President of Purdue University, Lafayette, Ind.
- SMITH, CHARLES EMORY, LL. D.,
Postmaster-General; ex-U. S. minister to Russia; editor of *The Press*, Philadelphia, Pa.
- SMITH, GERRIT, Brooklyn, N. Y.

- SMITH, GOLDWIN, LL. D., D. C. L., Toronto, Canada,
Formerly Regius Professor of Modern History, Oxford University; author of *Lectures on the Study of History*; *Translations from the Latin Poets*; *Essays on Questions of the Day*; etc.
- SMITH, HERBERT H., A. M.,
Naturalist, Carnegie Museum, Pittsburg, Pa.; formerly a member of the Geological Survey of Brazil.
- SMITH, JOHN JAY,
Late superintendent Laurel Hill Cemetery, Philadelphia, Pa.
- SMITH, MUNROE, A. M., J. U. D.,
Professor of Roman Law and Comparative Jurisprudence, Columbia University, New York.
- SMITH, THEODORE E.,
Vice-president, Spencerian Pen Company, New York.
- SNIDER, VAUGHAN,
Secretary, M. T. Richardson Company, publisher of *Boots and Shoes Weekly*, New York.
- SONDERN, FREDERIC E., M. D.,
Fellow of the New York Academy of Medicine, New York.
- SPAHR, CHARLES B., Ph. D.,
Editorial staff, *The Outlook*, New York.
- SPERRY, REV. WILLARD A., D. D.,
President of the Olivet College, Olivet, Mich.
- SPOFFORD, AINSWORTH R., LL. D.,
Formerly Librarian of Congress, Washington, D. C.; author of *Library of Historic Characters and Famous Events*, etc.
- STAGG, A. ALONZO, A. B.,
Associate Professor and Director of the Department of Physical Culture, University of Chicago, Chicago, Ill.
- STALEY, CADY, Ph. D., LL. D.,
President of the Case School of Applied Science, Cleveland, O.
- STANDISH, J. V. N., Ph. D.,
Ex-President of Lombard University, Galesburg, Ill.
- STANTON, ELIZABETH CADY,
Honorary president National American Woman Suffrage Association; joint author of *The History of Woman Suffrage*; New York.
- STANTON, THEODORE, A. M.,
Journalist and author, Paris, France.
- STANWOOD, EDWARD, A. M.,
Editorial staff of *The Youth's Companion*, Boston, Mass.
- STARBUCK, REV. CHARLES C., A. M., Andover, Mass.
- STEINER, BERNHARD C., A. M., Ph. D.,
Librarian of Enoch Pratt Free Library, Baltimore, Md.; author of *History of Education in Connecticut*.
- STEINITZ, WILLIAM,
Late chess editor of the *New York Tribune*, New York.
- STEPHENS, W. P.,
Yachting editor, *Forest and Stream*, New York.
- STEPNIAK, SERGIUS,
Russian agitator; author of *The Career of a Nihilist*; *Underground Russia*; *Turks Within and Without*; *Historical Poland and the Muscovite Democracy*; etc.
- STERRETT, JOHN ROBERT SITLINGTON, Ph. D.,
Newton Professor of Greek Language and Literature, Amherst College, Amherst, Mass.
- STEVENS, EDWIN A., Hoboken, N. J.
- STEVENS, REV. GEORGE B., Ph. D., D. D.,
Buckingham Professor of New Testament Criticism and Interpretation, Yale University, New Haven, Conn.; author of *The Pauline Theology*, etc.
- STEVENS, W. LE CONTE, Ph. D.,
Professor of Physics, Rensselaer Polytechnic Institute, Troy, N. Y.
- STEWART, MCLEOD,
Barrister; ex-mayor of Ottawa, Ont.
- STEWART, OSCAR MILTON, Ph. D.,
Instructor of Physics, Cornell University, Ithaca, N. Y.
- STILLMAN, WILLIAM J.,
Artist and critic; correspondent of the *London Times*; Rome, Italy; author of *In the Track of Ulysses*; *The Acropolis of Athens*; etc.
- STOCKBRIDGE, HON. HENRY, Baltimore, Md.
- STOCKTON, ALFRED A., LL. D., D. C. L., Q. C., M. P. P.,
Barrister, St. John, New Brunswick.
- STODDARD, JOHN TAPPAN, A. M., Ph. D.,
Professor of Chemistry and Physics, Smith College, Northampton, Mass.
- STRONG, REV. AUGUSTUS H., D. D.,
President of the Rochester Theological Seminary, Rochester, N. Y.
- STRYKER, REV. MELANCTHON W., D. D., LL. D.,
President of Hamilton College, Clinton, N. Y.
- STURGIS, RUSSELL, A. M., Ph. D., F. A. I. A.,
Ex-President of the Architectural League of New York, New York; author of *European Architecture, an Historical Study*, etc.
- SWITZLER, WILLIAM F.,
Editor and publisher of the *Missouri Democrat*, Boonville, Mo.
- SYMONDS, CHARLES S.,
President of the Utica City National Bank, Utica, N. Y.
- TALCOTT, H. W., lawyer, San Diego, Cal.
- TAUSSIG, FRANK WILLIAM, LL. B., Ph. D.,
Assistant Professor of Political Economy, Harvard University, Cambridge, Mass.; author of *Tariff History of the United States*.
- TAYLOR, JAMES M., D. D., LL. D.,
President of Vassar College, Poughkeepsie, N. Y.
- THOMPSON, ROBERT ELLIS, A. M., Ph. D., S. T. D.,
President of the Central High School of Philadelphia; formerly Professor of History and English Literature, University of Pennsylvania, Philadelphia, Pa.
- THOMPSON, WALTER J., real estate agent, Tacoma, Wash.
- THORNTON, WILLIAM M., LL. D.,
Formerly Chairman of Faculty, University of Virginia, Charlottesville, Va.
- THURBER, CHARLES H., A. M.,
Associate Professor of Pedagogy, Chicago University, and dean of Morgan Park Academy, Morgan Park, Ill.
- THURMOND, G. E.,
Superintendent of schools, Santa Barbara co., Cal.
- THURNEISEN, RUDOLPH, Ph. D.,
Professor of Comparative Philology, University of Freiburg, Baden, Germany; author of *Keltoromanisches*; *Mittelirish Verslehren*; etc.
- THURSTON, ROBERT H., LL. D., Dr. Eng.,
Director of Sibley College and Professor of Mechanical Engineering, Cornell University, Ithaca, N. Y.; author of *History of the Steam-engine*; *Materials of Engineering*; etc.
- THWAITES, REUBEN GOLD,
Author of *Story of Wisconsin*, and secretary of the State Historical Society of Wisconsin, Madison, Wis.
- TIDBALL, JOHN C.,
Brevet major-general U. S. army.

- TIELE, CORNELIS PETRUS,
Professor of Dogmatic and Practical Theology, of the Comparative History and Philosophy of Religions, and of the Babylonian and Assyrian Languages, University of Leyden, Leyden, Holland.
- TILLET, Rev. WILBUR F.,
Professor of Systematic Theology in Vanderbilt University, Nashville, Tenn.
- TORRANCE, STILES A.,
Cornell University, Ithaca, N. Y.
- TOWNSEND, MARTIN INGHAM, LL. D.,
Ex-Member of Congress, Troy, N. Y.
- TOWSE, J. RANKEN,
Editorial staff of *The Evening Post*, New York.
- TOY, CRAWFORD H., LL. D.,
Hancock Professor of Hebrew and other Oriental Languages, and Dexter Lecturer on Biblical Literature, Harvard University, Cambridge, Mass.; author of *The Religion of Israel*; *Judaism and Christianity*, *a Sketch of the Progress of Thought from Old Testament to New Testament*; etc.
- TRATMAN, E. E. R., C. E.,
Associate editor *Engineering News*, New York.
- TRUAX, CHARLES,
President Chas. Truax, Greene & Co., makers of artificial limbs, Chicago, Ill.
- TRUMBULL, Rev. HENRY CLAY, S. T. D.,
Editor of *Sunday-school Times*, Philadelphia, Pa.
- TUCKER, R. SCHUYLER,
Secretary, J. B. Brewster & Co., coach and carriage builders, New York.
- TURNER, FREDERICK JACKSON, Ph. D.,
Professor of American History, University of Wisconsin, Madison, Wis.
- TUTTLE, HUDSON, Berlin Heights, Ohio.
- TYLER, LYON GARDINER, A. M., J. U. D.,
President of the College of William and Mary, Williamsburg, Va.
- TYLRR, Rev. WILLIAM S., LL. D.,
Williston Professor of the Greek Language and Literature, Amherst College, Amherst, Mass.
- TYNDALL, JOHN, LL. D., F. R. S.,
Late Professor of Natural Philosophy and Superintendent of the Royal Institution, London, England.
- VAIL, CHARLES D.,
Registrar of Hobart College, Geneva, N. Y.
- VALENTINE, MILTON, D. D., LL. D.,
Professor of Systematic Theology in the Seminary of the General Synod of the Lutheran Church, Gettysburg, Pa.
- VAN AMRINGE, J. HOWARD, Ph. D., L. H. D.,
Professor of Mathematics and dean of the School of Arts, Columbia University, New York.
- VAN NAME, ADDISON, A. M.,
Librarian, Yale University, New Haven, Conn.
- VENABLE, CHARLES S., LL. D.,
Professor of Mathematics, University of Virginia, Charlottesville, Va.
- VINCENT, JOHN H., D. D., LL. D.,
Bishop of the Methodist Episcopal Church, Buffalo, N. Y.
- WADDILL, JOHN B.,
State insurance commissioner, Springfield, Mo.
- WALKER, FRANCIS AMASA, A. M., Ph. D., LL. D.,
Late President of Massachusetts Institute of Technology; superintendent U. S. census 1870, 1880; author of historical, statistical, and economical works.
- WALLACE, JOSEPH, attorney-at-law, Springfield, Ill.
- WARD, LESTER F., A. M., LL. D.,
Palæontologist in charge of Fossil Plants, U. S. Geological Survey, Washington, D. C.; author of *Dynamic Sociology*, etc.
- WARFIELD, Rev. BENJAMIN B., S. T. D., LL. D.,
Professor of Didactic and Polemic Theology, Princeton Theological Seminary, Princeton, N. J.; author of *The Divine Origin of the Bible*, etc.
- WARFIELD, ETHELBERT D., LL. D.,
President of Lafayette College, Easton, Pa.; author of *The Kentucky Resolutions of 1798*.
- WARNER, Hon. DONALD T., Salisbury, Conn.
- WARREN, HOWARD CROSBY, A. M.,
Assistant Professor of Experimental Psychology, Princeton University.
- WARREN, MINTON, A. B., Ph. D.,
Professor of Latin, Johns Hopkins University, Baltimore, Md.
- WATSON, GEORGE C., M. S.,
Assistant agriculturist, Agricultural Experiment Station, Cornell University, Ithaca, N. Y.
- WEEDEN, W. B.,
Of Taft, Weeden & Co., agents of the Weybosset Mills, Providence, R. I.
- WELLING, JAMES C., LL. D.,
Formerly President of Columbian University, Washington, D. C.
- WELLINGTON, ARTHUR M., C. E.,
Late editor *Engineering News*, New York.
- WELLS, Hon. DAVID A., LL. D.,
Late U. S. Special Revenue Commissioner, Norwich, Conn.
- WENDELL, BARRETT, A. B.,
Assistant Professor of English, Harvard University, Cambridge, Mass.
- WHEELER, BENJAMIN IDE, Ph. D.,
President of the University of California; author of *Analogy and the Scope of its Influence in Language*; and joint author of *Introduction to the Study of the History of Language*; etc.
- WHITE, HORACE,
Editor-in-chief, *Evening Post*, New York.
- WHITE, ISRAEL CHARLES, M. E.,
Professor of Geology, West Virginia University, Morgantown, W. Va.
- WHITEHEAD, THOMAS,
Commissioner of Agriculture, State of Virginia; author of *Virginia: a Handbook*; Richmond, Va.
- WHITFORD, Rev. W. C., D. D.,
President of Milton College, Milton, Wis.
- WHITNEY, JAMES A., A. M., LL. D.,
Counselor-at-law, New York; formerly editor of *The American Artisan*, and first President of the New York Society of Practical Engineering.
- WHITNEY, WILLIAM D., Ph. D., LL. D., M. N. A. S.,
Late Professor of Sanskrit and Comparative Philology, Yale University, New Haven, Conn.
- WHITSITT, WILLIAM H., D. D.,
Professor of Church History, Baptist Theological Seminary, Louisville, Ky.
- WHITTAKER, ROBERT,
City editor of *The Daily Advocate*, Stamford, Conn.
- WILEY, HARVEY W.,
Chief of the Division of Chemistry, U. S. Department of Agriculture, Washington, D. C.

- WILLARD, DE FOREST, M. D.,
Clinical Professor of Orthopædic Surgery, Department
of Medicine, University of Pennsylvania, Philadel-
phia, Pa.
- WILLARD, FRANCES ELIZABETH, LL. D.,
Late President of the World's Woman's Christian Tem-
perance Union.
- WILLCOX, Capt. CORNELIS DE W., U. S. army,
Bureau of Information, Adjutant-General's office, Wash-
ington, D. C.
- WILLIAMS, GEORGE H., Ph. D.,
Professor of Inorganic Geology, Johns Hopkins Univer-
sity, Baltimore, Md.
- WILLIAMS, HENRY SHALER, Ph. D.,
Professor of Geology, Yale University, New Haven,
Conn.
- WILLIAMS, JOHN E., insurance agent, Streator, Ill.
- WILSON, Gen. JAMES GRANT, D. C. L.,
Author and editor; President of the New York Gene-
alogical and Biographical Society, New York.
- WILSON, L. N.,
Clark University, Worcester, Mass.
- WINCHESTER, CALEB THOMAS, L. H. D.,
Professor of English Literature, Wesleyan University,
Middletown, Conn.
- WING, HENRY H., M. S.,
Assistant Professor of Animal Industry and Dairy Hus-
bandry, Cornell University, and deputy director and
secretary of the Agricultural Experiment Station,
Ithaca, N. Y.
- WINGATE, CHARLES F.,
Sanitary engineer, New York.
- WINN, HENRY,
Lawyer, Boston, Mass.; candidate of the People's Party
for Governor of Massachusetts in 1891.
- WISSER, Lieut. JOHN P., U. S. army,
Assistant Professor of Chemistry, Mineralogy, and Ge-
ology, U. S. Military Academy, West Point, N. Y.;
author of a *Report on the Military Schools of Eu-
rope*, etc.
- WOOD, Rev. CHARLES JAMES, A. B., S. T. B.,
Rector of St. John's Church, York, Pa.
- WOOD, DE VOLSON, A. M.,
Professor of Engineering, Stevens Institute of Technol-
ogy, Hoboken, N. J.
- WOOD, F. E.,
Principal of Wood's Business College, Scranton, Pa.
- WOOD, HORATIO C., M. D., LL. D., M. N. A. S.,
Professor of Materia Medica, Pharmacy, and General
Therapeutics, and Clinical Professor of Nervous Dis-
eases, Department of Medicine, University of Penn-
sylvania, Philadelphia, Pa.
- WOODBURY, WALTER E.,
Editor of *The Photographic Times*, New York.
- WOODWARD, CALVIN MILTON, A. B., Ph. D.,
Professor of Mathematics and Applied Mechanics, dean
of School of Engineering and director of Manual-
training School, Washington University, St. Louis,
Mo.
- WOODWORTH, Rev. FRANK G., D. D.,
President of Tougaloo University, Tougaloo, Miss.
- WOOLFOLK, ADA S.,
Of the College Settlement in New York.
- WOOLSEY, THEODORE S., LL. B., A. M.,
Professor of International Law, Yale University, New
Haven, Conn.
- WORMAN, JAMES H., A. M.,
Formerly editor of *Outing*; formerly Professor of Mod-
ern Languages, Danville University, Tenn.
- WORSTELL, Miss MARY V.,
Editorial department, *St. Nicholas* magazine, New
York.
- WRIGHT, ALBERT A., A. M.,
Professor of Geology and Natural History, Oberlin Col-
lege, Oberlin, O.
- WRIGHT, C. B., A. M.,
Librarian, Middlebury College, Middlebury, Vt.
- WRIGHT, CARROLL DAVIDSON, A. M., LL. D.,
U. S. Commissioner of Labor; acting superintendent of
the eleventh census; Joseph Banigan Professor of
Political Science, McMahon Hall of Philosophy, Cath-
olic University of America, Washington, D. C.
- WURTZ, HENRY, A. M., Ph. D., New York.
- WYCKOFF, W. O.,
Of Wyckoff, Seamans & Benedict, manufacturers of
typewriters, New York.
- YATES, J. STUART, A. M., LL. B.,
Barrister, etc., Victoria, British Columbia, Canada.
- YOUMANS, WILLIAM JAY, M. D.,
Late editor of *The Popular Science Monthly*, New
York.
- YOVTCHEFF, E. S., Cambridge, Mass.
- YULE, Maj.-Gen. HENRY, C. B.,
Late of the Royal Engineers, Bengal; London, Eng-
land.
- ZACHOS, JOHN C.,
Late curator of library, Cooper Union, New York.
- ZÖCKLER, OTTO,
Professor of Ecclesiastical History and Apologetics,
University of Greifswald, Germany.

INTRODUCTION.

THE world moves, and we must move with it. So long as there is life and activity around us, no book of reference like a great cyclopædia can remain forever perfect in all its parts. The story of the past may be true and unalterable, but it must have an added chapter when the sun goes down and to-day becomes another yesterday. By far the greater part of a work like this, if it is well done in the beginning, remains trustworthy for a long time. But in certain matters frequent revision is desirable. In our country the most urgent call for this is created by the Federal Census, which is taken every tenth year. Others are occasioned by the mortality among eminent men; changes in the progressive sciences; discoveries, treaties, and alteration of political boundaries. These furnish the reason why this revision of the "Universal Cyclopædia and Atlas" now follows closely upon the thorough revision that it underwent only five years ago. The new figures of the Census of 1900 have been inserted in the articles on the States and cities; while every article on an important American city has also been subjected to careful revision by a competent person in the city itself, and thereby many items of information not touched by the census have been freshened. In some foreign countries there has been a new census, and the figures, so far as available, have been used. Men of thought and action whose history is written here have passed away, and others have been promoted to higher rank or have achieved new successes; the religious denominations have fresh results to show in their various activities; political changes have come with each revolving year; and the destructive operations of war, from which the world is seldom free, still go on. These are now recorded, the numerous maps have been subjected to careful scrutiny and correction, and a number of new maps have been inserted. The present revision has been made with every attention to accuracy, and it is believed to be sufficient to adapt the work to the needs of to-day and keep good its character as *the best cyclopædia* now offered to American readers.

ROSSITER JOHNSON.

September, 1901.

P R E F A C E .

THIS Cyclopædia first appeared in 1874, under the title of Johnson's Universal Cyclopædia, and at once took a leading place among the great works of General Reference. In 1884-86 it was subjected to a thorough revision by a large staff of distinguished editors and contributors. Many important articles were at that time rewritten, many new ones were added, and every new impression that came from the press had the advantage of such revision as could be made without changing the identity of the plates. It was subjected in 1892-95 to a still more thorough revision, and was greatly extended and reset in larger type; and another new edition, in twelve volumes, with appendices containing nearly two thousand new articles, is now issued under the title UNIVERSAL CYCLOPÆDIA AND ATLAS, with several new maps, the census figures of 1900, and such corrections as were necessary to bring it down to date.

The original plan of the work comprised five main features :

I. A special editor, recognized as an authority, in charge of each department.

II. Original work by distinguished specialists, chosen by the different departmental editors because of their thorough acquaintance with the subjects on which they wrote, and their ability to present these subjects in a way that would satisfy both the scholar and the general reader. Original Plan.

III. An analytical method of treating the larger and more complex subjects by presenting "each elementary topic under its own heading," thus avoiding the more lengthy treatises fitted only for professional experts, and facilitating ready reference by presenting in alphabetical order information adapted to the wants of men and women busily occupied with the affairs of life.

IV. The authentication of each article of importance by appending to it the author's name.

V. The inclusion among the biographies of brief sketches of noted *living men and women* in every department of learning, science, and action.

While many minor changes were introduced, the editors of the successive editions saw no reason to depart from this very admirable plan. In the edition of 1892-95 it was strengthened and developed at many points; the spelling of proper names was made uniform throughout the work, and more in keeping with modern usage; a new but simple system of respelling was introduced to indicate the pronunciation of difficult names; etymologies were added by the editor of the philological department whenever they seemed to be necessary; a more complete system of cross-references was introduced and carefully used; and a more compact method of treatment made it possible for the editors to introduce thousands of new articles. In the present greatly extended edition these admirable features have all been retained.

In General Physics, the department in charge of Edward L. Nichols, Professor of Physics in Cornell University, many of the articles—for example, that on *Acoustics*, prepared by Professor Ogden N. Rood—needed little change. Others were considerably revised, while several were somewhat abridged in order to make room for such new subjects of a special nature as had recently attracted great attention. Physics. The editor pre-

pared at least two hundred new articles on electricity and its applications. Among the more elaborate articles in this department may be mentioned *Electricity*, *Electric Lighting*, *Electric Discharge*, *Hygrometer*, *Ice*, *Induction Coil*, *Interference*, *Laboratory*, *Lightning*, *Lightning-rods*, *Liquids*, *Liquefaction of Gases*, *Pneumatics*, *Polarization*, *Radiometer*, *Spectroscope*, *Spectrum*, *Thermometer*, *Thermometry*, *Voltmeter*, etc., by Professor Nichols himself; *Electric Railways* and *Electric Motors*, by Professor Harris J. Ryan, of Cornell University; *Fluorescence*, by President Henry Morton, of the Stevens Institute, Hoboken, N. J.; *Magnetism* and *Transformers*, by Professor Frederick Bedell, of Cornell University; *Terrestrial Magnetism*, by Professor Frank H. Bigelow, of the U. S. Weather Bureau; *Thermodynamics*, by Professor Ernest Merritt, of Cornell University; *Refraction of Sound*, *Safety-lamps*, *Stereoscope*, *Stroboscope*, *Vision*, etc., by Professor W. Le Conte Stevens, of the Rensselaer Polytechnic Institute, Troy, N. Y.; *Thermo-electricity*, *Units*, *Wattmeters*, etc., by Professor H. S. Carhart, of the University of Michigan; and *Waves*, by Professor J. S. Ames, of Johns Hopkins University. Some of the latest articles are *Chronophotography*, *Kathode Rays*, *Liquefaction of Hydrogen*, *Liquid Air*, *Luminescence*, *Radiation*, *Standards of Light*, *Storage Batteries*, and *X-rays*, by Professor Nichols; *Telegraphy without Wires*, by Professor Ernest Merritt; *Transmission of Power*, by W. S. Franklin, Professor of Physics, Lehigh University; *Uranium Rays*, by O. M. Stewart, Instructor in Physics, Cornell University; and *Force of Gravity*, by Erasmus D. Preston, of the U. S. Coast and Geodetic Survey.

The department of the Higher Mathematics and Astronomy was intrusted to Professor Simon Newcomb, LL. D., the editor of the *Nautical Almanac*, and then Professor of Mathematics and Astronomy in Johns Hopkins University. He sought to give in condensed form under each head an account of the established facts, the latest discoveries, and the most mature opinions on the various topics in his department. Technical details were for the most part avoided, in the belief that the few who need them will ordinarily resort to special treatises on the subject—and these are named in the bibliography appended to each of the more important articles, as, for example, those on *Astronomy*, *Solar Parallax*, *Stars*, and *Time*, by Professor Newcomb himself, and those on the *Sun* and the *Spectroscope*, by Professor C. A. Young, of Princeton University.

The science of Chemistry was and is making great advances, and applications of the results of recent discoveries are finding their way into the manufactures in many directions. Since the preceding edition of the Cyclopædia was prepared important changes then in progress had been accomplished. The great Periodic Law had been established, and was manifesting its influence in every department of the science of Chemistry. Professor Remsen, the editor of the department, sought to present everything likely to be of interest to the general reader as well as of value to the practical student. Many new articles were prepared, notably the one on *Chemistry*, and all articles retained from the former edition were so revised as to represent fully the present state of chemical knowledge. An article on *Acetylene* is now added, by Edward Renouf, Collegiate Professor of Chemistry, Johns Hopkins University. Many discoveries of chemical substances, probably elementary, have been made since the last previous printing of the Cyclopædia, and an article on each of these is now given, by Dr. Marcus Benjamin, of the U. S. National Museum. Dr. Benjamin has also written a new article on *Perfumery*.

The treatment of Geology was enlarged by the addition of special chapters on *Structural Geology*, or the arrangement and interrelation of rock masses; on *Dynamic Geology*, or the agen-

cies by which rocks and rock structures are produced; and on *Geologic Technology*, or the methods employed by the geologist in determining the horizontal and vertical distribution of rocks, in representing this distribution by means of maps and sections, and in discriminating between rocks by means of their composition and minute

Geology.

structure. In the article on *Historic Geology* the physical changes and life changes which characterize the various periods of geological chronology receive more attention than in previous editions. Each geological period is described in a special article devoted to the subject, and the number of short articles on American formations is much increased. The article on *Rocks*, rewritten by an eminent specialist, Professor George H. Williams, of Johns Hopkins University, was greatly enlarged, and the articles on individual rocks, such as granite, gneiss, etc., were rewritten or carefully revised. Among the more prominent articles in Applied or Economic Geology may be mentioned *Geology of Petroleum and Natural Gas*, by Mr. I. C. White, the mining engineer who originated the "anticlinal theory" of gas occurrence; the articles *Asphalt*, *Bitumen*, and *Petroleum*, by Professor S. F. Peckham, formerly of the University of Minnesota; *Building-stone*, by Dr. G. P. Merrill, curator of rock collections in the U. S. National Museum; and *Artesian Wells* and *Well-drilling*, by Mr. F. H. Newell, topographer U. S. Geological Survey, in charge of the investigation of water-supply with reference to irrigation. The department of Mineralogy was in charge of Mr. Charles Kirchoff, editor of the *Iron Age*, New York, who himself revised most of the articles. The articles on Gems and Precious Stones were revised or rewritten by the eminent specialist, Mr. George F. Kunz,

Mineralogy.

gem-expert for Messrs. Tiffany & Co. and of the U. S. Geological Survey. In the department of Physical Geography, which was united with Geology, under the charge of Mr. Grove K. Gilbert, chief geologist of the U. S. Geological Survey, the material was arranged so as to distribute under such heads as *Valleys*, *Mountains*, *Volcanoes*, *Continent*, *Islands*, and *Ocean* much that was previously gathered into an extended article on the

Physical Geography.

Earth. In process of reconstruction a genetic classification of topographic features was adopted, and in other ways attention was directed to their mode of origin. Among articles in this department that may be mentioned are those on *Earth*, *Earthquakes*, *Valleys*, *Mountains*, and *Volcanoes*, by the associate editor; *Glaciers*, *Ocean*, *Lakes*, and *Rivers*, by William M. Davis, Professor of Physical Geography in Harvard University; *Gulf Stream*, *Kuro Siwo*, and *Deep-sea Explorations*, by Dr. William H. Dall, formerly in charge for many years of explorations and surveys by the U. S. Coast Survey; *Thermal Springs*, by Mr. Arnold Hague, of the U. S. Geological Survey; and *Floods*, by Mr. Thomas Russell, of the U. S. Weather Bureau, in charge of river-flood predictions.

In Meteorology such changes were introduced as to represent its present state both as a science and an art; and new articles were prepared describing the phenomena named by such new but familiar terms as are used in the bulletins of the National and State Weather Bureaus. This, with Climatology, was in charge of Professor

Meteorology.

M. W. Harrington, chief of the U. S. Weather Bureau, who had made a special study of these subjects for many years. The article *Climate*, embodying the most recent conclusions on that subject, may be specially mentioned as coming from the pen of the asso-

Climatology.

ciate editor himself. Attention may also be called to the article *Clouds*, by Mr. A. L. Rotch, of Blue Hill Observatory. Political or Descriptive Geography, one of the largest departments in the Cyclopædia, was also cared for by Professor Harrington. In this great work he had as collaborators Mr. Gardiner G. Hubbard, president of the National Geographic Society, Washington, D. C.; Mr. Cyrus C. Adams, president of the department of Geography

in the Brooklyn Institute of Arts and Sciences, who had written articles on many African topics and on out-of-the-way places in every part of the world; Mr. Herbert H. Smith, a naturalist, who had been engaged for more than twenty years in special geographic and scientific explorations in tropical America, and traveled extensively in South America, Mexico, and the West Indies; and Dr. Robert Lilley, the managing editor, who resided for many years in China and Japan, and traveled extensively in the Far East. The number of articles in the geographical department was very considerably increased, and additional space was given to those regions which had awakened special interest in consequence of recent explorations. Attention may be called to the elaborate article on *Africa* by the editor of the department, as well as to Spanish and Portuguese America, the South Sea islands, Central Asia, and British India. The descriptions of the large cities were intrusted to persons selected for their local knowledge as well as for their personal fitness: *Constantinople*, for example, written by Professor E. A. Grosvenor, late of Robert College, Turkey; *London*, by Mr. Francis Espinasse, a well-known literary worker of that city; and *Paris*, by Mr. Theodore Stanton, for several years a resident of the French capital.

Many new geographical articles are now added, all written by Mr. Cyrus C. Adams, who has also revised a number of the older articles. Among the important articles given in the Appendix is a new and full description of the *Philippine Islands*, placed there because of lack of space in the body of the work. Some of the other added titles of new and supplementary articles are *Change-of-day Line*, *China*, *Cuba*, *Devil's Island*, *Egypt*, *Fashoda*, *France*, *German Empire*, *Greece*, *Iceland*, *Nyassaland*, and *Witwatersrand*.

The Universal Cyclopædia is notably full in its treatment of U. S. towns and cities. The articles dealing with these have been revised by persons on the spot and familiar with the localities they describe, and thanks are due to the many local journalists and others who have responded to the call for information in regard to their towns. Canadian towns and villages have also been included, and the most recent census returns of population, manufactures, etc., have been fully utilized.

Biology, through the researches of such men as Darwin, Huxley, and Virchow, has attained a position of great prominence among the sciences, and has in recent years laid much claim to public attention and thoughtful study. This subject is very fully cared for in articles which will be found to embody the most recent discoveries and discussions. Special mention may be made of the articles *Biology*, by Professor Theodore Gill; *Bacteriology*, by Dr. Billings and Dr. Abbott; *Darwinism* and *Evolution*, by Professor J. S. Kingsley; as well as of an able anti-Darwinian article, by Sir J. W. Dawson, of Montreal, probably the most eminent living opponent of Darwinism.

In the department of Zoölogy, Comparative Anatomy, and Animal Physiology, in charge of President David S. Jordan, of the Leland Stanford Junior University, California, all the shorter articles were carefully revised, and nearly all the longer ones rewritten. An effort was made to avoid as far as possible all strictly technical terms, and to adapt all discussions and descriptions to those who have not been trained in zoölogical science. The only considerable departure from this general method of treatment is in the elaborate article by Professor E. D. Cope on *Comparative Anatomy*—a departure thought necessary on account of the importance and peculiar nature of the subject. President Jordan had the assistance of Professor Charles Henry Gilbert, Ph. D., in general zoölogy; of Professor Oliver P. Jenkins, Ph. D., in several physiological and anatomical subjects; of Professor J. S. Kingsley, of Tufts

College, who dealt chiefly with invertebrate zoölogy, and wrote most of the articles on Insects, Crustacea, and Worms; and lastly, in vertebrate zoölogy, of Mr. Frederic A. Lucas, a curator in the U. S. National Museum in Washington, who wrote the article on *Fisheries*, and revised or rewrote a large number of the articles on birds (such as those on the *Auk*, *Capercaillie*, and *Dodo*), and on many other subjects, e. g. those on the *Armadillo*, *Crocodile*, *Elephant*, *Taxidermy*, and *Zoölogical Geography*. The article *Entomology*, finely illustrated, was furnished by Professor J. Henry Comstock, of Cornell University; that on the *Bee* by his assistant, Mr. McGillivray; and that on *Pisciculture* by Dr. Tarleton H. Bean, assistant U. S. Fish Commissioner, and curator of the fishes in the National Museum. This department was so exhaustively treated that no supplementary matter was found necessary other than an article on the *Gypsy Moth*, by Professor Kingsley, and a few short items by Mr. F. A. Lucas.

In arranging for the department of Botany and Vegetable Physiology, Economic Botany was assigned to Professor L. H. Bailey, of Cornell University, who took charge of Agriculture, Horticulture, and kindred subjects; and the more general subjects of Botany as a science to Dr. Charles E. Bessey, Professor of Botany in the University of Nebraska. In order to adapt this whole department to the modern state of the science, many of the old articles were omitted, and many new ones introduced. The article *Botany* is entirely new, and is in accord with the modern idea that the term includes the whole vegetable kingdom, and not merely flowering plants and ferns. Mention may also be made of the articles *Bacteria* and *Vegetable Histology*. One of the features of the present edition is the attention paid to the orders of plants, as well as to plant diseases and plant histology.

Palæontology, in the department of Mr. G. K. Gilbert, is treated in four principal articles and a number of minor ones. The history of ancient life is given in three articles: *Fossil Plants*, by Dr. Lester F. Ward, of the Smithsonian Institution; *Fossil Invertebrates* (both in a separate article and in the article *Palæontology*), by Dr. H. S. Williams, Professor of Geology in Yale University; and *Fossil Vertebrates*, by Professor O. C. Marsh, palæontologist of the U. S. Geological Survey, and president of the National Academy of Sciences.

Anthropologic science covers a wide and varied field. Attention may be called to an article on *Anthropology*, by Major J. W. Powell, director of the U. S. Bureau of Ethnology; one on *Criminal Anthropology*, by Dr. Robert Fletcher, of the Army Medical Museum, now supplemented by a new one on *Criminology*, giving much additional information, by Mr. F. Sturges Allen, a member of the New York Bar; another on *Anthropometry*, by Dr. J. S. Billings, superintendent of the Army Medical Museum; and the article on *Man*, by Dr. Daniel G. Brinton, a professor in the University of Pennsylvania, who had long been engaged in anthropologic researches. Major J. W. Powell had charge of that branch of the subject which relates to American Archæology and Ethnology. The editor of this department has probably devoted more time and thought than any other person to the ethnic relations of the aborigines of America, and his investigations enable him to speak with a confidence which perhaps no one else would be entitled to. His classification of the Indians of North America will be found of great interest and value to those who as yet have had but limited facilities for the study of the subject. The materials here brought together have never been published in any other cyclopædia, and to an important extent they are new to science. Among Major Powell's collaborators, besides Dr. Billings, Dr. Brinton, and Dr. Fletcher, above referred to, mention may be made of Mr. Frank H. Cushing, formerly chief of the Hemenway exploring expedition, which operated in New Mexico and Arizona; Rev. J. Owen Dorsey, formerly a mis-

sionary among the Ponca Indians; Mr. Albert S. Gatschet, Mr. J. N. B. Hewitt, an Iroquois Indian, Mr. F. Webb Hodge, Professor William H. Holmes, and Col. Garrick Mallery, all of the Bureau of Ethnology at Washington.

The departments of Language and Literature were very carefully planned and arranged for, with a view to making the Cyclopædia as strong on its literary side as it has ever been on its scientific side. It is confidently believed that in no other general cyclopædia can such a complete, comprehensive, and scholarly presentation of these subjects be found. Professor (now President) Benjamin Ide Wheeler, the editor in charge of Philology. Linguistics and Comparative Philology, strove to present the phenomena of language in the light of their historical significance, and to treat these in accordance with the methods of the modern science of historical grammar, as distinguished from the merely descriptive methods of earlier linguistic discussions. This and the great advances made in linguistic science necessitated an almost entire abandonment of the old material in the Cyclopædia, and a new grouping and distribution of the topics. The plan of his work includes the following divisions of the new matter:

(a) Articles on the various groups or families of languages, such as the Indo-European, the Semitic, and the Teutonic. These articles undertake to characterize each group, with reference to its geographical location and distribution, its division into separate languages and dialects, with the determining marks or other characteristics of the division, its historical development, and its main characteristics of sound, form, and syntax, considered from a strictly scientific point of view.

(b) Articles on each separate language or dialect that has attained the position of a literary language, with discussion of its main characteristics, geographical extent, division into dialects, and with references to the most important lexicographical and grammatical treatises, as well as to convenient handbooks for acquiring a practical knowledge of the language.

(c) Articles explanatory of the technical terms of scientific and descriptive grammar, as of prosody or metre.

(d) Articles on various phases of general grammar, the philosophy of language, the history of scientific grammar, and the history of writing.

(e) A brief etymological explanation of all titles in the Cyclopædia whose form or meaning could be made clearer by the addition of such an etymology. In selecting the material to be used in these etymological explanations, the etymology is not viewed as an end unto itself, as may be the case, for example, in an etymological dictionary, but rather as a practical convenience for the purposes mentioned. All these etymologies were supplied by Professor Wheeler himself.

In carrying out this widely comprehensive plan the associate editor called to his aid some of the most eminent specialists to be found in Europe and America. Semitic Languages were assigned to Professor C. H. Toy and Professor D. G. Lyon, of Harvard University, and to Professor Jewett, of Brown University; Iranian Languages to Professor A. V. Williams Jackson, of Columbia College; Germanic Languages to Professor H. C. G. Brandt, of Hamilton College; Scandinavian Languages to Professor George L. Kittredge, of Harvard University, and later to Professor Carpenter, of Columbia College, New York; Slavic Languages to Professor Jagič, of Vienna; Lithuanian and other Baltic Languages to Professor Bezenberger, of Königsberg, Prussia; Celtic Languages to Professor Thurneysen, of Freiburg, Germany; Low German Languages to Professor Collitz, of Bryn Mawr, Pennsylvania; Romance Languages to Professor E. S. Sheldon, of Harvard University; Prosody, Metre, etc., to Professor M. W. Humphreys, of the University of Virginia. Among individual articles, attention may be directed to *Language*, by Pro-

fessor W. D. Whitney, of Yale University; *Sanskrit*, by Professor Charles R. Lanman, of Harvard University; *English*, by Professor Albert S. Cook, of Yale University; *Pāli*, by Professor T. W. Rhys Davids, of London; *Greek*, by Professor Frederick D. Allen, of Harvard; *Prākṛit*, by Professor Hermann Jacobi, of Bonn, Germany; *Chinese, Korean, and Japanese*, by Dr. Addison Van Name, librarian of Yale University; *Egyptian*, by Rev. Charles R. Gillett, librarian of Union Theological Seminary, New York; *Syntax*, by Professor B. Delbrück, Jena, Germany; *Inscriptions*, by Dr. Isaac H. Hall, of the Metropolitan Museum, New York; *Pronunciation, Punctuation, and Lexicography*, by Professor O. F. Emerson, of Cornell; and *Ablaut, Umlaut, Alphabet, Gothic, Modern Greek, Folk-etymology*, etc., by the associate editor.

In the treatment of the various subjects that come under the head of Greek and Roman Literature, in charge of Professor B. L. Gildersleeve, of Johns Hopkins University, an effort was made to bring into relief the important facts of the lives and careers of the different authors, to present their leading characteristics in a few sharp, clear lines, and to indicate the great editions of the various works; and, generally, to point out the best and most accessible sources of information. The Latin section of the department was assigned to Professor Minton Warren, of Johns Hopkins University, and Dr. Alfred Gudeman prepared biographical sketches of the great classical scholars of modern times. The article *Greek Literature* is by Professor F. D. Allen, of Harvard University, and that on *Homer* by Professor Thomas D. Seymour, of Yale University. Professor J. R. S. Sterrett, of Amherst College, had charge of *Greek Antiquities*, and Professor George L. Hendrickson, of the University of Wisconsin, of *Roman Antiquities*.

Greek and Roman
Literature.

English Literature, that is, Literature in English wherever produced, was in charge of Professor Henry A. Beers, of Yale University. Several hundred new articles were introduced, chiefly notices of authors, and everything was brought down to date. Professor Beers carefully revised and supplemented the excellent article on *English Literature*. The article *Anglo-Saxon Literature* was carefully revised by its author, Professor F. A. March, of Lafayette College. A new article on the *Novel* was written by Thomas Sergeant Perry, author of *English in the Eighteenth Century*, and another, by Professor Charles Davidson, on *Miracle-plays*. The one on *Browning* is by Professor Hiram Corson, of Cornell University. The biographies of *Carlyle, Pope*, etc., are written by Professor Beers himself. An interesting article on *Canadian Literature*, by Professor Goldwin Smith and G. Mercer Adam, includes an account of the French-Canadian as well as of the English Literature of Canada.

English Literature.

The important department of Comparative Literature, at the head of which Professor A. R. Marsh, of Harvard University, labored so assiduously and effectively, is practically a new feature in cyclopædia-making. His aim was to bring foreign literature to our very doors in a series of sketches prepared by persons so familiar with their subjects that they can give the main lines of each foreign literature without wasting words upon needless or vague descriptions and characterizations. His plan also includes a brief biography of every writer of real importance and interest in all these foreign literatures, the selection of these names, and the writing of the biographies themselves, being left, as far as possible, to the authorities who had undertaken the preparation of the main articles. The bibliographical information which follows each article will give the reader an indication of the latest discussions of the subject in hand, and enable him to supplement the information given, if he so desires. In arranging for this department, Sanskrit and allied literatures were assigned to Professor Charles R. Lanman; Indo-Iranian to Professor A. V. Williams Jackson; Semitic to Professor C. H. Toy; Assyrian

Comparative Literature.

and Chaldee to Professor D. G. Lyon; Egyptian to Rev. Charles R. Gillett; Chinese, Korean, and Japanese to Dr. Addison Van Name, of Yale; Arabic to Professor J. R. Jewett; German to Professor Julius Goebel, of Leland Stanford Junior University; Scandinavian to Professor G. L. Kittredge, of Harvard, and Professor D. K. Dodge, of the University of Illinois; Catalan to Professor T. F. Crane, of Cornell; Italian, Basque, and Roumanian to Professor E. S. Sheldon, of Harvard; French to Professor Canfield, of the University of Kansas; while Provençal Literature, Humanism, etc., were cared for by the associate editor himself. Among the special articles may be mentioned *Ballad Poetry*, by Professor Francis J. Child, of Harvard University; *Beast-fables*, by Professor Kittredge; and *Finnish Language and Literature*, by Professor R. B. Anderson.

Attention may here very properly be called to the fact that this is the first cyclopædia ever published that contains an account of the already extensive and important literature of South America, together with notices of the most eminent South American writers, both past and present. Now that South America is attracting so much attention, both in the U. S. and in Europe, this feature will, it is hoped, be found both useful and interesting.

All the articles that come within the scope of the departments of History, Politics, and Education, reserved for the special care of the editor-in-chief, were carefully revised. All the historical articles were critically examined, many of them rewritten, and a considerable number of new subjects for the first time introduced into the Cyclopædia. Among those from the pen of the editor-in-chief may be mentioned *Bacon's Rebellion*, *Berlin Congress*, *Columbus*, *Modern Egypt*, *Frederick the Great*, *Mecklenburg Declaration*, *Napoleon*, *Nullification*, *United States*, *George Washington*, and *Waterloo*.

In the field of politics, while numerous articles on questions involving matters of a partisan nature were intrusted to eminent representatives of the several parties, political topics of a non-partisan nature were written by scholars thoroughly versed in what may be called the science of comparative politics. In accordance with this method such articles as those on *Democratic Party*, *Republican Party*, *Free Trade*, *Protection*, *Reciprocity*, etc., are written by persons advocating these doctrines, while such articles as *Lobby*, *Law-making*, *Caucus*, *Ballot Reform*, *Civil-service Reform*, *Representative Government*, and other topics of a kindred nature are treated by scholars who approach the subject from a non-partisan point of view. An effort has thus been made to give to this particular department of the Cyclopædia the exceptional strength that must be called for by the present state of political science. Prominent among these articles may be mentioned *Government and Political Parties*, by the editor-in-chief; *Ballot Reform*, by Professor J. W. Jenks, of Cornell University; *Civil-service Reform*, by Dorman B. Eaton and Theodore Roosevelt; *Prohibition* and *Prohibition Party*, by Miss Frances E. Willard; and *Free Trade*, by the Hon. D. A. Wells.

The articles on educational subjects required even more rigorous treatment, for the reason that since the first edition of the Cyclopædia was issued the methods, if not the systems, of education had been completely revolutionized. A new article on *Education* was prepared by Chancellor W. H. Payne, of the State Normal University in Nashville, Tenn. This has been supplemented in the present edition by articles on the *Literature of Education*, *Methods of Education*, and *Nature-study*, by Charles H. Thurber, Professor of Pedagogy in the University of Chicago; an article on *Child-study*, by William L. Bryan, Professor of Philosophy and vice-president of Indiana University; and an article on *Manual Training*, by Professor C. M. Woodward, of Washington University, St. Louis, Mo. The articles on *Agricultural College*, *Agricultural Experiment Station*, *College*, *Schools*, and many other educa-

tional subjects of a kindred nature, are by the editor-in-chief. The article on *Schools* has been supplemented by a fine series, including *Kindergarten*, by Professor W. N. Hailmann; *Common Schools*, by Professor Earl Barnes, of the Leland Stanford Junior University; *Primary Schools* and *Secondary Schools*, by Professor Thurber; *Normal Schools*, by President De Garmo, of Swarthmore College; *Theological Schools*, by Nathaniel Schmidt, Professor of Semitic Languages and Literature, Theological School of Colgate University; *Medical Schools*, by Henry M. Hurd, Professor of Psychiatry, Johns Hopkins University; *Law Schools*, by James Barr Ames, Bussey Professor of Law, Harvard University; *Technical Schools*, by President Mendenhall, of the Worcester Polytechnic Institute, Worcester, Mass.; *Trade Schools*, by C. R. Richards, Director of the Department of Science and Technology, Pratt Institute, Brooklyn, N. Y.; *Schools of the Fine Arts*, by Mr. William A. Coffin, of the Society of American Artists; *School Gardens*, *Vacation Schools*, and *School Statistics*, by Professor Thurber. The article on *University* is by President D. C. Gilman, of Johns Hopkins University, and the descriptions of institutions of learning were prepared, almost without exception, either by the officers at the head of such institutions or by persons doing the work under official direction.

The department of Economics, or Political Economy, under the general charge of Professor (now President) Arthur T. Hadley, of Yale University, was extended so as to include on the one hand the whole science of Sociology, and on the other the great domain of Finance, public and private. The different subjects not treated by the associate editor himself were intrusted to the hands of the most eminent specialists that could be found. The method pursued in former editions of dealing with controverted questions, by giving both sides a hearing, was retained; while systematic articles on *Finance*, *Currency*, *Taxation*, *Tariff*, *Reciprocity*, etc., furnish an impartial presentation of facts to supplement or correct the arguments of special advocates. There is a much fuller treatment of social problems than formerly. Carroll D. Wright deals with the *Factory System*; Henry George with the *Single Tax*; H. N. Hyndman, of London, with *Socialism*; Stepniak with *Nihilism*; Jacob A. Riis with *Tenement-houses*; Professor Giddings with *Sociology*; etc. In consequence of the great advances in recent years in the treatment of social and economic questions, the space given to these subjects was more than doubled.

First in order among the Industrial Arts comes Agriculture, which, with Horticulture, Forestry, and Economic Botany, was placed in the editorial charge of Professor Liberty H. Bailey, of Cornell University. He not only subjected all the articles that were retained from the former edition to a most thorough revision, but wrote or secured many new articles of prime importance. Among these may be mentioned *Butter*, by Professor H. H. Wing, of Cornell; *Cheese*, by Professor James P. Robertson, Dairy Commissioner of Canada; *Ensilage* and *Reaping and Mowing Machines*, by Professor I. P. Roberts, of Cornell; and *Forestry*, by Mr. B. E. Fernow, chief of the Forestry division of the U. S. Department of Agriculture. The article on *Horticulture*, by the associate editor, will be found to embody briefly, but as fully as is practicable, the results of the latest investigations and experience in the production of the different kinds of grains, fruits, and vegetables.

Mining and Metallurgy are very fully treated by Mr. Charles Kirchhoff, who has endeavored to embody in the several articles which come within the scope of his department the results of the most recent experience in both of these branches. Such articles as *Coal*, *Aluminium*, *Blast Furnace*, *Tin*, *Tin-plate*, etc., clearly show his methods and the value of what he has done.

The editor of the department of Mechanical Science endeavored to present the whole field of Applied Science, as exhibited in the mechanical arts, in the simplest, most concise, and most complete manner possible, and the history, structure, and principles of construction of all important inventions and machines, accuracy being secured by obtaining contributions from acknowledged authorities in each class. Every department of manufacturing industry receives attention. The very complete article on the *Steam-engine*, contributed to the former edition by the late Professor Trowbridge, was revised by his successor, Professor F. R. Hutton. The articles on *Flying-machines* and *Aëronautics* are by the associate editor himself.

Dr. Mansfield Merriman, Professor of Civil Engineering in Lehigh University, well known as a teacher and investigator in technical science and as the author of standard technical books, had charge of the department of Civil Engineering. The most important new articles prepared by Dr. Merriman for this edition of the Cyclopædia are *Arch, Bridges, Block System, Creeping of Rails, Flexure, Hydraulics, Mountain Railways, Moment, Roads, Stresses, and Viaduct*. He revised and brought down to date a number of articles like those on *Brick, Cements, Leveling, and Surveying*, and introduced many short articles, such as those on *Adhesion, Abutment, and Ballast*. A still larger number of articles were prepared by engineers and professors of distinction, among whom it will suffice to mention Gen. Henry L. Abbot, whose article on *River Hydraulics* was retained and revised; Mr. Elmer L. Corthell, C. E., who rewrote the articles *Ship-canal* (on which Mr. Cyrus C. Adams has now furnished a supplementary article, giving later facts), *Ship-railways, Jetties, and Levees*. Mr. J. James R. Croes, a civil and hydraulic engineer of wide experience, supplied articles on *Aqueducts, Canals, and Reservoir, Street and Suburban Railways, etc.*; Mr. Joseph P. Frizell revised the articles *Hydrostatics, Turbines, Water-works*, and a number of shorter articles, written by him for former editions; Mr. Lewis M. Haupt, C. E., wrote the articles *Breakwater, Docks, Dredging, and Harbors*; Mr. William Rich Hutton, chief engineer of the Hudson River Tunnel, revised and consolidated all the articles on *Tunnels and Tunneling*, and supplied the biographical sketches of European engineers of note; Dr. Mendenhall rewrote the article describing the *U. S. Coast and Geodetic Survey*; Dr. Cady Staley, president of the Case School of Applied Science, Cleveland, O., contributed the article on *Sewerage*; and that on *Plumbing* is by Mr. George S. Pierson, civil and sanitary engineer, Kalamazoo, Mich. The article *Railways* was revised by its author, Col. Julius W. Adams; and Mr. A. M. Wellington, editor, and Mr. E. E. R. Tratman, associate editor, of the *Engineering News*, New York, wrote new articles on *Railway Equipment and Railway Operation*. All these articles are freely illustrated whenever the nature of the subject requires it. The historical development of Civil Engineering, both as an art and as a science, is noted.

Everything pertaining to Navigation and Naval Science generally was in charge of Admiral Luce, as in former editions. The more important topics were submitted to experts, who in some instances revised the old articles, but for the most part supplied entirely new articles. *Ship-building*, by Commodore Philip Hichborn, U. S. Navy, may be mentioned; also *Armor and Submarine Navigation*, by Professor Philip R. Alger, U. S. Navy; *Ships of War*, by F. T. Bowles, Assistant Naval Constructor, U. S. Navy; *Torpedo-boats*, by Lieut. George F. W. Holman, U. S. Navy; and *Nautical Schools*, by Lieut.-Commander Charles Belknap. New articles are now added on *Resistance of Ships, Screw Propeller, and Search-light*, by W. F. Durand, Associate Professor of Marine Engineering, Cornell University.

The field of Military Engineering and the Science of War was in charge of Professor James Mercur, of West Point Military Academy. The articles on *Tactics, Organization, Fortifications, Arms, Armor, Gunnery, etc.*, were brought up to the present time, with indications, when possible, of the directions in which future developments may be expected. Articles of this nature were placed in the hands of specialists. It will suffice here to mention such names as Gen. Henry L. Abbot, on *Explosives, Torpedo*; Gen. Brialmont, of Belgium, on *Intrenched Camps*; Lieut. J. C. W. Brooks, Fourth Artillery, on *Projectiles*; Capt. L. L. Bruff, on *Machine and Rapid-fire Guns*; Capt. J. W. Ingalls, on *Gunpowder*; Major O. H. Ernst, on *War, Siege, and Fortification*; and Gen. John C. Tidball, on *Ordnance*. The articles on *Army, Arsenal, Brevet, and Discipline* are by Professor Mercur himself, who also wrote or revised many of the articles describing battles. New articles are now added on *Electro-ballistics* and on *Range-finders and Position-finders*, by Lieut. I. N. Lewis, of the Board of Ordnance and Fortifications; also one on *Military Insignia*, by Lieut. Cornelis De W. Willcox, of the Army Bureau of Information. Science of War.

Medical Science has made most remarkable and interesting advances during recent years. There is scarcely any department of medicine or surgery that has not been profoundly influenced or quite revolutionized by the germ theory of disease. The results of the latest investigations were embodied in several articles dealing with this theory and its developments. The list of specialists secured by Dr. Pepper, the editor of this department, includes the names of many of the most eminent authorities in the United States. All matters pertaining to *Materia Medica* were attended to either by Dr. H. C. Wood or by Dr. H. A. Hare; *Veterinary Medicine* and diseases of animals, by Dr. Leonard Pearson; *Anatomy, Histology, etc.*, by Dr. Piersol; *Surgery, Tracheotomy, etc.*, by Dr. John Ashhurst, Jr.; *Obstetrics*, by Dr. P. F. Mundé, of New York; *Pathology, etc.*, by Dr. W. T. Councilman; *Leprosy and Skin Diseases*, by Dr. George H. Fox; *Anatomy of the Ear*, by Dr. St. John Roosa; *Cholera, Cancer, Bright's Disease, etc.*, by Dr. Pepper; and *Medical Jurisprudence*, by Dr. Seneca Egbert. Medicine and Surgery.

Of the *Æsthetic Arts*, Music was in charge of Mr. Dudley Buck, who expunged much that was purely technical in the former edition in order to make room for many new articles on various musical subjects. Painting, Sculpture, Architecture, and Archæology were under the superintendence of Dr. Russell Sturgis, who remodeled the method of treatment, with the view of establishing a better proportion between the more important and the less important articles. In former editions of the Cyclopædia the Fine Arts were for the most part treated by literary men and scholars who approached their subjects from without. In the remaking the work was done by persons who had devoted their lives principally to the fine arts, and this resulted in a more intelligent general treatment of the subjects that come within the scope of the department. In the important field of Classical Archæology a large part of the work was done by Professor Alfred Emerson, of Cornell University. The very able article in the former edition on *Roman Archæology*, by Professor Helbig and Professor Lanciani, of Rome, was revised by the latter. European Art was in the hands of Mr. W. J. Stillman, of Rome; Modern Painters were described by Mr. William A. Coffin, secretary of the Society of American Artists. Professor A. D. F. Hamlin, of Columbia College, New York, wrote on *Architecture* and architectural subjects generally. Decorative Art in its different branches was treated with special care by the associate editor; and it will be found that Fresco-painting, Silverware, Painted Pottery, Embossed The Fine Arts.

and Chased Armor, Tapestries, and other subjects of a kindred nature are treated with the fullness each topic seems to deserve.

Dr. W. T. Harris, U. S. Commissioner of Education, and Professor J. Mark Baldwin, Ph. D., of Princeton University, had editorial care of Philosophy, Psychology, and Ethics. Dr. Harris took great pains to present each topic in the light of its historical development, and endeavored to present the more obvious thoughts which the great thinkers of the past have left us on the problems of life. Under various titles the essential characteristics of the Greek and German philosophic movements are indicated. The scholastic philosophy receives additional attention; and the New Philosophy, based on observation, and especially on the study of the functions of the brain and the cerebral ganglia, is treated at considerable length. This department was more particularly in charge of Professor Baldwin, who has now added many new articles. Among the articles contributed by Professor Baldwin, the following may be mentioned: *Genetic Psychology*, *Genius*, *Hypnotism*, *Ideal Feelings*, *Illusion*, *Imagination*, *Instinct*, *Love*, *Metaphysics*, *Muscle-sense*, *Pain and Pleasure*, *Perception*, *Psychology*, *Psychometry*, *Psycho-physics*, *Self-consciousness*, *Sensation*, *Sentiment*, *Suggestion*, *Suicide*, *Thought*, *Utilitarianism*, and *Will*. The article on *Induction* is by Professor Ormond, of Princeton; that on *Moral Philosophy*, by Professor Dewey, of the University of Chicago; that on *Memory*, by Professor J. Cattell, of Columbia College; and that on *Symbolic Logic*, by Professor Halstead, of the University of Texas. Attention is directed to Dr. Harris's fine article on *Hindu Philosophy*, and to the splendid series of six articles by Professor Garbe, of Königsberg, on the six darshanas or schools of Hindu philosophy, viz., *Mīmāṃsā*, *Nyāya*, *Sāṅkhya*, *Vaiśeṣhika*, *Vedānta*, and *Yoga*.

It has always been the policy of the editors of this Cyclopædia to hold the balance fairly in controverted matters, and to be impartial in every way. In no department has this policy been more rigorously carried out than in that which relates to religious belief and Church polity. In the last remaking the venerable Dr. Schaff, of Union Theological Seminary, New York, at first had charge of General Church History and Biblical Literature, and the Rev. Samuel Macauley Jackson, D. D., LL. D., Professor of Church History in New York University, took charge after Dr. Schaff's death. Seven other associate editors had charge of the History, Polity, and Dogmatics of as many sections of the Christian Church, and a bare list of their names is a sufficient indication of the strength of the Cyclopædia in theological and ecclesiastical matters. For the sake of completeness they are here given in alphabetical order:

Willis J. Beecher, D. D., Professor of Hebrew Language and Literature in Auburn Theological Seminary.

George P. Fisher, D. D., LL. D., Professor of Church History in Yale University.

John F. Hurst, D. D., LL. D., bishop in the Methodist Episcopal Church, and Chancellor of the American University, Washington, D. C.

Henry E. Jacobs, D. D., LL. D., Professor of Church History in the Evangelical Lutheran Theological Seminary, Mt. Airy, Philadelphia.

John J. Keane, D. D., bishop in the Roman Catholic Church, and Rector of the Catholic University of America.

William Stevens Perry, D. D. (Oxon.), LL. D., bishop in the Protestant Episcopal Church in the U. S., Davenport, Iowa.

William H. Whitsitt, D. D., Professor of Church History in the Baptist Theological Seminary, Louisville, Ky.

To these names should be added those of the Rev. J. W. Chadwick, of Brooklyn, N. Y., to whom were referred all matters connected with Unitarianism, Universalism, etc.; and the Rev. J. H. Garrison, D. D., Editor of the *Christian Evangelist*, St. Louis, Mo., who prepared the articles which relate to the Disciples of Christ.

Among individual articles not coming within the scope of any of these departments may be mentioned one on the *Mormon Church*, by Mr. Byron Groo, of the *Salt Lake Herald*; another on *The Friends*, by Professor Gummere, of Haverford College; one on *Christian Endeavor*, by the Rev. F. E. Clark; and one on *The Salvation Army*, by F. de L. Booth-Tucker.

Law is a twofold department: (a) Municipal, Civil, and Constitutional Law, and (b) International Law. During the progress of about the first third of the work the former was in charge of President Henry Wade Rogers, of the Northwestern University, and thereafter of Francis M. Burdick, LL. D., Dwight Professor of Law, Columbia University, who received important aid from the following professors in the Columbia University School of Law: Frank J. Goodnow, A. M., LL. B.; William A. Keener, LL. B.; George W. Kirchwey, A. B.; Munroe Smith, A. M., J. U. D. Mr. F. Sturges Allen, a member of the New York Bar, wrote many important articles and revised many others, and has now added still more, including *Expert Testimony*, *Farm Laws*, *Handwriting*, *Liquor Laws*, *Lunacy Laws*, *Police Powers*, *Probate Courts*, and *School Laws*. The department of International Law was in charge of Professor Theodore S. Woolsey, of Yale University, who endeavored to give, under a number of separate headings, rather than under one, a complete practical treatment of the subject. Among individual articles of this nature may be mentioned *Asylum*, *Balance of Power*, *International Arbitration*, *International Law*, *Belligerency*, *Blockade*, *Exterritoriality*, *Extradition*, *Naturalization*, *Treason*, and *Treaties*.

Almost every elaborate article in the Cyclopædia is accompanied by copious bibliographical information, so that the student who desires to pursue the subject further may know where to turn for the information he seeks. This has always been a feature of the Cyclopædia, but in no other edition has it been so thoroughly carried out. Wherever possible, reference is made to special rather than to general treatises, to works in English, either original or translated, in preference to works in foreign languages, and to recent and accessible rather than to out-of-the-way books.

In organizing the editorial staff no separate provision was made for the great department of Biography. It was arranged that each editor should have charge of the biographies in his own department, selecting the names of persons considered worthy of a place in the Cyclopædia, and preparing or arranging for the preparation of the biographical sketches. This arrangement has greatly increased the value of the Cyclopædia, as the sketches have the authority of men familiar with the standing and achievements of the persons described. They are all written on the same model, as far as possible, and an effort is made to have each indicate instantly just who the person was or is, and his or her relative importance. Many biographical sketches are now added in the Appendix, including notices of persons prominent in connection with important events, discoveries, etc., since the general revision was completed.

A very large number of miscellaneous articles which do not come within the scope of any of the editorial departments were arranged for by the editor-in-chief, with the assistance of Professor

Miscellaneous. C. H. Thurber, M. A., of the University of Chicago. Among these may be mentioned such subjects as games and sports (*Base-ball* and *Foot-ball*, by Professor A. Alonzo Stagg, formerly of Yale, now of the University of Chicago; *Cricket*, by Professor F. B. Gunnere, of Haverford College; *Physical Education*, by Professor D. A. Sargent; *Curling*, by the Hon. John Johnston, of Milwaukee, Wis.; *Chess*, by W. Steinitz; *Whist*, by R. F. Foster; and *Lacrosse*, *Lawn Tennis*, *Croquet*, *Golf*, etc., by others equally well qualified); *Cookery*, by Miss Parloa; *Dress*, by Mrs. Jenness Miller; *Preservation of Food*, by Marion Harland; *Clubs*, by Hobart Chatfield Chatfield-Taylor; *College Fraternities*, by W. H. Baird, of New York; *Charity Organization*, by C. D. Kellogg; *Women's Rights*, by Susan B. Anthony and Elizabeth Cady Stanton, etc.

A new feature of this Cyclopædia is the introduction of etymologies—prepared by Professor (now President) Benj. Ide Wheeler—when such would serve to fix in the mind either (1) the sig-

Etymology. nification of a term by the indication of its historical relations, or (2) the form of the term itself by associating with it other known terms. Most of the terms which require etymological explanation fall under one of the three following heads: (a) Scientific terms constructed out of Greek or Latin elements: It has generally been deemed sufficient in these cases simply to indicate the Greek or Latin words entering into the construction, without comment as to the principle of structure, etc. (b) Words of Romance origin: These have generally been traced back along the route by which they entered English to their Latin form, or to their source in other languages. (c) Teutonic words: These, or their Old English forms, have been brought into comparison with the cognate forms in other Teutonic languages, especially Modern German, and finally reduced through their fundamental Teutonic form to such comparison with their Indo-European cognates as seemed practicable and serviceable.

In tracing the history of words a careful discrimination must be made between descent and adoption. In the case of descent, as from Indo-European to Teutonic to Old English to Middle English to Modern English, or from Indo-European to Latin to Old French to Modern French, the sign > has been universally employed, the movement from the older to the younger being viewed as from greater to less, i. e. the sign is interpreted as an arrow-head. The opposite sign < is used in tracing back the line of descent, as from Middle English to Old English, etc. The colon (:) has been used to connect forms which represent in sister languages or dialects descent from one and the same word; e. g. French *mûr* : Italian *maturo* : Spanish *maduro* < Latin *maturus*. In the case of adoption, attention has been first of all directed to the route by which the word came, and when the citation of the form in an intermediate stage seemed unnecessary this route has been indicated by use of "viâ," e. g. *abundance* viâ Old French from Latin *abundantia*. To indicate adoption the word "from" has been universally employed, e. g. *feast* from Old French *feste*, but when no essential change of form is involved the sign = is used; e. g. *fête* = French *fête*; Latin *cœnobium* = Greek *κοινόβιον*. The common and confusing use of the word "from" as indicating derivation is displaced by the expression "deriv. of" (derivative of); thus Latin *capita'lis*, deriv. of *caput*. The word "from," while always implying a loan from another language, may, however, also cover derivation from a loan-word, when the necessities of space forbid the enumeration of all the steps in the history of the form; thus "*conduct*, from Latin *condu'cere*."

As the pronunciation of foreign names is often a source of much difficulty, even to many well-educated persons, an effort has been made to remove this difficulty by introducing a simple system of phonetic respelling, a key to which is given on another page. No refinements have been attempted, the purpose being simply to represent in a fairly accurate manner the sounds of the names respelled. The pronunciation adopted in cases of doubt is that of the most approved authorities. As a rule, English names need no such respelling, the pronunciation being sufficiently shown by indicating the primary accent, but names that are irregularly pronounced, e. g. Cholmondeley (chŭm'lēē), have been respelled. No attempt has been made to use in every case a separate symbol for each distinct sound, as such a scheme would necessarily be intricate, and, to a great extent, confusing to those for whose benefit it is intended. Different sounds which are so nearly alike as not to be distinguished by the ordinary observer have been represented by the same symbol. Thus Spanish *b* and *v*, and German *w*, are represented by the symbol *v*; Spanish *j*, German *ch* and *g* (when following immediately after the vowels *a*, *o*, *u*), and Russian *kh* have all been represented by the symbol *kh*; while Spanish *d*, Danish *d* (at the end of a syllable), and English *d* have been represented by the letter *d*. It has not been thought best to indicate the peculiar gutturals of the Oriental languages, as they could not be pronounced even with approximate accuracy except by persons already familiar with them.

Pronunciation.

In the typographical execution of the Cyclopædia, as well as in the editorial work, no effort has been spared to achieve the highest possible excellence. The maps have all been carefully revised by competent geographers, and many new ones added. Many new illustrations have been introduced, including a fine series of colored representations of birds, birds' eggs, cereals, orchids, fungi, poultry, pigeons, art porcelain, rugs, etc., which will convey through the eye more information than could be given by mere word descriptions.

Although the Cyclopædia is the work of a very large number of different writers, each preserving to a certain extent his own individuality of method, it has been the aim of the editor-in-chief to bring the whole into such reasonable proportions and such uniformity of style as the importance of the various subjects has seemed to require and the individuality of the writers would permit. To guard in every practicable way against typographical errors, the proofs have been read not only by the proof-readers in the printing-house and by the individual writers, but also by the managing editor and his editorial assistants, and by several experienced proof-readers, in the office of publication; and, finally, they have all been subjected to the scrutiny of the editor-in-chief.

The result of all these efforts is given to the public in the confident hope that something has been accomplished for the wider dissemination of accurate knowledge.

KEY TO THE PRONUNCIATION.

<p>aa..... as <i>a</i> in <i>father</i>, and in the second syllable of <i>armada</i>.</p> <p>ää..... same, but less prolonged, as in the initial syllable of <i>armada</i>, <i>Arditi</i>, etc.</p> <p>a..... as final <i>a</i> in <i>armada</i>, <i>peninsula</i>, etc.</p> <p>ă..... as <i>a</i> in <i>fat</i>, and <i>i</i> in French <i>fin</i>.</p> <p>ay or ā.. as <i>ay</i> in <i>nay</i>, or as <i>a</i> in <i>fate</i>.</p> <p>āy or ā.. same, but less prolonged.</p> <p>ã..... as <i>a</i> in <i>welfare</i>.</p> <p>aw..... as <i>a</i> in <i>fall</i>, <i>all</i>.</p> <p>ee..... as in <i>meet</i>, or as <i>i</i> in <i>machine</i>.</p> <p>ě..... same, but less prolonged, as final <i>i</i> in <i>Arditi</i>.</p> <p>e..... as in <i>men</i>, <i>pet</i>.</p> <p>e..... obscure <i>e</i>, as in <i>Bigelow</i>, and final <i>e</i> in <i>Heine</i>.</p> <p>ê..... as in <i>her</i>, and <i>eu</i> in French <i>-eur</i>.</p> <p>î..... as in <i>it</i>, <i>sin</i>.</p> <p>ī..... as in <i>five</i>, <i>swine</i>.</p> <p>ĩ..... same, but less prolonged.</p> <p>ō..... as in <i>mole</i>, <i>sober</i>.</p> <p>ō..... same, but less prolonged, as in <i>sobriety</i>.</p> <p>o..... as in <i>on</i>, <i>not</i>, <i>pot</i>.</p> <p>oo..... as in <i>fool</i>, or as <i>u</i> in <i>rule</i>.</p> <p>õ..... as in <i>book</i>, or as <i>u</i> in <i>put</i>, <i>pull</i>.</p> <p>oi..... as in <i>noise</i>, and <i>oy</i> in <i>boy</i>, or as <i>eu</i> in German <i>Beust</i>.</p> <p>ow..... as in <i>now</i>, and as <i>au</i> in German <i>haus</i>.</p>	<p>ö..... as in <i>Göthe</i>, and as <i>eu</i> in French <i>neuf</i>, <i>Chintreuil</i>.</p> <p>ÿ..... as in <i>but</i>, <i>hub</i>.</p> <p>ÿ..... obscure <i>o</i>, as final <i>o</i> in <i>Compton</i>.</p> <p>ü..... as in German <i>süd</i>, and as <i>u</i> in French <i>Buzançais</i>, <i>vu</i>.</p> <p>y or l.... see <i>l</i> or <i>y</i>.</p> <p>yu..... as <i>u</i> in <i>mule</i>.</p> <p>ÿü..... same, but less prolonged, as in <i>singular</i>.</p> <p>ch..... as in German <i>ich</i>.</p> <p>g..... as in <i>get</i>, <i>give</i> (never as in <i>gist</i>, <i>congest</i>).</p> <p>hw..... as <i>wh</i> in <i>which</i>.</p> <p>kh..... as <i>ch</i> in German <i>nacht</i>, <i>g</i> in German <i>tag</i>, <i>ch</i> in Scotch <i>loch</i>, and <i>j</i> in Spanish <i>Badajos</i>, etc.</p> <p>ñ..... nasal <i>n</i>, as in French <i>fin</i>, <i>Bourbon</i>, and nasal <i>m</i>, as in French <i>nom</i>, Portuguese <i>Sam</i>.</p> <p>ñ or n-y.. Spanish ñ, as in <i>cañon</i>, <i>piñon</i>, French and Italian <i>gn</i>, etc., as in <i>Boulogne</i>.</p> <p>l or y.... French <i>l</i>, liquid or mouillé, as (-i)ll- in French <i>Baudrillart</i>, and (-i)l in <i>Chintreuil</i>.</p> <p>th..... as in <i>thin</i>.</p> <p>th..... as in <i>though</i>, <i>them</i>, <i>mother</i>.</p> <p>v..... as <i>w</i> in German <i>zwei</i>, and <i>b</i> in Spanish <i>Cordoba</i>.</p> <p>sh..... as in <i>shine</i>.</p> <p>zh..... as <i>s</i> in <i>pleasure</i>, and <i>j</i> in French <i>jour</i>.</p> <p style="text-align: center;">All other letters are used with their ordinary English values.</p>
---	--

NOTE.

