware, when in one corner I noticed a big, dusty glass shade, and under it,—dusty, too,—broken, and without tail, sat my old elaborate friend, the china bird of Paradise, but only a mere shattered skeleton of his former self. I thought of the good fellow who made it, but never completed it, and I felt glad that he could no longer see it.

This story seems to me to teach a lesson to the sculptor to be careful not to spend his time on the representation of what can be more readily and permanently expressed in another art.

If a work in sculpture is fragile and easily damaged, it might have been a better subject for a painter, on whose flat canvas can be put the lightest, and most delicate, and elaborate object in nature.

Of all forms, the nude human figure is the most essentially sculptural; for the reason that it consists of broad smooth surfaces, generally convex, undulating one to another, and sufficiently large, at least in the size of nature, to have strength to be permanent when imitated in the sculptor's brittle material of marble. So in this respect there is little danger in the treatment of flesh; but there are other difficulties, as we shall see presently.

But I wish to insist to you on the extreme value of broad flesh forms, and the exquisite gradations of light and shade which the nude presents to you. You must look upon these delicate gradations as the most beautiful words of your language. It is here alone that you can compete with, and I almost venture to say surpass, the power of the painter. He cannot express these forms so beautifully and absolutely as you can. Compare for a moment what you may happen to consider the finest pictorial rendering in the world of the nude human figure; compare this with the Lyssus, the Theseus, the upper part of the Venus of Melos, the Hermes of Praxiteles, or the Torso Belvidere. I might, but I will you must allow that a sculptor here obtains the higher position. The painter will be generous enough, I hope, to concede to us this advantage; for our field is contracted, whereas his includes almost all objects and effects, and extends as far as the eye can see.

When the figure is draped, it is only under peculiar circumstances that sculpture can retain this mastery, only when the coverings such as is not to destroy the form below it, and when it is in itself beautiful in form, and can take lines that are harmonious with the figure.

We can see an instance of this in the lovely group of the Fates, from the Parthenon, where the flesh forms are covered with a thin muslin-like drapery, arranged and treated with consummate skill, so as to still reveal the figure and the

movements of it. In these draperies the effect of nature is so truthfully represented in detail and small forms that the spectator, in his admiration and excited interest, overlooks the liberties the sculptor has taken with the manner in which the larger folds of the draperies fall. These he has kept close to the limbs, where, in nature, they certainly would fall away, and would obscure them. The form of the folds of nature could never be exactly like these carved ones, but the effect produced is like that which nature might be imagined to assume under the most favourable conditions.

In looking at this group one becomes convinced that the sculptor who made it had an ideal within him which he sought to express by the selection and representation of the most beautiful forms in nature at his disposal. He translated into the permanent material of marble nothing without the leave of nature, but accommodated nature to the material.

Although the large forms of the figure are visible almost throughout the group, still there is no appearance of scantiness of drapery, so perfect is the judgment with which the folds are arranged and massed. Even in its present fragmentary state, headless and almost armless, it seems to me by far the most beautiful group in the world; but how magnificent must it have been when, above the delicate drapery, rose the two lovely Greek heads side by side, one sympathetically touching the other, while a little lower, contrasting with the minuteness of the muslin folds, the generous rounded arms added the proper complement of flesh and a balance of mass to the composition of the group.

If we attempt to get an effect similar to the Greek statue or relief by placing a carefully made muslin Greek dress upon a living model, we soon discover the impossibility of it. This can be made a fair test, for it is possible to obtain dresses that are practically the same in form and texture as those used by the Athenian sculptor; and it is also possible, in England, to obtain models that are physically not unlike the Greeks. But the effect, I say, cannot be thus produced for the reason that the sculptor, in making the masterpiece of art to which I have alluded, selected and modified the folds of the real dress. He realistically adhered to the forms of nature with regard to the flesh, but not in the folds of garment. These are kept in subservience, yet not allowed to appear meagre and thin. The projection of the highest part of the folds away from the flesh is generally true to what it might be in nature, but the shadows are deeper. This is a convention, of course, arrived at, no doubt, in order to express the feeling which the spectator has when looking at nature, of the presence of the figure beneath the garment, which presence is given, in a living figure, by the slight movements and swaying of the folds, just revealing from time to time the important and structural forms.

Since the Greeks employed such conventions, and with such an admirable effect, and since, I argue, these can legitimately express nature, we may surely be forgiven if, in our effort to represent the impression which the human figure gives us, we select and modify the garments worn nowadays.

Before the reign of Charles II. it may be said that in England all costume represented in art was that of the time in which the work was produced. But during the reign of that monarch it became customary in sculpture to represent a person of important position, dressed either in the toga of the Roman citizen, or, if he were a soldier, in the dress of a Cæsar. This peculiar custom has been revived from time to time up to the beginning of our century, as we may see by many of the statues in the private squares in London, but of late there has been a hold stand made against it, and there at last seems to be a hope that we may again have sculpture that shall be a real representation of an Englishman as he lives.

All good art is representative of the age that produces it; so, manifestly, in representing that in which we live, we ought not to drape our statues as either the Greeks or Romans did. We know that the dress of the figures forming the procession of Athenians in the frieze of the Parthenon was the daily dress of Athens, and it seems to me that it is our duty to express in art the dress of our time, even though it may be difficult in many cases to persuade ourselves that it is aesthetically beautiful. We need not follow the fashion from year to year. I would go so far as to advise that we

ould choose the dress for a statue (if it is ideal and yet modern subject) from any costume that has been customary during any part of our life. We ought, at any rate, to have on the dress worn in its home.

I would like to remind you of the numerous works of sculpture which have been produced in France, of late by the just treatment of temporary costume.

Although we are sometimes startled, and annoyed perhaps, at the extremes of realistic art often to be seen in Paris, yet one cannot but admire with enthusiasm such portraits as those by Chapp and Delaplanche, or allegorical groups as those by Barrias, in high modern costume is boldly employed.

Several of these groups are commemorative of the defence which certain cities in France made against their enemies during the war of '70.

Subjects of everyday life have been modelled with a fine judgment and with success, by Dantan, Albert-Lefevre, Pech, and others. Lefevre's statue, entitled "Bread," is an excellent example of a realistic yet sculptural rendering of a robust and handsome young peasant woman carrying leaves of bread.

We find that the most sculptural garments possess nowadays are those in which fashion is least force, and where the dress has adapted itself most naturally to the occupation of the wearer, and the longer it has been worn the more worthy it is of your study. The folds stand of falling accidentally, first in this position and then in that, have discovered their proper place, and fall there with a certainty that has become a principle.

Even the thickest and most stubborn of materials, such as leather, becomes valuable to the artist when worn long enough; it is not necessary to accentuate the patches and holes and ugliness,—these are accidental, while the folds are essential. It is quite extraordinary how the human figure will assert its form through clothing after long wear. The effect is summed up, of course, the typical, and for that very reason, of most value to the sculptor. In this way a statue can be clothed, and the form will be sufficiently visible to retain its proportion and action.

The proper and true depth of fold and consequent shadow in the various parts of a garment covering the human figure can only be deduced in that which is well worn. To attempt to do so in clothing that is at all now is soon found to be hopeless.

Even in London one sees not unfrequently among the navvies, or those workmen who dig at the foundations of buildings, men who look sculptural in their wrinkled corduroy trousers, buckled in at the knee with a strap, in a loosely-fitting shirt, soft and pliable, not made into a hard, white board, to be worn in front like a sandwich-man's placard. The navvy's dress is adapted to his work, and is, we may conclude, but little affected by fashion.

As an instance of an improvement in costume of our own time,—an improvement, by reason that it is better adapted to the occupation of the wearer,—I will cite that of the cricketer, who, fifty years ago, when playing an important match, did not wear on his head the close-fitting cap now customary, but in its place wore that all cylindrical hox with which we are so well acquainted, and which we designate a chimney-pot, but which our friends the Americans prefer to call a long-sleeved hat.

The countryman is still in many places sculptural, and may be, I think, realistically treated, though in modelling him one need not imitate the textures of his dress and their contrasts; these essentially belong to the painter's art. They do not consist of form that we can all tangible, so are not for the sculptor. Often from the ease with which an effect can be obtained by the direct, though imperfect, imitation of textures as a means of giving contrast, an inexperienced student will employ this means to the neglect of the proper form, of which the textures are the mere surface. Texture is closely allied to colour, about the use of which in sculpture I now wish to say a word, since that is another element in the imitation of nature.

Polychromatic or many-coloured sculpture, seems to have been used in every age; and at first thought it, perhaps, appears to us as if colour might be a means to accomplish the end of adding another charm to beauty of form, and to make sculpture more than a partial representation of nature. It, moreover, has the argument in its favour of having been used by

the Greeks at the best period of their art. But we must bear in mind in what positions it was used, and for what purpose.

It was used decoratively in the frieze of the Parthenon at a height of 40 ft. above the spectator, at which elevation it was probably necessary to accentuate the flow of the design, and at the same time to harmonise with the highly-coloured building. This frieze, as you well know, was a continuous mural decoration running round the entire inner wall or cella of the temple, and for the figures to have had sufficient effect at that height without colour, would have necessitated making the projection and depth of relief so great as to destroy the apparent structure of the wall which carries the superimposed roof. The ceremonies connected with the polytheistic worship of the Greeks were sumptuous and brilliant, and, as in the Roman Catholic churches of the present day, the greater number of the statues immediately near the shrine or altar were coloured, in order to bring before the mind of the worshipper the presence of the deity, more distinctly than by the abstract and partial representation given by a colourless statue.

I have said that the sculptor ceases to imitate nature closely when the material does not admit of it, so that we get conventions due to material used in representation.

A convention which is admirable in one material would not, perhaps, be so in another. For instance, a support in the form of a stump of a tree or some accessory (although the subject might not require it) might be necessary in a marble statue to give sufficient strength, but would not be at all required in a bronze one. Also for the sake of compactness and consequent strength, the limbs in a marble statue should not be extended so as to become weak and unsupported; but in bronze there is no occasion for this restriction. So that bronze can be more extravagant, more elaborate,—can be built up piece by piece, can undertake a greater variety of subject, be more picturesque, more dramatic, more realistic than marble,—but since its dark colour does not admit of the delicate gradations and harmonies of form being perfectly seen, it will ever be less of the sculptor's material for the most beautiful and, therefore, the highest class of subject than statuary marble.

There is something about a block of marble that fascinates and almost invites a man to become a sculptor. Our first attempts with the hammer and chisel, however, prove that it is a serious matter to become even skilful in handling these tools.

This is, nevertheless, a training of the hand which every sculptor student ought, I think, to undergo. It is, I believe, a fact that a great number of those students who have taken the highest honours in sculpture in these schools have been good carvers of marble. It does not follow that every good carver will be a good designer, but he will be a better designer if he can carve and his work will be more workmanlike and solid.

Whilst on the question of materials, perhaps I may say a word or two about terra cotta. We have examples annually produced in which the dictum of Sir Joshua, whence we started, seems to be reversed, and "imitation is made the end of art." It is the facility with which much realism can be given in this material, and the consequent ease with which a meretricious effect can be obtained in it, which tempts many who are somewhat inexperienced in art to model in terra-cotta. The shrinking of the clay of about one-tenth of the linear measurement during firing in the furnace, and the chance of contortion and breakage, make this material unfavourable for employment. Although its field is wide, and beauty can sometimes be expressed in it, yet it is only really successful in portraying strongly-marked character, which does not lose by the somewhat unattractive surface of the dry, burnt clay. There have, however, been, both lately and during the Renaissance, extremely fine portrait busts made in terra-cotta; a great number of these latter are found to have a somewhat smoother surface than the modern ones. This smoothness depends considerably on the character of the clay and the amount of firing to which it is submitted, and although the effect is not so crisp and sharp as that of our modern examples, yet it is well to remember that a smooth surface is durable, and can be cleaned, whereas I fear many of the modern works of art in this material require a glass

shade over them to preserve their charm. But I think we have come to dislike glass shades, and to prefer that sculptures large and small should be permanent and not fragile. In small pieces of sculpture there is a great pleasure in being able to take the work into one's hand and examine it at will; this, of course, necessitates a durable material and a fairly smooth surface. Small bronzes have a great advantage in this respect, and happily the more a bronze is handled the more pleasant it is to look at, unless it is an antique, and has a corroded surface,—that is, unless the bronze is changed into an oxide of copper, and so is beautiful in its delicacy of colour. This lovely green is, of course, the heauty of decay. How far it is advisable to reproduce this effect in modern bronzes is a question; to do so is, perhaps, rather like a painter attempting to make old masters. The surface of bronze should be beautiful, but it should be made so by its form, and not by its colour.

I can imagine our modern houses containing with advantage a far greater number of small sculptures than they do at present.

The walls of most houses are covered with modern pictorial art in some form or other, but our rooms are devoid of sculpture, our mantelshelves and pieces of furniture are not decorated with it. Blue plates balanced on their edge in constant peril of their homogeneous existence occupy these sites. It should be one of the duties of the sculptor to try and displace these blue plates, and put small bronzes in their stead: he has only to make really good small statues, and he will do it, or, at any rate, he will get his small statues standing in front of the blue plates, which will serve as a good background for them.

You will find that wax is the best material in which to model small sketches and statuettes. It is sufficiently rigid to require but little support, yet plastic enough to be fashioned into any form that the sculptor's mind can conceive, and is capable of being finished in point of surface to the minutest detail. It can be modelled and cast in bronze, while the original model remains. This is not the case with clay, which must usually be destroyed during moulding.

Before concluding, let us once more consider what is the right procedure for a sculptor to pursue, should he attempt to make a statue possessing beauty and grace.

It is to be hoped that he has an idea or faint vision in his mind of what he is going to do before beginning his sketch. But let us suppose his sketch made and carried sufficiently far to indicate the idea and composition of the work. The frame or skeleton for the clay figure is set up, and the model arrives and tries to take the position of the sketch at the direction of the sculptor.

The model, though perhaps excellent in proportion, and good in detail of form, fails to embody what the sculptor has imagined, and, moreover, cannot perhaps assume the action suggested in the sketch. This is often a sad moment for the sculptor, for if he has not conceived his design truthfully, he suddenly becomes aware of the fact.

Now, what is he to do? Is he, in making his statue, to cast away his idea and sketch, and imitate the form of the model before him to the uttermost of his power? Or is he merely to enlarge his sketch to the size of his statue, and refer only to the model to correct serious errors of proportion?

The first method would lead to nothing but what a perfect cast from nature would give us, and would be at best only a study. The second would result in a work essentially conventional and mannered, constructed on knowledge previously acquired, probably from the antique, and would not possess enough nature in it to excite human interest.

We see examples in sculpture of both these methods, but our true course lies between their extremes.

When you have conceived an idea for a statue, and have fixed your idea in a sketch, then have nature before you as much as your purse will afford, and should you find that your sketch is essentially untrue and structurally impossible, let it give way to what nature dictates; you will gradually perceive that your idea can be expressed by an action that is possible to the model.

Do not confine yourself to one model alone; for your object, in this case, is not to make a portrait, but let every form possess the impression of having been worked out from

nature, and let your good taste be shown by the selection of the forms employed.

And, lastly, as regards the subject which you should choose, I will only say a word. Let it be worthy of representation, and not merely dependent on a passing fashion or conceived to satisfy the vulgar love of novelty. As sculptors and co-workers with the men who made those inspiring statues twenty-three centuries ago, set your faces against anything that may tend to make your art other than what would be an ennobling influence to your fellow-men.

Illustrations.

WE shall be glad to receive any drawings intended for the Royal Academy Exhibition, which their authors may wish to see illustrated in our pages, to be photolithographed before sending in to the Academy, and published (as far as possible) during the time the Exhibition is open. Where desired, we will make ourselves responsible for the delivery of such drawings at the Academy on the proper day, but cannot undertake to see to the return of them after the close of the Exhibition.

Drawings can be accepted, either in line for ordinary photo-lithography, or in colours for reproduction by other processes. It may be as well to observe, in regard to the question of time, that the processes for reproducing from coloured drawings require rather longer time than photo-lithography from line-drawings demands.

The receiving days at the Academy are March 27th, 28th, and 30th, for paintings and drawings, and March 31st for sculpture.

MERSEY TUNNEL RAILWAY STATIONS.

The line for which the Mersey Railway Company has Parliamentary powers commences by a junction with the London and North-Western and Great Western joint lines at Tranmere, Birkenhead, and after passing under the river Mersey extends to the Central Station in Liverpool, the whole length of the line being about three miles. The length of the tunnel is 1755 lineal yards, measured between the shafts, of which about 1,250 yards are actually below the river bed.

We have previously given some account of the work when in course of operation.*

The engineers are making special provision to insure a thoroughly satisfactory system of ventilation, and no expense nor forethought is being spared towards attaining this very important end.

The railway, when constructed, will accommodate the large traffic at present existing between Liverpool and Birkenhead, and, in addition to this, will bring the Great Western and North Western trains, which at present stop at the Birkenhead terminus, into the heart of Liverpool, and will also convey the traffic of the Great Northern, the Midland, and the Manchester, Sheffield, and Lincolnshire Railways directly into Birkenhead.

The Company have under view the necessity that will exist for important extensions, and are this year applying to Parliament for junctions with the lines of the Mersey Docks and Harbour Board on each side of the river, thus forming direct communication for goods traffic between the Docks of Liverpool and Birkenhead.

It is satisfactory to know that the cost of this railway per mile will not exceed one half that of the Metropolitan Railway in London, although the traffic will probably be quite as large and important.

The engineers are represented on the works by Mr. A. H. Irvine, the resident engineer, Messrs. Waddell, the contractors, being represented by Mr. James Prentice, their agent, and Mr. D. A. Davidson, their engineer.

The station buildings are being carried out from the designs and under the superintendence of Mr. G. E. Grayson, of Liverpool.

We give illustrations of two of them, viz.: James Street, Liverpool, and Hamilton-street, Birkenhead.

* *Builder*, March 15, 1884.

The level of the rails in James-street is 92 ft. below the street level, and in Hamilton-street 103 ft. 6 in.

In addition to the stone staircases there will be three passenger hoists, each accommodating eighty persons.

These hoists ascend to the lower booking halls, which are level with the foot-bridges crossing the main lines.

The James-street elevation is to be faced with white stone, and that of the Birkenhead station with red terra-cotta.

The stations internally including the booking halls will have the walls lined with glazed bricks.

The height and size of the towers have been regulated by the levels of the tanks required by Messrs. Easton & Anderson in connexion with their hydraulic machinery.

The upper floors of the James-street building are arranged for suites of offices, with a separate entrance, staircases, and passenger-lift.

TWO SEMI-DETACHED RESIDENCES, DRUMMOND-STREET, MONTREAL, CANADA.

THESE have been completed for Messrs. H. C. Scott and H. G. Strathy, during the past year, and are built of Montreal limestone, lined with brick.

The houses, although harmonising in character and grouping, differ in plan, as well as in elevation, thus giving an individuality to each.

The style adopted is an adaptation of that in vogue in France during the time of Francis I., but owing to the severe winters of Canada, heavy snowfall has to be considered, and a frequent descent of the mercury below zero, necessitating the preparation for, and providing of double windows, and other contrivances for equalising the temperature indoors, so that some modifications would have to be made in almost any European style which might be adopted.

These houses are heated throughout with hot water, and the principal rooms and staircases are finished in hard woods. Most of the painted and ornamental glass came from the studio and works of Messrs. Guthrie, Sauchiehall-street, Glasgow, and the gates, &c., were supplied by Messrs. Steel & Garland, and the Coalbrookdale Company, of London.

The cost of each house, exclusive of stabling, &c., was a little over 3,000*l.* sterling.

The architects are Messrs. Taylor & Gordon, of London and Montreal.

"ART AND WORK."

UNDER this title, Mr. Owen W. Davis is bringing out shortly a remarkably interesting collection of drawings of decorative work of various styles and periods. From the plates for this work we reproduce two, concerning which Mr. Davis sends the following remarks:

Italian Fountains, Vases, &c.

"These designs are taken from the celebrated 'Hypnerotomachia Poliphili'—a rare and costly Italian work, by Francis Colonna, a Dominican monk. The book was published at Venice in 1499, and was probably printed by Aldus. Although the written matter, which consists of a supposed contest between imagination and love, is a hotchpot of fact, fable, and antique lore, intermingled with amorous rhapsodies, the woodcuts with which the work is profusely illustrated are the best, in the simple style of line-drawing, that Italy has ever produced.

No. 1 is a frieze of amorini, dolphins, vases, &c., gracefully arranged with foliage; No. 2, a terminal vase; Nos. 3 and 6 are fountains; No. 4 is a lamp-stand; and Nos. 5 and 7 are ornamental vases.

The 'Poliphili' designs, which are evidently of the old Padua-Venetian School, have been attributed to Raffaele and Alessandro Botticelli, as well as Andrea Mantegna, but the British Museum catalogue ascribes the drawings to Bernini.*

Animals, Plants, &c., from Fifteenth-century Woodcuts.

These clever engravings, so full of motif in design, as well as spirited in execution, are

* We may say with Byron:—"Powers eternal! such names mingled!"—Ed.

obtained by the simplest means which an artist could employ. They are taken principally from the 'Ortus Sanitatis,' printed at Mentz in 1493, which is a work on Natural History, by Jacob Meydenbach. No. 1, a Water plant; No. 2, a hidden Fruit and Serpent; No. 3, Figs; No. 4, Dwarf Mallow; No. 5, a Water Subject; No. 6, Swans; No. 9, the Plant Magwort (*Botris*); Nos. 7 and 8 an Eagle and a Fish reproduced from the 'Herbal,' by Mattioli, a work of 1545 date.

We would call attention to the 'colours' thrown into the examples Nos. 1, 2, 4, and 6, the engraver having artistically cut the interfoliage in *intaglio*.

It is noteworthy that the two plates here published are dated respectively 'Meutz, 1493' and 'Venice, 1499,'—eight years' difference, at places not 400 miles apart.

Both illustrations are executed up to the earnest power of the artists employed in two separate countries."

SKETCHES FOR THE PUGIN TRAVELLING STUDENTSHIP

THE sketches of the south porch at Gloucester Cathedral and St. Margaret's Tower, Leicester (not St. Mary's), as it was unfortunately printed off on the plan before the mistake was discovered, are reproduced from pencil sketches by Mr. W. H. Bidlake, who has gained the Pugin Travelling Studentship at the Institute this year with a very excellent collection of drawings, from among which these are selected. In regard to the tower, Mr. Bidlake writes,—

"In Mediaeval times those in the diocese of Lincoln who enjoyed the luxury of a fire were subject to a tax of one farthing, known as 'smoke farthing' or 'Lincoln farthing.' The sum realised by this means was usually devoted to the maintenance and repair of the fabric of the cathedral, but sometimes that portion which was collected from the inhabitants of a local town, by special injunction of the bishop, diverted to defray the expense of any building of an ecclesiastical nature that was in progress in the neighbourhood. St. Margaret's, Leicester (which in the diocese of Lincoln), was such a privilege, and its tower has been built by 'smoke farthings,' the injunction of the bishop being extant."

ARCHITECTURAL SOCIETIES.

Leeds and Yorkshire Architectural Society.—At the meeting of this society, on Monday evening last, a paper on "Architectural Competitions" was read by Mr. Cole A. Adan, President of the London Architectural Association.

York Architectural Association.—At the meeting of this Association, on the 19th inst., Mr. H. Thorp, of Leeds, read a paper on "Colours in Decoration." Mr. Pollard, the President, occupied the chair.

Edinburgh Architectural Association.—The usual fortnightly meeting of the association was held in the Professional Hall, on Monday evening. The President, Mr. G. Washington Browne, was in the chair, and, after some preliminary business, introduced the lecturer, Mr. J. C. Watt, who took for his subject "The Poetic Aspects of Architecture." The lecture was concluded by a reference to the characteristics and emotions common to poetry and architecture, particularly sublimity, symbolism, and association.

Glasgow Architectural Association.—The lecture of the session was by Mr. William Paton Buchan, his subject being "Internal Plumber-work." There was a good attendance, and the vice-president occupied the chair. Plumber-work, Mr. Buchan said, was much less generally understood than the kindred subjects of drain and Sanitary Engineering, and slowly but surely ousting role of thumb. The long-wishes for sanitary regulations now proposed by the Corporation were, almost without exception, commended. These, if decided upon, would place Glasgow among the foremost of cities in this respect.

Dundee Institute of Architecture.—Prof. Canclley delivered an interesting lecture before the members of this Institute on the 18th inst. His subject was "Some Chemical Facts Connected with Plumber-work in Dwelling-houses." The lecture was chiefly devoted to a discussion of the corrosive action of various kinds of water on lead, copper, and zinc.

ROMAN RENAISSANCE.*

I beg to introduce to your notice some account of the ecclesiastical architecture of Rome during the sixteenth, seventeenth, and eighteenth centuries. My reason for choosing such a subject is that it was suggested by the competition for the new Oratory Church at Brompton, which took place in the year 1878; and in the particulars furnished for the guidance of the competitors the first clause was to the effect that the style should be "Italian Renaissance." In response to this invitation a number of gentlemen (about forty) furnished designs of unusual merit, but, on careful examination of the drawings during the time they were exhibited to the public, the impression conveyed to me was that the words "Italian Renaissance" were not quite grasped by some of the competitors, whose designs were in the style of the old basilicas, while others savoured of the Byzantine and Romanesque character. I thought, therefore, that as Rome is considerably removed from the city of London, and that to visit it means a sacrifice of a deal of time to the younger members of this Association, an account of some of the principal churches erected in that city during the before-mentioned periods would not be uninteresting. You are already fully aware that Gothic architecture never took root in this most interesting city of the world, for during the period of Pagan Rome such a style was never dreamed of; and, secondly, on the Romans being converted to Christianity, they found their ancient temples and basilicas very convenient and suitable for the functions of the newly-embraced faith, and so they continued to use them, restoring or rebuilding such portions as was demanded by the destroying hand of time, until the rebuilding of St. Peter's, about the year A.D. 1500, when our Perpendicular architecture reached the zenith of its glory. This circumstance was an event of considerable moment in the history of the revival of Classic architecture in Italy. Artists and sculptors (for I believe architecture was not practised at this time as a distinct profession) were called in from every direction, in some cases to patch up, and in others to pull down, the existing churches, and to furnish new designs after the model of the great cathedral, but on a very diminutive scale; that is to say, every church should, if means permitted, be crowned with a cupola; while in the other cases the dimensions and historical interests connected with such buildings as S. Paolo fuori le Mura (St. Paul outside the Walls), St. Giovanni in Laterano (St. John Lateran), S. Maria Maggiore (St. Mary Major), made the question of rebuilding too serious to be entertained, but they were, nevertheless, subjected to such additions and alterations after the new style that in some cases all traces of the original structure had fled. Take, for instance, S. Giovanni. This basilica was founded by Constantine at the instigation of St. Silvester in the fourth century, who is said to have personally assisted in digging the foundations. The façade was designed by Alessandro Gallilei in 1734, and the whole of the interior was metamorphosed by Borromini (who appears to have had the lion's share of architectural practice) in the same degree that Winchester Cathedral was under the direction of the talented Bishop, William of Wykeham. The dimensions of this church are very large, consisting of five aisles, originally divided by stone or marble columns, which in the middle of the seventeenth century showed signs of weakness, and Borromini was then consulted. In the emergency he suggested the idea of encasing the columns, and filling up every alternate arch with solid masonry, and facing the nave walls with plasters of the composite order, reaching from the floor to within a short distance of the ceiling. These solid piers were adorned with large niches of a very debased style of art, and in which were placed statues of the Apostles, of colossal dimensions. This arrangement was finally carried out, and if we could only overlook the shortcomings in the detail I think we must confess that the architect displayed high ability in his manner of dealing with the awkward task placed before him. The great ornament of this church is the first chapel on the left-hand side, and known as the Corsini Chapel. It is square on plan, but has

a large recess on each of the four sides, thus giving it the form of a Greek cross, the whole is surmounted by a cupola, and adorned with paintings and marble of the most precious description. It is really one of the treasures of Rome, and every architectural student who is privileged to visit that city should not forget to fix it indelibly on his mind as well worth seeing.

The next church of importance is that of S. Maria Maggiore, but as this basilica has experienced little or no alteration since the date it was founded, A.D. 352, I cannot dwell upon it here, except to allude to such portions as would fall under the title of this paper: consequently I beg to call your attention to the Chapel of the Blessed Sacrament, commonly called the Sixtine Chapel. It was erected from the designs and under the direction of Cavalier Fontana (one of the most gifted architects of his time), and in my estimation this work is not equalled by anything else in the city of Rome. Its plan is most beautifully conceived, and its interior elevation and decorative treatment is certainly equal in merit to the plan. It is one mass of marble, gold, and fresco, so beautifully and tastefully arranged that the eye of the most educated artist could not be offended at it. I have the good fortune to possess both a plan and a section of it, which are also displayed in De Rossi's collection of chapels. There can exist no doubt but that this gem is the acme of perfection in the Renaissance style of architecture, and what every architect at the period would have done if his ability and the means at his disposal permitted it. Its *ris-à-vis* is that known as the Borghese. It is very similar in plan to the other, but not so rich in treatment. It is, nevertheless, an important adjunct to this ancient and magnificent church, where any young and enthusiastic disciple of architecture could take up his quarters for a couple of months and well occupy his time by carefully delineating the multitude of precious works of art, both plastic and polychromic, which present themselves at every nook and corner within its sacred walls. I would now be anxious to dwell on the merits of San Paolo fuori le Mura, and also on those of San Lorenzo, but the subject of this paper will not permit me: consequently I must pass them over in silence and give place to recent structures, which more particularly concern my subject.

The plan of the churches during the period of the three centuries mentioned at the commencement of this paper was governed in no small degree by the site upon which the church was to be built. If the ground would permit, it was a repetition on a small scale of St. Peter's; that is to say, the plan should be rectangular,—the nave and transepts forming the cross, and the intersection being crowned by a dome, with the aisles utilised as chapels; in fact, very similar to that of the Oratory Church. And if the site was very irregular (which frequently happened), and would not permit of a Latin-cross plan, it was made either circular or octagonal, with all the outlying corners utilised as sacristies and offices, which, in most cases, were ingeniously dealt with, only we must bear in mind that it must have a cupola.