The values of most of the signs used in the above Key are plainly shown by the examples given. But those of ö, ü, ch, kh, ñ, and v, which have no equivalents in English, can not be sufficiently indicated without a brief explanation, which is here given.

ö. The sound represented by this symbol is approximately that of -u- in *hurt* or -e- in *her*, but is materially different from either. It is properly pronounced with the tongue in the position it has when *ā* is uttered and with the lips in the position assumed in uttering *ō*.

ü. This vowel is produced with the lips rounded as in uttering *oo* and with the tongue in the position required in uttering *ee*, into which sound it is most naturally corrupted.

ch and kh. These are both rough breathings or spirants made with considerable force, *ch* being made between the flat of the tongue and the hard palate, and *kh* between the tongue and the soft palate. *ch* approaches in sound to English *sh*, but is less sibilant and is made further back in the mouth; *kh* is a guttural and has a hawking sound.

l or y. These are both used to represent the sound of French *l* mouillé, in (-i)ll- and (-i)l, which resembles English -y- in *lawyer*. Final *l*, that is, (-i)l, may be approximated by starting to pronounce *lawyer* and stopping abruptly with the -y-.

ñ or n-y. The consonants represented by ñ (Spanish ñ, French and Italian *gn*, etc.) are practically equivalent to English -ni- or -ny- in *bunion*, *bunyon*, *onion*, etc., and except when final are represented by n-y. Final ñ, as French -gn(c), may be produced by omitting the sound of -on in the pronunciation of *onion*.

v. This may be pronounced by attempting to utter English *v* with the use of the lips alone.

See PREFACE (p. xli.) and the article PRONUNCIATION OF FOREIGN NAMES.

THE UNIVERSAL CYCLOPÆDIA.

A

the first letter of the alphabet. As the leading letter of the alphabet, A inherits its position from the ancient Phœnician alphabet, and as it evidently did not there indicate the vowel *a*, it can not be said to owe its primacy to the peculiar character of this vowel. (See ALPHABET.) Its original name, aleph, was pronounced alpha

by the Greeks. An old English name, *A-per-se*, or *Aper-se*, i. e. "A by itself," like *E-per-se*, etc., probably an adaptation of the Byzantine $\epsilon \psi\iota\lambda\delta\nu$ ("e simple" to distinguish from *ai*) and $\delta \psi\iota\lambda\delta\nu$ (to distinguish from *oi*), is now nearly obsolete (but cf. *ampersand* = & perse &). A with a stroke above it (*á*), in the ancient Greek, denoted the first numeral, but *α* with the stroke beneath stood for 1,000. In logic, A is the sign employed to denote a universal affirmative proposition. A¹ (or "A No. 1") is often applied in mercantile affairs to denote any article of the very highest class. In registering vessels, A designates the character of the hull of the vessel, while the figure 1 marks the efficient state of her anchors, cables, stores, etc. In Latin, A stands for several proper names, especially for the prænomen *Aulus*. For other uses of A as an abbreviation, see ABBREVIATIONS.

Revised by B. I. WHEELER.

A: a note in music, the major sixth of the scale of C major. It is the standard tone from which as a starting-point most instruments are tuned. See **PITCH**.

Å, å: Swedish *a*; sounded as English long *o* (*ō*).

A, Ab, or Abs: a Latin particle signifying "from," "off," "away," and forming the prefix of a multitude of English words, as *abduct*, to "lead or take away"; *abstract*, to "draw away or from"; *avert*, to "turn away." This must be discriminated in modern English from other *a* prefixes of various origin, as in *abed*, *alive*, *once a year*, where *a* represents the old English preposition *an*, or in *amuse*, *avenge*, where *a* is a French representative of Latin *ad*.

Aa: the name of several rivers or streams in Germany, Switzerland, Holland, Russia, and France. It is supposed to signify "water," and to be etymologically related to the Latin *aqua*. The Icelandic word for "river" is *á*. In Swedish this primitive form becomes *å*, and in Danish *aa*, and these syllables become very often the termination of names of rivers in the three countries mentioned. **Aach**, or **Ach**, another form of the same, constitutes a part of several geographical names, as *Aachen* (the German of Aix-la-Chapelle), *Biberach*, etc.

Aachen: See **AIX-LA-CHAPELLE**.

Aageson, **SVEND**: Danish historian; flourished in the second half of the twelfth century. He wrote *Compendiosa historia regum Daniæ*, the first continuous history of Denmark. It is written in Latin, and describes Denmark from Skjold down to the year 1185. The latest Danish translation of Aageson's work is by Fenger (1842).

Aal'borg: a seaport of Denmark, in Jutland, on the south shore of the Lymfiord, through which vessels pass into the Cattagat, and 63 miles N. W. of Aarhuus (see map of Europe, ref. 4-G). The number of vessels arriving here annually amounts to about 600. Pop. (1890) 19,503.

Aa'li Pash'a, **MEHEMED EMIN**: Turkish statesman; b. in 1815 at Constantinople; was appointed Minister of Foreign Affairs Aug. 15, 1845, which position he filled three times from 1846 to 1853. In Dec., 1845, he became chancellor of the divan, in 1846 pasha, and in 1852 for the first time grand vizier, which position he afterward held several times. In 1855 he represented Turkey at the conferences of Vienna and Paris, and signed the treaty of Paris of Mar. 30, 1856. In May, 1864, he presided at the conference of European powers for settling the Roumanian question. In 1867, while the sultan undertook a tour over the Continent, Aali Pasha was appointed regent of the empire. In the same year he went to Candia to settle the difficulties there. D. Sept. 6, 1871.

Aall, **JAKOB**: b. at Porsgrund, Southern Norway, July 27, 1773; studied theology at the University of Copenhagen, afterward natural history and mineralogy at the mining-school of Freiberg; settled in 1799 on his estate, Näs Iron-works, near Arendal; and divided his time between the development of his extensive possessions, public business, and literary occupations. He was one of the most prominent among the representatives who assembled at Eidsvold in 1814 and formed the present free Norwegian constitution, and he sat in the Storting from 1816-30. D. Aug. 4, 1844. His *Erindringer som Bidrag til Norges Historie fra 1800 til 1815* (3 vols., 1844-45) is one of the principal sources of the history of Norway during that period. He also published a translation of Snorre Sturlason's *Heimskringla* (2 vols., 1838-39).

Aar: a river of Switzerland, rising in the Grimsel and Schreckhorn mountains in the canton of Bern; forms the remarkable fall of Handeck; traverses the lakes of Brienz and Thun, and enters the Rhine opposite Waldshut; length, 175 miles. It is navigable from Thun to its mouth. **AAR** is also the name of several rivers of Germany.

Aa'rau: a town of Switzerland; capital of Aargau, on the river Aar, 63 miles by railway W. of Zurich (see map of Switzerland, ref. 3-F). It has manufactures of silk and cotton stuffs, mathematical instruments, etc. In 1798 it was the capital of the Helvetic republic. Pop. about 6,000.

Aard-Vark [Dutch of S. Afr. *aarde*, earth + *vark*, pig; Lat. *porcus*]: literally "earth-pig"; a mammal (*Orycteropus capensis*) of the order *Edentata*, found in South Africa. It is a plantigrade, is about 5 feet long, including the tail, burrows in the ground if pursued, and quickly enters so far that it is beyond the reach of the pursuer. It feeds on ants, seeking its prey by night; it readily breaks down the walls of the ant-hills, catching the insects with its long prehensile and slimy tongue. Its flesh is often used as food. A second species (*Orycteropus aethiopicus*) inhabits Northeastern Africa.

Aard-Wolf [Dutch of S. Afr. earth-wolf]: lit. "earth-wolf"; a carnivorous digitigrade mammal (*Proteles cristatus*).

Aard-Vark.

tus), a native of South Africa. It is about equal in size to a fox, and resembles a hyana in most details of structure and in general appearance, differing conspicuously in the greatly reduced molar teeth, which are almost rudimentary. It burrows in the ground, has nocturnal habits, and feeds on small insects, larvæ, and decomposing animal substances.

Aar'gan (Fr. *Aargovie*): a canton in the north of Switzerland, bounded on the N. by Germany, on the E. by Zurich, on the S. by Lucerne, and on the W. by Basel and Solothurn. Area, 542 sq. miles (see map of Switzerland, ref. 2-F). The chief rivers are the Aar and the Limmat. It consists chiefly of fertile and well-cultivated hills. Its minerals are unimportant, but it has remarkable paleontological remains in its rocks. Fruit of all kinds is produced in large quantities, and many cattle are raised here. It has important cotton-factories. There are mineral springs at Baden and Schinznach. Pop. (1880) 198,645, of whom 108,029 were Protestants, 88,893 Roman Catholics, 489 belonged to other Christian churches, and 1,234 were Jews; (1894) 190,246. Aargau formed part of the canton of Bern until 1798, but was erected into a separate canton after the Helvetic republic was proclaimed, and was organized in 1803. The constitution dates from 1841, and was revised in 1852 and 1862. Capital, Aarau. See Müller's *Der Aargau*.

Aar'huus: a seaport of Denmark, on the east coast of Jutland, on the Cattegat, 37 miles S. E. of Viborg (see map of Europe, ref. 4-E). It has a cathedral, a museum, a library, and various manufactories. Pop. (1880) 24,831; (1890) 33,308.

Aar'on (Heb. אהרן): the first high priest of Israel; was a great-grandson of Levi, unless there are omissions in the genealogy. He was three years older than his brother Moses (Ex. vii. 7). They had a sister, Miriam, and perhaps an older sister (Ex. ii. 4). An impulsive and eloquent man, he was appointed spokesman to Moses, whom he assisted in the deliverance of the Israelites from the bondage in Egypt. He died on Mount Hor, which is still called the "Mountain of Aaron," and was succeeded in the priesthood by his son Eleazar.

Revised by W. J. BEECHER.

Aaron ben-Asher: Jewish scholar of Tiberias of the tenth century. The variations in the text of our Hebrew Bibles are almost exclusively in the vowels. One of the two existing recensions, the Occidental or Palestinian, is the work of Aaron ben-Asher, and is generally preferred to that of his rival, Moses ben-Naphtali. The famous codex, called after Ben-Asher, was preserved at Berëa (the biblical Helbon), and is the original of our present Masoretic text. See Strack, *Prolegomena*; Graetz, *History of the Jews*.

C. H. TOY.

Aaron, SAMUEL: Baptist minister and educator; b. in 1800 at New Britain, Pa.; ordained in 1829; held pastorates at New Britain and Norristown, Pa., and at Burlington and Mt. Holly, N. J. He also gained great reputation as a teacher in various schools, especially at Treemount Seminary, near Norristown, and the Mt. Holly Institute. He was the author of various text-books. D. at Mt. Holly, N. J., Apr. 11, 1865.

Aar'sens, or Aarssens, FRANCISCUS van: b. at The Hague in 1572; son of the Dutch statesman Cornelis van Aarsens (1543-1624). The younger Van Aarsens was sent to the court of France as resident in 1598, and as ambassador in 1609 and in 1627; to Venice from 1609 to 1615, and again in 1619; to England in 1626 and in 1640, when he negotiated the marriage between the Prince of Orange (William II. of Nassau) and the Princess Mary, daughter of Charles I. of England. D. in 1641.

Aa'sen, IVAR ANDREAS: Norwegian writer; b. at Aasen in Söndmøre, Aug. 5, 1813; was at first a school-teacher, but subsequently devoted himself wholly to the study of the Norwegian dialects. He was supported in this study by the Dronheim Association of Sciences, which furnished him the means of visiting all parts of the country. He wrote *Det Norske folkesprogs grammatik* (1848); *Ordbog over det Norske folkesprog* (1852; new and much improved ed. 1873); and *Norske ordspog* (1856).

Aas'vær, or Vaero, Islands: a group of islands under the Arctic circle, about 10 miles from the Norwegian coast, formerly leased for a small price to two poor fishermen. At present they are one of the most important fishing-places in Europe. About Dec. 10, when the herrings arrive, over 10,000 fishermen come here, and in two or three weeks catch about 200,000 kegs of herrings. From Jan. 1 to Dec. 1 the

islands are inhabited by only a few families. (For location, see map of Norway and Sweden, ref. 5-D.)

Ab, or Abs: See A.

Ab: the eleventh month of the Jewish civil year, and the fifth of the ecclesiastical year, corresponding to part of July and part of August.

Abab'de: a village of Middle Egypt, on the east bank of the Nile, 8 miles S. of Beni-Hassan. Near it are the ruins of the ancient Antinoë (or Antinoöpolis), a city built by the Emperor Hadrian (or Adrian) in honor of his favorite Antinoüs.

Ab'aca: See MANILLA HEMP.

Ab'aco, or Great Abaco: the largest of the Bahama islands, 80 miles long; its N. E. point is in lat. 25° 51' N., lon. 77° 5' W. Area about 96 sq. miles (see map of North America, ref. 9-H). Carleton is the chief town.—LITTLE ABACO lies W. of the northern part of Abaco. Population of the two about 2,400.

Ab'acus [Lat., from Gr. ἀβαξ, reckoning-board]: a calculating instrument used in mercantile transactions by the ancient Greeks and Romans. It is still used by the Chinese, the Japanese, etc., and to a certain extent is used in a very simple form in the schools of Europe and America to illustrate addition and subtraction. As thus used, it usually consists of several parallel wires stretched from side to side of a rectangular frame, each wire carrying ten sliding beads, or counters. The wires represent successive *orders* of units,

Chinese abacus.

and the counters stand for *units* of the several orders. The Chinese abacus, or swan-p'an (literally "reckoning-board"), called in Japan *soro-ban*, has seven (or six) beads on each wire, divided into two unequal sections by a crosspiece, with five beads on one side and two (in Japan generally one) on the other. Each bead in the larger section represents one, and in the smaller section five (units, tens, hundreds, etc., as the case may be). Reckoning on the swan-p'an is decimal. One is represented by pushing up to the crosspiece a single bead on the larger section of the wire chosen to represent unity; 6 may be added to that by pushing up another bead on the same section of the wire and bringing down one of the two beads on the shorter section; 20 may be added to that by pushing up two of the five beads on the wire next on the left; and 800 by pushing up three of the five beads on the wire to the left of *that*, and bringing down one of the two on the shorter section of the same wire, and so on. The swan-p'an serving merely to set down the successive steps of a mental calculation. It is used for the most elaborate calculations, but has the drawback that in case of error one can not go back over these successive steps to find out where the error is. *Ab'acus Pythagor'icus* was anciently a name for the multiplication table. The word has also an architectural meaning, and signifies the level tablet placed between the entablature and the capital of a column.

Revised by R. LILLEY.

Abâd: an affix of Persian origin, signifying "abode," and occurring in the names of many cities in the East; as *Hyderâbâd*, the "abode or city of Hyder."

Abâd: the name of several kings who reigned in Moorish Spain. Abâd I. was the first Moslem king of Seville. He began to reign in 1023 and died in 1042. Abâd III., the last of this dynasty, died in 1095.

Abad, DIEGO JOSÉ, S. J.: Mexican Latinist and poet; b. July 1, 1727, in the state of Michoacan, Mexico; became in 1741 a member of the Jesuit Society, and devoted himself to

teaching. In 1767, when the Jesuits were expelled from Mexico, Abad, then rector of the College of Querétaro, was obliged to go into exile in Italy, where he lived for some years at Ferrara. Before leaving Mexico he had begun to write his greatest work, a Latin poem entitled *Heroica de Deo Carmina*. The first twenty-nine cantos of this were published in Cadiz in 1769; and this edition was followed by three others at short intervals, each containing more matter than the preceding (Venice, 1773; Ferrara, 1775; and the final, complete edition, Cesena, 1780). This last edition Abad never saw, as he died in Barcelona, Sept. 30, 1779.

A. R. MARSH.

Abad'don: a Hebrew name (meaning "destruction") applied to the angel of the bottomless pit; the same as the Asmodeus of Tobit iii. 8, and the Apollyon of Rev. ix. 11.

Abalone: See EAR-SHELL.

Ab'ana: the name of one of the rivers of Damascus mentioned in the Bible (2 Kings v. 12). Its identification with the modern Barada is now generally accepted. See Porter's *Five Years in Damascus* (1855).

Abancay, ab-an-kí': town of Peru, in the department of Cuzco; situated on the river Abancay, 74 miles W. S. W. of Cuzco (see map of South America, ref. 5-B). It has large sugar-refineries, and there are silver mines in the vicinity. Pop. estimated at about 1,200.

Aban'donment [from the Fr. *abandonner*]: in law, used in several senses, depending upon the subject to which it is applied:

1. *In Insurance*.—In certain cases of partial loss abandonment is the transfer by the insured (at his election) of the entire property to the insurers, in order to claim a total loss. The insurers would thus become the owners of the property in its impaired condition. This act is called abandonment, and the "total loss" thus occasioned is termed constructive. It is applicable particularly to marine insurance. The rules by which the subject is governed in Great Britain differ somewhat from those in force in the United States. The general principle is that a serious injury must have happened by a marine peril to the ship or cargo (the value must have usually been diminished more than one-half), or the purposes of the voyage as to the ship must have been substantially defeated, as in the case of an embargo for an indefinite time. The act of abandonment must be exercised by the insured not upon mere conjecture, but upon credible information, and without delay. No particular form is necessary.

2. *As to Personal Property*.—The act of an owner who casts away or otherwise relinquishes personal property, so as to cause his ownership to cease. This may readily occur in the case of property at sea. The intent is a principal subject of inquiry. Property in this condition is otherwise called "derelict."

3. *Real Estate*.—Abandonment in this branch of the law applies to the relinquishment of incorporeal rights, such as easements. There can be no abandonment of the ownership of the land itself. This must be parted with by some recognized mode of conveyance, such as a deed, or the principle of estoppel must be invoked or the rules of the statute of limitations.

4. *By Husband or Wife*.—In the legal relation of husband and wife the word abandonment is frequently employed as an equivalent to *desertion*. It is in some instances defined by statute.

5. *In the Civil Law*.—In this law a person could escape responsibility for a tort or trespass committed by his slave or animal by abandoning the slave or animal to the person injured.

Revised by HENRY WADE ROGERS.

6. In old ecclesiastical law *abandonment to the secular arm* meant the handing over of offenders by the church authorities to the civil power for such punishment as could not be administered by the ecclesiastical tribunals. In the case of the clergy, degradation from their priestly rank preceded such transfer to the secular authorities. W. S. PERRY.

Abano, PIETRO d' (also called *Petrus de Apono* or *de Padua*): b. in 1246 at Abano, near Padua; studied Greek at Constantinople, mathematics at Padua, and medicine at Paris, and settled at Padua, where he taught alchemy and astrology according to the methods of Averroës, and practiced medicine, also according to Arabic methods, with such success that he could charge Pope Honorius IV., who called him to Rome to consult him, 400 ducats a day. Envious of his fame and riches, the clergy denounced him as a sorcerer,

as possessor of the philosopher's stone, etc., and the Inquisition sentenced him to be burned. He died a natural death, however, in the dungeon at Padua, in 1315 or 1316, and his corpse was rescued by a friend, but his image was burned in the public square. His principal work, *Conciliator differentiarum, quæ inter philosophos et medicos versantur*, has often been reprinted.

Abar'ca, JOAQUIN: a Spanish bishop and leader of the absolutist party; b. in 1780; made a bishop by Ferdinand VII., on account of his zealous advocacy of the principles of absolutism. Subsequently he became prime minister of Don Carlos, but after a time fell into disfavor for being too moderate. He was banished, and died in 1844.

Aba'rim (meaning "regions beyond"): a mountain range of Moab, on the east side of Jordan, opposite Jericho, mentioned in Num. xxvii. 12 and elsewhere. Pisgah is either the same as Abarim or a part of it. This line of mountains rises to the height of nearly 3,000 feet above the Mediterranean, and more than 4,000 feet above the Dead Sea. As seen from Jericho or the Mount of Olives, the summit of the range is apparently almost level. But recent explorers report considerable inequalities of surface. The highest of the peaks, still called Mount Nebo or Nebbeh, is thought to be the Nebo from which Moses viewed the Land of Promise (Deut. xxxiv. 1-4).

Abascal', JOSÉ FERNANDO: Spanish commander; b. at Oviedo in 1743. He entered the army in 1762; served against the French and the British; became intendant of New Galicia; and in 1804 was appointed Viceroy of Peru. He was an able and popular ruler, and accomplished much for the people of Peru. In 1812 he was made a marquis. He was recalled in 1816. D. at Madrid, June 30, 1821.

Aba'sia: See ABKASIA.

Abatement [from the Fr. *abattre*, to strike away]: a legal term of various application:

1. *Title to Real Estate*.—The intrusion or wrongful entry of a stranger upon land after its owner's death, and before the entry of an heir or devisee, and thus keeping him out of possession. The wrong-doer is termed an abator.

2. *Nuisances*.—The act of destroying or removing a nuisance, which may take place without legal process. No unnecessary damage must occur, and the act must be done without a breach of the peace.

3. *Legacies and Debts*.—In respect to legacies and creditors' claims, the word means a proportionate reduction of them where there are not sufficient assets to make full payment.

4. *Pleadings*.—The effect on an action at law of a plea showing that the writ or declaration is defective and incorrect. A defendant may assert by a "plea in abatement" that the plaintiff's action ought to cease by reason of some informality or irregularity. It is called a *dilatory* plea, because it does not meet the case upon the merits. Such pleas are not favored in modern law, and there is a tendency to confine them by statute within narrow limits. If the cause is abated on such grounds, a new action may be brought.

5. *Practice*.—The termination of a litigation by the occurrence of some event during its progress, such as the death or disability of a party. In a court of law the regular effect of the death of a party was to cause the action to abate altogether. In a suit in equity proceedings were suspended, and might be revived by established methods. Similar rules were applied to disabilities, such as the coverture of a female party to an action. The effect of this doctrine is largely modified in codes of procedure in the United States, and in Great Britain by the "Common Law Procedure" act. Under these statutory regulations an action may, after the death of a party, be continued by or against his representatives, on motion to the court in which the action is pending. The application is subject to regulations to prevent unnecessary delay. There are certain actions in which there can be no revival. An instance is that of a cause of action for a personal wrong (tort). This is said to "die with the person." In other words, it can not be prosecuted by or against the executors or administrators of a party sustaining or inflicting the wrong.

Revised by HENRY WADE ROGERS.

Abatement: in heraldry, anything added to a coat-of-arms to denote inferiority or disgrace. This is an absurdity, because a coat-of-arms is a statement of the honorable position of its bearer and not of his discredit. The only abatement in use is the BEND SINISTER (*q. v.*).

Abattis, or **Abatis** [Fr.]: in fortification, a bulwark or obstruction formed by trees felled and placed side by side, so that their tops are directed toward the enemy. Sometimes the smaller branches are lopped off and the ends of the larger branches sharpened. See FORTIFICATION.

Abattoir: a public establishment in which cattle, sheep, etc., are killed, with such sanitary arrangements as will guard the population of a city against the nuisances of private slaughter-houses. This improvement originated in Paris in 1807, and has been adopted in New York and other large cities.

A Battuta [It.]: in music, in strict or measured time.

Abat-voix [from Fr. *abattre*, to beat down, and *voix*, the voice]: a sounding-board, generally of shell-shape, placed behind, and projecting over, a rostrum or pulpit, for the purpose of throwing the speaker's voice in any desired direction. Notable instances are found in Trinity and Grace churches in New York city and in Trinity church in Boston.

Abauzit, a-bō'zee, FIRMIN: French Protestant philosopher and mathematician; b. at Uzès, Languedoc, Nov. 11, 1679; educated at Geneva; traveled in England and Holland, and wrote several works on theology, antiquities, etc. He was a friend and correspondent of Sir Isaac Newton, who esteemed him highly, and he was profoundly versed in many branches of learning and science. He died in Geneva, Mar. 20, 1767.

Abadie, ANTOINE and ARNOULD MICHEL d': two brothers and French travelers; b. in Dublin in 1810 and 1815; explored Abyssinia and Upper Egypt between 1838 and 1848; traveled up the White Nile, and even visited Darfur. Their more important works are *Nouvelles du haut fleuve Blanc*; *Note sur la route du Darfour*; *Sur les nègres Yambo*; *Géodésie d'Éthiopie*, etc. (1860-63); and *Douze ans dans la Haute-Éthiopie* (2 vols., 1868). Their collection of Ethiopic and Amharic manuscripts, numbering 234, was until recently the largest in Europe. Arnould died Nov. 13, 1893.

Abadie, JACQUES: eminent scholar and divine of the Reformed faith; b. at Nay, in Bern, about 1657. So distinguished was he for his learning that, on the completion of his course of study at Sedan, he received the degree of doctor in theology, although but seventeen years of age. After ministering in a French church at Berlin for some years, he accompanied Marshal Schomberg, in 1688, to England, where he became minister of the French church in the Savoy, London. Having received episcopal ordination, King William made him Dean of Killaloe, Ireland. He published a defense of the Revolution of 1688, but is best known by his religious treatises, the most important of which were *Traité de la Vérité de la Religion Chrétienne*, and its continuation, *Traité de la Divinité de Jésus-Christ*, and *L'Art de se connaître soi-même*. D. in London, Sept. 25, 1727.

W. S. PERRY.

Abbandonamen'te [It.]: in music, "with self-abandonment"; despondingly.

Abbas', or, more fully, **Abbas-Ibn-Abd-il-Moot'talib**: a paternal uncle of Mohammed, and the ancestor of the dynasty of Abbassides; b. at Mecca about 566 A. D. He fought against Mohammed at the battle of Bedr, but was afterward converted, and rendered important services to that prophet.

Abbâs I., or **Shâh Abbâs**, surnamed THE GREAT: King of Persia; b. in 1557; son of Mohammed Mirza. He began to reign about 1584, and distinguished himself by his ability and energy. In 1605 he defeated the Turks in a great battle, and recovered the Persian provinces which they had occupied. D. at Kaswin, Jan. 27, 1628.

Abbâs-Mîr'za: son of Fatah Ali Shah, King of Persia; b. in 1783. He commanded the Persian army which was defeated by the Russians in 1811. He was a prince of superior talents, and promoted the introduction of European culture and military tactics into Persia. He died before his father at Meshed, Dec., 1833.

Abbâs Pasha: Viceroy of Egypt (the third of the present dynasty); a grandson of Mehemet Ali; b. at Yedda, in Arabia, in 1813. He succeeded his uncle, Ibrahim Pasha, Nov. 9-10, 1848, and d. July 13, 1854. He was succeeded by his uncle, Saïd Pasha.

Abbassides, or **Abbasides** (Lat. *Abbasidæ*; called by the Arabs BENI ABBÂS, i. e. sons or descendants of Abbas): a celebrated dynasty of caliphs who reigned at Damascus,

and afterward at Bagdad, from 762 to 1258 A. D. They traced their genealogy to Abbâs, the uncle of Mohammed. To this dynasty belonged the caliphs Harun-al-Rashid and Al-Mamun.

Abbate, NICCOLO dell': historical painter; b. in Modena, 1512; d. at Fontainebleau, 1571. He is best known by his frescoes in the castle of Fontainebleau, from designs by Primaticcio. See his life by Reiset, Paris, 1859.

Abbé: an ecclesiastic, or student of theology, supported by the revenue of a monastery, though he did not always become a priest. Abbés often devoted themselves to literature or were tutors in wealthy families. Before the French Revolution the king could nominate 225 *abbés commendataires*, whose offices were sinecures. The term is still applied in French-speaking countries to all who dress as ecclesiastics. See ABBOT.

Abbe, CLEVELAND, M. A., Ph. D., LL. D.: meteorologist and writer on meteorological subjects; b. in New York city, Dec. 3, 1838; graduated in 1857 from the N. Y. City Free College; studied engineering and astronomy at Ann Arbor and was instructor there 1859-60; was aide in the coast survey longitude work under Dr. B. A. Gould at Cambridge, Mass., 1860-64; resided at the Pulkowa Observatory, Russia, 1864-66; later was assistant in the U. S. Naval Observatory; in 1868 became director of the Cincinnati Observatory, where he organized a system of daily telegraphic weather-reports and predictions for the benefit of the Chamber of Commerce of that city. He was Professor of Meteorology in the signal service and assistant to the chief signal officer 1871-91. Since July 1, 1891, senior meteorologist of the Weather Bureau. He devised and initiated the present system of standard time. He was a delegate to the International Meridian Conference, Washington, 1884, and the International Meteorological Conference at Munich, 1892. He is a member of the National Academy and other scientific societies. His scientific publications have been very numerous, and are characterized by a high order of learning and ability and by a keen appreciation of the advances of science abroad. Among his writings may be mentioned: *Dorpat and Pulkowa* (1868-70); *Weather Bulletin of Cincinnati Observatory* (1869-70); *Solar Spots and Terrestrial Temperature* (1869); *Suggestions on the Use of Weather Reports* (1871); *Observations of Coggia's Comet* (1874); *Report of Committee on Standard Time* (1879); *Annual Reports of Progress in Meteorology* (1872-89); *Report on Meteorological Observations during the Expedition to the West Coast of Africa* (1891); *A Plea for Terrestrial Physics* (1891); *Atmospheric Radiation* (1892); *A Treatise on Meteorological Apparatus* (1887); *Preparatory Studies for Deductive Methods in Meteorology* (1889). M. W. HARRINGTON.

Abbeoku'ta, or **Abeokuta** (i. e. under the rock): a large town of Western Africa; capital of the kingdom of Egba, in Yoruba; built on granite hills around a rock 250 feet high; on the left bank of the Ogun river, 120 miles N. W. of Benin (see map of Africa, ref. 5-C). The late Negro bishop Crowther established a newspaper here in the Egba language; the number of Christians is estimated at 2,000. The city was founded in 1825, has rapidly increased, and has become an important missionary station. The surrounding country, called Egbaland, comprises an area of nearly 3,000 sq. miles. Pop. of the town estimated at 150,000; of the adjacent dependent country, 50,000.

Abdess [O. Fr. *abbesse* < Late Lat. *abbatis'sa*]: the superior of a convent of women, elected for life, and solemnly admitted to office by a bishop, corresponding in rank and authority to an abbot, except that, not being capable of receiving holy orders, she can not execute the functions of the priesthood nor perform any act implying real spiritual jurisdiction. In England abbesses were permitted to attend ecclesiastical councils. At the council of Beaufield, A. D. 694, they were not only present but signed the decrees before the priests. Among the Celts they presided over religious houses occupied jointly by monks and nuns, and this custom prevailed among the Celtic monastic missions in France and Spain, and even in Rome itself. The title of abbess is applied in Hanover, Würtemberg, Brunswick, and Schleswig-Holstein to the lady superiors of Lutheran seminaries and sisterhoods to which conventual endowments and realty were transferred at the period of the Reformation.

W. S. PERRY.

Abbett, LEON: lawyer and politician; b. in Philadelphia, Oct. 5, 1836; studied law; removed in 1862 to Hoboken,

N. J.; elected corporation attorney 1863, and member of the Assembly in 1864; settled in Jersey City 1866; elected to the State Senate in 1874; elected Governor by the Democratic party in 1883, and again at the expiration of the term of his successor; associate justice of the Supreme Court of New Jersey, 1893. D. in Jersey City, Dec. 4, 1894.

Abbeville, ab'veel': fortified city of France; on the river Somme; in the department of Somme, on the Northern R. R., 36 miles by rail N. W. of Amiens (see map of France, ref. 2-E). It contains a fine cathedral and manufactories of woolen cloths, etc. Abbeville has in late years been made famous by the discovery of many interesting relics of prehistoric man in the valley of the Somme at that place. Pop. (1896) 19,669.

Abbeville C.-H., ab'be-vil: capital of Abbeville co., S. C. (for location of county, see map of South Carolina, ref. 5-C); on main line Georgia, Carolina and Northern R. R., and terminal of Abbeville branch of Columbia and Greenville R. R.; 97 miles from Columbia, S. C., and 133 miles from Atlanta, Ga.; has a 20-ton cottonseed-oil mill, 3 gineries, 1 shoe-factory, 2 banks, 2 weekly newspapers, a good hotel, 6 churches, and a public-school system. Pop. (1880) 1,543; (1890) 1,696; (1900) 3,766.
EDITOR OF "PRESS AND BANNER."

Abbeville Treaties: two treaties; one between Henry III. of England and Louis IX. of France, May 20, 1259; the other between Henry VIII. of England and Francis I. of France, Aug. 18, 1527. By the former Henry III. gave up all claim to Normandy, Anjou, Touraine, Maine, and Poitou; but he was guaranteed possession of some other provinces of France, which he was to hold as fiefs, and was to sit with the peers of France as Duke of Guienne, and was to drop the titles of Duke of Normandy and Count of Anjou.

Abbey, EDWIN AUSTIN: genre painter and illustrator; b. in Philadelphia, Pa., in 1852. Best known as an illustrator of periodicals and books. His subjects are mostly found in English songs and tales. He works equally well with pen and ink and with the brush, but as a pen-draughtsman he enjoys a world-wide reputation. Among his principal works in illustration are drawings for *Selections from the Poetry of Robert Herrick*; *Old Songs*; Goldsmith's comedy *She Sloops to Conquer*; and *As You Like It*, *The Tempest*, *All's Well that Ends Well*, and *The Merchant of Venice*. He is notably successful as a story-teller in illustration, and possesses a fine talent for composition. Member of the Society of American Artists (1881); American Water-Color Society; and Royal Institute of Water-Color Painters, London. Received a second-class medal, Munich International Exhibition, 1885; first-class medal, Universal Exposition, Paris, 1889. Principal pictures: *Slage Office* (1876); *The Evil Eye* (1877); *Lady in a Garden* (1878); *Rose in October* (1879); *The Wandering Minstrel*; *The Sisters*; *The Widower* (1883); *Reading the Bible* (1884); and *Visitors* (1890). Began his art studies at the Pennsylvania Academy of Fine Arts, Philadelphia. Has resided in England since 1883; studio in London.
WILLIAM A. COFFIN.

Abbey, HENRY E.: theatrical manager; b. in Akron, O., 1848; began his career as manager for Edwin Adams in 1870; acted as manager for Lawrence Barrett, Lotta, Sara Bernhardt, Patti, Neilson, Mrs. Langtry, Henry Irving and others with great success. D. in New York, Oct. 17, 1896.

Abbey, RICHARD: Methodist clergyman and author; b. in Genesee co., N. Y., Nov. 16, 1805; removed to Illinois in 1816, and to Natchez, Miss., in 1825. In 1844 he entered the ministry in the Methodist Church, and was afterward a member of the Mississippi Conference of the Methodist Episcopal Church South. He published *Lettters to Bishop Green on Apostolic Succession* (1853); *End of the Apostolic Succession*; *Creed of All Men* (1855); *Ecclesiastical Constitution* (1856); *Church and Ministry* (1859); *Diuturnity* (1866); *Ecce Ecclesia* (1868); *The City of God and the Church-makers* (1872); *Baptismal Demonstrations*; *Divine Assessment*; *Strictures on Church Government*; and *The Divine Call to the Ministry*. D. Oct. 23, 1891.

Abbitib'bie, or **Abbitib'be**: a lake and a trading-station in British North America, 200 miles S. of James's bay, with which they are connected by the Abbitibbie river. (For location, see map of North America, ref. 5-G.)

Abbon of Fleury (in Latin, *Ab'bo Floriacen'sis*): French monk; b. near Orleans in 945; was one of the most learned men of his age; wrote an *Epitome of the Lives of Ninety-one Popes*. D. in 1004.

Abbon the Crooked (*Ab'bo Cer'nuus*): Northman by birth; became a monk of St. Germain-des-Prés; d. about 923; described the siege of Paris by the Northmen (885-887) in a Latin poem, a French translation of which is found in Guizot's *Collection des documents relatifs à l'histoire de France*.

Ab'bot [Late Lat. *Abbas*, -is, Gr. ἀββάς, from Syriac *abbā*, father]: the superior of a convent or monastery, and an ecclesiastic of high rank in the Roman Catholic Church. Abbots are ranked, as prelates of the Church, next to bishops; and have the right to vote or speak in the general councils, if the territory to which their jurisdiction extends be not included in a diocese, or if they be heads of several associated monasteries. In England there were formerly a number of *mitred abbots*, who sat and voted in the House of Lords.

Abbot of Misrule, or **Abbot of Fools**: called in Scotland the "Abbot of Unreason"; a title given in the Middle Ages to the master of revels, and especially to the person appointed to preside over Christmas festivities.

Abbot, BENJAMIN, LL. D.: teacher; b. at Andover, Mass., Sept. 17, 1762; graduated at Harvard College in 1788. He was principal of Phillips Academy at Exeter, N. H., for fifty years (till 1838). Among his pupils were Daniel Webster, Alexander H. Everett, Edward Everett, Lewis Cass, Jared Sparks, and George Bancroft. Of fine character and courtly manners, he had great power over his pupils. D. at Exeter, N. H., Oct. 25, 1849.

Abbot, EZRA, D. D., LL. D.: b. in Jackson, Me., Apr. 29, 1819; graduated at Bowdoin College 1840; became in 1856 assistant librarian in Harvard College; in 1872 professor of New Testament criticism and interpretation in the Cambridge Divinity School; published *Literature of the Doctrine of a Future Life* (1864-71). He also served as assistant and editor of such works as Norton's *Gospels*, Hackett's revision of Smith's *Bible Dictionary*, Noyes's *New Testament*, and Hudson's *Concordance*. Wrote *The Authorship of the Fourth Gospel* (1880); prepared *The Literature of the Doctrine of a Future Life*, an exhaustive bibliography originally appended to W. R. Alger's *History of the Doctrine of a Future Life* (published in 1871; new ed. 1878); was member of the Bible Revision Committee; and shortly before his death was tendered the Doctorate in Divinity, though a layman, by the University of Edinburgh. In 1888 a large octavo volume of his critical essays was published, including *The Authorship of the Fourth Gospel*, in an expanded form. D. at Cambridge, Mass., Apr. 28, 1884.

Abbot, FRANCIS ELLINGWOOD, Ph. D.: writer on philosophical and religious subjects; b. in Boston, Mass., Nov. 6, 1836; graduated at Harvard University; had charge of Unitarian congregations at Dover, N. H., and Toledo, O.; editor of *The Index*, 1870-73; author of *Scientific Theism* (1885); *The Way out of Agnosticism, or the Philosophy of Free Religion* (1890); and numerous essays and articles in the *North American Review* and other periodicals.

Abbot, GEORGE, D. D.: b. at Guildford, Surrey, England, Oct. 19, 1562, and educated at Balliol College, Oxford, where he became Master of University College in 1597, and was thrice appointed Vice-Chancellor. His name appears second on the list of the eight Oxford divines chosen to prepare the translation of the N. T. (except the Epistles) of King James's version. His preferment was rapid. Appointed Bishop of Lichfield and Coventry in 1609, he was translated to London within a month, and became Archbishop of Canterbury in Jan., 1611. He was noted for his liberal principles, and was a rival or opponent of Laud. He refused to allow the reading of the king's declaration, permitting sports and pastimes on the Lord's day, at Croydon, where he happened to be at the time. D. at Croydon, Aug. 4, 1633. Among his numerous works his *Geography, or Brief Description of the Whole World*, is remembered on account of its reference to the earliest American colonization. His *Exposition of the Prophet Jonah*, published in 1600, was reprinted in 1845.

Abbot, HENRY LARCOM: U. S. army officer; b. Aug. 13, 1831, at Beverly, Mass.; graduated at West Point 1854; became colonel of engineers Oct. 12, 1886; served as assistant on Pacific R. R. surveys, 1854-57; and was associated with Gen. Humphreys on the hydrographic survey of the delta of the Mississippi, 1857-61, the result being set forth in an elaborate report, *Physics and Hydraulics of the Mississippi River*. Gen. Abbot served in the Manassas campaign in 1861; engaged at Blackburn's Ford and Bull Run (wounded and breveted captain); in the construction of the defenses of

Washington, 1861-62; in the Virginia Peninsula, 1862; engaged at Yorktown (brevet major) and in the Seven Days operations before Richmond; as chief topographical engineer of Banks's expedition to the Gulf of Mexico, 1862-63; as colonel of the First Connecticut Artillery Volunteers, in command of siege artillery before Richmond in 1864-65 (brevet lieutenant-colonel U. S. A., and brevet brigadier-general U. S. V.); engaged in various actions; as chief of artillery at the capture of Fort Fisher, 1865; and in command of a brigade in the defenses of Washington in 1863. Brevet colonel and brigadier-general U. S. A. Mar. 13, 1865, and brevet major-general U. S. V. Since the war he has superintended defenses, commanded the engineer battalion, devised the adopted system of defending the coasts with submarine mines, and inaugurated the Engineer School of Application at Willets Point. He was an observer in the solar eclipse expedition to Sicily, 1870; a member of commission to devise plan for protecting alluvial basin of the Mississippi against overflow, of board to reorganize pontoon equipage of the army, of the Gun-Foundry Board, of the Fortification Board of 1885, of the Board of Ordnance and Fortification, and of many others; president of the permanent Board of Engineers, and Engineer of the Northeast Division, since 1888; member of the National Academy of Sciences; of the American Philosophical Society; of the American Academy of Arts and Sciences, and of other societies. Author of various works on professional subjects. Degree of LL. D. conferred by Harvard University in 1886. Retired for age Aug. 13, 1895. Revised by JAS. MERCUR.

Abbot, JOSEPH HALE: b. at Wilton, N. H., Sept. 26, 1802; graduated at Bowdoin College 1822; was tutor there 1825-27; Professor of Mathematics and of Modern Languages at Phillips Academy, Exeter, N. H., 1827-33; principal for several years of a ladies' seminary at Boston, and subsequently of the Beverly High School; was long the recording secretary of the American Academy of Arts and Sciences, to whose *Transactions* he contributed papers on pneumatics and hydraulics; wrote in favor of Dr. Charles T. Jackson in the "ether controversy"; and was an assistant of Dr. J. E. Worcester in the preparation of his *Dictionary*. D. at Cambridge, Apr. 7, 1873.

Abbot, SAMUEL: a merchant of Boston; b. at Andover, Mass., Feb. 25, 1732, was one of the founders of the theological seminary at Andover, toward the building of which he gave \$20,000 during his lifetime and \$100,000 at his death. He also contributed large sums for various other charitable purposes. D. at Andover, Apr. 30, 1812.

Abbotsford: the seat of Sir Walter Scott; on the right bank of the Tweed, about three miles from Melrose Abbey. It is surrounded by beautiful scenery. This estate was purchased in 1811 by Sir Walter, who expended a large sum of money in the erection of a picturesque and irregular pile of buildings. It has remained in the family to the fourth generation. See SCOTT, SIR WALTER.

Ab'cott, AUSTIN, LL. D.: son of Jacob; b. at Boston, Mass., Dec. 18, 1831; educated in New York city; admitted to the bar about 1852; practiced his profession in partnership with his brother, Benjamin Vaughan; was dean of New York University Law School; published two novels, *Conecut Corners* and *Matthew Caraby*; and aided Benjamin in the preparation of his legal publications. D. in New York, Apr. 19, 1896.

Abbott, BENJAMIN: Methodist preacher; b. in Pennsylvania in 1732. He traveled and preached extensively in his native State, in New Jersey, Delaware, and Maryland, and was one of the chief founders of his denomination in those States. His native eloquence was extraordinary. His autobiographical records, embodied in Firth's *Life of Abbott*, are among the most remarkable of the early writings of Methodism. D. at Salem, N. J., Aug. 14, 1796.

Abbott, BENJAMIN VAUGHAN: law writer; b. in Boston, Mass., June 4, 1830; graduated from the University of the City of New York in 1850, after which he studied law, and was admitted to the bar. He applied himself to law writing, his works and compilations amounting to nearly 100 volumes of digests, reports, and treatises. In 1870 he was appointed by President Grant one of the three commissioners to revise the statutes of the United States. As secretary of the New York Code Commissioners, he prepared in 1865 the draft of a penal code for New York, the same being done under the direction of the commissioners. D. in Brooklyn, N. Y., Feb. 17, 1890. HENRY WADE ROGERS.

Abbott, EDWARD, D. D.: son of Jacob; b. in Farmington, Me., July 15, 1841; educated in New York city; studied theology at Andover; was a pastor in Boston, 1865-69; associate editor of *The Congregationalist* from 1869 to 1878, when he entered the Episcopal Church. He wrote several religious books for children, a *Paragraph History of the United States* (1876), and other historical treatises, and edited *The Young Christian*, by Jacob Abbott, with a life of the author. Revised by GEORGE P. FISHER.

Abbott, EDWIN, D. D.: teacher and author; b. in London, 1838; educated in the City of London School and at Cambridge University (B. A. 1861, M. A. 1864); engaged in teaching, 1862; head master of the City of London School, 1865-1889; Hulsean lecturer in Cambridge, 1876; select preacher at Oxford, 1877; author of *Bible Lessons* (1872); *Through Nature to Christ* (1877); *How to Write Clearly* (1872); *Francis Bacon* (1885); and numerous theological publications.

Abbott, EMMA A.: popular soprano singer; daughter of a music teacher; b. in Chicago, Dec. 9, 1849; early attracted the attention of Clara Louise Kellogg, through whose influence she became soprano in the Church of the Divine Paternity, New York. This congregation having raised a fund for her musical education, she went to Paris, where she studied singing under Madame Marchesi, and acting under Charles Feehter. In Paris she married E. J. Wetherell, of Massachusetts, Feb. 26, 1874. She began her professional career with Gye in London, but soon returned to the U. S., where she organized the "Emma Abbott Opera Company," traveling extensively, and presenting large works on a small scale at popular prices. She amassed a large fortune. D. Jan. 5, 1891, in Salt Lake City, Utah, where she was on a professional tour. Her husband had died two years earlier. Personally Miss Abbott was much beloved.

Abbott, GORHAM DUMMER, LL. D.: a younger brother of Jacob Abbott; b. at Hallowell, Me., Sept. 3, 1808; graduated at Bowdoin College in 1826; and took a part of the theological course at Andover in the class which graduated in 1831. He was pastor for three years at New Rochelle, N. Y., and for thirteen years principal of the Spingler Institute in New York city. He published *The Family at Home*; *Nathan Dickerman*; *Mexico and the United States* (1869); and other works. D. at South Natick, Mass., July 31, 1874.

Abbott, JACOB: a prolific and popular writer; b. at Hallowell, Me., Nov. 14, 1803; graduated at Bowdoin College in 1820; studied theology at Andover, Mass., from 1822 to 1824; was tutor in Amherst College from 1824-25, and Professor of Mathematics in the same institution from 1825 to 1829; was principal of the Mount Vernon School (for young ladies) in Boston from 1829 to 1834, when he was ordained and took charge of the Eliot church in Roxbury (till 1836). For several years he made his home in New York city, though frequently absent in foreign countries. His reputation as an author was established by the *Young Christian Series*. But he is best known as the author of *The Rollo Books* (28 vols.); *The Franconia Stories* (10 vols.); *Harper's Story-Books* (36 vols.); and other juvenile works. D. at Farmington, Me., Oct. 31, 1879.

Abbott, JOSEPH C.: b. in Concord, N. H., July 15, 1825; became a lawyer and journalist; commanded a regiment during the civil war, and was breveted brigadier-general. He removed to North Carolina in 1865, and was U. S. Senator from North Carolina, 1865-71. D. Oct. 8, 1882.

Abbott, Sir JOHN JOSEPH CALDWELL, D. C. L.: Canadian statesman; b. at St. Andrew's, P. Q., Mar. 12, 1821; educated there and at McGill College; admitted to the bar in 1847; represented Argenteuil in the Canadian Assembly 1857-67, and the same constituency in the Dominion Parliament almost continuously from 1867 till called to the Senate in 1887. He was a member of the executive council of Lower Canada, 1862-63; Conservative leader of the Government in the Senate; and upon the death of Sir John A. Macdonald in the spring of 1891 succeeded him as Premier, but resigned on account of ill health, Nov. 25, 1892. He became a member of the Cabinet formed by his successor, Sir John Thomson, but without portfolio. He was associated with Sir Hector Langevin in the Letellier mission to England in 1879; was appointed a member of the Queen's privy council in 1887; was for some years solicitor for the Canadian Pacific R. R. Co.; was dean of the faculty of law in McGill College for ten years; and a director of the Bank of Mon-

treal. He was author of the *Insolvent Act of 1864, with Notes, etc.* (Quebec, 1864). He was knighted in 1892. D. in Montreal, Oct. 30, 1893.
NEIL MACDONALD.

Abbott, JOHN STEVENS CABOT: brother of Jacob; b. at Brunswick, Me., Sept. 18, 1805; graduated at Bowdoin College in 1825; at Andover Theological Seminary in 1829; and was settled as minister in Worcester, Roxbury, Nantucket, and New Haven. Among his works are *The Mother at Home*; *History of Napoleon Bonaparte*; *History of the Civil War*; his American histories, and his *History of Napoleon III.* D. at Fair Haven, Conn., June 17, 1877.

Abbott, JOSIAH GARDNER: jurist; b. in Chelmsford, Mass., Nov. 1, 1815; graduated at Harvard in 1832; and was admitted to the bar in 1835. He was a member of the Constitutional Convention of Massachusetts in 1853, and of the Electoral Commission of 1877 to which was referred the disputed presidential election. He was a judge of the Superior Court of Massachusetts, for Suffolk County, from 1855 to 1859. In 1878 he was nominated by the Democratic party for Governor of Massachusetts, but was defeated. In 1874 he was elected a member of Congress, having previously served in the Legislature of his State as a Representative and as Senator. D. at Wellesley Hills, Mass., June 2, 1891.
HENRY WADE ROGERS.

Abbott, LYMAN, D. D.: Congregationalist minister, editor, and author; b. at Roxbury, Mass., Dec. 18, 1835; graduated at New York University, 1853. After having studied law, he studied theology; was pastor at Terre Haute, Ind., 1860-65; pastor of the New England church in New York, 1866-69; editor of *The Illustrated Christian Weekly*, 1871-76; and, from 1876, of *The Christian Union* (now *The Outlook*). He succeeded H. W. Beecher as pastor of Plymouth church, Brooklyn, in 1888, and resigned in Nov., 1898. Among his numerous writings are *Commentaries upon Matthew and Mark* (1875), *Luke* (1877), *John* (1879), *Acts* (1876), and *Romans* (1888), and a sketch of the *Life of Henry Ward Beecher* (1883). In association with T. J. Conant, he prepared *A Dictionary of Religious Knowledge*. A course of Lowell lectures by him on the *Evolution of Christianity* was published in 1892.
GEORGE P. FISHER.

Abbrevia'tio Placito'rum (abbreviation of pleadings): in legal history, an abstract of ancient pleadings made prior to the Year-Books. See YEAR-BOOKS.

Abbreviations [Lat. *abbreviationes*, from *abbre'vio*, *abbrevia'tum*, to shorten, from *bre'vis*, short]: customary shortenings of words and phrases used in writing, in order to save time and space. They are formed by the omission of some letters or words, or by the substitution of arbitrary signs. In mediæval manuscripts abbreviations are so numerous that special study and training are required to decipher them. For denoting moneys, weights, and measures, characters which are not properly abbreviations are used as such: for instance, ° ' " for degrees, minutes, and seconds; \$ for dollar; £, pound (money), etc.

The following are the more important abbreviations in common use:

āā, *ana*, of each.
@, *ad*, at.
A. A. G., Acting Assistant Adjutant-General.
A. A. G., Assistant Adjutant-General.
A. B., *Artium Baccalaureus*, Bachelor of Arts; also Able-bodied Seaman.
A. B. C. F. M., American Board of Commissioners for Foreign Missions.
Abp., Archbishop.
A. C., *Ante Christum*, before Christ.
Acct., account.
A. D., *Anno Domini*, in the year of our Lord.
Ad. or Adv., adverb.
A/d, after date.
Adj., adjective.
Adj't., adjutant.
Ad lib., *ad libitum*, at pleasure.
Admr., administrator.
Admx., administratrix.
Æt. or ætat. = *ætatis* [anno]; i. e. in the year of his (or her) age.
A. G., Adjutant-General.
A. H., *Anno Hegira*, in the year of the Hegira (flight of Mohammed).
Ala., Alabama.
A. M., *Anno Mundi*, in the year of the world.
A. M., *Ante Meridiem*, before noon.
A. M., *Artium Magister*, Master of Arts.
Anon., anonymous.
Ans., answer.
A/o, account of.
Apr., April.
A. Q. M., Assistant Quartermaster.
A. R. A., Associate of the Royal Academy (London).
Ari., Arizona.
Ark., Arkansas.
A/s, account sales.
Atty., attorney.
A. U. C., *Ab Urbe Condita*, from the Founding of the City (i. e. Rome).
Aug., August.
A. V., Authorized Version.
A. Y. M., Ancient York Masonry.
b., born.
B. A. or A. B., Bachelor of Arts.
Bart. or Bt., Baronet.
Bbl., barrel.
B. C., before Christ; British Columbia.
B. C. L., Bachelor of Civil Law.
B. D., Bachelor of Divinity.
B/E, Bill of Exchange.
B. I., British India.
B. L., Bachelor of Laws, *legum baccalaureus*.
B/L, Bill of Lading.
Bp., Bishop.

Brig.-Gen., Brigadier-General.
Bro., brother.
B. S., or B. Sc., Bachelor of Science.
B/S, Bill of Sale.
Bush., bushel.
B. V., Blessed Virgin, Lat. *Beata Virgo*.
C., *centum*, a hundred; also centigrade and central.
C., Cousul; also chapter.
Ca., *circa*, about.
C. A., Chartered Accountant.
Cal., California.
Cal. or Kal., Calends or Kalends.
Cautab., *Cantabrigiensis*, of Cambridge.
Cap., *capitulum*, chapter.
Capt., Captain.
C. B., Companion of the Bath; also Cape Breton.
C. C., Caius College.
c. c., cubic centimeter.
C. C. P., Court of Common Pleas.
C. E., Civil Engineer.
Cent or c., *centum*, hundred.
Cf., *confer*, compare.
C. F. I., Cost, freight and insurance.
C. G. H., Cape of Good Hope.
C. G. S., centimeter-gramme-second.
C.-H., court-house.
Chap. or ch., chapter.
Chrou., Chronicles.
C. J., Chief Justice.
C. M., common meter.
c. m., centimeter.
Co., company; also county.
C. O. D., cash on delivery.
Col., Colonel; also Colorado.
Coll., college.
Colo., Colorado.
Com., Commodore, Commissiour.
con., *contra*, against.
Conn. or Ct., Connecticut.
Cor., Corinthians.
Cor. Sec., Corresponding Secretary.
Cos., cosine.
Coss., *Consules* or *Consulibus*, consuls (of Rome).
Cr., creditor.
Crim. Con., criminal connection or conversation.
C. S. A., Confederate States of America.
Ct., Connecticut.
Cum Div., with dividend.
Cwt., a hundredweight.
Cyc., cyclopædia.
d., *denarius*, penny, pence; also died.
D., five hundred; also Denarius, Dutch.
D. A. G., Deputy Adjutant-General.
Dak., Dakota.
Dan., Daniel, Danish.
D. C., District of Columbia; also *da capo*, from the beginning.
D. C. L., Doctor of Civil Law.
D. D., Doctor of Divinity.
D. D. S., Doctor of Dental Surgery.
Dea., Deacon.
Dec., December.
Deg., degree.
Del., Delaware; also *delineavit*, he designed (on engravings).
Dept., department.
Deut., Deuteronomy.
D. F., *Fidei defensor*, Defender of the faith.
Dft., defendant; draft.
D. G., *Dei gratiâ*, by the grace (or favor) of God.
Dis., discount.
Dist., district.
Div., dividend.
Do., ditto, the same.
Doz., dozen.
Dr., Doctor; also debtor.
D/s, days' sight.
D. Sc., Doctor of Science.
Dub., Dublin.
D. V., *Deo volente*, God willing.
Dwt., pennyweight.
E., east.
E. & O. E., errors and omissions excepted.
Ebor., *Eboracum*, York.
Eccl., Ecclesiastes.
Eccles., ecclesiastical.
Eccelus., Ecclesiasticus.
E. C., East Central (postal district of London).
Ed., editor, edition.
Edin., Edinburgh.
E. E., Errors excepted; Electrical Engineer.
e. g., *exempli gratiâ*, for example.

E. I., East Indies.
E. I. C., East India Company.
E. M. F., Electro-motive Force.
Encyc., encyclopædia.
E. N. E., east-northeast.
Eng., English; Engineers.
Eph., Ephes., Ephesians.
E. S. E., east-southeast.
Esth., Esther.
Esq., Esquire.
et al., *et alii*, and others.
etc., *et cætera*, and the rest; i. e. other such things; and so forth.
Et seq., *et sequens*, and the following.
Ex d. or ex div., *ex dividendo*, without the dividend.
EXR., executor.
Exod. or Ex., Exodus.
Exon., *Exonia*, Exeter.
Exx., executrix.
Ez., Ezra.
Ezek., Ezekiel.
F. or f., *frauc*, florin, farthing, foot.
F. and A. M., Free and Accepted Masons.
F. or Fahr., Fahrenheit.
F. A. A., Free of all Average.
F. A. I. A., Fellow of the American Institute of Architects.
F. A. S., Fellow of the Antiquarian Society; Fellow of the Society of Arts.
F. B. S., Fellow of the Botanical Society.
F. D., *Fidei defensor*, Defender of the faith.
Feb., February.
F. F. V., first families of Virginia.
F. G. S., Fellow of the Geological Society.
fl., florin.
Fla., Florida.
F. L. S., Fellow of the Linnæan Society.
F. O. B., Free on board.
F. P. A., Free of Particular Average.
F. R. A. S., Fellow of the Royal Astronomical Society.
F. R. C. P., Fellow of the Royal College of Physicians.
F. R. C. S., Fellow of the Royal College of Surgeons.
Fri., Friday.
F. R. G. S., Fellow of the Royal Geographical Society.
F. R. S., Fellow of the Royal Society.
F. R. S. E., Fellow of the Royal Society of Edinburgh.
F. R. S. L., Fellow of the Royal Society, London; also Fellow of the Royal Society of Literature.
F. S. A., Fellow of the Society of Antiquaries.
F. S. S., Fellow of the Statistical Society.
ft., foot.
fur., furlong.
F. Z. S., Fellow of the Zoölogical Society.
g., gramme.
Ga., Georgia.
Gal., Galatians.
gal., gallon.
G. B., Great Britain.
G. C. B., Grand Cross of the Bath.
G. C. M. G., Knight Grand Cross of St. Michael and St. George.
G. C. S. I., Knight Grand Commander of the Star of India.
G. M., Grand Master.
Gen., General; Genesis.
Ger., German.
Gov., Governor.
Gr., Greek.
gr., grain.
G. T., Good Templars; Grand Tiler.
Gtt., *gutte*, drops.
Hab., Habakkuk.
Hag., Haggai.
H. B. C., Hudson's Bay Company.
H. B. M., His (or Her) Britannic Majesty.
Hdkf., Handkerchief.
h. e., *hoc est*, this is.
H. E., His Eminence; His Excellency.
Heb., Hebrews.
hhd., hogshead.
Hist., history.
H. I. H., His (or Her) Imperial Highness.
H. M. S., His (or Her) Majesty's Ship.
Hon., Honorable.
Hos., Hosea.
H. P., Horse-power.
H. R., House of Representatives.

H. R. H., His (or Her) Royal Highness.	M. A., Master of Arts.	Parl., Parliament.	Sc. or Ss., <i>scilicet</i> , to wit; also <i>sculpsit</i> , he engraved it (on engravings).
H. S. H., His (or Her) Serene Highness.	Macc., Maccabees.	P. C., Privy Councillor.	S. Dak. or S. D., South Dakota.
H. S. S., <i>Historiæ Societatis Socius</i> , Fellow of the Historical Society.	Mad. or Mme., Madame.	P. E. I., Prince Edward Island.	S. E., southeast.
I., Is., or Isl., island.	Mag., magazine.	P. E., Protestant Episcopal.	Sec., Secretary; also second.
Ia., Iowa.	Maj.-Gen., Major-General.	Per Ann., Pr. An., <i>Per Annum</i> , by the year.	Sept., September.
Ibid. or Ib., <i>ibidem</i> , in the same place.	Mal., Malachi.	Per Cent., <i>Per Centum</i> , by the hundred.	sin., sine.
Id., <i>idem</i> , the same.	Mar., March.	Per pro., <i>Per procurationem</i> , by procuration; on behalf of.	S. J., Society of Jesus.
Id., Idaho.	Masc., Masculine.	Pet., Peter.	S. J. C., Supreme Judicial Court.
i. e., <i>id est</i> , that is.	Mass., Massachusetts.	Ph. D., <i>Philosophiæ Doctor</i> , Doctor of Philosophy.	Skr., Sanskrit.
I. H. S., <i>Iesus Hominum Salvator</i> , Jesus Saviour of men.	Matt., Matthew.	Phil., Philippians, Philip.	S. M., <i>Sa Majesté</i> , His (or Her) Majesty.
Ill., Illinois.	M. B., Bachelor of Medicine.	Phila., Philadelphia.	Sp. or Span., Spanish.
in., inch.	M. C., Member of Congress.	Philem., Philemon.	S. P. Q. R., <i>Senatus Populusque Romanus</i> , the Roman senate and people.
incog., <i>incognito</i> , unknown.	Md., Maryland.	Philom., <i>Philomathes</i> , a lover of learning.	Sq. or Seq., <i>sequens</i> , the following; pl., <i>Sqq.</i> , <i>sequentes</i> .
Ind., Indiana.	M. D., <i>Medicinæ Doctor</i> , Doctor of Medicine.	Pinxt. or pxt., <i>pinxit</i> , he painted.	Sq., square.
Ind. Ter., Indian Territory.	Me., Maine.	pl., plu. or plur., plural.	SS., saints; also esses, a collar worn by knights and others in heraldry.
Inf. or inf., <i>infra</i> , below.	M. E., Methodist Episcopal, or Mechanical Engineer.	plff., plaintiff.	Ss. or Sc., <i>scilicet</i> , to wit; namely.
In lim., <i>in limine</i> , at the outset.	Mex., Mexico or Mexican.	plupf., pluperfect.	Ss., <i>semis</i> , half.
In loc., <i>in loco</i> , in the place.	M. H. S., Massachusetts Historical Society.	P. M., <i>Post Meridiem</i> , after noon.	S. S. C., Solicitor before the Supreme Courts (of Scotland).
I. N. R. I., <i>Iesus Nazareus Rex Judæorum</i> , Jesus of Nazareth, King of the Jews.	Messrs. or MM., Messieurs, gentlemen.	P. M., Postmaster.	S. S., Sunday-school.
Inst., institute.	Mic., Micah.	P. O., Post-office.	S. S. E., south-southeast.
inst., <i>instante (mense)</i> , in the present month.	Mich., Michigan.	P. O. O., Post-office order.	S. S. W., south-southwest.
Int., interest.	Minn., Minnesota.	P. of H., Pat. of Husbandry.	St., saint; street.
Inv., invoice.	Miss., Mississippi.	Pop., population.	S. T. D., <i>Sacrosanctæ Theologiæ Doctor</i> , Doctor of Theology.
I. O. O. F., Independent Order of Odd Fellows.	Mlle., Mademoiselle.	Port., Portuguese.	S. of T., Sons of Temperance.

	p. a., Participial adjective.		

Abbre'viator: a notary of the papal court and of the church councils, whose business is to prepare briefs and perform various important services as secretary. The number of these notaries was formerly about seventy-two.

Abbt, THOMAS: German author; b. at Ulm in 1738. He became Professor of Mathematics at Rinteln in 1761, and contributed to the improvement of the German language. His chief works are *Vom Verdienste* (On Merit, 1765) and *Vom Tod fürs Vaterland* (On dying for the Fatherland, 1761). D. at Bückeberg, Nov. 3, 1766.

Abd: an Arabic word which signifies servant or slave, and forms the prefix of many Oriental names, as Abd-Allah, "servant of Allah," Abd-er-Rahman, "servant of the Merciful" (i. e. of God).

Abd-el-Hamid: the adopted Arabic name of one DU COURRET, a French traveler (b. in 1812), who set out in 1834 for the East; visited Egypt, traveled up the Nile; through Abyssinia; to the shores of the Red Sea; and returned along the Red Sea to Cairo. He embraced Mohammedanism, and assumed the name of Abd-el-Hamid. After having been imprisoned in Persia for political reasons, he was released through the intervention of France, and returned to his native country in 1847. In 1848 he was dispatched by the Government to Timbuctoo. He published the result of this exploration in *Mémoire à Napoléon III.* (1855); he also published *Médine et la Mekke* (3 vols., 1855). D. at Cairo, Egypt, Apr. 1, 1867.

Abd-el-Ka'der (Arabic, servant of the Powerful, i. e. of God): a distinguished Arab chieftain; b. near Mascara, in Algeria, in 1807. His father, Mehi-ud-Din, was a marabout, or religious noble, of no little influence. Algeria having been invaded by the French in 1830, Abd-el-Kader was chosen emir (prince) by the Arabs of that country. He defeated the French at Maäta in 1835. A treaty of peace was concluded in 1837. In 1839 hostilities were again renewed, and in the war which followed, against a power so much superior to his own, Abd-el-Kader displayed extraordinary energy, combined with a marvelous fertility of resources, but he was at length, in 1847, obliged to yield to overwhelming odds: he laid down his arms on condition that he should be sent to Alexandria or St. John d'Acre. But, in direct violation of the terms of capitulation, he was taken to France, where he was detained as a prisoner until 1852. In 1860, when the Christians of Syria were threatened with massacre by the fanatical Mohammedans of that country, Abd-el-Kader, with extraordinary diligence and at the risk of his own life, protected many thousands of those defenseless people so long as the danger lasted. In 1864 he paid a visit to Egypt, where he was well received by the viceroy, and received from M. de Lesseps a piece of land. He also joined the order of Freemasons. In 1865 he visited Constantinople, where he was received with great honors. In 1867 he attended the Universal Exhibition at Paris. Abd-el-Kader wrote in the Arabic language a work which he sent to the French Academy, and which was translated into French by Dugat under the title *Rappel à l'Intelligent, avis à l'Indifférent* (1858). He also contributed important notes and commentaries to Daumas's *Les Chevaux du Sahara*. See *Life* by Churchill (Lon. 1867). D. at Damascus, May 26, 1883.

Abd-el-Latif: an Arabian historian and physician; b. at Bagdad in 1162. He wrote a valuable work on the history, antiquities, and geography of Egypt, of which De Sacy published a French version. D. in 1231.

Abd-el-Wahâb: founder of the sect of Wahabites or Wahâbees; b. in Nejed, Arabia, 1691. He recognized the Koran, and endeavored to reform the Mohammedan religion, which he affirmed had become corrupted. D. in 1787. See WAHÂBEEES.

Abde'ra (Gr. Ἀβδηρα): an ancient city of Thrace, noted as the birthplace of the philosopher Democritus. The stupidity and ignorance of the people of Abdera was proverbial.

Abd-er-Rahman III.: surnamed AN-NÂSIR-LIDIN-IL-LAH, or AL-NASSER-LIDÎNILLAH; a celebrated caliph; b. about 888 A. D. He began to reign at Cordova in 912. He was distinguished as a patron of learning and the arts. During his long reign the Moslem empire in Spain was raised to the highest pitch of prosperity. D. in 961.

Abdication: the renunciation of an office, generally an office of supreme importance. The legal right of abdication has been disputed on several grounds, and it is at least questionable. It is asserted by the opponents of kingly power that a king has not a right to abdicate, because he has not a right to reign. Advocates of constitutional monarchy often take the ground that inasmuch as kings can reign only

with the formal consent of the nation, therefore the right to reign is a compact which can be dissolved only with the consent of both parties. From the point of view of divine right, abdication is generally regarded as unlawful, for the reason that the monarch is invested with power not by his own will, and therefore can not of his own choice divest himself of this power. In answer to this position it has been argued that if monarchy is a divine institution, it follows that it is the monarch's duty to leave nothing undone to accomplish his mission, even to withdrawing from the throne, whenever it seems to him that the public interest demands that sacrifice from him. According to English law, the king may not abdicate except with the consent of Parliament. Subtle legal distinctions, however, are seldom of great importance, inasmuch as it will not often occur that a nation will desire to keep a monarch upon the throne after he wishes to renounce it. There is probably no example in history of a successful attempt on the part of the people to resist a determined purpose to abdicate on the part of a monarch. The following are the most noteworthy instances of the abdication of monarchical power. In A. D. 305 the imperial authority was abdicated by the Emperors Diocletian and Maximian. In Savoy, Amadeus abdicated the throne in 1494; Victor Amadeus in 1730; Charles Emmanuel in 1802; Victor Emmanuel in 1820; and Charles Albert in 1849. In Poland, Henry III. abdicated in 1574; Augustus in 1707; Augustus Stanislas in 1735; and Poniatowski in 1795. Charles V. of Spain and Germany gave up the royal and imperial crowns in 1555. Philip V. in Spain abdicated in 1724, and Charles IV. in 1808. Queen Christina of Sweden abdicated in 1654; Louis of Holland in 1810; and Louis of Bavaria in 1848. In France, Napoleon I. renounced the throne in 1814 and in 1815; Charles X. in 1830; and Louis Philippe in 1848. In every instance in France, however, abdication has followed revolution or forcible expulsion from the seat of authority. In English history there have been two cases only, and these have not been very clearly defined. Richard II. abdicated in 1399; and James II., in 1685, though he did not formally abdicate, was declared by Parliament to "have withdrawn himself out of the kingdom," and to have "abdicated the government." C. K. A.

Abdo'men [Lat. *abdo'men* (gen. *abdom'inis*), from *abdere*, to hide]: the part of the human body which lies below the diaphragm. The important secretory and excretory organs—the liver, pancreas, stomach and intestines, spleen and kidneys—occupy the abdominal cavity. The abdomen is closed in by a muscular anterior wall (the belly muscles); by a posterior bony wall (the spinal column); by the diaphragm above, and by the pelvic bones and organs below. The interior is lined with a smooth serous membrane, which covers the walls and is reflected over the organs, which are thus completely inclosed in folds of the membrane, which is called the *peritoneum*. The reflections of the peritoneum serve also as ligaments to hold the organs in place without allowing them considerable freedom of motion. The usual position of the organs is as follows: The stomach lies to the left and immediately beneath the lower ribs, and not rarely it is completely hidden beneath the ribs. The spleen is situated laterally at the left extremity of the stomach; the liver occupies a position on the right side similar to that occupied by the stomach and spleen on the left. The kidneys lie to either side of the spinal column on the posterior wall of the abdomen and about the level of the lowest ribs. The small intestines take up the central part of the abdominal wall; the large bowel passes from the right groin upward toward the liver, then transversely across the abdomen, and finally descends along the left side into the pelvis. See also PERITONEUM. W. P.