These octagonal or circular churches are so numerous, and so worthy of being imitated, that I think it would furnish quite sufficient material for a separate paper. In our own country, when an idea is entertained of erecting a church, a piece of ground is purchased that would, if possible, admit of the fabric standing detached, with light and air, and perhaps a burial-ground, surrounding it, but this arrangement in Rome was seldom if ever indulged in at this period, a custom arising, no doubt, from the fact that the city was surrounded by a wall, which naturally in troublesome times increased the value of the land to such an extent as to render this luxury impossible; so that, as a rule, they were packed in between and lacked up by a host of dwellings in such a manner as to deprive us of forming an idea of what the external architecture of these churches might have been, had circumstances permitted the architect the indulgence of an undisputed area (excepting the façades, to be alluded to hereafter). This misfortune may probably account for the conspicuous absence of side windows and the recourse to top lighting. If this assumption is correct, I must only repeat the old adage "That out of evil comes good,"

for we must all admit that the most satisfactory method of illuminating a large building is either by obtaining light from above or by some large opening over the entrance end. In the South of Europe this question is more easily disposed of than is possible in the City of London, in consequence of the brilliancy of the atmosphere with which the former is favoured. Our own St. Paul's to wit; for I do not hesitate to say that, did its cupola exist in Southern Italy, the cartoons which are now being exhibited to the public and placed *in situ*, intended as a suggestion for its future embellishment, would be fully seen and appreciated by the public, but which I fear (and I regret to say it as they are so beautiful) will be lost for ever in a region of darkness. The usual method of covering the churches of Rome is to give them a wagon-headed ceiling of concrete, penetrated by smaller jack-vaunts, a necessity caused by the clearstory windows. Now this arrangement of covering the nave gives the architect a considerable amount of responsibility and also anxiety, in consequence of the immense lateral thrust exercised by the vault, for it must be remembered that the builders of this age had not the opportunity of using Portland cement, but were confined to the ordinary lime and pozzolana and thin brick in use at this date, about 14 in. to 1½ in. thick; with these materials it was necessary that the vaulting should be of great thickness so as to secure efficient strength and stability. In one case, where I had the privilege of going up into the roof, it gave me an opportunity of making an examination of the material itself, and I found it composed of coarsely-made concrete, 2 ft. thick at the crown instead of 7 in., which I have ventured to risk at the Oratory Church. Notwithstanding this great thickness of material there was a rent running the whole length of the nave, threatening the utter destruction of the building, and to prevent such a catastrophe the springing of the vault was secured by wrought-iron ties, 3 in. square on section.

Having described the principles which actuated the architects of this age, I think I may now allude to and describe some of the churches erected by them, which I would consider as typical of the style of the period, and which could be more or less imitated with advantage in this country, only I must caution you to beware of the so-called ornament of the later period, for if you study that you will be sure to fall, as it is impossible for any one to imagine a more grotesque and monstrous medley than is exhibited scattered broadcast over some of these buildings and altars, utterly disfiguring and destroying what might have been, in the case of its absence, a very fair specimen of architecture. This disease arises from the thirst for light and shade, anything that would break the tranquillity of architectural lines; in fact, it may be summed up as a sculptor's notion of architecture, such as I have frequently seen in many cemeteries, designed and executed by "monumental masons." The refinement acquired by Greece was entirely ignored, and the glorious examples with which they were themselves surrounded were passed by unheeded. Severity, grace, and delicacy were all sacrificed for this carved rubbish, no matter how different it may be.

But notwithstanding these blemishes, the interiors of the churches of Rome have and will continue to excite an interest to the traveller which we certainly cannot boast of in the case of our few examples of Renaissance churches at home, because, in the first place, there is no admission to them except on Sundays, and even if it were otherwise, there remains little or nothing to be seen. The first church I shall describe is that of St. Ignazio, designed by Padre Oratio Grassi, and commenced 1626; it is one of the most important in the city, and belongs to the order of Jesuits, having an internal length of 270 ft. with a nave 60 ft. wide and 100 ft. high. The proportions of this church I consider excellent, and the general arrangement is very simple, having the cross formed by the nave and transepts; in each aisle are three chapels, with two additional ones on each side of the sanctuary, all crowned with a small cupola. The pilasters in the nave are of the Corinthian order, fluted, and rest on the floor, not on pedestals; this arrangement answers exceedingly well in a church where fixed benches and pews are practically unknown,

* Possibly the sculptors will demur to being classed with "monumental masons."—Ed.

* A paper by Mr. H. A. K. Gribble, read at the meeting of the Architectural Association on the 20th inst., as elsewhere mentioned.

organise an excursion or a series of excursions to Rome and other cities of pre-eminent interest to the student of architecture.

Mr. J. A. Gutch, in supporting the vote of thanks, remarked, with reference to internal colour-decoration, that such specimens as he had seen of it, at any rate in Gothic structures, did not encourage one to be enthusiastic about it. Very possibly in Classic structures, where there were larger masses, and the lines were not so numerous, the use of colour might be made more satisfactory, but in Gothic the multiplicity of the constructional features militated against the successful use of colour. In the Chapel of the Hospital of St. Cross, near Winchester, for example, the constructional lines had been quite obliterated or concealed by the colour which had been applied. Mr. Gribble had awarded the palm for Gothic steeples to Antwerp, but he (Mr. Gutch) could not agree in that award, although the Antwerp steeples were very wonderful; but he quite concurred in the enlogium which had been passed upon the steeple of St. Mary-le-Bow, Cheapside. While agreeing with what had been said as to the value of the study of the Renaissance churches, he thought it would be a long time before we had another era of Renaissance church-building in England.

Mr. G. Richards Julian believed that we were approaching a period in which Classic architecture would meet with increased favour. In his opinion, the reason why Classic architecture had hitherto so egregiously failed in this country was that our architects had allowed rules and formulae to become their masters instead of making them their servants. It should be remembered that the Italian Renaissance of the fifteenth century was coeval with the commencement of the modern world. We belonged to the modern world, and he believed that in the long run Renaissance architecture would not fail to assert itself and come to the front. But he was very sorry to see that in the present revival so very much attention was being paid to the Dutch and Early German Renaissance,—commonly called "Queen Anne," though it was not "Queen Anne." There was much that was picturesque and quaint in that kind of work, but the fault that he found with it was that the architects who designed it, instead of aiming at beauty of proportion and refinement of detail, aimed exclusively at mere "quaintness," which in the works copied from was often the result of grotesque proportions and coarse detail,—defects due to the ignorance of the old builders. It seemed to him to be a great pity that men of undoubted genius should allow themselves to imitate false proportions and ungraceful detail.

Mr. G. H. Bagrove, having said a few words as to what he regarded as the sometimes unhappy effect of entasis on pilasters, the motion for a vote of thanks to the reader of the paper was carried, with much applause, and Mr. Gribble briefly replied.

COMPETITIONS.

Proposed New Training College, Norwich.—The Committee of Management, with the assistance of their assessor, Mr. Ewan Christian, subject to certain modifications in respect of arrangement, and to conditions as to verification of estimate, have provisionally accepted the design of Messrs. Oliver & Leeson, of Newcastle-on-Tyne, architects. They desire to thank the other architects from whom they have received plans for the trouble they have taken in preparing their designs.

London Endowed Schools.—This competition has at last been decided. Forty-six designs were received, including one from an architect in Buffalo, U.S. The governors examined them in the first instance, and made a selection of six, but afterwards called in Mr. Reyle, architect to the Manchester School Board, and Mr. Lewis, of Newcastle, to give independent reports on the whole forty-six designs. Each of the reports placed the design marked "Bona fide" first, on the ground of excellence of plan and architectural treatment, but expressed doubts whether it could be executed for the stipulated sum of 2,000l. The governors, therefore, called upon the author (who was found to be Mr. Charles Bell, F.R.I.B.A., of London) to prove his estimate at his own cost before adopting his plans. This Mr. Bell has done by obtaining estimates, the lowest being 1,784l., to which was added the cost of desks, bell, and sundry

fittings, amounting to 268l., making a total of 2,047l., including cost of quantities, without which the amount would be 1,997l. The governors, therefore, have appointed Mr. Bell their architect, and the works will be proceeded with at once in strict accordance with the competition plans.

Newbury District Hospital.—Designs by ninety-four architects were received in this competition, and were carefully inspected by Mr. Alfred Waterhouse, A.R.A., who selected eight designs for further consideration, viz., those by the following:—Messrs. Beazley & Burrows, Mr. C. W. Montford, Messrs. Newman & Newman, Mr. J. B. Phillips, Mr. H. G. Turner, Messrs. Webb & Tubbs, and Mr. W. H. Woodruffe. Mr. Waterhouse eventually gave his decision in favour of Mr. Henry G. Turner, of 1, Great James-street, London, W.C., and the Trustees, acting on this advice, have determined to adopt Mr. Turner's plans and employ him as their architect.

Abingdon Cottage Hospital.—The design of Mr. Charles Bell, F.R.I.B.A., of London, has been selected for the building out of six submitted in limited competition. The hospital will be erected at the cost of Mr. J. C. Clarke, M.P.

BUILDERS' CLERKS' BENEVOLENT INSTITUTION.

The eighteenth annual meeting of this excellent Institution was held on Tuesday evening last at the new offices, 21, New Bridge-street. The President elect, Mr. James Greenwood (of the firm of J. & J. Greenwood), in the chair, supported by the outgoing President, Mr. Joseph Randall (Kirk & Randall), and Messrs. Thos. F. Rider, Thos. Stirling, T. Bishop, E. Brooks, J. Robson, Burchell, C. K. Turpin, G. Bugg, and other friends and supporters. Letters expressing the regret of their writers at their inability to be present were read from Mr. Edward Conder and Mr. Arthur Cates, F.R.I.B.A., the latter congratulating the committee on being able to present so gratifying a report.

The report and balance-sheet, read by the secretary, Mr. H. J. Wheatley, showed that the Institution has been increasingly successful during the past year in enlisting sympathy and support, though, as was pointed out by one or two of the speakers at the meeting, there are large numbers of builders' clerks who do not subscribe to the Institution. The report, after expressing the indebtedness of the Institution to the outgoing President, Mr. Joseph Randall, stated that the amount of the annual subscriptions is to the charity during the year was 271l. 15s.; of donations, 397l. 7s.; and of dividends on Stock, 70l. 2s., making altogether the sum of 739l. 4s., being an increase of 88l. 7s. 5d. over the total of the preceding year. In addition to the foregoing amounts, the committee have received the sum of 99l. 4s. 1d., being the legacy (less duty) bequeathed by the late William Phillip Ward, whose nephew, Mr. Thomas Peto Ward, was directly instrumental in founding the Institution. The disbursements during the year amounted to 266l. 18s., expended in pensions and temporary relief; while the general expenses for rent, printing, advertising, secretary's salary, collector's commission, &c., amounted to 23l. 10s. On the course of the year, two additional pensioners (viz., Mrs. M. E. Robinson and Mrs. A. P. Friend) have been elected on the Relief Fund, bringing up the total number of pensioners to fourteen, the males receiving 25l., and the females 20l., per annum. An election had also taken place in connection with the Orphan Fund, the result being that Edith A. M. Friend was elected and was duly nominated a scholar in the Orphan Working School (per presentation of the Institution), in succession to Ethel M. Jeffreys, whose school-term expired at Christmas. At the annual festival, held at the Holborn Restaurant, the sum of 418l. 2s. 6d. was obtained in response to the earnest appeal of the President of the year (Mr. Joseph Randall). The report concluded with the announcement that Mr. James Greenwood had consented to accept the office of President for the coming year.

The Chairman, in moving the adoption of the report, expressed his determination to do all he could to further the prosperity of the Institution, especially in the way of setting forth its claims upon builders' clerks as a body.

Mr. Thomas F. Rider, in seconding the motion, suggested that the Institution, prosperous as it was, might be still more useful and prosperous if means were taken to make its objects widely known. Possibly, too, the time had arrived when the committee might take into consideration the advisability of increasing the pensions from 25l. to 30l. for the men, and from 20l. to 25l. for the women.

The report and balance-sheet were unanimously adopted, and on the motion of Mr. Thomas Stirling, seconded by Mr. Edwin Brooks, a vote of thanks was given to Mr. Randall for his services as President during the past year.

On the motion of Mr. Burchell, seconded by Mr. G. Bugg, Mr. James Greenwood was elected

President; Mr. Edwin Brooks was re-elected treasurer; Messrs. G. Bugg, B. C. Fox, J. C. Holding, E. W. Holland, E. C. Roe, and T. W. Winney, were re-elected to serve on the committee; and Messrs. S. J. Thacker, T. Stirling, and T. Bishop were re-elected auditors; and a vote of thanks (proposed by Mr. E. C. Roe, and seconded by C. K. Turpin) was given to Mr. Greenwood for presiding.

ELECTION OF A DISTRICT SURVEYOR.

At the meeting of the Metropolitan Board of Works on the 20th inst., the first business was the election of a District Surveyor for the District of South-east Deptford, in the room of the late Mr. John Whichcote. There were thirty-one candidates, viz., Messrs. A. Ashbridge, T. Batterbury, H. H. Bridgman, C. W. Brooks, H. Cheston, S. F. Clarkson, J. S. Edmeston, G. Edwards, R. F. C. Francis, W. Grellier, J. Hamilton, W. J. Hardcastle, A. Harland, E. Hazelhurst, G. Inskip, G. Jackson, L. Karslake, G. A. Lean, W. H. Lees, H. Lovegrove, H. McLauchlan, E. Marsland, T. E. Mundy, R. C. Murray, W. H. Nash, O. Renton, W. Smallpeice, W. L. Spiers, W. H. Stevens, H. W. Stock, and E. Street. These were first reduced in the usual way by voting on all the candidates, and retaining the six who received the highest number of votes, who were Messrs. A. Ashbridge (27 votes), S. F. Clarkson (22), W. J. Hardcastle (25), W. H. Lees (29), E. Marsland (25), E. Street (26). The subsequent voting was as follows:—

	Second	Third	Fourth	Fifth	Final
	Vote.	Vote.	Vote.	Vote.	Vote.
Ashbridge.....	27	21	—	—	—
Clarkson.....	16	10	—	—	—
Hardcastle.....	15	—	—	—	—
Lees.....	29	30	30	—	—
Marsland.....	24	21	24	21	16
Street.....	24	21	18	11	—

Mr. Lees was therefore declared elected.

THE "MAGASINS DU PRINTEMPS."

SIR,—Permit me to compliment you and your artist, Mr. Cooper, on the very excellent example of wood engraving,—the "Magasins du Printemps,"—in the *Builder* of the 21st instant. For an architectural illustration nothing could be better. J. MURGATROYD, F.R.I.B.A.

Manchester, Feb. 23, 1885.

** We have had other evidence that the views we expressed in our leading article of January 3rd as to the merits of wood-engraving as a means of illustration are shared by some at least of the architectural profession; and Mr. Cooper certainly merits a compliment for thorough and conscientious execution of this class of work.

THE ROYAL ARMS.

SIR,—The circumstances following may be worthy of your notice in connexion with Mr. E. Cockburn's letters printed in the *Builder* of the 24th of January last [p. 152] and the 21st of February current [p. 284]. A few days before the royal review which was held on the 25th of August, 1881, in the Queen's Park, Edinburgh, her Majesty ordered that the standard to be hoisted at the saluting-point should be the Royal Standard of Scotland, and not that of England, bearing in its first and fourth quarters "the ruddy lion rampant in gold." Our sovereign's interposition proved the more grateful, inasmuch as many countrymen's susceptibilities had suffered through the raising of the English standard on a similar occasion, "in that" same place, about twenty-five years ago. M. OF M.

SIR,—In thanking Mr. Cockburn for the trouble he has taken in answering my inquiry about the Royal Arms in Scotland, permit me to say that Lower is the authority I referred to, but owing to his "Curiosities" not being indexed it was only by accident that I came across it a few days since. It mentions that on the accession of James VI. to the English throne a great controversy arose between the Heralds of the two nations as to which should use the first quarter, and that the matter was referred to Sir William Segar, who produced a learned treatise of *imaginary heraldry* by tracing the lions of England and Scotland back to 1500 years before the Christian era! Much must have been highly gratifying to the dwellers North and South of the Tweed respectively, and to his Majesty in particular. J. B.

"Black, White, and Red Lead."—This was the title of the third of the present series of free lectures to artisans, which was delivered by Professor Church at Carpenters' Hall, on Wednesday evening. We defer our report.

"NON-ACCEPTANCE OF LOWEST TENDER."

SIR,—With reference to the letters of "Fairplay," 133, Mr. Wm. White, F.S.A., p. 217, and Mr. W. Hoffmann Wood, F.G.S., p. 252, of your journal, an either of the two latter gentlemen quote a case where damages have been obtained by a contractor who was invited, and whose tender, although the lowest, was not accepted? I was invited by a firm of architects at Bedford to tender for the erection of a steam-mill at that place; and, although my tender was the lowest (and verbally accepted), I received two days later a letter from the architects that their client had accepted a higher tender, and upon asking for an explanation of such extraordinary proceedings, was told that it was on the ground that the accepted party was a neighbour.

I may add that at the foot of the invitation were these words,—"The lowest tender will not necessarily be accepted."

CONTRACTOR.

SIR,—The statement I made in my letter of the 14th inst. [*Builder*, p. 252] is perfectly correct. I shall be glad to give "Bona Fides" my authority if he will write to me.

W. HOFFMANN WOOD, F.G.S.
14, Park-square, Leeds. Feb. 24.

FIREPROOF FLOORS.

SIR,—We note that in your otherwise favourable notice of our new Illustrated Catalogue of Constructive Ironwork in the *Builder* of last week [p. 253], you take exception to the fact that the iron beams shown in concrete floors have equal flanges at top and bottom, instead of having upper flanges of reduced area.

Without entering on the question of the relative merits on the flanges of joists thus used, we may point out that rolled joists of unequal flanges are not made, as such sections would be inapplicable to the majority of purposes for which iron beams are employed.

Of course, in cast-iron girders this difficulty would not occur, but equally cast-iron girders are not suitable for fireproof floors. With wrought-iron beams it is a different matter, as the rolls from which they are produced would have to be specially cut at very considerable expense to make this alteration.

ROWNSON, DREW, & Co.

DAMP DWELLINGS.

SIR,—In reference to Mr. Bird's letter (p. 252), "water finds its way through the roof, it may run down the rafter and be deposited on the top of the damp wall. See that the roof is sound, also the gutters.

If it should be unmistakable that the damp drives through the wall, give the outer surface a good coat of the following solution every three years:—one-third of a pound of paraffin wax to one gallon of benzoline. The wax must be dissolved in a portion of the benzoline over a slow fire, and must be applied on a dry warm day. Keep the solution from the air, as the benzoline evaporates rapidly. Pour out a small quantity for use, and add more benzoline as it evaporates. The paper should be washed off and not re-papered for twelve months, as all moisture at present in the wall will have to dry out inwards.

X.

The Student's Column.

DESCRIPTIVE GEOMETRY.—IV.

IN the early French Renaissance, roofs are seldom made to mitre at 45 degrees, but the narrow side is generally steeper than the long side; this is perhaps the secret of their elegance.

We may, therefore, have to find the intersection in plan and elevation of two roofs of different slopes, and even in cases where the

Fig. 20.

* Then why are they not made for this special purpose? is a waste of material, and an inert weight on the connection, to put them with large top-flanges into concrete, unless it is very bad concrete. A beam in good concrete really requires no top-flange.—Ed.

walls of the building, and therefore the eaves of the roof, are not at right angles, as in fig. 20.

The two following problems will show the method to be used:—

Find the intersection of the planes P and Q, of which the vertical traces belong to different elevations.

In this case we have two ground-lines L T and L' T', the horizontal traces of the planes

Fig. 21.

Fig. 22.

Fig. 23.

will be P^h and Q^h , but the vertical traces will be for the one P^v , for the other Q^h , which signifies that the trace of Q belongs to the elevation on line L' T'. To find the intersection of the planes P and Q we use an auxiliary plane, H, of which we can readily draw the intersections A and B with the planes given, for being horizontal lines, their plans A^h and B^h are parallel to the horizontal traces P^h and Q^h . The point y, where A and B meet belongs to the intersection of which x is another point; therefore the line x y is the intersection required, which we can draw both on the plan and on one of the elevations. (See fig. 21.)

The second problem is that of our Renaissance roofs.

Find the intersection of the planes P and Q given by their horizontal traces (eaves in case of roofs), and their respective slopes α and β .

We solve that problem by cutting the planes by two elevation planes on the lines L T and L' T' at right angles with the traces P^h and Q^h ; and, thanks to the angles of slope given α and β , we can readily draw the vertical traces

P^v and Q^v of the planes, so that the problem is brought back to the preceding one. (See fig. 22.)

Find in a roof plan the point where a straight line perpendicular to the elevation enters a roof the eaves and slope of which are given.

This is again solved by means of both an auxiliary elevation and an auxiliary plane: Let P^h be the eaves of the roof, the angle α its slope, L T the ground-line of the elevation, A the straight line the elevation of which is only a point A'. If we intersect our roof by an auxiliary elevation on the ground-line L' T' at right angle with the eaves we know its trace

P¹, thanks to the angle *a* of its slope. If we suppose an auxiliary horizontal plane, Q, passing by the line A, its trace on our elevation will be Q¹, and on our auxiliary elevation it will be Q² at the same height over L¹T¹ as Q¹ is over L.T. On the auxiliary elevation we see where the horizontal plane Q cuts our roof, and we can easily draw the plan L² of its intersection, for it is parallel to the eaves, the point x² is therefore the plan of the point where the line A enters the surface of the roof. (See fig. 23.)

Find the intersection of any straight line, A, with a plane, P, given by its traces.

For this you take an auxiliary elevation, the ground-line of which is A². This elevation plane will, of course, contain the line A itself. You get A² by drawing the elevation of one of its points b, b¹ being at the same height above A¹ as b¹ was above L.T. If we intersect the plane P by a horizontal auxiliary plane Q, we shall get a horizontal line l of P, which will cut the auxiliary elevation plane in c², through which the new trace P² passes. The point x², where this trace and the line A² meet, is the point of intersection required; its plan will be x² and its elevation x² at the same height above L.T. as x² was above A². (See fig. 24.)

Fig. 24.

There are different ways of solving the above problem, but they all rest on the same principle; viz., take through the line an auxiliary plane, find the intersection of that auxiliary plane with the plane given. Where this intersection and the given line meet is the point required.

Books.

Spon's Architect's, Builder's, and Contractor's Pocket-book of Prices and Memoranda for 1885. Edited by W. Younge, Architect. Twelfth edition. London and New York: E. F. and N. Spon. 1885.

This very useful little book, which is really a "pocket" book, and compresses a great deal of information into a most conveniently small volume, is one of the most useful of the kind to architects, not so much on account of its price lists as for the amount and variety of useful memoranda on materials and methods and formulae which it contains. Some of the items are old-fashioned; the "orders" still appear in their pure Vitruvian form, and the words "Doric order" in the index still direct the reader to a form of architecture which no one

now overthinks of when speaking of "Doric." A tyro getting hold of the book might be entirely misled by this. Of course no architect would be likely to refer to a pocket-hook of this kind for "the orders"; but if this is retained as part of the contents of the book there should, at least, be some reference to the fact that the orders as given are Roman only, and that there is such a thing as Greek Doric, or rather Doric proper, with which the Vitruvian so-called Doric has really no affinity whatever. We have called attention to this before. The notes for arriving at the weight of castings are likely to lead some readers astray, if the pattern is of deal, as this varies so much in weight, some Gelfe deals being nearly as heavy as pitch-pine; patterns should be made of pine. There are also some notes on "Smoky Chimneys," page 32, that we think might be far added to. We live in a time of plenty, so far as advertised chimney-curers go, but the "universal cure" has not yet been made, though there are a good many calling themselves "universal," and they nearly all are chimney-tops, where, undoubtedly, in nineteen cases out of twenty, the chimney itself must be cured.

There are many new formulae and tables of strengths that are given from the best sources, and there are many well-known ones that altogether make up a great amount of useful information, and fill the first half of the book, in which the subjects are arranged alphabetically. The second part is devoted to a schedule of prices. We notice some notes on the value or cost of walling built of concrete blocks, the prices of which are good, but the prices of the "patent" concrete floors are very high, although they are the makers' own prices. In all cases it should be clearly shown whether the prices include contractor's profit; those on page 243 for brickwork seem in some cases low, if they are inclusive of this, while those on page 246 are high at 14s. 10s. per rod if all labour beyond laying is to be priced, and in many cases the prices are too high for use in valuing ordinary contract work.

The prices of timber are the most complete of any given by price-books. A distinction is drawn between doors and other joiner's work, and steam-mad joinery. Nearly all joiner's work in the present times is made by machinery, being finished only by hand. The prices of the joiner's work are decidedly too high. This is, however, a fault we find in all price-hooks.

RECENT PATENTS.

ABSTRACTS OF SPECIFICATIONS.

3,513, Pressing Bricks, Coal, &c. W. Johnson.

This machine consists of a standard, in front of which is a sliding carriage with a plunger or block, to which is attached the "former" or pressing plate. An oscillating beam coupled to the plunger by a short rod gives motion to the carriage from the crank shaft. The brick or other substance to be pressed is pushed forward by a bell-crank lever, and is forced out of the form by another lever actuated by a cam driven from the main crank-shaft.

6,007, Noria or Bucket Mechanism for Raising Liquids. J. Welton.

This consists of a chain of buckets which discharge into a wheel with spiral blades, which carry the water to the discharge at the centre. There is a cone inside which directs the discharge on one side, and notches in the wheel to receive the bolts of the chain. If the chain should break for any reason so as to catch it. Hooks or bars projecting from the buckets pivot on notches in the wheel to effect the discharge. There are cross-bars in buckets to prevent solid blocks passing and blades to prevent the buckets upsetting on entering the water.

7,597, Water Waste Preventer and After-Flush combined. H. Trotter.

Refers to a water-waste preventing apparatus and an after-flush combined for water-closets; it may be fitted to any cistern. To the bottom of the cistern below the discharge-valve is fitted a casing. In this casing there is a small conical cistern provided with an air-pipe, and with a valve at the bottom which is closed on pulling the chain. The conical cistern is raised by the pull rod or chain till it lifts the discharge-valve. The discharge-valve delivers into the conical cistern and overflows into the down-pipe. When the rod is released the main discharge-valve closes, and the valve at the bottom of the conical vessel opens and delivers the after-flush.

1,763, Improvements in Household Fire-escapes. W. H. Gaze.

This is a closed up fire-escape, which opens out in sections from any floor-level, but is protected from

being opened from the ground level by a locking arrangement. The steps are of iron tube, and the sides are of angle iron. Segmental stays are fitted at intervals above the level of each window-sill. These stiffen and support the structure when opened out for use.

928, Tip-Wagon. C. Batten.

The wagon tips on a pivot fixed to the under-frame near the rear end of the vehicle. Two standards one on either side of the wagon, each carrying a small roller or pulley-wheel, is fixed to the framing near the tail-board. When the van is tipped the rollers move along the rollers, and the tail-board is moved outward and upward. On bringing back the wagon the tail-board is returned to the closed position.

2,149, Slide Rule. L. G. Ram.

The rule consists of two pieces of wood held together by metal strips. A sliding scale is between them, and the two rules carry ivory sliders between them. The scales are for engineering calculations, and are marked with strains and stresses, loads, &c.

3,220, Flush Pan Closet. John Friend.

This water-closet is formed in a cylindrical plunger chamber in connexion with the closet basin. The plunger is made of tinned copper in the form of a taper pipe 3 in. in diameter, and 2 in. at the bottom, and is securely trapped by a cap on the top which carries off waste or overflow. A disc of rubber on flexible material is secured to the end of the plunger to serve as a valve which fits into a conical valve seat. A crank is attached to the plunger for lifting the valve in the cistern above, which is fitted with the usual service-box.

3,123, Use of Iron Plates in place of Brick Jamb's in fixing Grates and Chimney-pieces. W. T. Allen.

Consists of wrought or cast iron plates fixed perpendicularly on each side of an ordinary grate, and to extend to the back of the flue with another plate of the same material, having its face moulded, fixed horizontally across the top of, and to rest on, the side plates, and fastened to them. The horizontal plate extends from the back of the flue, and projects so as to form the chimney-piece. The plate also contains an aperture for the flue.

5,928, Builder's Stage. J. E. Doughty and P. E. Kranich.

This is a builder's stage attachable to and serving to strengthen ladders. A wooden platform, with channel iron sides, is hinged to an angle iron frame. This frame is hooked at the top to fit on the spokes of a ladder, and is further secured to the ladder by a cross-bar. The platform is fixed at any desired elevation or inclination by thumbscrews, passing through guides attached to the platform, and through the pivoted stays. A rack sliding frame, with a padded end, bears on the wall, and serves to stiffen the ladder, and is secured by a catch, which which can be withdrawn by a sliding rod under the platform.

APPLICATIONS FOR LETTERS PATENT.

Feb. 6.—1,651, J. Elam, Improved Fire Grates, &c.—1,678, A. Marriott, Heating Buildings by Means of Hot-water or Steam.—1,683, A. M. Clark, Improvements in Lathing.

Feb. 7.—1,729, J. Morrison, jun., and A. Enley, Excavating or Digging Machines.—1,734, E. Busbally, an Improved Cowl.

Feb. 9.—1,747, T. Perrott, Moistening and Improving the Surfaces of Grindstones, &c.—1,749, H. Stockman, Improvements in Water Meters.—1,763, J. Rowe, Improvements in Riveted Joints.—1,777, G. H. Chubb and G. Exton, Door Locks, Latches, and Furniture.—1,778, J. Thomlinson, Manufacture of Plaster or Cement.

MEETINGS.

SATURDAY, FEB. 28.
 Architectural Association.—Visit to Houses in Collingham-gardens end St. Paul's School, Kensington. Assemble at School at 3 p.m.
 Builders' Foremen and Clerks of Works Institution.—Annual Dinner, Holborn Restaurant, 6.30 p.m.
 London Sanitary Protection Association.—Annual Meeting, 4 p.m.
 MONDAY, MARCH 2.
 Royal Institute of British Architects.—Special General Meeting of Members, to elect the Royal Gold Medalist, 8 p.m.
 Royal Academy.—Mr. G. Aitchison, A.R.A., on "Staircases." I. 8 p.m.
 Society of Arts (Cantor Lectures).—Mr. J. M. Thomson on "The Chemistry of Pigments." II. 8 p.m.
 Female School of Art.—Distribution of Prizes by the Duchess of Westminster in Prince's Hall, Piccadilly, 3 p.m.
 Victoria Institute.—Mr. J. Hassall on the question, "Was Primitive Man a Savage?" 8 p.m.

Society of Engineers.—Mr. Arthur Biggs on "American Engineering Enterprise." 7.30 p.m.
 Royal Institute of the Architects of Ireland (Dublin).—Council.
 Archæological Section, Philosophical Society of Glasgow.—Mr. David Barclay on "The Cleansing of the River, and a Substitute for Water-closets."
 Clerks of Works Association.—Mr. G. R. Webster on "A Simple Method of Perspective Drawing." 7 p.m.

TUESDAY, MARCH 3.
 Birmingham Architectural Association.—Mr. W. Donthday on "Symbolism in Art." 7.30 p.m.
 Institution of Civil Engineers.—Mr. W. Strondley on "Locomotive Engines." 8 p.m.
 Society of Biblical Archaeology.—M. Edmond Naville on "The Inscription of the Destruction of Mankid, on the Tomb of Ramesses III." 8 p.m.