Abdomen: in entomology, the hindmost of the three regions into which the body of an insect is divided. It is composed, typically, of eleven rings or segments, more or less distinct from each other, but the number is often less. It contains a portion of the intestines and the sexual organs. In the perfect insect its segments have attached to them no well-developed legs or wings. In many insects its last segments bear appendages of various uses and forms, as pin-cers, stings, ovipositors, etc. In some insects the abdomen is not well differentiated from the thorax. D. S. J.

Abdominales [Lat. *abdominalis*, pertaining to the *abdo'men*]: a term formerly used for a large group of fishes containing numerous families, such as the *Esocidæ*, pikes, *Cyprinidæ*, carp, *Clupeidæ*, herrings, *Salmonidæ*, trout, etc., now placed in several orders. The order Abdominales of

Linnæus contained all the true or bony fishes in which the ventral fins are placed beneath the abdomen, well back of the pectorals. Cuvier used it for a sub-order of soft-rayed fishes with abdominal ventrals, not connected with the shoulder girdle. Johannes Muller restricted this sub-order by removing those species in which there is no communication between the air-bladder and intestine. F. A. LUCAS.

Abduc'tion [Lat. *ab*, away + *ducere*, lead]: in law, the forcible or fraudulent carrying away of a person. It is usually confined to the removal of females with a view to their marriage or seduction. It is allied to the word *kidnapping*, which would include the case of males. Abduction is an offense severely punished by statute law both in Great Britain and in the U. S.

Abd-ul-Aziz' (written in French *Abdoul-Aziz*, and in German *Abd-ul-Asis*): a son of Mahmud II.; b. Feb. 9, 1830; succeeded his brother, Abd-ul-Medjid, as Sultan of Turkey, June 25, 1861. He reduced the imperial civil list from 75,000,000 piasters to 12,000,000; abolished among other barbarous practices that of assassinating the sons of the princesses, favored the introduction of Western manners and customs, and did much to destroy the old and cherished traditions of the Turks. Deposed May 29, 1876, and is supposed to have been assassinated June 4, 1876. See TURKEY.

Abd-ul-Hamid II.: Padishah or Sultan of the Turkish Empire; thirty-fourth of the dynasty of Othman; b. in Constantinople, Sept. 5, 1842; second son and fourth child of Abd-ul-Medjid (*q. v.*); adopted by his father's second wife, who was childless. He was brought up with his brother Murad in the harem, and received but little education. In 1867 his uncle, Abd-ul-Aziz, then Sultan, took him with him to Paris to the exposition of that year, and what he saw there developed in him a love of study, which greatly improved his mind. On the deposition of Abd-ul-Aziz (May 29, 1876), Murad, eldest son of Abd-ul-Medjid, succeeded, but proving incompetent from insanity he was deposed Aug. 31, and Abd-ul-Hamid was invested with the sword of Othman Sept. 7, 1876, as Abd-ul-Hamid II. He is said to belong to the "Old Turkish" party, and has thus far carried on the government with doubtful success.

Abd-ul-Medjid' (written in French *Abdoul-Medjid*, and in German *Abd-ul-Medschid*): Sultan of Turkey; eldest son of Mahmud II.; b. in 1823. He succeeded his father July 1, 1839, when his capital was menaced by the victorious army of Mehemet Ali, Viceroy of Egypt. This danger was averted by the intervention of England and other great powers in July, 1840. He favored religious liberty and the reforms which his father had initiated, but his good will was partially frustrated by the resistance of his fanatical subjects. He died June 25, 1861, and was succeeded by his brother, Abd-ul-Aziz. See TURKEY.

Abeceda'rians: a sect founded in the sixteenth century by a person named Storck, who professed that learning was not necessary, not even the knowledge of the alphabet (A B C, hence their name), for the proper understanding of the Scriptures.

A'Becket, THOMAS: See BECKET.

A'Beck'ett, GILBERT ABBOTT: a humorous English writer and lawyer; b. in London, Jan. 9, 1811. He contributed to the *London Times* and *Punch*. Among his works is *The Comic Blackstone* (1844-46). D. at Boulogne-sur-Mer, Aug. 30, 1856.

Abeel', DAVID, D. D.: missionary to the Chinese; b. at New Brunswick, N. J., June 12, 1804. He published *A Journal of a Residence in China* (1829-33); *A Missionary Convention in Jerusalem* (1838); and *The Claims of the World to the Gospel*. D. at Albany, Sept. 4, 1846. See memoir by Williamson (N. Y., 1848).

A'bel: the second son of Adam and Eve; killed by his brother Cain. He is regarded as a type of faith and as the first martyr. See Genesis iv. and Hebrews xi. 4.

Abel, CARL, Ph. D.: philologist; b. at Berlin, Nov. 25, 1837; educated in the universities of Berlin, Munich, and Tübingen; has traveled extensively in Europe and America in the interests of linguistic research; has acted as Ilchester lecturer at Oxford University; has lectured before philological societies in England and Berlin; Professor of Linguistics in the Berlin Humboldt Academy of Science. Author of numerous contributions to philological and other periodicals; and of *Linguistic Essays* (1880); *Koptische Untersuchungen* (1878); and *Russland und die Lage* (1888).

Abel, NIELS HENRIK: mathematician; b. at Findö, Norway, Aug. 5, 1802. He gained distinction by his discoveries in the theory of elliptic functions, and was highly eulogized by Legendre. D. at Christiania, Apr. 6, 1829.

Abelard, or **Abailard**, PIERRE: French philosopher and dialectician; b. near Nantes, in 1079. He studied under the Nominalist Roscellinus and the Realist William de Champeaux. About 1115 he succeeded William in the school of Notre Dame, and there gathered about him pupils from all parts of Europe. Though he sought to avoid the extremes of both Nominalism and Realism, his doctrines may be called Nominalistic. He became the tutor of Eloise, the young niece of the Canon Fulbert, and fell in love with her, and his affection was returned. Upon the interference of the uncle they fled together into Brittany, where Eloise bore a son. They were married, but afterward Eloise denied this marriage and returned to her uncle's house that she might not interfere with Abelard's advancement in the Church. She was brutally treated by her uncle and fled to Abelard, who placed her at her own request in the nunnery of Argenteuil. Fulbert, for revenge, waylaid and terribly mutilated Abelard. Repentant and in deep humiliation, Abelard retired to the Abbey of St. Denis. Afterward, solicited eagerly as a teacher, he founded the monastic school at Nogent-sur-Seine, known as Paraclete, which, when he became Abbot of St.-Gildas-de-Rhuys, he gave to Eloise and a sisterhood under her care. He died Apr. 21, 1142, at St. Marcel priory, Chalons, while on the way to Rome to defend himself against a charge of heresy. His body was given into the keeping of Eloise, who, twenty years later, was buried at his side. From Paraclete, their remains were removed to Paris (1800), and in 1817 they were laid in a single sepulchre in Père la Chaise. Abelard was the most prominent of the founders of Scholasticism, and exerted a powerful influence upon the intellectual activity of his time. See Charles de Rémusat's *Abelard* (Paris, 1845); Cousin's *Introduction to the Works of Abelard*; Berlington's *History of Abelard and Heloise*; and Wight's *Abelard and Eloise* (New York, 1853).

A'belites, or **Abe'lians**: a sect of Christians who lived in Northern Africa in the fourth century. They enjoined marriage without carnal intercourse in order not to propagate original sin, claiming in support of their practice the example of the patriarch Abel. They adopted children, who were brought up to the same kind of marriage. They were extinct before the time of Augustine (fifth century).

Aben, **Ebn**, or **Ibn**: a prefix to many Arabic proper names, denoting "son of."

Abenaquis: same as ABNAKIS. See ALGONQUIAN INDIANS.

A'ben Ez'ra: b. at Toledo about 1100; d. on the island of Rhodes about 1175; wrote commentaries which show great progress in the department of biblical exegesis. Those on Isaiah (1873-77, 4 vols.), Canticles (1874), and Proverbs (1880) have been translated into English. See *The Isaiah* for Friedländer's essay on him.

A'bensberg: a town of Bavaria; 18 miles S. W. of Ratisbon; has a castle and a mineral spring (see map of the German Empire, ref. 7-F). Here Napoleon defeated the Austrians Apr. 20, 1809. Pop. 2,300.

A'ber: a Cymric term signifying "meeting-place of waters," occurs as a prefix to names of places in Great Britain—e. g. Aberdeen. It is probably etymologically related to the Persian *ab*, water. The corresponding Gaelic term is *Iuiver*—e. g. Inverness.

Aberbrothwick: See ARBROATH.

Abercorn, JAMES HAMILTON, First Duke of: b. Jan. 21, 1811; succeeded his grandfather as Marquis of Hamilton in 1818; and became Lord-Lieutenant of Ireland in 1866, which position he held until 1868, when he was created Duke of Abercorn, and when the Derby Ministry returned to power he was restored in 1874 Lord-Lieutenant of Ireland; held the office till 1876. D. at Baronscourt, Tyrone, Oct. 31, 1885.

Ab'ercrombie, JAMES: British general; b. in 1706; in 1758 took command of 50,000 men in New York, in order to recover the fort which the French had taken. On the 8th of July he attacked Ticonderoga, but was repulsed by the French with great loss, and was soon removed from the command. D. Apr. 28, 1781.

Abercrombie, JAMES, D. D.: Episcopalian clergyman and scholar; b. in Philadelphia, Jan. 26, 1758; preached there,

and there died June 26, 1841. His sermon preached on the death of Alexander Hamilton produced no little excitement in consequence of his condemnation of the practice of dueling. Dr. Abercrombie's *Lectures on the Catechism* was for years a standard authority.

Abercrombie, JOHN, M. D.: Scottish physician; b. at Aberdeen, Oct. 10, 1780. He graduated as M. D. in 1803, practiced in Edinburgh, and attained the reputation of being the first consulting physician in Scotland. He published *Inquiries Concerning the Intellectual Powers of Man* (1830) and *The Philosophy of the Moral Feelings* (1833), which were highly esteemed. D. at Edinburgh, Nov. 14, 1844.

Abercrombie, JOHN JOSEPH: soldier; b. in 1798 in Tennessee; graduated at West Point in 1822; colonel Seventh Infantry Feb. 25, 1861; and Aug. 31, 1861, brigadier-general U. S. volunteers. He served chiefly on the Western frontier (1822-61); as adjutant First Infantry (1825-33); in the Black Hawk war in 1832; in the Florida war 1837-40; engaged at Okee-cho-bee (brevet major); in the war with Mexico 1846-48; engaged at Monterey (wounded and breveted lieutenant-colonel), Vera Cruz, Cerro Gordo, and aide-de-camp to Maj.-Gen. Patterson 1846-47; as superintendent of recruiting service 1853-55. In the civil war served in the Shenandoah campaign 1861-62; engaged at Falling Waters; in the Virginia Peninsula 1862; engaged at Fair Oaks (wounded) and Malvern Hill; and till 1864 in command of troops before Washington, D. C. Brevetted brigadier-general U. S. A. for long and faithful services, and retired from active service June 12, 1865. D. at Roslyn, N. Y., Jan. 3, 1877.

Abercromby, Sir RALPH: British general; b. at Menstry, near Tullibody, Clackmannanshire, Oct., 1734; entered the army in 1756. After the peace of 1783 he passed ten years at home in retirement. He distinguished himself in the disastrous campaigns in Holland in 1794 and 1795. In 1795 he took command of an expedition sent to the West Indies, where he captured several islands from the French. He was the second in command of the army which the Duke of York led to Holland in 1799, and was appointed in 1800 commander-in-chief of the expedition to Egypt, which was then occupied by the French under Bonaparte. The British army, which landed early in Mar., 1801, was attacked by Menou, near Alexandria, on the 21st of that month. In this action the French were defeated, but Sir Ralph was mortally wounded, and died Mar. 28, 1801. He was distinguished for superior talents, bravery, and humanity. See his life by his son James (1861).

Aberdare: a town in Glamorganshire, Wales, which has rapidly increased from a small village to a place of importance (see map of England, ref. 11-E). It has extensive collieries, iron and tin works. Pop. (1891) 35,533.

Aberdeen' (i. e. mouth of the Dee): a city and seaport of Scotland; the capital of the county of Aberdeen; on the North Sea, 93 miles N. N. E. of Edinburgh (see map of Scotland, ref. 8-J). It is a handsome city, with spacious streets and granite houses, and is celebrated as a seat of learning. Among the principal public buildings are the town-house, several churches, and Marischal (pronounced mar'shal) College, founded in 1593. Aberdeen has a good harbor and an extensive trade, the chief articles of export being fine cotton and woolen fabrics, granite, grain, cattle, and fish. Here are flourishing manufactories of cotton and woolen goods, combs, machinery, etc. Old Aberdeen, about a mile N. of the new city, is the seat of King's College and University, founded in 1494, united with Marischal College in 1860 as the University of Aberdeen. The Free Church Divinity College was built in 1850. Pop. (1891) 121,905. The parliamentary borough sends two members to Parliament.

Aberdeen', or Aberdeen'shire: maritime county in N. E. of Scotland; bounded N. and E. by the North Sea, S. by Kincardine, Forfar, and Perth, and W. by Inverness and Banff; area, 1,970 sq. miles. The Grampian range of mountains extends along the southern boundary of this county, which contains several high peaks. Among these are Ben-Macdhui, 4,296 feet, and Cairngorm, 4,090 feet high. It is drained by the Dee and the Don. The principal rocks are granite and mica-slate. More cattle are raised in Aberdeen than in any other county in Scotland. Pop. (1871) 244,607; (1881) 267,990; (1891) 281,331. The United Diocese (in the Scottish Episcopal Church) of Aberdeen and Orkney is composed of the county of Aberdeen (less Huntley), parts of Banff and Kincardine, and the Orkney and

Shetland islands. The see of Aberdeen was founded A. D. 1100, that of Orkney A. D. 1120; the two were united in 1857.

Aberdeen, EARLS, Viscounts Formantine, Barons Haddo, Methlie, Tarves, and Kellie (in the Scottish peerage since 1682), Viscounts Gordon (in the peerage of the United Kingdom since 1814), and baronets (in the Scottish peerage since 1642), one of the most prominent noble families of Great Britain, an offshoot of the ancient Scotch family of the Gordons.—Sir John Gordon of Haddo was in 1642 created a baronet by Charles I. for services rendered to that monarch in the battle of Turriff.—Sir George Gordon of Haddo was Lord High Chancellor of Scotland when in 1642 he was created an earl. He was an uncompromising opponent of William of Orange. D. in 1720.

Aberdeen: capital of Monroe co., Miss. (for location of county, see map of Mississippi, ref. 5-H); on the west side of the Tombigbee river. It buys and ships about 20,000 bales of cotton yearly, and has fine Federal and State court-houses; the finest public-school buildings in the State; one of the best river bridges in the South; and considerable trade. It has 5 grist-mills, saw and planing mill, steam brick-factory, ice-factory, large steam spoke-factory, foundry and machine-shop, and 4 steam cotton-gins. It is the junction of branches of the Mobile and Ohio, Illinois Central, and Kansas City, Memphis and Birmingham R. Rs. Pop. (1880) 2,339; (1890) 3,449; (1900) 3,434. EDITORS OF "EXAMINER."

Aberdeen: railroad center and capital of Brown co., S. Dak. (for location of county, see map of South Dakota, ref. 5-F); on Chicago, Milwaukee and St. Paul, Chicago and Northwestern, Great Northern and Northern Pacific R. Rs. Pop. (1890) 3,182; (1900) 4,087. EDITOR OF "NEWS."

Aberdeen, GEORGE HAMILTON GORDON, Fourth Earl of: British statesman; b. in Edinburgh, Jan. 28, 1784; graduated at Cambridge in 1804. He began his public life as a Tory, was sent as ambassador to Vienna in 1813, and was raised to the British peerage as Viscount Gordon in 1814. In 1828 he became Secretary of State for Foreign Affairs in the Cabinet of the Duke of Wellington, with whom he resigned in Nov., 1830. He was reappointed to that office by Sir Robert Peel in 1841, gradually abandoned the high Tory principles, and favored a pacific foreign policy. In 1846 he resigned office with Sir Robert Peel, after whose death (1850) he was regarded as the chief of the Peelite party. He became, in Jan., 1853, Prime Minister in a Cabinet formed by a coalition of parties. In 1854 England was involved in a war against Russia, to which measure Lord Aberdeen gave a reluctant support. Either from this cause or because the war was conducted with ill success the ministers became very unpopular. Lord Aberdeen resigned Jan. 30, 1855, and was succeeded by Lord Palmerston. D. in London, Dec. 14, 1860.

Aberdeen, GEORGE JOHN JAMES, Fifth Earl of: oldest son of the preceding; b. Sept. 28, 1816; was for a number of years, as Lord Haddo, a member of the House of Commons, where he voted with the Liberals; succeeded his father in the peerage in 1860. D. Mar. 22, 1864.

Aberdeen, JOHN CAMPBELL HAMILTON GORDON, Seventh Earl of: a British statesman; b. Aug. 3, 1847; succeeded to his title Jan. 27, 1870; graduated at Oxford as M. A. in 1871. He began political life as a Conservative; was in 1875 a member and later the chairman of a royal commission to investigate the subject of railway accidents; and in 1877-78 a member of the Committee of the House of Lords on Intemperance. In 1880, having become a Liberal, he was appointed Lord-Lieutenant of Aberdeenshire; and for the years 1881-85 he was High Commissioner to the General Assembly of the Church of Scotland. Appointed Lord-Lieutenant of Ireland by Mr. Gladstone in 1886, he became extremely popular with the Irish people in his mission of carrying out the Home-Rule policy of that time. He was appointed Governor-General of Canada in 1893, and served until Nov., 1898.

Abergavenny (commonly pronounced ab-er-gā'ne): market-town of England; in Monmouthshire, on the Usk, which is here joined by the Gavenny, and crossed by a fine bridge, 13 miles W. of Monmouth. Pop. about 8,000.

Abergavenny, EARLS OF, and Viscounts Nevill (in the peerage of Great Britain, 1784), Barons of Abergavenny since the time of Henry III.: a prominent noble family in the peerage of Great Britain.—WILLIAM NEVILL, Fifth Earl of, was born Sept. 16, 1826, and succeeded his father in 1868. His oldest son and heir is REGINALD WILLIAM BRANSBY, Viscount Nevill, b. Mar. 4, 1853.

Ab'ernethy, JAMES, F. R. S. E., Commander of the Order of Leopold: civil engineer; past pres. Inst. C. E.; b. at Aberdeen, Scotland, in 1815; educated at various schools. At the age of fifteen he became assistant to his father on the extension of the London docks, and later served under Telford. In 1841 he was resident engineer of Aberdeen harbor works, and later, as engineer-in-chief, designed and built the lock and dock there, which were opened in 1848. From 1842 to 1852, as surveying officer to the Admiralty, he examined and reported upon many important works, harbors, docks, and river improvements, designed or under construction. Hydraulic power for working lock-gates was first applied by him to the gates of a lock and dock which he built at Swansea. In 1850, as chief engineer, he completed the Birkenhead docks, and at the same time designed and built Laird's ship-building yards, with various graving-docks and other appliances. In 1860-66 Mr. Abernethy built the Turin-Savona R. R. and the Cavour Canal, in Italy. His design for the improvement of the Danube through Vienna, submitted in competition with several eminent engineers, was selected by the Government Commission. In 1868-70 he designed and constructed the dock at Newport, with extensive coal-shipping machinery, and in 1879 the Prince of Wales dock at Swansea. As consulting engineer to the Marquis of Bute, he supervised the modern docks at Cardiff. The Hull docks, 46 acres of water, 2 miles of quay walls, were built in the bed of the Humber, reclaiming 200 acres of land. In 1877 works for the reclamation of Lake Aboukir, Egypt, were directed by him, reclaiming 20,000 acres. In 1882 he advised the construction of the Manchester ship-canal, and became its consulting engineer; became associate of the Inst. Civil Engineers in 1844, member in 1856, and president in 1881. D. Mar. 8, 1896.

Abernethy, JOHN: an eminent English surgeon; b. in London, Apr. 3, 1764; grandson of John Abernethy (a noted Dissenting minister, b. at Coleraine, Ireland, in 1680), and a pupil of John Hunter. He was chosen assistant surgeon of St. Bartholomew's Hospital, London, in 1787, and in 1815 chief surgeon of the same. As a lecturer on anatomy and surgery he gained immense popularity. He published in 1809 an important work *On the Constitutional Origin and Treatment of Local Diseases*, the doctrines of which have greatly contributed to improve the science of surgery. Many anecdotes are related of his eccentric manners and of his witty or petulant speeches to his patients. D. at Enfield, Apr. 28, 1831.

Aberra'tion [Lat. *ab*, away + *erra're*, wander]: a term variously employed; in optics it denotes a failure in the rays of light to come to the same focus when refracted by a lens or reflected from a concave mirror. There are two kinds of optical aberration—viz., chromatic (from the Greek *χρῶμα*, color) aberration, or aberration of refrangibility, and spherical aberration, or aberration of sphericity. In astronomy also there is the aberration of the celestial bodies, sometimes (but less correctly) termed the aberration of LIGHT (*q. v.*).

1. *Chromatic Aberration, or Aberration of Refrangibility.*—A convex lens brings rays of light which fall upon it to a focus by virtue of its refracting power. But since the variously colored rays which form white light are differently refracted, it follows that when light is converged by a convex lens it is refracted to different foci. The violet rays, being the most refrangible, form a focus nearest to the lens; while the red rays, being the least refrangible, form a focus farthest from the lens. Thus in place of one focus there are, in reality, an almost infinite number—viz., one for each of the differently refracted rays (the rays even of the same general color being not all refracted equally), and in the order of violet, indigo, blue, green, yellow, orange, red. Hence the rays do not meet at the same focus of the lens; and this deviation of the foci is called the *chromatic aberration* of a lens.

2. *Spherical Aberration, or Aberration of Sphericity.*—Lenses and mirrors are usually ground with spherical surfaces, and so long as the aperture does not exceed eight or ten degrees the rays of homogeneous light refracted or reflected by different parts of them meet very nearly at the same focus of the lens or mirror. But as the aperture of a spherical mirror increases, the rays reflected from the edges cross each other at a point on the axis nearer to the mirror than those which are reflected from portions of the mirror near its center. Thus the rays are deviated from the true focus of the mirror. Again, with regard to spherical lenses of large aperture, the rays which pass through the lens near

its circumference are refracted to a point nearer to the lens than those which pass through its central portion. In the case of mirrors this deviation of light from the focus is called *spherical aberration by reflection*, while in the case of lenses it is called *spherical aberration by refraction*. It may be remedied by giving lenses and mirrors parabolic surfaces, a plan which is almost invariably followed in the construction of specula for astronomical purposes.

3. *Aberration of the Celestial Bodies*, often (but less correctly) termed the *aberration of light*, in astronomy, an apparent displacement of a celestial object, due to the progressive motion of light. This aberration is caused—1, by the motion of the earth in its orbit; and, 2, by the motion of the observed celestial objects. It was discovered by Bradley in 1727. This astronomer reasoned that, if the earth's motion bears only an appreciable relation to the velocity of light, we ought to expect that the rays from a star would seem to come from a point nearer than is actually the case to that point in the heavens toward which the earth's course is directed. The phenomenon he had observed corresponded exactly with this explanation. The change of place due to the velocity of light, estimated from the eclipses of Jupiter's satellites, corresponded (within the limits of observational error) with the observed changes in the apparent positions of the fixed stars. It follows, from a consideration of the earth's path, that each star appears to describe a small ellipse about its true place. This fact is of great importance in its direct bearing on observational astronomy, but it is perhaps no less important on account of the evidence it supplies as to the motion of the earth.

The correction of the observed position of a celestial object for aberration gives the true position for the moment when the light which makes it visible left it; but this is not the true position for the moment of observation, except on supposition that the observed object is at rest. If the body itself is in motion, then, in addition to the correction of position for aberration, there must be a correction for the amount of proper motion which has taken place in the interval since the light which makes it visible left it. In order to make this correction we must know the rate of proper motion and the distance of the body. If the absolute proper motion of the body is given in miles, or length measure, and not the apparent in angular measure, and is parallel to the motion of the earth, then the whole correction may be treated as aberration, by taking the sum or the difference of the velocities per second of the two bodies, according as they are in the opposite or in the same direction, and comparing this with the velocity of light. If the velocities of the two bodies are in the same direction and equal, their difference is zero, and the correction is *nil*. Hence a body moving in the same direction as the earth, and with the same velocity, is unaffected in apparent position by aberration. The same will be true of a body not moving in the same direction as the earth, provided that when its velocity is decomposed into rectangular components, one of which is parallel to the earth's motion, this latter component velocity is equal to the earth's velocity and in the same direction.

It follows from the foregoing that the bodies of a group or system, as observed the one from the other, are unaffected by aberration in consequence of any common motion in which all participate alike, but that they suffer displacement from this cause only in consequence of their relative motions. The moon partakes of the annual motion of the earth round the sun, but suffers no aberration on that account; and so the sun, though it may have a proper motion in space, is unaffected by this cause in its apparent position, as viewed from the earth or from any other member of the solar system, since this motion is one in which all the bodies of the system equally participate.

Revised by S. NEWCOMB.

A'bert, JOHN JAMES: soldier; b. at Shepherdstown, Va., Sept. 17, 1788; graduated at the U. S. Military Academy in 1811; immediately resigning, he became a lawyer in the District of Columbia; and in the war with Great Britain, 1812-15, served as private in the militia at the battle of Bladensburg, Aug., 1814. Appointed brevet major of U. S. Topographical Engineers Nov. 22, 1814, he was placed in charge of the bureau Mar. 19, 1829, and on the organization of an independent corps of that title was made, with rank of colonel, its chief, July 7, 1838. Retired from active service Sept. 9, 1861. D. at Washington, D. C., Sept. 27, 1863. As an officer, and as chief of Topographical Engineers, Col.

Abert exercised an important agency in the development of the earlier national works of civil engineering in the U. S. —e. g. the canal around the falls of the Ohio at Louisville, the Chesapeake and Ohio Canal, the Potomac aqueduct, etc. His exhaustive report on water-supply, in connection with the Chesapeake and Ohio Canal (1838), is a standard of reference. He was a member of the Geographical Society of France and of other learned societies.

Abey'ance [O. Fr. *abeance*; à, at + *beer* < Late Lat. *bada're*, gapc]: a legal term signifying expectation or suspense. It is used to indicate the condition of property where there is no person in whom its ownership is vested. In the law of real estate it is generally applied to a fee, which is said to be in *abeyance* when there is no particular owner of the inheritance. It has been laid down that a fee can be in abeyance only while there is a freehold estate (or life-interest) in the land vested in some person. It is denied by writers of high authority that a fee can be in abeyance. The tendency of modern law certainly is to discountenance this theory, and to reduce the cases of abeyance to the narrowest possible limits. The term has been applied in some instances to personal property, as in case of captures at sea in time of war, as to the title after capture and before condemnation in the prize court.

Ab'gar, or Ab'garus (Gr. Ἀβγαρος), written also **Abagarus, Agbarus, and Augarus**: a name common to several kings of Edessa, in Mesopotamia. The fourteenth of these kings, Abgar Uchomo, is said to have been in correspondence with Christ. The genuineness of this correspondence has found defenders even in the nineteenth century.

Abgil'us, JOHN: son of the King of the Frisii; became a Christian, and accompanied Charlemagne in several of his expeditions. He received the title of prester, or priest, on account of the excessive severity of his life. He is not to be confounded with the Mongolian Prester John of the eleventh century.

Abhorrrers: name given to the court party or supporters of Charles II. in his disapproval of petitions for the reassembling of Parliament (1680), because in their addresses they expressed *abhorrence* of the petitions of the Whigs, who were termed *petitioners* or *addressers*.

Ab'bib (after the Babylonian captivity called NISAN: see Neh. ii. 1): the first month of the Hebrew sacred year and the seventh of the civil year, beginning with the new moon of March.

Ab'ich, WILHELM HERMANN: b. in Berlin, Dec. 11, 1806; studied natural science at the university of his native city; traveled in Italy and Sicily; and published *Erläuternde Abbildungen von geologischen Erscheinungen, beobachtet am Vesuv und Aetna 1833 und 1834* (1837), and *Ueber die Natur und den Zusammenhang der vulkanischen Bildungen* (1841); was appointed Professor of Mineralogy at Dorpat in 1842; and undertook extensive explorations in the Caucasus, Armenia, and Northern Persia, the results of which he communicated partly in the annals of the Academy of St. Petersburg, partly in independent works, the principal of which are—*Ueber die geologische Natur des armenischen Hochlandes* (1843); *Vergleichende geologische Grundzüge der kaukas.-armenischen und nord-persischen Gebirge* (1858); *Sur la Structure et la Géologie du Daghestan* (1862). D. at Graz, July 2, 1886.

Ab'bies (Lat. fir-trec): a genus of coniferous trees which have leaves growing singly on the stem, and the scales of whose erect cones are deciduous. Formerly the genus included the firs, spruces, and hemlocks, but it is now restricted to the firs alone, of which there are eighteen species, all in the Northern Hemisphere. Nine are North American. *A. balsamea* is the balsam-fir of the Eastern U. S.; *A. subalpina* and *A. concolor* occur in the Rocky Mountains; *A. alba* is the silver fir of Europe. All afford valuable timber, and the balsam-fir yields Canada balsam. See PICEA, TSUGA, and PSEUDOTSUGA. CHARLES E. BESSEY.

Ab'ila: capital of the tetrarchy of Abilene; identified with Sûk, on the right bank of the Barada, near the point where it breaks through the Antilibanus range of mountains toward the plain of Damascus. It was on the great road between Heliopolis and Damascus, 32 miles from the former city and 18 miles from the latter. There was another Abila E. of the Jordan, a few miles S. of the Yarmuk (or Hicromax), the northern boundary of Gilead.

Ab'ildgaard, NIKOLAI ABRAHAM: one of the founders of the Danish school of painting; b. in Copenhagen in 1743; d. at Frederiksdal, June 4, 1809. He took a deep interest in the education of Thorwaldsen, and Eckersberg was one of his pupils. His influence on Danish art was very great. R. B. ANDERSON.

Abilene, ab-i-lee'née: an ancient tetrarchy, whose capital was ABILA (*q. v.*). It is impossible to fix its limits. Luke (iii. 1) speaks of it as the tetrarchy of Lysanias, who was apparently a son of the Lysanias mentioned by Josephus. See Kraft's *Topographie Jerusalems* (1847).

Abilene, ab'i-leen: city; capital of Dickinson co., Kan. (for location of county, see map of Kansas, ref. 5-G); on the Smoky Hill river, and the Atch., Top. and S. Fé, the Chi., Rock Is. and Pac., and the Union Pac. railways; 96 miles W. of Topeka, 162 miles W. of Kansas City, Mo. It contains 12 churches, 4 school buildings, a Roman Catholic academy, a national bank with capital of \$50,000, 2 private banks, and a daily and 3 weekly periodicals; and has several elevators, flour-mills, electric-light plant, and excellent water. Pop. (1890) 3,547; (1900) 3,507.

EDITOR OF "REFLECTOR."

Abilene: capital of Taylor co., Tex. (for location of county, see map of Texas, ref. 3-F); on Texas and Pacific R. R.; 161 miles W. by S. of Fort Worth; is connected by stage with Anson, Haskell, and Ballinger; has 7 churches, 3 public schools, 1 roller flour-mill, 2 roller corn-mills, 2 cotton-gins, electric lights, etc. Pop. (1890) 3,194; (1900) 3,411.

EDITOR OF "REPORTER."

Abim'elech (the royal father): I. A king of Gerar, a city of the Philistines, in the time of Abraham (Gen. xx. 1, sq.). II. Another king of Gerar in Isaac's time (Gen. xxvi.), perhaps a son of the foregoing. III. Another Philistine king (Ps. xxxiv. title). IV. A son of Gideon (Judges ix.), who was during three years a self-constituted king over a great part of Israel. Revised by W. J. BEECHER.

Ab'ingdon: a market-town of Berkshire, England; on the Ock, where it joins the Isis; 51 miles W. N. W. of London (see map of England, ref. 11-H). It contains a fine memorial of Prince Albert, erected in 1864, and surmounted by his statue. It has a free grammar-school. Pop. (1891) 6,557.

Abingdon: city of Knox co., Ill. (for location of county, see map of Illinois, ref. 4-C); at the crossing of the C., B. and Q. and Iowa Central R. Rs., 10 miles S. of Galesburg and 85 miles N. E. of Quincy. It is surrounded by a rich agricultural district, and is the seat of Hedding College (controlled by the Methodist Episcopal Church), and of the Abingdon Normal College; has 3 churches and several flourishing manufacturing establishments. Pop. (1890) 1,321; (1900) 2,022. PUBLISHERS OF "ENTERPRISE."

Abingdon: capital of Washington co., Va. (for location of county, see map of Virginia, ref. 7-B); in a township of same name, on two railroads, 315 miles W. S. W. of Richmond. It has three female colleges of high grade, excellent public free schools for white and colored children, post-office and court-house, an extensive iron-foundry, cigar and pipe factories, brickworks, woolen factory, canning and other factories. The county was organized in 1776, and is the first spot of earth named in honor of George Washington. Emory and Henry College is in this county, and a large male academy, both flourishing institutions. Immense deposits of salt, gypsum, and iron ore are found here, and a large part of the salt used in the Southern States during the civil war was obtained from salt-wells bored in this vicinity. Pop. (1880) 1,064; (1890) 1,674; (1900) 1,306. EDITOR OF "VIRGINIAN."

Abiogen'esis [Gr. ἄβιος, lifeless + γένεσις, origin]: a name proposed as a substitute for *spontaneous* or *equivocal generation*, i. e. the doctrine that certain animals or plants have spontaneously originated, and without birth from previous living beings. As yet, there is no direct evidence that such generation ever takes place. See GENERATION, SPONTANEOUS. Revised by D. S. JORDAN.

Abipo'nes: a tribe of Indians living in the Gran Chaco, in the Argentine Confederation. They lived formerly W. of the Paraná, between lat. 28° and 30° S., between Santa Fé and Santiago del Estero, but at present have removed toward Corrientes. The Abipones are of high stature, good swimmers, and tattoo themselves. Long lances and arrows with iron points are their weapons. In 1783 their number was estimated at 5,000, but they have been reduced to 100 at the present day. They are related to the Tobas.

Abka'sia, or **Aba'sia**: a narrow territory in Western Asia, belonging to Russia; between the Caucasus Mountains and the Black Sea, which bounds it on the S. W. It is now under the government of Kutais. The inhabitants, under the Emperor Justinian, became Christians, but subsequently embraced Mohammedanism. They are kindred to the Circassians, and, like the latter, have emigrated in large numbers.

Ablaut: a German term which has fairly established itself internationally in the technical language of scientific grammar. Its best English equivalent is *vowel-gradation*. It applies to that variation of vowel among words of the same Indo-European root, as in English *sing, sang, sung*, and Greek *λείπω, λέλοιπα, ἔλιπον*, which depends upon causes no longer active or discernible in the separate languages of the family. Ablaut is an Indo-European phenomenon produced under conditions existing in the parent Indo-European speech. Umlaut, or mutation, is a distinctively Teutonic phenomenon produced under conditions existing in the separate life of the Teutonic languages, thus: in *foot, feet; cow, kine; louse, lice; Frank, French*, where the cause of the vowel change is the influence of a following *i* sound upon the pronunciation of the root vowel. The Indo-European *mūs* (nom. sing.), *mūses* (nom. plur.), appeared in Greek as *μῦς, μύες*; in Latin as *mūs, mures*; and in primitive Teutonic—i. e. before the division into dialects—as **mūs, *mūsiz*. The Teutonic vowel *i* in the second syllable of **mūsiz*, which represented thus the original vowel *e* of the Indo-European nom. plur. ending *-es* (cf. *πῶδ-ες*), was the cause of the change of *ū* to *ī* in the plural of our *mouse, mice* = Old English *mūs, mȳs*. See UMLAUT.

Sharply distinguished from these vowel changes are the phenomena of ablaut. The latter, as they appear in the Teutonic or other Indo-European languages, are simply inheritances from the parent speech. They may be *utilized*, as they are notably in the Germanic family, owing to the decay of the endings, for the distinguishing of meanings, but they no longer exist in any relation to the conditions that produced them. These can be discerned only by reference through the methods of comparative philology to the parent Indo-European speech. The relation, for instance, of

- (1) *ziehen, zog, gezogen, to*
- (2) *binden, band, gebunden,*

is clearer in the Gothic

- (1) *tiuhan, tauh, tōhans,*
- (2) *bindan, band, bundans,*

but not evident, until the systems are reduced to the Indo-European form:

- (1) *deuk, douk, duk,*
- (2) *bhendh, bhondh, bhndh.*

These two systems are illustrated in Greek by

- (1) *ἐ-λεύ(θ)-σομαι, εἰλή-λουθ-α, ἦ-λυθ-ον,*
- (2) *ἐ-γέν-ετο, γέ-γον-α, γί-γν-ομαι.*

The ablaut of German *giessen, goss, gegossen*, corresponds to Gothic *giutan, gaut, gutum*, and Greek *χέτω, χοφή, κέχυνται*.

The original cause for the phenomena of ablaut is to be found in the peculiar conditions of word and sentence accent in the Indo-European parent speech. Thus by the withdrawal of the accent the original root-elements *ei, eu, el, er, en, es*, etc., were reduced to *i, u, l, r, n, s*, etc. Thus Greek, *εἶμι, ἴμεν* (orig. **imēn*), cf. Skr. *ἔμι, ἴμας*. So *χεῖμα, χυτός; φεύγω, φυγεῖν; πείθω, πειθέσθαι; Φείδομαι, Φιδεῖν; δέρεται, δρακεῖν (r > ρα); αἶθω, ἰθαρός*, etc. The cause of differentiation between the *e* grade and the *o* grade is not so definitely determined (*λέγω, λόγος; νέμω, νόμος; λείπω, λέλοιπα; δέρομαι, δέδορκα*; Gothic, *steigan, staig*; English, *sing, sang*, etc.), but it most probably had its origin in a variety of musical pitch—i. e. the *e* grade occurs with stress and high pitch, the *o* grade with stress and lowered pitch. The chief systems of Indo-European ablaut may be grouped as follows:

1. *ē : ō*: zero, as *πέτομαι, ποτή, πτέσθαι; πα-τέρ-ες, εὐπά-τορες, πα-τήρ, εὐπά-τωρ, πα-τρ-ά-σι*.
2. *ǣ : (ō?)*: zero, *ἀγός, στρατ-ἄγ-ός*. Skr. *j-mán* (path).
3. *ō*: zero, *ὀδμή, ὀδ-ωδ-α; πρωί, πρό, πρ-ί-ν*.
4. *ē : ō : ə* ("obscure" vowel): *τίθημι, θωμός, θετός*.
5. *ā : ō : ə*: *φάμι, φωνή, φάμέν*.
6. *ō : ō : ə*: *δίδομι, δόσις*.

BENJ. IDE WHEELER.

Ablu'tion [Lat. *ab*, away + *lu'ere*, wash]: a religious ceremony of the Roman Catholic Church, signifies the washing of the sacramental cup and of the hands of the priest. The various editions of the *Directorium Anglicanum* give minute directions as to the ablutions recommended for use

in the ritual of the Church of England. In the American Episcopal Church ceremonial ablutions are disallowed, on the recommendation of the House of Bishops, in the public worship.

Abnakis: See ALGONQUIAN INDIANS.

Ab'ner (the enlightener): uncle of Saul, the first King of Israel. Abner became commander-in-chief of Saul's army, and for some time after the death of the king he was the chief support of Ishbosheth, his successor; but subsequently went over to the side of David, then King of Judah. With David he found such favor that Joab was jealous and slew Abner, cir. 1048 B. C., according to Ussher.

Revised by W. J. BEECHER.

Åbo (Sw. pronunciation, *ō'boo*): Russian city and seaport, on the Aurajoki near its entrance into the Gulf of Bothnia; lat. 60° 26' 58" N., lon. 22° 17' E. (see map of Russia, ref. 5-B). It was built by Eric IX. of Sweden in 1157, was subsequently taken by the Russians, and in 1809 was, with the whole of Finland, ceded to Russia. It was the capital of Finland until 1819, and is now the see of a Lutheran archbishop. It has a cathedral, a town-hall, and a custom-house. The University of Åbo, having been destroyed by fire in 1827, was rebuilt at Helsingfors. Pop. (1897) 32,184.

Åbo-Björneborg: a government of Finland; bounded by the governments of Vasa and Tavastehus, and by the Gulfs of Finland and of Bothnia. Area, 9,332 sq. miles. The chief occupation of the inhabitants is commerce and ship-building. The government has also some factories. Pop. (1897) 413,351, nearly all Lutherans. Chief town, Åbo.

Åbo, Peace of: a peace concluded Aug. 17, 1743, between Sweden and Russia. It put an end to the war begun by Sweden at the instigation of France in 1741. During this contest, and through the misconduct of the Swedish generals, the Russians gained entire possession of Finland. The greater part of this territory they offered to restore on condition that Sweden should elect the Prince of Holstein-Gottorp successor to the throne. This condition the Swedes complied with, and the treaty of peace was accordingly signed at Åbo.

Abolition of Slavery: See SLAVERY.

Aboli'tionists: a name applied to those persons—more particularly in the U. S.—who were distinguished for their zeal against the institution of slavery.

Abomey, *ab-ō-mā'*: an African town; capital of the kingdom of Dahomey; lat. 7° 30' N., lon. 2° E. (see map of Africa, ref. 5-C). It contains several royal palaces. Captured by the French under Gen. Dodds, Nov. 21, 1892. Pop. estimated at from 50,000 to 60,000.

Aborig'i-nes [Lat. derivative from phrase *ab ori'gine*, from the beginning]: the earliest original inhabitants of a country—that is, those who occupied it at the period when it began to be known, and who either were (according to a once prevalent opinion) indigenous to the soil or had emigrated thither before the dawn of history. Some of the ancients supposed they had always inhabited the same soil, and sprang from it, as the Athenians, who thence called themselves *autoch'tones* (from *αὐτός*, itself + *χθών*, earth, soil, land); i. e. sprung from the land or soil itself. But the Romans and modern nations use the word *aborigines* to designate those inhabitants of a country of whose origin nothing certain is known. Thus the Indians of America are properly called *aborigines* because they were found there at its discovery, and as to their origin we have only their own tradition (which is not uniform), that their ancestors came from a distant region in the northwest.

Abortion [Lat. *abortio*, from *abori'ri*, miscarry; *ab* + *ori'ri*, appear]: the premature delivery of the human fœtus, or its expulsion before it is capable of sustaining life. The term is popularly understood as applying to the expulsion of the fœtus before the sixth month of gestation. A child born as early as the seventh month of pregnancy not infrequently lives, the case being referred to as simply one of premature birth. And a child born after the seventh month, but before the natural period of parturition, which dies at once and in consequence of the premature delivery, is a case of abortion. A premature delivery may be either natural or artificial. A natural abortion may be caused by various accidental or pathological conditions. Artificial abortion is usually caused by drugs, which excite uterine contractions, and thereby cause the expulsion of the fœtus, although not

infrequently produced by mechanical means. A resort to either method is extremely dangerous to the woman's life. Artificial abortion may or may not be criminal, according to circumstances. Premature labor produced for the purpose of saving the life of either the mother or the child is justifiable. But premature labor produced with the malicious intent of prematurely getting rid of the product of conception, and thus preventing the birth of a living child, is criminal. The Roman law did not regard an unborn child as a human being, and a woman procuring her own miscarriage was not liable under the Lex Julia against homicides, but she was liable as for an *extraordinarium crimen*. Among the Anglo-Saxons abortion is said to have been regarded as an ecclesiastical offense only. In England and in the U. S. the law governing abortion is at the present time statutory. These statutes vary greatly in different States, both as to the nature of the crime and as to the penalty imposed. In some it is not an indictable offense to produce an abortion unless the woman was "quick" with child, while in others the act of criminal homicide is possible from the earliest stage of gestation. See OBSTETRICS. HENRY WADE ROGERS.

Aboukir: See ABUKIR.

Aboulia: See WILL.

About, aã'boo', EDMOND: French novelist and political writer; b. at Dieuze (Meurthe), Feb. 14, 1828. In 1868 he wrote, as one of the contributors to the *Gaulois*, a series of witty and satirical letters, in consequence of which that paper was suppressed by the authorities; but he was nevertheless assisted by the imperial Government, which in 1870 appointed him councilor of state. At the beginning of the war he was for a short time war correspondent for the *Soir*. Sept. 14, 1872, he was arrested by the Germans, but was released Sept. 21. He published in 1855 a work on modern Greece, *La Grèce contemporaine*, which was much admired. He had been sent to the French school of art in Athens by his Government. Among his works are novels entitled *Tolla* (1855); *Germaine* (1857); a political treatise on *The Roman Question* (1860); *Madelon* (1863); *Le Progrès* (1864); *La vieille roche* (3 vols., 1865-66); *L'infame* (1867); *Les mariages de province* (1868). His *Le Roi des Montagnes* (1856) is one of his best works. D. Jan. 17, 1885.

Aboville, FRANÇOIS MARIA, Count: French general; b. at Brest, Jan. 23, 1730. He directed the artillery at Yorktown, Va., in 1781, and was inspector-general of artillery under Napoleon I. D. Nov. 1, 1819.

Abrahamel', or **Abarbanel'**: b. in Lisbon, 1437; d. in Venice, 1508; traced his pedigree back to King David; was a minister of state to Ferdinand and Isabella of Spain, but was in 1492 exiled as a Jew; lived mostly in Italy, whence he made short journeys to other countries, and wrote, besides some commentaries, his *Herald of Salvation*, an elaborate exposition of the Jewish doctrine of the Messiah, first printed at Saloniki in 1526.

Abracadabra': a cabalistic word, probably of Persian origin (and connected with *abraxas*), occurring first in writings of Qu. Severus Sammonicus (c. 200 A. D.), and highly prized in former times as a magical formula. Written in the form shown in the annexed figure, and worn as an amulet, it was supposed to be efficacious in the cure of fevers and other ailments.

Abraham, originally **Abram**: the founder of the Israelitish race; b. at Ur in Chaldæa. The date is unknown. Bunsen makes it about 2850 B. C., Hales 2153 B. C., and Ussher 1996 B. C., and others later still. He migrated to Canaan with a numerous tribe (Gen. xii. 5; xiv. 14, etc.), and lived there in tents. His faith was tried by long waiting, and he is known as the "father of the faithful" and the "friend of God." But the thing mainly emphasized in the Bible accounts is the promise that God made to him. Subordinately, the promise is that he shall have a numerous posterity, including "kings," and "a nation" made up of "an assembly of nations" or "of peoples," which shall inherit the land of Canaan forever (Gen. xii. 2; xvii. 6-19; cf. xxviii. 3; xxxv. 11; xlvi. 4, etc.). Chiefly, the promise is that in him and his posterity all mankind shall be blessed (Gen. xii. 3, etc.); and in view of this his name was changed

to Abraham, "father of multitude" (Gen. xvii. 4-5; Rom. iv. 17). Here "multitude of nations" is a different phrase from "assembly of nations" in the texts cited above. See Gen. xi.-xxv.; Acts vii.; Gal. iii.; Heb. xi. 8-19.

W. J. BEECHER.

A'braham-a-Sanc'ta-Cla'ra: a popular German preacher and Augustine friar, whose name was ULRICH MEGERLE; b. in Baden, June 4, 1642. He was appointed preacher to the imperial court at Vienna in 1669, and published many religious works. His sermons were seasoned with witty, humorous, or whimsical expressions. D. Dec. 1, 1709.

A'brahamites: a sect of Bohemian deists, who are said to have rejected all parts of the Bible except the Ten Commandments and the Lord's Prayer. They were suppressed in 1783.

Abrantes, DUKE OF: See JUNOT.

Abraxas: a kind of gem found in Syria, Egypt, and Spain, and used by the Gnostics as an amulet. These abraxas stones were of various forms, but all had the word abraxas, or abrasax, engraved on them in connection with certain mystical symbols, mostly consisting of fantastical figures, composed of the body of a serpent, the head of a bird, and other incongruous parts. The word abraxas was first used by the Egyptian Gnostic Basilides (*q. v.*), and denoted not the supreme being, but the assemblage of the 365 world-spirits; the letters composing the word expressing, according to the Greek numeration, the number of 365. His disciples, who used gems of this kind as amulets or talismans, and after whom they are often called Basilidian stones, spread them all over Egypt and Syria, and in the fourth century the disciples of Priscillianus carried them to Spain.

Abridg'ment [Fr. *abrégé* < Lat. *abbrevia're*, shorten]: a condensation or compendium of a book or literary work. In the law of copyright an abridgment, when fairly made, is regarded as a new work, and accordingly its publication is not an infringement of the copyright. A distinction is taken in the legal decisions between an abridgment and a compilation. The latter is more readily regarded as an infringement, as the words of an author are reproduced, while in a true abridgment the thoughts are expressed in other words and in a condensed form.

Abro'lhos (i. e. open your eyes): a group of small rocky islands which belong to the State of Bahia, Brazil. The largest of these, Santa Barbara, 40 miles from the coast, has a lighthouse in lat. 17° 58' S., lon. 38° 42' W.

Abrun'zi and **Molise**: a political division of Italy, comprising the provinces of Abruzzo ulteriore I., Abruzzo ulteriore II., Abruzzo citeriore, and Molise, or Campobasso. It extends from the Apennines to the Adriatic, between the parallels of 42° and 43° (see map of Italy, ref. 6-E). Though it has a coast line of about 100 miles, it has no good harbor. It is very mountainous, and was formerly much infested by brigands. Lake Fucino is within it. The principal towns are Teramo, Aquila, Chieti, Solmona, Isernia, and Campobasso. Area, 6,487 sq. miles. Pop. (1891) 1,360,378.

Ab'salom: third son of King David, by Maacah, a Syrian princess, was remarkable for his personal beauty. Having, by his popular arts and fair speeches, gained the favor of the people, he rebelled against his father and raised a large army, which was defeated by the army of the king. Retreating from this battle, Absalom was killed by Joab, although David had given orders that his life should be spared. See 2 Samuel xiii.-xix.

Ab'salon, called also **Axel**: an eminent prelate and general; b. in Iceland in 1128; was a liberal patron of learning, and was distinguished for his wisdom in council. He was one of the ministers of the Danish King Waldemar I., and became Archbishop of Lund in 1178. D. in 1201.

Ab'scess [Lat. *absces'sus*, from *abs*, away + *ce'dere*, go, because the pus separates itself from the rest of the body]: in surgery, a circumscribed collection of pus in any part of the animal organism, as distinguished from "purulent infiltration," which designates such a collection not circumscribed. The term "diffuse abscess" is, however, applied, though improperly, to purulent infiltration. An "acute abscess" is one which is the result of active inflammation. "Cold abscess" is the result of chronic inflammation, and is commonly of tubercular origin. The tendency of an acute abscess is to "point" or "come to a head"; that is, from the outward pressure of the accumulating pus, the walls yield mechanically in the direction of least resistance. In favor-

able cases the evacuation of the pus, natural or artificial, is the initiation of recovery; but if the abscess be of the "cold" variety, or be deep-seated and extensive, or be associated with dissemination or septicæmia, the question of recovery becomes a much more complicated one. In general, abscess is detected by observation of the general and local symptoms. The general symptoms are fever and subsequent rigors; the local are "pain, heat, redness, and swelling," followed by softness and fluctuation of the fluid contents. See Pus.

Revised by WILLIAM PEPPER.

Abscis'sa [Lat. *absci'ndere*, p. partic. *abscissus*, cut off, se. *linea*, line]: in geometry, that one of a pair of cartesian co-ordinates which is measured on the fundamental axis. See Co-ORDINATES.

Absenteeism: habitual absence from one's post of duty or the like; specifically habitual absence from the country or district from which one's revenues are received, as owners of large estates who spend their incomes in other countries. This practice is very prevalent among the Irish nobility and gentry, and to it some political economists ascribe the poverty of Ireland in part. "A petition on Irish absenteeism was presented to Parliament as early as 1380, during the reign of Richard II., . . . and in the reign of Henry VIII. the estates of several non-resident landlords were seized." Feb. 17, 1634, the Irish Parliament passed a law fining the nobility of the kingdom of Ireland dwelling within England or elsewhere out of the realm, and from 1715 to 1753 a tax of four shillings on the pound was levied on all profits, fees, pensions, etc., derived from Ireland in cases where the recipients did not reside in Ireland at least six months of the year. See Townsend's *Manual of Dates*.

Absinthe [Fr., wormwood, from Lat. *absin'thium*]: a liqueur much used in France, prepared from alcohol mixed with volatile oil of wormwood, oil of anise, and other ingredients. It has peculiarly intoxicating effects, which are due to the oil of wormwood, the state resulting from its use being very different from the result of alcohol poisoning. Trembling, vertigo, fearful dreams, and epileptiform convulsions are among its severer consequences. Absinthe drinking is one of the most dangerous forms of stimulation yet invented—the more so because its immediate consequences are usually more agreeable than those of alcohol. The best absinthe is made in Switzerland.

Absolute [Lat. *ab*, from + *solu'tus*, loosed]: originally, loosed or freed from all conditions; entirely independent; hence positive, unconditional, unlimited. As a scientific term it is the reverse of relative, as *absolute velocity*. In metaphysics it represents the unconditioned infinite and self-existent. Absolute monarchy is that which is not limited or restricted by constitutional checks.

Absolute Alcohol: See ALCOHOL.

Absolu'tion, CANONICAL: the act of freeing from censure.

Absolution, SACRAMENTAL: the remission of sin which a duly authorized priest in the Roman Catholic Church grants to a penitent rightly disposed. The Lutheran Church (*Augsburg Confession*, arts. xi., xxv.; Luther's *Small Catechism*) retained absolution as the individualization of the general promise of the Gospel declared to the penitent and believing.

Absorokas: See SIOUAN INDIANS.

Absorp'tion [Lat. *ab*, from + *sorbe're*, suck]: the function by which nutritive matter is absorbed into an animal or plant. The active agent in absorption is the living protoplasm of the cells. Root-cells absorb water and solutions; leaf-cells, gases. Cells absorb from one another, and thus cause a movement of the water and other matters in the plant.

CHARLES E. BESSEY.

Absorption, ELECTRIC: a phenomenon occurring when a dielectric, not perfectly homogeneous, is charged and discharged. When, for example, a plate of glass serves as the dielectric of a condenser, it is found that the coatings of the latter after discharge soon begin to show difference of potential again, the charge continuing to rise for an appreciable interval of time, and reaching a value which is a considerable fraction of the original charge. This "residual" charge, as it is called, is due to electric absorption. Clausius, and independently Maxwell, early attributed this phenomenon to non-homogeneity of the insulating medium. It has since been shown (Rowland and Nichols, *Phil. Mag.*, series 5, vol. xi. p. 414) that a homogeneous substance, such as crystallized calcite, when used as a dielectric, develops no residual charge.

E. L. NICHOLS.

Ab'stinance [Lat. *abs*, from + *tene're*, keep]: the act or state of abstaining, as from food, drink, etc. The days of abstinence or fasting noted in the Prayer-Book of the Church of England and in that of the disestablished Church of Ireland under this head are: (1) The forty days of Lent; (2) the Ember days at the four seasons, being the Wednesday, Friday, and Saturday after the first Sunday in Lent, the Feast of Pentecost, Sept. 14, Dec. 13; (3) the three Rogation days, being the Monday, Tuesday, and Wednesday before Holy Thursday, or the Ascension of our Lord; (4) all the Fridays in the year, except Christmas day. In the American Prayer-Book, Ash-Wednesday and Good Friday are specifically noted as "fasts," and the occasions above given are spoken of as "other days of fasting, on which the Church requires such a measure of abstinence as is more especially suited to extraordinary acts and exercises of devotion."

W. S. PERRY.

Abstinence, TOTAL: abstention from the use of intoxicating beverages. Total abstinence was practiced in early ages by the Nazarites and Rechabites, mentioned in Scripture. Some of the Hebrew prophets vigorously inveigh against the prevalence of drunkenness, yet hardly indicate total abstinence as the proper remedy. The *ESSENES* (*q. v.*)—a Jewish sect contemporary with the Messiah—were distinguished for temperance in eating and drinking, eschewing generally the use of flesh and wine. Mohammed peremptorily forbade the use of wine as a beverage by his followers. In the feudal ages, societies designed to shield their members and others from the evils of drunkenness were often formed, but not on the basis of absolute disuse of stimulants. The discovery of alcohol by an Arabian chemist about 1000 A. D. had, through the art of distillation, greatly expanded and intensified the evils of intemperance, especially in Northern Europe, where beer had generally been the most potent stimulant attainable by the masses. The discovery and settlement of America, largely increasing the average rewards of manual labor, especially on this continent, rendered intemperance more common, by increasing the ability of the common people to purchase alcoholic stimulants; and the U. S., especially throughout the half century succeeding its Declaration of Independence, was hardly equaled in the prevalence of intoxication even by the British and Scandinavian kingdoms, and was unapproached by any other nation.

The earliest known organization of a total abstinence society in the U. S. was "The Temperate Society of Milton and Northumberland" (Saratoga co., N. Y.), founded by Dr. Billy J. Clarke in 1808, which at its commencement had forty-three members. Distilled liquors and wines were absolutely prohibited by its rules, but not the moderate use of beer. In 1813 was formed the "Massachusetts Society" for the suppression of intemperance. In 1826 the American Temperance Society was organized. The evils resulting from the free use of ardent spirits were so general and glaring that kindred societies were soon formed in many cities, villages, and rural townships, the movement being strongly aided, especially among zealous Christians, by Dr. Lyman Beecher's *Six Sermons on Intemperance*. Dr. Eliphalet Nott, president of Union College, was also early and honorably distinguished as a pioneer in the temperance cause. It was not till 1833 that, at a national meeting of the friends of temperance, held in Philadelphia, the principle of "total abstinence from all that may intoxicate" was propounded, only to be voted down; but it was again proposed, and adopted, at a national convention held at Saratoga Springs in Aug., 1836, and became henceforth the basis of the temperance movement, to which a great impulse was given by the "Washingtonians" (in good part reformed drunkards), who began their work in 1841, and for a time seemed destined to sweep all before them. The Washingtonian effort gradually spent its strength and faded out, being succeeded by new organizations, whereof the "Sons of Temperance," "Good Templars," "Rechabites," "Good Samaritans," and "Cadets of Temperance" are still active and flourishing.

The total abstinence movement in Great Britain first attracted public attention in 1831. The "pledge" to drink no intoxicating liquors was first adopted by a national gathering at Manchester in 1834. It has never yet become so influential in that as in this country, and its upholders have only ventured to ask of Parliament a "permissive" act—that is, one allowing any locality to forbid and outlaw the liquor traffic by a majority vote—and this has never been conceded.

In Ireland total abstinence was first effectively commended by Father Mathew, who persuaded great numbers of his countrymen to take the pledge. See PROHIBITION.

Revised by C. K. ADAMS.

Abstinent: a Christian sect of Gaul and Spain in the latter part of the third century A. D., who condemned marriage and the use of flesh-meats and wine, declaring that they were made by the devil and not by God.

Abstract of Title: See the Appendix.

Abstraction [Lat. *abstractio*, from *abs*, from, and *trahere*, draw]: the process whereby the mind reaches the abstract notion or conception, that is, one which has reference to a quality or property of an object without further definition of the object itself. For example, color, virtue, government are abstract ideas. They apply equally to a number of cases, and so are opposed to *concrete* ideas, which denote particular objects only. See THOUGHT.

Any abstract or theoretical consideration, which seems to have no immediate application to facts is also an abstraction.

The sciences which deal mainly with symbolic quantities and general formulas, rather than with particular concrete facts, are called *abstract sciences*—notably mathematics, logic, and metaphysics. They use the deductive method, and are often called “deductive” as opposed to the “inductive” or “natural” sciences. See INDUCTION.

Abt, FRANZ: musician; the most popular song composer Germany ever produced; b. in Eilenburg, Prussian Saxony, Dec. 22, 1819. He was at first intended for the Church, but his father dying while Franz was at the University of Leipzig, the support of himself and his widowed mother devolved on him, and he became a teacher, but continued to study music. His first compositions—a set of dances and some songs—were published in Leipzig, in April, 1838, and soon after he was appointed conductor of the Leipzig Philharmonic Society, and he subsequently held similar positions elsewhere. He married in Sept., 1841. His famous song *When the Swallows Homeward Fly* was first published in Stuttgart, and made his fame. He wrote many songs, and was especially successful in writing for male voices. In 1872 he visited the U. S., and conducted many concerts in Boston, New York, Newark, and other cities. He also conducted a performance of Wagner's *Tannhäuser* in New York. He died on Mar. 31, 1885. His published works run up into the thousands. He had a remarkable gift of melody, and almost every singing society in Germany and in the U. S. has sung some of his songs. D. E. HERVEY.

Abu: an Arabic word, signifying father, occurs as a prefix to many Oriental names, as Abû-Bekr, “father of the virgin.” It corresponds to Hebr. *Ab*, as in Abraham, “father of a multitude,” Absalom, “father of peace.”

Abu: a mountain of India, in Rajputana, connected with the Aravali range; about 5,000 feet above the level of the sea. It is a celebrated place of pilgrimage for the Jains, who have four temples at Dilwara, near the middle of the mountain. One of these is said to be the most superb of all the temples of India.

Abubekr', or Aboo-Bekr: a caliph, the first of Mohammed's successors; b. in Arabia about 570 A. D. His original name was Abd-el-Kaaba, which was exchanged for Abu-Bekr (i. e. father of the virgin), because his virgin daughter Ayesha was married to the prophet. He began to reign in 632 A. D., and died in 634, leaving a high reputation as a man and a ruler.

Abukir', or Aboukir: a fort and village of Egypt, on the site of the ancient Canopus, and on the seacoast at the west side of Abukir bay, 15 miles N. E. of Alexandria. In Abukir bay Admiral Nelson gained a decisive victory over the French fleet, Aug. 1, 1798. Here the Turks were defeated by the French under Napoleon I., July 25, 1799, and the French by the British, Mar. 21, 1801.

Abulca'sis, or Abulka'sis (written also **Abul-Kasem**), KHALAF EBN ABBAS: Arab physician and surgical writer; b. near Córdoba, in Spain. His principal work was published in 1778 under the title of *Abulcasis de Chirurgia* (Arab, “Al-tassrif”). The part devoted to surgery is regarded as the most valuable treatise of the kind that has come down to us from early times. D. about 1117.

Abulfa'raj, GREGORIUS: learned historical writer; b. in Armenia in 1226; became maphrian or primate of the eastern division of the Jacobite Christians in 1266. He wrote in Syriac and Arabic several valuable works, among which

is a *History of the Dynasties*. D. in 1286.—There was also a famous Oriental poet, Ali Abulfaraj (897–997).

Ab'ul-Fazl: eminent Oriental historian, who in 1574 became vizier or prime minister of the great Mogul Emperor Akbar. He was a wise and liberal statesman. He was assassinated in 1608. Among his important works are a history of Akbar, called *Akbar Nameh*, and *Institutes of Akbar* (Ayeen Akbari).

Abul'feda: a Moslem prince and author; b. at Damascus about 1273. He fought with distinction for the Sultan of Syria against the Tartars or Mongols, and was rewarded with the title of Prince of Hamah. He wrote an important work entitled *An Abridgment of the History of Mankind*, and another, *The Description of the Countries*, which is regarded as the best Arabic work on geography that is extant. D. in 1331.

Abu'na (our father): a title given to the head or patriarch of the Abyssinian Christians.

Abu Simbel: a place in Nubia, on the west bank of the Nile, 1,014 miles above Cairo and 8 miles above the Second Cataract. It contains two of the best-preserved specimens of the great rock-hewn temples of ancient Egypt; one of which has four sitting colossal statues, which are almost the largest stone figures existing. The sculptures of both temples are of very great value. See IPSAMBUL.

Abu'tilon: a genus of mostly shrubby plants of the mallow family, including about seventy species, which are widely distributed in warm climates. Many are cultivated in green-houses—e. g. *A. insigne*, *A. striatum*, *A. vitifolium*, etc. *A. avicennae*, from India, is a common roadside weed in many parts of the U. S., where it is called velvet-leaf.

C. E. B.

Abutment: the stone structure which receives the horizontal thrust of an arch, or the pier of a bridge built on the shore and connecting it with the street. The mass of masonry to which the cables of a suspension-bridge are anchored is also sometimes called an abutment. See ARCH, BRIDGES, FOUNDATION, and MASONRY. M. M.

Aby'dos: an ancient city of Upper Egypt; on the left bank of the Nile; 5 or 6 miles from the river, and about 100 miles below Thebes. Here are the ruins of a temple of Osiris and a temple of Memnon, in which Mr. Bankes discovered in 1818 the celebrated tablet of Abydos, now in the British Museum. A second tablet of Abydos, containing seventy-six shields, was discovered by Mariette in 1865. Bankes's tablet contained only twenty-six shields.

Aby'dus, or Aby'dos (Gr. Ἀβυδός): an ancient city on the Hellespont opposite Sestos, where Xerxes crossed over to Europe on a bridge of boats, 480 B. C. It was also celebrated for its connection with the story of Hero and Leander.

Ab'yla and Cal'pe: the pillars of Hercules, standing on both sides of the Straits of Gibraltar, Abyla in Africa.

Abyssin'ia (Ar. *Habash*, mixed): an African empire, formerly Ethiopia, now *Abyssinia and Shoa*, by the addition of the large kingdom of Shoa on the S. E. It lies E. of the Nile and nearly opposite the Straits of Bab-el-Mandeb, with Nubia on the N., Eritrea between it and the Red Sea, the Somali and Galla lands on the S., and Nubia on the W. On the S. W. the boundary is ill defined. It is of a long, elliptical form, with its greatest length N. and S., and extends from 7° N. to 17° N., and from lon. 36° to 42° E. It is entirely cut off from the Red Sea by Eritrea, but approaches it within a few miles near Massowah. The area is about 190,000 sq. miles, and the latest estimates of the population place it at 4,500,000. The principal subdivisions are Tigré on the N. and N. E., Amhara and Gojam in the center, Shoa in the S. E. and the smaller dependencies of the Shan-kalla in the W., and Galla and Kaffa lands in the S. and S. W. The Afar or Danakil and the Adal countries on the lowlands adjoining the Red Sea are now parts of Eritrea.

Topography.—In its present form Abyssinia occupies the highlands of Ethiopia which rise abruptly from the lowlands to the E., and consist of extensive table-lands from 6,000 to 10,000 feet above the sea, diversified by mountains and river gorges. The chief range of mountains forms a crescent about the large central Lake Tana, concave toward the E. They are highest in the N., where they reach 15,000 feet, and the higher peaks are always covered with snow. The principal rivers are tributary to the Nile. The Abai or Blue Nile leaves Lake Tana at its S. E. angle, and, first taking a southeasterly course, sweeps around the moun-

tainous province of Gojam, falling into the Nile proper at Khartum. The Atbara, also a branch of the Nile, drains the most of the country to the N. of Tana, while the waters of the S. flow southward into Lake Rudolf, about lat. 5° N. There is little drainage into the Red Sea. Lake Tana (Tzana or Dembea) is divided into nearly equal portions by the parallel 12° N. and the meridian 37° 2' E. It is 5,658 feet above the sea; is nearly circular, and about 40 miles in diameter; has an area of about 3,000 sq. miles, and is in places very deep. The rocks are usually granite, gneiss, or schists, but trap and basalt are common, and fossiliferous rocks of the Jurassic age have been observed. Denudation has gone on extensively, leaving narrow valleys and cañons, which are sometimes 3,000 or 4,000 feet deep. The country is very picturesque, and seems as if broken up and tossed about; the mountains are abrupt and precipitous, the passes few and difficult, and the scenery wild and fantastic.

Climate.—This is generally temperate and salubrious, both because of the great elevation and because the hot season is terminated early by the midsummer rains. The rainfall is light in the N., but increases southward.

Productions.—The vegetation of the table-lands and mountains is that of the temperate zone, with little forest growth; that of the ravines is more tropical. The large tropical animals are not rare at the lower elevations in the S. The spotted hyæna is everywhere so common as to be a pest. Honey forms an important part of the food of the people. The ravages of locusts are often very serious.

The people are essentially pastoral, and tillage is comparatively little practiced. The cattle are small; the sheep are of the fat-tailed kind. Goats are raised in large herds. Horses are common and excellent. Abundant crops of maize, wheat, barley, pease, beans, and tobacco can be raised; coffee, cotton, the sugar-cane, and the date-palm will thrive in many places, as also will the orange, lemon, pomegranate, and banana in lower altitudes. A fine-grained millet called *teff* is used for making bread. Myrrh, balsam, and several valuable medicinal plants are found here.

Inhabitants.—The population is made up of a heterogeneous collection of races—Coptic, Arabian, Jewish, and Negro. The political ascendancy has long belonged to a race which calls itself Ethiopian, and is of Arabian descent. This people speaks a dialect of the old Ethiopic language which is of the Semitic linguistic family. (See AMHARIC.) The Abyssinians were converted to Christianity in the fourth century by Frumentius, who was consecrated bishop by St. Athanasius. They are still members of the Alexandrian Church, and consequently Monophysites. The head of the Church, or *abuna*, is always a Copt, appointed by the Patriarch of Alexandria, but his power is shared by a native dignitary who controls the monastic orders. Jews are common, and date from very early times. They are called Falashas. There are also many Mohammedans and heathens.

The manners of the Abyssinians are rude and warlike, and their civilization is of the early feudal type. The literature is entirely religious. Teaching is restricted to the clergy, and consists in instruction in grammar, choral singing, and the recitation of sacred texts. It is gratuitous, but given to a selected few only, and these form a somewhat influential class of *literati*.

History.—There have been many changes of family in the rulers during the historic period, but until recently they have all belonged to a royal line said to have descended from the Queen of Sheba. During the captivity many Jews settled here, and brought with them a knowledge of the Jewish religion. Under the Ptolemies the Greeks established colonies in Ethiopia, and brought their arts with them. The ancient kingdom of Anxume, of the first and second centuries, was at one time nearly coextensive with modern Abyssinia. At Axum, the site of the ancient capital, many vestiges exist which show its former greatness. Christianity was introduced between 330 and 360 A. D., and about 470 a great company of monks seems to have established itself in the country. In the sixth century Abyssinia conquered Yemen in Arabia, and held it sixty-seven years. This was the greatest period in their history, but it was soon ended by the destructive zeal of the early followers of Mohammed. In 960 the Jewish Princess Judith gained the throne, and it remained in the hands of her descendants until 1268, when it passed again to the old royal line. The Portuguese missions began about the end of the fifteenth century, and were due to the old search for Prester John. Between 1528 and 1540 the country was overrun by Mohammedan armies, and the Portuguese were called on for succor. There followed a period of Jesuit

ascendency, until 1633, when they were expelled. The best-known figure in the history of Abyssinia in recent times is King Theodore. He was b. in 1818, and crowned King of Ethiopia in 1855. He was an able and energetic man, and extended greatly the boundaries of the kingdom. He took the English into his favor, until the disrespect shown a letter which he addressed to the Queen of England caused his feelings to change. This finally resulted in sending a large English force into Abyssinia, the storming and capture of Magdala, and the suicide of Theodore on the 13th April, 1868. His death was followed by a period of anarchy, until Prince Kassai was crowned as Johannes II. in 1872. After his death in 1889, Menelek II., King of Shoa, succeeded in gaining the crown.