WEDNESDAY, MARCH 4.
 Royal Academy.—Mr. Alfred Waterhouse, A.R.A., on "Westminster Abbey." 8 p.m.
 Builders' Foremen and Clerks of Works Institution.—Ordinary meeting, 8.30.
 Carpenters' Hall, London Wall (Free Lectures to Artisans).—Mr. Thomas Bishill, F.R.I.B.A., on "The Shoring of Buildings." 8 p.m.
 British Archæological Association.—(1) Mr. E. J. L. Scott on "Early MSB. relating to Tenby and its Locality." (2) Mr. H. Syer Cuming on "The Old Traders' Signs in Peterborough." 8 p.m.
 British Museum.—Mr. W. St. C. Boscaawen on "Assyrian and Babylonian Antiquities." II. 2.30 p.m.
 Society of Arts.—Professor H. S. Hele Shaw on "The Evolution of Machines." 8 p.m.

THURSDAY, MARCH 5.
 Institution of Civil Engineers.—(Students' Meeting).—Professor Urwin on "Water-Motors." 8 p.m.
 Society of Antiquaries.—Ballot for the Election of Fellows, 8.30 p.m.
 Royal Archæological Institute.—(1) Mr. W. T. Watkin on "Roman Inscriptions discovered in Britain in 1884." (2) Mr. J. L. Stalshmidt on "Church Bells." 4 p.m.

FRIDAY, MARCH 6.
 Royal Academy.—Mr. G. Aitchison, A.R.A., on "Staircases." II. 8 p.m.
 Architectural Association.—Mr. John Slater, B.A., on "Building Stones." 7.30 p.m.
 Royal Institution.—Prof. C. T. Newton, C.B., on "The German Discoveries at Pergamum." 8 p.m.
 Lincoln Diocesan Architectural Society.—By Museum.—Prof. J. F. Hodgkiss on "Medieval English Remains." III. The Monk. 2 p.m.

SATURDAY, MARCH 7.
 Edinburgh Architectural Association.—Visit to Corstorphine Church and neighborhood.

Miscellaneous.

Surrey Archeological Society.—The annual general meeting of this Society was held on Wednesday last, the 25th inst., at 8, Danes' Inn, Strand, and was numerously attended by the members. Viscount Midleton, President of the Society, occupied the chair, and moved the adoption of the report of the council and the balance-sheet. Among other matters, the council, in the report, expressed regret at the death of H.R.H. the Duke of Albany, late President of the Society, and Mr. R. A. Godwin-Austen, F.R.S., a member of the council; in the place of the former they had elected Viscount Midleton as President of the Society. A discussion ensued, in which Messrs. Granville Leveson-Gower, F.S.A., R. G. Rice, Curling, Ralph Nevill, F.S.A., H. Maude-Lay, Major Heales, and the Rev. R. M. Blakiston took part. One subject discussed was the desirability of forming a County Museum and Library, which was strongly urged. It was resolved to refer the suggestion to the council, and ultimately the report and balance-sheet were unanimously adopted. The retiring members of the council, and the other officers of the Society, including the auditors, Messrs. J. T. Lacey and W. F. Potter, and the honorary secretary, Mr. Thomas Milhorn, were re-elected, and the proceedings closed with a vote of thanks to the President.

Large Sale of Building Land at Lewisham.—On Monday evening Mr. Richard J. Collier conducted a very successful sale of building land, at the Plough Tavern, Lewisham. The property submitted comprised the second portion of the Priory Estate, at Lewisham, containing sixty-nine lots. There was a very large attendance, and preliminary to the several lots being offered Mr. Collier announced that the Priory Mansion had been subdivided into two houses, and that, in consequence, the ancient residence, which possessed a special historical interest, would be preserved. He added that half the mansion, with eleven plots, had been previously sold. At the sale on Monday all the plots, with the exception of eight, were sold at prices much better than those obtained at the previous sale, the front lot, containing 18ft. frontage and 100 ft. deep, selling for 150l. each, whilst the majority of the back lots realised about 4l. per foot frontage. The kitchen garden, and remaining portion of the mansion were bought in. The total proceeds of the sale amounted to about 5,000l.

British Archaeological Association.—At the meeting of this Association on the 18th inst., Mr. Thomas Morgan, F.S.A., in the chair, it was announced that the unsafe condition of the ruins of Carew Castle, noticed during the recent Congress at Tenby, had been reported to the owner, Mr. E. G. Carew, of Cromcombe Court, and that works of repair had been arranged for. These will be strictly limited to the upholding of the building, to prevent injury by frost or tempest, and nothing will be done to take off the appearance of the building as a ruin. Mr. Loftus Brock, F.S.A., reported the existence of a large portion of old London wall, now visible in the street of the same name, at Moorgate, just to the west of All Hallows Church. It is now revealed by recent excavations for buildings, having been buried by the accumulated earth of centuries. A paper on "The Roman Baths of Bath" was then read by the Chairman. After referring to Mr. Irvine's conjectural restoration, which appears to be well supported by more recent discoveries, the lecturer proceeded to describe in detail the whole of the building now revealed, tracing the portions uncovered from their first discovery. The paper was illustrated by several paintings and drawings prepared by the Misses Morgan. Another portion was then read of the paper prepared by the Rev. G. F. Browne on the remarkable Cross in Leeds Church. The shaft is covered with figure subjects having reference to old Norwegian or Scandinavian myths unique in England.

The Surveyors' and Auctioneers' Clerks' Provident Association.—We have received the first annual report and financial statement of this Association, which has its registered office at the Auction Mart, Tokenhouse-yard, E.C. The President is Mr. Daniel Watney, and the list of Vice-Presidents includes the names of many well-known surveyors and auctioneers. The report gives the result of twelve months' work ending 31st of December, 1887. The appeal for subscriptions to form the reserve fund of the Association has resulted in the receipt of a gross sum of 1,431l. 2s., of which 1,365l. is from donations and 86l. 2s. from annual subscriptions. This sum has been appropriated to the various objects entitled to it under the rules; the greater part to the benevolent and superannuation funds. The members' subscriptions amounted to 32l. 7s. 9d. The committee express their sense of obligation to the donors who have so generously provided a fund which gives the Association a present secure position, and must have an important influence on its prospects. About sixty applications for membership have been received. Of these twenty-four were not completed, eighteen having fallen through, and six being declined, or deferred for a time, on medical grounds. The Committee appeal to employers to direct the attention of their clerks to the Association, and to the advantages offered to them by a society so intimately connected with the profession. The Committee deplore the loss of Mr. George Trist, one of the trustees, who was a liberal subscriber to the Association.

Paper made from Sawdust.—A roller pulp machine has been invented by Mr. Pond, of Rutland, Vermont, by which sawdust, shavings, chips, and pieces of wood can be made with great rapidity into a pulp of clean, fine fibre. The machine will also manipulate the stalks of cotton, sugarcane, wild hemp, &c., at the rate of from 2 tons to 3 tons of dry pulp per diem. The resulting pulp is stated to be far superior to any other form of wood pulp, because the fibre is preserved intact and the cellulose is left with it, giving it great strength, softness, and pliability. The tensile strength per square inch of newspaper, which contains from 50 to 75 per cent. of ground wood pulp, is said to be from 8 lb. to 12 lb., and to stand a test of 17 lb. to the square inch, showing that it is much stronger than paper made from one-third rags. The woods most adapted to the process are the soft woods, such as spruce, fir, pine, poplar, and hemlock, the latter making the strongest fibre, being quite equal to jute in strength. Besides the manufacture of paper, the pulp can also be utilised for woodware, such as pails, barrels, and mouldings.—*Iron.*

Iron Buildings for the Soudan.—Messrs. Clark, Bennett, & Co. (Limited), of Rathbone-place, W., have received instructions from the War Office to erect and ship in fourteen days thirteen corrugated iron buildings for stores for service in the Soudan, covering an area of about 25,000 super. feet.

The Tower of St. Magnus' Church, London Bridge.—Owing to the dilapidated state of the stonework, the rector and churchwardens have found it necessary to undertake the work of restoration of the tower of the Church of St. Magnus the Martyr, Lower Thames-street. Upon completion of the scaffolding, the architect was called upon to survey and report to the vestry upon its state, which was found to be much worse than was at first anticipated, requiring a large portion of its cornice to be reinstated, many of them being split and splintered off at the joints, owing to the regrettable practice of inserting iron cramps into the stone when the tower was built. The cramps will be removed wherever practicable, and reinstatements made throughout in solid Portland stone. The restoration of the tower has been undertaken by the well-known church builders, Messrs. Dove Brothers, of Islington, under the direction of Mr. A. Billing, of Bank-chambers, Tooley-street, S.E.

A Conference on Cholera.—A conference of representatives of the principal countries of Europe will shortly be held, at the invitation of the Italian Government, in Rome, for the purpose of discussing the steps which it is advisable to take in the event of an outbreak of cholera occurring. We understand, although no definite arrangement has yet been arrived at, that England will be represented by Sir W. G. Hunter, K.C.M.G., and Dr. Thorne Thorne, of the Medical Department of the Local Government Board. Should the rumour regarding the appointment of English representatives be confirmed, we congratulate the Government upon the choice it has made, feeling sure that the opinion of the medical profession and sanitarians of this country will be fully and clearly enunciated, although we can perhaps hardly hope for many, if any, new precautions to be adopted in the event of a cholera epidemic.—*London.*

Colonial and Indian Exhibition, London, 1886.—Messrs. Henry S. King & Co. have received the appointment of sole official agents for India. Mr. C. Pardon Clarke, C.I.E., Keeper of the India Section of the South Kensington Museum, has, by special permission of the Lords of the Committee of Council on Education, departed for Bombay charged with a special mission by H.R.H. the Prince of Wales, Executive President of the Exhibition. Mr. Clarke's special duty will be to make arrangements for the illustration on a large scale of the handicrafts of India by the selection of native artisans, who will be brought to England, and work at their several trades in the exhibition.—*Overland Mail.*

Serious Fire at a Builder's.—One of the most alarming fires that had ever been witnessed in Newbury and district occurred on Saturday morning, the 21st inst., at four o'clock. The whole of the Albert Steam Joinery Works and Moulding Mills, the property of Mr. Samuel Elliott, were completely destroyed. The works are situated to the north of the town, and occupied several acres. The true origin of the fire is unknown, but it is supposed the bearings got heated. The destruction to the machinery alone is estimated at 8,000l. The total loss is estimated between 25,000l. and 30,000l.

The Blackburn and East Lancashire Infirmary.—The annual meeting of the Governors of this Institution was held a few days ago. The Board of Management, in their report, refer with satisfaction to the recent enlargement of the Infirmary. The cost of the new wing and lodges was 4,897l. 15s. 6d. The entire cost has been defrayed. The wing and lodges were erected by Messrs. Thomas Higson & Sons, from the plans and under the superintendence of Mr. A. W. R. Simpson, of Blackburn, architect to the Board.

The Chemistry of Pigments.—The first of a course of two Cantor Lectures on this subject was given in the hall of the Society of Arts on Monday evening last, by Mr. J. M. Thomson, F.C.S. The lecture dealt with the nature and division of colours, the deleterious actions on white pigments, and methods for counteracting the same. The second lecture, to be delivered on Monday evening next, March 2, will be devoted to an examination into the chemistry of coloured pigments and of certain organic and special pigments.

The Female School of Art.—The annual distribution of prizes to the students of the Female School of Art will take place in the Prince's Hall, Piccadilly, on Monday afternoon next. The Duchess of Westminster will officiate.

Lower Clapton.—Upton House "Ty School, the first industrial, or rather, "tr school, built by the School Board for Lower Clapton, has just been erected in the Urawich Lower Clapton. It has a frontage of 100 ft. and with the kitchen garden, drill-yard, occupies nearly an acre of ground. It is of stocks, with red facings, arches, &c., the main entrance being of Portland stone and oak doors. Although not an ordinary "B school, it nevertheless partakes largely of the same style. The architect is Mr. E. R. R. The builder is Mr. C. Cox, St. George's V Hackney, and the clerk of works, Mr. V. Butson. The numerous details connected with this class of building have been carefully studied. The governor's house is complete, though separate from the main building. The apartments of the labour-masters, &c., at the back of the centre of the main building, and command a complete view of both of the dormitories, sick and day wards, school class rooms, large dining-hall, bath-lavatory, laundry, and workshops, besides various stores, &c. The kitchen and connected therewith are complete in arrangement, and the reception and disinfecting are quite distinct. The drainage has been carried out in two separate systems, or soil and the other for surface-water, &c., various inlets to the latter being carried side, and delivered over stoneware (Donlton's) underneath stones with gratings. Messrs. Longden & Co. have executed the heating, cooking, and laundry apparatus (all of which are worked by steam), as also fire hydrants, &c. The lavatory is furnished with three rows of Butson's Patent Lavi Apparatus; gas-fittings are by Messrs. St & Sons; the electric bells and speaking-connecting the entire building, by Messrs. & Co.; the disinfecting apparatus by M. Benham & Sons; and the tar-paving by M. Hobman & Co.

Craven House, Northumberland-av. Messrs. Archibald Smith & Stevens, hydraulic engineers, of Queen's-road, Battersea, has been instructed to erect one of Stevens' Major's patent hydraulic suspended passenger lifts at Craven House, Northumberland-av. This will be worked by water supplied to the mains of the London Hydraulic Engineering Company.

TENDERS.

For the superstructure of a block of offices at the corner of London Wall and Little Winchester-street, E.C. F. T. Pilkington, architect. Quantities by Mr. Barnett:—
 Saunders 231,380 0
 Higgs & Hill 23,793 0
 Shurmer 23,100 0
 Lawrence 23,795 0
 Bayes 22,500 0
 McGregory 22,500 0
 Reading 22,480 0
 Simpson & Co. 22,230 0
 Shaw 22,064 0
 Perry & Co. 21,835 0
 J. O. Richardson 21,670 0
 Brown & Son 21,590 0
 Hobbs 21,550 0
 Mowlem & Co. 21,500 0
 Gearty 21,434 0
 Merton 21,137 0
 Brass & Son 20,873 0

For the erection and completion of two small blocks at the Broadway, Crouch End. Mr. W. Smith, architect:—
 Cowley 4394 10
 Hirst 385 0
 Mattock Bros. 345 0
 Darnford & Langham 293 0
 J. O. Richardson (accepted) 293 0

Accepted for alterations and additions to a warehouse, Crown-court, Milton-street, E.C. Mr. W. Pate, architect:—
 J. O. Richardson 2479 0
 [No competition]

For building five shops in the Old Kent-road, S.E. Mr. T. Bachhouse, Mr. W. C. Reed, architect, Adelphi-place, London Bridge:—
 Legg 41,990 0
 Smith 1,497 0
 Cross 1,397 0
 Marriages 1,250 0

For alterations to shop-fronts and houses in E street, S.E., for Mr. T. Bachhouse, Mr. W. C. Reed, architect:—
 Greenow 2,385 0
 Batey 250 0
 Wood 199 0
 Kemp 168 0

For repairs to premises, High-street, Bromley, E. Mr. Robert Higgs, architect and surveyor, 7, Katharine-street, Croydon:—
 Tucker 2,298 0
 Barrell 227 0
 Maffett 210 0
 Grubb (accepted) 178 0

PETITIONS, CONTRACTS, & PUBLIC APPOINTMENTS.

Epitome of Advertisements in this Number.

COMPETITIONS.

Table with 4 columns: Nature of Work, By whom required, Premium, Designs to be delivered, Page. Includes entry for 'of a Pier' by Met. Asylums Board.