In return for the assistance which he had received from Italy, whose colony of Eritrea bounds Abyssinia on the north, Menelek surrendered to Italy the province of Hamasen and concluded a treaty (May 2, 1889) and a convention for "mutual protection," which Italy construed as giving her a protectorate over the country. Menelek having denounced this interpretation friction resulted, and hostilities were begun in the course of which the Italians captured Adowa (*q. v.*) and several important points in the interior, from which, however, they were driven one by one, and on Mar. 1, 1896, met with a crushing defeat near Adowa, in which they lost 10,000 men in killed and wounded (including 5,600 Italians), and 1,550 who were carried off as prisoners. Italy now sued for peace, and on Oct. 26, 1896, a treaty was signed in which the independence of Abyssinia was recognized, and a new boundary between Eritrea and Abyssinia was fixed.

The chief exports are skins, ivory, butter, gums, and mules, forwarded mainly through Massowah. British imports amounted in 1887 to \$70,000; in 1888 to \$16,000; in 1889 to \$6,000. The falling off is due to internal wars and the replacement of British goods by Italian. The Maria Theresa silver dollar piece, an Austrian coin still struck off by the Austrian mint for the African trade exactly as it was in 1780, is the favorite money, but bales of cloth and bags of salt are used for the same purpose. Towns are numerous, but small. The most important, politically and commercially, are: Gondar, capital of Amhara, 5,000; Adua or Adowa, capital of Tigré, 3,000; Aksum or Axum, ancient capital, 5,000; Antalo, former capital of Tigré, 1,000; Ankober, former capital of Shoa, 7,000; Licheh, present capital of Shoa, 3,000; Amba-Mariam, 4,000; Mahdera-Mariam, 4,000; Besso and Sokoto, important trading-centers, each 1,500.

The literature on Abyssinia is extensive. The travels of Bruce, Rohlf, Wilkins, Heuglin, Rüppell, Lefebvre, Harris, Antinori, Stern (about the Jews), and Lejean may be consulted. D'Abbadie's *Memoirs*; Blanford's *Geology and Zoölogy of Abyssinia*; Raffray's *Abyssinie*; Hartmann's *Abyssinien und die uebrigen Gebiete der Ostkueste Afrikas*; Réclus's *Universal Geography*, vol. x.; Massaja's *Mission in Ethiopia* (Italian); d'Abbadie's *Géographie de l'Éthiopie* (1890); and Münzenberger's *Abessinien und seine Bedeutung für unsere Zeit* (1892) may be mentioned. Levasseur has published a study of the area and population of Ethiopia in the *Bulletin of the International Statistical Institute*. Modern Italian geographical literature has much information about this country. Cora has published special maps of Eritrea, etc. (Turin, 1881 to 1890). MARK W. HARRINGTON.

Acacia [Gr. ἀκασία, first mentioned by Dioscorides (c. 100 A. D.); of doubtful origin, possibly connected with ἀκή, point]; a genus of *Leguminosæ*, found in Asia, Africa, America, and Australia, comprising many beautiful trees, among which is *A. arabica*, which produces some of the gum-arabic of commerce, but the most and best is yielded by *A. verec.* (See GUMS.) Catechu is an extract from the wood of *A. catechu* of India and Burma; this and other species are much valued for timber, etc. The species with willow-like foliage, cultivated in conservatories, are nearly all Australian.

Acacia arabica.

Acacians: followers of Acacius, Bishop of Cæsarea, 340–365. The Acacians are generally classed as moderate Arians (*q. v.*), but differed from them in not holding the doctrine that Christ was a created being, and from the Semi-Arians in not holding (as they did) that Christ was of a like substance or essence with the Father. The Acacians simply

held that Christ was *like* the Father. The doctrines of Acacius were condemned at the Council of Sardica, 347, and at the Council of Seleucia, 359.

Acad'emy [Gr. Ἀκαδημία; properly Ἀκαδήμεια; Lat. *academia*; Fr. *académie*]: originally a garden or grove in a suburb of Athens, or the school of philosophy which Plato founded in that place. The name is supposed to have been derived from Academus or Hecademus, a mythical person who, according to Greek tradition, presented the garden to the people of Athens. The modified systems or schools of philosophy which the successors of Plato adopted were designated by the titles of the Middle and the New Academy. Academy in the U. S., as in the United Kingdom, is used to designate a superior school, or institution of learning, intermediate in grade between a college or university and a common school. An "academy" and a "high school" have substantially equivalent courses, but in use "academy" more frequently refers to a private school and "high school" to a public school. An academy is also a school for instruction in a special art or science, as the West Point Military Academy. The word academy is also applied to a society of authors, savants, or artists, founded for the improvement of literature, science, or art. The first institution of which we read at all corresponding to this idea was the Museum, a society of scholars established at Alexandria by Ptolemy Soter in the third century B. C., which concentrated in that city all that was most eminent in science, philosophy, poetry, or criticism. The Jews in different cities, the Constantinopolitan emperors, and the Arabian caliphs founded societies of the same description. Charlemagne, among his various efforts for the propagation of literature, collected an association of learned men, who read and compared the works of antiquity, and gave themselves in their academic intercourse the assumed names of different ancient authors. But this institution was dissolved at the death of Alcuin; nor do we find any memorial of a similar society, except a few among artists, chiefly in France, until after the taking of Constantinople by the Turks, when the Greek scholars driven into Italy held literary meetings, which gradually assumed a more regular form. In 1560 a society called the *Academia Secretorum Naturæ* was founded at Naples in the house of Baptista Porta, but was abolished by a papal interdict. It was, however, succeeded by the *Academia Lyncei* at Rome, of which Galileo was a member, the objects of which, like those of the former, were chiefly connected with the pursuit of natural history. From the beginning of the seventeenth century academies multiplied in Italy. Among the most eminent of those bearing a philosophical character was the *Academy del Cimento* at Florence in that century; and in more recent times the *Academy of Sciences* at Bologna deserves to be mentioned with honor. But Italy has been most prolific in academies of literature and philology, which form by far the greatest number in the catalogue of 550 such institutions which have been enumerated as existing or having existed in that country. A general and somewhat ridiculous fashion prevailed in the seventeenth and eighteenth centuries among literary men of that country of forming themselves into societies for the promotion of literary objects, to which they gave fanciful symbolic names, every member assuming in his own person some analogous appellation. Among the most celebrated was the *Academy* (It. *Accademia*) degli Arcadi at Rome, of which the meetings were held in a meadow, and the members enacted shepherds and shepherdesses. It was founded about 1690, and still subsists, having various affiliated societies in other places. The *Accademia degli Umidi*, one of the oldest of these associations, became afterward the Florentine Academy. The *Accademia degli Intronati* ("of the deafened"), degli Umoristi ("of the humorists"), and others with similar quaint appellations, have acquired celebrity in Italy. Of her philological academies the most illustrious is the *Accademia della Crusca* (i. e. "academy of the bran" *), founded at Florence in 1582, which by its famous dictionary established the Tuscan dialect as the standard of the national language. It is now incorporated with the *Accademia Fiorentina*.

The first institution of this kind in France, the *Académie Française*, was founded in 1635 by Cardinal Richelieu. It was formed for the purpose of refining the French language and style, and, although in its first period it was chiefly remarkable for the adulation which it bestowed on its vain

* In allusion to its office of winnowing or purifying the national language.

though able founder, it became in process of time by far the most celebrated and influential of all European literary societies. It consisted of forty members, and a place among them was eagerly sought after for a long period as one of the highest honors which could be attained by an author. Like that of La Crusca, it published a dictionary of the national language in 1694. The Royal Academy of Sciences was founded by Louis XIV. in 1666, and published 130 volumes of memoirs up to the year 1793, when it was abolished by the Convention. The Academy of Painting and Sculpture and that of Inscriptions and Belles-Lettres were the other two principal academies of Paris. The latter was founded by Colbert in 1663, and remodeled in 1701. At the Revolution all four were abolished, and in 1795, at the suggestion of Condorcet, the National Institute of France was established in their stead. It consisted of four classes, arising out of the four academies of which it was composed. According to its reorganization by Napoleon in 1806, these classes were remodeled, and each of them consisted of a certain number of sections, each furnished with a specified number of acting and corresponding members. The first class, or that of sciences, had 63 members and 100 correspondents; that of languages, 40, and 60 correspondents; that of history and antiquities, 40, and 60 correspondents; that of the arts, 28, and 36 correspondents. The first, third, and fourth each named 8 foreign associates. In 1816 the Institute was again remodeled by Louis XVIII. The four classes again took the name of academies, and became more independent of one another, their joint property being managed by a commission of 8 members, 2 from each, under the superintendence of the Minister of the Interior. The first academy (that of sciences) retained the same number of members; the second and third were reduced to 38 and 37, respectively; the fourth was increased to 40. To the Academy of Inscriptions and Belles-Lettres and that of Sciences was added a class of free academicians, of the number of 10, with no privilege except that of attendance. The Academy of Arts had the right to choose its own number of free members.

Of similar institutions in Germany, the oldest was the *Academia Naturæ Curiosæ*, a scientific association, founded in 1662 in Franconia, afterward taken under imperial protection, when it received the name of the *Academia Cæsaro-Leopoldina*. The Royal Academy of Sciences at Berlin was founded in 1700 by Frederick I. of Prussia; Leibnitz was its first director. Other German academies of sciences are those of Göttingen, established in 1750; the Bavarian Academy at Munich, established in 1759, chiefly for history, and in 1829 divided into three sections; and the Saxon Association of Science, founded in 1846, and divided into two classes. The Imperial Royal Academy of Sciences at Vienna originated in 1846. Turkey established a similar institution in 1851, and Egypt in 1859. The Imperial Academy of Sciences at St. Petersburg was founded by Catherine I., and endowed by Catherine II. with great munificence, but established on the French model. She separated from it the Academy of Arts.

In Great Britain the name academy has been chiefly confined to associations for promoting the arts. The Royal Academy of Arts was founded in 1768, and consists of forty members. It has separate professors of painting, architecture, anatomy, and perspective, and a council of nine is elected annually. The Academy of Ancient Music was founded by private association in 1710; the Royal Academy of Music, under the patronage of George III., but dissolved shortly after. The present Academy of Music was founded in 1822. The principal literary and philosophical societies, answering in character to the branches of the French Institute, are: 1. The Royal Society of London, which is confined to objects of a scientific character. It had its origin as early as 1645, but was established by royal charter in 1662. Its acts have been published under the name of *Philosophical Transactions* from 1665 to the present day. 2. The Antiquarian Society, which was established in 1751, and whose acts are published under the title of *Archæologia*. 3. The Society of Arts, which originated in 1718. 4. That of Literature, which was founded in 1823. Besides these, there are numerous societies which bear the name of the peculiar branch of science to which their exertions are confined. The Royal Society of Edinburgh obtained a charter in 1783, and another with more liberal provisions in 1811.

Among the most valuable published transactions of academies and similar societies, besides those already mentioned,

are those of Colbert's *Académie des Inscriptions et Belles-Lettres* (50 vols. 4to, from 1701 to 1793); those of the Institute being continuations of the memoirs of the former academies of which it was composed; those of the Royal Academy of the Sciences and Belles-Lettres at Berlin—at first in Latin, then in French (from its remodeling in 1744 by Frederick the Great), now in German; the *Acta* of the Imperial Academy of St. Petersburg; the *Commentarii* of the Academy of Bologna; and the *Antichità d'Ercolano*, published by the Herculanean Academy of Naples. The Vetenskapsakademiens Sällskap at Stockholm has published over 100 vols. of its valuable *Transactions*.

The American Academy of Sciences and Arts was founded in 1780 by the Council and House of Representatives of Massachusetts. The National Academy of Sciences of the U. S. (*q. v.*) was incorporated by the Thirty-seventh Congress in 1863. The Academy of Natural Sciences of Philadelphia was founded in 1812. Besides a valuable scientific library it contains one of the best natural history collections in the world, especially rich in birds. The American Academy of Political and Social Science was organized in Philadelphia in 1889. It has a membership of several thousand, holds regular meetings in Philadelphia, and publishes the *Annals of the A. A. P. S. S.*, which contain papers of scientific value in the field covered by the organization.

Revised by C. H. THURBER.

Acadia (Fr. *Acadie*): the French settlements S. of the Gulf of St. Lawrence, dating from 1603, called Nova Scotia. Acadia originally included New Brunswick and a part of Maine. It was the subject of frequent quarrels between the French and English on account of the valuable fisheries near its coast, and was finally ceded to Great Britain in 1713. The inhabitants having refused to take the oath of allegiance to the British king and to bear arms against the French, the governor and his council resolved to remove them to the other British provinces. The French settlers, 8,000 in number, were forced to give up their property, and in 1755 about 2,000 were sent off in such haste that many families were separated. This event has furnished the subject of *Evangeline*, one of Longfellow's most admired poems.

Acajut'la: a town and seaport in the Central American republic of Salvador; situated on the Pacific Ocean, 12 miles S. of Sonsonate (see map of Central America, ref. 5-E). It consists, besides the custom-house and the dwelling of the captain of the port, of a large warehouse, almost entirely in ruins at present, and a few huts and sheds. Under the Spanish rule it was for a long time the only port on the west coast between Acapulco and Realejo; at present it is second in importance in Salvador, and has over one-third of the foreign trade of this republic. The chief article of export here is Peruvian balsam, of which 20,000 lb. are annually exported.

Acaleph'æ, or **Acalephs** [Gr. ἀκαλήφη, a nettle]: a group of the *Cœlenterata*, equivalent to the sub-class *Scyphomeduse*; containing the marine animals commonly known as jellyfishes or sea-nettles. They are umbrella-shaped animals with radiate structure, and are composed of soft, transparent, gelatinous material, containing only a very small proportion of solid matter. On bright days they are found in great numbers floating near the surface along nearly all shores, propelling themselves slowly through the water by contractions of their umbrellas. Suspended from the center of the disk is the peduncle or manubrium, the lower margin of which is commonly produced into four large arms, which serve pre-eminently for the capture of food. These are often lobed and fringed, and produced into long, trailing streamers. The mouth is typically at the end of the manubrium, and communicates by an œsophagus with the stomach, placed centrally near the lower surface of the disk. Prolongations of the stomach, often forming a fine network of tubes, extend outward to the margin of the umbrella, to which they carry nourishment. The gastric cavity contains contractile tentacles, which secrete a digestive fluid. In common with the oral arms and other tentacles of the body, these are richly provided with stinging or nettle cells, which enable these animals, in spite of their soft, delicate texture, to capture living prey. A nettle-cell consists of a small capsule filled with a poisonous or irritating fluid, and contains a spirally coiled filament provided with retrorse barbs. On touching a foreign body the filaments are forcibly ejected, and pierce the outer tissues of the prey, carrying with them some of the fluid contents of the capsule. The margin of the disk is divided into a number of lobes, in the

recesses between which are the marginal sense bodies, the *rhopalia*. Each of these consists of a shortened modified tentacle, covered over by a lobe of the disk, and has developed in connection with it the organs of special sense. Eye specks, auditory sacs, and olfactory grooves have been described. At the base of the marginal bodies are nerve-ganglia, representing the central nervous system. These are connected, on the one hand, with the sense organs; on the other, with a network of nerve-fibers which ramify over the sheet of muscular tissue covering the lower surface of the umbrella. The four genital glands occupy special cavities in the umbrella near the base of the manubrium. Their contents can usually be detected by their brighter coloration. The sexes are usually separate. The development is complicated through the alternation of sexual with asexual forms. (See ALTERNATION OF GENERATIONS.) The egg develops into a small ciliated larva, which, after swimming about freely for a time, attaches itself by one end and assumes a polyp-like form. It is then known as the *Scyphistoma*. This reproduces asexually by a process of repeated transverse division, giving rise to a series of saucer-shaped individuals, which remain connected to form a cone attached by its smaller end, and called the *Strobila*. The individuals thus formed separate later, become free swimming, and assume gradually the characters of the sexually mature jellyfish. In exceptional cases only is the development direct from the egg to the mature jellyfish. The acalephs are all more or less phosphorescent. The term acaleph has been variously used by different zoölogists, sometimes in a wider or narrower sense, and has now been generally abandoned as the scientific name of any group of animals. See SCYPHOZOA.

An aculeph.

CHAS. H. GILBERT.

Acantha'ceæ: the ACANTHUS FAMILY (*q. v.*).

Acanthas'pis [Gr. ἄκανθα, thorn + ἄσπις, shield]: a genus of buckler-headed fishes found fossil in the corniferous limestone of Ohio. It somewhat resembles *Cephalaspis*, the buckler or carapace bearing similar denticulated spines, but the plates on the head are covered with a peculiar vermicular ornamentation, and are not soldered together.

Acan'thophis [Gr. ἄκανθα, thorn + ὄφης, a serpent]: a genus of venomous serpents allied to the viper, found in Australia. They have a horny spine at the end of the tail. The genus includes the dreaded death-adder, *Acanthophis antarctica*, one of the most venomous of known reptiles.

Acanthopteryg'ians, or **Acanthopterygii** [Gr. ἄκανθα, thorn + πτέρων, wing]: the order of spiny-rayed bony fishes in the system of Cuvier. This order includes those fishes in which the anterior rays of the dorsal and anal fins are normally formed by bony spines. There is usually a spine in each ventral fin. The perch, bass, mackerel, etc., are examples. This is the largest order of fishes, comprising in general the most specialized forms.

Acanthur'idæ [literally the thorn-tailed family; from Gr. ἄκανθα, thorn + οὐρά, tail]: the lancet-fishes or surgeon-fishes; a family of spiny-rayed fishes abounding in the tropical seas, and especially noted for the presence of a spine on each side of the tail at the base of the fin. In the typical species this spine is very sharp, movable, and shuts forward into a groove when not in use. It is sharp as a knife, and has suggested for these fishes various names, recalling a surgeon's lancet. See TEUTHIDIDÆ.

Acan'thus (Gr. *ἄκανθος*): a genus of herbaceous plants, natives of Southern Europe, belonging to the family *Acanthaceae*. The most remarkable species of this genus are the *Acanthus mollis* and the *Acanthus spinosus*, which have large white flowers and shining leaves of a beautiful form. The leafage of the Corinthian and Com-

Natural form of the leaf.

Leaves artistically modified.

posite Orders (*q. v.*), and of a great deal of Byzantine and other mediæval architecture, is generally considered a study of the acanthus.

Acanthus Family (*Acanthaceae*): mostly herbaceous flowering plants, with gamopetalous corollas and superior compound ovaries. They are related to the bignonias, bladderworts, figworts, etc. There are 1,350 species, mostly in warm climates.

A Cappella, in music, in chapel (or church) style. This is frequently understood by modern musicians as signifying a vocal composition *without accompaniment*, as the early church compositions were unaccompanied. When accompaniment is employed with a *cappella* pieces, the word denotes that the instruments are simply to play in unison with the voices, not a separate part of their own. The phrase is Italian, and is sometimes written *alla cappella*. DUDLEY BUCK.

Acapul'co: a seaport-town of Mexico; on the Pacific Ocean, and in the state of Guerrero, 190 miles S. S. W. of Mexico; lat. 16° 50' N., lon. 99° 53' W. (see map of Mexico, ref. 9-G). The harbor is nearly landlocked, and is one of the best in the world. The climate is hot and unhealthful. It formerly commanded the whole trade between the Spanish dominions in America and those in the East Indies. Since the discovery of the California gold mines it has again become one of the most important ports of Mexico. The harbor is so deep that large ships can anchor close to the granite rocks. The steamers which ply between Panama and San Francisco touch here regularly. The greater part of the town was destroyed by an earthquake in 1852. Pop. about 3,000.

Acari'na: the mites, an order of small insects belonging to the class *Arachnida*, and containing the mites, ticks, etc. Some of them feed on animal, others on vegetable substances, and many of the latter are very injurious to vegetation. Some of them are free and lead a wandering life, while others are parasitic, living on other animals. Those of the former class have their mouths furnished with distinct mandibles, and are often found in great numbers in old cheese, brown sugar, and dried fruit, and in the cabinets of entomologists. One of the most destructive of these is the *Acarus destructor*. Those of the latter class possess a sucker, by which they adhere to the skins of animals, where they are supplied with nourishment. A few species of the *Acaridae* are aquatic, and have their legs furnished with hairs, by means of which they swim with facility. The *Acaridae* are propagated by eggs, and are extremely prolific. When mature they have eight legs, the young or imperfectly developed animals having only six.

Revised by DAVID S. JORDAN.

Acarna'nia: a district of ancient Greece; bounded N. by the Ambracian Gulf, E. by the river Achelous, and S. and W. by the Ionian Sea. According to tradition, it was named from Acarnan, the son of Alemæon. It is mostly occupied by well-wooded hills or mountains. Acarnania and Ætolia constitute a nomarchy or province of modern Greece, with an area of 3,013 sq. miles. Pop. (1889) 162,020.

Ac'arus [a modern latinization of Gr. *ἄκαρι*, mite; *ἀ-*, not + *καίρω*, cut]: a genus of minute animals, including the common mite found in figs and other dry provisions (the *Acarus domesticus*), and many other species. (See ACARINA.) The itch is caused by a small mite which burrows into the skin (the *Sarcoptes scabiei*).

Accad (or *Akkad*): according to the Old Testament, the name of one of the four cities which formed the beginning of the kingdom of Niurod, in the land of Shinar (Gen. x. 10). The cuneiform literature of the Mesopotamian valley is the source of all further information regarding it. From this source we learn that Accad was the royal residence of Sargon I., the oldest King of Babylonia yet known to history. According to Nabonidus, the last Semitic King of Babylon (555-537 B. C.), Sargon ruled 3,250 years before his time—i. e. about 3800 B. C. The literary character of this ancient king gave to the city its great fame. Its chief deity was the goddess Anunit or Ishtar, to whom an old Babylonian king, Sagaraktijash, built the principal temple within its walls. It is mentioned all the way down through Babylonian history, even as late as the time of Cyrus, under the name *Agade*. Its present site has been a matter of much conjecture, but was apparently identified by the Wolfe expedition to Babylonia in 1884-85 (*Report*, pp. 24, 25) in the mound *Anbar*, on the Euphrates, almost due W. of Bagdad and N. W. of the ruins of Babylonia.

Accad also designated a particular section of the country of Babylonia. The oldest kings of Babylonia, and the kings of Assyria who conquered and ruled this territory, almost uniformly attached to their names "King of Sumer and Accad" or "King of the land of Sumer and of Accad." These two names were the venerated ancestral designations of the territory which was later termed "Babylonia."

Sumer indicated lower Babylonia, stretching from its extreme southern limits as far N. at least as Mugheir, the ancient Ur of the Chaldees. Accad was the name of upper Babylonia, reaching from its northern boundary near the lower Zab river southward as far as and including at least Erech (Warka). It probably derived its name from its chief city, Accad, and included within its territory the four great cities of Gen. x. 10. At present there are no data for determining its exact southern boundary, the boundary line between Accad and Sumer. Upon these two names are built the designations Accadian and Sumerian, which are applied by some scholars to hypothetical dialects discovered in the original (Semitic) language of Babylonia. IRA M. PRICE.

Ac'ca Lauren'tia: a woman to whose grave the ancient Romans brought sacrifices on the occasion of a festival, on the tenth day before the calends of January. According to a Roman legend, she married the rich Tarrutius, and upon her death left her whole property to the Roman people; while, according to another legend, she was the nurse and foster-mother of Romulus and Remus.

Accelerando: in music, with gradually increasing velocity of movement.

Accelera'tion [Lat. *accelera'tio*; *ad*, to, more + *celera're*, hasten]: the rate of change of the velocity of a moving-body, such as takes place when the body is falling under the influence of gravity. It is measured by the increment of the velocity in a unit of time.

Acceleration of gravity is the amount of acceleration which is produced by the action of gravity on a body falling in a vacuum. It is independent of the nature or chemical constitution of the body. It is approximately 32 feet per second; that is to say, if a body be allowed to drop from a state of rest in a vacuum for the period of exactly one second, it will, at the end of the second, be falling with a velocity of 32 feet per second. The acceleration, however, increases from the equator toward the poles. At the sea-level it is expressed in meters by the formula

$$g = 9.80606 - 0.02503 \cos 2\phi,$$

ϕ being the latitude of the place. See FALLING BODIES.

Acceleration of the Moon's Mean Motion.—It is found, by the comparison of ancient eclipses with modern observations, that the moon now moves around the earth somewhat faster than it did two thousand years ago. This acceleration was found by Laplace to arise from the secular diminution of the eccentricity of the earth's orbit. Its amount is such that at the end of a century the moon is about eight seconds farther advanced in her orbit than she would have been had she continued with the uniform motion which she had at the beginning of the century. S. N.

Accelerator: (1) in anatomy, a certain muscle that expedites the discharge of urine. (2) In photography, anything, as a chemical substance, used to shorten the necessary time of exposure of a sensitized plate or paper; also, any chemical added to the developing fluid to hasten its action. (3) A cannon, often called accelerating-gun, having supplementary powder-chambers the charges of which are intended

to explode in succession after the firing of the main charge, to accelerate the velocity of the projectile.

Ac'cent: The Latin *accen'tus* (*ad*, to + *can'ere*, sing) from which this is derived is merely a translation, like most other Latin grammatical terms, of the Greek term *προσφῶδια* (*πρός*, *ἀεῖδω*), which was used by the Greek grammarians to include all the written signs added to the letters to guide pronunciation—thus the marks of long and short quantity, the rough and smooth breathings, the apostrophe, hyphen, and hypodiatole, as well as the three accents proper. The modern use of the term includes a variety of distinct meanings: (a) The accent marks for acute (´), grave (`), circumflex (ˆ), as used, e. g., in Greek and French. In the former they denoted a variety of musical pitch accompanied, as can now be proved, by a distinction also of stress; in the latter they indicate only a variety of vowel quality, and that now often only of historical value. Sometimes these marks have a merely diacritical value, as in English *learn'ed*. (b) A peculiar coloring of the pronunciation in the dialect of an individual or locality; brogue. (c) The increased stress of voice upon certain syllables either of words in ordinary pronunciation, or of a verse in metrical rendering, or of the measures in music.

The word-accent is that element of enunciation which gives individuality to the separate word. When a word loses its individuality and merges itself under the accent of another word we call it an enclitic or proclitic; thus in English *don't*, Greek *λόγος τις*. The Greek word-accent reflects in its general outlines the "free" accent of the parent Indo-European speech, and though it is restricted to the last three syllables of the word, as in Latin, it may in different words fall upon any one of these, as in the nouns *κίνδυνος*, *ἐχίνος*, *παρθένος*, *ἐκυρός*. The essential antiquity of these variations is guaranteed, however, by the many striking correspondences with the Sanskrit accent; thus, *πούς*, *ποδός*, *πόδα*: *pād*, *padás*, *pádam*; *πέντε*, *πάντα*; *ἀστὴ*, *ἀστῆ*; *ἐγών*, *ἀνάμ*; *γένος*, *γένος*; *βατός*, *γατά-s*; *δώδεκα*, *δωδεκά*, etc. This word-accent persists in modern Greek as a peculiarly strong stress accent in general upon the same syllable where it was written in ancient Greek. In the Romance languages the stress is generally upon the syllable which had it in the parent Latin, though in French the distribution of the stress throughout whole breath-groups of words and complication with the musical or pitch accent often make it very difficult to locate the stress. The pro-ethnic Germanic speech developed the special law of accenting the initial syllable, except in compound verbs, where the prefix was unaccented. Traces of this exception survive in the vocalism as well as accent in modern German; cf. *ur'theil*, *erthei'len*, *an'wort*, *entsprech'en*. Loan-words often show a foreign accent; thus, *Offizier'*, *Saison'*, *Concert'*, *Quatitäl'*; so loan-elements, *studier'en*, *Druckerei'*. The English accent, while tending to confirm the Germanic rule, still shows in its variety, and sometimes also in its uncertainty, how imperfectly the language has as yet assimilated the diverse materials it has employed. Thus French accents survive in *cavalier'*, *engineer'*, *devotee'*, *battoon'*, *violin'*, *gazette'*, *picturesque'*, *distress'*, *affair'*, *complete'*, *excess'*, etc. Early English writers used also *prison'*, *forest'*, *tabour'*, *battaite'*, *tangage'*, etc. Other Romance accentuations survive in *sona'ta*, *mula'tto*, *tobac'co*, *volca'no*, etc. Latin accentuation persists in *diplo'ma*, *diagno'sis*, *dicta'tor*, *specta'tor*, *lyce'um*, *Septem'ber*, etc. The accent often serves to distinguish words: *tor'ment* (noun), *tor'ment* (verb); cf. *minute*, *frequent*, *compact*, *expert*. Derivatives are often influenced by their primitives; as, *agree'able* (*agree'*), *divi'ner* (*divine'*), *withdraw'al* (*with-draw'*), *reli'able* (*rely'*), etc.

BENJ. IDE WHEELER.

Accent: in music, a stress or emphasis given to certain notes or parts of a bar in a composition. It is analogous to the accent upon certain syllables of words in pronunciation or the reading of verse. It is divided into two kinds—grammatical, and æsthetic or oratorical. The first kind of accent is nearly always regular in its occurrence, falling upon the first note of the bar. When this is not the case, it should be clearly indicated. Long measures of time have in addition a secondary accent, just as in the case of a long word. As a general rule, the grammatical accent should not be unduly emphasized, but marked only so as to harmonize with the rhythm. The æsthetic accent is irregular, and, as the name implies, depends upon taste and feeling, just as do the accent and emphasis made use of by the orator. In vocal music, it should correspond with the accented syllables of words.

Accen'tor [Lat. the warbler]: a genus of warblers, including the hedge-warbler (*Accentor modularis*), a familiar

Accentor.

and abundant European bird, brown above, steel colored beneath. Its song is fine, but short. The *Accentor alpinus* of the Alps is a larger bird.

Accentua'tion: in ecclesiastical music, the pitch and modulation of the voice. A threefold division is usual—(1) simple, (2) moderate, or (3) strong. Some writers in applying the term to chanting reckon seven forms of modulation in the portions of the service sung by the officiating priest and his assistants, viz.: the *immutable*, *medium*, *grave*, *acute*, *moderate*, *interrogative*, *final*.

Accep'tance: an engagement to pay a bill of exchange at maturity, or the bill itself after it has been "accepted," by writing the word "accepted" across its face, with the date on which it is payable and the name of the acceptor. See BILL OF EXCHANGE.

Accep'tants, or **Constitu'tionists**: a name given in 1713 to the Jesuits in France who accepted the constitution or bull Unigenitus issued by Pope Clement XI. The Jansenists, who rejected the pope's bull, were called Appellants or Recusants, and appealed to a general council. They were imprisoned and persecuted, but after the death of Louis XIV., the Regent, the Duke of Orleans, prevailed on the greater part of the recusant bishops to accept the bull, with certain modifications. The Appellants continued their resistance after the Unigenitus became national law (1730).

Ac'cessary or **Ac'cessory** [Late Lat. *accessor'ius*, adj. The form in *-ory* is properly adjec., that in *-ary* subst., the latter being formed after the type of nouns like *adversary*, *emissary*, Lat. *-arius*]: in criminal law a participant in a felony who is not the chief actor, and is not present at its commission, but yet in some way is connected with it, either before or after the fact (or act committed). An accessory before the fact is one who, though not present, procures, counsels, or commands another to commit it. An accessory after the fact is one who, knowing a felony to have been committed, receives, relieves, comforts, or assists the felon.

In offenses below the grade of felony there are no accessories. All implicated are regarded as principals. By the common law of England the same rule is applied to the case of treason. In manslaughter, as defined by common law, there can be no accessory before the fact.

Acces'sion [Lat. *accessio*, a going to; *ad*, to + *ce'dere*, go]: in law, a species of title to property borrowed from the civil (or Roman) law, and defined to be the right to all which one's own property produces, whether that property be movable or immovable, and the right to that which is united to it by accession, either naturally or artificially. By this principle the increase of an animal belongs to its owner, or a building becomes the property of the man on whose soil it is erected. An important instance of the application of this doctrine is found in the manufacture by one person of materials belonging to another. The property in its manufactured state belongs, in general, to the owner of the materials. A leading exception to the principle is that if the manufacturer, acting in good faith, without the consent of the

owner, changes the identity of the materials, as if he converts grapes into wine, or grain into whisky, he will become the owner of the manufactured article. This rule would not be applied in favor of a willful wrongdoer. The word "accession" is also used to indicate the fact of succession in government, such as the "accession" of a new dynasty in monarchies, as in the case of the House of Hanover in England.

T. W. DWIGHT.

Accessory, or Accessary: in painting, anything introduced into a picture that is not an essential part. In an historical painting the human or animated figures are the principal objects, and all the others are accessories.

Ac'cidens, or Per Accidens (i. e. by accident): a Latin phrase used by the older philosophers to denote an effect not following from the nature or essence of the thing, but from some accidental quality. It is opposed to *per se*: thus, fire burns *per se*; heated iron burns *per accidens*.

Ac'cident [Lat. *accidens*, happening; ad. to + *ca'dere*, fall]: in logic, one of the predicables; in its strictest logical sense it is that which may be absent from or present in the subject, the essence of the species to which the subject belongs remaining the same. Thus if it be predicated of a man that he is "walking," or that he is "a native of Paris," the first expresses what is termed a separable accident, the latter an inseparable; i. e. the individual may cease to walk, but can not cease to be a native of Paris, but neither of these alters the species, man, to which the individual belongs. It is to be observed with regard to the accident, as well as the other predicables, that they exist only relatively to each other, so that the same quality may be accidental when predicated of the species which is a property when predicated of the individual. Thus "malleability" is an accident of the subject "metal," because many metals are not malleable. But it is one of the properties of gold and iron, etc., as distinguishing these from the non-malleable metals.

Accident: in equity jurisprudence, such an unforeseen event, misfortune, loss, act, or omission as is not the result of any negligence or misconduct in a party. It is, however, difficult to bring all the cases in which the court assumes jurisdiction within the bounds of a definition. Some of the leading cases of interference by the court are—1. Where negotiable or other instruments have been lost, and there is no adequate remedy in a court of law. 2. Where a clause has been inadvertently omitted from or inserted in an instrument. The court in such a case makes the instrument conform to the intent of the parties. 3. Penalties and forfeitures. In this class of cases the court relieves against the penalty or forfeiture where the injury occasioned by the breach of duty is susceptible of complete compensation, as in the case of an omission to pay rent on an appointed day. There would be no relief in case of a willful wrong, nor where the forfeiture is in the nature of a statutory remedy for a breach of duty. 4. Cases of omission, through inadvertence or want of knowledge of facts, to defend an action. The court has power to allow the necessary steps still to be taken. It is a general rule that the court will not interfere in favor of a mere volunteer, such as a donee or devisee in a will. Thus if a seal were accidentally omitted from a conveyance made without consideration, or a clause were omitted from a will, there would be no relief. It is a further rule that relief will not be granted as against a purchaser who has acquired legal rights in good faith and for a valuable consideration. Revised by HENRY WADE ROGERS.

Accidental Colors: See COLORS, ACCIDENTAL.

Accident-Insurance: that form of insurance that provides indemnity for bodily injuries effected through external, violent, and accidental means, the amount payable being determined by the results of injuries, death, disability, or dismemberment.

Insurance against accident seeks to provide indemnity not for any injury occasioned by an accident, but simply and solely for loss of time or productive power resulting wholly from external, violent, and accidental means. Bodily injuries, broken bones, falls, and bruises are insured against only as they cause disability to carry on the usual business of the insured, or as they occasion loss of limb, sight, or life, thereby reducing or entirely destroying productive capacity. Life-insurance is based on a certainty; accident-insurance on a mathematical possibility. The former is inclusive insurance, the latter supplementary.

Statistics of accidents furnish a basis for insurance against accidents as mathematically certain as the table of mortality

for life insurance. Of 100,000 people, whose exposure to accident is substantially the same, a certain number will be killed, a certain number will break their limbs, and a certain number lose the sight of an eye, etc.

EARLY HISTORY.—Mention is made of the practice of ship-owners insuring the lives of their masters against the perils of the sea in the ancient sea-laws of Wisby, as early as 1541. In 1665 the Dutch Republic, then at war with England, issued a proclamation announcing the amount of recompense that would be awarded to soldiers wounded in the service of the country, and establishing a fixed value for loss of limbs, feet, hands, or eyes. It promised for loss of both eyes, 1,500 livres; both arms, 1,500 livres; right arm, 450 livres; both hands, 1,200 livres, etc.

Accident-insurance proper is of very recent origin, dating practically from 1848, when *The Railway Passengers Assurance Company* in Great Britain was organized, and actually began the business of furnishing insurance against railway accidents. The credit of inaugurating the modern system of accident-insurance in its widest scope, however, must be given to Edward Riley, Actuary of *The Accidental Death Insurance Company*, which, in 1850, issued the first policy providing "compensation for bodily injuries occurring to any person or persons from any accidental or violent cause or causes not occasioning death."

In the next six years several new companies were organized, some to afford general accident insurance on the same lines as *The Accidental Death Insurance Company*, others to insure only special classes or against special hazards. Among these companies wide variations existed as to classification of risks and rates: for though the fact that individuals of various occupations are exposed to varying hazards had been recognized by all, and an attempt had been made to fix the rates for each class, yet the statistics necessary for classifying risks in determining rates were not in existence, and it was only in 1857 that a careful classification was made, based upon a large number of risks of several years' experience, and such restrictions and safeguards as experience had shown to be necessary were added to the policy.

IN THE UNITED STATES.—The first company to successfully undertake accident insurance in the United States, *The Travelers Insurance Company*, of Hartford, was organized in 1863 by James G. Batterson, who had made a careful study of the business as conducted in Great Britain. He found it necessary, however, to formulate a classification of risks differing in many respects from the English classification on account of the different industrial and transportation conditions in the United States. The rates and the form of policy were essentially the same as those in use in England, and provided for \$5,000 in case of accidental death, and \$25 a week up to twenty-six weeks during disability from accident.

The project was treated with ridicule at first, but a series of great railroad disasters during 1864 and 1865 brought it prominently to the public notice. A host of small companies soon entered the field, but all ultimately either retired from business or were absorbed by *The Travelers*.

PRESENT FORM OF ACCIDENT POLICY.—The common form of accident policy, both in the United States and Great Britain gives \$1,000 for death, loss of hand and foot, or both hands, or both feet, or total loss of sight; \$500 for loss of either leg at or above the knee, or right hand; \$200 for loss of one foot or left hand, etc. The amounts vary in detail in the different companies. A weekly indemnity of \$5 is paid for total disability, limited to 200 weeks, and \$2 per week for partial disability, whereby the insured is rendered incapable of performing one or more important duties of his trade or profession. As a protection against the possibility of fraudulent claims, the weekly indemnity is generally limited to a sum not to exceed the weekly earnings of the insured.

The cost of such a policy in non-hazardous occupations varies from \$4 to \$5 for each principal sum of \$1,000. There are many variations in use, such as policies paying double benefits for accidents of travel, paying for death or indemnity only, insuring against accidents of travel only, etc.

CLASSES OF RISK.—Professional and business men, whose occupations expose them to very little hazard, are classed as Select or Preferred, and are insured at the lowest rates. Of this class each year one in every fifteen meet with such injuries as to entitle them to indemnity.

Men who are exposed to an additional risk incident to their occupation, not particularly hazardous, are divided

into ordinary or medium classes, paying 50 to 100 per cent. more for their insurance than the preferred class. In these two classes the ratio of injured is about one in eight or ten. Other occupations are further grouped in classes, hazardous, extra hazardous, special, etc., according to hazard of occupation. The ratio of injured in these classes is very large, the average of all classes being one in seven. In determining the class to which those engaged in a given occupation should be assigned, it is necessary to consider not only liability to accident, but also how far a trifling accident is likely to disable. A slight cut or bruise of the forefinger would not incapacitate a salesman from attending to his duties, but might prevent a watchmaker from pursuing his ordinary occupation. Again, a sprained ankle or a sore foot might totally disable a machinist, but would only partially disable a man of sedentary occupation. Policies have been greatly liberalized since the early years of the business: benefits have been largely increased and extended; rates have been lowered; restrictions largely removed; and partial disability and change of occupation provided for.

TWO CLASSES OF COMPANIES.—In the United States accident insurance is carried on by two classes of companies: stock companies, and assessment companies. The former include a number of large and powerful corporations, many of which also conduct other branches of insurance—life, health, employers' liability, or surety. The assessment associations have been as a rule successful only as they confine themselves to insuring a certain class or occupation.

STATISTICS OF BUSINESS.—Owing to different systems of computing in the various companies and associations, it is impossible to arrive at the exact figures of the business at the close of a year. The amount of insurance in force December 31, 1900, was approximately \$2,420,000,000, and the amount paid out in benefits about \$4,600,000, distributed among some 16 stock companies and 45 mutual assessment companies, the former doing a little over 70 per cent. of the business.

In Great Britain the business is carried on by 47 companies and associations, exclusive of a large number of small local associations. The large stock companies carry on accident insurance as one of a number of branches of the business. In France there are 14 companies; in Germany, where a system of compulsory social insurance is now in force, 26 companies; Austria, 9; Norway and Sweden, 8; Russia, 6; Switzerland, 5; Belgium and Holland, 7; Balkan States, 3.
GEO. W. ELLIS, Editor *Traveler's Record*.

Accidents (that is, *casualties*): See **Block System**, for accidents to railway trains; **Bridges**, for failures of bridge structures; and **Reservoirs**, for disasters caused by the breaking of embankments.

Accipitres, ak-sip'i-treez [plur. of Lat. *accipiter*, a hawk; of doubtful etymology, but probably compounded of **āci-*, swift (cf. Gr. *ἄκίς*) + *pet-*, fly (cf. *praepes*, *-petis*, of swift flight, Gr. *πέτομαι*, fly)]: the name given by Linnaeus to an order of carnivorous birds, including the eagle, vulture,

hawk, and owl. More recent ornithologists have named this order *Raptores*. This order comprises all the true birds of prey. As may be seen in the accompanying illustrations, the beaks and claws of the *Accipitres* are marvelously adapted, by their sharpness and curvature, to the predatory habits of these birds. See **RAPTORES**.

Ac'cius, Lu'cius (sometimes called *Attius*): the most distinguished Latin tragic poet; son of a freedman; b. at Pisaurum 170, and lived to an advanced age, perhaps

as late as 86 B. C. Cicero, his great admirer, alone refers to seventeen plays, and about fifty titles of tragedies and 700 verses are known to us. Most famous were the *Atreus*, *Epigoni*, *Epinausimache*, and *Philocteta*. He wrote also two *Prætextæ*—i. e. tragedies based upon Roman history. His *Didascalica* treated in verse of Greek and Roman poetry, and especially of the drama. He wrote on agriculture a work entitled *Praxidica*, and *Annales* in epic measure. Accius was also a grammarian, and proposed several orthographical reforms. See O. Ribbeck, *Tragicorum Romanorum Fragmenta* (Leipzig, 1871), pp. 136-227 and 281-285.
M. WARREN.

Acclamation [Lat. *acclamatio*, a shouting at; *ad*, to or at + *clama're*, shout]: a shout or some similar demonstration of approval, or the like; especially a spontaneous outburst of approbation or applause in a public or deliberative assembly. A motion or proposition is adopted by acclamation when the assent is so nearly unanimous that the counting of votes is omitted. The different modes of electing a pope are called scrutiny, acclamation, and inspiration.

Acclimatiza'tion: the process of becoming inured to a climate at first injurious. In general, the term is synonymous with acclimation, but some writers restrict the application of the latter term to man, and others use it to distinguish the spontaneous process of adaptation to climate, and use acclimatization to denote the act of man in aiding the process by transferring and selecting the species and varieties. In scientific discussions the word acclimatization is now preferred. The most diverse opinions are held in regard to acclimatization, some even denying its existence. This confusion arises from a misconception of the meaning of the term. A plant or animal becomes acclimatized only when it has overcome some injurious feature of climate. Many organisms possess a sufficient elasticity of constitution to allow them to become quickly cosmopolitan as soon as competition with other species is removed and they find means of becoming disseminated. Such plants or animals simply become *naturalized* when transferred to a foreign country, as is the case with most if not all of the weeds which have invaded our fields from Europe. Some plants and animals have been disseminated in many diverse climates because of the protection afforded by man, who, by skillful planting and cultivating, or by shelter, overcomes in great measure the adverse influences of climate. Such beings are simply *domesticated*. From these remarks it will be seen that it is difficult to determine in any case whether an organism has actually overcome any influence of climate; and the difficulty is particularly great in the case of animals—especially of man—because they possess to some extent the power of protecting themselves from inclemencies, or of migrating to avoid them. In the case of man, the commonest instances cited of acclimatization are those in which immunity from fevers or other diseases comes to be enjoyed; but disease is not an attribute of climate. Another misconception which has confused the discussion of acclimatization is the common notion that the adaptation relates simply to relative temperature; but adaptation to humidity, progression of seasons, cloudiness, and other phenomena are equally the subjects of our inquiry.

The definition is equally satisfied whether the adaptation takes place in the modification of the constitution of an individual animal or plant, or whether it is expressed in a variation of habit in the offspring. The discussion is clarified if it is divided as follows:

- I. Acclimatization through a change in the individual plant or animal.
 - A. Through modification of constitution.
 - B. Through modification of habit.
- II. Acclimatization through variation in offspring.
 - C. Through variation in constitution.
 - D. Through variation in habit.

It is difficult in any case to determine if acclimatization occurs in an individual plant or animal which is transferred to a new climate, especially through a modification of constitution (A). There is no doubt, however, that modification of habit (B), by which the individual evades some injurious feature of climate, sometimes occurs. This is best seen in plants, in which leafing and flowering occur relatively earlier in the season as the individual is moved northward. By this means the plant accomplishes its growth before overtaken by frost. But it is through variation in offspring that acclimatization is unequivocal. Most of the tender fruit-trees illustrate acclimatal variation in constitution (C).

Thus it is well known that the peach-tree endures lower temperature in New York than in Delaware and Maryland; and this illustration can be applied to many plants. Most plants and animals exhibit, under necessity, an acclimatal variation in habit (D) in the offspring. Indian corn may be taken as an example, although this plant is often cited in proof of the assertion that acclimatization does not exist. In certain tropical or sub-tropical regions the season of growth of Indian corn extends through six months. As it is taken toward the poles, its season shortens in accommodation to the climate, until in some parts of Canada it matures in less than three months. This shortening of season—or earliness—is associated with other variations, as smallness of stature, a tendency to sucker, and the change from dent corn to flint. In general, it may be said that acclimatization is only one of the expressions of variation induced in all animals and plants by the change of environment, and that there is every reason to expect its occurrence in any organism to a greater or less extent when occasion demands it. L. H. BAILEY.

Accolade [viâ Fr. from Ital. *accollare*, to embrace about the neck]: the embrace by which a sovereign formerly conferred knighthood. Later a gentle blow or “dub” on the shoulder of the candidate with the flat of a sword was substituted for the embrace.

Accol'ti, BENEDETTO: Italian writer and lawyer; b. at Arezzô in 1415; became chancellor of the republic of Florence in 1459. He wrote a Latin history of the crusade which Godfrey of Bouillon conducted to Palestine. This was the basis of Tasso's great poem. D. in 1466.

Accommodation and Adaptation: See the Appendix.

Accommodation Paper: See BILL OF EXCHANGE.

Accom'plice [extension of older *complice*; Lat. *complex*, interwoven]: one of several persons associated in a crime. In its broadest use it includes all connected with the offense, whether as principals or accessories; but it is generally applied to those who give evidence against fellow criminals.

Accord: in music, concord; the relation of two sounds which are agreeable to the ear.

Accord' and Satisfac'tion: in law, the word “accord” by itself denotes an agreement, but as used in this common phrase it denotes an agreement between the parties to a legal claim or demand that something different from a complete payment or discharge, according to the terms of the claims, shall be received in satisfaction thereof; and such accord, if it have the proper legal requisites and result in the satisfaction agreed upon, is a complete defense to a suit upon the original demand. This defense is available in actions both of contract and of tort. The subject is governed by well-settled rules, such as that the thing to be done must not be uncertain, that it must be advantageous to the injured party, and that the agreement must be fully carried into effect. Thus it would not be a valid accord to give the injured party something to which he was already entitled; as e. g. to pay a portion of the debt when the whole became due. Sometimes a new agreement, though unperformed, amounts to a satisfaction of a prior claim, but this happens only when there is a positive agreement to this effect.

GEORGE CHASE.

Accor'dion: a musical instrument in which the tones are produced by the vibration of metallic springs moved by wind, which is applied by a bellows. It was invented by Damian, a Viennese, about 1829.

Accoucheur, a-koo-shér': a physician who assists women in child-birth. See OBSTETRICS.

Account' [remotely from the Lat. *ad*, to + *computa're*, calculate]: a computation or calculation; a statement of the receipts and payments of one who acts in a fiduciary relation, as an executor or a trustee, or a statement showing in detail the transactions between merchants or others who have dealt together. An account current is one that is open, running, and unsettled. An account stated is one which has been adjusted between the parties, and a balance struck. An account may also become stated without any express agreement, and by implication, as where one of two merchants who have dealt together draws up a formal statement of their dealings and sends it to the other, and the latter receives it and retains it without objection for a reasonable time. He is thus presumed to assent to its correctness.

Account, or account render, is the name of a common-law action which lay against one who by virtue of his position or office ought to have rendered an account and refused to do

so. This action is now almost obsolete. A court of equity has much more complete power to grant relief in all cases of mutual accounts, and in cases where the taking of an account is incidental to other matters over which that court has jurisdiction. Some of the instances in which an account may be taken on the one ground or the other are agency, general average, apportionment, contribution between sureties, waste, trusts, express or implied, including administration, guardianship, and partnership. In suits for an account both parties are deemed to be substantially plaintiffs for many purposes, and an affirmative decree may be made for the defendant, if a balance be found in his favor, as well as for the plaintiff. T. W. DWIGHT.

Accountant: the officer of a company who has the care of its books and accounts, and who makes up for it periodical statements and balance-sheets. In Great Britain the business is recognized as a distinct profession, and includes also the management and realization of bankrupt and other estates. Institutes of accountants, incorporated by royal charter, exist in London (founded 1880), Edinburgh (1854), Glasgow (1855), and Aberdeen (1867). A member of one of them is termed a chartered accountant (C. A.).

Accra: See AKKRA.

Accre'tion [Lat. *accr'e'tio*, *ad*, to + *cres'cere*, grow]: a gradual accumulation; specifically in law, the gradual accumulation of soil along the banks of a river or the sea, formed by the washing of the water. In the case supposed the increase belongs to the owner of the adjacent land. If the increase be sudden, the alluvion formed upon the seashore or navigable river belongs to the state.

Ac'erington: a manufacturing town of England; in Lancashire, in a deep valley, and at the junction of two railways, 13 miles E. of Preston and 19 miles N. by W. of Manchester (see map of England, ref. 7-G). It has increased rapidly in population and importance, and is considered the center of the cotton-printing business. It has also extensive manufactures of cotton cloth, and coal mines in which many of the inhabitants are employed. Among the public buildings is a fine Gothic church built in 1838. Pop. (1881) 31,435; (1891) 38,603.

Accuba'tion [Lat. *accuba'tio*; *ad*, to, beside + *cuba're* lie]: the reclining posture in which the ancient Greeks and Romans took their meals. Two or three couches were spread around the dining-table, each of which was capable of containing three persons. The guests lay on their left sides, their heads or elbows being supported by pillows, the feet of the first being behind the shoulders of the second, and those of the second behind the third. The middle place was generally deemed the most honorable.

Ac'cum, FRIEDRICH: German chemist; b. at Bückeberg in 1769. Having removed to London in 1793, he became Professor of Chemistry in that city about 1802. He promoted the use of gas for illumination by a valuable work entitled a *Practical Treatise on Gaslight* (1815). He wrote other works. D. in Berlin in 1838.

Accu'mulated Force [accumulated, from Lat. *accumula're*; *ad*, to + *cumulus*, heap]: the power of a moving body to overcome resistance. When a force acts on a body so as to produce its motion, the force must be in excess of the resistance to the motion, and, as power is imparted to the body at each instant, this is termed accumulated force. Thus if a strong man should pull on a rope attached to a ship at rest, but floating free in still water, his efforts at first would seem unavailing, because his strength would be so slight compared with the *vis inertiae* (which is proportioned to the weight) of the ship. If, however, he continue to pull steadily, the force applied will gradually impart a slow motion to the vessel. This is an example of the accumulation of force, which, however, is less manifest in this instance, owing to the fact that not merely the *vis inertiae* of the vessel but also the weight and friction of the opposing water are to be overcome. But let us suppose a mass of iron or lead of many thousand tons to be suspended by a huge chain or cable extending to an immense height.* In this case, as there would be no appreciable resistance from the air, the constant application of a very small force would at length, by accumulation, communicate a rapid motion and pro-

* It is obvious that if the chain or cable were not very long, the weight soon after it began to move (acting like a pendulum) would necessarily rise considerably higher than the point at which it was first suspended; hence a great part of the force applied would be lost in overcoming the attraction of gravitation.

digious momentum to the huge mass in question—a momentum which a force applied in an opposite direction and a thousand times as great could not suddenly overcome, and indeed could only overcome at all by a continual application in an opposite direction.

Accumulator (*storage battery* or *secondary battery*): a form of voltaic battery in which the electro-motive force after using can be restored to its initial value by passing an electric current through the cell in the reverse direction. In practice the electrodes of accumulators are almost invariably lead plates, which have been coated with a preparation of the oxides of that metal. The liquid is dilute sulphuric acid, sp. gr. 1.15, or an acidulated solution of some sulphate. In the original process of producing a secondary cell, as described by Planté, the coatings were formed upon the surface of the lead by long-continued action of the current. The result of passing the electric current through an electrolytic cell, the terminals of which consist of lead in dilute sulphuric acid, is gradually to deposit spongy lead upon the electrode through which the current leaves the cell, and an oxide of lead, PbO_2 , at the other terminal. When the two lead terminals have thus become coated, the electrolytic cell has been converted into a voltaic battery, and is capable, in turn, of generating electric current in any circuit with which it may be connected. Such a cell is called an accumulator. After being exhausted, it may be replenished over and over again by the electrolytic process just described. The present practice in the construction of storage batteries is founded upon the Faure process, which consists in applying preparations of the higher and lower oxides of lead to the surface of the plates before "forming" them by the action of the current. In this way the "forming process," which is both tedious and expensive, is much shortened, and the amount of active material on the plates is greatly increased.

The electro-motive force of storage batteries, when newly charged, is 2.2 volts, which rapidly falls when the cell is used to about 2 volts, then slowly to 1.8 volts, at which point the battery is ready for recharging. The percentage of electrical energy recovered from a secondary battery during discharge is from 75 to 85 per cent, the latter proportion being rarely attained under the conditions of operation met with in commercial practice.

Accumulators possess several advantages over primary batteries: (1) Their internal resistance is very small, so that in any outer circuit of good conductivity very large currents can be obtained from a single cell. (2) The source of energy in the primary battery is the oxidation of some metal, as zinc. In the accumulator it may be derived from the consumption of some cheaper fuel, as coal, or from falling water, or even from the action of the wind.

The disadvantages are the considerable first cost of the cells, the great weight per unit of storage capacity, and the tendency of the plates to rapid deterioration after having been in service for a certain time.

At the present time (1892) the development of the accumulator has reached its highest point in Germany, where this form of battery bids fair to take an important place in the industrial application of electricity. In that country single cells are manufactured which will furnish a current of 600 ampères for three hours, or 275 ampères for ten hours, the weight of the cell being 560 kilog.

In the latest form of accumulator the leaden plates are reduced to a very slight grating or grid, which is completely filled with the active material. The weight of the cell is thus reduced to a minimum, and the life of the plate is increased.

One of the earliest uses of the storage battery was in street-railway work, but the great weight of the battery has proved a serious objection to this method of propulsion. Upon the water, where the battery can be used in place of other ballast, no such difficulties arise; and wherever there is considerable traffic over short distances, electric propulsion by means of accumulators has been found a very satisfactory substitute for steam.

Upon the Thames, above London, the number of electric launches is already so large and is increasing so rapidly as to make it seem probable that steam navigation in such localities will be entirely superseded.

Many substitutes for lead and oxides of lead in accumulator cells have been proposed, but no other materials have as yet stood the test of long-continued application.

In static electricity the word accumulator is applied to an apparatus by means of which a considerable charge of electricity is gathered in a condenser by automatic repetition of

what is known as "electrophorus action." See ELECTROPHORUS, ELECTRICAL MACHINES, and REPLENISHING. The term *replenisher* is more frequently used for such machines.

E. L. NICHOLS.

Accusative: See DECLENSION.

Aceldama, a-sel'da-ma [Aramaic, field of blood]: a potter's field, said to have been situated S. of Jerusalem, and purchased by the Jewish priests with the money received by Judas for betraying Christ. It was set apart for a burial-place for strangers dying in Jerusalem, and is still shown on the hills S. of Mt. Zion.

Acéph'ala [Gr. ἀκέφαλα, adj. neut. plur., headless; ἄ-, not + κεφαλή, head]: a class of mollusks, usually called the *Lamellibranchiata*, and including the oyster, clam, mussel, etc. See MOLLUSCA.

Acéph'ali: in the early Christian Church, bishops exempt from the jurisdiction of their patriarchs; also the Eutychians who, when Pope Felix rejected (452) the Emperor Zeno's *Henoticon*, broke away from Peter Mongus, Patriarch of Alexandria.

Acer'ra (anc. *Acer'ra*): town of Italy, in the Campagna, 7 miles by railway N. E. of Naples (see map of Italy, ref. 7-F). It has a cathedral and a seminary. The sluggish channels of the Agno render the place unhealthy. Pop. 15,768.

Acetab'ulum [Lat. vinegar cup or cruet]: one of the suckers on the arms of the cuttlefish and other dibranchiate cephalopods, which are hence termed *Acetabulifera*. In anatomy, acetabulum signifies the cavity of the hip joint. In entomology, it is the socket on the trunk of an insect in which the leg is planted.

Ac'etate: one of a class of salts derived from acetic acid (*q. v.*). The acetates are all soluble in water, and, for the most part, crystallize readily. Many of these are extensively used either in dyeing or for medical purposes. The following are among the most important: *Aluminium Acetate*.—This salt exists only in solution, being decomposed by evaporation. It is largely used in dyeing and calico-printing as a mordant, and is prepared by precipitating alum with lead acetate, lead sulphate being thrown down, and a mixture of aluminium acetate and potassium sulphate remaining in solution. *Ammonium Acetate*.—The neutral acetate is a white crystalline salt, readily soluble in water and alcohol, and evolving ammonia on evaporation, so that it is difficult to obtain it in its crystalline form. Its solution is known in pharmacy as *Spir'itus Mindere'ri*. *Copper Acetate*.—Copper forms several acetates; the normal salt is known as crystallized verdigris. It forms dark, bluish-green prismatic crystals, which are efflorescent and very poisonous. There are three basic acetates of copper, all contained in common verdigris, which is largely used both as a pigment and as a mordant in dyeing. It is obtained by submitting metallic copper to the joint action of air and acetic acid. *Copper Aceto-arsenite*.—A beautiful but very poisonous green pigment, known in commerce as arsenic green, imperial green, Paris green, and Schweinfurt green. It is insoluble in water, and is prepared by boiling verdigris and arsenious acid together. *Iron Acetate*.—Iron forms two acetates; the only one of importance, however, is the ferric acetate, which is generally prepared by mixing ferric sulphate with lead acetate. It has not been obtained in the crystalline state, but forms a red-brown solution, which decomposes on ebullition. A very crude mixture of the ferrous and the ferric acetate, known as pyrolignite of iron, is largely used as a mordant in dyeing black. *Lead Acetate*.—Lead forms a normal and several basic acetates. Normal lead acetate (known as sugar of lead) is a white crystalline salt, having a sweet astringent taste. When oxide of lead is digested with a solution of normal acetate, the tribasic acetate is formed in long, silky needles. A solution of this salt is frequently used on account of its power of precipitating many vegetable substances, such as gum and coloring-matters. It is used in medicine under the name of Goulard water or Goulard extract (*liquor plumbi subacetatis*). *Potassium Acetate* is a very deliquescent salt, and is obtained with difficulty in a crystallized state; it melts to a limpid liquid below redness. It exists in the juices of many plants, and is prepared artificially for medicinal purposes by neutralizing acetic acid with potassium carbonate. *Sodium Acetate*.—An efflorescent crystalline salt, prepared by saturating acetic acid with sodium carbonate. On evaporation it separates in large transparent prisms. It is similar in its medical properties to potassium acetate.

Revised by IRA REMSEN.

Acetic Acid [Lat. *acētum*, vinegar]: the most common of the vegetable acids, and the essential constituent of vinegar. It is composed of carbon, oxygen, and hydrogen. It occurs in the juices of many plants, and in some animal secretions. It is produced by the decomposition and oxidation of many organic bodies. It is prepared from weak alcoholic liquids, as wine, cider, and beer, by oxidation, "acetous fermentation," and by the destructive distillation of wood, "pyroligneous acid."

The chemical formula of acetic acid is $C_2H_4O_2$. Alcohol can be converted into acetic acid by bringing it into contact with spongy platinum, from which it absorbs oxygen. (See FERMENTATION.) Crystallizable or glacial acetic acid, the most concentrated form of acetic acid, is obtained by distilling dry acetates with concentrated sulphuric acid.

Acetic Ethers: acetates of the alcohol radicals, such as ethyl acetate ($C_2H_5C_2H_3O_2$); methyl acetate, "æther lignosus" ($CH_3C_2H_3O_2$), found in crude wood vinegar; amyl acetate ($C_5H_{11}C_2H_3O_2$), made by distilling potassium acetate, fusel oil, and sulphuric acid.

Acetone, or **Pyro-acetic Spirit**: a limpid, mobile liquid of agreeable odor and biting taste, like that of peppermint. It is made by heating acetates. It is manufactured from calcium acetate or acetate of lime, and used in the preparation of chloroform. It mixes with water, alcohol, and ether, and dissolves many camphors, fats, and resins. Acetone represents a class of organic bodies called ketones.

Acetylene: See the Appendix.

Achæan League: a confederation of Grecian cities formed about 280 B. C. Previous to the invasion of Macedonia by the Gauls, the Achæans had performed an insignificant part in the history of Greece, but soon after that event four Achæan towns formed a league for mutual protection. Aratus of Sicyon induced his native town to join the league (251 B. C.), and was himself made strategos (general-in-chief) of the confederacy. Corinth joined the league in 243 B. C., and was soon followed by Epidaurus, Megara, and several other cities. Philopœmen, called the "last of the Greeks," became strategos of the league in 208 B. C. In 191 B. C. the confederacy included Sparta, Athens, and nearly all the cities of the Peloponnesus, and for fifty years maintained the cause of Grecian independence against the Ætolians and against the encroachments of Rome. The confederates, under Diæus, were defeated at Corinth by the Roman General Mummius, and Southern Greece was made a Roman province under the name of Achaia (146 B. C.). The Achæan confederacy may be said to furnish the most perfect example of the federative system which ancient Greece affords, and its history forms one of the most glorious chapters in the annals of ancient times.

Revised by R. LILEY.

Achæans (Gr. *Ἀχαιοί*): one of the four races of inhabitants of ancient Greece. The name is often extended in the Homeric poems to the whole Greek people. The Achæans proper inhabited parts of Thessaly, and in the Peloponnesus they anciently occupied Argos, Laconia, and the neighboring regions, whence they were, for the most part, expelled by the Dorians, the exiles settling along the northern shore of the Peloponnesus, and founding there a new community. They remained an obscure people till the founding of the ACHÆAN LEAGUE (*q. v.*).

Acha'ia (Gr. *Ἀχαια*): state of ancient Greece; in the north part of the Peloponnesus; bounded E. by Sicyonia, N. by the bay of Corinth, and S. by Arcadia and Elis (see map of Greece, ref. 16-J). It was about 65 miles long from E. to W. The surface was hilly or mountainous. Achaia and Elis constitute a province of modern Greece. Area, 1,901 sq. miles. Pop. (1889) 210,713. In the days of the New Testament writers, Achaia signified the whole Peloponnesus.

Acha'o: a town of Chili; on the northeastern end of Quinchao island, Gulf of Ancud; on the east side of the northern end of the island of Chiloe; approximate lat. 42° 20' S., lon. 74° 20' W. Pop. of commune, 13,873.

Achard, *ã-shaar'*, FRANZ KARL; b. in Berlin, Apr. 28, 1753; studied physics and chemistry, and published *Vorlesungen über Experimentalphysik* (4 vols., 1791-92); made extensive researches and experiments with reference to the production of sugar from the beetroot, the results of which he published in 1799-1800, and received from the Prussian king the estate of Cunern in Silesia for the purpose of establishing there a beetroot-sugar manufactory; succeeded in 1806 in developing the true practical process of manufacturing, and brought the establishment into splendid condition,

especially during the enforcement of the continental system; wrote *Die europäische Zuckerfabrikation aus Runkelrüben* (3 vols., 1809). D. Apr. 20, 1821.

Achard, LOUIS AMÉDÉE EUGÈNE: French novelist; b. in 1814; was contributor to the *Courrier de Paris* in 1845, and after the revolution of 1848 became a political writer in the camp of the royalists. He wrote, among other works, *Belle-Rose* (1847); *Histoire d'un homme* (1863); *Souvenirs personnels d'émeutes et de révolution* (1872); *Histoire de mes amis* (1874). D. Mar. 25, 1875.

Acha'tes: a friend and companion of Æneas (*q. v.*), noted for his fidelity. The proverbial phrase *fidus Achates* is often applied to a man who is a devoted follower of his chief.

Achelo'us (Gr. *Ἀχελῷος*), now **As'pro-Pot'amo**: the largest river of Greece, rises in Mt. Pindus, flows nearly southward, forms the boundary between Acarnania and Ætolia, and enters the Ionian Sea after a course of about 100 miles.

Achenbach, *aa'khen-baäk*, ANDREAS: landscape and marine painter; b. in Cassel, Germany, Sept. 29, 1815. Pupil of the Düsseldorf Academy; member of the Berlin, Amsterdam, and Antwerp academies. Works by him are in the principal German galleries and in private collections in the U. S. Received, among other honors, a first-class medal at the Paris Exposition, 1855; Legion of Honor in 1864.

WILLIAM A. COFFIN.

Achenbach, HEINRICH: a German jurist and statesman; b. Nov. 23, 1829; became, in 1860, Professor of German Law at the University of Bonn; entered the Prussian Diet in 1866; fought (though a Conservative) on Falk's side in the Kulturkampf; and became, in 1873, Minister of Commerce, Agriculture, and Public Works. He founded and edited for many years *Zeitschrift für Bergrecht*, and his *Das französische Bergrecht* (1869), *Das deutsche Bergrecht* (1871), etc., have greatly influenced mining legislation. D. Potsdam, July 10, 1899.

Achenbach, OSWALD: landscape painter; brother and pupil of Andreas; b. in Düsseldorf, Feb. 2, 1827. Painted many pictures of subjects in Switzerland and Italy. Works in the National Gallery, Berlin, and many are owned by collectors in the U. S. Second-class medal, Paris Salon, 1861; Legion of Honor, 1863.

WILLIAM A. COFFIN.

Achenium, *a-kee'ni-ūn*, or **Acheue**, *a-keen'* [for *achænium*, Gr. *â-* not + *χαλνείν*, gape]: a dry, hard, one-seeded, indehiscent fruit or pericarp, such as that of the buttercup and the thistle.

A'chenwall, GOTTFRIED: German writer on statistics; b. at Elbing in 1719; reputed to have originated statistical tables. He became Professor of Philosophy at Göttingen about 1750. He introduced the term *Staatswissenschaft* (politics), by which he proposed to include all the knowledge essential to statesmanship. D. in 1772.

Acheron, *äk'er-on* (Gr. *Ἀχέρων*): the ancient name of a river of Elis; also a river of Epirus. It was also applied in mythology to a river of the infernal regions; the bitter stream over which the souls of the dead were ferried by Charon.

Acheron'tia, or **Death's-head Moths** [from *Acheron*, in the Greek mythology a river of the dead]: a genus of moths, belonging to the family *Sphingidæ*. There is found in Great Britain and other European countries a species of this genus (the *Acheron'tia at'ropos*), having on the back of the thorax a remarkable representation of a human skull, and it has hence received the name of death's-head moth. This is a very handsome insect, and is from 4½ to 5½ inches in expanse of wing. It is much dreaded by the ignorant and superstitious, who consider its appearance to be ominous of evil. It does not hesitate to attack beehives,

devouring the honey and putting the bees to flight. Though possessing no weapons of defense that have yet been discovered, it appears to suffer no harm from its armed enemies. Its larva is a large caterpillar about 5 inches in length, with beautiful markings; the color is a kind of greenish yellow, and the back is traversed by lines partly blue and partly white, speckled with black spots. The caterpillar feeds mostly on the leaves of the potato plant; and it retires deep

Death's-head moth.

into the earth, and changes into a chrysalis in the month of September. It emerges the following June or July, transformed into a perfect insect. This moth is seen most frequently in the mornings and evenings of autumn.

Acheru'sia: I. A lake in Epirus, into which the river Acheron flows. II. A cavern in Bithynia, near the city of Heraclea; through it Hercules is said to have dragged Cerberus up to the light of day.

Achill, *akh'il*, or **Eagle Island**: an island off the west coast of Ireland, forming part of the county of Mayo (see map of Ireland, ref. 7-B). It is about 15 miles long by 12 miles broad. Pop. about 5,000. On the coast is a sheer precipice 2,200 feet high.

Achil'les (Gr. Ἀχιλλεύς): a famous Grecian warrior, the hero of Homer's *Iliad*; son of Peleus, King of Thessaly, and the sea-nymph Thetis. From the name of his father, he was often called Peli'des. At the siege of Troy he was pre-eminent for courage, strength, and swiftness, but, having been offended by Agamemnon, he refused to fight. When, however, his friend Patroclus had been killed, he returned to the war to avenge his death. He slew Hector and many other Trojans. According to a poetic legend, his mother, by dipping him in the river Styx, had rendered him invulnerable in every part except his heel, by which she held him. He was killed with an arrow by Paris, who shot him in the heel.

Achilles Tatius: author (about 450 A. D.) of a popular Greek romance, *The Story of Leucippe and Clitophon*, largely borrowed from the still more popular romance of Heliodorus. He is said to have become a Christian and a bishop, but the immorality of his work is peculiarly heathen. Achilles is distinctly inferior to Heliodorus; there are too many speeches, letters, and descriptions of works of art. Edited, with commentary, by Fr. Jacobs (1821); revised text, by Hercher, 1858; translated into English by R. Smith (Bohn's Classical Library). See Rohde, *Griechischer Roman*, p. 472.

B. L. GILDERSLEEVE.

Achil'les' Ten'don, or **Tendon of Achilles** (in Lat. *ten'do Achil'lis*): the tendon which connects the muscles of the calf of the leg with the bone of the heel. It is the strong band which is felt at the posterior part of the foot behind the ankle. The name is given in allusion to the mythological tale of the famous Grecian warrior Achilles, who was said to have been held by the heels by his mother Thetis as she bathed him in the river Styx shortly after his birth. This is said to have rendered him invulnerable in all parts save that which was held above water, and his death was finally caused by an injury to the heel. This tendon plays an important part in one of the forms of club-foot in which it becomes contracted, so that the toe is kept permanently drawn downward.

W. P.

Achil'li, GIOVANNI GIACINTO, Dr.: Italian Protestant; formerly a Dominican friar; b. at Viterbo in 1803. He left the Roman Catholic communion about 1839, and issued an Italian version of the New Testament, which is regarded by some as the best in that language. In 1850 he went to Great Britain, where, as "Father Achilli," he lectured extensively, and where he became involved in a lawsuit (in 1852) which he brought against Dr. John Henry Newman for slander. The case was tried before Lord Campbell, and a verdict given for the plaintiff. Dr. Achilli has also been Professor of the Italian Language and Literature in the English College at Malta.

Achin', or **Acheen'**: the northwestern portion of the island of Sumatra, formerly an independent state, now nominally a Dutch political district (see map of East Indies, ref. 5-A). The Dutch declared war against the Sultan of Achin in 1873, and in 1878 they formally extended their administration over his dominions. As an administrative district, Achin consists of the western extremity of the island for about 250 miles, and includes the large island of Labuan on the S. and many small ones. Area, about 20,000 sq. miles. Pop., 445,000 natives (mostly Malay in origin), 2,000 Chinese, and 242 Europeans (1891). About one-half of the territory, in the interior and occupied by more than half of the population, is still unconquered. See SUMATRA. M. W. H.

Achromatic [Gr. ἀ-, without + χρώμα, color]: transmitting light without decomposing it into its constituent colors; applied to telescopes and microscopes, the objectives of which are constructed of such a combination of glasses as will refract rays of all colors to nearly the same focus. See TELESCOPE.

Achromatin: in biology, that constituent of the substance of the nucleus of a cell which does not stain, or only slightly so, with the coloring reagents. See CELL.

Achro'matism [see ACHROMATIC]: absence of coloration. (See CHROMATIC ABERRATION under ABERRATION.) A prism of flint glass will cause a certain amount of refraction and of dispersion, and if a similarly shaped prism of the same glass be placed behind it, in the reverse position, the refraction and dispersion in one direction by the first prism will be exactly neutralized by the refraction and dispersion in the opposite direction by the second prism, and as a result there will be no refraction and no color. But suppose a prism of *crown glass*, having the same dispersion as the one of flint glass, be placed behind the latter in the reverse position, the two dispersions, being opposite and equal, will neutralize each other, and the result will be white light; but the mean refractions being different, they will not neutralize each other, and the beam of light will pass through achromatic, or almost free from color, but refracted more or less. As a lens may be looked upon as a combination of prisms with curved surfaces, achromatic lenses may be produced in the same way as achromatic prisms. Absolute achromatism is perhaps unattainable by art, owing to the spectra from different dispersive media not having an exact proportionality to one another. This is called *irrationality of dispersion*. It may be remedied in some degree by introducing a third lens of plate glass in addition to the flint and crown glass lenses. An under-corrected lens is one in which the correcting lens of flint does not quite accomplish the purpose, and the violet ray will come to a focus a little within the red. In an over-corrected lens the error is of the opposite kind, and the order of colors inverted.

Acid [Lat. *a'cidus*, sour]: one of an important class of chemical compounds, of which acetic acid, sulphuric acid, hydrochloric acid, nitric acid, phosphoric acid, and oxalic acid are well-known examples. In general terms, all acids have an acid taste; they have the power to change certain vegetable colors, as blue litmus, which they change to red; and, further, and this is the most characteristic property of acids, they form compounds known as salts when brought together with the so-called bases. Some compounds have the power to neutralize acids, and are themselves neutralized at the same time. The meaning of this can be illustrated by taking a simple case. Hydrochloric acid acts energetically upon many things; it has in a marked degree the properties of acids. Sodium hydroxide, or, as it is also called, sodium hydrate or caustic soda, also acts energetically upon many things. The name caustic suggests the character of the substance. Sodium hydroxide is a marked example of the class of compounds called bases. Now, when hydrochloric acid and sodium hydroxide are brought together, the two act upon each other in such a way as to cause the formation of sodium chloride and water, the marked properties of both the acid and the base being destroyed, both being, as we say, neutralized.

In chemical language the change is represented thus:

The sodium chloride formed is the substance familiar to all as *salt*. It has none of the striking properties of the acid and base from which it is derived.

Whenever an acid and base act upon each other, they are neutralized, and a salt and water are formed. The salts thus formed differ widely from one another in their properties. Examples are potassium nitrate, KNO_3 , derived from nitric acid and potassium hydroxide, or caustic potash; sodium sulphate, Na_2SO_4 , derived from sulphuric acid and sodium hydroxide; sodium carbonate, Na_2CO_3 , derived from carbonic acid and sodium hydroxide; copper sulphate, or "blue vitriol," CuSO_4 , derived from sulphuric acid and copper hydroxide.

Acids contain hydrogen as the essential constituent, and most of them contain oxygen. So commonly is the latter element contained in them that it was for a long time regarded as the essential constituent, and the name oxygen, from the Greek *ὀξύς*, acid, and *γενεῖν*, to form, is a reminder of this view.

A base contains a metallic element, as potassium, sodium, calcium, iron, copper, zinc, together with hydrogen and oxygen. Thus the substances named below are bases:

Potassium hydroxide.....	KOH.
Sodium hydroxide.....	NaOH.
Calcium hydroxide.....	Ca(OH) ₂ .
Ferric hydroxide.....	Fe(OH) ₃ .
Copper hydroxide.....	Cu(OH) ₂ .
Zinc hydroxide.....	Zn(OH) ₂ .

When a salt is formed from an acid and a base, the metal of the base enters into the acid in place of the hydrogen, and the hydrogen combines with the hydrogen and oxygen of the base to form water, thus:

HNO ₃ + Nitric acid.	KOH = Potassium hydroxide.	KNO ₃ + Potassium nitrate.	H ₂ O. Water.
H ₂ SO ₄ + Sulphuric acid.	2NaOH = Sodium hydroxide.	Na ₂ SO ₄ + Sodium sulphate.	2H ₂ O. Water.

Chemists distinguish between strong and weak acids. Among the strongest are the three well-known ones, hydrochloric, nitric, and sulphuric acids. Boric acid, from which borax is derived, silicic acid, from which are found the silicates, and most vegetable acids, such as citric, tartaric, oxalic, and malic acids, are weak. These expressions are not generally used in a very definite sense, but their meaning is clear enough for most purposes. Again, acids are said to be monobasic, dibasic, tribasic, etc. Examples of monobasic acids are hydrochloric and nitric acids; of dibasic acids, sulphuric and oxalic acids; and of tribasic acids, phosphoric acid:

Hydrochloric acid.....	HCl.
Nitric acid.....	HNO ₃ .
Sulphuric acid.....	H ₂ SO ₄ .
Oxalic acid.....	H ₂ C ₂ O ₄ .
Phosphoric acid.....	H ₃ PO ₄ .

The basicity depends upon the number of hydrogen atoms in the molecule. If there is but one, the acid is monobasic; if two that can be replaced by metallic atoms, the acid is dibasic; if three that can be replaced by metallic atoms, the acid is tribasic.

IRA REMSEN.

Acidim'eter [from Lat. *ac'idum*, acid + Gr. *μέτρον*, measure]: an instrument for determining the strength of an acid by its saturating power. It usually consists of a glass tube graduated into 100 equal parts, and containing an alkaline liquor of known strength, the proportion of which requisite to saturate a given quantity of any acid is the equivalent of that acid. See CHEMICAL ANALYSIS and VOLUMETRIC ANALYSIS under ANALYSIS.

Acipeuser'idæ: See STURGEON.

Acireále, ã-chee-rã-aa'lay: a town and seaport of Sicily; in the province of Catania; at the mouth of the river Aci, near the foot of Mt. Etna, and 7 miles by rail N. E. of Catania. (See map of Italy, ref. 10-F). It is built mostly of lava, has many fine edifices, and is an important health resort. Here are mineral springs and the Cave of Polyphe-mus. Pop. 35,000.

Ack'ley: railroad junction, Hardin co., Ia. (for location of county, see map of Iowa, ref. 4-H); 132 miles W. of Dubuque; has five churches, a convent in charge of the Sisters of Mercy, and a soap-factory. Pop. (1880) 1,517; (1885) 1,473; (1890) 1,286; (1900) 1,445. EDITOR OF "ENTERPRISE."

Acknow'edgment: in law, the act by which one who has executed an instrument declares or acknowledges, before some authorized officer, that it is his act or deed. The term is also applied to the officer's certificate of this fact indorsed on the instrument. The general object of an acknowledgment is twofold: first, to comply with the recording acts, so that the instrument may be lawfully recorded; secondly, to give the instrument such authenticity that it may be put in evidence in courts of justice, without further proof of its execution. As a general rule, it is not necessary to the validity of the instrument, though the laws of some of the States provide that a wife's conveyance of real estate or release of dower is invalid unless on a private examination apart from her husband she acknowledges that she executed it freely and without fear or compulsion of her husband. This rule is borrowed in its substance from an English practice under a so-called statute of fines. The officers generally authorized to take acknowledgments are judges and clerks of courts, mayors, justices of the peace, commissioners of deeds, and notaries public.

Acknowledgments of conveyances of real estate should correspond in form with the requirements of the law of the

State where the land is situated, though that law sometimes permits them to be valid if they conform to the law of the place where they are executed.

Ac'land, ARTHUR H. D.: See the Appendix.

Acland, HENRY WENTWORTH, M. D., D. C. L., F. R. S.: b. in 1815; educated at Christ Church, Oxford, where he took his degree of M. D. in 1848. He was one of the founders of the University Museum, and became in 1858 Regius Professor of Medicine. He accompanied the Prince of Wales to America in 1860; and published *The Plains of Troy* (1839), a *Memoir on the Visitation of Cholera in Oxford in 1854*, and scientific and medical papers. D. Oct. 15, 1900.

Acóme'tæ [literally the sleepless, from Gr. *ἀκοιμητος*, sleepless; *ἀ-*, not + *κοιμᾶσθαι*, fall asleep]: an order of monks, sometimes called Watchers, which was founded at Constantinople early in the fifth century. They performed divine service day and night, and were divided into three classes, each of which had its share of duty. They established many monasteries, and were held in high estimation. Studius, a Roman noble and a member of this order, built a monastery called Studium, and the monks were styled Studitæ. Having afterward favored the doctrines of Nestorius, their credit declined.

Ac'olyte [Lat. *acolythus acolitus* for more correct *acolūthus* = Gr. *ἀκόλουθος*, attendant]: the highest of the four minor orders in the Roman Catholic Church. The acolyte assists at mass by presenting the wine and water and by carrying the lights. The order is mentioned by Pope Cornelius in the third century, and must still be received by candidates for the priesthood, though its functions are often performed by laymen.

Acoua: See KERESAN INDIANS.

Aconca'gua: one of the highest peaks of the Andes; in Chili, lat. 32° 39' 40" S., lon. 70° 1' 43" W., on the frontier between Chili and the Argentine Republic. Its height is 23,910 feet above sea-level.

Aconca'gua: a province of Chili; bounded N. by Coquimbo, E. by the Argentine Republic, S. by Santiago and Valparaiso, W. by the Pacific. Area, 5,840 sq. miles. This province is the most mountainous part of Chili, and contains the highest peak of the Chilean Andes, Aconcagua. The climate is very dry, and owing to the high mountain ranges there is very little vegetation in this province. Pop. in 1878, 135,190; (1885) 144,125; (1895) 113,165. Chief town, San Felipe.

Ac'onite: a plant of the genus *Aconitum* and the family *Ranunculaceæ*. The Old World contains many species of this genus, some of them, particularly *Aconitum ferox* of India, very poisonous. *Aconitum napellus*, or monkshood, a native of Europe and Asia, is the plant which yields most of the aconite used in medicine. Several species occur in the U. S. The "winter aconite" (*Eranthis*) of Europe is of the same family, but is more nearly related to hellebore.

Acouitia: See MONKSHOOD.

Ac'orus Cal'amus (sweet flag): a medicinal plant of the family *Araceæ*. Its aromatic stem (rhizoma) is used as a stomachic and tonic. It is a native of both continents.

Acos'ta, GABRIEL: Jewish reformer; b. in 1594 in Oporto, Portugal; educated in the Roman Catholic religion, but went to Holland, where he embraced the faith of his fathers, and changed his name to Uriel. He was condemned and persecuted as a heretic by the rabbis, and died by suicide in 1647. His autobiography was published in Latin and German in 1847.

Acotyledonous Plants [Gr. *ἀ-*, without + *κοτυληδών*, cup-shaped cavity, from *κοτύλη*, cup]: an old term applied to the flowerless (and therefore seedless) plants, as ferns, mosses, fungi, etc. It is now rarely used. CHARLES E. BESSEY.

Acoustics, a-koos'tiks [Gr. *ἀκουστικός*, pertaining to hearing; *ἀκούειν*, hear]: the study of the nature, the production, and the perception of sound.

Strictly speaking, sound is a sensation which is produced when vibrations of a certain character are excited in the auditory apparatus of the ear. These vibrations are generated by progressive tremors in the atmosphere, called sound-waves, the nature of which we shall briefly consider. Let it be premised that the particles of the air, and of all elastic media, are ordinarily maintained in a state of equilibrium and rest by mutually repellent forces. If any particle be disturbed from its position of equilibrium, it must be by an impulse received from some body foreign to the medium;

and when so disturbed it is solicited to return by a force directly proportioned to the distance, or *amplitude*, of its displacement from that point. Also, the velocity with which it will be animated on reaching in its return the point of original rest will be directly proportioned to the extreme amplitude of its displacement; so that, in virtue of its inertia, it will make an equal and similar excursion in the opposite direction. When in its return from this it reaches once more the point of equilibrium, it will have passed over the entire range of its movement in both directions; and this is said to constitute one complete oscillation or double vibration.

From the law of force above stated the following deductions are made by the help of the calculus: Put a to represent the extreme amplitude of displacement; V , the maximum velocity of the vibrating particle (the velocity with which the particle passes the point of equilibrium, expressed by the distance such velocity, continued uniformly, would carry a body in one second of time); T , the time of a complete double vibration; and π , the ratio of the circumference to the diameter of the circle. Then $V = 2\pi\frac{a}{T}$, and $T = 2\pi\frac{a}{V}$; from which last expression it appears that the time of vibration is constant, whatever be the amplitude of displacement, since a varies directly as V .

But in an elastic medium one particle can not be displaced from the position of equilibrium without disturbing the equilibrium of its nearest neighbors. The neighboring particle toward which it is driven will begin, almost but not quite in the same instant, to move in the same direction; and this will disturb the next, and through it the third, and so on, the tremor being rapidly propagated throughout the medium. The distance to which this tremor will have reached when the particle first disturbed has completed one entire double vibration is the length of the sound-wave, or of one complete undulation.

The relation between vibration and undulation may be made more clear by the following illustration. Since VT is the distance accomplished in time, T , with velocity, V , and since $VT = 2\pi a$, it follows that if, with radius, $a = CA$ or CB , we describe a circle, $ADBE$, a particle, p , will describe the circumference, $ADBE$, with velocity, V , continued uniform, in the same time, T , in which the vibrating particle p performs a complete double vibration on the diameter AB . If p leaves D in the same instant in which p passes C , the two will be together at B , and again at A ; and it is further provable that, at any intermediate instant, the line joining p and p' , as FG or HK , will always be parallel to CD , and perpendicular to AB . Also, that if the

FIG. 1.

arcs of revolution be reckoned from D , and the time from D to F , or from D to H , be called t , the distance $y = CG$ or CK , of p from the point of equilibrium, C , will always be representable by the formula $y = a \sin 2\pi\frac{t}{T}$; and the velocity, v , of the same particle will always be $v = V \cos 2\pi\frac{t}{T}$.

Now the rapidity of the propagation of the tremor through the elastic medium is, for all tremors producing the sensation of sound, vastly greater than the velocity v or V ; and this velocity of propagation is uniform, although the several velocities of the particles of the medium which successively take up the tremor, diminish with the increase of distance from the origin, because of the diffusion of the exciting force through a constantly increasing number of particles. This diminution for moderate distances may be disregarded. If the foreign body which disturbs p be, for instance, the limb of a tuning-fork making 500 double vibrations per second, the time of describing CB will be but the 2,000th part of a second. During this time the tremor in the air will advance more than 6 inches, while CA will hardly exceed $\frac{1}{10}$ th of an inch. The velocity of propagation in this case therefore exceeds the mean velocity of vibration more than 240 times. But if we consider the movement of p through CB to be made up of an indefinite number of exceedingly minute elementary motions, these elementary motions will have all the different velocities corresponding to the possible values of FG between C and B ; and each one of these velocities will be successively transmitted along the line of propagation, one behind the other; so that, when p reaches B and comes to rest,

all these velocities will still be living in a row of particles extending over a distance of 6 inches, the largest being foremost, and the least, which is zero, being that of the particle p itself. As p returns toward C , it leaves its next neighbor toward the right partially unsupported, and that neighboring particle follows it. There occurs then a second series of propagated movements, all the molecules moving in the returning direction, though the tremor advances, forming the wave of dilatation, as the former was the wave of compression. Sound-waves may accordingly be represented graphically by a curved line, as in Fig. 2, where the portion of the

FIG. 2.

curve above the horizontal straight line represents the wave of compression, and the part below the wave of dilatation. The ordinates to the different parts of this curve represent the velocities animating the particles in the different parts of the wave, those above being advancing velocities, and those below receding.

FIG. 3.

The distance between M and N is the length of a complete undulation, commonly represented by λ . Then if x (Fig. 3) be taken to represent any distance from the point of rest, C , of the disturbing or sounding body, the distance, y , of the particle at x from its place of equilibrium will be expressed by the formula

$$y = a \sin 2\pi\left(\frac{t}{T} - \frac{x}{\lambda}\right);$$

and the velocity animating that particle at the instant by the formula

$$v = V \cos 2\pi\left(\frac{t}{T} - \frac{x}{\lambda}\right).$$

For examples under the first formula, let $t = nT$; i. e. let p have made an exact number of complete oscillations; then by giving different values to x we ascertain the condition of corresponding points along the line. Thus if $x = 0$, we have $y = 0$; or p is at this moment in its position of equilibrium.

Making x successively $= \frac{\lambda}{8}, \frac{\lambda}{4}, \frac{\lambda}{2}, \frac{3\lambda}{4}, \lambda, 2\frac{1}{2}\lambda$, and substituting these values, we have the corresponding values of y equal to $-a\frac{1}{\sqrt{2}}, -a, 0, +a, 0$; positive signs indicating displacement to the right, and negative signs the reverse.

For examples under the second formula, let $t = nT$, as before, and put $x = \frac{\lambda}{6}, \frac{\lambda}{3}, \frac{2\lambda}{3}, \frac{7\lambda}{8}, \frac{5\lambda}{3}, \frac{\lambda}{2}, \frac{7\lambda}{4}$, successively.

We shall then have $v = +\frac{1}{2}V, -\frac{1}{2}V, -\frac{1}{2}V, +\frac{1}{10}V, -\frac{1}{2}V, V, 0$, for the corresponding velocities; positive signs indicating movement toward the right, and negative signs the reverse. The signs of displacement and movement for the same particle are half the time alike and half the time unlike.

Velocity of the Propagation of the Sound-Waves in the Air.—This has been the subject of a considerable number of experiments, of which we give below the most important. In 1822 a determination of this kind was undertaken by some members of the French Academy; the stations selected were at Montlhéry and Villejuif, the distance being 18,622·27 meters. Cannon were alternately discharged at the two stations at night, and the time which elapsed between the flash and the perception of the sound noted. On the first night twelve and seven shots were heard—on the second only one. The result was, that at a temperature of 0° C. sound travels with a velocity of 331·2 meters per second. It is somewhat strange that to this important experiment only two nights were devoted.* We have besides this the more careful experiments of Moll and Van Beek† in the following year, who obtained for their result at 0° C. 332·05 meters per second; and finally we must add the experiments of Bravais and Martins,‡ who measured the velocity of sound in a slanting upward direction from the Lake of Brienz to a station on the Faulhorn, obtaining as result at 0° C. a

* *Ann. de Chim. et de Phys.*, t. xx, p. 210.† *Pogg. Ann.*, bd. v. s. 351, 469.‡ *Pogg. Ann.*, bd. lxvi. s. 851

velocity of 332·37. This last experiment is interesting as showing that sound travels with the same velocity in an upward direction as on a level, as is required by the formula of Laplace.

Recently several pieces of apparatus have been devised by which the velocity of sound can be measured when the distance traveled over is only a few feet; so that it is now possible to make this experiment in a small apartment. Suppose that we generate a sharp, short sound at the open extremity of a tube, the other end being closed by a membrane; the sound-impulse, reaching the closed end of the tube, would announce its arrival by giving the membrane a little push outward; and if we had fastened on it a pencil, this might be caused to make a mark on a sheet of paper at the same instant. Let us now imagine that we had, near each other, *two* such tubes, the second one being longer than the first, but bent so that both still terminated side by side, each with its membrane and pencil, and that finally our sheet of paper, instead of being stationary, were in motion. Then, under these circumstances, the sound-wave traveling through the shorter tube would make its mark first, and the paper would have a chance to move a few inches before receiving the pencil mark due to the companion wave; and if we knew the rate of the paper's motion, it is evident that we could easily calculate the velocity with which the sound had traveled through our apparatus. This general explanation will give an idea of the principle involved in a number of new contrivances, with some of which it is even possible to experiment at various temperatures and on other gases than our atmosphere. A simple and cheap apparatus of this kind was, in 1866, devised by Dr. Ernst Neumann,* a school-teacher in Dresden; the difference in the paths of the sound-waves was about 20 feet, although the length of the apparatus was only 3 feet; the sound was generated by the discharge of a child's brass cannon. The paper was attached to a circular disk arranged with a handle, which enabled the experimenter to revolve it with a velocity of only one turn per second, which was roughly accomplished by watching a seconds pendulum, consisting of a ball attached to a string having a length such as to cause it to vibrate seconds. The mean of a number of experiments gave a result far more accurate than would have been expected. Using the same general idea, but causing the sound-waves to act on little gas-burners connected with the two membranes, in the same year Ivan Zoch,† in Erlangen, contrived a far more delicate instrument, with which he obtained results rivaling those of the French Acad my in 1822, although in his case the difference of the paths was only 3 or 4 feet. With it he measured the velocity in various gases, and by driving a current of air through during the experiment was actually able to ascertain the change due to this cause. A somewhat similar idea was used in this fruitful year by Prof. Quincke,‡ of Berlin, in a very beautiful contrivance, where, unlike the two preceding, the signal was given not to the eye but to the ear, the two sounds being made to destroy each other, producing silence in a manner presently to be explained. With this instrument Dr. Seebeck§ has proved that in *small* tubes sound travels slower than in the open air, partly, as it would seem, owing to friction, and partly to loss of heat developed by the sound-wave itself through conduction by the walls of the tube. He has also shown that in *small* tubes the velocity is less in the case of deep notes than with those which are higher.

Laplace's formula for the velocity of sound in gases and vapors is

$$v = \sqrt{\frac{g h}{d} K};$$

v = the number of meters traversed by the sound-wave in a second of time; g = the accelerating force of gravity = 9·8088 meters; h = the height of the mercury in the barometer reduced to the height it would have at 0° C.; d = the specific gravity of the gas, mercury at 0° being taken as unity; K = the quotient of the specific heat of the gas at a constant pressure, divided by its specific heat at a constant volume = 1·42. It is seen from this formula that the velocity is directly proportional to the square root of the pressure the gas is under, and inversely proportional to the

square root of its specific gravity. It is evident also that the velocity is independent of the height of the barometer, for a change in the barometer affects not only h in the numerator, but also d in the denominator, in such a way that the value of the fraction remains constant. No term relating to the distance of the sounding body enters the formula; hence the velocity is independent of the distance—that is, of the amplitude of the sound-wave. The following is the convenient formula for calculating the velocity of sound in air at various temperatures:

$$v = 333 \cdot M \sqrt{1 + at};$$

a = coefficient of expansion of air for 1° C. = 0·003665; t = the temperature in degrees of the centigrade scale; M standing for meters. It was also found experimentally that sound moves quicker with the wind and slower against it; the final velocity being in the one case equal to the sum, in the other equal to the difference, of the velocity of wind and that of the sound-wave itself. In gases, the velocity of sound, of course, as indicated by the formula, increases with the temperature; in air this increase is about 2 feet per second for each degree centigrade. The velocity of sound in oxygen gas at 0° C. is 1,040 feet; in carbonic acid, 858 feet; in hydrogen, 4,164 feet.

In 1827 Colladon and Sturm determined experimentally the velocity of sound in fresh water. The experiment was made on Lake Geneva, and it was found to be 4,714 feet per second at a temperature of 15° C. Laplace has also given a formula for the velocity of sound in liquids:

$$v = \sqrt{\frac{g}{\lambda}};$$

g as before = 9·8088 meters, and λ is the amount which a column of the liquid one meter long shortens under a pressure equal to its own weight; it hence is necessary to determine the compressibility of the liquid in order to employ this formula, as the velocity is inversely proportional to the square root of the compressibility. The velocity of sound in alcohol at 20° C. is 4,218 feet; in ether, at 0°, 3,801; in sea-water, at 20° C., 4,768.

The velocity of sound in solids can be calculated by this last formula, and can also be experimentally determined; that in

	At 20 C°.	At 100°.
Gold is	5,717.....	5,640.
Lead is	4,030.....	3,951.
Copper is	11,666.....	10,802.
Iron is	16,822.....	17,386.

The Intensity of Sound varies inversely as the square of the distance of the sounding body from the ear; it is also proportional to the square of the amplitude of the sound-wave. Thus far we can hardly be said to possess a phonometer or instrument for the purpose of comparing the relative intensities of two sounds or sets of sound-waves; hence we must regard with interest the step taken in this direction by Prof. A. M. Mayer, of Hoboken, who, by employing small vibrating flames and the principle of interference, succeeded in solving this problem in certain cases. For details we must refer the reader to the original article published in the January number of the *American Journal of Science and Arts*, 1873.

Reflection of Sound.—The waves of sound can be reflected like the waves of light, and obey the same law, the angle of incidence being equal to the angle of reflection; this can be proved indirectly with the aid of spherical or parabolic mirrors, though, from the circumstance that the sound-waves are large relatively to such reflecting surfaces as can be used, the experiments are far more difficult than with the almost infinitely shorter waves of light. The author has recently contrived a new method by which the reflection of sound can be studied, and the relative reflecting powers of different substances examined. A circular disk with open and closed sectors, or with sectors of different materials, is made to revolve rather slowly near a sounding reed, in such a way that the sound is from time to time re-enforced by reflection. The result is that a sound resembling "the beats" is produced, these alternations of sound and comparative silence disappearing when the disk is made complete, or when its alternate sectors are composed of substances having the same power of reflection. The same apparatus can be used to determine the relative powers of different bodies for the transmission of sound. Echoes are cases of the reflection of sound, and the wonderful power of very long tubes in conveying sounds to a great distance is due to the same property.

* Pogg. Ann., cxxviii. s. 307.

† Pogg. Ann., cxxviii. s. 497.

‡ Pogg. Ann., cxxviii. s. 177.

§ Pogg. Ann., cxxxix. s. 104. Compare also the experiments of Regnault on this subject (*Comp. Rend.*, t. lxvi. p. 209); also those of Kundt (*Pogg. Ann.*, cxxx. s. 337); and finally those of Schneebeli (*Pogg. Ann.*, cxxxvi. s. 296).

Refraction of Sound.—Sound-waves can be refracted or bent out of their course by denser or rarer bodies in a manner corresponding to light; this can be demonstrated by the use of a large lens of carbonic acid inclosed in a thin membrane, when it will be found that the sound-waves from a watch will be concentrated just as a glass lens concentrates the rays of light. Recently the refraction of sound has been directly studied with a prism, according to the method which has long been used in light. Prof. C. Hajech generated sound-waves in the interior of a box, *b*, by the aid of a bell which was struck by clockwork; traveling along a tube, *t*, they reached the prism, *P*, and were refracted by it as indicated in Fig. 4. The amount by which they were bent out

FIG. 4.

of their path was ascertained by moving the ear over the graduated circle, *cc*, which was in an adjoining room till the position of maximum intensity had been ascertained. The sides of the prism were made of thin membrane, of paper, or finally of sheets of mica. Experiments were performed on hydrogen, ammonia, illuminating gas, carbonic acid, and on sulphurous acid gas. Besides these gases, two liquids were also employed—ordinary water and water saturated with common salt. Among other results it was found that the same prism refracted waves of different lengths (or different tones) alike. The results of these measurements corresponded with those indicated by the known velocities of sound in the substances employed, taken in connection with the explanation of refraction as given in the undulatory theory of sound.

Sound-Waves rendered Visible.—Quite recently this feat has been accomplished by the German physicist Töpler, who employed the snap of an electric spark for the generation of the sound-wave, and then illuminated it by the instantaneous light of a second spark. He was thus not only able to see with distinctness a simple sound-wave, but also to observe its reflection, refraction, and the interference of two sound-waves. (Pogg. Ann., cxxxi. s. 180, 1867.)

Inflexion of Sound-Waves.—From the circumstance that the sound-waves are not minute relatively to the obstacles they encounter, it happens that they manifest this property of traveling around corners in a high degree. The corresponding experiments with light require some care, but the inflexion of sound-waves is something that we with difficulty escape from, obstacles placed in their path casting but little acoustic shadow.

Interference of Sound-Waves.—Thus far we have occupied ourselves with single sets of waves, and have supposed the particles of air to be acted on by only one wave at a time. It will, however, more commonly happen that it is necessary to deal with particles which are at the same instant being acted on by more than a single wave. Let us take the simplest case, and suppose our particles acted on by two equal and similar sound-waves; now, it may happen under these circumstances that the two waves agree in their action, any particular layer of air being at the same moment subjected to a condensation or rarefaction from both these sources. When this happens the motion of its particles will be twice as great, and we shall hear a louder sound. But something else is equally likely to occur: it may happen that just at the moment when the layer ought to be condensed by one wave, its companion attempts to rarefy or expand it; these two motions will then neutralize each other, and instead of sound we shall have silence. This can be illustrated with two similar organ-pipes which give exactly the same note; sounding them both together may give a louder tone, or one which is quite faint. If closed organ-pipes are used, the silence, as far as the musical note is concerned, is quite complete, nothing but the hoarse noise which is always mingled with it being perceptible. We can com-

bine both these experiments into a single one by employing organ-pipes which give slightly different tones; if now both sets of waves start fairly together, the condensations and rarefactions being in harmony, this state of things can not long remain, owing to the inequality in their length, as is shown in Fig. 5, where condensation is marked heavily,

FIG. 5.

rarefaction lightly. Already at 1 the condensation coincides with the rarefaction; farther on, at 2, the old state of things has returned; and the condition at 3 is the same with that at 1. Hence in this experiment we must expect to have alternations of sound and silence, the tone rising and swelling to a maximum, then dying away again to repeat itself, etc. These alternations are called *beats*, and furnish even to the unmusical ear a very accurate means of judging of the identity of musical tones. Having considered briefly these general properties of sound-waves, we pass on to some of their distinguishing characteristics. Among the most important of these is—

Length of Sound-Waves.—The pitch of the note, other things being equal, depends on the length of the wave; long waves give low notes—short waves, those that are high. The longest waves, in the air at a temperature of 0° C., which are capable of producing the sensation of sound, have a length of about 66 feet. The tone, from a musical point of view, is imperfect, and in order to remove this defect entirely it is necessary to shorten the wave to about $27\frac{1}{4}$ feet. On the other hand, when the waves are reduced to a length of three or four tenths of an inch, they again become inaudible; to have a useful musical effect their length must be increased to about 3.2 inches. Instead of speaking of the length of the sound-waves, which evidently must vary with temperature, it is more customary to use the number of vibrations producing a given sound; thus, as sound travels at the rate of 1,090 feet per second in the air at 0° C., it follows that a wave 66 feet long will execute in a second $16\frac{1}{2}$ vibrations, and one which is $27\frac{1}{4}$ feet long, 40 vibrations, etc. We give below a table, arranged in octaves, of the number of vibrations of the notes used in music:

$16\frac{1}{2}$	33	66	132	264	528	1056	2112	4224
$\overline{\overline{C}}$	\overline{C}	C	c	\overline{c}	$\overline{\overline{c}}$	$\overline{\overline{\overline{c}}}$	$\overline{\overline{\overline{\overline{c}}}}$	$\overline{\overline{\overline{\overline{\overline{c}}}}}$
$\overline{\overline{C}}$	$\overline{C'}$	C	c	$\overline{c'}$	$\overline{\overline{c''}}$	$\overline{\overline{\overline{c'''}}}$	$\overline{\overline{\overline{\overline{c''''}}}}$	$\overline{\overline{\overline{\overline{\overline{c'''''}}}}}$
$\overline{\overline{C_2}}$	$\overline{C_1}$	C	c	$\overline{c_1}$	$\overline{\overline{c_2}}$	$\overline{\overline{\overline{c_3}}}$	$\overline{\overline{\overline{\overline{c_4}}}}$	$\overline{\overline{\overline{\overline{\overline{c_5}}}}}$
$\overline{\overline{c-3}}$	$\overline{c-2}$	$\overline{c-1}$	$\overline{c^0}$	$\overline{c^1}$	$\overline{\overline{c^2}}$	$\overline{\overline{\overline{c^3}}}$	$\overline{\overline{\overline{\overline{c^4}}}}$	$\overline{\overline{\overline{\overline{\overline{c^5}}}}}$
$\overline{\overline{ut-2}}$	$\overline{ut-1}$	$\overline{ut-1}$	$\overline{ut_2}$	$\overline{ut_3}$	$\overline{\overline{ut_4}}$	$\overline{\overline{\overline{ut_5}}}$	$\overline{\overline{\overline{\overline{ut_6}}}}$	$\overline{\overline{\overline{\overline{\overline{ut_7}}}}}$

As will be seen, several modes of notation are employed, the last being the French—that preceding, the method proposed by Sondhaus for scientific purposes. In large organs C with $16\frac{1}{2}$ vibrations is reached, the effect being imperfect:

the piano reaches a with 3,520 vibrations, and sometimes c with 4,224. The highest note employed in the orchestra is d_5 , with 4,752 vibrations (piccolo flute). The practical range in music is from 40 to 4,000 vibrations, embracing seven octaves. The human ear is, however, able to reach eleven octaves; that is, the sensation of sound is produced by vibrations varying from $16\frac{1}{2}$ up to 38,000 in a second.

It is not difficult to measure the length of the sound-waves or the number of vibrations producing them; a very simple means is with the siren of Cagniard de Latour. This instrument consists of a circular revolving disk, C F (Fig. 6), which is provided with fifteen small apertures cut in its substance in a slanting direction; below this disk is a second one, which is stationary, and also provided with a similar set of holes. When air is driven through the apparatus by a wind-bellows the upper disk is set in rotation after the manner of a reaction mill, which has the effect of rapidly opening and closing the set of apertures, so that when a sufficient velocity of rotation has been attained, the pulses of air rushing through produce a low musical note, the pitch rising with the velocity or number of vibrations communicated to the air in a second. Upon the axis is an endless screw, E H,

which, acting on a toothed wheel, S, registers the number of turns made by it in a given time—say, in fifteen seconds. In using this apparatus it is only necessary to raise the pitch of the note furnished by it till it is in unison with the note

FIG. 6.

whose number of vibrations we wish to determine. If, then, this unison is maintained for fifteen seconds, we can, without calculation, read the required number of vibrations directly on the dial-plate of the sirene; then, by dividing the velocity of sound in the air by this number, we have the length of the wave. In the case of a tuning-fork the number of vibrations can be still more directly ascertained by attaching to one of its arms a small piece of fine wire or a minute portion of a feather, and causing this to act as a pen on a revolving cylinder. This latter is covered by a sheet of paper which has been smoked by burning camphor, and when set in revolution registers the vibrations made by the tuning-fork on the lampblack surface. Seconds marks are simultaneously impressed on the smoked paper by an electro-magnetic attachment; so that afterward it is not difficult to obtain the desired result with a high degree of accuracy. There are also other methods of measuring the length of sound-waves, based on the principle of interference, and Prof. Mayer, of Hoboken, has succeeded in measuring wave-lengths in the air. (*American Journal of Science and Arts*, for Nov., 1872, p. 387.)

The Form of a Sound-Wave.—In all that has preceded, and also in the formulas for the sound-wave, we have assumed that the particles of air swing backward and forward, obeying the law of the pendulum; and this is true for pure, simple tones, such as those furnished by tuning-forks. The ear is so constructed as to be able to take up these pendulum-like vibrations, which then produce appropriate sensations in the brain, but it is not capable of directly taking up vibrations which are executed according to laws different from that of the pendulum. Let us take a simple case, and suppose the air acted on by two pendulum-like sets of impulses, due to the joint action of two tuning-forks, one of which in a second executes twice as many vibrations as the other. The particles of air will then obey a new law, and will assume positions and velocities which are the *resultants* due to the action of the two original forces, and the form of the wave will be entirely altered. When this new kind of wave strikes upon the ear it is instantly analyzed into its two constituents, which independently affect their corresponding nerve-fibrils, and a peculiar sensation is produced, due to the presence of two distinct sensations; indeed, as Helmholtz, to whom we owe these interesting facts, has shown, it is possible after some practice to actually recognize the two original constituents. If we add a third, a fourth, or any number of new sets of impulses, the law changes with each, and also the resulting form of the wave, and consequently the final sensation. Conversely, if by any other means we generate waves having forms *not normal*, and present them to the ear, they will instantly be analyzed into a sufficient number of normal forms to meet the requirement, and a corresponding number of sensations will be produced. For example, reed-pipes, or a reed alone, furnish waves with an abnormal form, and the sound from them is analyzed, as Helmholtz has shown, by the ear into sixteen to twenty sets of normal waves or pure simple tones. We may add here that, as in this example, it is not necessary that these distinct sets of waves or notes should be independently generated, but merely that the original wave should have a form capable of being analyzed into these simple constituents. Even the form of the wave furnished by the sirene is not

normal; along with its proper or fundamental note the octave is *virtually present* in an amount which is often somewhat embarrassing. These higher notes, which accompany the proper or fundamental tone, are called overtones, or harmonicals, and it is their presence which determines the quality of the sound, or its *timbre* or *clang-tint*. In the case of tuning-forks the overtones are absent, hence the hollow and somewhat poor character of the sounds they emit; with closed organ-pipes they are scarcely present to any extent, though more so with open pipes, where the first and second overtones can be distinctly recognized—i. e. the octave and the twelfth. In reed-pipes they are present in great abundance and strength, so as quite to change the character of the fundamental note; the same is true of stringed instruments. It is the presence of these overtones which enables us to distinguish between different instruments, even when sounding the same fundamental note, and finally which, as we shall see, enables us to recognize the voices of different persons under similar conditions. Our inability to distinguish at once the presence of particular overtones is simply the result of want of practice, and is shared alike by the musical and unmusical. This can be corrected by practice, or by the use of the resonators contrived by Helmholtz. These instruments have usually the form of a hollow sphere, open at both ends of its diameter; one of these openings has a shape adapting it for insertion into the ear; the other aperture is larger, its size being determined by experiment. The size of this opening and the capacity of the sphere are so related that when the sphere is placed in connection with the ear the experimenter is rendered comparatively deaf to all notes but one, the strength of this latter being greatly exalted by the instrument. The analysis of which we have just spoken was to a great extent effected by the aid of these contrivances, a large number of these spheres being of course necessary for purposes of investigation. We may add here that Mr. R. Koenig, so celebrated for his beautiful acoustic apparatus, has pushed this matter one step further, and by connecting these resonators with manometric capsules and small gas-flames has succeeded in rendering *visible* the phenomena of which we have been speaking, thus enabling a person who is deaf still to pursue these investigations.

Cause of Dissonance or Discord.—This peculiar effect, which sometimes attends the reception of two or more sets of sound-waves, has also recently been explained by the investigations of Helmholtz, which have thrown a flood of light on this obscure subject. It has for a long time been known that when two sets of sound-waves are simultaneously presented to the ear, the relation between their length being in some simple proportion, such as 1 : 2, 2 : 3, 3 : 4, or 4 : 5, an agreeable effect is produced, the sounds seeming to melt into each other, producing what is known as consonance; while, on the other hand, more complicated relations often generate discord. To account for this, many fanciful theories have been proposed, of which we will merely allude to that of Leibnitz, who imagined that the mind delighted in the perception of simple mathematical relations, and was displeased by the reverse! It is hardly necessary to say that this is not the true explanation, which we must seek in certain relations of the nerves of sensation to external stimulating causes. The nerves of vision, touch, and hearing are endowed with the following property: when stimulated, the sensation produced is at the first instant at a maximum, and rapidly becomes less intense; if, however, the nerves are allowed to rest for small intervals of time, they quickly regain their former sensitiveness, and this process may be repeated indefinitely. If, now, we expose the eye, for example, to light, we obtain the maximum sensation; then the periodic withdrawal and return of the light may readily be so arranged as to produce in succession a long series of these maxima of sensation, which quickly become disagreeable, and even may be dangerous; it is the case of a flickering light, whose bad effects are so well known. The sensation of tickling is strictly analogous to the above, and is produced by corresponding causes. The nerves have, however, another well-known property; after stimulation the sensation produced is found to remain, or “persist,” for a minute interval of time with undiminished strength; so that in the case of light and sound, if the successive stimulations follow each other at sufficiently rapid intervals, these evil effects are naturally abolished, and only continuous sensations are perceived. Discord is, then, as Helmholtz has ascertained, due to the presence of the beats, or to rapid alternations of sound and comparative silence, they corre-

sponding to the flickerings of a flame. When from any cause these beats follow each other at the rate of about 33 in a second, the discord is at its maximum, becoming more tolerable with twice this number, and finally disappearing altogether as their number is increased to about 120 in a second. On the other hand, if the beats follow quite slowly—for example, at the rate of three to five in a second—the effect is not unpleasant, and can even be employed in music, suggesting as it does the idea of trilling. Discord is then due to the production of beats by the interference of the overtones, which almost always accompany the fundamental notes, and, as has been shown by calculation, this can be entirely or partially avoided only by the use of such simple ratios as those above indicated. For further details we must refer the curious reader to the original work of Helmholtz (*Die Lehre von den Tonempfindungen*, 1865).

Effect of communicating Motion to the Source of Sound or to the Ear.—In all the foregoing it has been tacitly assumed that during experiment the position of the source of sound and of the recipient ear remained invariable; when this ceases to be true, certain curious changes are produced, which recently have grown into importance, owing to their correspondence with certain optical phenomena by which it is possible to study the motion of the fixed stars toward or away from our planet. Let us suppose that the sounding body is stationary, and that the ear of the observer is moved with some rapidity toward it; then it will result that in a given time the observer will receive a larger number of impulses than at first, and that the pitch of the sound will be correspondingly elevated. The same effect will be produced by moving the sounding body toward a stationary ear. And from the same cause it is evident that motion of the ear away from the source of sound will lower the pitch of the note, etc. These ideas were first brought forward by Christian Doppler in 1842, and since then have been repeatedly subjected to the test of experiment. Dr. Ballat, in Belgium, with the aid of a locomotive and a party of musicians, proved their correctness in a quantitative manner, and Dr. Mach has contrived an apparatus with a moving reed-pipe by which they can be studied in an ordinary room; and finally by the use of tuning-forks Prof. Mayer, of Hoboken, has succeeded in illustrating them before large audiences. (*American Journal of Science and Arts*, April, 1872, p. 267.)

The Voice.—As the human vocal organs are built essentially on the plan of a reed-pipe, it is desirable at the start to understand the construction and action of one of these instruments. A reed-organ pipe consists, then, of two parts, a vibrating tongue or reed, and a variously shaped pipe. When connected with a wind bellows the reed is thrown into vibrations, and, after the manner of a siren, permits the air to pass through in a series of puffs, which, linking themselves together, generate a musical tone. The waves furnished by the reed are not, however, normal in form, but, as previously explained, have a form such as would be generated by the joint action of a fundamental normal tone or wave, combined with a set of shorter waves or overtones: in other words, practically it furnishes a fundamental note with a series of strong overtones, the particular fundamental note and corresponding set of overtones depending on the construction of the reed itself and the manner in which it is tuned. The function of the pipe is to strengthen any or all of these notes; thus conical pipes strengthen all the overtones up to a certain height, excluding those that are not much longer than the aperture of the pipe itself, while cylindrical pipes strengthen the odd overtones, or those whose rates of vibration are related to each other, as 1, 3, 5, etc. Hence the pitch of the note is determined by the rate of the reed's vibrations—the quality, or clang-tint, of the sound by the shape and size of the pipe. In the human vocal organs the reed is supplied by two vibrating membranes at M (Fig. 7), called the vocal cords. For the production of sound it is necessary that they should be stretched, and that at the start the opening between them should be closed. Air is then forced through them from the lungs; they are set in vibration, and allow it an interrupted passage, exactly as in the case of a reed, as has been shown by experiments on the living and dissected larynx, or with the aid of artificial vocal cords made of sheet india-rubber. The pitch of the voice depends on the extent to which the membranes are stretched. Müller, by increasing the tensive force $\frac{1}{2}$ oz. up to 18 oz., raised the tone with one of his dissected preparations more than two octaves. The pitch depends also to some extent on the strength of the cur-

rent of air employed, rising as the latter is increased. The human voice includes not quite four octaves, though no one single voice would be able to compass a scale of this extent. The pitch also, other things being equal, depends on the

FIG. 7.

length of the vocal cords; that of men is about 18 mm., with women it is only 12. The clearness of the voice depends on the accurate closure of the slit between the cords, from time to time, while they are in operation. Theory and experiment alike point to the fact that when the vocal cords are set in action waves having an abnormal form are generated, corresponding to a fundamental note with a set of overtones. The function of the cavity of the mouth and nose C C' (Fig. 7) is to strengthen or weaken the fundamental tone and various sets of the overtones; and in this action the size of the opening of the mouth also plays an important part; thus the quality of the sound uttered, or its clang-tint, depends finally on the shape and size of the cavity of the mouth and nose. This cavity, then, corresponds to the pipe of a reed-organ pipe. The vocal cords retaining all the time the same tension, by altering the shape and size of the cavity of the mouth and its opening we can generate sounds having a different clang-tint, as, for example, Ah, O, etc. It is not even necessary to set the vocal cords into action if a complex sound consisting of many tones is supplied from some outward source; thus we were informed by President Barnard, of Columbia College, that by taking advantage of the complex sounds or noise of a railroad-car, and by varying suitably the cavities just referred to, he succeeded in producing musical notes in rapid succession, such as the notes of any familiar melody, at pleasure.

The Vowel Sounds are the simplest which can be uttered by the human voice, and have frequently been made the object of investigation. In 1831 Willis in England found that by mingling certain tones produced by reed-pipes he could to some extent imitate the vowel sounds. (*Pogg. Ann.*, bd. xxiv. s. 397.) In this mode of working there is the obvious difficulty that reed-pipes furnish large sets of notes, so that it is not possible to obtain very accurate knowledge by such experiments. More recently Helmholtz, with the aid of his resonators, above described, succeeded in analyzing the vowel sounds, although they present greater difficulties than most other sounds of equal complexity. This results from the circumstance that, from childhood upward, we all have been accustomed to regard the tones of the vowel sounds as independent wholes, making no attempt to ascertain their musical components, since in the case of a vowel sound the clang-tint is all important, and is indeed the only means by which we judge of its identity. Helmholtz ascertained that vowel sounds are produced by the presence of a fundamental note mingled with its higher

overtones in various proportions; he even was able to prove that the intensity of the highest of these overtones varies somewhat in different individuals, being greater in voices that are shrill than in those whose sound is softer. Having finished this labor, he undertook the artificial reconstruction of the vowel sounds from pure constituents. These are best furnished by vibrating tuning-forks. One of these instruments, alone by itself, furnishes a tone which at a little distance is quite inaudible, but by causing it to vibrate directly in front of a hollow *metallic* cylinder of exactly the right capacity its sound is greatly strengthened, and can be distinctly heard in a room of large dimensions. The cylinder is of course entirely closed, with the exception of a circular opening at the end near the fork. When the fork is thus caused to vibrate in connection with a resonator, the sound is instantly extinguished if the aperture in the cylinder be closed, but as it is gradually opened the sound correspondingly gains in intensity; so that it is evidently in the power of the experimenter to regulate the loudness of the tone produced. A tuning-fork, however, soon ceases to vibrate, and accordingly must be provided with a contrivance to obviate this difficulty. By placing it between the arms of an electro-magnet having the form of a horseshoe, it can be caused to vibrate for any period of time, provided the magnetic attraction is intermittent, and always exercised at exactly the right moment. This is accomplished by breaking and re-establishing the electric current with the aid of another tuning-fork, which vibrates at exactly the same rate; and the second fork, being also provided with a similar electro-magnet, is able independently to maintain itself in vibration for any length of time, as is the case with the vibrating attachment so often found on electrical apparatus for medical purposes. It would not be possible with this arrangement to sustain in vibration a third fork whose rate was a *little* slower or faster than that of its two companions: but if its rate should be exactly twice, three, or four times as great, this end could easily be accomplished; for then, though the attractive impulses might be fewer than desirable, at least they would always be rightly timed. Hence it is evident that a series of forks whose rates of vibration are as 1, 2, 3, etc., can be kept simultaneously in vibration by a contrivance of this nature. This was, then, the plan actually employed by Helmholtz; keys being connected by strings with the valves of the resonators, and being opened by the pressure of the fingers, the proper notes were obtained with the desired strength. Helmholtz's vowel sound apparatus, as made by Mr. Koenig, of Paris, consists of eight tuning-forks with their resonance cylinders, the fork which establishes and regulates the current being on a separate stand. These forks give the following notes: Ut_2 , Ut_3 , Sol_3 , Ut_4 , Mi_4 , Sol_4 , Ut_5 , Si_5 . When all these forks are set in vibration, their resonance cylinders remaining closed, only a low humming sound is heard, but by pressing one or more keys the corresponding notes are called forth with any desirable degree of strength. The German vowel sound *u* can be approximately imitated by sounding the Ut_2 fork alone, or better by adding the two first overtones—i. e. the octave and twelfth, Ut_3 and Sol_3 . *O* is obtained with a weak Ut_2 and strong Ut_4 ; Ut_3 , Sol_3 , and Mi_4 mingling to a small extent. The German *a*, with Ut_5 and Mi_4 strong; Ut_3 , Ut_4 , Sol_4 having a moderate strength. In the same language the *æ* is given by Mi_5 and Sol_5 strong, with the notes Ut_4 , Ut_5 , Sol_4 weaker; and finally the *e* by the aid of Sol_5 , Si_5 , and Ut_6 strong; Ut_3 and Ut_4 being weaker.

Of course, since only pure musical notes are employed, they can only reproduce the musical constituents of the vowel sounds; hence the effect resembles the sound of the vowels as sung rather than pronounced. Corresponding with these remarkable experiments, Helmholtz also found it possible to imitate with the same apparatus certain varieties of organ-pipes; at least to reproduce the musical constituents of their tones, though of course the noise with which they are often accompanied was absent; he in addition imitated the nasal tones of the clarinet by the use of a portion of the forks, while the joint action of the whole set gave the softer tones of the bugle-horn. For exciting the apparatus into action he used only two of Grove's cups, though other experimenters have since then found it somewhat difficult of manipulation, and an attempt has been made by Appun to replace it by a series of reeds provided with resonators, with which it has been found possible to reproduce some of the sounds in question (*u* and *a*).^{*} We

must here mention the remarkable results attained in the last century by Prof. v. Kempelen in Vienna with his speaking-machine, which more recently has been greatly perfected by the two Fabers, uncle and nephew.* Some time ago the latter exhibited in Columbia College, New York, this wonderful apparatus, which is capable of uttering not only syllables, but words and sentences with a certain mechanical precision. In it the human vocal organs are directly imitated by vibrating plates of ivory, and it is remarkable that it is operated on by only fourteen keys or stops, which give the five vowels and the nine consonants, *l, r, w, f, s, b, d, g, sch*. The other consonants are produced partly by combinations of the above, and partly by increasing the strength of the current of air from the bellows. For the purpose of causing the machine to speak French, an extra attachment is provided, whereby more nasal tones can be generated. Mr. Faber has also connected with it a singing attachment, in which, by means of quick changes in the form of the vocal cords, the musical scale can be executed.

Consonants.—These sounds are generally regarded not as constituted of notes having any particular musical relation to each other, as in the case of the vowel sounds, but rather as consisting of different varieties of noise. Thus as examples of explosive noise we have *p* and *b*, *t* and *d*, *k*, *g*, *q*; of frictional noise, *s*, *z*, *sch*, *l*, *f*, *v*, *m*, *n*, and *h*; of intermittent noise, *r*.† The mechanical mode by which the consonants are produced is to a considerable extent understood, but their actual acoustic elements resist all attempts at complete analysis. That they have an acoustic character can not, however, be doubted, and some progress has been made toward ascertaining the natural pitch of their predominant notes. Thus upon repeating (in German) the consonants *b, k, t, f, s*, it will be found that *b* is the deepest in tone, *s* the highest; and that, taken together in the above order, they constitute a series of perceptible musical gradations. For further information we must refer the reader to the original investigations of Dr. Oskar Wolf, who seems to have succeeded in actually determining the pitch of the predominating constituent in the case of most of the consonants.‡

The Ear.—The sensation of sound is produced by the stimulation of certain nerve-fibrils in the interior of the ear, and this result is brought about by the *sound-waves* in the following manner: These waves first strike upon the external ear, and possibly are, to some slight extent, concentrated by it; afterward they travel along the tube D (Fig. 8), and reach the tympanum or drum of the ear at

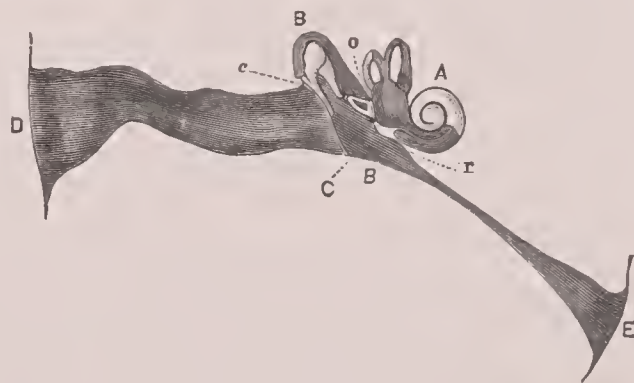

FIG. 8.

C. This consists of a thin membrane which closes the external passage, and which is capable of being set in vibration or of responding to an immense variety of waves or impulses. It may here be remarked that a catholicity of this kind has not thus far been observed in experiments on membranes artificially stretched, whose range is found to be far more limited. There is also some reason to believe that the tympanum is capable of a certain degree of "accommodation" to the sounds that are presented to it, following the well-known analogy of the eye in this respect. Attached to the inner side of the tympanum is a series of three small bones, called respectively the malleus, *c*, the incus, and the stapes, *o* (the hammer, the anvil, and the stirrup. See Fig. 8). These bones are rather closely bound together, and transmit the vibrations of the tympanum finally to the stirrup, which is destined to communicate

them to the inner ear. The portion we are now engaged with has a communication with the mouth by means of the Eustachian tube, E, which is closed except in the act of swallowing; its function is to preserve an equilibrium between the pressure of the air in the middle ear and that on the other side of the drum. While the middle ear is filled with air, the inner is filled with a liquid, and is completely inclosed for protection in solid bone. In Fig. 9 a

FIG. 9.

section of the inner ear is given. SSS are the semicircular canals cut open; V is the vestibule; o and r are the foramen ovale and the foramen rotundum; C is a section of the cochlea. We give in addition a *plan* of the ear, after Helmholtz (Fig. 10), the cochlea, for the sake of clearness, being supposed to be unrolled. A is the vestibule; C the cochlea; a the foramen ovale; b the foramen rotundum; f the nerves of hearing. The sacs at d contain attached to their walls small crystals of carbonate of lime in contact with the nerves, and their function, as it appears, is to render us sensible of simple short sounds or shocks, which probably would not affect the vibratory apparatus presently to be described. They act as *drags* on the nerves when the latter vibrate with the water in which they are bathed, and thus produce sensation. This is the simplest portion of the apparatus for hearing, and is found in many of the lower animals, where the more complicated arrangements are entirely absent. These sacs contain also, in connection with the nerves, certain microscopic hairs, that are quite elastic and brittle, and probably capable of being set into vibration when the particular notes to which they are tuned are presented to them, just exactly as a tuning-fork can be set in vibration by the waves proceeding from a second fork of the same pitch. (See Fig. 11.) In the cochlea we also find a membrane (the organ of Corti) with a great number of fine microscopic cords stretched in it, which probably have the same function. The reader will find, by opening a piano and pressing the foot upon the right-hand pedal, that if then the vowel sounds, for example, are pronounced in a loud, clear voice over the strings, it will result that the strings which are capable of giving the notes of which they are built up will be set in vibration, and will echo back somewhat faintly the original sounds. And so it is probably in this portion of the ear; these microscopic strings, being thus set in vibration, stimulate the nerves connected with them and produce corresponding sensations. If the

FIG. 10.

sound is compound or the form of the wave abnormal, this sound is analyzed into its constituents, since the cords (and rods) can only execute normal vibrations; which circumstance explains much that was said under the head "Form of the Wave"; and we see finally that the clang-tint is the

sensation produced by the simultaneous action of two or more of these strings upon their appropriate nerves. The cochlea contains about 3,000 of these strings, and if, with Helmholtz, we suppose that 200 of them are useful for rendering us sensible of tones not used in music, there will remain for the musical tones proper 2,800 for the seven octaves, or 400 for each octave, 33½ for each half tone. Now, according to the experiments of E. H. Weber, skillful musicians can distinguish ¼ of a half tone, which is a smaller quantity than corresponds to the number of these strings. It would appear, then, that in this case *two* of these strings are at the same time excited into action, and the musician by practiced attention is able to notice which of them vibrates the more strongly.

As rendering the above views more probable, we may mention the experiments of Von Hensen on the ears of crabs, which he inclosed in an artificial ear corresponding to the labyrinth. The ears of these crustaceans are partially external, and consist of sets of hairs capable of vibration, connected with the nerves, as in the case we have just been considering. When different notes were sounded, Von Hensen was able with the microscope to notice that certain hairs responded, etc.* The functions of certain portions of the ear are still involved in much obscurity; this is the case, for example, with the three semicircular canals, concerning whose object and use we possess as yet no certain information. Among the fishes the myxine has one of these canals, the lamprey has two, the higher forms three; and it appears that in birds of prey they become highly developed.

In closing this article it may be proper briefly to mention the results obtained with the *phonautograph* of Scott and Koenig. This may be regarded as a gigantic ear, endowed with the power of permanently registering the vibrations of its own tympanum. It consists of a parabolic mirror, M (see Fig. 12), of zinc, which concentrates the sound-waves,

and causes them to set in vibration a thin membrane, t, which is provided with a "pen" attached to its center. The vibrations are in this way finally inscribed on the surface of a revolving cylinder, C, which is covered with paper smoked by burning camphor. The figure gives a view of this apparatus seen from above. With this instrument Koenig succeeded in obtaining the autographic curves to single notes, or to the joint action of several within the compass of an octave. Donders, however, was able after much trouble to obtain the complex curves due to the vowel sounds. For u (German) it was a common sine curve, as it should be; this was also true for ü and i, the instrument being able to reproduce neither the weak overtones of the first nor the high overtones of the second. The form of the curve altered with the pitch of the voice uttering the vowel, but changes in dialect produced only slight modifications. With diphthongs the duration of the sound and modifications due to change from one diphthong to another were rendered visible. Consonants spoken just before a vowel altered only the beginning of the curve, and produced only a corresponding modification when uttered immediately after the vowel. The duration of a in the word daag = 42, in dagen = 37, in

FIG. 11.

FIG. 12.

* Von Hensen, *Studien über das Gehörorgan der Dekapoden*; Von Siebold u. Kölliker, *Zeitschrift für wiss. Zoologie*, bd. xiii.

dag = 16 vibrations, each single vibration consuming $\frac{1}{16}$ of a second, so that the actual durations were 0.16, 0.142, 0.061 of a second of time.

O. N. ROOD.

Acoustic Telegraph: any telegraphic system in which messages are received by ear. The Morse system of telegraphy as practiced in the U. S., where the "sounder" takes the place of the "recorder," is an example. See TELEGRAPH.

Acoustic Telephone: a telephone in which the voice is transferred between the transmitter and receiver by means of sound-waves traveling along the wire or other conductor connecting them. No electric current, as in other telephones, is used. Acoustic telephones are of comparatively limited application, their range of effective use rarely exceeding a mile. Over short distances, however, they may be made to give excellent service. See TELEPHONE.

Ac'qui, ak'kwee: a town of Italy, in the province of Alessandria, on the Bormida; 21 miles by rail S. S. W. of Alessandria (see map of Italy, ref. 3-B). Here are iodide and sulphate-of-lime waters, which are much frequented, and ruins of an old Roman aqueduct. Acqui is of great antiquity, and its hot sulphur baths were known to the Romans, who called the place *Aque Statiellæ*. Good wine is made in the vineyards of the district, and the rearing of silkworms is followed with much care. It has a cathedral, several fine buildings and silk factories, a royal college, and is a bishop's see. Pop. 11,300.

Acquit'tal: [O. Fr. *aquiter*; Lat. *ad* + *quieta're*, settle]: in law, a release from a contract or other obligation; more usually employed in criminal practice, where it denotes a judicial deliverance from a charge of guilt, either by a verdict of not guilty by a jury upon a trial, termed "acquittal in fact," or by mere operation of law, as where one has been charged simply as accessory, and the principal is acquitted. An acquittal is a bar to any future prosecution for the same offense. In the U. S. this is secured by a constitutional provision that "no person shall be twice put in jeopardy for the same offense." The judicial construction of this clause prevents a second trial for the same offense after an acquittal.

A'cre [from the Ang.-Sax. *acer* or *æcer*, a field, etymologically allied to the Lat. *ager* and Ger. *Acker*]: a superficial measure of land; equal to 4,840 sq. yards. The "English" or statute acre of Great Britain is the same as the acre of the U. S. Forty-eight Scotch acres (now seldom used) are equal to 61 statute acres. The Irish acre (now seldom used) contains 7,840 sq. yards. The Welsh acre, or *erw*, contains 4,320 sq. yards. A French acre contains about one *arpent* and a half.

Acre, ak'er, Ak'ka, or **St. Jean d'Acree** [Phœnician *Acho*, and called by the Greeks *Ptolema'is*]: a city and seaport of Syria; on the Mediterranean; 30 miles S. of Tyre and 8 miles N. of Mt. Carmel; lat. 32° 54' N., lon. 35° 6' E. (see map of Palestine, ref. 5-D). The "key of Palestine," it has been the scene of many famous sieges and battles. It was taken by the Crusaders in 1104, and retaken by the Saracens in 1187. In 1191 it was recovered by the Crusaders (under Guido of Jerusalem, Philip of France, and Richard the Lion-hearted of England), and held by them till they were finally driven out of Palestine in 1291. Bonaparte besieged it for sixty days in 1799, but failed to take it. In 1840 it was bombarded and captured by the English fleet. Pop. about 8,000, of whom 5,600 are Moslems.

Acre'lins, ISRAEL: a clergyman; b. at Ostaker, Sweden, Dec. 25, 1714; was educated at Upsal, and was appointed in 1749 a provost to take charge of the Swedish congregations on the Delaware. After a sojourn of seven years in the U. S., he returned to Sweden in 1756. He wrote a description of the Swedish colonies in America (1759). D. Apr. 25, 1800.

Ac'robat [viâ Fr. *acrobate*, from Gr. *ἀκρόβατος*, walking on tiptoe, climbing aloft; from *ἄκρος*, highest + *βαίνειν*, go]: a rope-dancer, or person who entertains the public by performances on the tight rope or slack rope, and by gymnastic feats of agility, such as vaulting and tumbling.

Acrob'ates (i. e. the acrobat): a genus of Australian marsupials, which contains only the "opossum mouse" (*Acrobates pygmæus*), which has a fold of skin running along the sides of its body, as in the flying squirrel. It is about 4 inches long, and shows remarkable powers of leaping. It feeds on insects, and on honey which it obtains from flowers.

Aerocerau'nia [from *ἄκρον*, a peak or promontory, *κεραυνός*, thunder]: the ancient name of a chain of mountains on the western coast of Greece, and extending into the sea by a bold promontory; so called because violent thunderstorms are said to be frequent in that region. The modern name is Chimara. The Aeroceraunian promontory is Cape Linguetta; lat. 40° 27' N., lon. 19° 18' E. (see map of Greece, ref. 14-II).

Ac'ro-Corin'thus: a steep, rocky hill near the city of Corinth, in Greece; about 2,000 feet high. On this hill stood the Acropolis or citadel of Corinth. The view from the top is very extensive and beautiful.

Acrog'enous [Gr. *ἄκρον*, tip + *γεν-*, come into being]: growing only at the apex of the stem. Conferva, molds, etc., are plainly acrogenous. The term was formerly applied to mosses and ferns exclusively (class *Aerogens*), but has fallen into disuse, as it is now known that all the larger plants are as truly aerogenous as these. CHARLES E. BESSEY.

Aero'lein, Acryl'ic Al'dehyde, C₃H₄O: an intolerably pungent body produced by the dehydration of glycerin. It is always produced when neutral fats containing glycerin are subjected to destructive distillation, and is the chief cause of the offensiveness of that operation. It is the substance that acts so strongly upon the eyes when in cooking meats the fats are heated too high.

Aeron'ycal, or (more correctly) **Aeronychal** [Gr. *ἀκρόνυχος*, at evening, from *ἄκρον*, extremity + *νύξ*, night]: in opposition, diametrically opposite. A star or planet is said to be acronycal when it is opposite to the sun, or passes the meridian at midnight. It rises acronycally when it rises as the sun sets, and sets acronycally when it sets as the sun rises.

Aerop'olis [Gr. *ἀκρόπολις*, citadel; from *ἄκρος*, highest + *πόλις*, city]: the citadel of an ancient Grecian city, usually built on the peak or top of a hill. The Acropolis of Athens was especially celebrated, and was adorned with the Temple of Minerva or Athena, called the Parthenon, the Erechtheum, the Propylæa or gate-house, and a number of smaller buildings, monuments, and statues, among which was a colossal statue of Athena which must have been visible many miles at sea.

Aeros'tic [etymologically spelled *acrostich*; cf. *distich*; Gr. *ἀκροστιχίς*, from *ἄκρος*, extreme + *στίχος*, line]: a poem so contrived that the first, last, or other series of letters of the lines shall form some name or phrase. Sir John Davies wrote twenty-four hymns to Astræa, each of which is an acrostic on Elizabetha Regina (Queen Elizabeth). On a somewhat similar principle, in the poetry of the Hebrews the initial letters of the verses were made to correspond to the letters of the alphabet in their proper order. The 119th Psalm affords perhaps the most remarkable example of this. Every line in the first division of the psalm begins with א (aleph), and in the second division with ב (beth), and so on.

Act: (1) in dramatic literature, a division of a drama; it is again subdivided into scenes. The Greek dramas of the old model were naturally divided into separate portions by the choric odes (or stasima), which occur at intervals, during which the stage was left to the sole occupation of the chorus. Nevertheless, the Greek writers do not notice this division in express terms; nor do we know the origin of the famous rule of Horace, that every dramatic piece should be restrained within the limits of five acts, neither more nor less. The division into acts must be in great measure arbitrary, although rules have been laid down by various writers to define the story or plot which should be contained in each of them. Thus Vossius gives it as a rule that the first act should present the intrigue, the second develop it, the third be filled with incidents forming its knot or complication, the fourth prepare the means of unraveling it, which is finally accomplished in the fifth.

(2) In legal and political language, an act is a law or statute which is approved and ordained by the legislature, as an act of Parliament, an act of Congress. The proposed law is called a bill until it has passed through the first, second, and third readings, and has been approved by both Houses of Parliament (or Congress) and signed by the executive. An act which binds the community at large is a public one, while one that operates merely upon particular persons is said to be a private or special act.

(3) In the English universities, an act is an exercise performed by students before they receive a degree. The student who is said "to keep the act," and is called the respondent.

chooses certain propositions, which he defends by syllogisms. Several other students, called "opponents," who are nominated by the proctor, try to refute his arguments.

ACT OF SETTLEMENT, in Great Britain, is the title of the statute 12 and 13 of William III. c. 2, by which the crown was limited to the House of Hanover, and all Roman Catholics were excluded from the throne.

ACT OF SUPREMACY, the statute by which the supremacy of the British crown in ecclesiastical matters within the realm was established (1 Eliz. c. 1).

Ac'ta Diur'na (daily acts): also called *Ac'ta Populi*; an official gazette or journal published by authority in ancient Rome. It contained brief notices of the transactions of public assemblies, legal tribunals, etc., as well as of private events—births, marriages, divorces, deaths, etc. Julius Cæsar was the first to order that the Acta Diurna should be drawn up in regular form and exposed on a tablet in a public place, where they could be read and copied. They were afterward deposited with the state archives.

Revised by M. WARREN.

Ac'ta Erndito'rum (acts of the learned): the first literary journal founded in Germany; was established at Leipzig in 1682 by Otto Mencke and others. It had a high reputation, and was continued until 1782.

Ac'ta Mar'tyrum (acts of the martyrs): a collection of the lives of Christian martyrs. The most noted is that of Ruinart (Paris, 1689), commemorating the martyrs of the first four centuries.

Ac'ta Sancto'rum (acts of the saints): a collection of the lives of Christian saints of all ages. The most extensive collection is that of the Jesuit Bollandists, which begins with January and follows the calendar. The first volume appeared in 1643; the fifty-fourth, which comes down to Oct. 14, in 1793; the fifty-fifth in 1845; the sixtieth, which comes down to Oct. 29, in 1867; the sixty-first in 1875; the sixty-fifth in 1892. See *Études sur les Bollandistes*, by Pitra (Paris, 1850).

Actæ'on (Ἀκταίων): in Greek mythology, a famous hunter, grandson of Cadmus. It is said that he was changed into a stag and killed by his own hounds because he had seen Diana bathing.