CONTRACTS.

Table with 5 columns: Nature of Work, By whom required, Architect, Surveyor, or Engineer, Tenders to be delivered, Page. Includes entries for paving, building houses, and various materials.

PUBLIC APPOINTMENTS.

Table with 5 columns: Nature of Appointment, By whom Advertised, Salary, Applications to be in, Page. Includes entry for 'the Works' by Croymond Union.

Accepted for supplying about 150 tons of iron pipes and special castings for the Claines Local Board, Worcester.

Table listing quantities of iron pipes and castings: 6-inch pipes, 4-inch pipes, 3-inch pipes, Special castings (flange), Special castings (plain).

For building house, 'The Chestnuts' and stabling at Ashford, Middlesex, for Mr. J. Coppin.

Table listing quantities of building materials: Gibson, Southall; Staines & Son, Great Eastern-street; Richardson, New Hampton; Lucas & Son, Kensington-square; Johnson, Wandsworth; Kearsley, L'Abbeville.

For the erection of Longton Endowed Schools, Mr. Charles Bell, architect, London.

Table listing quantities of building materials for Longton Endowed Schools: Bromage, Fenton; Barlow, Stoke; Collis, Longton; Insip, Longton; Gallimore, Newcastle; Yoxall & Heath, Trent; Cope, Turnstall.

For the erection of Board Schools at Herne Bay, Kent, for the Herne School Board.

Table listing quantities of building materials for Board Schools at Herne Bay: Schofield; Martin, Wells & Co.; Allen & Sons; Ingleton; Ansell; Rodda; Amos & Foad; Cloake & Weston; Strubsole; Siff; Smith & Sons; Corneius; Wise; Greenwood; Adams, Herne Bay.

For new front at 213, Oxford street, for Mr. A. Gianella, Mr. Banister Fletcher, architect.

Table listing quantities of building materials for new front at 213, Oxford street: Perry & Co.; B. E. Nightingale.

For first portion of villa residences in Belle-Vue-road, Hendon. Mr. Banister Fletcher, architect.

Table listing quantities of building materials for villa residences in Belle-Vue-road: J. Elacott.

For the erection of five houses on the Beaver Estate, Ashford, Kent, for Mr. C. F. Herbert.

Table listing quantities of building materials for five houses on the Beaver Estate: Bingham, Headcorn; Wood, Ashford; Goldfinch, Whitstable; Warrington, Teutenden; Uarwin, Folkestone; Brooks, Folkestone; Paigham, Great Chart; Jeal, Sandgate; Castle, Folkestone; Giles F. W. Ashford.

For erecting house, shop, warehouse, and factory, No. 21, Bishopgate, for Mr. Henry Mead.

Table listing quantities of building materials for house, shop, warehouse, and factory: E. Conder; Dove Bros.; W. Shurmer; C. Forrest; E. Lawrence & Sons; Colls & Sons; J. H. Johnson; Wm. Brass & Son; W. & F. Croaker; Ashby & Horner; J. Chessum; Stimpson & Co.; E. B. Nightingale; J. & J. Greenwood; Jackson & Todd; Matlock Bros.; W. Scrivener & Co.

For excavators, bricklayers, masons, carpenters, joiners, slaters, plasterers, and smith's work, in the erection of a shop and dwelling-house in Fisherton-street, Salisbury, for Mr. F. C. Carter.

Table listing quantities of building materials for shop and dwelling-house in Fisherton-street: George Dolman, Salisbury; Edward Witt, Salisbury; Gilbert Harris, Salisbury; W. J. & C. S. Young, Salisbury.

Accepted for rebuilding two shops and houses at Easter-place, Holloway-road, Messrs. Roberts & Barnard, surveyors, Chancery-lane.

Table listing quantities of building materials for rebuilding two shops and houses: J. Beale.

Accepted for enlarging class-rooms, &c., at Board Schools, Reading, Messrs. Morris & Stallwood, architects.

Table listing quantities of building materials for enlarging class-rooms: J. H. Margraves.

For pulling down and re-building the Queen's Head public-house, Charlotte-street, Commercial-road, E., for Messrs. Truman, Hanbury, Buxton & Co. Mr. J. T. Newman, architect, 2, Fenchurch-street, Fenchurch-street. Quantities by Messrs. Curtis & Sons:—

Robert Marr	£2,049 0 0
W. Shurmur	2,043 0 0
J. Morter	2,031 0 0
Hearle & Son (accepted)	1,855 0 0

For alterations at the Lord Raglan Tavern, Shernhall-street, Walthamstow, Essex, for Mr. Sharp. Mr. H. F. Simmonds, architect, Cambridge Heath:—

Wood	£485 0 0
Hughes	460 0 0
Mower	437 0 0
Jennings	435 0 0
Ling & Needham	363 0 0
Lipscomb	352 0 0
Barton	325 0 0
Probert (accepted)	390 0 0

For erecting a new office in East St. Helen's street, Abingdon, for Messrs. Sedgfield & Fryce, solicitors. Mr. John George T. West, architect, Abingdon:—

Thomas Barrett, Abingdon (accepted)	£146 0 0
-------------------------------------	----------

* The lowest of two tenders received.

For alterations and repairs at a house in Bridge-street, Abingdon, for Miss E. Mundy, of the Manor House, Culham. Mr. John George T. West, architect, Abingdon:—

James Walter, Oxford	£320 0 0
J. Dover, Oxford	280 0 0
E. Williams, Abingdon	289 0 0
C. Hunt, Abingdon	279 0 0
George Thatcher, Abingdon	249 0 0
D. Stroud, Abingdon (accepted)	256 0 0
Thomas Barrett, Abingdon	220 0 0

For alterations and repairs to the Butchers' Arms Inn, Uffington, for Messrs. T. and J. W. Townsend, brewers and millers, of Abingdon. Mr. John George T. West, architect, Abingdon:—

John Willis, Faringdon	£475 0 0
Shepherd, Faringdon	409 0 0
Alfred Parker, Faringdon	376 0 0
C. Aldworth, Hanger	371 11 6
W. & J. Wheeler, Faringdon	295 0 0
J. Wheeler, Wantage	289 1 6
E. Williams, Abingdon	279 0 0
Thomas Barrett, Abingdon (accepted)	299 0 0

Accepted for new shop-front and fittings at 182, Kentish Town-road, for Messrs. Hull & King:—

R. A. Lamprell, Brighton	£265 12 0
--------------------------	-----------

Accepted for new shop-fittings, No. 2, East-street, Taunton, for Messrs. Hull & King:—

R. A. Lamprell, Brighton	£188 0 0
--------------------------	----------

For laying 550 feet of pipe-sewer and manholes and ventilators in Middle-road, Howe Park, Wood Green, N., for the Directors of the National Liberal Land Company. Mr. George Pooley, surveyor:—

J. C. Trueman	£145 0 0
S. Clifton	129 0 0
W. Carter	114 12 0
T. Adams	98 10 0
W. Nicholls (accepted)	93 0 0

For new shed, together with store room, subway, and appurtenances, at Oatsroy Mills, Midgeley, near Halifax. Mr. T. L. Patchett, architect, Halifax. Quantities by architect:—

Mason's Work (labour only).
Joseph Gaukrodger, Warley, near Halifax.
Fronfounder's Work
Wood Brothers, Sowerby Bridge.
Plumber's and Glazier's Work.
William Alderson, Luddenden.
Plasterer's and Slater's Work.
J. & T. Alderson, Luddenden.
Carpenter's and Joiner's Work.
(Day-work.)
[Total of work let, £1,512.]

Accepted for the erection of four houses, West Side Estate, Clapham Common. Mr. Frederick Lea, architect:—

J. B. Gerrans	£1,400 0 0
---------------	------------

Accepted for the conversion of house, 118, St. John's-hill, S.W., into shop. Mr. Frederick Lea, architect:—

J. B. Gerrans	£355 0 0
---------------	----------

For rebuilding the Queen's Head public-house, Charlotte-street, Whitechapel, E., for Messrs. Truman, Hanbury, & Co. Mr. J. T. Newman, architect:—

If Concrete	If Wood
Floors.	Floors.
R. Marr	£2,490 0 0

J. Morter	2,031 0 0
Hearle & Son	1,855 0 0
* Accepted.	

SPECIAL NOTICE.—Lists of Tenders frequently reach us too late for insertion. They should be delivered at our Office, 46, Catherine-street, W.C., not later than Four p.m. on THURSDAYS.

TO CORRESPONDENTS.

O. F.—H. R. B.—C. F. M.—A. S.—O. C. H.—"Sanatarium" (correspondent should send name, whether for publication or not).
W. W.—P. L. B. (quotes received).—J. P. Madrid.—C. F. (cannot advise on mere descriptions).—M. M. M. Roxburgh, Man.—R. G. P. (next week).—T. B. & Co.—S. W. & P.—W. A. W.

All statements of facts lists of tenders, &c. must be accompanied by the name and address of the sender, not necessarily for publication.
We are compelled to decline pointing out books and giving addresses.
Notes.—The responsibility of signed articles, and papers read at public meetings, rests, of course, with the authors.
We cannot undertake to return rejected communications.
Letters or communications beyond mere news items which have been duplicated for other journals, are NOT DESIRED.
All communications regarding literary and artistic matters should be addressed to THE EDITOR: all communications relating to advertisements and other factitious business matters should be addressed to THE PUBLISHER, and not to the Editor.

PUBLISHER'S NOTICES.

CHARGES FOR ADVERTISEMENTS.
SITUATIONS VACANT, PARTNERSHIPS, APPRENTICESHIPS, TEAR, AND GENERAL ADVERTISEMENTS.
Six lines (about fifty words) or under 4s. 6d.
Each additional line (about ten words) 6s. 6d.
Terms for Series of Trade Advertisements, suitable for advertisements on front page, Competitions, Contracts, Sales by Auction, &c. may be obtained on application to the Publisher.

SITUATIONS WANTED.
FOUR Lines (about THIRTY words) or under 2s. 6d.
Each additional line (about ten words) 4s. 6d.
PREPAYMENT IS ABSOLUTELY NECESSARY.
* Stamps must not be sent, but all small sums should be remitted by Cash in Registered Letter or by Money Order, payable at the Post-office, Covent-garden, W.C. to
DOUGLAS FOULDRINE, Publisher.
Addressed to No. 46, Catherine-street, W.C.

Advertisements for the current week's issue must reach the Office before THREE o'clock p.m. on THURSDAY.
The Publisher cannot be responsible for DRAWINGS, TESTIMONIALS, &c. left at the Office in reply to Advertisements, and strongly recommends that of the latter OFFERS ONLY should be sent.

SPECIAL.—ALTERATIONS IN STANDING ADVERTISEMENTS or ORDERS for DISCONTINUING same, must reach the Office before FIVE o'clock on WEDNESDAY MORNINGS.

PERSONS Advertising in "The Builder," may have Replies addressed to the office, 46, Catherine-street, Covent-garden, W.C. free of charge. Letters will be forwarded if addressed in envelopes are sent, together with sufficient stamps to cover the postage.

TERMS OF SUBSCRIPTION.

"THE BUILDER" is supplied gratis from the Office to residents in any part of the United Kingdom at the rate of 3s. per annum. Forwards. To countries within the Postal Union, 2s. per annum. Remittances payable to DOUGLAS FOULDRINE, Publisher, No. 46, Catherine-street, W.C.

Railway Rates.

THE interest taken in this question is growing rapidly, and the national character of it is being increasingly recognised by the public at large. So long as it was regarded as a contest between the Railway Companies and Trade Associations, it attracted little notice outside commercial circles, but the more the Bills were studied the more apparent it became that there were few classes who were not more or less affected by their provisions; though to no class, perhaps, can the question be so practically important as to builders, contractors, and manufacturers and purveyors of building material, who are constantly sending heavy loads by rail all over the country. The columns of the daily press have been thrown open for the discussion of the subject, and much has been said on both sides upon the many points involved. As the question will now be shortly before Parliament, a brief sketch of the more important of these points, with a *résumé* of the arguments for and against them, may prove of interest. The nine companies who are introducing these Bills state that they are doing so in accordance with the recommendations of the select Committee of 1881-2, and that they are framed generally so as to carry out the suggestions of that body. There is not the slightest doubt, however, that the Bill pronounced by the President of the Board of Trade last year as stimulated them to action. In fact, the Chairman of the Great Western, at their half-yearly meeting, stated that their desire was to meet, as far as possible, the views expressed in the course of the negotiations over the Bill referred to. That measure was framed in conformance with the memorials of trade associations showing that Parliamentary inquiry into railway rates had become imperative, and, as Mr. Chamberlain had to abandon it, the present Bills may be regarded as the answer of the railway companies to the traders' challenge. We have already mentioned the four principal objections taken to the Bills, and may take these as heads for our remarks:—

1. That the companies are, by their Bills, seeking a general increase of their merchandise rates. It is a well-known fact, and one that is frequently brought forward in railway law cases, that the companies do not always charge the maximum rates authorised under the existing Acts. That is to say, they have a right to charge such high rates that in some cases they are too high to be enforced,—the

traffic will not bear it. They now seek for confirmation of these powers, and, in some cases, for authority for still higher rates. The companies say that, in looking at the proposed rates, they should be compared with the maximum charges at present authorised, and not with the actual rates now in force, and that such a comparison would show but little difference except where their present powers are insufficient to pay them. They further say that they are willing to leave those cases in which they ask for increased powers in the hands of a Parliamentary Committee. In the present depressed state of trade this is naturally regarded with alarm. By the companies' own argument it is allowed that the present actual rates are below their statutory powers, and yet complaints come in from all quarters that these rates are excessive, and are destroying trade and driving it away altogether from various manufacturing districts. The companies, in seeking powers to retain, and in some cases advance, their maximum rates, give the impression that, so soon as opportunity offers, they will advance the present actual rates; and, though they claim to be merely framing simple and equitable mileage scales, there is no sign of any abatement in the opposition on this head.

2. That the proposed classification is improper and unjust to traders. The classification referred to is framed on the basis of the Railway Clearing House classification, which has been used by all the railways of any importance for many years. The legal classifications of goods are hardly worth the name, so few articles being enumerated. They are really of no service whatever,—except for lawyers to fall back upon in cases of disputed rates, when they find that it suits their purpose. The classification to be submitted to Parliament is elaborate and comprehensive, and makes provision for nearly all articles of commerce that can be mentioned. It is the result of the whole experience of the past, as the Railway Clearing House add to their classification every year new or hitherto unprovided-for articles of commerce. There are eight classes, viz.:—two for heavy mineral traffic, designated M(a) and M(b); special class (S) for other heavy and undamageable articles; and classes 1 to 5 for general merchandise.

This is a decided improvement upon the old system, and if the unfair provisions complained of were modified the rejection of the Bills on this count would not be advisable. In reality, the rates are at the present time governed almost as much by the Railway Clearing House classification as by Acts of Parliament, and had not the companies taken the opportunity of advancing certain articles a class higher

there would have been but little objection to this clause; but they have taken the course just indicated; and this, it will be seen, involves a further increase in the freightage of articles so dealt with. In this matter, again, the companies rely upon a full inquiry in committee resulting in any defects in the classification being rectified, claiming that it has been compiled with great care and difficulty, in order to replace the antiquated measures regarded as useless by both parties.