Ac'tian Games: games celebrated at Actium, in Greece, in honor of Apollo. They were restored by Augustus to commemorate his victory over Antony at Actium (31 B. C.).

Actiniidæ [from Gr. ἄκτις, -ίως, ray + -ιδæ, family name]: a family of radiated marine animals, the sea-anemones, closely allied to the coral polyps, but growing singly instead of in colonies, and possessing no hard skeleton. They are cylindrical in form, with very contractile muscular walls, and attach themselves very firmly by one end, the pedal disk.

One of the actiniidæ.

The upper end of the cylinder is closed by the oral disk, which bears around its margin several rows of hollow tentacles. The mouth is an oval slit in the center of the disk, and from its edge an œsophageal tube, often called the "stomach," hangs downward, and opens freely below into the general body cavity. The latter is a sac in which digestion is carried on, and represents both body cavity and stomach. Its peripheral portion is divided into a number of compartments by means of thin partitions or mesenteries, which extend inward from the body wall, many of them joining the œsophagus. Below the latter their inner edges are free, and bear the gastric filaments together with other long, slender threads, richly provided with batteries of stinging cells. (See ACALÉPHÆ.) The genital glands lie embedded in the mesenteries. A nervous system is developed, but special sense organs seem to be wanting. Some of the sea-anemones are among the most beautiful of marine animals, their radiating tentacles and brilliant coloration suggesting the names by which they are known, sea-anemones, See-Rosen, anthozoa, etc. They occur in vast numbers along the shores, and often fairly carpet the rocks exposed at low tide. When

disturbed, or when thus exposed, they contract themselves into an unsightly ball, withdrawing from view the sensitive oral disk and its tentacles, leaving exposed only the tougher body wall. The latter is often covered with sand and broken shells, and the contracted animals thus simulate in color the rocks to which they are attached. DAVID S. JORDAN.

Ac'tinism [from the Gr. ἄκτις, -ίως, ray]: the chemical action of light. The rays of the sun produce three important effects: thermal, chemical, and optical. All rays, without exception, produce heat when intercepted, in direct proportion to their kinetic energy. All, so far as known, have chemical action; a single group only, lying between narrow limits as to wave-length, affects the eye. Actinism is the term commonly applied to the chemical action of light, an action scarcely less important than the thermal and optical effects, since in all probability many essential processes in nature, such as the formation of chlorophyll and the accompanying reactions so necessary to plant life, are dependent upon it. Those rays which lie beyond the violet of the visible spectrum are generally known as the actinic rays, for the reason that the reactions by means of which actinism was first investigated, such as the combination of hydrogen and chlorine, and the modification of certain salts of silver and of other metals, chiefly employed in photography, are most marked in the violet and the ultra violet.

When a beam of compound light is dispersed by the prism, the most energetic action upon the chloride of silver is found in the violet rays of the spectrum; but this effect, as shown by Stokes, extends very far into the darkness beyond the violet. Stokes made the additional remarkable discovery that these non-luminous rays become luminous when certain substances are presented to them. Such substances, among others, are solution of quinine sulphate, infusion of horse-chestnut bark, glass tinted yellow by oxide of uranium, and fluor-spar. This phenomenon was named, by its discoverer, *fluorescence*. (See FLUORESCENCE.) The heating effect of the prismatic spectrum, on the contrary, is found to be more remarkable in the red than anywhere else among the luminous rays; while the maximum heating effect is entirely outside the spectrum, and in the dark. This discovery, made long ago by Sir William Herschel, is a counterpart to the more recent one of Stokes just mentioned; and both taken together show that the sunlight, as dispersed by the prism, spreads through a wide space, in which the rays exciting vision occupy only the middle part.

The luminous, heating, and chemical effects of light being so broadly different, it was natural, in the earlier stages of this investigation, to ascribe them to agencies or forces essentially differing from each other in physical character. It was common, therefore, to say that the sunlight is made up of three independent species of rays: the colorific, the calorific, and the chemical.

Instead of the word chemical, Dr. Draper, of New York, proposed, in 1842, to substitute the term *tithonic* to distinguish the rays of the class last mentioned; this term being derived, by a fancied analogy, from the beautiful myth of Tithonus and Aurora. Sir John Herschel, a little later, suggested the term *actinic*, which ultimately prevailed. To the three kinds of rays above mentioned, Dr. Draper, in 1844, proposed to add a fourth, under the name phosphorogenic rays; that is to say, rays which cause certain substances, which have been acted upon by them, to continue for some time afterward to *phosphoresce*, or to give light in the dark. Dr. Draper believed it to have been established by his experiments that these rays, though imparting to material bodies the light-producing power, are themselves totally distinct from light. It is now perfectly well established, however, that, physically considered, the sunlight is homogeneous, the variety of effects produced by it being consequences of the different degrees of rapidity with which the vibrations of the luminiferous ether are performed, and being especially dependent on the nature of the surface and of the substance upon which the rays are received.

The actinic properties of light have formed the basis of an art having an almost endless variety of useful applications. For particulars in regard to this, see PHOTOGRAPHY. See also Abney, *A Treatise on Photography*; Meldola, *The Chemistry of Photography*. Revised by E. L. NICHOLS.

Actinom'eter [from Gr. ἄκτις, ray + μέτρον, measure]: an instrument for measuring the sun's radiation. The earliest form was described by Herschel in 1825; other forms are due to Pouillet, Violle, Crova, and Langley. The principle

made use of consists in determining the initial rate of heating of a thermometer bulb when exposed to the direct rays of the sun, the water equivalent of the bulb being known. The loss by radiation, etc., is controlled by surrounding the bulb by a spherical shell, which is maintained at a constant temperature.

The name has also been applied to instruments for measuring the brightness of daylight or sunlight by means of its chemical action. To this class belong the hydrogen-chlorine actinometer suggested by Draper, and later elaborated by Bunsen and Roscoe—an instrument for determining the intensity of illumination from the rapidity with which a mixture of the two gases combines under exposure to form hydrochloric acid. To the same class belongs Dr. Henry Draper's apparatus for the reduction of ferric to ferrous oxalate, under light exposure, by the reaction,

Much better than these was the recording actinometer of Bunsen and Roscoe, afterward perfected by Roscoe, and independently modified and elaborated by Abney, in which carefully prepared chloride-of-silver paper of standard sensitiveness was exposed for a definite interval of time, and under uniform conditions, to the action of the light to be measured.

It must be said of all chemical actinometers that they are ill adapted to afford exact indications of the intensity of sunlight. On the one hand, whatever reaction may be selected, the effect will depend upon the presence of some particular group of rays, and will not be directly proportional to the intensity of that group; on the other hand, daylight, owing to the selective absorption of the earth's atmosphere, varies widely in composition, so that the ratio of intensity of the particular wave-lengths upon which we depend for the chemical reaction to the total intensity fluctuates. The indication of the chemical actinometer is therefore not a direct measure of the solar radiation. As a means of showing the chemical activity of sunlight for a given class of sensitive salts such instruments serve a useful purpose. See Herschel, *Edinburgh Journal of Science* (1825), and Pouillet, *Comptes Rendus* (1838); Violle, *Annales de Chimie et de Physique* (1877-79); Langley, *Researches on Solar Heat*, p. 45 (professional papers of the Signal Service, No. 15); Bunsen and Roscoe, *Pogg. Annalen*, c. ci. cviii.; Abney, *Treatise on Photography*, p. 247. E. L. NICHOLS.

Actinom'etry: the measurement of solar radiation. The instruments chiefly employed for this purpose are various forms of actinometer (*q. v.*) and the pyrhelimeter of Pouillet; all of which are designed for the determination of the total energy derived from the sun's rays in a unit of time, per square centimeter of surface exposed to radiation, without reference to the composition of the ray. The researches of Langley, Crova, Vogel, and others on solar radiation have shown the inadequacy of the usual methods. The complete solution of the great problem with which actinometry has to deal will involve the study of the action of each wave-length separately, and of the ever-varying constitution of sunlight, as modified by the absorption due to the earth's atmosphere. See **BOLOMETER**, **RADIATION** (in the article **HEAT**), and **SPECTROPHOTOMETER**. E. L. NICHOLS.

Ac'tion: in law, a proceeding before a court of justice by one person against another to obtain redress for the infringement of a right, in the manner prescribed by law. This definition would exclude such proceedings as mandamus and prohibition. The word is not properly applied to courts of equity, but the corresponding proceeding is there termed a suit. A civil action is instituted for the enforcement of a private right or the redress of a similar wrong. In reference to the place in which they are to be brought, they are either local or transitory. Civil actions are either real, personal, or mixed. Criminal actions are prosecuted in the name of the state against some person charged with the commission of a crime. The distinction between real and personal actions refers to the point whether the recovery of land is sought, or damages by way of compensation, or specific personal property. An action is local when by a rule of law it must be brought in a particular locality, such as a county. Actions not so localized are termed transitory. Penal actions are brought to enforce a penalty imposed by law for the commission of a prohibited act. Common law actions are those which can be maintained without the aid of a statute, while those which are based on statutes are called statutory actions.

The number of actions under these rules is quite consider-

able. The distinctions between them are sometimes subtle and perplexing. There is a marked tendency in this country to modify or to do away with them, and to establish a single form of civil action, embracing proceedings both in law and in equity. Revised by H. W. ROGERS.

Action (local): in voltaic cells, see **BATTERY**.

Ac'tium (now called **A'zio**): a promontory and town of ancient Greece, in Acarnania, near the entrance of the Ambracian Gulf (see map of Greece, ref. 16-I). Here occurred the great naval battle of Actium (31 B. C.), between Octavius Cæsar and Mark Antony; the former gained a decisive victory.

Activity: See the Appendix.

Acton, JOHN EMERICH EDWARD DALBERG, Lord: b. in 1834; elected to Parliament for Carlow in Ireland in 1859. He belonged to the liberal Catholic party, in whose interest he founded the *Home and Foreign Review*, which was published 1862 to 1864, when it was condemned by the English Roman Catholic hierarchy. In 1865 he was returned to Parliament from Bridgnorth by a majority of one, but on a scrutiny he was unseated, and in 1869 created a peer of the United Kingdom by the title of Baron Acton of Aldenham. In the same year he repaired to Rome on the assembling of the Ecumenical Council, where he rendered himself conspicuous by his opposition to the definition of the dogma of papal infallibility. In 1887 Lord Acton was made D. C. L. at Oxford, and in 1890 was elected to an honorary fellowship at All Souls College, Oxford, a distinction shared only by Mr. Gladstone. Educated in early life under the direction of the celebrated Dr. Ignatius von Döllinger, of Munich, Lord Acton's intimacy with this distinguished theologian ended only with the death of Von Döllinger.

Revised by W. S. PERRY.

Act of Parliament: See **ACT**.

Acts of the Apostles: See **APOSTLES**, **ACTS OF**.

Acts of Uniformity: acts passed by the Parliament of England in 1549, 1559, and 1662, the object of which was to secure in every congregation of the Church of England the same form of public prayer, administration of the sacraments, and other rites. The act passed in 1662 is still in force, though an amendment, or an amended act, was adopted, 35 and 36 Victoria, cap. 35, providing for a shortened form of service for morning and evening prayer on any day other than Sunday, Christmas day, Ash-Wednesday, Good Friday, and Ascension day, and also supplying services for other special occasions.

Actuary: primarily a clerk; one who keeps records. The term is used more especially to designate those officers of business corporations whose duty it is to apply the doctrine of chances to financial matters. The work of the actuary is the basis for the business of life-insurance.

Actus: a term used in scholastic philosophy to mean actuality as opposed to potentiality. Two kinds are distinguished: First act is the being or existence of a thing—that determination whereby pure being is particularized or differentiated so as to constitute this being in contrast to that being. Second act, called also immanent or transient act, is the operation or activity of the thing which passes over to another thing in the shape of influence or causality. *Actio immanens*, or immanent act, is an action that does not proceed beyond the being—contemplation, for example—while *actio transiens*, or transient act, proceeds out to another. *Actus purus* is an important distinction in theology, meaning a being which has all its possibilities realized, so that it is a perfect being. God is *actus purus*, and not a mixed being containing potentiality. These distinctions are derived from Aristotle, *actus* being equivalent to *ἐνέργεια*, and *actus purus* being equivalent to *ἐντελέχεια*. See Thomas Harper, *The Metaphysics of the School*, and Pierre Nova's *Dict. de Terminologie scolastique*. W. T. HARRIS.

Ac'upuncture [as if from Lat. *acupunctu'ra*; *acū*, with a needle + *pun'gere*, prick]: the surgical operation of puncturing a diseased part with needles. The operation of introducing needles for curative effects has been practiced in the Orient from prehistoric times; the same mode of treatment was in vogue among Western nations, and was largely used in Europe during the Middle Ages. Acupuncture consists in the introduction of long needles directly into a diseased part, such as the muscles of the back in lumbago or those of the thigh in sciatica. Practically no pain is given, and if the needles are sharp and clean no injury results. Six

or more needles are inserted deeply into the affected part and allowed to remain for ten or more minutes. The improvement is sometimes marvelous and immediate. W. P.

Ada: on railroad, Hardin co., O. (for location of county, see map of Ohio, ref. 3-D); 57 miles W. of Crestline, 15 miles E. of Lima, in the midst of a rich agricultural region; has but few factories, but is an educational center, the Ohio Normal University, with over 3,000 students, being located here. Pop. (1880) 1,760; (1890) 2,079; (1900) 2,576.

EDITOR OF "RECORD."

Adagio, a-daa'jō [Ital. *adagio*, at ease]: Italian musical term, denoting a slow movement of measure of time.

Adai: See CADDOAN INDIANS.

Adair, a-dār', JOHN: general; b. in South Carolina in 1759. He commanded a body of Kentuckians at the battle of New Orleans in 1815, and was Governor of Kentucky from 1820 to 1824. He was U. S. Senator (1805-06) and member of Congress (1831-33). D. May 19, 1840.

Adal, ää-daal': a narrow tract of Eastern Africa, bordering on the Red Sea, and extending from Massowah to the Strait of Bab-el-Mandeb, now a part of the Italian colony of ERITREA (*q. v.*).

Adalbert: a descendant of the famous Saxon family, the Counts of Wettin; was appointed Archbishop of Hamburg and Bremen—to which diocese the whole of Scandinavia belonged—in 1043 by the emperor, Henry III., and in 1050 Leo IX. made him legate to the North. Endowed with a powerful intellect and an irresistible eloquence, and possessed of a vast ambition, he formed a plan for combining Germany and Scandinavia into a northern patriarchate—a plan which, if realized, would have changed not only the history of Germany, but probably that of the Roman Catholic Church. But all his exertions were frustrated by the resistance of the Norwegian King Harald, by the intrigues of Cardinal Hildebrand, and by the death of his great patron, Henry III. He now confined himself to German politics, and gained such an ascendancy over the young Henry IV. that for years he was the actual ruler of the empire. In 1066 his enemies, the Archbishops of Mayence and Cologne, succeeded in expelling him from the court; the Billmeyer, a rival Saxon family, invaded his territory; and the Slavs burnt down Hamburg. But Adalbert came victorious out of all his trials. In 1069 he returned to the imperial court, and vindicated himself in his position till his death, Mar. 16, 1072. See Grünhagen's *Adalbert, Erzbischof von Hamburg* (1854).

Adalia, or **Satalieh** (anc. *Attalia*): a seaport of Turkey in Asia; in Anatolia, on the gulf of the same name; 175 miles S. E. of Smyrna, in lat. 36° 52' 2" N., lon. 30° 45' E. (see map of Turkey, ref. 6-E). It is built on the slope of a hill, has narrow, dirty streets, and a small but good harbor. Tropical fruits are exported hence. Pop. estimated at 13,000, of whom about 3,000 are Greeks.

Adam [Heb. אָדָם, i. e. man]: the first man (see Gen. i., ii. and iii.); supposed to have been created, according to the Hebrew chronology, 4004 B. C., and according to the Septuagint chronology 5411 B. C., though some writers contend that no chronology of the creation of man was intended to be given in the Bible. See PRE-ADAMITES.

Adam, ADOLPHE CHARLES: French composer; b. July 24, 1803; published numerous popular operas and ballets, of which the most celebrated are *Le postillon de Longjumeau*, which was played for the first time in 1836, and gained great applause; *L'roi d'Yvetot* (1842); *Richard in Palestine* (1849); and *La jolie fille de Gand* (1839). D. May 3, 1856. Best known in the U. S. by his *Cantique de Noël* (holy night).

Revised by DUDLEY BUCK.

Adam, Mme. EDMOND (née *Juliette Lamber*): author; b. at Verberie, 1836; married first M. la Messine, and afterward M. Edmond Adam, who was prefect of police in Paris during the Franco-German war. Mme. Adam remained in Paris during the siege, and published her experiences in *Le siège de Paris: Journal d'une Parisienne* (1873), which has been followed by numerous works, mainly on political and social subjects, especially the condition of women. She founded the *Nouvelle Revue*, and conducted it with great ability from 1879-86.

Adam, GRAEME MERCER: Canadian author; b. at Loanhead, Midlothian, Scotland, in 1839. He was educated at Edinburgh; went to Canada in 1858, and engaged in literary work and publishing in Toronto; removed to New York

in 1876, and helped to found the publishing-house since developed into the John W. Lovell Publishing Co. He returned to Toronto in 1878; established *Canada Educational Monthly* in 1879, and was its editor for five years. In 1880 he became editor of *Canadian Monthly*, established by Prof. Goldwin Smith and himself some time before. Among his works are: *The Northwest, its History and its Troubles* (Toronto, 1885); *Outline History of Canadian Literature* (1886); and, in conjunction with Ethelwyn Wetherald, *An Algonquin Maiden* (1887).

NEIL MACDONALD.

Adam, ROBERT: British architect; b. at Kirkcaldy, Scotland, in 1728; d. in London in 1792. He designed several important buildings, among which may be mentioned the University, St. George's church, and the Register House, Edinburgh. He is best known by his work on the ruins of the palace of Diocletian at Spalatro, published in 1764. This is, except the work of Stuart and Revett, the most important archæological book of the eighteenth century.

RUSSELL STURGIS.

Adam of Bremen (*Adam Bremensis*): the author of a history (in four books) of *The Propagation of the Christian Religion in North Germany and Scandinavia* from the time of Charlemagne down to Henry IV., to which work is added *A Geographical Description of Denmark and the Countries beyond Denmark* (Sweden, Norway, Iceland, Greenland, the Faröes, etc.). The year of his birth is not known, but he was invited from Magdeburg to superintend the high school of Bremen, and all the schools of the Bremen church, in the year 1067. He was one of the best educated men of his time. He was thoroughly acquainted with the Church fathers, such as Hieronymus, Ambrosius, Orosius, Cassiodorus, Gregory of Tours, Gregory the Great, and Beda. He had diligently studied the heathen poets, Vergil, Horace, Juvenal, Perseus, and Lucan, who were his favorites. Among the prose-writers he gave special attention to Sallust, Cicero, Macrobius, Solinus, and Martianus Capella. With such preparation he went to work toward the close of his life to write the history of the Church of the North. In order to get the facts he went personally to Denmark, where he visited Svend Estridson, "who knew the history of the barbarians by heart, as if it had been written." Adam succeeded in getting at all the facts, and produced, writing in Latin, the most complete and the most reliable work on the propagation of Christianity in the North that we have. The appendix to his work, which gives a pretty complete geographical description of the North, is especially valuable, for it contains a distinct mention of America, which had been discovered by the Norsemen. After Adam has described Iceland and Greenland, he says: "Besides, he (Svend Estridson, King of Denmark and nephew of Canute the Great) mentioned another land which had been discovered in this ocean (the Atlantic), which is called Vinland, because the vine, producing excellent wine, grows there spontaneously; and corn grows there abundantly without being sown. This we know, not from fabulous conjecture, but from positive statements of the Danes." Adalbert, Archbishop of Bremen, died in 1072, and Svend Estridson in 1076. Adam of Bremen's book being written after Adalbert's death, and before the death of Svend Estridson, it must have been composed some time between 1072 and 1076. Whether Adam himself died immediately after the completion of his celebrated work is not known. According to the *Church Book* of Bremen he died on Oct. 12, but the year is not given. He was buried in a grove that was once his property, but which he had donated to the cloister of Romeslo. The oldest translation of his work is into French by De Chastelus of Saumur in the year 1796. It was translated into German by Miesegaes (1825), and by Laurent (1850). The geographical appendix was translated into Swedish by Peringskjöld in 1817, and into Danish by Suhm in 1790. The whole work appeared in a Danish translation in Copenhagen by P. W. Christensen in 1862. R. B. ANDERSON.

Adamant [Gr. ἀδάμας, -ντος, a hard metal, invincible; from ἀ-, not + δαμᾶν, tame]: the ancient name of the diamond, is also a word used to denote a substance of extraordinary hardness and strength or durability.

Adama'wa: a semi-independent territory in Central Africa; between the parallels 5° and 10° N. lat., and lon. 10° and 15° E.; formerly considered a province in the great native kingdom of Sokoto, now within the "sphere of interest" of the German Cameroon district, while Sokoto proper is in the British "sphere" of influence. It is in part on the upper waters of the Benue river, the principal tributary of

the Niger, in part in the Congo basin, and in part is drained directly into the Bight of Benin. The Benue valley is fertile and highly cultivated; the remainder is little known. The country is occupied by various African tribes, but the political ascendancy is in the hands of a race called the Fulbe. The capital is Yola, on the Benue, in lat. 8° 50' N., lon. 13° 30' E. Pop. about 12,000. Mt. Alantika, 25 miles S. S. E. of Yola, is the highest mountain (9,800 feet).

Adami, JOHN GEORGE: See the Appendix.

Ad'amites: a heretical sect said to have sprung up in the north of Africa in the second century. They rejected marriage and appeared naked in their assemblies, which were called paradises. This name was also assumed by a sect of fanatics who arose in Bohemia in the fifteenth century and advocated a community of wives. They still exist in Bohemia, and are said to be guilty of great excesses, though outwardly discreet.

Adamnan, SAINT: abbot of the early Irish Church; b. about 625 in Donegal; elected Abbot of Iona 679; d. Sept. 23, 704; author of *Vita Sancti Columbæ*, which is the chief source of information about the early Scotch-Irish Church. The work forms vol. vi. of *Scottish Historians* series (1857), edited by Dr. Reeves for the Bannatyne Society of Edinburgh.

Adams: town of Berkshire co., Mass. (for location, see map of Massachusetts, ref. 2-C); on a branch of the Boston and Albany R. R.; contains Mt. Greylock, 3,505 feet high, the highest point in Massachusetts. The town formerly included what is now known as *North Adams*, which was set off in 1878 as a separate town. Adams is a typical New England manufacturing town; has 7 churches and a fine school system. It is connected with North Adams, 5 miles distant, by an electric railway, and is also within easy access of the Fitchburg R. R. The S. branch of the Hoosac river flows north through the town. The principal industry is the manufacture of textile fabrics. Pop. (1880) 5,591; (1890) 9,213; (1900) 11,134.

EDITOR OF "FREEMAN."

Adams: on railroad, Jefferson co., N. Y. (for location of county, see map of New York, ref. 2-G); 156 miles W. N. W. of Albany; seat of Adams Collegiate Institute; has 4 churches, electric lights, water-works, 2 malt-houses, a machine-shop, and carriage, furniture, canning, and sash and blind factories. Pop. (1880) 1,250; (1890) 1,360; (1900) 1,292.

EDITOR OF "JOURNAL."

Adams, BROOKS: author; son of Charles Francis Adams; b. in Quincy, Mass., June 24, 1848; was graduated at Harvard, 1870. Studied in Harvard Law School one year; then went to Geneva as secretary to his father, whither the latter had been sent as arbitrator of the Alabama claims. Was admitted to the bar, and practiced till 1881. Since that time has devoted himself to literary work. Author of *The Emancipation of Massachusetts* and *The Law of Civilization and Decay*.

Adams, CHARLES BAKER: naturalist; b. at Dorchester, Mass., Jan. 11, 1814. He graduated at Amherst College in 1834; served as tutor there 1836-37; was Professor of Chemistry and Natural History in Middlebury College, 1838-47, when he became Professor of Zoölogy and Astronomy in Amherst College, which post he held till his death, Jan. 19, 1853. He wrote reports upon the geological survey of Vermont; also *Contributions to Conchology*.

Adams, CHARLES FRANCIS, LL. D., D. C. L.: diplomatist; son of John Quincy Adams; b. in Boston, Aug. 18, 1807. He graduated at Harvard in 1825, and was admitted to the bar in 1828. In 1848 he was nominated for Vice-President by the Free-soilers, who supported Mr. Van Buren for the presidency. He published *Life and Works of John Adams*. Having joined the Republican party, he was elected a member of Congress in 1858 and in 1860. In 1861 he was appointed minister to Great Britain, the duties of which position were during the civil war very arduous and critical. He performed these duties with much ability and prudence, and returned in 1868. In 1871 he was appointed one of the arbitrators on the Alabama claims. D. Nov. 21, 1886.

Adams, CHARLES FRANCIS, JR.: b. at Boston, Mass., May 27, 1835; graduated at Harvard 1855; was admitted to the bar 1858; served as an officer of cavalry in the civil war, rising to the brevet rank of brigadier-general; has since taken a prominent part in the discussion of social, economical, and political questions; has written in the *North American Review* on railroad management, and was appointed railroad commissioner for Massachusetts in 1869; author of

Chapters of Erie (1871); *Three Episodes of Massachusetts History* (1892). For several years he was president of the Union Pacific Railway, from which office he resigned in 1890.

Adams, CHARLES KENDALL, A. B., A. M., LL. D.: educator and historian; b. at Derby, Vt., Jan. 24, 1835; educated at the University of Michigan, and in Germany, France, and Italy; Assistant Professor of History and Latin, University of Michigan, 1863-67; Professor of History, University of Michigan, 1867-85; non-resident Professor of History, Cornell University, 1881-85; became President of the Cornell University, 1885; resigned in May, 1892, and two months later accepted the presidency of the University of Wisconsin. Prof. Adams founded the Historical Seminary in the University of Michigan in 1869, and was thus the first to introduce the seminary method of instruction in history into the U. S. On the establishment of the School of Political Science in the University of Michigan he became its dean. He took an active part in the organization of the American Historical Association, of which he was president in 1890. Author of *Democracy and Monarchy in France* (New York, 1872; German version, Stuttgart, 1873); *Manual of Historical Literature* (New York, 1882); *British Orations* (New York, 1884); *Christopher Columbus, his Life and Work* (New York, 1892); and of a large number of papers on historical and educational topics in the *North American Review*, *The Forum*, *New Englander*, *The Contemporary Review*, and other periodicals. Editor-in-chief of *Johnson's Universal Cyclopædia* (1892). C. H. THURBER.

Adams, EDWIN: actor; b. in Medford, Mass., Feb. 3, 1834; first appeared in Boston, Aug. 29, 1853, at the National theater as Stephen in *The Hunchback*. When Booth's theater was opened in Feb., 1867, Adams played Mercutio and other prominent characters. He is best known by his personation of Enoch Arden, which made him a great favorite. He appeared with Edwin Booth in a number of Shakespeare's plays. D. in Philadelphia, Oct. 25, 1877. B. B. VALLENTINE.

Adams, HANNAH: one of the first women in the U. S. to engage in literary pursuits; b. at Medfield, Mass., in 1755. She wrote a *View of Religions* (1784); *History of New England* (1799); *Evidences of Christianity* (1801); *History of the Jews* (1812); *Letters on the Gospels*; an *Autobiography*; and other works. D. at Brookline, Mass., Nov. 15, 1832.

Adams, HENRY: historian; son of Charles Francis Adams; b. in Boston, Feb. 16, 1838; graduated at Harvard College, 1858; was private secretary to his father while the latter was minister to England, 1861-68; became Professor of History in Harvard College in 1870; editor of the *North American Review*, 1870 to Oct., 1876; author of *Essays in Anglo-Saxon Law* (1876); *Historical Essays* (1871); *Life of Albert Gallatin* (1879); *John Randolph* (1882); *Documents Relating to New England Federalism, 1800-1815* (1877); *History of the United States, 1801-1817* (1889-91, 9 vols.). C. H. T.

Adams, Rev. HENRY CADWALLADER: philologist and novelist; educated at Oxford, where he graduated B. A. in 1840. Author of *The Cherrystones* (1851); *Greek Delectus* (1851); *Latin Delectus* (1852); *Greek Text of the Gospels* (1855); *Twelve Foundations, and other Poems* (1858); *Schoolboy Honor* (1861); *Baldersconrl, or Holiday Tales* (1865); *Tales upon Texts* (1869); *The Winborough Boys* (1870); *Frank Lawrence*, 3 vols. (1873), etc., etc.; *Wykehamica, a History of Winchester College* (1878); *Perils in the Transvaal* (1887). W. S. P.

Adams, HENRY CARTER, Ph. D.: economist; b. at Davenport, Iowa, Dec. 31, 1852; educated at Iowa College and Johns Hopkins University; was first a fellow, then a lecturer in the latter institution; lecturer at Cornell University; professor in the University of Michigan; statistician to the Interstate Commerce Commission; and had charge of the transportation department of the eleventh census. He has written: *Public Debts* (1887; 2d ed. 1890); *Outlines of Lectures upon Political Economy* (1881; 2d ed. 1886); *Taxation in the United States, 1789-1816*, in Johns Hopkins University Studies (1884); *Relations of the State to Industrial Action*, published by the American Economic Association (1887); *Relation of American Municipalities to Quasi-Public Works*, published by the same association; *Annual Reports of the Statistics of Railways in the United States*, published by the Interstate Commerce Commission (1889-91). C. H. T.

Adams, HERBERT BAXTER, Ph. D.: Professor of History; b. April 16, 1850, near Amherst, Mass.; educated in the public schools of Amherst, at Phillips Exeter Academy, Amherst College, and Heidelberg University; appointed Fellow of History at the Johns Hopkins University 1876; Associate in History in 1878; associate professor in 1883, and university professor in 1891; historical lecturer at Smith College, Northampton, Mass., 1878-81, and at Chautauqua, 1888-91; was awarded the Regents' prize by Chancellor George William Curtis for the best published account of university extension; took an active part in 1884, with Prof. C. K. Adams, Justin Winsor, and Andrew D. White, in organizing the American Historical Association, and has been secretary of the society since its foundation. Editor of *The Johns Hopkins University Studies in Historical and Political Science*, and of *Contributions to American Educational History*. Author of *Maryland's Influence in Founding a National Commonwealth*; *The Study of History in American Colleges and Universities*; *The College of William and Mary*; and *Thomas Jefferson and the University of Virginia*. C. H. THURBER.

Adams, Rev. JASPER, D. D.: b. at East Medway, Mass., Aug. 27, 1793; graduated at Brown University in 1815; Professor of Mathematics there (1819-24); president of Charleston College, S. C., in 1824 and again in 1827-36, of Geneva (now Hobart) College in 1825-27. He was (1838-40) chaplain and Professor of Moral Philosophy at the U. S. Military Academy. His principal literary work was *The Elements of Moral Philosophy*, which won the high commendation of Mr. Justice Story. D. Oct. 25, 1841.

Revised by W. S. P.

Adams, JOHN: second President of the U. S.; b. at Braintree, Mass., Oct. 19, 1735, O. S.; graduated at Harvard College 1755; studied law, and was admitted to the bar in 1758. For this profession he was well fitted by a clear, sonorous voice, a ready fluency of speech, and a quick conception. In 1764 he married Abigail Smith, a woman of superior intelligence. His attention was drawn to political affairs by the passage of the Stamp Act in 1765, and he offered on that subject a series of resolutions which were very popular. He removed to Boston in 1768, became one of the most courageous and prominent advocates of the popular cause, and was chosen a member of the General Court (the Legislature) in 1770.

He was one of the delegates that represented Massachusetts in the first Continental Congress, which met in Sept., 1774. He distinguished himself in Congress by his capacity for business and for debate, and advocated the movement for independence when the majority of the members were inclined to temporize and to petition the king. In May, 1776, he moved and carried a resolution in Congress that the colonies should assume the duty of self-government. In June a resolution that the U. S. "are and of right ought to be free and independent" was moved by Richard Henry Lee, seconded by Mr. Adams, and adopted by a small majority. Mr. Adams was a member on the committee of five appointed June 11 to prepare a declaration of independence, in support of which he made an eloquent speech, about July 2. He was the chairman of the board of war appointed in June, 1776, and was sent as commissioner to France in 1778, but returned in July, 1779. Having been appointed as minister to negotiate a treaty of peace and commerce with Great Britain, he went to Europe early in 1780. Conjointly with Franklin and Jay he negotiated a treaty, the preliminary articles of which were signed Nov. 30, 1782. He was employed as minister to the court of St. James from 1785-88, and during that service wrote his *Defense of the American Constitutions* (1787). In 1789 he became Vice-President of the U. S., and about that time identified himself with the Federal party, by which he was re-elected to the office of Vice-President in 1792.

In 1796 Mr. Adams was chosen President of the U. S., receiving 71 electoral votes, while his competitor, Thomas Jefferson, received 68 votes. He sympathized with the anti-Gallican party, and pursued the policy of neutrality between France and Great Britain. Involved in a quarrel with the French Directory, which interfered with the maritime interests of the citizens of the U. S., he sent Mr. Murray as minister to France early in 1799, in order to avert a war. This act gave much offense to the Federalists, and broke the unity of that party. Among the unpopular measures for which Mr. Adams was held responsible were the Alien law and the Sedition law. In 1800 he was the Federal candidate for the office of President, but he was not cordially sup-

ported by Gen. Hamilton, the favorite leader of his party. Receiving 65 electoral votes, he was defeated by Thomas Jefferson, who received 73 votes.

Mr. Adams then retired from public life to his large estate at Quincy, Mass., and gave his attention partly to agriculture. The general neglect and odium which he experienced were at last compensated by the election of his son John Quincy to the presidency of the U. S. He died on July 4, 1826. It is a curious coincidence that of the three Presidents of the U. S. who have died on that anniversary (Adams, Jefferson, and Monroe), two had signed the Declaration of Independence. Revised by R. LILLEY.

Adams, JOHN COUCH: astronomer; b. in Cornwall, England, June 5, 1819; educated at Cambridge, where he obtained the position of Senior Wrangler, 1843. In 1841 he began to search for the causes of the irregularities in the motion of Uranus. He ascertained that they were caused by the attraction of a planet then unknown, and thus shares with Leverrier the honor of the discovery of Neptune, for which he received the Copley medal in 1848. In 1851 he was elected president of the Royal Astronomical Society; and in 1858 became Professor of Mathematics in the University of St. Andrews (where he taught until May, 1859), and about the same time was appointed Lowndean Professor of Astronomy and Geometry at Cambridge, an office which he held until his death, Jan. 21, 1892. In 1861 he succeeded Prof. Challis as director of Cambridge Observatory, and in 1866 received the Royal Astronomical Society's gold medal for his investigations regarding the lunar parallax and the secular acceleration of the moon's mean motion. He was one of the British delegates to the International Prime Meridian Conference held at Washington in 1884.

Revised by R. LILLEY.

Adams, JOHN QUINCY: sixth President of the U. S.; b. in Braintree, Mass., July 11, 1767. He was eldest son of President John Adams and his wife, Abigail Smith, who was descended from the family of Quincy. In 1778 he was placed at a school in Paris, and in 1780 passed to the University of Leyden. He returned home in 1785, and finished his education at Harvard College, where he graduated in 1788, after which he studied law with Theophilus Parsons, and was admitted to the bar in 1791. Having gained distinction by some political essays, he was appointed minister to The Hague in 1794. In 1797 he married Louisa Catherine Johnson of Maryland, and in the same year was sent as minister to Berlin, from which he was recalled in 1801, when the Republicans obtained power.

He was elected a Senator of the U. S. by the Federalists in 1803, but voted for Jefferson's embargo in 1807, and thus separated himself from the Federal party and lost his seat in the Senate in 1808. Before this date he had distinguished himself as a public speaker, and had been appointed Professor of Rhetoric at Harvard College (1805). In 1809 he was sent as minister to Russia. He was one of the commissioners that negotiated the treaty of peace with Great Britain, signed Dec. 24, 1814, and he was appointed minister to the court of St. James in 1815. In 1817 he became Secretary of State in the Cabinet of Monroe, in which position he remained eight years. In 1824 four candidates for the presidency were presented—John Q. Adams, Andrew Jackson, Henry Clay, and William H. Crawford—all of whom professed to be Democrats. Mr. Adams received 84 electoral votes, Jackson 99, Crawford 41, and Clay 37. As neither had the requisite majority, the election devolved on the House of Representatives, which chose Mr. Adams. This result was due to the influence of Henry Clay, and when Mr. Adams nominated him as Secretary of State, the friends of Jackson accused Adams and Clay of "bargain and corruption," but the charge is not generally credited. His administration was opposed by a powerful party, formed by a coalition of the Jacksonians with the friends of Crawford. This party had a majority of the members of Congress, and, uniting on Gen. Jackson as their candidate, triumphed in the election of 1828, when Mr. Adams received only 83 electoral votes out of 261, which was the whole number.

In 1830 he was chosen by the voters of his native district to represent them in Congress, in which he distinguished himself by his application to business, his assertion of the right of petition, and his resolute opposition to what he considered to be the encroachments of the slave power. He continued to represent the same district in Congress for seventeen years, during which he maintained a position independent of a party. He was seized with paralysis in

the Capitol on Feb. 21, 1848, and died on the 23d of that month. In religion he was a Unitarian. He left many writings in prose and verse, which have been published; also a voluminous diary of his public life.

Adams, JOHN QUINCY: a grandson of the preceding, and son of Charles Francis Adams, noticed above; b. at Boston, Mass., Sept. 22, 1833; graduated at Harvard in 1853. He was the Democratic candidate for Governor of Massachusetts in 1867 and 1868, but was both times defeated. He was also a candidate for the vice-presidency in 1872, on the ticket with Charles O'Connor. D. Aug. 14, 1894.

Adams, JULIUS WALKER: b. in Boston, Mass., Oct. 18, 1812; entered the U. S. Military Academy, June, 1830; assistant engineer of Stonington and Providence R. R. 1832, Norwich and Worcester R. R. 1836, Western R. R. of Massachusetts 1839, Albany and Schenectady R. R. 1842, U. S. dry-dock, Brooklyn navy-yard, 1844, Cochituate water-works, Boston, 1846; superintending engineer New York and Erie R. R. 1846; chief engineer Central R. R. of Kentucky 1852, Memphis and Ohio R. R. 1855; engineer for establishment of a system of sewers in Brooklyn, N. Y., 1856; engineer of New Haven water-works 1860. Served with credit as colonel of the 67th New York Vols., and was wounded at Fair Oaks. Since then has been engaged in many important hydraulic works; chief engineer city of Brooklyn; past president American Society of Civil Engineers; member of New York Academy of Science; author of various scientific papers; and consulting engineer to department of public works, New York.

Adams, NEHEMIAH, D. D.: theologian; b. at Salem, Mass., Feb. 19, 1806; graduated at Harvard in 1826, and at Andover Theological Seminary in 1829. He first settled at Cambridge in 1829, and in 1834 became pastor of the Essex Street church in Boston. He resigned his pastorate in 1870. He published several theological and other works, and a *South Side View of Slavery* (1854), which was severely condemned by the opponents of slavery. He had a high reputation for scholarship and pulpit eloquence. D. Oct. 6, 1878.

Adams, SAMUEL: patriot and orator; a second cousin of President John Adams; b. in Boston, Sept. 27, 1722; graduated at Harvard College in 1740; and became a merchant, but was not successful in business, and soon abandoned it. In 1765 he was chosen to represent Boston in the General Court of Massachusetts, in which he distinguished himself by his courage, energy, and oratorical talents, and acquired great influence. Before the Revolution he was an unflinching advocate of the popular cause, and took such an active part in political meetings that he was one of the two leading patriots who were excepted from a general pardon offered in 1775. He was a member of the first Continental Congress, which met in Sept., 1774, and he signed the Declaration of Independence in 1776. He remained in Congress about eight years, was afterward elected to the Senate of Massachusetts, and was a member of the State convention which ratified the Federal Constitution in 1788. His political affinities connected him with the Republican (or Jeffersonian) party. He was elected Governor of Massachusetts in 1794, was re-elected twice, and retired to private life in 1797. He died Oct. 2, 1803. In religion he was a decided Calvinist. In the letters and other writings of John Adams occur several passages which express a high opinion of the talents and merits of Samuel Adams, in whose productions he says may be found "specimens of a nervous simplicity of reasoning and eloquence that have never been rivaled in America." See W. V. Wells's *Life and Public Services of Samuel Adams* (3 vols. 8vo, 1865).

Adams, SARAH (Flower): poet; b. at Great Harlow, Essex, England, Feb. 22, 1805. She married Mr. W. B. Adams in 1834. Her principal work is *Vivia Perpetua* (1841), a dramatic poem dealing with the life of the early Christians. She was the author of many hymns, the best known of which is *Nearer my God to Thee*. D. August, 1848.

Adams, Rev. WILLIAM, D. D.: b. at Monaghan, Ireland, in 1813; educated at Trinity College, Dublin, and at the General Theological Seminary in New York city; was one of the founders of Nashotah Theological Seminary in Wisconsin, where, till his death, Jan. 2, 1897, he held the chair of Systematic Divinity. Besides numerous contributions to religious papers and reviews, he published *Mercy to Babes* (New York, 1847); *Elements of Christian Science* (Philadelphia, 1850); and *A New Treatise on Baptismal Regeneration* (New York, 1871).

W. S. P.

Adams, Rt. Rev. WILLIAM FORBES, D. D., D. C. L.: first missionary bishop of the American Episcopal Church in the jurisdiction of New Mexico and Arizona; b. in Ireland, Jan. 2, 1833. Removing in his boyhood to Tennessee, he was admitted to the bar in Mississippi, but was ordained deacon Dec. 27, 1859, and priest July 29, 1860. At the time of his election to the episcopate he was rector of St. Paul's in New Orleans. Consecrated Jan. 17, 1875; resignation, on account of physical disability, accepted by House of Bishops, Oct., 1877. Translated to the see of Easton, Md., 1887.

W. S. P.

Adams: WILLIAM HENRY DAVENPORT: author and journalist; b. in 1828; editor of *The Scottish Guardian*, 1870-77; published an annotated edition of Shakespeare; *The Bird World*; *The Arctic World*; *Memorable Battles in English History*; *Heroes of the Cross*; *England at Sea*; *Woman's Work and Worth*; *The Merry Monarch*; *Good Queen Anne*; *The White King*; *Witch, Warlock, and Magician*, etc. D. Dec. 30, 1891.—His son, W. DAVENPORT, has published a *Dictionary of English Literature*; *Famous Books*; and three collections of annotated poetry.

Adams, WILLIAM T.: a popular writer, known under the pseudonym of Oliver Optic; b. in Medway, Mass., July 30, 1822; published about a hundred works for children—viz., *The Riverdale Series* (1860); *Young America Abroad Series* (1866-69 and 1871-77); *Great Western Series* (1875-81), etc.; edited *Student and Schoolmate* (1858-66); *Our Boys and Girls* (1867-75); *Our Little Ones* (1886); and *Oliver Optic's Magazine*. D. Mar. 27, 1897.

Adam's Bridge: a chain of sand-banks and coral reefs extending from the N. W. point of Ceylon to the coast of India. Like Adam's Peak, it is associated with the legend of a visit by Adam to Ceylon. It is more than 30 miles long. Some of the banks and reefs are dry, and none are covered to a depth of more than 3 or 4 feet at high water. There are two or three tortuous channels through them, but these are practicable only for small craft, and for them only in calm weather.

M. W. H.

Adam's Needle: See YUCCA.

Adam's Peak: a mountain in Ceylon in lat. 6° 52' N., lon. 80° 32' E.; height, 7,230 feet. It is considered by the Buddhists as the holy center of the world. A temple is situated on the highest portion of the peak, under which the footprints of Buddha and Sripadam (i. e. luck) are said to be seen. Buddha is said to have left those traces upon his last visit to the earth. The Brahmans and Mohammedans also consider it a holy mountain—the former, because they consider Buddha as an avatar (incarnation) of Vishnū; the latter, because they ascribe the footprints to Adam, who is said to have here mourned for 1,000 years his expulsion from Paradise, standing on one foot. The shadow of the peak at sunrise shows some unique peculiarities. See Abercromby, *Seas and Skies in many Latitudes* (1888).

Adamson, PATRICK: b. at Perth, Scotland, in 1543; was licensed as a preacher; studied law, and went to France as tutor to a young gentleman; returned in 1573, took orders, and became minister of Paisley; was made Archbishop of St. Andrews in 1576 by his patron, the Earl of Morton, Regent of Scotland. He had many contests with the Presbyterians respecting episcopacy. D. Feb. 19, 1592.

Adan, LOUIS ÉMILE: painter of figure subjects; b. in Paris, Mar. 26, 1839. Pupil of Picot and Cabanel. First-class medal, Paris Exposition, 1889; Legion of Honor, 1892. One of the best of his works is *Autumn Evening* (1882). *The Ferryman's Daughter* (1883) is in the Luxembourg Gallery, Paris. Studio in Paris.

W. A. C.

Ada'na: a city of Asia Minor; on the river Sihoon; about 30 miles from the sea and 18 miles E. of Tarsus (see map of Turkey, ref. 6-G). It has some trade in grain, wine, cotton, etc. Here are interesting ancient remains. Pop. (1885) 45,000.

Adanson, MICHEL: French naturalist; b. at Aix, Apr. 7, 1727; educated at the college of Plessis. He went to Senegal in 1748 to explore the natural history of that region, in which he passed five years in his arduous and dangerous enterprise, and collected an immense number of animals and plants. He published, after his return, a *Natural History of Senegal* (1757), and *The Families of Plants* (1763), in which he opposed the artificial system of Linnæus. In 1759 he was elected a member of the Academy of Sciences. D. Aug. 3, 1806.

Adanso'nia: a genus of plants of the family *Sterculiaceae*; named in honor of the great naturalist, M. Adanson.

Adansonia.

The *Adansonia digitata*, or baobab, is found in tropical Africa, and is one of the largest trees in the world. It does not grow very high, but its trunk is often more than 20 feet in diameter. The fruit of the baobab is called monkey-bread. By a loose and vague overestimate some of these trees have been said to be 5,000 years old.

A'dar: the sixth month of the civil and the twelfth of the ecclesiastical year of the Jews, beginning with the new moon of February.

Ad'da (anc. *Ad'dua*): a river of Northern Italy; rises in the Valtellina, among the Rhetian Alps, and enters Lake Como, which is an expansion of this river. After issuing from that lake it flows nearly southward through Lombardy, and empties itself into the Po 7 miles above Cremona. Length of river and lake, about 130 miles.

Ad'dax: the *Oryx* (or *Ad'dax nasomaculatus*) of the naturalists; a large antelope found in North Africa and Arabia. Its broad-spreading hoofs enable the animal to obtain a firm foothold upon the dry and yielding sand. Its horns, which are from 3 to 4 feet long, are beautifully twisted into a spiral, having two and a half turns. The general color of the addax is a milk-white, but there is a black patch of hair on the forehead, and it has a dark-brown mane, with more or less of reddish brown mixed with gray on the head, shoulders, and part of the back.

Addax.

Ad'der: a common name of the viper or of any venomous serpent belonging to the family *Viperidae*. The name is popularly applied in the U. S. to several non-venomous snakes, as the "spreading-adder" (*Heterodon platyrhinus*).

Addington, HENRY: See SIDMOUTH.

Addington, ISAAC: b. in Boston, Mass., Jan. 22, 1645; member of House of Representatives and Speaker in 1685; opposed the administration of Sir Edmund Andros, and on its overthrow in 1689 became clerk of the Council of Safety, to whom the people committed the government; secretary from his appointment in 1690 till his death; judge of the court of common pleas, 1693-1702; chief justice of the Superior Court, 1702-03. He was many years chosen to the council, and was judge of probate court, 1702-15. D. Mar. 19, 1715.

Ad'discombe House: situated about a mile from Croydon, England; was formerly the residence of the Earl of Liverpool, and was purchased in 1809 by the East India Company, and opened by them in 1825 as a collegiate institution for the education of cadets for the whole of their military service except the cavalry. It is now called the Royal India Military College.

Addison: Steuben co., N. Y. (for location of county, see map of New York, ref. 6-E); on Canisteo river, and main line of New York, Lake Erie and Western R. R., 30 miles W. of Elmira; has 2 large union school-houses, 4 churches, 2 sash, door, and blind factories, plow-handle and step-ladder factories, 2 boot and shoe factories, and the foundry and machine-shops of the Addison and Pennsylvania R. R. Co. Tobacco is largely grown in the neighborhood. Pop. (1880) 1,596; (1890) 2,166; (1900) 2,080. EDITOR OF "ADVERTISER."

Ad'dison, JOSEPH: an English humorist, moralist, and author of great merit and celebrity; b. at Milston, near Amesbury, in Wiltshire, on May 1, 1672. He was a son of Lancelot Addison. In 1687 he entered Queen's College, Oxford, from which he passed to Magdalen College in 1689. He became a good classical scholar, and as a writer of Latin verse probably excelled all his contemporaries. At an early age he enjoyed the friendship and patronage of Dryden, Lord Somers, and Montagu (Lord Halifax), the last

of whom persuaded him to enlist as a Whig in the civil service of the state. Having in 1699 received a pension of £300, he visited France and Italy, and wrote a charming *Letter from Italy*, in verse, addressed to Lord Halifax (1701). He lost his pension on the death of William III. (1702), and returned home in 1703. His next work was *The Campaign*, a poem on the battle of Blenheim (1704), which was greatly admired, and he was rewarded with the office of commissioner of appeals. He afterward produced his interesting *Travels in Italy*, and *Rosamond*, an opera. He was appointed Under-Secretary of State in 1706, and was elected to Parliament in 1708. His diffidence disqualified him for public speaking, but this defect was compensated by his success as a political writer. He became in 1709 secretary to Lord Wharton, Lord-Lieutenant of Ireland, and contributed to the *Tatler*, of which his friend Richard Steele was the editor. On Mar. 1, 1711, Addison and Steele began to issue daily *The Spectator*, the most elegant and famous periodical and miscellany that ever appeared in England. Addison wrote the best of the essays, which form an epoch in literary history.

The Spectator ceased to appear daily in Dec., 1712, but was revived as a tri-weekly paper in 1714. Among his other works are the tragedy of *Cato* (1713), which was received with great applause, an ingenious *Dialogue on Medals*, and a series of able political papers called *The Freeholder* (1715). In 1716 he married the proud and un congenial Dowager Countess of Warwick, and early in 1717 was appointed Secretary of State. He resigned this office in 1718, and died in London, June 17, 1719, leaving only one child, a daughter. His marriage appears not to have been happy. Addison was greatly distinguished for his wit and colloquial powers. See Johnson's *Lives of the Poets*; Macaulay, *Critical and Historical Essays*; Aiken, *The Life of Addison* (1843); and Courthope's *Addison* (1884).

Addison, LANCELOT, D. D., father of Joseph Addison; b. at Meaburn Town Head, Westmoreland, England, in 1632; educated at Queen's College, Oxford; was seven years chaplain at Tangiers; became a royal chaplain about 1670. Dean of Lichfield 1683, and Archdeacon of Coventry in 1684. D. 1703.

Addison's Disease, or Suprarenal Melasma: a rather rare disease, the most obvious symptom of which is a gray-black or bronze color of the skin, gradually coming on. The chief lesion discovered after death is a cheesy degeneration of the suprarenal capsules, the result of a peculiar chronic inflammation. Patients usually suffer from extreme debility, depression of spirits, pain in the epigastrium and back, often accompanied by dyspepsia, vomiting, diarrhoea, and grave nervous symptoms. No remedy is known, and the disease, though careful nursing is extremely useful, is probably never cured. It receives its common name from the late Dr. Addison, of Guy's Hospital, London, England.

Address, FORMS OF: See FORMS OF ADDRESS.

A'delaer, CORT SIVERTSEN: naval commander; b. at Brevig, Norway, Dec. 16, 1622; served in the Dutch navy under Tromp, 1637-45; entered the Venetian service, and distinguished himself greatly in many actions; broke (May 13, 1654) with a single ship through a Turkish fleet consisting of 67 galleys stationed in the Dardanelles, and sank or burned 15 of the enemy's vessels; left Venice in 1661, and was placed at the head of the Danish navy in 1663, which he remodeled after the Dutch fashion. D. Nov. 5, 1675.

Ad'elaide (named after Queen *Adelaide*, the consort of William IV.): city; capital of South Australia; situated on both sides of the river Torrens, 8 miles from its entrance into the Gulf of St. Vincent (see map of Australia, ref. 7-G). It was founded in 1836, is the seat of an Anglican and a Roman Catholic bishop, and contains a government-house, an assay-office, a theater, and extensive manufactures. Pop. (1887) 111,300; (1895) 144,352. Port Adelaide, 7 miles N. N. W. of the city, with which it is connected by railway, is the center of the commerce of the colony. It has a heavy trade in copper and lead ores, grain, and wool.

Adelbert College of Western Reserve University: founded in 1826 under the name of Western Reserve College, and located at Hudson, O. A theological department was opened in 1828 and continued till 1859. A medical department was established in Cleveland in 1843, and was transferred to the Western Reserve University in 1884. In 1882 the college was transferred to the city of Cleveland, changing its name and receiving from Mr. Amasa Stone

\$450,000 of endowment and \$150,000 in buildings, and also about 20 acres of land from citizens of Cleveland. It has excellent buildings and a library of about 25,000 volumes. There are three courses of study, viz., classical, modern languages and Latin-English, and much attention is given, through electives, to practical training in chemistry, physics, and biology. For the purposes of this training there are three laboratories. The invested funds amount to \$700,000, the real estate and apparatus to \$300,000. The president is Rev. Charles F. Thwing, D. D. There are eleven professors and five instructors and lecturers. A gymnasium was added to the equipment in 1888. The college is distinctively a Christian institution, though not denominational. See WESTERN RESERVE UNIVERSITY. E. BUSHNELL.

Adelsberg: a small market-town of Carniola, Austria (see map of Austria-Hungary, ref. 8-D). A short distance from the town is the Adelsberg Grotto, which is one of the best known caverns of the world. It consists of five different parts, and is full of beautiful formations, stalactites, incrustations, and stalagmites. The length is $2\frac{1}{2}$ miles; temperature in the cave, 48° F. The cave was well known in the Middle Ages, and rediscovered in 1818.

Adelung, FRIEDRICH, von: German philologist; b. at Stettin, Feb. 25, 1768; became a resident of St. Petersburg, and preceptor to the grand duke who was afterward the Emperor Nicholas. He wrote on the Sanskrit language and literature, but his greatest services to scholarship were due to his investigations into the foreign sources of information for Russian history. His *Kritisch-literarische Uebersicht der Reisenden in Russland bis 1700* (1846) is the most important of his works in this direction. D. in St. Petersburg, Jan. 30, 1843.

Adelung, JOHANN CHRISTOPH: philologist, an uncle of Friedrich von Adelung; b. at Sparteckow, in Pomerania, Aug. 8, 1732. His reputation is founded chiefly on his *Attempt at a Complete Grammatico-Critical Dictionary of the German Language* (*Versuch eines vollständigen grammatisch-kritischen Wörterbuches der Hochdeutschen Mundart, 1774-86*). Among his other works is one on language, entitled *Mithridates oder allgemeine Sprachen-Kunde*, one of the most important of the early works on comparative philology. D. at Dresden, Sept. 10, 1806.

Aden, ā'den (i. e. Eden): Aden proper is a small volcanic peninsula on the south coast of Arabia, about 100 miles E. of the Straits of Bab-el-Mandeb (see map of Persia and Arabia, ref. 10-E). It was taken possession of by Great Britain in 1839. Later a small peninsula to the eastward and the coast between were purchased—making a total area of 70 sq. miles. Pop. (1891) 41,910, excluding the troops, mostly Mohammedans. Aden has an admirable position, and is strongly fortified. Its climate, though hot, is dry and salubrious. It was early an important port in the trade between Europe and India, but with the discovery of the route by the Cape of Good Hope it fell into decadence. With the opening of the Suez Canal it again rose into importance, becoming a coal-ing and watering station. It is a free port, and its trade is almost entirely a transshipment one. A sort of protectorate has been extended by Great Britain over the neighboring inland region, having an area of about 8,000 sq. miles, and a population of about 130,000 (estimated). See also PERIM, SOMALI COAST, SOCOTRA, and KURIA MURIA ISLANDS.

M. W. H.

Aden and Perim': a possession of Great Britain on the Gulf of Aden, and includes, besides the above named, the Somali Coast protectorate, Socotra, and the Kuria Muria islands. The government is subordinate to the Bombay Presidency, and is administered by a political resident, who is also commander of the troops. The only government revenue is from the duty on liquor, arms, opium, and salt.

Aden, GULF OF: that part of the sea lying between Arabia and Aden, and extending from the Strait of Bab-el-Mandeb to the Indian Ocean or Arabian Sea. On some maps this is marked as the Arabian Gulf. Length about 500 miles.

Adept': a person who is skillful or well versed in any art or science; formerly applied especially to an alchemist who was supposed to have discovered the secret of turning base metal into gold, or to have found the philosopher's stone.

Aderno, a-der'nō (anc. *Adranum*): a town of Sicily; at the foot of Mt. Etna; 17 miles N. W. of Catania; remarkable for the number of its convents and nunneries (see map of Italy, ref. 9-F). Portions of the ancient city still remain. Pop. (1881) 20,163.

A'dersbach Rocks: a remarkable group of high and detached sandstone rocks, near the village of Adersbach, in the northeast part of Bohemia. They present fantastic forms, and occupy an area of several miles in extent. One of the pinnacles is over 200 feet high.

Adet, PIERRE AUGUSTE: a French chemist and politician; b. at Nevers in 1763. He was sent by the French Directory as ambassador to the U. S. in 1795, but he suspended his functions in 1797, for the alleged reason that the U. S. Government had violated its neutrality. D. in 1832.

Adfoo: See EDFU.

Adhesion [Lat. *adhae'sio*; *ad*, to + *haere're*, stick]: in botany, the union of contiguous parts, as when the petals adhere and form a monopetalous corolla; the calyx often adheres to the ovary, and then seems as if it grew from the apex of it. This tendency causes great diversity of appearance in the organs of plants.

Adhesion, FORCE OF: the resistance of friction which exists between two surfaces at the moment when one begins to slide on the other. The force of adhesion is approximately proportional to the normal pressure between the two surfaces. The adhesion of the driving-wheels of a locomotive upon the rails of a track is about one-fourth or one-fifth of the weight that rests upon them. If the frictional resistances are greater than the adhesion, the wheels will revolve and the locomotive move forward; if the frictional resistances are less than the adhesion, the wheels will slip on the rails, and no forward motion will result. The force of traction is measured in any particular case by the horizontal pull required to start a locomotive with its train, and the greatest load which a locomotive can draw is that which has a frictional resistance equal to the adhesion.

MANSFIELD MERRIMAN.

Adian'tum: a genus of ferns, whose spores are produced on the margin of the leaves in short fruit-dots. There are many species, of which the maidenhair fern, *A. capillus-veneris*, and *A. pedatum* are common in the U. S.

Adiaph'orites: [from the Gr. *ἀδιάφορος*, indifferent]: a name given to Melancthon and his adherents, who were charged with making serious concessions to the Roman Catholics in the *Leipzig Interim* of 1548. Under *adiaphora* or non-essentials, such as the use of altars, pictures, lights, etc., it was alleged, matters involving fundamental articles of faith had been included. The chief opponents of Melancthon were Flacius and Amsdorf. A decision was reached in the *Formula of Concord*, art. x.

Adiathermancy: See DIATHERMANCY.

Adige, aa'dēe-jā (Lat. *Ath'esis*): a river of Italy; rises among the Alps in the Tyrol, where it is called the Etsch. Flowing southward, it passes by Trent, and enters Lombardy. After passing by Verona, it flows nearly southeastward, and falls into the Gulf of Venice about 13 miles N. E. of Adria. It is a rapid stream, about 220 miles long. It is navigable from its mouth to Trent, but the velocity of the current impedes navigation.

Ad'ipocere [viā Fr. *adipocire*, from Lat. *adeps*, fat + *ce'ra*, wax]: a substance which results from the decomposition of animal bodies, and resembles spermaceti, or a mixture of wax and fat. Human bodies buried in wet ground are often reduced to this condition, and are often supposed to be petrified.

Ad'ipose: of the nature of fat; fatty. Adipose tissue is an animal tissue which contains the fatty matter. It presents an aggregation of very small spherical pouches or vesicles filled with fat or oil. This tissue is organized and vital, but the fat is not.

Adiron'dack Mountains: an oval mountain tract in Northeastern New York, including parts of Hamilton, Essex, Franklin, and Clinton counties, and having an area of 5,000 sq. miles. Among its peaks are Mt. Marcy, 5,379 feet; Mt. McIntyre, 5,183 feet; and Mt. Dix, 4,916 feet, the highest summits in the State. The mountains consist of crystalline rocks, and about their flanks these are overlapped by Cambrian and Silurian sediments. Their surface characters were greatly modified by the Pleistocene ice-sheet, which traversed them from N. to S., scouring the soil from their summits and higher slopes, and depositing the material in an irregular way in the mountain valleys, so as to obstruct the drainage and produce a great number of lakes. Though densely forested, the tract is unsuited for agriculture, alike in soil and climate, and it is thus naturally reserved as an

immense park for purposes of rest and recreation. Through the game laws and timber laws of the State, it has been still further protected in the interest of the sportsman and tourist, so that its broad forests still abound in deer and other game and its waters in trout. G. K. G.

Adirondaek Park: a public park, established in 1892, situated within and occupying the larger part of the great forest of Northern New York. It includes Hamilton County, the large town of Wilmurt in Herkimer County, the western half of Essex, the western part of Warren, the southern part of Franklin, and the southeastern part of St. Lawrence County. It contains 2,807,760 acres, an area equal to that of the State of Connecticut. In character the lands are:

Primeval forest.....	1,575,483	acres.
Lumbered forest*.....	1,027,955	"
Denuded.....	50,050	"
Burned.....	13,430	"
Waste.....	18,526	"
Water.....	57,104	"
Wild meadows.....	495	"
Improved.....	64,717	"

Of the virgin forest about 50 per cent only of the trees are conifers; the rest are hardwoods, the maple, birch, and beech predominating largely. Within the park boundaries the forest is in good condition, and the small areas of burned land are rapidly reforesting themselves. The park is situated on an immense plateau, which extends throughout its entire area, with an average elevation of 1,800 feet above tide. It contains extensive mountain ranges, the highest peak, Mt. Marcy, attaining a height of 5,379 feet. There are eighteen other mountains within the park whose altitudes exceed 4,000 feet, while peaks of lesser height appear in every direction. There are over 1,200 bodies of water, varying in size from lakes 15 miles long to little mountain ponds. Twenty large rivers drain the region, part of them flowing to the Hudson, the others to the St. Lawrence. The park abounds in grand and beautiful scenery, its combination of mountains, lakes, rivers, and forests having no equal in this respect. Its waters are so connected that the tourist and his guide can make various journeys of over 100 miles each without retracing the route, the entire distance being traveled in a light "guide-boat," except occasional "carries" or portages varying in length from a few rods to three miles, or thereabouts. The hotels are numerous and excellent, and of classes to suit all. In each locality there are good, trusty guides, whose services can be secured at a moderate price. The region affords also an opportunity for coaching and driving, a good road leading through the beautiful and impressive scenery lying along the route from Westport and Elizabethtown through the Keene valley, by the Cascade lakes and Lake Placid, through the Wilmington Notch, to the Au Sable Chasm, a drive of 98 miles. The region abounds in fish and game. The lakes, in addition to their natural supply, have been fully stocked with fish from the State hatcheries. The smaller streams contain a plentiful supply of speckled trout.

But the Adirondaeks have a priceless value as a sanitary resort, the beneficial effect being particularly noticeable in pulmonary diseases. The Adirondaek Sanitarium, at Saranac Lake, in which consumptive patients only are treated, reports a percentage of permanent cures, together with a separate percentage showing permanent relief, which is unsurpassed in any other climatic resort.

The law establishing the park was passed in 1892. But the State lands at this time comprised only one-third of its area, leaving the remainder to be acquired by subsequent appropriations. The officers of the park consist of a superintendent, assistant superintendent, two inspectors, and a small number of foresters. They are appointed by the State Forest Commission, an honorary board of three members, who have the control and management of the park and other State forests. The principal object in establishing and maintaining the park is the preservation of its forests, the protection of the watersheds that supply the State rivers and canals, and the inauguration of a forest management that will insure a future and perpetual supply of timber. Its maintenance as a pleasure and health resort is incidental and subordinate to the main object. See *Report N. Y. State Forest Commission*, for 1891; also *Guide-book to the Adirondaeks*, by S. R. Stoddard, Glens Falls, N. Y. WILLIAM F. FOX, Supt. of State Forests.

* Lands from which spruce, pine, or hemlock trees have been taken, leaving a good hardwood forest, interspersed with young conifers.

Ad'it [Lat. *ad'itus*, approach; *ad*, to + *ire*, go]: a horizontal passage and entrance into a mine, designed partly to drain water from it. Adits occur chiefly in mountainous regions, and are sometimes several miles long.

Adja'cent Angle: an angle contiguous to another, so that one side is common to both angles.

Ad'jective [Lat. *adjecti'vus*, annexed; *ad*, to + *ja'cere*, lay]: in grammar, a word joined to a noun, in order to qualify the general idea expressed by it.

Adjective Law: rules of procedure or practice, as distinguished from the substantive law, or the law which courts are established to administer.

Adjourn'ment: the postponement of the proceedings of the U. S. Congress, or of either House of the British Parliament, or of any public or private deliberative body, from one time to another time, either fixed or indefinite. In parliamentary usage it differs from prorogation, which is an act of royal authority, whereas the power of adjournment is vested in each House respectively.

Ad'jutant, or Adjutant-bird: an East Indian bird (*Lep-top'tilus ar'gala*) allied to the stork. It is about 5 feet high, has long legs and an enormous bill, and can swallow a cat or a small leg of mutton with the greatest facility. It is very useful as a scavenger, cleansing the streets and public squares of various offal and dead animals. The famous marabou feathers are obtained from the adjutant and a kindred species, the marabou of Africa.

Adjutant-General: the principal agent of the commander of an army in publishing orders. The same agent of the commander of a division, brigade, geographical division, or department is styled assistant adjutant-general. The laws of the U. S., however, provide for but one adjutant-general, with the rank of brigadier-general, made by regulations chief of a bureau of the war department, and charged, under the general, with details affecting army discipline, with the recruiting service, records, returns, etc.; two assistant adjutants-general, with the rank of colonel; four with the rank of lieutenant-colonel; and ten with the rank of major. The bureau duties of adjutants-general and assistants are: publishing orders in writing; making up written instructions, and transmitting them; reception of reports and returns; disposing of them; forming tables showing the state and position of corps; regulating details of service; corresponding with the administrative departments relative to the wants of troops; corresponding with the corps, detachments, or individual officers serving under the orders of the same commander; and the methodical arrangement and care of the records and papers of his office. The active duties of adjutants-general consist in establishing camps; visiting guards and outposts; mustering and inspecting troops; inspecting guards and detachments; forming parades and lines of battle; the conduct and control of deserters and prisoners; making reconnoissances; and in general discharging such other duties as may be assigned them.

Adler, CYRUS: See the Appendix.

Adler, FELIX: b. at Alzey, Germany, Aug. 13, 1851; son of Samuel Adler; graduated at Columbia College, and subsequently studied at Berlin and at the University of Heidelberg, where he obtained the degree of Doctor of Philosophy. Returning to the U. S., he was Professor of Hebrew and Oriental Literature at Cornell University from 1874 to May, 1876. On May 15, 1876, he inaugurated the Society for Ethical Culture, a religious movement the principal tenets of which he briefly describes as follows: "There is a principle of unity in nature, all the laws of which are adumbrations of an underlying unity. The same principle of unity is obligatory in the sphere of action, and imposes its imperative mandate on the will." The society has founded a system of district nursing among the poor, a free kindergarten, a workingman's school, where technical and art education are made integral parts of the course of instruction, and a family home for neglected children. He published in 1877 a series of discourses, *Creed and Deed*, in addition to which he lectures weekly in Chickering Hall during the winter. The society has its center in New York, and has a branch at Chicago. Revised by C. H. THURBER.

Ad'ler, GEORG J., Ph. D.: German philologist; b. at Leipzig in 1821; emigrated to the U. S. in 1833. He was for some time Professor of German in the University of New York. He wrote several German-and-Latin school manuals and an excellent German-and-English dictionary. D. in New York, Aug. 24, 1868.

Adler, Rev. HERMANN, Ph.D.: Jewish rabbi and author: b. May 29, 1839, in Hanover; educated at University College, London, and at the universities of Prague and Leipzig; appointed principal of the Jews' College in London, 1863; drew public attention to the persecutions of the Jews in Russia by his article on *Recent Phases of Judaism*, published in 1881; elected chairman of the Council of Jews' Colleges in 1887. Author of sermons on *The Jews in England*; *Is Judaism a Missionary Faith?*, etc.

C. H. T.

Adler, SAMUEL: Jewish rabbi; b. at Worms, Dec. 3, 1809; studied philology and philosophy at the universities of Bonn and Giessen, 1831-36; Rabbi of Alzey, 1842-57; called to Emanu-El Temple, New York, 1857, of which he became emeritus rabbi in 1874; an acknowledged authority on matters of Jewish erudition, and an ardent friend of religious and political progress. D. in New York, June 9, 1891.

C. H. T.

Adlercreutz, CARL JOHAN, Count: Swedish general; b. in Finland, Apr. 27, 1757; served against Russia in 1788, and in the Finnish war of 1808. On Mar. 13, 1809, in consequence of several unpopular actions of the king, Gustavus IV., he arrested the king in the name of the people, which act gained him great popularity. D. Aug. 21, 1815.

Adler Sal'vius, JOHAN: Swedish ambassador and diplomatist; b. in Strengnäs, Sweden, in 1590; and d. at Stockholm in 1652. He was sent by Gustavus Adolphus on various missions of importance, and during the Thirty Years War he enjoyed the fullest confidence of that monarch. After the conclusion of peace he was created a councilor and baron.

Adlersparre, GEORGE, Count: Swedish officer and statesman; b. in Jemtland, Mar. 28, 1760; took part in the wars of 1788 and 1808 against Russia, and in the deposition of Gustavus IV. He received many indications of favor from the new king, but was dissatisfied with the result of the revolution, because he had not gained as much influence as he desired. He published, from 1830-33, a number of secret documents, as well as his correspondence with Charles XIII. and others, in consequence of which he was sentenced to pay a fine. He nevertheless continued to publish these documents. D. in Wermland, Sept. 23, 1835.

Adme'tus (Gr. Ἄδμητος): son of Pheres, who was the mythical founder and first King of Pheræ in Thessaly. He was one of the Argonauts, and took a part in the Calydonian Hunt. He won the hand of Alcestis by coming to the suit in a chariot drawn by boars and lions, that being a condition imposed by the bride's father, Pelias. The god Apollo procured from the Fates a grant that Admetus might be exempt from death if his father, mother, or wife should die for him. The touching story of Alcestis and her devotion, death, and restoration to life form the subject of one of the most celebrated tragedies of Euripides.

Administra'tion: literally "management" or the conduct of business. The word is often used to indicate the action of the executive department of government, as distinguished from the legislative and judicial. It sometimes is employed with reference to trust funds, but its technical meaning is the management or disposition, according to law, of the personal estate of an intestate or of a testator having no executor. The common-law distinction between heirs on the one hand and executors and administrators on the other should be noted. When an owner of real estate died, his estate devolved upon his heirs, who were persons related to him by blood; when an owner of personal property died, leaving a testament or will, that branch of his estate devolved upon his executors, if such were named; if there were none, then upon administrators appointed by a court of justice. Administration in this sense was in England under the control of the ecclesiastical courts until 1857, when it devolved upon a newly created court of probate. In the U. S. it is generally vested in special tribunals termed probate or orphans' or surrogates' courts. By such a court administration is conferred on the person or persons entitled to it by the local rules of law. It is in general committed first to the widow or husband, then to the children, and then to the other next of kin, in a prescribed order. The court has power of selection among the next of kin in equal degree. These provisions are substantially copied from early English statutes. The person thus intrusted with the administration is called an administrator. The court grants him "letters of administration" as evi-

dence of his authority. He represents the deceased. He must make an inventory of the personal estate, collect the assets, and convert the property into cash, pay the debts, render an account, and distribute the balance in his hands among the persons entitled to it. He is a trustee, and under the control of a court of equity as well as of the probate court.

When the deceased leaves a will, but there is no executor, the person to whom administration is granted is termed an administrator "with the will annexed" (*cum testamento annexo*). In this case the will is to guide the administrator in his duties. Should an administrator die before his duties are fulfilled, another is appointed to perform the residue of his functions, called "administrator *de bonis non*."

While an administrator exercises full control over the personal estate of the deceased, his authority is confined to it unless it is insufficient to pay debts; in which case the probate court generally has by statute the right to direct him to sell enough of the real estate to satisfy them.

Letters of administration confer no power to bring actions in foreign states. Where there are assets in another state or country, a subordinate or ancillary administrator is appointed, who acts under the direction of the foreign court, and remits according to its order any funds which he may receive to the principal administrator. T. W. DWIGHT.

Administrative Law: that branch of public law which deals with the various organs of the sovereign power considered as in motion. It includes such subjects as the collection of the revenue, the collection of statistics, sanitary measures, the regulation of military and naval forces, the organization of schools, the supervision of places of amusement, the protection of the coinage, the poor laws, etc.

HENRY WADE ROGERS.

Administrator: See ADMINISTRATION.

Admirable Crichton, The: See CRICHTON, JAMES.

Ad'miral [Fr. *amiral*, from Arab. *amir*, commander; cf. *ameer*, *emir*]: the title of a naval officer of the highest rank. The English word was formerly *amiral*, as in Milton's *Paradise Lost*. Vice-admiral is the title of the officer next in rank to the admiral; and a rear-admiral is the third in the scale. Admirals are frequently called *flag-officers*, from the fact that the symbol of their rank is a flag.

The grades of rear-admiral and commodore in the U. S. navy were first established by act of July 16, 1862, which provided that the number of each grade shall not exceed 9 rear-admirals, 18 commodores, 36 captains, etc. By act of Congress of Dec. 21, 1864, the President was authorized to appoint from the rear-admirals one vice-admiral, who should be the ranking officer in the navy of the U. S., and whose relative rank with officers of the army shall be that of lieutenant-general in the army. This grade was created for and bestowed upon Rear-Admiral Farragut. By act of July 25, 1866, it was provided that the number of officers of each grade on the active list should be one admiral, one vice-admiral, 10 rear-admirals, 25 commodores, etc. The rank of admiral thus created was bestowed upon Vice-Admiral David Farragut, succeeded by David D. Porter. A law was passed abolishing grades of admiral and vice-admiral when said grades became vacant. These grades have now (1892) become vacant by the deaths of the distinguished officers who held them. Congress in 1882 provided for a reduction of the active list to six rear-admirals, 10 commodores, etc.

S. B. LUCE.

Ad'miralty [from *admiral*]: the tribunal which has cognizance of maritime causes. This court was established in England about the time of Edward III., and was at first held before the Lord High Admiral or his deputy. At present, admiralty jurisdiction is there exercised by the judge of the admiralty, who holds an instance or a prize court by means of separate commissions; the former being the ordinary admiralty court, and the latter being a special tribunal instituted in time of war to take cognizance of matters pertaining to prizes. In the U. S. exclusive admiralty and maritime jurisdiction is by the Constitution delegated to the Federal courts.

It was for a long time an unsettled question whether the word as there used had the limited sense employed in the early English statutes of 13 and 15 Rich. II., restricting admiralty jurisdiction, or whether it had a wider signification. The latter view has finally prevailed, principally owing to the arguments of Mr. Justice Story; and the word embraces not only cases occurring on tide-waters, but on

navigable streams above tide-water, including the Great Lakes. It rests with Congress to determine upon what court the jurisdiction shall be conferred. It has accordingly vested it in the first instance in the district court. No distinction is taken here between the instance and the prize court.

Admiralty jurisdiction is either civil or criminal. Its civil jurisdiction embraces cases of maritime contracts (such as affreightment, repairs of ships, bottomry bonds, pilotage, seamen's wages, and salvage), general average, collisions, and maritime trespasses in general. The principles and course of practice of the court in civil cases are in the main derived from the Roman or civil law.

Revised by HENRY WADE ROGERS.

Admiralty: the office of Lord High Admiral of England, or the commissioners for executing the office of Lord High Admiral, commonly known as the Board of Admiralty. The head of the board, or minister of marine, is styled First Lord of the Admiralty.

Admiralty Islands: a cluster of islands in the Pacific, N. E. of New Guinea, forming part of the BISMARCK ARCHIPELAGO (*q. v.*). The largest is nearly 60 miles long, and is in lat. 2° S., lon. 147° E.

Admission of New States: See TERRITORY.

Admis'sions: in the law of evidence, acknowledgments or concessions by a person of the existence of certain facts. When they relate to the matter in dispute, they are admissible in evidence against the party making them. They may be made either by a party to an action or by some one identified with him, as by a partner. The admissions of an agent will affect his principal. Those made by a predecessor in interest will affect his successor. Thus the admissions of an ancestor will charge an heir. In form, an admission may be either direct or implied from conduct, or in some instances even from silence. The effect of an admission is usually only to raise a presumption against the party, which he may rebut; but some admissions are regarded as of so high a character that the law will not allow them to be contradicted. See ESTOPPEL.

Adol'phus (or **A'dolph**) of NASSAU: elected Emperor of Germany in 1292, as successor to Rudolph of Hapsburg. In 1298 the German princes transferred the imperial crown to Albert, but Adolphus refused to abdicate. A war ensued between these rivals, and Adolphus was killed in battle near Worms, July 2, 1298.

Adol'phus Fred'erick: Duke of Holstein-Gottorp and King of Sweden; b. May 14, 1710. He was elected Bishop of Lübeck in 1727, Crown Prince of Sweden July 3, 1743, and became king on April 5, 1751. The Swedish nobles continued their arrogance under him to the utmost, so that at last he threatened to resign. In consequence of this the Parliament revoked the restrictions of the royal prerogatives. D. Feb. 12, 1771.

Adol'phus, JOHN: an English historian and lawyer; b. Aug. 7, 1768. He was noted for eloquence, and practiced with great success in criminal causes. His defense of Thistlewood, accused of treason in 1820, was highly commended. His principal work is a *History of England from the Accession of George III.* (7 vols., 1802-45). D. in London, July 16, 1845.

Ad'onai [an ancient plural of Heb. אֲדֹנָי, Lord, with suffix denoting a pronoun of the first person; cf. Fr. *monsieur*]: a term applied in the Hebrew Scriptures to God. Owing to the veneration of the Hebrews for the most sacred name of the Deity, Jehovah (or Yahveh) was not pronounced in reading the Scriptures; but Adonai was read instead of it wherever it occurred. When the Hebrew text came to be vocalized, the proper pointing of Adonai, אֲדֹנָי, was given to יהוה, so that to the eye it reads Yehovah instead of Yahveh. See JEHOVAH.

Adon'ic (in Lat. *versus Adonius*): a measure consisting of a dactyl and a spondee, or rather of an irrational dactyl (see DACTYL) and a trochee. In classic poetry it is used only as a clausula. As an independent verse it is employed in the familiar Latin hymn:

Plaudite caeli,
Rideat aether.

Ado'nis (Gr. Ἄδωνις): a youth celebrated in ancient poetic legends as a model of youthful beauty and a favorite of Venus. Addicted to the pleasures of the chase, he was killed by a wild boar. An annual festival in honor of Adonis,

called Adonia, was celebrated in Asia Minor and other countries bordering on the Mediterranean. He was called Thammuz by the Hebrew writers.—ADONIS was also the name of a river which rose in Mt. Lebanon, and flowed through Phœnicia into the sea.

Adonis: a genus of herbaceous plants, of the family *Ranunculaceæ*, natives of Europe. Several species of this genus are cultivated for the beauty of their flowers.

Ad'onists: those biblical critics who maintain that the Hebrew vowel points usually written under the consonants of the word Jehovah are not the points which properly belong to that word, but those which belong to the words *Adonai* and *Elohim*.

Adop'tian Con'troversy: a controversy which originated in Spain near the end of the eighth century. Felix, Bishop of Urgel, and Elipandus, Archbishop of Toledo, advanced the doctrine that Christ was by nature and generation the Son of God only as regards his divine nature, but as to his human nature he was merely the Son of God by adoption. Those who espoused these views were called Adoptionists (in Lat. *Adoptiani*). They have been called the Nestorians of the West. No particular notice was taken of them so long as they confined the propagation of their opinions to Mohammedan territory, but when they undertook to spread the new doctrine in the Frankish empire Charlemagne promptly put a stop to it by convening two synods, one at Ratisbon (792), another at Frankfort (794), both of which condemned Adoptionism as heresy. Elipandus, who still adhered to his views, d. in 799. Felix recanted at the Council of Aix-la-Chapelle in 799. D. in 816.

Adop'tion [from the Lat. *ad*, to, for + *optio*, a choice]: in law, is the taking a child of other parents as one's own. The practice, which was common in ancient Rome, was recognized by the civil law, and is found in countries and states where that law and its modifications still prevail. In some other states the matter is regulated by statute. The parents, guardians, next of kin, or other legal representative of the child, must in general give consent after notification of the intent to adopt. Adopted children do not, in most countries, inherit property coming from collateral relatives of the adoptive parents. Adoption is usually authorized by a probate court or other established authority after due notice. The adoption of an adult person is known in the civil law as adrogation.

Ador'no, ANTONIO: a doge of Genoa, who was driven out and re-established three times in succession. By his persuasion the Genoese agreed to the treaty, signed Oct. 26, 1396, which rendered them subjects of Charles VI. of France.

Adour, a river of Southwestern France, rises in the Pyrenees and enters the bay of Biscay a few miles below Bayonne, which is on its bank. Length, about 200 miles. It is navigable to Dax.

Adowa: the capital of the Abyssinian province of Tigré; in lat. 14° 12' N., lon. 39° 3' E.; in a well-cultivated and populous plain 6,500 feet above the level of the sea, near the ruins of Aksum, the former capital of Abyssinia (see map of Africa, ref. 4-G). It is the most important commercial town of Abyssinia. Pop. 3,000.

A'dra (anc. *Abde'ra*): a seaport of Spain, in Andalusia, 46 miles S. E. of Granada (see map of Spain, ref. 20-F). Here are extensive lead mines. Pop. 11,320.

Adrain, ROBERT, LL. D.: b. at Carrickfergus, Ireland, Sept. 30, 1775; served as an officer in the rebellion of 1798; was badly wounded; escaped to the U. S.; was Professor of Mathematics in Rutgers College (1810-13), Columbia College (1813-25), and the University of Pennsylvania (1827-34). D. at New Brunswick, N. J., Aug. 10, 1843.

Adrar: See RIO DE ORO.

Adraste'a [Gr. Ἀδράστεια, deriv. of ἄδραστος, not to be escaped; ἀ-, not + διδράσκειν, escape]: a Greek surname or epithet for the goddess Nemesis, who administered retribution for iniquity.—Also a nymph of Crete, to whom, with Ida and the Curetes, Rhea intrusted the infant Zeus in the Dictæan grotto.

Adras'tus (Gr. Ἄδραστος): King of Argos, and a contemporary of Theseus; father-in-law of Polynices. He commanded the famous expedition called the war of the "Seven against Thebes," to restore Polynices to the throne of Thebes. This enterprise, which was not successful, was a favorite theme of ancient epic and tragic poets.

A'dria, or Ha'dria: an ancient town of Italy, situated between the Po and the Adige, in the province of Rovigo, 13 miles E. of Rovigo (see map of Italy, ref. 3-D). It was in ancient times a seaport on the Adriatic, but it is now 14 miles from that sea. Pop. (1881) 15,806.

A'drian: city and railroad center (for location of county, see map of Michigan, ref. 8-J); capital of Lenawee co., Mich., 30 miles W. of Toledo and 74 miles W. S. W. of Detroit, is intersected by the river Raisin, which furnishes water-power. The city has fine schools, the Central public-school building costing \$100,000. It has also a mineral spring, a Masonic temple, costing \$100,000, and an opera-house. Adrian College, a Methodist institution, is finely located on the western boundary of the city. Adrian has a variety of manufactures, among which may be mentioned railroad cars, furniture, electric appliances, canning-works, straw and felt goods, and brick and tile machines. Pop. (1880) 7,849; (1890) 8,756; (1900) 9,654.

EDITOR OF "TIMES AND EXPOSITOR."

Adrian, Emperor of Rome: See HADRIAN.

Adrian I.: a native of Rome; elected pope in 772. His dominions were invaded by the King of the Longobards, against whom Adrian was defended by Charlemagne. Under this pontiff Rome enjoyed more than usual prosperity. D. in Rome, Dec. 25, 795.

Adrian IV. (NICHOLAS BREAKSPEAR): the only Englishman who ever attained the dignity of pope; b. near St. Albans. He became Cardinal-Bishop of Albano in 1146, and was chosen pope in 1154. He was a strenuous asserter of papal supremacy. D. at Anagni, Sept. 1, 1159.

Adrian VI.: b. at Utrecht, Mar. 2, 1459; was a preceptor of the Emperor Charles V.; succeeded Leo X. in 1522. He favored reform, and was honest and virtuous. D. in Rome, Sept. 14, 1523.

Adria'ni, JOHN BAPTIST, or GIOVANNI BATTISTA: b. at Florence, Italy, in 1513. He became in 1549 Professor of Eloquence in the University of Florence, and held that office till his death; wrote a history of his own times (i. e. an. 1536-1574). D. in 1579.

A'drianists: disciples of Simon Magus, who flourished about A. D. 34. They were probably a branch of the Simonians, and named from some prominent disciple.

Adriano'ple (anciently *Adrianopolis*, or Hadrian's city; Turk. *Edreneh*): a large city of European Turkey, on the river Tundja near its confluence with the Maritza (the ancient Hebrus); 137 miles W. N. W. of Constantinople (see map of Turkey, ref. 4-D). The name is derived from the Roman Emperor Hadrian, who founded a city here. It was the capital of the Ottoman empire from 1361 until 1453. Here is the famous mosque of the Sultan Selim, which is said to be the finest Moslem temple extant, and has four lofty minarets. Among the other public structures are a palace, the bazaar of Ali Pasha, and an aqueduct by which the city is supplied with water. Here are extensive manufactures of silk, cotton, and woolen stuffs. Among the exports are opium, leather, wool, and attar of roses. Adrianople is the residence of the governor-general of the vilayet Edreneh, and of a Greek bishop. Pop. about 100,000.

M. W. H.

Adrian's Wall: See HADRIAN'S WALL.

Adriat'ic Sea (Lat. *Mare Adriaticum*): a portion of the Mediterranean, lying between Italy on the one hand and Illyria and Albania on the other. The name is derived from the town of Adria. It is about 500 miles long from N. W. to S. E., and has a mean width of about 100 miles. The N. W. part of it is called the Gulf of Venice, and at the S. E. end it is connected by the Strait of Otranto with the Ionian Sea. The N. E. coast is rocky and begirt with a great number of islands. The depth and extent of the Adriatic have been greatly diminished by deposits of sand and mud and by the formation of alluvial tracts along the shore. The encroachment of the land is most remarkable on the W. and N. W. coasts of the Gulf of Venice.

Adul'lam: a city of Judah; the seat of a Canaanite king, and evidently a very ancient place. Its site has been identified by Ganneau with 'Aid-el-Ma (the Arabic equivalent of Adullam), about 8 miles N. E. of Eleutheropolis (modern Beit-Jibrin), which is traditionally located 6 miles S. E. of Bethlehem. The famous cave of King David is in a hill about 500 feet high. The sides of the valley are full of caves.

Adulteration: defined by Hassell as the intentional addition to an article of any substance or substances the presence of which is not acknowledged in the name under which the article is sold, for the purposes of gain, deception, or concealment. Every civilized country has enacted laws to prevent and punish adulteration, and throughout Europe these laws are stringent and, for the most part, rigidly enforced. Although Germany protects her own citizens against adulteration, many articles manufactured there "for export" are specially exempt from the provisions of her adulteration laws. Nearly every article made by man for man's use is or has been debased by man for purposes of gain. Numerous excuses have been urged in defense of adulteration. Several of these bear so directly on the subject that they are worthy of mention. One is that popular taste and desire demand certain adulterations; for example, pickles and pease colored green with copper salts often find a readier sale than those uncolored. Another excuse is that the public demand cheapness, and to meet this demand competition forces on the market articles that are more or less spurious. A third excuse is that certain additions must be made to perishable foods to make them keep. These excuses are all plausible, but the answer to each is obvious. The substances employed for the different purposes of adulteration are numerous, and depend upon the object aimed at. Thus for increase of bulk or weight of a given article a cheaper inert substance is added. To increase attractiveness, coloring-matter is used. To add flavor, a cheap compound, usually made from essential oils or ethers, is utilized. Very commonly all three of these forms of adulteration are seen in one adulterated article. The adulteration for bulk so reduces the natural color and flavor that artificial coloring and the addition of some flavoring-essence are necessary to conceal the fraud.

The sanitary aspect of adulteration is its most important one. The adulteration of articles of food, drink, or drugs with substances that are in themselves harmless but inert effects harm by reducing the natural strength and properties of the adulterated article. The nourishing properties of the food or beverage are impaired, or the drug does not do the work intended by its prescriber. Poisonous or harmful adulterants are frequently used. The writer in numerous instances has detected manufacturers of food-articles adding to their products, for the purposes of adulteration, such substances as Paris green, chromate of lead, mercurial pigments, borax, salicylic acid, copper salts, poisonous aniline pigments, cocculus indicus, mineral earths, etc.

The most important and serious adulteration, however, is that practiced in connection with the milk supply. Milk is often the exclusive food of babes and invalids. Consequently its reduction means the robbing of these of their proper nourishment. Any deleterious substance added to it affects a class of individuals who are most susceptible to deleterious influences. It is very easy to adulterate milk, and the profits derived from the practice are enticing. The adulteration of milk at the present time is usually effected by the addition of water, coloring-matter such as annatto, turmeric, and antiseptics or antiferments, such as carbonate of soda, borax, etc., or by the removal of the cream, either wholly or in part. Such substances as calves' brains, gelatin, starch, or chalk are never used at the present time. The addition of water and, in some cases, the removal of the cream may be detected by means of the lactometer. The lactometer is a delicate hydrometer which indicates the specific gravity at a temperature of 60° F., between 1.00000 (the specific gravity of pure water) and 1.03480. On the scale the specific gravity of water is indicated by 0°, the specific gravity of 1.03480 by 120°, the space between 0° and 120° being divided into 120 equal parts. The 100° mark indicates a specific gravity of 1.02900. The results of many thousand tests with the lactometer have conclusively shown that milk from a healthy cow in normal condition will never show a specific gravity of less than 100°, at a temperature of 60° F. If, then, a sample of milk stands below 100° on the lactometer, at 60° F., the sample has been adulterated by the addition of water. The space between 0° and 100° being divided into 100 equal parts, each part indicates 1 per cent. If, therefore, the milk tested has a specific gravity indicated by 90°—that is, if the lactometer floats at 90°—it is safe to assume that at least 10 per cent of water has been added. It must be remembered that in average milk the lactometer will stand at points between 105° and 115°, at 60° F. From 5 to 15 per cent of water may therefore be added to average milk without bringing it below 100° on the lactometer. The

proper method of using the lactometer is as follows: The milk to be tested is thoroughly mixed by stirring, a sample taken, and the latter warmed or cooled, as the case may be, to 60° F. The lactometer is carefully placed in it, and the mark at which it floats noted. Now remove the lactometer, and observe the character of the film adhering to it. If this runs off readily, and is thin and bluish, and if the sample has a watery taste, the lactometer standing below 100°, it is certain that water has been added. If the appearance and taste are as above stated, the lactometer standing at some point higher than 100°, the milk has been skimmed, or skimmed and watered. As skimmed milk has a specific gravity much greater than whole milk, the cream, its lightest constituent, having been removed, it will stand high when tested by the lactometer, and will, of course, have a thin appearance and a flat taste. On the other hand, cream will stand at points much below 100° on the lactometer, but it is impossible to confound cream with milk, and much less with milk that has been watered. If the lactometer floats at some point greater than 100°, the appearance being whitish and the taste of the milk creamy, we may assume that the milk has not been adulterated by the addition of water or by the removal of cream. The removal of cream may be detected by means of the cream-gauge, which consists of a hollow glass cylinder divided into 100 equal parts. The milk is placed in it, the cream allowed to rise, and the amount noted. Each division, of course, represents the percentage of cream present. The removal of cream may also be detected by means of the lactoscope, that devised by Prof. Feser being a convenient form for use. This instrument is constructed on the principle that the transparency of a layer of milk is inversely as the quantity of fat in the milk. It consists of a hollow glass cylinder doubly graduated, one scale giving the number of cubic centimeters of water used for the dilution, the other indicating the percentage of fat. In the lower part of the cylinder a small cylindrical piece of opaque white glass is fixed, which is marked with black lines. In testing a sample of milk 4 cubic cm. are transferred to the apparatus by means of a pipette. Water is then gradually added, the mixture being thoroughly shaken after each addition, until all the black lines on the cylinder can be read, when the scale indicates the percentage of fat in the milk. Adulteration of milk by water from an infected source has frequently caused outbreaks of typhoid fever. The adulterator is not fastidious as to the purity of the water he adds. The writer has found frogs and small water-snakes in milk adulterated with water in New York city.

Malt beverages, ale and beer, are very commonly adulterated. The color of these drinks should be due solely to the degree of heat to which the malt has been subjected in the kiln, or to the ripeness and color of the hops used. To attain a perfect color great care must be exercised. Careless brewers, when they fail to attain it in the proper way, use burnt sugar. Beer is also flavored artificially by the addition of such bitters as *pieric acid*, *cocculus indicus*, and *strychnia*; also *quassia*, *wormwood*, and *gentian*. Drugs in great variety are used in the adulteration of ale and beer. In nearly every large city several so-called brewers' druggists may be found. Some of these drugs are used to give the beer an appearance of strength, and to make it froth or "head" well. For this purpose *alkalies*, *iron* and *salt* are employed. Occasionally *cream of tartar* is added to give the beer a hardness characteristic of age.

Wines.—The adulteration of wines is practiced in a variety of ways. Coloring-matter is added; commonly some coal-tar product, such as *fuchsine*; occasionally *Brazil-wood* or *logwood*. Wines are frequently fortified by the addition of *alcohol*, and flavored by means of various flavoring agents. The writer once detected a manufacturer of wine (so called) in the city of New York, who managed to produce a rather attractive-looking wine without the use of a single grape. His method was as follows: A decoction was made from dried peaches, which was carefully strained and fermented. After fermentation had reached a certain point it was stopped by heat and the addition of *salicylic acid*; a certain amount of *alcohol* and artificial flavor were then added, and a red color imparted to it by means of *fuchsine*. *Salicylic acid* is a common adulterant of wine, being added to insure against loss by souring. Very large amounts of this substance are frequently found in specimens of wine. This is in consequence of each person through whose hands the wine has passed, being afraid of its spoiling while in his possession, having added a little of the acid and being ignorant of the fact that it was previously adulterated.

Whisky, gin, brandy, rum, and the like are made by the following means: Proof spirits are reduced by the addition of water to a proper degree, and flavored with a flavoring-essence made of an etheric compound. *Vinegar* is adulterated by being reduced with water, and subsequently fortified by means of *sulphuric* or *hydrochloric acid*. The coloring-matter used is *burnt sugar*. *Cider* is usually adulterated with *salicylic acid* in order to make it keep.

Olive Oil.—Cotton-seed oil has become the almost exclusive adulterant used to debase olive oil, although mustard-seed oil is still used to some extent for this purpose.

Confectionery has been one of the most commonly adulterated articles. At the present time the manufacturers of candy are so closely watched that the practice is rare. Substances used to adulterate confectionery for bulk are *terra alba*, *starch*, finely powdered *asbestos*, *sawdust*, *Indian meal*, *glue*, etc. For color, nearly every poisonous pigment known to man has been employed.

Sugar.—The adulterants of cane-sugar are mainly *terra alba* and *glucose*. The latter substance, being *hygroscopic*, must be mixed with the cane-sugar very soon before sale, otherwise the admixture of the two will result in a solid mass. *Ground quartz* and *sand* have also been detected as sugar adulterants.

Honey.—Cane and grape sugar are very frequently added to strained or extracted honey and bee-bread used to strengthen the diluted flavor.

Tea and *coffee* are both subjects of the adulterator's art. Green teas are "faced" and "painted." This is done by shaking the leaves in pans and dusting over them powdered *soapstone* and *Prussian blue*. "Lie tea" is an example of Chinese dexterity. "Spent" tea leaves are rolled up by the nimble-fingered Celestials, who deposit in the center of each leaf a few grains of sand to add to its weight. The Chinese also sometimes add *sulphate of iron* to "spent" tea leaves to color the resulting infusion, and make it appear stronger than ordinary. Many kinds of leaves other than those of the tea-plant are added to tea; *rhododendron*, *chrysanthemum*, and *willow leaves* are examples.

Coffee.—The commonest adulterants of ground coffee are *chicory* and dried *blackstrap molasses*. *Roasted wheat*, *acorns*, *sawdust*, *Venetian red*, *pease ground* and *roasted*, and *beans* are also used. The unground coffee bean is frequently treated in a curious way: Mexican and South American coffees are made to resemble Java by putting the beans of the former into large boxes and causing them to swell through the medium of steam heat. After the berries have attained the size of those from Java, they are colored brown with *burnt umber* or some other brown pigment. Damaged coffee is painted by revolving it in large boiler-iron cylinders, while it is sprinkled with a mixture of *chromate of lead* or *turmeric* and *Prussian blue*, which restores its bright green color.

Bread.—The adulterants of bread are principally *alum* and *sulphate of copper*, added to effect whiteness.

Flour.—Damaged wheat flour is easily repaired by the addition of *alum* and *carbonate of soda*. This is done to harden the partially decomposed gluten and to correct acidity due to decomposition. Occasionally the hydrated *sulphate of lime* is added to flour. To increase the bulk *terra alba* has been used.

Mustard and *spices* are very difficult to obtain pure. Adulterants of the former are *turmeric* and *naphthaline-yellow*, and, for bulk, *wheat flour*. The spice adulterants may be purchased by the barrel of many wholesale spice firms, and are called by the slang term "P. D." As the adulteration of spices has little, if any, sanitary significance, the practice is practically unrestricted. "P. D." is made from *sawdust*, *ground nutshells*, and *ground olive pits*, colored with *mineral earths*, when color is necessary.

Butter.—*Annatto*, the only coloring-matter that can be used in connection with this substance, can hardly be considered as an adulterant, nor can the use of *oleomargarine* in its place when the latter is sold under its own name. *Starch* is said by some authorities to be an adulterant of butter. The writer has never been able to verify this statement. Foreign fats (i. e. fats other than milk fats), however, are frequently added to butter to increase its bulk.

Jellies and *jams* are adulterated in a very ingenious manner. To enable the jelly to "jell" with a minimum amount of *sugar*, *gelatin* or *glue* is added. The use of these substances also permits the manufacturer to utilize *glucose* in the manufacture of his wares. The compound of *glucose* and *glue* is colored with an *aniline dye*, usually *fuchsine*, and

a body is imparted to the mass by adding dried apples that have been stewed in water almost to solidity, and strained under pressure. Cider jelly is also used as a basis for the various fruit jellies. To convert the basis into any desired jelly, the manufacturer adds one of the flavoring-ethers and a red color, usually fuchsine, and the result is attained.

Flavors.—The various natural fruit flavors are all imitated and adulterated by means of the artificial flavoring-ethers. These are compounds of wine, wood, and potato ethers. Thus, for example, pineapple oil is made by combining wine ether with butyric acid and then dissolving the resulting product in alcohol.

Drugs.—The commonest adulteration of drugs is by means of damaged or "spent" drugs of the same kind as those adulterated. The essential oils are often reduced, the more expensive ones by admixture with essential oils of less cost. Thus, for example, the oil of peppermint is frequently diluted with the oil of pennyroyal. The fixed oils are also used to adulterate the essentials. This practice is easily detected by the fact that the boiling-point is reduced in proportion to the amount of the adulteration.

Tobacco is frequently adulterated by the addition of some flavoring agent. It is also colored by means of various pigments. For the former purpose hippuric acid and various fruit flavors and flavoring-ethers are used; for the latter, aniline pigments and lead chromate are utilized. Snuff, especially, is adulterated with this latter substance. Lime is also used very commonly to adulterate snuff.

The Detection of Adulteration.—Before proceeding to the examination of any article for the purpose of discovering whether it is adulterated or not, it is necessary to become thoroughly acquainted with the appearance and structure of the article itself. If the substance be in a state of powder, nothing more is necessary than to place a very minute portion of it upon a glass slide, add a drop or two of water, cover it with a microscope cover-glass, and place it under the microscope for observation. A sample of known purity of the same kind as the article to be examined can be observed side by side with that suspected. The difference will be obvious. If the substance be a solid one, it is necessary to make some thin slices of it, and proceed as in the first case. The microscope is specially fitted for the detection of organized structures and substances, whether animal or vegetable. The best method of detecting chemical adulterants and salts is by the use of chemical reactions and analysis.

CYRUS EDSON.

Adultery: sexual intercourse between two persons who are not husband and wife, and one or both of whom are married. This act has been punished by the laws of some nations with great rigor—among the ancients often with death. In English law the act is not treated as a temporal crime, but left to the cognizance of the spiritual courts. A civil action for damages may by common law be brought by a husband against one who has committed adultery with his wife. This is called an action "for criminal conversation." It is also a ground of divorce—at first partial, but now, by statute, total. In some of the States of this country adultery has been made a crime, while in others the English law in its substance still prevails, and only the civil proceedings are allowed.

Advancement: in law, is a provision of money or other property, made by a parent for a child in advance or anticipation of the estate or distributive share to which such child would be entitled on the parent's death. An expenditure for the education and maintenance of a child is not regarded as an advancement. It must be made with a view to a portion or settlement in life. The parent's intent is the main subject of inquiry. In the English law of real estate it only applies in case of several female heirs, who take the interest called coparcenary. In the American law of descent the subject is of general application. The effect of an advancement is to reduce the child's share to that extent, estimating the value as of the time of the receipt. An advancement differs from a debt in that the latter can be recovered by action, while the former can only be deducted from a distributive share. It is at the option of the person advanced to bring in to the general distribution the amount received or not. In the English law the act of bringing it in is termed hotchpot. The doctrine strictly applies only to cases of intestacy. There is a cognate doctrine termed "ademption," applicable to the case of property left by will. In this country the subject is often governed by statute, sometimes establishing distinct rules

for real and personal estate. The word "advancement" is also used in the law of trusts to indicate that a purchase of land made in the name of a wife or child or other person as to whom the purchaser stands in the place of a parent shall actually belong to such person, and shall not, by the fiction of a resulting trust, revert beneficially to the purchaser.

T. W. DWIGHT.

Advancement of Science: See AMERICAN ASSOCIATION FOR ADVANCEMENT OF SCIENCE, and BRITISH ASSOCIATION FOR ADVANCEMENT OF SCIENCE.

Ad'vent [Lat. *adventus*, from *ad*, to + *venire*, come, referring to the coming of Christ]: the period of four weeks preceding Christmas, with which the ecclesiastical year begins. Roman Catholics and many members of the Anglican communion observe Advent by abstaining from public amusements and nuptial festivities. The Greek Church lengthens the period to six weeks.

Revised by W. S. PERRY.

Ad'ventists: a body of Christians whose distinctive characteristic is a belief in the speedy advent or second coming of the Lord Jesus Christ. In 1833 William Miller (*q. v.*) was led by the study of the prophecies of the Bible to the belief that the second advent and the final judgment would occur in 1843. He had at one time about 50,000 followers; and notwithstanding the failure of this and other predictions fixing a definite date, there are, it is believed, about 70,000 members of the Adventist churches, who at present do not presume to foretell the period of the second advent, but live in expectation of that event. They are congregational in church government, practice immersion, and in general hold the orthodox views. With the exception of the Evangelical Adventists, they believe in the ultimate annihilation of the wicked, and in the sleep of the dead until the final judgment. They are divided among six denominations (the numbers are from the census of 1890), viz.: 1. EVANGELICAL ADVENTISTS: this is the original body, formed 1845; differs from all the other bodies in affirming conscious suffering of the lost in the middle state and the eternity of future punishment; they number 1,147 members; their organ is *Messiah's Herald* (Boston). 2. SEVENTH-DAY ADVENTISTS: formed 1845; consider observance of Saturday as the Sabbath and foot-washing obligatory; number 28,991 members; their organ is *The Advent Review* (Battle Creek, Mich.). 3. THE CHURCH OF GOD: a seceding branch of the preceding, formed 1866; denies the application of Rev. xiii. 11-17 to the U. S.; numbers 647 members; organ, *The Advent and Sabbath Advocate* (Stanberry, Mo.). 4. LIFE AND ADVENT UNION: originated 1848; organized 1864; numbers 1,018 members; has members in Great Britain; organ, *The Herald of Life* (Springfield, Mass.). 5. AGE TO COME ADVENTISTS: originated 1851; organized 1881; numbers in U. S. and Canada 4,000; organ, *Words of Cheer* (Brooklyn, N. Y.). 6. ADVENT CHRISTIANS: formed 1861; is found in all the States (25,816 members), Canada, England, Ireland, and India; organ, *The World's Crisis* (Boston, Mass.).

Revised by S. M. JACKSON.

Ad'verb [Lat. *adverbium*; *ad*, to + *verbum*, verb, a formal translation of Gr. *ἐπιρρημα*, *ἐπί*, to + *ῥῆμα*, verb]: one of the parts of speech in grammar. The adverb in all languages is indeclinable (though sometimes subject to the change of form known as comparison), and is used to express some modification of a verb, adjective, or other adverb, as to place, time, cause, manner, intensity, certainty, conditionality, quality, quantity, etc. The function of an adverb is often performed by a sentence or part of a sentence. Most English adverbs are formed by adding the suffix *ly* to an adjective or its root, though many are not thus formed.

Adverse Possession: See DISSEIZIN.

Advertisements (eccles.): certain statements of principles, rules, suggestions, and directions drawn up by the Elizabethan bishops, and issued for the guidance and direction of the Church. In the Folkestone ritual case (*Ridsdale vs. Clifton et al.*, Sir James Stephen, Q. C., contended that the "advertisements had not the force of law, but were a mere administrative act, done by the bishops of that time, not merely without the authority of the queen, but the queen expressly withholding her authority, for reasons still on record." The judgment of the Lords of the Judicial Committee of the Privy Council, on the appeal of *Ridsdale, clerk, vs. Clifton*, was that the advertisements of Queen Elizabeth issued in 1566 were a "taking of order" within the act of Parliament, by the queen, with the advice of the metropolitan.

W. S. PERRY.

Advocate [Lat. *advocatus*, one summoned to aid; *ad*, to + *voca're*, call]: in ecclesiastical and civil law courts, same as counselor or counsel in common law courts. The term by which the members of the bar in Scotland (following the civil law) are known is the Faculty of Advocates. In a popular sense, the word denotes a defender or protector generally, especially one who pleads for his client in open court.

Advocate, Lord: the public prosecutor of criminals and the senior counsel for the Crown in civil causes in Scotland. He is sometimes styled king's (or queen's) advocate, and is the first law-officer of the Crown for Scotland.

Advocate of the Church (Lat. *advocatus ecclesie*): in the Middle Ages, a canon or a layman, often a prince or baron, who assumed the protection of a bishop's see, a monastery, or a particular church. Sometimes the office was hereditary, when it appears to have implied the duty of defending the Church's rights by force of arms. Oftener, perhaps, it was held by an *advocatus causarum*, a person appointed by a prince to defend the Church temporalities in secular courts of law. They often administered justice in the name of the Church. They collected tithes and other revenues, and were frequently priests who enjoyed lucrative benefices. The people suffered so severely from their oppressions that Pope Urban III., in 1186, undertook to reform the abuse; but so great was the opposition of the Church and nobles that it was not for many years that the evil was modified.

Advocates, Faculty of: the associated members of the legal profession in Scotland. This society was formed in 1532.

Advocates' Library: the largest library in Scotland, belongs to the Faculty of Advocates, and is located in Edinburgh. It was founded in 1682 by Sir George Mackenzie, and contains about 200,000 volumes. It ranks as the fourth library in the number of volumes in Great Britain.

Advocatus Diaboli [i. e. the devil's advocate]: in the Roman Catholic Church, a person whose business is to magnify the faults or detract from the merit of those who are proposed to be canonized as saints. He is opposed by an *advocatus Dei*, or God's advocate.

Advowson [from O. Fr. *avoison* < Lat. *advocatio*, orig. the duty and right of an advocate or defender]: in English law, the right of presentation to an ecclesiastical benefice or a vacant living in the Church. The right of advowson is given by Blackstone in his commentaries as an instance of an incorporeal hereditament, of which no bodily possession can be had, but which exists solely in contemplation of law. Advowsons are of two sorts, *appendant* and *in gross*. The lord of a manor by building a church acquired the right of nominating the minister, and as long as this right continues annexed to a manor it is called an advowson appendant. When the advowson exists as a personal right, independent of any manor or land, it is said to be in gross. Most of the benefices of the English Church are presentative advowsons. Of nearly 12,000 church benefices, about one-half belong to the Crown, the bishops and other higher clergy, the universities, etc.; the remainder are in the gift of private persons. In most cases, however, the bishop has a right to reject the appointee if he chooses. They may also be either *presentative*, where the patron presents the parson to the ordinary; or *collative*, where the bishop is both patron and ordinary; or *donative*, where the patron puts the clerk in possession without presentation to the ordinary; or *elective*, as in the case of advowsons held by cathedral chapters or trustees and others.

Revised by W. S. PERRY.

Adyar: an aristocratic suburb of Madras (*q. v.*).

Echmal'otarch [Gr. *αἰχμαλωτάρχης*, from *αἰχμάλωτος*, captive + *ἄρχεω*, rule]: the title of the governor of the captive Jews residing in Chaldæa, Assyria, and the adjacent countries. He was called by the Jews themselves *roschgaluth*, chief of the captivity.

Ædile [Lat. *ædilis*, pertaining to buildings (*ædes*)]: a Roman magistrate who superintended the temples and other public buildings, the public games and spectacles, and performed various other duties. Two curule ædiles were annually elected. There were also "plebeian ædiles." Colonies and other towns had ædiles. This office was one of dignity and honor, though reckoned as a minor magistracy. See Schubert, *De Romanorum Ædilibus* (1828).

Ædon (Greek *Ἄδων*): in Greek mythology, a daughter of Pandareus of Ephesus. According to the *Odyssey*, she was the wife of Zethus, King of Thebes. Envious of Niobe, her brother Amphion's wife, she attempted to slay the eldest son of the latter, but by mistake killed her own child, Itylus. Zeus changed her into a nightingale, whose sad notes are the expressions of Ædon's woe. There are other and different traditions as to Ædon's crime and suffering, but in all she is transformed into the nightingale.

Æge'an Sea [Lat. *Ægæum Mære*; Gr. *Αἰγαῖον πέλαγος*, perhaps from *αἰγίς*, a squall, though other etymologies have been given], or **Grecian Archipelago**: the name given by the ancients to that part of the Mediterranean which lies between Asia Minor and Greece. Its length from N. to S. is about 400 miles, and its breadth about 200. It is very deep, and incloses numerous islands, several of which are of volcanic origin, while others are composed of white marble. Many of them rise to the height of 1,600 feet.

Ægidius Colou'na: an eminent schoolman; born at Rome in 1247 of an illustrious stock. He joined the order of Augustinian Hermits, and was a pupil of Aquinas and Bonaventura. In 1292 he became prior-general of his order. He went to France, where Philip the Bold made him tutor for his son, afterward Philip the Fair. In 1296 he became Archbishop of Bourges. For many years he taught with applause in the University of Paris, and was called *Doctor Beatus et Fundatissimus* and *princeps theologorum*. D. Dec. 22, 1316. He left a great number of writings, most of which are now in MS.

Ægilops: a genus of grasses, now united with *Triticum* (wheat), notable for containing *Æ. ovata*, of Southern Europe, which some botanists consider to be the wild state of wheat.

Ægi'na (Gr. *Αἴγινα*), **Egina**, or **Engia**: an island of Greece; in the Gulf of Ægina (*Saronicus Sinus*), 20 miles S. S. W. of Athens (see map of Greece, ref. 17-K). It is 8 miles long and nearly the same in width. It is of an irregularly triangular shape. Area, 33 sq. miles. The western half is a fertile plain; the remainder is diversified by mountains, hills, and valleys, which produce almonds, wine, olive oil, etc. This island is celebrated for its architectural remains. See **ÆGINETAN SCULPTURES**. Pop. 6,000. At the N. W. end of the island is the modern town of Egina. Mt. St. Elias, the highest point of the island, is in lat. 37° 42' N., lon. 23° 30' E. The island is difficult to approach.

Ruins in Ægina.

Ægina, GULF OF (the ancient *Saronicus Sinus*): a portion of the Ægean Sea lying between Attica and the Morea. It contains the islands of Ægina and Salamis.

Æginetan Sculptures, ee-jin-ee'tan: a collection of ancient sculptures discovered on two pediments of a ruined temple of the Doric order in the island of Ægina about 1811. They were removed in the same year and sold to the Crown Prince of Bavaria (afterward King Ludwig I.). By him they were placed in the Glyptothek at Munich. They have been much restored by Thorwaldsen, but are still of the greatest value as specimens of Greek sculpture of a period shortly before its culmination. RUSSELL STURGIS.

Ægir, ee'-gèr: in Scandinavian mythology the god that presides over the stormy sea. He entertains the gods splendidly every harvest and brews ale for them. The name still survives in provincial English for the sea-wave in rivers.

Ægi'ra (Gr. *Αἴγιρα*): one of the twelve cities of the ancient Achaean confederation in Greece. It probably stood near the sea and on the river Crius, though its site is not well known at present. It was famous chiefly for its temples of Zeus, Apollo, Artemis, and Aphrodite Urania (the "heavenly Venus," a goddess who was especially worshiped here), as well as of other divinities. This town is called *Hyperesia* by Homer.

Ægis: the shield of Zeus, from *αἴξ*, a "she-goat," so called because, in his contest with the Titans, Zeus wore the

hide of the goat Amaltheia, which had suckled him in his infancy, together with the head of the Gorgon.

Ægis'thus (Gr. Αἴγισθος): in classic mythology, a son of Thyestes, and an adopted son of Atreus. He seduced Clytemnestra while Agamemnon was absent, and was her accomplice in the murder of that king. He was killed by Orestes.

Ægium (Gr. Αἴγιον; now *Vostitza*): a city of ancient Greece. It belonged to the Achæan League, and after 373 was the chief city in that confederation, of which it was long the capital. It had a good harbor. Remains of its ancient buildings are yet to be seen. The modern town is a place of some importance (see map of Greece, ref. 16-J). It is surrounded by gardens. On Aug. 23, 1817, it was visited by an earthquake which destroyed two-thirds of the houses. Pop. (1879) 5,311.

Ægospot'ami (Gr. Αἴγος ποταμοί): a small river and a town in the Thracian Chersonese, where the Spartan Lysander defeated the Athenian fleet in 405 B. C. This victory ended the Peloponnesian war. A large ævolite fell near this place about 465 B. C.

Ægypt'us (Gr. Αἴγυπτος): a son of Belus and a brother of Danaus, became King of Arabia, and conquered the country which derived from him the name of Egypt. According to a legend he had fifty sons, who were murdered (except one) by the daughters of Danaus. See DANAIDES.

Ælian (*Claudius Ælianus*) of **Præneste**: flourished about 200 A. D.: an entertaining writer in spite of his peevish Greek style and his untrustworthiness. In the seventeen books of his *Nature of Animals* he gossips and moralizes about the ways of beasts. In the fourteen books of his *Miscellaneous Information* (Ροικίλη ἱστορία) the anecdotes deal chiefly with mankind. The *Rustic Letters* preserved under his name are not genuine. Ed. by Hercher (1864); the *Varia Historia* by Perizonius (1701); the *De Animalium Natura* by Jacobs (1832), in 2 vols. See W. Schmid, *Ælian* (1893).

Ælius Sti'lo, LUCIUS (surnamed also *Præconinus*): a Roman knight from Lanuvium, regarded as the most learned man of his time (about 100 B. C.), and the first Roman philologist; was the teacher of Cicero and Varro; and devoted himself to the criticism and interpretation of the early Latin poets, the laws of the Twelve Tables, and the Salian hymn. See F. Mentz, *De L. Ælio Stilone* (Leipzig, 1888). M. WARREN.

Æne'as (Gr. Αἰνέας): the hero of Vergil's *Æneid*, was, according to tradition, the son of Anchises and the goddess Venus. He was one of the most valiant defenders of Troy against the Greeks. According to Vergil, he, after many adventures and disasters, settled in Italy, and married Lavinia, the daughter of King Latinus. The origin of the Roman state is traditionally ascribed to him and his heirs.

Æne'id (Lat. *Æne'is*): the title of Vergil's great epic. See VERGIL.

Æo'lia (Gr. Αἰολία), or **Æo'lis** (Gr. Αἰολίς): a region of Asia Minor, so called from the Æolians, who settled there and founded several cities on different parts of the coast. It was more especially in Lesbos, and along the neighboring shores of the Gulf of Elea, that they finally concentrated their principal colonies and formed a federal union, called the Æolian League, consisting of twelve states and several inferior towns.

Æolian Harp: a simple musical instrument, the sounds of which are produced by the vibration of strings moved by wind. It is formed by stretching eight or more strings of catgut, tuned in unison, across a wooden box, which is placed in an open window. Athanasius Kircher (1602-80) was the inventor.

Æolians [so named from *Æolus*, a son of Hellen]: one of the primitive tribes of the ancient Greeks. They were the dominant race of Thessaly and Bœotia. They founded on the western coast of Asia Minor many states or cities, among which were Smyrna and Mitylene. The Æolic dialect was harsh, and approached the character of the Doric. It preserved the digamma for a long time. The fragments of Alcæus and Sappho present the typical Æolic language. See ÆOLIA.

Æol'ipile, or **Æol'ipyle** [Lat. *Æolus* + Gr. πύλαι, doorway]: an instrument that illustrates the expansive force of steam when generated in a closed vessel. It is said to have been invented by Hero of Alexandria (second century

B. C.), and consists of a hollow metallic ball, having two hollow arms in the same axis with their tips bent in opposite directions. When the ball is filled with water and heated, steam issues from the narrow orifices of the arms with sufficient force to cause the ball to revolve. It was thought to illustrate the origin of the winds; hence the name.

Æolus, ee'ō-lūs: son of Hellen, brother of Dorus, father of Sisyphus; ruled over Thessaly; reputed to be the founder of the Æolic branch of the Greek race. Often confounded with *Æolus*, the "god of the winds," who was the son of Hippotas and reigned over the Æolian islands. He was an astronomer, and the reputed inventor of sails.

Æ'on (Gr. αἰών): an age, a period of time; also eternity. The Gnostics used the word æons as meaning distinct entities or virtues that emanated from God before time began.

Æpi'nus, FRANZ MARIA ULRICH THEODOR: b. at Rostock, Dec. 13, 1724; studied medicine, physics, and mathematics; became Professor of Physics in St. Petersburg in 1757; was appointed teacher of physics to the Czarowitz Paul, and superintendent of the normal schools of Prussia. D. at Dorpat in Aug., 1802. He improved the microscope, invented the electrophorus, discovered the electrical polarity of tourmaline, and wrote *Tentamen Theoriæ Electricitatis et Magnetismi* (1759); *Réflexions sur la Distribution de la Chaleur sur la Surface de la Terre* (1762); *Description des nouveaux Microscopes* (1789), etc.

Æpyornis: See the Appendix.

Æra'rians (Lat. *ærarii*): a class of inhabitants of ancient Rome who did not belong to any of the tribes or centuries, and who had no civic rights except the protection of the state. Any citizen, no matter how high his rank, for bad conduct might be degraded to the rank of an ærarian by the censors, but the punishment was not in all cases a lifelong one. The Cærites seem to have been ærarians; at any rate, the disfranchisement of a citizen was sometimes called "*in Cæritum tabulas referri*," or "being placed in the list of Cærites." Persons declared infamous became ærarians. This class is also believed to have included a large number of small retail merchants, who came to Rome from the provinces without authority, and were received into no tribe. Ærarians paid a heavy tax, but were exempt from military duty.

Æra'rium: the public treasury in the temple of Saturn at Rome, in which money and the public accounts and archives were kept. Besides the regular treasure, there was an *ærarium sacrum*, or reserve, and later a military treasury. The fund belonging to the *populus*, or patricians, was called *publicum*, and kept in a separate treasury, though in the same building.

Æ'rated Bread [from the Lat. *ær*, air]: an unfermented bread, the ingredients of which are wheat flour, salt, carbonic acid, and water. The carbonic acid is thoroughly mixed with the flour and water in air-tight vessels by means of machinery especially adapted to this purpose, so that the bread is as light as the best fermented bread.

Æ'rated Waters: acidulous or alkaline waters impregnated with carbonic acid gas; they are extensively used to allay thirst in feverish conditions. The most common is *carbonic acid water*, incorrectly called soda-water, for it seldom contains soda. It is made by placing chalk or marble in a vessel with water and sulphuric acid, when the carbonic acid is evolved in the form of gas. The latter is afterward forced into water under pressure, so that the water dissolves about five times its own volume of the gas. It forms a brisk, sparkling liquid, with a pungent but pleasant taste. Leaden reservoirs for ærated water are dangerous. When copper lined with silver or tin is used, safety requires renewal of the lining at least once in two years. Carbonic acid water is, when iced, a most refreshing drink in seasickness and in many cases of disease. The effervescing draughts called *soda powders* and *seidlitz powders* are other forms of ærated beverages. In the former, bicarbonate of soda and tartaric acid are added to water in a tumbler, and a refreshing draught instantaneously prepared. *Seidlitz powders* contain tartrate of soda and potassa and bicarbonate of soda in one paper, and tartaric acid in the other; and when both are added to water, effervescence ensues, and the liquid is then taken. A more agreeable and useful *purgative* ærated water is the effervescing solution of citrate of magnesia in carbonic acid water, the invention of an American pharmacist. Ærated waters are also produced naturally. Water, as it comes from a spring, tastes different from the same water after being boiled; and this is due to the unboiled

water containing the gases oxygen, nitrogen, and carbonic acid—especially the latter—dissolved in it. Rain-water has a mawkish taste, chiefly because of the impurities dissolved in it; but when that rain water trickles down through the earth it is filtered and purified, and absorbs more or less air and gas. When it is dashed from ledge to ledge of rock, it becomes still more thoroughly aerated. A method is now in use for aerating the water-supply of a city, and the water is said to be much improved by the treatment. Many spring-waters are aerated in a peculiar way which confers upon them important medicinal properties. See MINERAL WATERS.

C. F. CHANDLER.

Aërial Perspec'tive: in painting, the art of giving due gradation to the strength of light and shade and the colors of objects, according to their distances; or the laws which regulate the apparent distances of bodies, as modified by the variations in the transparency of the air or in the brightness of the light.

Ærians: a heretical sect founded in the fourth century by Ærius, a native of Pontus. They were Homoiousians (i. e. they maintained that the Son was similar to the Father in essence, but not identical with him).

Aërodynam'ics [from Gr. *ἀήρ*, air, and *δύναμις*, power]: the dynamics of the air, and of gaseous bodies generally; the phenomena exhibited by gaseous bodies, whether at rest or in motion under the action of *forces*. The problems of aërodynamics are seldom treated independently; but are in part common to all fluids, gaseous or liquid. They present themselves in the consideration of innumerable questions in physics; e. g. the transmission of sound; the movements of projectiles; of the pendulum; of railway trains; also in pneumatics; in aëronautics; in the application of the force of the wind as a mechanical power; and to navigation, etc.

Revised by E. L. NICHOLS.

Aerøe, a'rø-e, or Arroë: a Danish island in the Baltic, 10 miles S. of Funen; 14 miles long and about 5 miles wide. It is fertile and well cultivated. Pop. about 12,400.

Aërolites: See METEORITE.

Aërom'eter [from Gr. *ἀήρ*, air, and *μέτρον*, measure]: an instrument formerly used to make the necessary corrections in pneumatic experiments to ascertain the mean bulk of gases.

Aëronau'tics [from Gr. *ἀήρ*, air + *ναυτής*, sailor]: the science or the art of floating in or of navigating the air. It involves the two principal departments, aërostatics and aërodynamics, of the branch of mechanics known as pneumatics, and also the subjects of fluid-friction and the resistance of a fluid to the motion of a solid body passing through its mass. It includes all forms of aërial navigation, whether by balloons, by flying-machines, or by any related forms of apparatus.

The machine or apparatus used in aëronautic practice is technically called an *aërostat*, and the science and the art of its application *aërostatics*. In recent times the subject has been distinguished definitely into two parts: aëronautics or aërostatics proper and *aviation* (from Lat. *avis*, a bird); the former comprehending the art and science of ballooning, the latter those of aviation, or flying like birds. *Aëronauts* pursue the first, *aviators* the second, of these methods in their attempts to navigate the air.

In the history of air navigation, aviation comes first in point of time. The art of ballooning is now about one century old; that of flying dates from a prehistoric geological age, when the birds succeeded the reptiles as the highest types of animal life. Prof. R. H. Thurston, writing in the *Forum* (Jan., 1890), thus speaks of the aërial motions of birds:

“This great problem was first solved during that act of creation the seven periods of which, according to the geologists, occupied unnumbered centuries; and the fish of the sea and the fowls of the air came into existence before their appointed ruler or any of his four-footed subjects. The pterodactyle, the great flying lizard, a giant even for that time, preceded the birds, and, like the flying animals accompanying it in the old triassic and liassic formations and in

the later deposits of geological history, illustrates the fact that every essential *datum* and principle of aëronautics must have been brought into a system of successful aërial navigation in times far antedating even the epoch of man's appearance on the globe. That the intervening periods have been periods of progress can hardly be doubted when the wonderful performance of contemporary birds is considered. The vulture is said to fly, at times, at the rate of above 100 miles an hour; the wild goose and swallow in their migrations make 90 miles an hour, according to Haswell; and the carrier pigeon has certainly flown long distances at rates of speed ranging from 60 up to 80 miles an hour, and for many hours together. The common crow ordinarily lounges across country at the rate of 25 or 30 miles an hour, the speed of a railway train.”

Pilatre de Rozier's first ascension in a fire-balloon, 1783.

The art of ballooning originated in the year 1783, with the experiments of Messrs. Charles and Robert, who improved upon those of Montgolfier, of a few weeks earlier, by the substitution of hydrogen for heated air in the filling of balloons. Stephen Montgolfier sent up his first balloons in June, 1783, after unsuccessful attempts in the autumn of the preceding year. In August of 1783 Charles and Robert

Charles' balloon, 1783.

sent up a balloon inflated with hydrogen, and in November Pilatre de Rozier successfully ascended in a Montgolfier “fire-balloon.” All these first attempts at aërial navigation were made at or near Paris. The interest then awakened in all departments of aëronautics has continued unabated down to the present. It still remains uncertain, however, what may be considered the most promising direction of improvement, looking to ultimate success in the rapid, safe, and commercially practicable navigation of the atmosphere. Thus far man has succeeded only in sustain-

ing himself in the air by buoyant floats, balloons; but the indications are that the weight and volume of machinery needed to impel, at any reasonable speed, the fragile and bulky mass required for its support in the air render it absolutely improbable that success will ultimately crown that system. On the other hand, the claims on the part of the aviators that, since birds and other much larger and heavier animals have been flying at enormous speeds and over thousands of miles in a single voyage since the days of the pterodactyle, the science and the art of aviation are established, and that therefore man has but to follow nature and imitate her forms of construction and adopt her proportions on a larger scale, are met by the statement that no form of motor has been, or can reasonably be expected to be, produced by man, having the small size and weight needed for the successful propulsion and support of a real flying-machine; while the problem of application of such power, even if once secured, is one of such delicacy, intricacy, and danger that its final solution must be taken as entirely beyond the limits of the vaguest probability. The facts are that the balloon has been made successful in raising and supporting aëronauts and their impedimenta, and that it has been found practicable to obtain a moderate speed, and to secure fair directing power, by the use of familiar systems of propulsion; but nothing that can be considered a success has yet been reached by man in the construction of aviatory machines.

Balloons have sometimes been of great size. This is necessary for elevation of any considerable weight, as the inflation of the balloon with common illuminating gas is the only commercially practicable system, and this gives a lifting power of but 1 lb. for each 30 cubic feet. Hydrogen gives a buoyancy of twice this amount. The earlier balloons were small, and useless for any practical purpose. Their magnitude grew with success, and Giffard built one at Paris, in 1878, 118 feet in diameter, containing 882,925 cubic feet, and capable of lifting a total of 55,120 lb., or, deducting weights of balloon and accessories (30,536 lb.), a net weight of 24,584 lb.*

Blanchard, who was the first to take up ballooning as a vocation, died in his bed in 1809, after having made sixty-six ascents without accident. His widow, however, who had served an apprenticeship with him in the new art, was killed in Paris in 1819 by a fall from a great height. Many ascents have been made in the cause of science; and the names of the brothers Godard; of Green, who made over 1,400 ascents; of John Wise, who made the distance from St. Louis, Mo., to Jefferson co., N. Y., 1,200 miles, in twenty hours; of Gay-Lussac and Biot, who, in 1804, made a most valuable series of meteorological and physical observations at the height of 19,000 feet, and thus made the first determination of the method of variation of temperature of atmosphere with altitude; of Glaisher, who rose to 37,000 feet with the aëronaut Coxwell, gaining still more accurate figures, at the risk of death from cold, as well as from the usual dangers of ballooning; of Flammarion; of De Fouville; and especially, recently, of the brothers Tissandier—these are familiar to all.

A remarkable letter containing anticipations of later inventions was written as early as May 24, 1784, by Francis Hopkinson, and addressed to Benjamin Franklin. In this letter it is suggested that the balloon be made, not spherical, but oblong or spindle shaped, and driven by a wheel at its stern. "This wheel," said the writer, "should consist of many vanes or fans of canvas, whose planes should be considerably inclined with respect to the plane of its motion, exactly like the wheel of a smoke-jack." Nearly three-quarters of a century later this idea came into actual application.

Balloons impelled by the power of men, or of machinery, exerted usually through a screw at their extremities, have been often made, and in some cases, even at an early date, with some degree of success. Many patents have been issued to inventors for such contrivances, but none have as yet been found applicable to commercial purposes. One of the most promising of the earlier inventions of this character was that of Rufus Porter (of the U. S.), devised about 1820, and built as a model about 1833. One of these machines was on exhibition at New York about 1835-40, and another at Washington. This was a cigar-shaped balloon, sustaining a car for passengers and machinery, and driven by a screw. This machine is reported by the newspapers at the time as flying rapidly, and sustaining itself for consider-

able periods of time. Later the same inventor built a much larger apparatus, its balloon being 160 feet long and 16 in diameter; but it proved a failure.

Rufus Porter's aëroport.

Balloons, self-impelling and dirigible, thus represent the latest and most effective devices of the aërostats, as distinguished from those of the aviators. These are all spindle-shaped balloons, driven by a screw, actuated by either man or steam power, or other form of energy, as electricity. In 1852 the inventor and engineer, Henri Giffard—especially famous as the discoverer of the curious instrument now

Giffard's aërial steamer, 1852.

familiar to all, the "Giffard injector"—constructed a balloon which he propelled by a steam-engine actuating a screw, and succeeded in obtaining so much speed as was necessary to give steerage way, thus producing the first dirigible balloon and air-steamship. He employed a balloon of ellipsoidal form, 3.66 diameters in length, a high-pressure engine, a small boiler, a screw having plane blades, and a very light system of construction. This experiment will always be famous as the first of its kind in the annals of aëronautics. Just twenty years later M. Dupuy de Lôme, the distinguished naval architect and engineer, employed man-power in the impulsion of a balloon of such size that he could carry ten or fifteen men, and actually applied the power of seven men to the work. He probably considered it imprudent to use a steam-engine in close proximity to a large mass of hydrogen gas; while the constantly varying weight, as fuel is consumed, is also an objection. The ideal motor is one which has constant weight, is free from danger from fire, and which concentrates large power within small compass and weight. The first two difficulties were overcome in the now celebrated experiments of the brothers Tissandier, and of Messrs. Renard and Krebs. Long anterior to this date (in 1833) Rufus Porter, already mentioned, had constructed a model 22 feet long and 4 feet in diameter, which, impelled by a steam-engine of compact design, had actually been driven at a somewhat rapid rate in exhibitions both at Washington and at New York.

M. Gaston Tissandier, the aëronaut, adopted the electric storage-battery, coupled with a dynamo-electric machine, as a source of power. He constructed for the exhibition of 1881 a model, 11 feet long and 4 feet in diameter, filled with hydrogen, and drove it at the rate of about 10 feet per second (about 7 miles an hour), as a maximum. With his brother, M. Albert Tissandier, he built another, over 90 feet long and 30 feet in diameter, fitted with a Siemens dynamo, driving a screw nearly 10 feet in diameter, and supplied with a current from an accumulator of their own invention weighing about 400 lb. This machine, carrying the two inventors, made at various times from 7 to 9 miles an hour for an hour or two together. Messrs. Renard and Krebs, experimenting, like their rivals, at Paris, also constructed a somewhat similar machine, 165 feet long and 27½ feet in diameter, impelled by a battery invented by M. Renard, a dynamo, and a screw 7 feet in diameter. This apparatus at

* With hydrogen the weight raised is $W = 0.0392 D^3$; where D is in feet.

various times in 1884 went from 12 to 15 miles per hour. The motor gave out about 5 horse-power, and the machine was able to take any course desired in a calm, and even to contend against a light breeze. This balloon made a number of voyages, occasionally to distant points, sometimes returning to its point of departure. Its car and impelling machinery constituted one of the most interesting of the exhibits of the French Government at the Paris Exposition of 1889.

Renard and Krebs' balloon, 1884.

These travels in the air of the bold French aëronauts have furnished data relating to the supporting-power, the resistance, and the force required for propulsion of such structures, which have been made by Mr. William Pole, the veteran English engineer, the basis of computations showing that it is apparently possible to-day to build an air-ship, 400 feet in length, which will attain a speed of 25 miles an hour. But it is usually considered by engineers familiar with the subject that at least double this speed must be reached before a satisfactory solution of the problem will be obtained.

It is obvious that to attain high speeds we must have low resistances and light weights, small loads, great power concentrated within the smallest possible compass, and the least possible weight per horse-power. The structure must be small, light, and well formed to pass rapidly through the air. The spindle shape adopted by the later aëronauts is the best of all known forms for this purpose.

Capt. Renard, in reporting on his experiments in the development of his balloon for purposes of war, states that he obtains the following formulas for resistance, R , and power, U , at varying speeds, the diameter, D , and speed, V , being given, all in metric measures:

$$R = 0.01685 D^2 V^2;$$

$$U = 0.01685 D^2 V^3;$$

$$U' = 0.0326 D^2 V^3;$$

where U' is the work on the screw-shaft. He computes that a speed of 22 miles an hour would demand for his balloon, if of 33 feet diameter, about 45 horse-power. It is supposed that speeds of 25 miles an hour or more have been attained; but the work is done by and for the Government, and no recent data are allowed to be published. Mr. Chanute gives the following table of those obtained and published to date, with his own computation of the power which each would require at 25 miles an hour in calms:

SCHEDULE OF NAVIGABLE BALLOONS.

By improvements in varnishing and rendering the tissue of the balloon impermeable to gas; giving the spindle-shaped vessel a form of minimum resistance; improving the construction and proportions of the screw, and of the steering-gear; securing stability and stiffness sufficient to permit the carrying of machinery; to permit driving at high speeds against the resistance of the air, and to turn and to land safely; and especially by securing some light and enormously powerful motor unimpeded by the embarrassments now met with in the storage of energy, the use of fire, or the dangers of high pressures, very considerable advances seem to be possible in this direction; but the general impression among engineers, as well as aëronauts, is that the practical limit will still be found within that which would constitute this apparatus a commercially valuable means of transportation of even passengers alone. Scientific investigations and the military art may find place and purpose for the dirigible balloon; but as yet there seems no probability of its coming into permanent employment for other purposes. If speeds of 25 or 30 miles an hour are to be attained and maintained for any appreciable time, balloons must be built of great size and at considerable cost. So much, however, it does seem safe to expect. Mr. Chanute gives the following estimate of the size and proportions of such a balloon, taking it as similar to La France, one of the best of the French constructions:

This air-ship would need a motor of about 180 horse-power, and the speed might be made, assuming a weight of the same as that of Renard, 130 lb. per horse-power, about 11 meters (36 feet) per second, or 25 miles an hour. The construction of a light motor is the great desideratum. It is stated that electric motors have been made of as little as 20 lb. weight per horse-power, and steam-engines have been built of less than 10 lb. weight per horse-power, including boiler.

It seems not at all impossible to construct balloons 1,000 feet (410 meters) long, 100 to 150 feet (31 to 46 meters) in diameter, which shall carry two or three tons weight at 35 to 40 miles an hour—in other words, aërial vessels as large as an ocean steamer of our day, but carrying two thousand times less weight of passengers and cargo. Maximum speeds must be high for success, since minimum speeds of 25 to 30 miles must be given to meet even ordinary winds. Navigable balloons, having speeds of 50 and possibly 75 miles an hour, seem desirable from this point of view, and it is impossible to say that they may not be ultimately obtained by continued development in the directions in which so much has already been accomplished.

Aviation is a branch of aëronautics which, as has been seen, dates back in nature to an early geological period, but one which is only now, after centuries of thought and many years of endeavor, taking such form as to lead authorities in science and in engineering to recognize the fact that an actual beginning has been made in the solution of some of the essential elements of the problem, as in the determination of the laws involved in the support and impulsion of properly shaped bodies in the air, the measurement of resistances, and the production of light and powerful motors. Within a comparatively few years societies have been formed in nearly every civilized country, composed of those who consider aviation a more promising line of invention and research than ballooning, and these societies, and individuals of similar views, have done much to determine the facts and laws prerequisite to intelligent design, construction, and operation of the flying-machine.

The flight of birds, and of animals of other kinds, is always presumed to involve the same principles as must any artificial flight by means of machinery. Early legends indicate that artificial flight was regarded as a possibility by the ancients, and previous to 1660 claims were advanced, as by Roger Bacon and by Robert Hooke, that flight could be and had been effected. Borelli, about 1680, however, proved that the skeleton of man is not suited for flight like that of the birds, and that his muscular system was unequal to the task of aviation by its own energy. Dr. Wilkins, the

ingenious Bishop of Chester, of the time of Cromwell, said: "I do seriously and upon good grounds affirm it possible to make a flying chariot, in which a man may sit and give such a motion to it as shall convey him through the air." Again: "It is not impossible, perhaps, that a man may be able to fly by the application of wings to his own body; as angels are pictured, and as Mercury and Dædalus are fained, and as hath been attempted by divers."

Elmerus, a monk of the thirteenth century, is said to have succeeded in imitating the flying squirrel, in partial self-support. Besnier, a locksmith of the seventeenth century, is also said to have passed over considerable distances, and over houses and rivers, gradually descending from a high starting-point; and the story is told, perhaps apocryphal, of the flight of a prisoner at Vienna, in the jail-yard, to a height of 50 feet or more. Many similar attempts are known to have been made in later times; but no one case of even approximate success is as yet recorded.

The earliest profitable studies in this field have been those relating to the methods of bird-flight, and their powers of lifting and of impulsion. Pettigrew, Marey, and De Luey have studied the motions of the wings of birds and insects, have learned the laws of fluid-resistance, and have paved the way to a real advance. The theory of propulsion has been long studied, and in some directions well established. It has been shown that weight is probably not objectionable in aerial navigation, but actually a necessity; not weight but volume constitutes the impediment. A bird is a heavy but compact structure, of which the essential characteristic is that it incloses great power within small volume. De Lucy's measurements of various flying creatures show an irregular, but still unmistakable, general direction of variation of wing-surface with size of animal. Comparing the ladybird and the stag-beetle, the pigeon and the stork, the sparrow and the crane, we find the area of wing per unit of weight carried to be nearly as the cube root of their weights. Taking as a fair figure that obtained from the larger bird, I find that a man of the ordinary weight should be able to fly with wings having an area of only about 40 sq. feet (nearly 4 sq. meters). De Villeneuve states that a bat having the weight of a man would need wings only 10 feet (3 meters nearly) long. Hastings makes the surface of each wing from 5 to 10 times $\frac{2}{3} \sqrt{W}$ where the area is measured in square centimeters and weight in grammes.

From the above it is seen that the required areas of wing-surface per unit of weight decrease rapidly with increasing size. As the writer has elsewhere remarked: "Thus the insects flutter wings of enormous area in proportion to their weight, at the rate of 200 or 300 vibrations per second; while the pelican makes but one per second, the area of surface employed being a minute fraction of that needed by the smaller creature, per unit of its own weight. The vulture is 100 times as heavy as the swallow, but its wings are only fifteen times as large. The Australian crane weighs 3,000,000 times as much as the gnat, while the latter has 150 times as much wing-surface per unit of weight. But the *power* demanded is very exactly proportional to the weight carried, and the muscles of the birds' wings weigh more than all the rest of the muscles of their bodies together. M. Hannel, from these facts, computes the spread of wing required by a flying man at about 20 feet, or about 150 sq. feet area. For a machine weighing 3.5 tons he makes the spread of wing demanded about 80 feet; and the writer has computed a still smaller figure."