3. That under the Bills preferential rates for foreign produce will be legalised and extended. This is hardly correct, as the question is not dealt with by the Bills at all. The point is, that it ought to be. We cannot conceive that Parliament would object to the insertion of clauses restraining the companies from continuing to give our foreign competitors this undue preference in the matter of freightage, if it is proved that home trade is thereby prejudiced. The companies look at it in this light. They are obliged (they say) to quote low rates for import and export traffic to large freighters to meet the demands of competing ports, and they do so without any wish to put home trade at a disadvantage. Mr. Oakley says these rates can equally be made whether the Bills pass or not, but he will find that this position will be assailed. Mr. Magniac's remarks upon this subject in a speech recently delivered at a meeting of the London Chamber of Commerce (at which Sir Edward Watkin was present) are very significant. He said that he considered it an injustice that a preferential rate should be given to foreign goods, and urged all commercial men to protest against this; and his remarks were received with applause. This point is certainly one which requires close attention, but we cannot see that it is affected by the measures under consideration.

4. That the right of the companies to charge station terminals will be recognised. This is the most important point involved, and the one upon which the opponents of the Bills seek their entire rejection. The companies claim the right to charge for services rendered at the forwarding and receiving stations, in addition to the mileage rates. As the law stands at present, they are only authorised to charge so much per mile, inclusive of all incidental services; but, as a matter of fact, they always charge for terminals,—that is, when dividing the receipts for through traffic, a certain sum is put aside to cover these services, the remainder being divided between the companies interested according to the distance conveyed. They are enabled to do this through the circumstance already dwelt upon,—viz., their powers being so frequently in excess of the rates employed. When called to account for

high rates, they can, in such cases as these, maintain their position by showing that they are within the limit. Sometimes, on the other hand, their powers are found to have been exceeded, and a statement is handed in showing how the rate is made up, when they try hard to get a judgment affirming their right to the items set down for terminals. Though the decisions of the courts have invariably been against the companies, one, at least, of the Railway Commissioners has confessed to considerable doubts as to the intention of Parliament with regard to these charges. We refer to Mr. Price, who, in delivering judgment in a case of this nature, stated that he was convinced that Parliament did intend to grant something for the use of stations at the time of passing the old Acts, but failed to express their intention in a sufficiently clear manner to enable him to give a decision in favour of the companies. After such remarks as these, it is but natural that the latter should redouble their efforts to obtain Parliamentary sanction for these charges; and accordingly clauses are inserted in the Bills under notice, to enable them to charge for terminals, the amounts to be such as the Railway Commissioners may consider reasonable. Now, as to the objections under this head. It must be remembered that these charges are to be in addition to the scale rates, it being allowed that the latter, in long distances, are too high to be used. It is, therefore, more upon short distances that the companies require power to add terminal charges. The opposition to the clauses is in consequence of the amounts to be added being left to the companies, subject to the approval of the Commissioners upon a case being brought before them. In this respect, the matter would remain as before,—a costly inquiry being necessary in every case to ascertain the opinion of the Commissioners as to the reasonableness of the demands. Recent law cases have shown that most exorbitant terminal charges are included in the rates. Again, when pressed, the companies will produce an analysis of the rate in dispute, showing the proportion going for terminals, to the sixteenth of a penny. This occurred in the case of Kempton & Great Western Railway,—which case, it may be mentioned, has again been re-opened at the instance of the defendants, showing the wearisome nature of a contest of this nature. In this case the rate was, we believe, 8s. 4d. per ton,—it was certainly exactly so many pence per cwt. (thus being convenient for calculation),—and it is quite safe to doubt very strongly if sixteenths of a penny per ton were thought of when the rate was quoted. It naturally follows that traders look very suspiciously upon analyses of this kind. It is certain that the amount of terminal charges would vary considerably in the case of different stations; as the cost of construction and maintenance, local rates, &c., is very different. The cost of cartage, too, is a great factor in determining these charges, as in large towns this amounts to some two or three times the sum for which it can be performed in smaller ones.

Altogether the question is a very complex one, and a satisfactory solution of it would be very acceptable to all concerned. But, whether rightly or wrongly, everybody is afraid that the effect of the Bills will be to increase the already heavy charges for freightage by rail. It is beyond question that, if they chose, the companies could advance many rates forthwith, without waiting for new powers, and no legislation can be regarded as satisfactory that would, in the slightest degree, add to the yoke. The Chairman of the North-Eastern says that he believes that for certain articles reductions will be effected, and that the cattle tolls,—which, it was feared, would be advanced,—will remain unaltered. Mr. Oakley, the Hon. Secretary of the Railway Association, asserts that the companies have not the slightest intention of acting against the interests of trade or agriculture; but the opponents of the Bills remain unconvinced. Every day brings additions to their ranks, opposition coming from all classes. Not the least significant is that of the Common Council of London, who, on the 12th day of

February, at a meeting presided over by the Lord Mayor, decided to oppose the Bills "in all their phases," and to communicate with other public bodies to secure united action. The same feeling seems to pervade all meetings held to consider the subject, except, of course, the half-yearly meetings of the Railway Companies themselves. The shareholders have, in most cases, had the principles of the proposed measures explained to them, and have agreed to the Bills being submitted; the London and North Western Company, however, having decided to hold a special general meeting for the consideration of theirs. The struggle will, doubtless, be confined to those interested in the matter, as Mr. Chamberlain, replying to a deputation which waited upon him in the early part of February, advised the opponents of the Bills to impress their objections upon their members, so that the latter would be in a position to submit them fully to Parliament. It may be inferred from this that the Government do not intend to interfere, Mr. Chamberlain, probably, having had enough trouble already over railway legislation. His suggestion is being carried out, and, at a meeting at Manchester on February 10, Mr. Agnew, M.P., was sanguine enough to assure his hearers that the Bills would never reach a second reading.

NOTES.

THE awards of the Institute of Architects for the Soane Medalion, the Tite Prize, and the Silver Medal for measured drawings of existing buildings, are mentioned in another column. The drawings have been on view at the Institute during the week. We concur in the selection in every case, but only with un-mixed satisfaction in the case of the silver medal. Mr. Coxhead's drawings of St. Mary Ottery are an admirable set, representing a great deal of labour, and very well drawn. For the Tite Prize Mr. Campbell's design was the only one that could be selected; it is far beyond all the others in ability, but it is very French Italian, so to speak, and there is rather too much of the "Casino" style about it. Not one of the competitors seems to have realised what sort of thing it was which was intended to be promoted by the bequest of Sir William Tite, who would be rather aghast if he could see the kind of work which is supposed to come under the head of "Italian Architecture." Mr. Mitchell's Soane design hits best the idea of a municipal mansion, and has the most force and character of the set, though it is too palpable an imitation of the style of drawing and detail of an eminent artistic architect. "Acanthus," to which the Medal of Merit has been given, is a grandiose palatial Italian design, sufficiently suitable to the occasion. "Semper pulchrior" is a very elaborate and finely-drawn *rifacimento* of Francis I. architecture, not unsuitable to the purpose; and there is character in the design "Weave truth with trust"; the drawing of the perspective barely does justice to the design. Most of the designs are a little too grandiose for the subject; and "Labor" is a town-hall rather than a mansion. It is a pity that the Council gave so many subsidiary medals for the measured drawings; several of the sets were very good; but to reward nearly all the competitors is lessening the value of the first prize.

THE thirteenth annual Congress of French Architects will open at the Hemicycle of the Ecole des Beaux Arts, on the 8th of June, and close on the 13th of June. The programme will include some interesting visits, among others to the "Imprimerie et la Librairie" the hospital constructed at the castle of the Duchesse de Galliera, at Clamart, the suburbs and other portions of the Louvre, and the architectural monuments of Rouen. Among the papers and discussions, besides the notice of architecture at the *Salon*, and of the "Congrès des Sociétés Savantes," at the Sorbonne, and the annual report as to prizes granted by the Société, there will be an archaeological paper by a member of the "Académie

des Inscriptions et Belles Lettres," a study on ceramic art, and a notice of the life and works of the late M. Paul Aladie. The programme of the Congress, which is in preparation by the secretaries of the "Société Centrale des Architectes," will shortly be published, giving the names of the architects who will direct the visits to buildings, as well as those of the readers of papers. A general meeting of the supporters of the "Caisse de Defence Mutuelle des Architectes" (now numbering 130) will be held during the Congress, for the purpose of settling definitely the constitution of that Association.

THE case of Spackman *versus* the Plumstead District Board of Works, which was before the House of Lords on the 26th ult., is of considerable importance to builders. The appellant had erected certain one-story shops on the forecourts of some houses in Lee High-road, which were considered by the Plumstead District Board to be beyond the general line of buildings, and the Board took proceedings under the 75th Section of the Metropolitan Management Act, 1862. On the hearing at the police-court, the magistrate, Mr. Marsham decided that he was not bound to accept the certificate of the Superintending Architect of the Metropolitan Board of Works with regard to the general line of buildings in the road as conclusive, and that he was at liberty to decide a line for himself, taking into consideration the line of buildings in other portions of the road not dealt with by the Superintending Architect's certificate. The Plumstead District Board, being dissatisfied with this decision asked for and obtained a case for the consideration of the Queen's Bench Division, who reversed the magistrate's decision, holding that the magistrate was bound to accept the Superintending Architect's certificate as final. This judgment was upheld by the Court of Appeal, the Master of the Rolls, however, dissenting. Mr. Justice Fry, in giving judgment, remarked that the Superintending Architect was, in his opinion, a better judge of technical questions than a magistrate, and that if his decisions were acted upon a more uniform practice would obtain with regard to lines of frontage that would be the case if the matters in dispute were subject to the judgment of different persons. This decision was upheld by the House of Lords, the peers present being the Lord Chancellor, Lord Watson, Lord Bramwell and Lord Fitzgerald, and the appeal was dismissed with costs. The question was consequently remitted to the magistrate to decide, in accordance with the finding of the Court of Appeal.

THE of the many travellers in North Italy give heed to the wonderful system of irrigation canals in Piedmont, which yield 125,550 gallons of water per second, distributed over 1,680,400 acres of land, while those of Lombardy yield 95,355 gallons over 1,680,400 acres. The Cavour Canal, constructed within the last few years, draws its supply from the rivers Po and Dora Baltea, and has a flow of 29,200 gallons per second, watering 40,000 acres at a cost of 32,000*l.* per mile, or a total of 1,600,000*l.* Its volume is now to be increased by 5,300 gallons per second. A smaller subsidiary canal gives 18,540 gallons per second, and cost 24,154*l.* per mile. The canals in this district are not only used for irrigation, but also for motive power, by which the water is raised to higher levels. On the steep slope of the Dora Baltea near Turin, three canals,—the Toreia, Aghiano and Rothe,—flow parallel to each other, though on different levels, the water of all these being used at the top of the hill, 62 ft. above the highest of them. A stream of 154 gallons per second is diverted from the Toreia Canal, and carried down the hill by a lead pipe, until it meets the Aghiano Canal. Here it is pumped up to the summit level by eight pumps worked by four turbines driven by a fall of water taken from the Aghiano, and allowed to fall into the Rothe, by joining which, it is available for irrigation. By this means not a drop is wasted. The Italian engineers have gone on the principle of constructing the works

on a vast scale, so as to have everything on a uniform arrangement, and avoid constant alterations, and by this means they have succeeded in utilising every drop of water and making North Italy a marvel of fertility.

THE mode in which not only architecture, but also landscape as affected by architecture, have been at various times profoundly modified by religious or political change, or by scientific discovery, is often overlooked. It was wholly ignored by many of the greatest Italian painters, who were wont to enrich their charming little views of Palestine in the time of Herod the Great with the turrets and spires of Catholic Italy. One of the latest examples of a silent but very noticeable change of the kind that has come to our knowledge is that of the introduction of corrugated iron, as a roofing material, into Southern Africa. Where springs or wells allow of the rich vegetation that rewards the industry of the Dutch colonists, among wastes of interminable sand, rise fruit or forest trees of exotic growth. Beneath their shade the farm-house,—the church, the store, the shanty, rise,—usually built of red brick, and roofed with plates of corrugated iron. As we can remember the first introduction of this material into our own country, some forty years ago, it is evident that this transformation of the African landscape must be of comparatively modern origin. Contemporaneously, and possibly with less obvious reason, the black and brown natives of the country have clothed themselves in European attire, shabby and ill-fitting trousers by no means adding to the picturesque ensemble of the scene.

IN reference to the discussion on "Roof Coverings" at the recent meeting of the Institute of Architects, Messrs. Barton & Sons, of Broseley, ask us to call attention to the fact that data as to the behaviour of the old hand-made roofing tiles in bad weather would not necessarily hold good in regard to the same class of tile as now made by machinery, with the angles all mechanically equal. They add some practical remarks as to the laying of tiles, which may be useful:—"Care should be taken that the tiles are put close up to each other, or the consequence is that they overrun each other, and in a very short distance along the course and in a very short distance along the course the overrun is sufficient to cause a straight joint, which, of course, can never be weather-proof. As every one knows, there is a slight difference in the shrinkage in burning, and the tiles will sometimes vary a little in width, causing an overrun, but the introduction of a special made narrower tile at intervals will restore the truth of joint. In this neighbourhood many roofs are covered with seconds or even thirds tiles, not good enough for the market, but being laid quite dry without any rendering, pointing, or torching, but with great care as to breaking joint, the roofs are weather-proof."

THE owners of the Marylebone Theatre were fined 25*l.* on Monday last by Mr. De Rutzen for neglecting to comply with a notice served upon them by the Metropolitan Board of Works requiring them to make certain structural alterations to the theatre in order to secure the reasonable safety of the public. The alterations which had not been carried out were the removal of the whole of the dressing-rooms, lumber-rooms, and store-rooms under the stage and auditorium; the construction of an additional staircase to the gallery; and the removal of the handrail and balusters of the principal staircase and the substitution of a close balustrade of brick or stone.

A SERIOUS accident has happened at Bournemouth from the sudden fall of part of a building in course of erection as a hydro-pathic establishment, on the West Cliff. A local paper says:—

"Between thirty and forty workmen, including bricklayers, carpenters, and labourers, were at work there on Saturday, several of them being engaged on some scaffolding on the fourth story. Suddenly, and from some unexplained cause, the chimney-stack gave way, and carrying with it a

large portion of a party-wall, together with an iron girder of unusual strength (about 7 cwt.), fell with a loud crash to the ground beneath, a distance of about 50 ft. The wooden joists of the two floors were, of course, completely smashed by the falling mass of brickwork, the weight of which is estimated at between eight and nine tons. Unfortunately five men were knocked from the scaffold, and fell with the brickwork, being more or less buried in the debris at the bottom. To use the words of a spectator, who, a moment before the accident, was counting the men at work on the building, the bricks came toppling down like a pack of cards, carrying the men with them."

From what we hear, we suspect that this was one of the cases in which buildings at Bournemouth (a great field of building speculation) are carried out by men who have taken up the trade of contractor without any of the special knowledge requisite to carry out buildings properly and safely. The injuries done to some of the men were very severe, and should any one of them not recover, we shall learn who is to blame; otherwise probably not. Should there not be a coroner's inquest on serious injuries as well as on deaths?

A CORRESPONDENT sends us the following advertisement:—

"BOROUGH OF LOUTH.—The Town Council will on the 10th day of March, 1885, APPOINT A BOROUGH SURVEYOR, at a Salary of 55*l.* No extras will be allowed.—For duties and further particulars apply to me. By order,

THOS. FALKNER ALLISON, Town Clerk,
Town Clerk's Office, Louth, 11th Feb., 1885."

What is the meaning of this? Is it expected that any one with the knowledge and experience to fill such a post adequately will accept such a salary?

THE Benchers of Gray's Inn recently pulled down and rebuilt the lofty wall on the west side of Gray's Inn-road, in front of Raymond's-buildings, but made no attempt to lighten its appearance by placing a dwarf wall and a palisade in lieu of the present wall, as they might have done. Looking to their indifference to the public advantage, it is perhaps too much to ask them to permit a glimpse to be obtained of their garden by the removal of the high wall on the south side of Theohald's-road, and the erection of a dwarf wall with an iron railing in place of the present unaccommodating enclosure to the garden. Let them call to mind what Lord Bacon, who once resided in Gray's Inn, says of the benefits derived from the contemplation of a garden.

THE Paris Society for the Protection of Works of Art (La Société des Amis des Monuments Parisiens) appears to be doing a good deal of work. Among the subjects considered at their last meeting were,—the restoration of the Porte St. Denis, the Hôtel Juigné (formerly the Hôtel Mazarin), the formation of a committee for protecting works of art by legislation, a hitherto unknown work of Philibert de Porme, the hemicycle of Delacroix at the Palais des Beaux Arts, the nomination of a committee to overlook future improvements and lines of frontage, a proposed site for the statue of Diderot, cleaning and scraping buildings, the arrangement of cemeteries, a communication from the English Society for the Protection of Ancient Buildings, topographical street names, and others. Among the members best known in England are MM. Cahanel and Yvon, as representing the painters, and MM. Garnier, Charles Lucas, Ruprich-Robert, Questel, and Vandremere, as representing the architects. Through the intervention of the society, the Porte St. Martin is to be repaired instead of being restored, as was at first proposed; and the front of the Hôtel de Chinay, 17, Quai Malaquais, formerly the Hôtel Mazarin, which has been recently purchased by the Government for the purpose of enlarging the École des Beaux Arts, is to remain untouched. The courtyard of the hôtel is to be covered with a glazed roof, and will be converted into a museum.

THE *Bulletin Mensuel* of the "Société Centrale des Architectes" contains a notice of Mr. W. H. White's book on "Archite-

cture and Public Buildings," by M. Charles Lucas. The book was noticed at length in our columns July 9, 1884. Our Paris *confère* thinks that Mr. White may have taken a somewhat too pessimist view of the state of public architecture in England; but it is worth note, as the accuracy of the facts and conclusions about architecture in Paris has been called in question by some reviewers in this country, that M. Lucas especially commends the accuracy of the work, which, he says, gives a real authority to it; and he regrets that the book was not written by a Frenchman, or, at least, translated into French. It appears to have attracted a great deal of notice in France.

THE current number of the *English Illustrated Magazine* contains a very interesting article, both artistic and practical, by Mr. Geo. Simonds, the sculptor, on the system of bronze casting à *cire perdue*, the only system by which true justice can be done to a work of fine art in bronze. It is illustrated by some sections showing the way in which the moulds for large statues are built up, and the arrangement of the conduits for pouring in the molten metal. It is an article of real value and interest.

TWO important pictures illustrative of Biblical subjects were simultaneously open to private view last Saturday; paintings so utterly opposite in their object and method that there was a kind of unconscious irony in the coincidence. One of these, at the Gallery of the Fine Art Society, in New Bond-street, was Mr. Holman Hunt's painting of the "Triumph of the Innocents," his second painting of the subject; the first one having occupied him long years of struggle with a mechanically defective canvas, or rather sheeting, which strained and distorted the work. The first picture is now in the way of being made good; but, in the meantime, the second has been painted, and Mr. Ruskin says it is the greatest sacred picture of the day. We can only say this would be, to our thinking, tantamount to a confession that "sacred pictures" are things *passés*. The painting represents the flight into Egypt, with the addition of an attendant band of the spirits of the murdered "Innocents," very plump and fleshy little spirits; but forming a bright galaxy of movement and colour round the central group. The spiritual children advance on a flood of spiritual water, which has a way of rolling out into great spherical bubbles within which are portrayed future events. Joseph, with his carpenter's basket and spare shoes slung on his back, is turning round, so we are told, to see if there are any signs of pursuit. Signal fires, "still lighted in Syria in time of trouble," are burning on the hills. Dogs come out of the mill-house to hark at the passers-by, as we suppose they "still do in Syria." It is needless to say that there is a great deal of superb painting of detail in the picture, unsurpassable in this way in its thoroughness; a wondrous light in the stars, a conscientious thoroughness in the execution of minor details, for it is Mr. Hunt's work. But in regard to the intellectual objects of painting, it is a picture only suited to the interest of children, or persons of very childlike perceptions. It is melancholy to see such technical power and such earnestness of work expended on the production only of an illogical blending of superstitious legend with over-acted realism, which will lose all the little interest it has before the present generation has lived its life out.

THE other work referred to, Munkacsy's "Calvary," which is being exhibited at the Egyptian Hall, Piccadilly, and which is probably one of the largest easel pictures ever painted, is the very antipodes of Mr. Hunt's picture in feeling and intention. Munkacsy aims at giving the event as it may have happened, without any assumption of the supernatural in any way. In remarking upon his former large work, "Christ before Pilate," we spoke of the remarkable realisation of the various personages and types of men repre-

sented. This is hardly so strongly seen in the present picture. What one feels most strongly in it, perhaps, is the painful accentuation of the reality of the punishment of crucifixion, the most cruel mode of execution ever practised by a civilised people. The groups round the cross,—the women, the Roman soldiers, with their air of perfunctory attendance "on duty," and the Rabbin discussing the matter, are thoroughly and powerfully rendered. But the general impression left by the picture is that it is not so much pathetic as painful. It illustrates, however, to a certain extent, what we regard as the true attitude of modern painting in dealing with religious narrative,—the historical and human attitude rather than the mystical; but something more, no doubt, is required, and that something Munkacsy does not seem to possess. The picture has no feeling. The extravagant laudations of it in print, put into the hands of visitors, are in very bad taste.

LETTER FROM PARIS.

We have already sufficiently noticed the industrial crisis which is throwing Paris off its balance, and it is unnecessary to insist on the desirability of opening as soon as possible the large labour-yards for the great public works which are needed. The question is not only an economic but a political one, and the situation is so grave that it is strange to find the Government so little occupied with it. The partial suppression of the fortifications of Paris, of which we spoke in our last letter, appears precisely the occasion ready to hand to furnish for a long time profitable employment to unemployed labour. The uselessness of this fortified *enceinte* is by this time demonstrated, and the bastions constructed not long since by M. Thiers having proved unequal, in 1871, to the task of repelling the German army, have, in fact, served no one's purpose except that of the Commune armed against the regular Government.

Great disappointment has accordingly been felt here that, in spite of the promises of his predecessors, the new Minister of War has opposed his formal *non possumus* to the claims of the Paris municipality. All the plans which it had been in some way authorised to carry out, all the projects which it had preferred, are cut short by the veto of the Committee of Fortifications, and the question seems only too likely to be buried for good and all.

In the mean time, while the stoppage of work continues and the distress is general, we are looking here and there for palliatives. The directors of the leading journals of Paris have taken the initiative in a *fête de bienfaisance* which is to be held on the 1st of April next. The Municipal Council have liberally put at the disposal of the committee the great range of rooms, scarcely completed, of the new Hôtel de Ville; there is to be a ball and a concert; the price of entry will be 20 francs, and 20,000 tickets will be put in circulation. The committee hope that, in spite of the pretty high price, curiosity will draw a great many persons, especially foreigners, to this monster *soirée*, of which the programme is really very attractive. We may add that M. Alphand, Directeur-Général de Travaux de Paris, is charged with the organisation of the *fête*. The name of this incomparable "metteur en scène" is a guarantee of success and of help for the poor of Paris.

Speaking of extensive works, we may observe that the contracts for the Gare St. Lazare, the enlargement of which we have already announced, have been let since 26th of February, and the work is now in full swing. This important work is under the care of M. Juste Lisch, Inspecteur-Général des Monuments Historiques, who is charged by the Compagnie de l'Etat to construct a monumental railway station between the Rue d'Amsterdam and the Rue de Rome.

How long shall we have, each month, fresh losses to mourn in the world of art? This month it is M. Du Sommerard, whose reputation was European, and whose unceasing care from 1814 to his death was to increase the treasures collected in the Musée de Cluny by his father, in collaboration with whom he wrote that extraordinary work of erudition on *Les Arts du Moyen-Age*. M. Du Sommerard had succeeded Chas. Blanc as member of the Académie des Beaux Arts. His death leaves a great void, and the Government are in great difficulty about a successor to him at the

Musée de Cluny. M. Alfred Darcel, Director of Les Gobelins, is, however, much talked of for the post. In that case, the administration of the latter establishment will be entrusted to M. Gerspach, chief of the Service des Manufactures Nationales.

The city of Paris, in its turn, has lost in the Comte de Licsville, joint curator of the Municipal Library, a patient collector, to whom we are indebted for the Musée de la Revolution, installed at the Hôtel Carnavalet. M. de Licsville, who had devoted his fortune to that curious collection of books, falence, fans, engravings, and jewels, had besides deposited at the Musée de Sèvres and at the Union Centrale des Arts Décoratifs a crowd of objects of great interest. He has left to the Municipality his house for the purpose of founding a school of design.

We will not quit this sad obituary subject without a word for another modest and conscientious artist, L'Heritier, the celebrated comic actor, who died the other day at the age of 78, and who has gladdened the hearts of several generations of playgoers. He formed part of that pleiad of actors now disappeared, who have distinguished the Palais Royal Theatre, —Grassot, Ravel, Numa, Alcide Touzé, Gil-Pérez, and Hyacinthe. The latter still plays, in spite of his advanced age, but is only the shadow of his former self.

The theatrical question plays a great part here. More than any other, perhaps, the population of Paris is greedy of spectacle. It is true there has been lately a notable veering about of public taste, formerly directed almost exclusively to the drama. There is now a great run on music, and the popular concerts directed by MM. Colonne, Benjamin Godard, and Lamoureux are very successful. Accordingly, the municipal administration, wishing to satisfy these new tendencies, has resolved to request the National Academy of Music to give, with the aid of certain subsidies from the municipality, thirty-six popular representations at low prices. The Municipal Council has looked favourably on this innovation, which will shortly be voted, and will permit slender purses and small fortunes to realise the splendour of the new opera house and the beauty of great Classic works hitherto reserved for a privileged class, at the same time that it will develop in the Republic the taste for serious musical art. This is not the only encouragement which the City of Paris has given to the art of music. It has instituted a great competition among all French artists for the composition of a grand symphony for orchestra, *solo*, and chorus. The scores to the number of seventeen are at present submitted to a jury of eminent composers, including Saint-Saëns, Mosseuet, Delibes, &c. The successful candidate, whose work will be performed at the cost of the municipality, will receive also a prize of 10,000 francs.

From the Opera House at Paris to the Theatre at Nice is a transition the more easy since the new building, which was inaugurated on the 7th February last, is, in some sort, a copy of the work of M. Charles Garnier. It will, no doubt, be remembered that the Theatre at Nice was destroyed in the terrible fire which had so many victims. The construction which has replaced it is the work of M. Aune, who has directed his special attention to expedients for avoiding such a catastrophe in future.* The interior decoration is very rich, and special mention is made of the lighting apparatus, the lustres, brackets, and candelabra executed at the foundry of the brothers Thiebaut, from the designs of Jules Coutan, a young sculptor of great talent.

For some years past the civil buildings of Paris and its neighbourhood have been the object of very important artistic work, and an important competition, organised by the Department of the Seine, for the decoration of the Mairie, at Courbevoie, has just been decided.

The prize has been carried off by M. Seon, pupil of M. Puvis de Chavannes, who, after the first decision, had for competitors MM. Delahaye and Picard, pupils of MM. Bonlange and Gérôme, and M. Chartran, pupil of M. Cabanel, and holder of the Grand Prix de Rome. The compositions of these different artists, which have been exhibited at the Hôtel de Ville of Paris, show much talent and technical ability; but these good qualities are spoiled by incredible

faults of composition. There is, especially, a *mélange* of realism and allegory, which appears the more out of place because the public taste has drifted far away from the Classic reminiscences and Academic traditions of the Ecole des Beaux Arts and the Villa Medici. Thus, for example, to symbolise betrothal, one of the competitors shows us, by the side of a young peasant girl fully dressed in modern costume, a veritable Arcadian *berger*, scarcely covered at all with the traditional animal's hide. The result is a contrast the more absurd, that the artist has given, as framework to his eclogue, a landscape sketched from actual locality. This contrast of nudity and modern dress is not only ridiculous, but almost improper.

It is also as the result of a public competition that there was executed the monument to Ledru Rollin, which was solemnly inaugurated on the 24th on the Place Voltaire. The statue of the celebrated tribune is the work of a young artist, —M. Steiner. It occupies the pedestal on which, before the war, stood the statue of Prince Eugene, now installed in the Jardin des Invalides.

While we are awaiting the annual *Salon*, exhibitions follow one upon another. After that of the water-colour artists, of which we spoke, here is a Union of lady artists, painters, and sculptors, about to open at the Palais de l'Industrie its fourth exhibition, which comprises nearly 300 works. There are some remarkable things there. Among them may be mentioned the very original sea pieces of Madame Elodie La Villette, the paintings of Mesdames Besnard, Ronner, and Annie Ayrton. Among the sculptures we may mention those of Madame Léon Bertain, President of the said Society, and of Claude Vignon (pseudonym of Madame Rouvier, the wife of the Minister of Commerce). The Society has consecrated two rooms to the work of a young Russian lady-artist, Mlle. de Bashkirtsaï, who died recently, and whose mother is about to found an annual scholarship for a poor artist who has obtained an award in the *Salon*.

We may mention, also, the exhibition of the works of Gustave Doré in the Boulevard St. Germain (from the 2nd of March to the 2nd of April); that of the works of Bastien-Lepage, which will be very shortly organised on the Quai Malaquais, in the rooms of the Hôtel Chimay, which the State is shortly about to acquire in order to enlarge the Ecole des Beaux Arts.

Lastly, from the 9th of March to the 9th of April, there will be held, in the Pavillon de Flore, an exhibition of works in black and white, which will include crayons, engravings, and drawings generally.

We are going to have at the Hôtel de Ville, where we are actively occupied with preparations for the *great fête* mentioned just now, a fine equestrian statue in bronze modelled by M. Fremiet. This eminent artist, from whom the Municipal Council have commissioned a grand candelabrum for the decoration of the State staircase, instead of confining himself to the ordinary vulgar caryatide holding a certain number of lamps, has conceived the happy idea of modelling a herald-at-arms, on horseback, in the costume of the fifteenth century, having on his body-armor the arms of the city executed in coloured enamel, and holding aloft a chandelier in his hand. This will give the principal light to the staircase. It is to be regretted that M. Fremiet has given to his work a green *patine* of a glaring tone which makes it look rather like plaster painted. But that is the one fault one can find, and it is not the less a bold work, of grand movement and frankly original.*

This "illuminating function" given to a statue recalls to our memory the celebrated colossal "Liberty" executed by M. Bartoldi for the City of New York. We learn that some Americans propose to offer to France, by public subscription, a reduction of this work, which will still not be less than 8 metres in height, and will be set up in Paris, in the Sixteenth Arrondissement, Place des États-Unis. The statue will be cast at the M.M. Thiebaut's foundry.

We conclude by announcing the recent creation, at the Gobelins, of a Museum of Tapestries, which will enable the public to appreciate the marvellous riches of our national manufacture. It is to M. Kaempfen, Directeur des Beaux Arts, that we owe the initiation of this excellent foundation, which will probably be of real service.

* An elevation and section of M. Aune's design will be found among the illustrations in the *Builder* of January 5, 1884.

* We hope to illustrate this work shortly.

WESTMINSTER ABBEY.*