The few experiments recorded on the lifting-power of birds and flying animals, as far as they go, indicate a limit at about one-half more than their own weight. The contemporary soaring birds have a maximum at about 30 lb. (14 kilog.), and the prehistoric eretaceous pterodactyles, gigantic reptiles, in some cases had weights approximating that of a man, and wings spreading 15 and 20 feet (7 to 9 meters). No natural limit is as yet known in this direction.

As an essentially important line of research, many experiments have been made to determine the lifting-power of planes sliding through the air at angles slightly inclined to the horizontal. The most extensive and fruitful have been those of Langley, at the Allegheny Observatory, and at the Smithsonian Institution at Washington. These researches were undertaken with a very elaborate and ingenious apparatus, including a whirling mast, turned by a powerful steam-engine, capable of driving the suspended plane in a circle of 60 feet diameter up to nearly 100 miles an hour peripheral speed, and a set of autographic measuring instruments for time, speed, lift, and resistance. It was promptly

shown that the time of fall of a horizontal plane is less when moving horizontally than when falling vertically, and that the rate increases as the lateral motion increases—a result of the inertia of the increasing weights of air affected by it—and leading at once to the conclusion that the rate of fall may be made insensible by sufficiently high speeds. This involves the proposition that at some very high velocity its behavior would be that of a body resting on a solid surface. Another singular but indisputable fact thus revealed is that such a plane may require actually less expenditure of energy to move it at high speeds than at low, where supporting itself by inclination to the horizon, the power demanded for its support diminishing faster than the resistance to forward motion increases. The "soaring speed," as that velocity is called at which the body is just sustained at its initial height, was determined for a variety of size and proportion of planes; and the forms as well as the speeds of the plane were found to have important influence. The final and most striking conclusion of the investigator is that, so far as power simply is concerned, mechanical flight is possible with such engines as we already possess, since one horse-power can sustain 200 lb. at 45 miles per hour (20 meters per second), and more at higher speeds, friction of the machine neglected—and this constitutes a large margin; engines now being in existence of but a fraction the specified weight. The best angle of the plane is always a very small one, usually between one and two degrees from the plane of its path, and is the less as the speed is greater. M. Drzewicki, at the Congress of Aëronauts and Aviators held at the Paris Exposition of 1889, presented formulas and computations indicating that an aëroplane, at an angle of $1^{\circ} 50' 45''$, meets sensibly the same resistance (simply as a plane) at all speeds, and that the work done is thus proportional to weight and speed; that aëroplanes proportioned for small velocities need comparatively large surfaces and small weights; that areas may be reduced as speeds increase; and that the less the area the greater the required speed and power. These conclusions, which had been anticipated in part by Mr. Octave Chanute, were shown to be corroborated by the known proportions of birds' wings, and hence it is to be expected that, where large bodies and heavy weights are to be dealt with, as in air-ships, very small areas per unit of weight will be necessary. He computes the power at about 5.87 horse-power per ton. Mr. Chanute figures the actual power exerted by a flying pigeon at about 10 horse-power per ton, at the same assumed speed, 25 miles an hour. These expenditures are less than are required at the same speeds in the propulsion of the dirigible balloon, and are, nevertheless, greater than are indicated as probable by Langley, who has shown the power demanded for flight to be but about 2 per cent of that computed on the earlier theories by Navier and others, and that air-friction may be neglected as comparatively small, while the weight of the supporting planes may be but a small fraction of the total weight they are capable of sustaining.

As a final conclusion, it may, perhaps, be asserted with some degree of confidence that at low speeds balloons promise the best results, and at high speeds, aviatory machines.

As was first shown by Mr. Curtis, the fact that conditions may be found under which high speeds are more economical of power in the support and propulsion of aëroplanes by the action of the air, as they pass through it, may be proved mathematically in the following manner:

Let the relations of power expended, resistance, and velocity be represented by the equation

$$T = R V; \\ = V W \tan a;$$

where W is the weight of the plane. Then we have, differentiating,

$$\frac{dT}{dV} = \left(W \tan a + V \sec^2 a \frac{da}{dV} \right);$$

in which $\tan a$ is very small and the sign of dT/dV is therefore controlled by that of da/dV . But experiment shows that V increases for best effect as a diminishes, and the sign of da/dV being negative, the term in which it is found is negative, and T thus decreases with increasing velocities of the plane. This deduction obviously is applicable not to a bulky mass moving at high velocity through the air, but only to the aëroplane, a thin, sharp-edged or wing-shaped plane. Where the aëroplane carries a load, a speed of maximum effect must be found at some comparatively low speed, since the resistance of the sustained body, however well shaped for such purpose, must vary

nearly as the square of its velocity. Air-resistance is very small, however, and it seems probable that this speed of best effect may be very high as compared with those attainable on land or on water. Speeds of 50 miles an hour and upward are apparently anticipated by the best authorities on this subject, assuming the mechanical difficulties completely overcome.

Flying-Machines, as already remarked, antedate balloons by geological periods, the first flying-machines having been the animated mechanisms of the reptile aviators of the cretaceous or earlier periods and of the birds. The flying-machine differs from the balloon in the fact that it is not only propelled but is also supported by its own actively exerted energy. The attempts of inventors to imitate this method of self-support and of flight by human power have been numerous but unsuccessful, and, as indicated by Borelli long ago, are not likely to prove successful. The skeleton and muscular system of man are not adapted to use in flight; nor has he the endurance needed for prolonged exertion of such intensity. The inventor is now seeking ways of making heat-engines or other motor machines serve his purpose in this direction. As the writer has elsewhere remarked, "The researches of Langley have shown the power demanded for flight to be about 2 per cent of the amount once supposed a minimum; we know that nature's energy can be directly converted into useful power through the production of electricity, as in the gymnotus, and possibly in all animal mechanisms; we know that the modern storage batteries are of ten times the weight that science indicates to be the limit of perfect efficiency; both steam-engines and electric accumulators have been made light enough and powerful enough to raise their own weight, with something to spare; the flying lemur, the flying squirrel, the rude sustaining-membranes that inventors have constructed, have sustained their heavy weights in drifting many yards." (*Forum*.) Man has thus every reason to assume at least the possibility of solving this problem, the last and most tantalizing of all presented to the inventor in the field of transportation. In this study the researches of Langley lend great encouragement. It is also true that encouragement may be found in other directions.

The operation of the animal machine teaches many lessons, some of which should prove profitable to the engineer in his endeavor to solve this problem. It illustrates a combustion without high temperature, and yet with very high efficiency—quite in opposition to the accepted ideas of thermodynamic transformations. This may mean some as yet unknown system of modification of heat energy; or it may indicate a production of electricity, rather than heat, from the chemical union of foods with oxygen; or it may lead to discoveries of methods of transformation of energy and of their useful application as yet undreamed of by our philosophers. This animal energy, however developed, is applied with great effectiveness to these as yet unsolved problems of the engineer. The great secret which our own most original inventors and physicists are endeavoring to penetrate lies there for study and test. It is to-day easy to predict the power required to give to any well-shaped body any stated velocity in the air; it remains to ascertain how that power may be produced as economically, and as concentrated in volume and weight of mechanism, as nature produces it.

The fact that man has surpassed nature in transportation on land and on the sea may be fairly taken as giving reason to assume the possibility of his similarly succeeding, once he has entered upon this new path, in aerial navigation. Although the animal machine is, as shown by Hirn and by Ruhlman, more efficient as a dynamic motor than any heat-engine, rising to 0.29, it is not to be expected that artificial flight, by use of wings and man's own muscular power, will ever prove successful. In seeking to construct flying-machines, capable of transportation of merchandise and passengers on some comparatively large and effective commercial scale, the machine consists of some equivalent for the wing of the bird, as the aeroplane tested by Langley and others, and a car or vessel, carrying machinery and load, the resistance of which must be allowed for at a rate approximating, if well formed, by Pole's formula: $R = 0.000195 d^2 v^2$, in pounds, feet and seconds being the units. This corresponds to the comparatively slight density of air: $\frac{1}{800}$ that of water. The size of wing, x , required for a given load, y , will bear some close relation to that observed in the birds, in which, by Hannel's formula, $x = y \log. 500$, nearly, in which x is in kilogrammes and y is the width of wing in meters.

Langley's experiments confirm for normal pressures the formula of Duchemin or Bossut, making the magnitude of

that pressure a simple function of the normal pressure when moving transversely to its own plane; but he shows that, although the form and aspect of the plane have little effect when moving normally, they become important when the plane is inclined to its path. Chanute's investigations confirm the conclusions of Langley, and numerous experiments with an immense variety of flying-machines have thrown some light upon the subject, but have thus far revealed but little real progress in application.

These machines are variously constructed to secure support and propulsion by means of wings, by screws, and by screws combined with aeroplanes. The most successful have recently been impelled by the energy stored in twisted threads of rubber. Pichancourt has made such "birds" capable of flying 50 to 100 feet; and many experimenters have employed the last-named combination. Of these, the most successful has been M. Penaud, or possibly M. Dandrieux, who makes a remarkably perfect imitation of the butterfly. None of these are more than toys, however, and usually support themselves but a few seconds. Mr. Lawrence Hargreaves has presented to the Royal Society of New South Wales accounts of more than a dozen self-propelling machines of his own construction, some of which have flown considerable distances, the driving-power being, in the best of them, compressed air operating a Brotherhood engine. His Nos. 13 and 14 flew at the rate of 10 to 12 miles an hour, and covered distances of 125 to 312 feet in 8 to 20 seconds. The inventor estimates that "400 lb. of tin tubing, silk, and steel wire would serve to carry one man 500 yards at 17 miles an hour." The motor constitutes one of the most difficult problems.

Marine steam-engines, with their boilers, weigh several hundred pounds per horse-power, while it is estimated that a successful aerial motor must weigh less than 50, and that it is desirable that it should even be much lighter than that. The lightest machinery yet built for continuous operation is that of the modern torpedo-boats, weighing sometimes less than 60 lb. per horse-power, and in occasional instances below 50. Stringfellow built an engine for aeronautic experiments weighing 13 lb. per horse-power, and Mr. H. S. Maxim has described one weighing less than 5,000 lb. to develop 300 horse-power.

Gas and inflammable vapor engines have been proposed for use in aeronautics; but they are as yet even heavier than the lightest steam-engines, and offer no promise of value. The best work thus far has given, as its product, gas-engines employing the vapor of petroleum and weighing between 80 and 100 lb. per horse-power. Electric power gives better results, and M. Trouvé has constructed such of moderate size, weighing about 20 lb. per horse-power, and in one case, in which aluminium was freely used in construction, about 8 lb. Commandant Renard employed a dynamo in his balloon which weighed 26.4 lb. per horse-power. The primary battery used with it weighed 66 lb. per horse-power, and the whole thus weighed 130 lb., a weight still much too great to be suitable for any self-supporting and self-impelling machine.

The most elaborate and instructive experiments with solid bodies driven through the air at high speeds were made by Mr. Maxim, whose work on aeroplanes corroborates that of Langley completely. He found the resistance due to friction of the surfaces of the body thus driven was imperceptible, and might be neglected as unimportant. He concludes that a motor weighing less, as a total, than 100 lb. per horse-power would, so far as that goes, make aerial navigation possible. His own steam-engine with a pressure of 250 lb., weighing with its accessories about 4,500 lb., is rated at 300 horse-power, or 15 lb. per horse-power. The machine is mainly of steel, this metal being found, as used, much lighter and stronger than similar parts made of aluminium.

Present indications seem to be, in the opinion of many aeronauts, that the use of the dirigible balloon will lead to the perfecting of the motor, and that ultimately the flying-machine, without supporting gas-bag, may come into use for speeds which can not be approached by the former. The dirigible balloon is so far perfected as to-day to constitute an important part of the equipment of every great army organization. French inventors have, as has been seen, constructed such machines capable of attaining about 15 miles an hour in calm weather, and it is supposed that they have, in later and unpublished plans, secured a much higher degree of efficiency. The German army is said to have similar machines in use in reconnoissance; and other nations now, and all must in time apparently, make use of this new

method of transportation for such purposes. "Captive" balloons are in use also in the French navy for purposes of reconnoissance, and it is found that they can be towed, by the ship of which they form a part of the equipment, at moderately high speeds.

Useful Results in Aërostation have, up to the present time, been hardly commensurate with the time, talent, risk, and actual loss of life and money, given to this development of the attractive, though still unpromising, scheme. Biot and Gay-Lussac, as early as 1804, ascended to the height of 23,000 feet in one case, and Messrs. Glaisher and Coxwell, in 1862, as already stated, attained a height of above 35,000 feet, and the former, in various ascents, secured much interesting and some important meteorological information and data. Mr. Glaisher sees no reason to anticipate any great improvement in the construction and operation of the balloon, and thinks it can only be expected to be of service where it can be employed in calms. Armies using the balloon for their special purposes have sometimes, as is said, found it valuable. The battle of Fleurys is said to have been decided largely by this advantageous use of the balloon (1794). In sieges, as at Mayence and Ehrenbreitstein (1799), they are said to have been used to advantage. The Austrians used them in 1849 before Venice, and the French in 1859 in the Italian campaign. In the U. S. the balloon was used by a balloon-corps attached to the Army of the Potomac, with results accounts of the value of which are contradictory. In the siege of Paris more than fifty balloons were used in transporting mails and other light material from the beleaguered city—a total of about 2,500,000 letters, weighing about 10 tons. Return mails were usually brought in by carrier pigeons taken out by the balloons.

The flying-machine, in the restricted sense of the term, has not as yet reached even the experimental stage of application. The difficulties which have seemed hitherto so formidable, not to say unconquerable, are now apparently disappearing in the light of exact investigation, and the man of science is taking the place of the ignorant inventor and schemer in the promotion of this work. A larger number of engineers and men of science now think it possible that the limits of human skill and inventive talent are set outside this latest and greatest of the problems of transportation and of aerial navigation. Many minds are constantly at work on the problem, and it seems not at all unlikely that real advances may be effected in the immediate future. This problem constitutes one of the greatest confronting the mechanic and the scientist. An immense amount of information, much exact data, and some knowledge of the laws involved in its solution, have already been acquired. As remarked by Pettigrew, "The land and the water have already been successfully subjugated. The realms of the air are alone unvanquished. These, however, are so vast and so important as a highway for the nations that science and civilization equally demand their occupation. . . . If the difficulties to be surmounted are manifold, the triumph and the reward will be correspondingly great. It is impossible to overestimate the boon which would accrue to mankind from such a creation. . . . If this day should ever come, it will not be too much to affirm that it will inaugurate a new era in the history of mankind, and that, great as the destiny of our race has been hitherto, it will be quite outlustered by the grandeur and magnitude of coming events."

R. H. THURSTON.

Aërostatic Press: a machine for extracting by atmospheric pressure the coloring principle from the raw material—wood, leaves, insects, etc.—used for the purpose of dyeing. The material is placed in a vessel between two horizontal partitions, both perforated with small holes. Liquid is poured on over the upper partition, and the air is drawn off from the bottom by means of a suction-pump. By this means the liquid is compelled by the pressure of the atmosphere at the top to force its way through the material, carrying with it in solution the required dye.

Aërostatics: that department of the science of mechanics which treats of the weight, pressure, and equilibrium of aëriiform fluids, and of the equilibrium of bodies sustained in them. It differs from *Aërodynamics*, another branch of the science, in being confined to the relations of forces acting in or upon such fluids when no motion results, while the latter refers to the phenomena observed when forces acting within or upon such fluids produce motion. *Pneumatics* (*q. v.*) covers both these departments. Aëronautics belongs properly to the first of these divisions. See AËRONAUTICS.

Æs'chines (Αἰσχίνης): Greek orator, and rival of Demosthenes (*q. v.*). B. at Athens in 389 B. C., he had a varied experience as a magistrate's clerk, as a soldier, and a brave one, and as a not oversuccessful actor. By his knowledge of the law, his native gift of eloquence, his distinguished appearance, he rose to prominence in public life. Sent to Philip of Macedon as a member of an embassy in 342 B. C., he went over to the peace-at-any-price party and to Philip, and after his return to Athens was accused of high treason by Timarchus and by Demosthenes. Both his adversaries were foiled. In 330, however, Æschines, who had been an active partisan of the Macedonians, brought a charge of illegality against Ctesiphon for proposing to reward Demosthenes with a golden crown, and the contest ended in a crushing defeat for Æschines. He was compelled to withdraw from Athens, and betook himself to Rhodes, where he is said to have opened a school of oratory. He died in exile, 314. We have three speeches of his, called in antiquity *The Three Graces*, which enable us to understand his high rank as an orator. Two of them may owe their special interest to the comparison with Demosthenes, but even if "they have more flesh, less muscle," they are full of life and grace. Edited by Bremi (1823), Benseler, with German translation (1858), Franke (1860), Schultz (1865), Weidner (1872).

B. L. GILDERSLEEVE.

Æs'chylus (Αἰσχύλος): in a certain sense creator of Greek tragedy; b. of a noble family at Eleusis, in Attica, in 525 B. C. The eldest of the three great tragic poets of Greece, he was at once the most sublime genius and the severest artist of the three. He fought bravely at Marathon (490 B. C.), Salamis, and Platea, and seems to have been prouder of his prowess than of his art. It was not until 485 that he gained the first prize in tragedy. He composed over seventy pieces and gained thirteen prizes. In 468, however, he was defeated by Sophocles, and soon afterward went to Sicily, where he was honored by Hiero of Syracuse. He died at Gela in 456, two years after his brilliant success with the *Oresteia*. According to tradition, he was killed by a tortoise, which an eagle let fall on his bald head, a story that is variously interpreted. Of his tragedies, which were brought out in sets of three—"trilogies"—only seven are extant: *Prometheus Bound*; *The Seven against Thebes*; *The Persians*; *The Suppliant Women*; *Agamemnon*; *The Choëphori* (Libation-bearers); and *Eumenides*. The last three form the only complete trilogy that we have; the *Oresteia*, or Story of Orestes, one of the most powerful and consummate works of art in all literature. Each play is an act: The Murder of Agamemnon, The Vengeance of Orestes, The Redemption from Bloodguiltiness. It is a plea for the Areopagus (*q. v.*), but it is much more. Critical editions by Dindorf, Hermann (1852), Kirchhoff (1880), Weil (1884), Wecklein (1885); with English notes by Paley (1870). Elaborate edition by Verrall has been begun (*Seven*, 1887, *Agamemnon*, 1889, *Choëphori*, 1893). English translations by Blackie, Browning (*Agamemnon*), Campbell, Fitzgerald (*Agamemnon*), Morshead (*House of Atreus*), Potter, Plumptre, Swanwick.

B. L. GILDERSLEEVE.

Æscula'pius (in Gr. Ἄσκληπιός): in classic mythology, the god of medicine; a son of Apollo. The poets feigned that he raised the dead to life—that he thus offended Pluto, who complained to Jupiter, who killed Æsculapius with a thunderbolt. He was afterward worshiped as a god, and a temple was erected to him at Epidaurus. According to Homer, he had two sons, Machaon and Podalirius. His descendants were called Asclepiadae.

Æsculin, or **Esculin** (C₁₅H₁₆O₉): a crystalline fluorescent glucoside obtained from the bark of the horse-chestnut and other trees of the genera *Æsculus* and *Pavia*. It possesses a bitter taste, and is converted by boiling a hydrochloric or dilute sulphuric acid into glucose and a bitter crystalline substance called asculetin, C₉H₆O₄, C₁₅H₁₆O₉ + H₂O = C₆H₁₂O₆ + C₉H₆O₄.

Æsir, ā'sir [the plural of Norse *As*, god, being]: the general name of the beneficent deities of the Norsemen. The principal Æsir are Balder, Frey, Freyia, Frigga, Heimdall, Odin, Thor, Tyr, Vali, and Vidar, which will be noticed under their respective heads.

Æsop (Lat. *Æsopus*; Gr. *Αἴσωπος*): a celebrated fabulist; b. about 620 B. C.; supposed to have been a native of Phrygia. He was a slave in his youth at Athens, but afterward obtained his freedom in consideration of his wit. Æsop became a generic name, and it is impossible to discern the original Æsopic fables. The current Greek Æsopic fables, edited by C. Halm, *Fabulæ Æsopicae*, Leipzig, 1852, are, in the main, prose paraphrases of BABRIUS (*q. v.*). For bibliography and further details, see BEAST-FABLES.

Æsopus, CLAUDIUS: a famous Roman tragic actor; a friend of Cicero; flourished about 75 B. C. His action was grave, dignified, and impassioned. He retired from the stage in 55 B. C.

Esthesiometer: See RECORDING APPARATUS, PSYCHOLOGICAL, in the Appendix.

Esthet'ics [Gr. *αισθητικός*, pertaining to the perception by the senses; *αισθῆσθαι*, perceive by the senses]: etymologically, the philosophy of perception. In modern philosophy the term is used to denote the scientific classification of the faculties through which we apprehend the beautiful and the sublime, and which give us the experience of the resulting emotions. It involves also the statement and discussion of the laws which should preside over and condition all forms of artistic production, the application of these general laws to the special branches of the fine arts in respect to criticism, and the history of the development of these laws in practice. The principles of aesthetics were in ancient times discussed by Plato, Plotinus, and St. Augustine; and in their application to poetry by Aristotle and Horace; and in relation to eloquence by Quintilian, and to style by Longinus. The term was first used in its modern sense in the eighteenth century by Alexander Gottlieb Baumgarten, Professor of Philosophy at Frankfort-on-the-Oder. He taught that there is in the mind a power or faculty for the appreciation of the beautiful—a power whose existence is not dependent on that of the intellect, though the latter may be necessary in order properly to direct and develop the æsthetic faculty. Psychologists have classed the operations of the mind under three general heads—namely, the intellect, the sensibilities, and the will. The proper object of the first is truth; of the second, beauty in its various forms, including harmony; and of the third, good or virtue. Æsthetics would consequently come under the second division, relating as it does to objects or qualities which appeal at once to the sensibilities, without any direct reference to the intellectual power.

There may be said to be two distinct schools, which differ radically respecting the true principles of æsthetic development and culture. The one, starting with the standard works of art, or with the most perfect models which nature offers us, and selecting from each what appears most pleasing or graceful, seeks, by means of these, either by direct imitation or indirect suggestion, to create a new work, which shall combine as many as possible of the elements of the original models. It is obvious that the merits of such a work can not in any case rise above the aggregate of the merits of the productions after which it has been copied. The other school, recognizing the fact that it is possible for transcendent genius to create forms of beauty which shall not only excel in their combined effect, but in their individual elements, everything that has ever been seen in nature or in art, seeks to cultivate the faculty of ideal conception, using the works of nature or the models of the great masters simply to improve the art of expression; or, in other words, the power to translate, as it were, our ideal conception into forms which can be understood and appreciated by the common mind. Those of this school would say that such works as the Apollo Belvedere, or Dannecker's celebrated statue of Christ, could never, in the first instance, be formed from actual nature—that, in fact, the very power of selecting the most beautiful forms, or the most beautiful elements of any particular form, implies the existence of an ideal faculty; for if the mind has not some standard in itself, but is wholly dependent on what it sees for its conception of beauty, why should it not copy the faulty as well as the beautiful? It is, in fact, by trying what it sees by the ideal standard in itself that it knows how to select the one and reject the other.

Æsthetics can not yet be considered a complete and sys-

tematically developed science, though several of the best minds of the last and present century have done much to investigate and explain its principles. Among the most important works on this subject are the following: Friedrich Theodor Vischer's *Æsthetik, oder die Wissenschaft des Schönen*; Hegel's *Æsthetik*—Bénard's French translation of this work was crowned by the French Academy; a second part of this work, devoted to the history of art in its three phases of symbolic, classic, and romantic (or Oriental, Greek, and Christian art), has been translated into English, and published in the *Journal of Speculative Philosophy*, while Hegel's introduction, containing a discussion of the nature of art, has been translated by Bernard Bosanquet; Cousin's *Le Vrai, le Beau et le Bon* (The True, the Beautiful, and the Good); Weisse's *System der Æsthetik* (2 vols., Leipzig, 1830); Jouffroy's *Cours d'Esthétique* (Paris, 1842); Ruge's *Neue Vorlesung der Æsthetik* (1837); Zimmermann, *Geschichte der Æsthetik* (Vienna, 1858); Dippel, *Handbuch der Æsthetik* (1873); Alison, *On Taste* (1784); Burke, *The Sublime and Beautiful* (1756); J. Baseom, *Æsthetics* (1862); H. N. Day, *The Science of Æsthetics*; J. S. Kedney, *Hegel's Æsthetics*; and especially Kant, *Kritik der Urtheilskraft*.

Revised by W. T. HARRIS.

Æstiva'tion [from the Lat. *æsti'vo*, *æstiva'tum*, to spend the summer, to retire for the summer season]: in botany, the manner in which the parts of a flower are folded in the bud before it has opened. The various forms of æstivation are called *valvate*, *imbricated*, *contorted*, *induplicate*, *reduplicate*, etc.

Æthelstan: See ÆTHELSTAN.

Æt'ians: the followers of Ætius, who was in the fourth century a deacon, and afterward a bishop. He was an Arian, but was considered a heretic by both orthodox and Arians. His doctrine, which briefly was that Father and the Son were entirely unlike in all respects, and followers were condemned in 359 A. D.

Æt'ius (sometimes incorrectly written Ætius): Roman general; b. in Moesia before 400 A. D. As commander of the Roman army in Gaul he gained important victories over the Visigoths, Huns, and other barbarians about 425–430 A. D. Ætius and Theodoric commanded the army which in 451 checked the victorious hordes of Attila the Hun, and defeated him in a great battle at Châlons. He was suspected of treachery by the Emperor Valentinian III., who killed him with his own hand in 454 A. D.

Æto'lia (Gr. *Αἰτωλία*): a state or country of ancient Greece; bounded N. by Thessaly, E. by Locris and Doris, S. by the Gulf of Corinth, and W. by the river Achelous. It was intersected by the river Evenus, the modern Phidaris or Fidaros. The surface is partly mountainous, the scenery magnificent, and the climate delightful. The range of Mt. Pindus extends along the northern part. The ancient Ætolians were a warlike, barbarous, and rude people in the age of Pericles. Ætolia now forms, conjointly with Acarnania, a nomarchy of the kingdom of Greece. See ACARNANIA.

Æfana'sieff, ALEXANDER NIKOLAIJEVITCH: b. in the Russian government of Voronezh, July 23 (11), 1826; studied at the university of Moscow; was secretary to the council of magistrates there. In 1863 he published a collection of Russian popular tales in 4 vols. (2d ed. 1873), and in 1869 a representation of the views of nature entertained by the ancient Slavs (3 vols.). D. Oct. 5 (Sept. 23), 1871.

Affida'vit [literally he made oath, or stated on oath; perf. third person sing. of Late Lat. *affidare*, to state or give on oath]: an oath in writing made before some person who has authority to administer an oath; a statement in writing signed by the party making it, and sworn to before some authorized officer, who appends and signs an official statement to that effect, termed a "jurat." By an extension of its original meaning it is made to include also cases where an affirmation, authorized by law, is taken instead of an oath. An affidavit is made *ex parte* and without cross-examination. It is much used in making various motions in court, and in proving conveyances executed before subscribing witnesses, so as to have them recorded. An affidavit is called *extra-judicial* when, though taken before an officer authorized to administer oaths, it is not itself required or authorized by law.

Affin'ity: in law, the relationship contracted by marriage between a man and his wife's kindred, and between a wife and her husband's kindred. In Great Britain marriage is forbidden between persons who are within the third degree

of relationship by affinity, and this prohibition is considered to be based on the law of God.

Affinity, CHEMICAL: a name given to that which holds the constituents together in a chemical compound. Thus water consists of hydrogen and oxygen held together in chemical combination. What holds them together we do not know, nor do we know in what condition they are; but it is convenient to give a name to the unknown cause, just as it is convenient to give a name to that which causes a body thrown into the air to return to the earth. As is well known, we call this unknown cause the attraction of gravitation, without thereby explaining what it is. The expression chemical affinity is coming to be used in a somewhat different sense from the above, but this more refined use can not be explained here.

IRA REMSEN.

Affirma'tion: in law, a declaration made by a witness as a substitute for an oath in a court of justice. This formula is used by Quakers and others who have conscientious scruples against oaths. In the U. S. the use of affirmations instead of oaths has become very common, experience seeming to have shown that the value of evidence and the force of obligations are not diminished thereby.

Affre, DENIS AUGUSTE: Archbishop of Paris; b. at St. Rome-de-Tarn, Sept. 27, 1793. He became vicar-general at Paris in 1834, and archbishop in 1840. During the insurrection of June, 1848, he made a generous effort to end the carnage by a personal appeal to the insurgents, but while he was speaking to them hostilities were renewed between the insurgents and the military, and he was mortally wounded by a ball, and died June 27, 1848. He left an *Essay on the Egyptian Hieroglyphics* (1834), and other works.

Afghanistan, aaf-gān-is-taan' [a name of Persian origin. The people call their country *Ca'-bul* (the valley of the Cabul river) and *Khorasan*, the rest of the country vaguely]: a country of Asia; lying between 30° and 38° 20' N., and the meridians 60° 30' and 74° 30' E. Its boundaries are largely political, and were settled on by Russia and Great Britain. On the N. lie the Turkoman desert, Bokhara (with the Oxus as boundary line), and the Pamirs. On the E. the boundary is in general that of British India. On the S. it is bounded by Baluchistan, and on the W. by Persia. Its form is roughly rectangular, but it has a long projection to the N. E., N. of the Hindu Kush mountains, and including Badakshan. The total area is about 257,000 sq. miles (about that of Texas), and the population is estimated at 5,000,000.

Topography.—It is for the most part a series of elevated table-lands, diversified by mountains. Only the valley of the Cabul river and a part of the southwest angle are below 4,000 feet above the sea, while a not inconsiderable part is above 7,000 feet. The Hindu Kush mountains enter in the N. E., and extend, under various names and at lower altitudes, along and near the northern boundary. The eastern border along the Indus valley is formed by the Suliman range, and from the head-waters of the Cabul river broken ranges extend finger-like S. and southwestward. The altitudes of the mountain peaks here are not so great as in Thibet and the Himalayas. The highest mountain is probably that north of Cabul, to which the name Hindu Kush is especially applied. It is probably 20,000 feet high, and the Kushan Pass near it rises to 15,000 feet. Westward the elevations do not surpass 17,000, and the Suliman peaks 13,000.

The most important and best known river is the Cabul (anc. *Kophes*). It rises in the Hindu Kush and its westward extension, and after a course of 250 miles for the Cabul proper, or 370 if its principal tributary, Kashkar—really the principal stream—is taken, it falls into the Indus at Attok. The Helmand (anc. *Etymander*) is but little known. It rises not far from the sources of the Cabul, and after a southwesterly course of 615 miles, 300 of which are unknown, it empties into the great Persian marsh or lake called Leistan. The Harut (245 miles long) also empties into this marsh. The Lora (200 miles long) is the most southern of the Afghan rivers. Its waters are usually exhausted in irrigation. The Hari-rud rises to the W. of Cabul, and flowing first W., then N., is lost in the Turkoman desert after a course of about 500 miles.

Climate.—The variety of climates is great, varying from the tropical climate of the Indus valley to the Alpine ones of the higher plateaus. At Cabul the traveler can pass in a day's journey from where the snow never falls to where it never melts. The summers are generally hot and the skies

clear. The rainfall is small, averaging less than 10 inches annually, except about the mountains. The melting of the heavy snows on the latter furnishes the streams with supplies which are extensively used for irrigation. The summer monsoons of India do not pass westward of the Suliman mountains, and what rain falls is generally confined to winter. Dust and sand storms are common, and sometimes assume the character of the Saharan simoon. Intermittent and remittent fevers, bowel complaints, rheumatism, stone, hæmorrhoids, and syphilitic diseases are common, the latter in their most repulsive forms.

Productions.—Northern Afghanistan is said to be rich in minerals. An excellent quality of iron is manufactured. Copper, lead, and gold are found in many places, the latter so far in small quantities. Badakshan has been famous for its precious stones. The native fauna and flora are poor. Agriculture is generally practiced with the aid of irrigation. There are two crops yearly. The one sown in autumn and reaped in summer consists of wheat and barley; the other, sown in spring and reaped in autumn, of rice, millet, and maize. The castor-oil plant, madder, and asafœtida abound. Vast quantities of the latter find their way to the Indian market. Among the fruits are the apple, pear, peach, apricot, pomegranate, grape, and fig. These form a large part of the food of much of the population, and they are exported in large quantities. The manufacture of silks, felts, carpets, dressed skins, and rosaries forms important industries.

Inhabitants.—The Ghilzais are the most numerous and the bravest of the Afghan clans. The political ascendancy is in their hands, and they at one time possessed the throne of Ispahan. They occupy the country between Herat and Kandahar. Certain large tribes speaking the same language and having the same customs, but living along the Suliman range, are rejected by the Ghilzais and called Pathans. The Hazaras are of the Mongol type, and occupy the mountains of the N. W. The Tafiks are probably the aborigines. They are a subject race, quiet, industrious, and frugal; speak a dialect of Persian, and are scattered over the whole country. There are also many modern Persians called Kizilbashs, who are chiefly to be found in the towns as merchants, doctors, and scribes, and are justly looked up to as a more educated and superior class. Their emigration began with the time of Nadir Shah (1737). There are also representatives in smaller numbers of other races. The Kizilbashs and the Hazaras are Suni Mohammedans; the others are Shiachs.

Government.—The government is monarchical and hereditary, but feudal in character, and the power of the prince depends much on his personality and fortunes. The country is divided into four provinces—Cabul, Turkestan, Herat, and Kandahar, and the districts of Badakshan and Wakhan in the extreme N. E. Each province is under a governor, under whom the nobles dispense justice in a feudal fashion. The laws in force are those usual in Mohammedan countries, and are fairly equitable, but exaction, spoliation, and embezzlement are all but universal.

The ameer is said to have had at the beginning of 1890 a regular army numbering 50,000 men. He has regularly embodied his foot levies, and he can call on his nobles and other important vassals for their mounted retainers. The artillery branch of the army is weak, and there are no trained engineers. The people are very turbulent and seem more fond of discord, alarms, and bloodshed than of quiet under a settled government. The hold of the ameer on the different parts of the country is always weak, and over the more distant parts it is rarely more than nominal. The revenues are subject to great fluctuations. In 1871-76 they were estimated by one of Shere Ali's ministers to average \$500,000 per year.

History.—What is now called Afghanistan is a mass of heterogeneous elements which have rarely been held together in one government. The Afghans themselves claim descent from King Saul. The name is first found in the history of Sultan Mahmud, of the eleventh century. Alexander the Great reached India by the Cabul river. The *Ariana* of Strabo corresponds roughly with the Cabul province, overpassing it on the W. and S. The ancient Greek kingdom of Bactria included the Cabul basin, and probably extended at times over the most of modern Afghanistan. The Indo-Seythian dominion occupied the country at about the beginning of our era. Various barbaric dynasties succeeded each other, among which appears a notable monarch, Kanishka, whose traditions can be traced for a thousand years afterward. About the end of the tenth century the country fell

into the hands of a powerful Mohammedan dynasty, certainly of Turkish and probably of Afghan race proper. To this family belonged the celebrated Sultan Mahmud of the eleventh century. In the latter part of the fourteenth century Afghanistan fell under the rule of Timur or Tamerlane, and remained with sovereigns of Mongol descent until its conquest by Persia (1642). Early in the eighteenth century control was wrested from the Persians by the native Ghilzais, who eventually conquered Persia itself, and held it for a few years. Nadir Shah recovered both Persia and Afghanistan, but he was assassinated in 1747, and succeeded by a noble Afghan, Ahmed Khan, who was the first to create Afghanistan as it is now known. He extended the boundaries of the country by extensive conquests, but anarchy soon followed his death. The next prominent figure in Afghan history is Dost Mohammed, who permitted a British resident at his court, with the result of losing his throne by a British invasion in 1838-39, but he regained it two or three years after, and retained it until 1863. He was succeeded by his son, Shere Ali Khan. In 1878 war was declared against him by Great Britain, and resulted in his deposition and the acknowledgment of his son, Yakub Khan. Riot and turbulence followed, until 1880 found Abdul Rahman Khan, a grandson of Dost Mohammed, in possession of the supreme power. During the armed struggle of Great Britain with the Afridi and other border tribes of northwestern India, in 1898, the Ameer with difficulty maintained a neutral position.

Large cities are not numerous in this country, and their population is fluctuating. The principal cities are Cabul (50,000 to 60,000 inhabitants); Kandahar (30,000); Herat (20,000 to 30,000); Istalip (18,000). The trade between Afghanistan and Bokhara is large; that between it and India is annually about—imports, \$1,500,000; exports, \$2,500,000. The rupee is the common silver currency; the gold is Russian or Bokharan. Shere Ali struck off a limited number of 6-rupee pieces. The roads are good, and trade is conducted on the backs of camels and horses. The rivers are not navigable.

MARK W. HARRINGTON.

Afghan Language and Literature: (1) *The Language:* *Afghan* (*Pushtū*, *Pashtō*, or *Puxtū*) is the language of the mountainous region of Eastern and Southeastern Afghanistan and of the N. W. borderland of British India. The name *Afghān* is the Persian designation of the speech, and is a word of uncertain origin; the people call themselves *Pushtūn* or *Pukhtūn*; they designate their language as *Pushtū* (*Pashtū*), or *Pukhtū*. There are two dialects recognized in the speech: the N. dialect, or *Pukhtū*; the S. dialect, or *Pushtū*. These two are distinguished, as in their respective names, *Pukhtū*, *Pushtū*, by the use of *kh* in the N. for *sh* in the S. dialect. The northern or *Pukhtū* dialect also has *g* where the southern, or *Pushtū*, has *zh*.

The Afghan language has been shown by its phonology to be a genuine Iranian tongue, and is now so accepted. It bears the same relation to the language of the AVESTA (*q. v.*) that the modern Persian does to the speech of the ancient Persian inscriptions. The geographical position of the Afghan has led to its receiving borrowed elements, (1) from Persia, (2) from the Hindustani of India, (3) from the Arabic. In phonology the Afghan presents many analogies to Avestan, but the Afghan has no *f*; it substitutes *p* for this letter. It has no aspirates, but has spirants. The Afghan has borrowed cerebrals from India. The Arabic alphabet is used in writing the language. In its inflections the Afghan shows greater signs of antiquity than the modern Persian. The noun declension has preserved the notion of grammatical gender and of an inflectional stem; the verb system distinguishes voice, mode, tense. There is little evidence of grammatical influence exercised from India. See IRANIAN LANGUAGES.

(2) *The Literature.*—The literature of the Afghans is partly written, dating from the fifteenth century, and partly oral. It all belongs to the eastern region near India, and it is not inconsiderable in extent. According to tradition, the oldest written work is a history of the conquest of Swāt (A. D. 1413-24) by Shaikh Malī, a chief of the Yūsufzais, and himself a leader in the campaign. Tradition also tells of a similar

history by Khān Khajō (1494), a successor of Shaikh Malī. There are some fragments of an Afghan writer, Bāyazīd Ansārī (A. D. 1550), called *Pir Rōshan*, "the master of light," the founder of a heretical sect. These fragments are chiefly preserved by being cited in the works of his orthodox opponent, Akhūn Darveza. The latter wrote more than fifty works; most of them are still unedited.

Besides the historical and theological writings the Afghan literature is rich in poetry. The oldest poetical works preserved are those of the Sufi, Mīrzā Ansārī (first half of the seventeenth century), who is imbued with the mystic and religious element. The warrior poet Khushāl Khān (1613-91), a prince of the Khatakas, was a favorite secular writer; while his contemporary Abdul Rahmān, from the neighborhood of Peshawar, was the most popular of the mystic poets. The elements of prince, warrior, and poet were also united in Ahmad Shāh (1724-73), the founder of the Durāni empire. The real poetry of the Afghans, however, is the ballad poetry, on legendary, romantic, amatory, political, or religious themes, sung by the *dum*, or wandering minstrel. A valuable collection of these has lately been made by the French scholar Darmesteter.

The best book for reference is J. Darmesteter's *Chants populaires des Afghans* (Paris, 1888-90), containing historical sketch, grammar, texts, and translation. Other useful works are Trumpp's *Grammar of the Pashto* (London, 1873); F. Müller's *Abhandlungen* (1863, ff.); the anthology of Raverty, *Gulshan-i-Roh, or Selections of Afghan Poetry and Prose* (London, 1861); Dorn, *Afghan Grammar* (1840); *Afghan Chrestomathy* (1847). A. V. WILLIAMS JACKSON.

Afium', or **Afium-Kara-Hissar** (black castle of opium): a city of Asia Minor, in Anatolia, 53 miles S. E. of Kutaieh (see map of Turkey, ref. 5-E). It is on a mountain side, is the residence of a pasha, and has a large trade in opium, whence its name. Here are numerous mosques, a citadel, and manufactures of carpets, arms, saddlery, etc. Pop. estimated at 50,000.

Afrago'la: an Italian town, in the province of Naples, noted for its manufactures of straw bonnets (see map of Italy, ref. 7-F). Pop. 19,000.

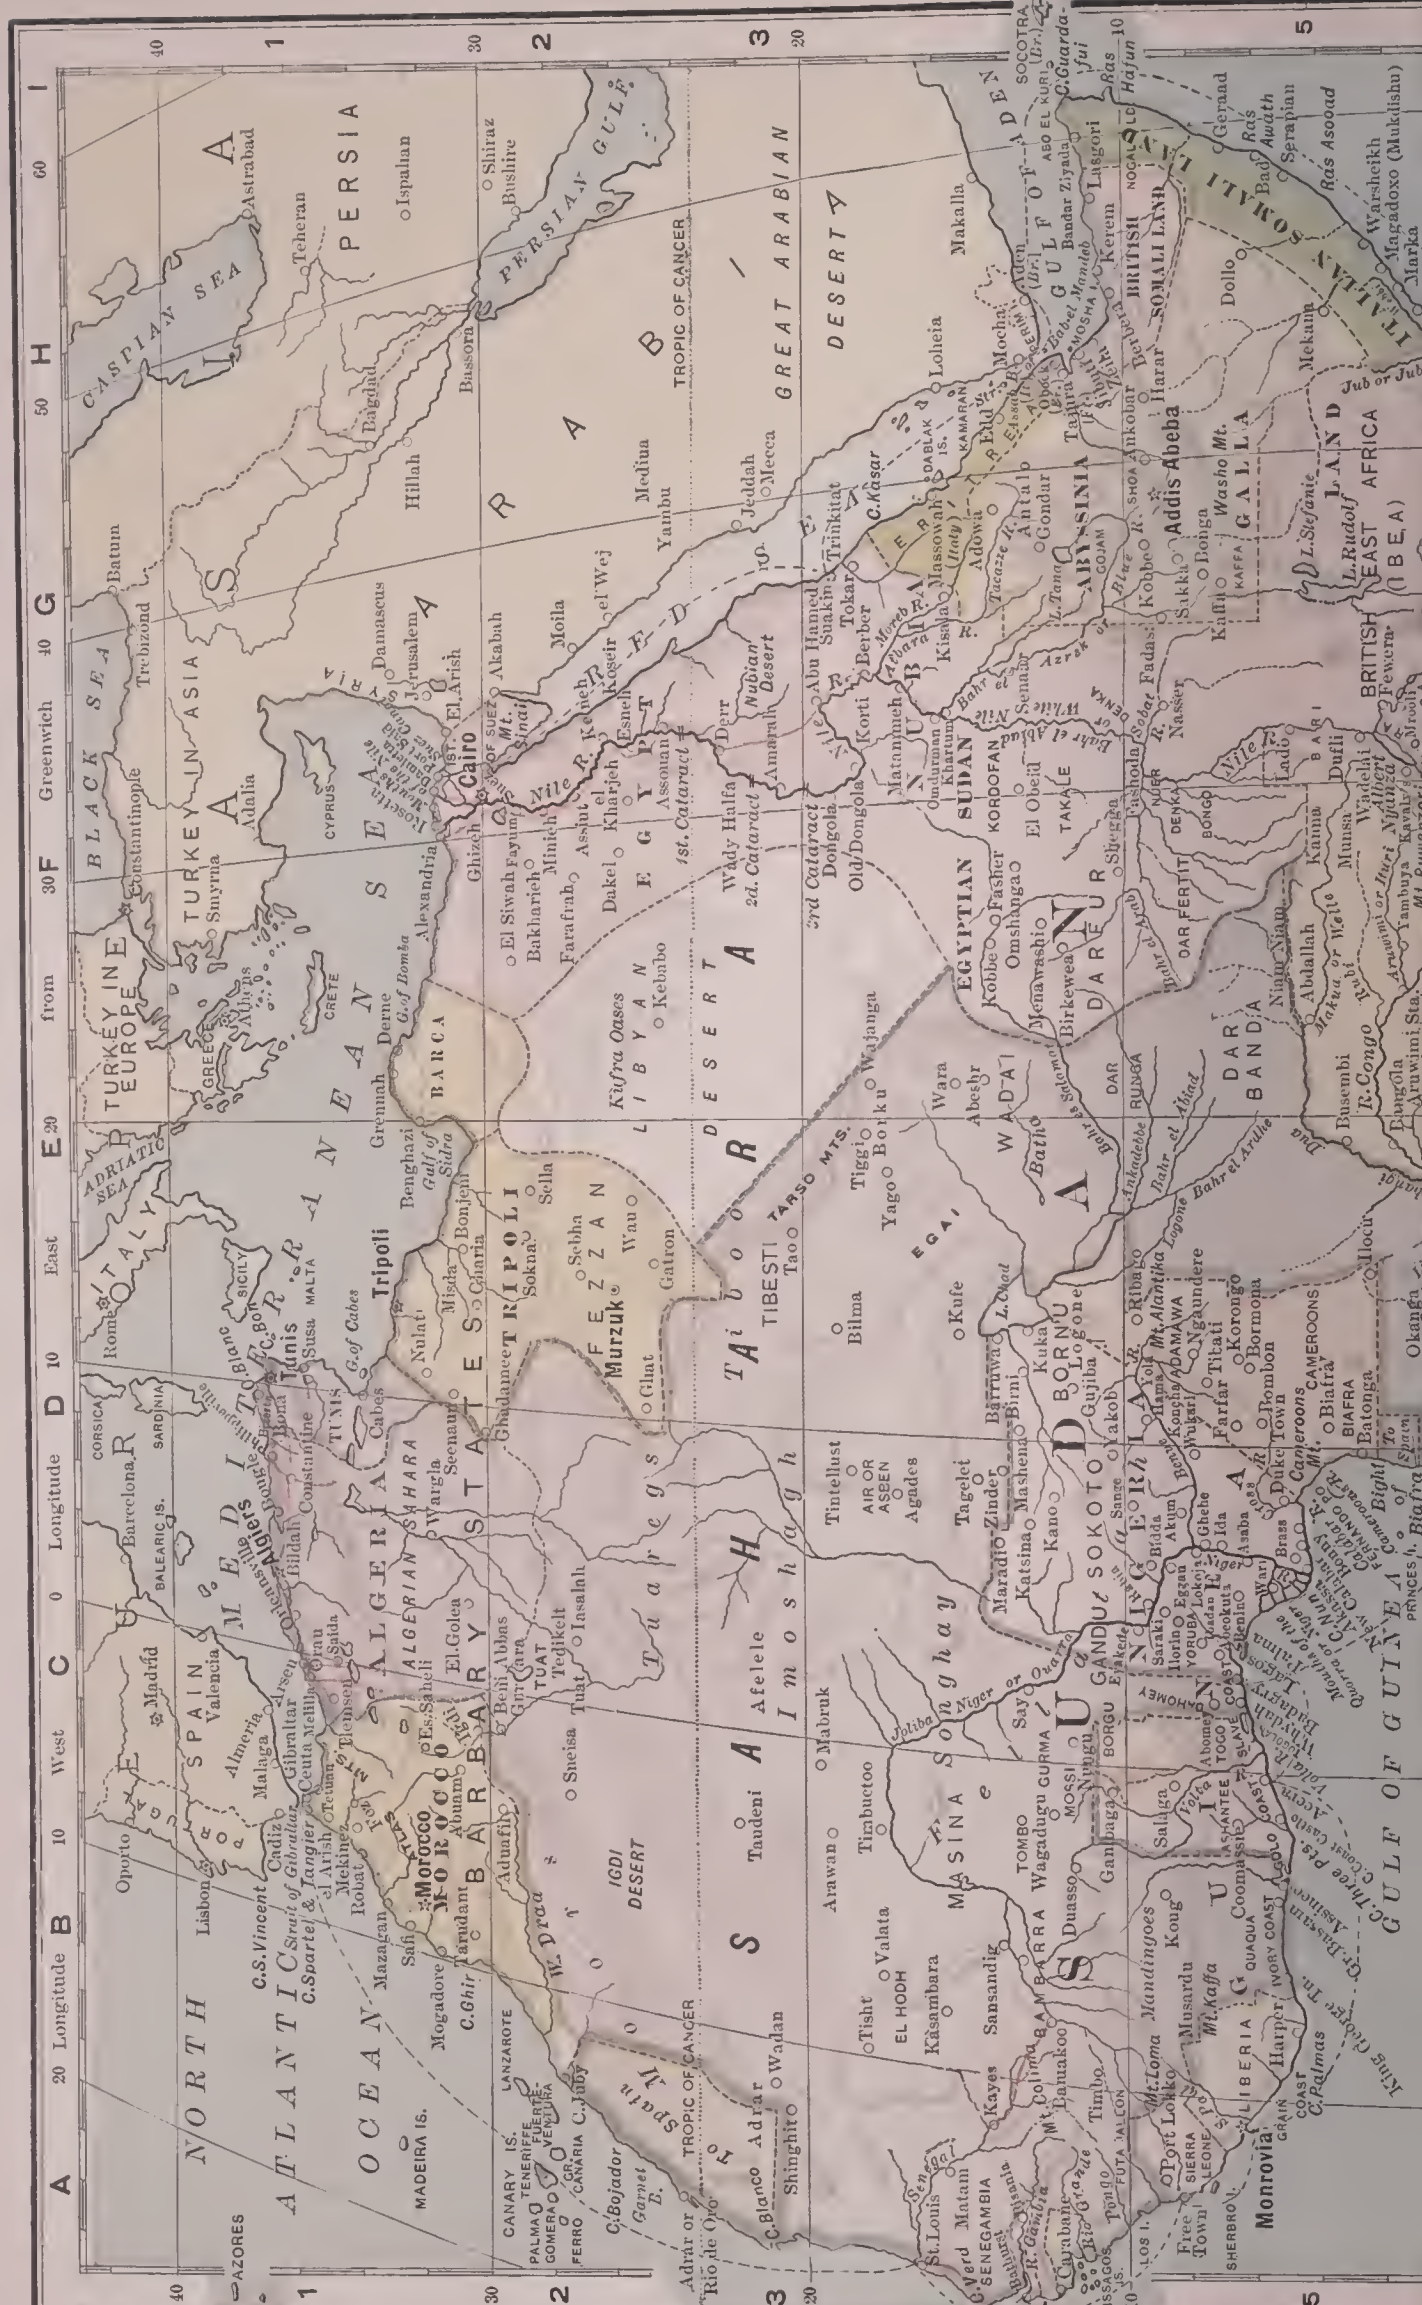

Afrancesa'dos, a-fran'-thā-saa'dō: a name given to those Spaniards who supported the French cause, or recognized Joseph Bonaparte as king, in 1808-13. They were proscribed or treated with severity by Ferdinand VII. after he was restored to the throne.

Afra'nus, LŪ'CIUS: Latin poet; b. about 150 B. C.; regarded by Quintilian as the leading representative of the *Fabula Togata*—i. e. comedy with subjects drawn from Roman life. His style shows the influence of Terence, and he admitted having borrowed much from Menander. More than forty titles and over 400 verses of his comedies have been preserved. See O. Ribbeck, *Comicorum Romanorum Fragmenta*, pp. 164-222. M. WARREN.

Africa [probably from the Carthaginian *Afrygah*, a colony, referring to Carthage, but gradually extended over the entire continent]: the most tropical and least known of the continents; extending from the northern point of Tunis, in lat. 37° 25' N., to the southernmost point of Cape Colony, lat. 34° 50' S., and from the vicinity of Cape Guardafui, lon. 51° 21' E., to Cape Verde, 17° 33' W. The true African islands extend still farther W.—to 28° W. in the Cape Verde islands. The length of the continent is about 5,000 miles, the breadth somewhat less.

PHYSICAL FEATURES.—Africa was formerly connected with Asia by the narrow isthmus of Suez, but since the completion of the Suez Canal (1869) it is entirely surrounded by water. It is separated from Southern Arabia by the narrow Straits of Bab-el-Mandeb, and from Spain by those of Gibraltar. The enormous coast-line is uniform and monotonous, seldom presenting mountains on the coast, and marked by few indentations. Good harbors are rare. The great Gulf of Guinea is merely an angle of the Atlantic Ocean between the western and southern extensions of the continent. At its bottom lies the Bight of Biafra, and on its northern margin the Bight of Benin, both only shallow depressions in the coast-line. The Greater and Lesser Syrtes form a broad extension southward of the Mediterranean Sea. (See SYRTIS MAJOR and SYRTIS MINOR.) The Gulf of Aden lies between the eastern angle of Africa and the south coast of Arabia. Delagoa, Algoa, False, St. Helena, Walvisch, Great Fish, and other bays are relatively small indentations of the coast.

The surface of the continent falls into two fairly well-

marked divisions, the northern table-lands and the central and southern plateaus. The first comprises the desert of Sahara, and consists of table-lands separated by "wadys," or dry water-courses, and margined by plains and depressed areas. The culminating point, as indicated by the wadys which radiate from it, is to the S. of Algeria and W. of Fezzan, in about lat. 25° N., lon. 5° E., and is called Imoshagh. There is on the N. a large table-land, fringing the desert and bordering the Mediterranean, extending from Morocco to Tunis. In South Algeria and Tunis are shallow salt-marshes (*shotts*), 100 feet or less below sea-level. In the Libyan waste are three small areas, Siwa, Sittra, and Birket el-Qarum, 80 to 141 feet below sea-level. No other areas in Africa, except Lake Assal, are known to lie below sea-level. South of Imoshagh, and extending to the Senegal and the Atlantic, is the desert proper, an irregular belt of shifting sands about 2,000 miles long, and from 100 to 200 miles broad. The wadys usually come to an end in this belt. The Sahara is diversified with hills and mountains, and contains many small oases or relatively fertile regions. Larger fertile areas are usually groups of oases along the wadys, as Air or Asbun in the center of the Sahara; Adrar, near the Atlantic; and Fezzan, S. of Tripoli.

The great plateau which occupies the most of Central and Southern Africa begins to the N. of Abyssinia. The eastern edge is the higher, and extends in a line which is but little broken to Mts. Kenia and Kilimanjaro, Lake Nyassa, and southward into Cape Colony, where it comes near to the coast. Turning northward from Cape Colony, it runs at lower elevations, but on the whole nearer the coast, to the Benue river, a tributary of the Niger, where it turns eastward and joins the wedge which extends northward over Abyssinia. The Western Sudan appears to be a lower extension of this plateau, culminating in the region of the upper Niger and Senegambia. The average height of the great plateau is probably about 3,500 feet. It averages highest in Abyssinia and lowest on the Gulf of Guinea. The great rivers generally take their rise within it, and show a series of falls or gorges where they leave it, as the cataracts of the Nile and the falls and gorges of the lower Congo. A large part of the southern portion of the plateau is occupied by an arid region, having about the same S. latitude as the Sahara has in the N. This is the so-called Kalahari desert, which is, however, not incapable of a successful grazing industry.

Rivers.—These present many features of interest. Some of them are among the greatest in the world, but these are all difficult of navigation in their lower course, because of bars at the mouths, cataracts, and gorges at no great distance inland, and there are other impediments, such as the enormous development of vegetation which bars the White Nile. The Nile is the first in historical interest, and also the longest. It was the nurse of Egyptian civilization, and yet its source was not known to moderns until the latter half of the nineteenth century. It rises in the feeders of the Victoria Nyanza, and, flowing northward, empties into the Mediterranean after a course of about 4,000 miles. Its basin includes upward of 1,000,000 sq. miles. On its course lie the Albert, Albert Edward, and some smaller lakes, and on its eastern branch Lake Tana in Abyssinia. It has few great tributaries, the chief one on the W. being the Bahr-el-Ghazal, and on the E. the Bahr-el-Asrak, or Blue Nile, and the Atbara. From the latter to the mouth, a distance of about 1,000 miles, there is no tributary with continuous flow. The lower Nile decreases in volume of water, because of excessive evaporation in the dry region through which it flows. The inundations, on which the prosperity of Egypt depends, come from the heavy equatorial rainfalls on the upper river.

The Congo is the second river in point of length (2,900 miles), but first in area drained (1,600,000 sq. miles) and in volume of water at its mouth. Its course strikes an enormous curve through the center of the continent, and its sources are less than 400 miles from the Indian Ocean. Next comes the Niger, which is also remarkable for the curve in its course; then the Zambesi, with its remarkable falls; the Shari, which waters the inclosed basin of Lake Chad; the Orange, and the Limpopo.

Lakes.—The great lakes in the interior of Africa were apparently known to the ancients, but to the moderns they were known only from the references in the classics until about the middle of the nineteenth century, and their exploration was not complete in general outline until the beginning of the last decade of that century. The lakes lie, for the most part, along the eastern rim of the great African

plateau already mentioned. The most remarkable series is on the upper waters of the Nile. The uppermost of this system and the largest African lake is the Ukerewe, or Victoria Nyanza (*Nyanza* is a native word meaning "lake" or "water"), lying just S. of the equator in lon. 32° to 35° E. It is roughly circular, about 180 miles in diameter, with an area of about 27,000 sq. miles, with many islands and fertile and populous shores. It is 3,800 feet above sea-level. Numerous lakes also belong to the Congo basin. The most remarkable and largest is lake Tanganyika, in lon. 30° E., and between lats. 3° S. and 8° S. It occupies a deep longitudinal basin running N. and S., and surrounded by mountains. It is about 400 miles long, but not more than 50 miles broad at its broadest part, averaging about 20 miles. Its elevation above the sea is 2,665 feet. Tanganyika has a small drainage basin and is semi-independent, the drainage into the Congo through the Lukuga being only occasional and apparently new in a geological sense. Belonging to the drainage system of the Zambesi is Lake Nyassa, which lies S. E. of Tanganyika and is parallel and similar to it. It is 1,570 feet above the sea, about 350 miles long and 40 broad, with an area of about 14,200 sq. miles. Lake Chad is the drainage center of an independent basin in the Central Sudan. It is a shallow lagoon, very variable in extent, thickly studded with islands, and is about 820 feet above sea-level. The waters are sweet and clear, and the overflow is carried off into the desert. Salt lakes are not uncommon. The most remarkable is Lake Assal, E. of Abyssinia, lying in a depression 571 feet below the Red Sea, and comparable to the Dead Sea.

Mountains.—The mountains of Africa do not form continuous chains except as they make a part of the ramparts of the great plateau, with the single exception of the Atlas mountains on the Barbary coast, and these form a rampart for the Saharan table-lands. The chief group of mountains disconnected with these systems is the Cameroon mountain with lower outliers, all volcanic, on the E., extending to the Bight of Biafra and thence, as a submarine range, rising above the surface in the islands of Fernando Po, Principe, St. Thomas, and Annobón. Few very lofty mountains are known in Africa. The main mountain mass occupies Abyssinia, but the highest point there is Buahit, estimated at only 16,000 feet; Mt. Kenia, E. of Victoria Nyanza, is about 18,350 feet high; and Mt. Kilimanjaro, S. of Kenia and the highest known point, is 19,750 feet high. The Barbary mountains are 6,000 to 14,500 feet. The Cameroon mountain has a height of 12,989 feet. The elevations are usually less than 10,000 feet in Africa. No lofty mountains exist S. of the Central Sudan, where earlier geographers placed the mountains of the Moon; but this name is now thought to belong to the little known Ruwenzori mountains, which lie near the equator and just N. of the Albert Edward Nyanza. They are said to reach an elevation of 16,500 feet. The well-known Table mountain is only 3,550 feet high.

Islands.—Africa is poor in islands as compared with the other continents, except Australia. The great island of Madagascar lies off its S. E. coast, from which it is separated by the Mozambique channel, 230 miles wide in its narrowest part. It is 980 miles long and 350 miles across in its broadest part. The other islands are small, and arranged along the coast or in groups. Of the former, Fernando Po and Zanzibar are the most important; of the latter, the Comoros (in the Mozambique channel), the Cape Verde islands, the Canaries, and the Madeira islands. The Azores are sometimes classed as African, but are more properly Atlantic islands. The Seychelles and Mascarenes, though far out in the Indian Ocean, are properly African, as they are connected with the Comoros by relatively shallow waters. Several of the great interior lakes are studded with islands.

CLIMATE.—The climate of Africa is essentially tropical, but is much modified by the extensive arid tracts to the N. and S. and by the elevation of the interior. The hottest region for the year is over the Sudan, where over an area 3,000 miles long; by 1,000 broad the mean annual temperature is 86° or more. The hottest region in summer is just N. of this, over the Sahara, where the mean July temperature is 97°. This is the largest hot region on the earth, and is only approximated by much smaller regions in Central India and Western Mexico. At the same time the daily temperature changes are here very great, and heat which in the afternoon makes the soil like fire and the wind like a flame may sink toward morning perilously near to frost. The mean temperature of the rest of the continent is from 75° to 80°—about that of Brazil—while for a narrow strip of coast extending from

Angola around to Natal the mean temperature is that of the Southern States. The aridity is severe over the northern third, and less so over the southern third, of the continent. Over the Sahara the precipitation varies from 5 inches annually to nothing. Over the Kalahari desert it is generally greater, ranging from 5 to 25 inches, or about that of the Missouri valley. In the central regions the rainfall is greater, and it is greatest over a large region between Kordofan and the Nile lakes, along the coast about the Bight of Biafra, and over the Sierra Leone coast. Here the annual rainfall is from 75 inches upward, and at Monrovia it reaches 130. In the tropical regions there are two rainy seasons. The first is in early summer. It is followed by a short relatively dry season, after which comes a rainy autumn. The winter and spring are dry. On each side of this area, and adjacent to the arid regions, there is but one rainy season, which occurs in middle and late summer. Near the Cape the rains occur in spring and autumn, with a dry season in late summer. Thunder-storms are common. Dangerous desert winds frequently occur, but Africa is free from hurricanes, except over the eastern island groups and about the Gulf of Aden.

GEOLOGY.—This is known only in fragmentary form, and the work of individual explorers at points widely separated is pieced together here with the greater difficulty because of an apparently independent order of geological events in this continent. In general, the massive crystalline or oldest rocks appear only along the rim of the great plateau already described. The tropical lakes lie in or near the eastern line of these rocks, and the Nile runs over or parallel to the long axis of their exposure. In the W. they are found close to the coast, and they extend along the N. shore of the Gulf of Guinea. The Paleozoic rocks are relatively scanty, while the Mesozoic are abundant. The Tertiary occurs over a large area in Egypt and Barca, and the Quaternary over the deserts, in the heart of the continent, and along the Gaboon and Sierra Leone coasts. The general outlines of the formations and the topography of the continent indicate that it has been relatively little disturbed in geologic times. In Abyssinia and Shoa, and E. of the Ukerewe, are large areas of recent eruptive rocks. Elsewhere they are few and their areas are small. The only active volcano known is Kirunga Gongo in the great lake region N. of Tanganyika. Earthquakes occur along the western Mediterranean coast.

FAUNA AND FLORA.—Both the plants and animals of Africa have characteristic features. The date-palm forms this feature for the north. In the south are miniature woods of heaths, some reaching the height of 12 or 15 feet. The cactuses of America are replaced by leafless, fleshy, and thorny euphorbias and similar plants. In the central regions there is a varied and rich flora, above the lower forms of which often rise the baobab, the oil and sago palms, the cotton-trees, and many other giants. The swamps are often covered with the papyrus, a tall aquatic plant, from the stem of which was formed the material which anciently took the place now occupied by paper. It is very abundant, especially on the upper Nile, where in some places it bars the navigation of the streams. Recent discovery has shown that Africa, like South America, possesses an enormous interior forest. It lies just to the W. of the northern part of the lake district, and runs apparently from lat. 5° S. to 3° N., with an average breadth of between 400 and 500 miles. This would give it an area of about 250,000 sq. m. This forest is almost unbroken; the trees rise to all heights up to 200 feet, and stand so close together that the direct rays of the sun are shut out from the traveler below. Traveling through the forest is very difficult, and Stanley's party were 160 days in crossing it. The population within the forest is very sparse, and consists in part of tribes of the dwarfish races.

In larger animal life the continent is especially rich. Among quadrupeds are the gorilla, chimpanzee, baboons, and mandrills. It is the chief home of the lion, and has many other representatives of the cat tribe. The bear, however, and the wolf and fox are almost entirely lacking. The elephant, rhinoceros, and hippopotamus are abundant. The antelope family here receives a remarkable development both in number of species and individuals. The quagga and zebra are characteristically African; while the horse apparently can not be acclimatized over the eastern tropical part of the continent. The giraffe is one of the most remarkable of existing animals, and is characteristically African, ranging from Cape Colony to Nubia and the Sahara. The birds are remarkable for the brilliancy of their plumage and the singularity of their habits. The largest living bird is the

African ostrich. Venomous reptiles are relatively few. The most important of the reptiles is the crocodile. The fly is extremely abundant and a great plague. One species, the "tsetse," is very destructive to cattle and sheep, but harmless to man and wild animals. The white ants form a scourge to the country, in that they occur in large numbers, and in their migrations devour everything that falls in their way.

ETHNOLOGY.—The most notable feature of the ethnology of Africa is that it is occupied by the Negro, Ethiopian, or black race. The original Negro domain seems to have occupied all Africa S. of the Sahara, and an extension eastward covering a large part of India and the most of Malaysia and Australasia. Whether the race was originally continuous or not, it is now divided into two distinct parts—the eastern or Papuan of the eastern archipelagoes from the Philippine islands to Australia, and the western or Negro proper occupying Central and Southern Africa and some of the African islands. The typical features of this race are the blackish velvety skin; the distinctly woolly hair, the individual hairs being not round but elliptical or flat in section; the bright, expressive, and lively black eye; the thick lips and flat nose; the projecting jaws, and the thick cranium, the sutures of which are said to close early in life. These features are most marked in the Guinea Negroes, and vary through many gradations in various tribes. The true African race is not so simple and uniform as might be expected, but, like the other great races, shows infinite complexity on closer study. Wave after wave of immigration and conquest seems to have swept over one portion or another of the continent, leaving sometimes patches of distinct tribes side by side or one inclosed in the other, ruling and subject peoples sometimes in the same territory, sometimes an intermixture of tribes, which, with the lack of historical data, make a problem the details of which still await resolution. And not only have the Negro sub-races and tribes undergone this intermixture, but branches of other races have taken part in it from the dawn of history, as the Carthaginians, Vandals, Arabs, Jews, and Turks. Through this maze of races and tribes the principal guide has been found to be the languages, and physical characters play a less important part. Guided by these, the following ethnological outline may be given as approximately correct.

1. *The Bantu family*, occupying the most of South Africa and extending to the equator and beyond. It includes the Zulus and Kaffirs, the Bechuanas and Basutos, the Swahili and Machinga, the Waganda, Ovambo, Basongo, Aduma, and numerous other tribes falling into several groups. On the west coast they extend as far N. as the Cameroons. They are dark, but not always black. In many of them, as in the Kaffirs, the Negro characteristics are so altered that they are sometimes called Negroid rather than Negro. Their common characteristic is to be found in the similarity of their languages, which all belong to one clearly distinct and remarkably homogeneous linguistic family. These languages are characterized by the simplicity and harmony of the syllables, each of which begins with a consonant and ends with a vowel, while consonantal juxtapositions are rejected; by alliterative concord in the words; and by a wonderful development of verbal inflexion, both initial and final. These features make the languages both very euphonious and very rich in capacity for expression. There are indications that the diffusion of this family of languages over South Africa is comparatively recent, and is due to the intrusion of a foreign element from the north.

2. *Dwarfish tribes* have been attributed to Africa from the earliest times, but the accounts of the classical writers were considered apocryphal until rediscovery vindicated their substantial accuracy. The earliest settlers in South Africa found among the larger and stalwart representatives of the Bantu family two groups of small men, whom they called Hottentots and Bushmen. Recent exploration brings to light, sparsely scattered in Central Africa, other tribes of still smaller men, who are undoubtedly the modern representatives of the pygmies of the ancient geographers. These tribes are generally supposed to be the aborigines; and while they undoubtedly find the warfare between them and their larger neighbors an unsuccessful one for them, on the whole, yet their smaller physical powers are in part compensated for by unusual activity and cunning and an especial skill in the manufacture of the poisons with which they tip their arrows and spears. The Hottentots dwell in the extreme south of Africa. Tradition points to their having formerly occupied a much larger territory than at present. They are small, but

not properly dwarfish. Their color is rather leathery brown than black. They are mild, social, and ingenious, and under British rule some are prosperous and civilized. A striking peculiarity of their language is the number of clicks and guttural sounds which it contains. The Bushmen are nearly allied to the preceding, but are of smaller stature, and lower in the scale of civilization. They are found over the arid region of South Africa, from Northern Cape Colony to Lake Ngami and the Ovambo river. The dwarf races of the north are still smaller, and more sparsely scattered. Dr. Schweinfurth discovered the Akkas in the N. E. Congo basin; Du Chaillu, the Obongo in the W. equatorial region; De Compiègne, a dwarfish people on the Ogowe river (1874). They have since been found by many travelers, but it was Stanley, in the account of his journey (1887-89), who made the world best acquainted with them. He found them in the great equatorial forest. He gives their height as between 3 feet and 4 ft. 6 in., and found one girl of seventeen years of age who was only 35 inches high. Wissmann measured forty Batua and got an average height of 4 ft. 7 in. Dr. A. Donaldson Smith (1895) found the Dume, or Doko, N. of Lake Stephanie. See ΡΥΘΜΥ.

3. *The Central African groups*, extending from the Bantu family on the S. to the Sahara on the N., present a confusion of tribes not yet unraveled. There is abundant evidence of commingling with the non-Negro tribes to the N. Several distinct stock languages have already been determined, and many more are believed to exist. The Abyssinians are a mixed race, with distinct Arab characters. To the S. of Abyssinia, in Kaffa, Galla, and Somali lands, the race is clearly Negroid, the language non-Negroid. The Tubus of the Eastern Sahara have apparently impressed their speech on many Negroid tribes to the S. and S. W. The Fulahs of West Sudan and Fans of Lower Guinea are distinctly non-Negro.

4. *The Berber race* occupies the Western Sahara and almost the entire Mediterranean coast. The name Berber is applied to the inhabitants of Northern Atlas. Elsewhere they are called by other names, as Shulu, Kabyle, and Tuareg. They are athletic, well formed, strong featured, brave, industrious, and are distinctly non-Negro, though their racial relations otherwise are still in dispute. Their language is peculiar, and is perhaps Hamitic. Many tribes have lost their original language, and now use Arabic. The Berber is an ancient race. The ancient Mauritanian and Numidian names by classical authors can be interpreted in Berber. The Moors are of mixed Berber and Arab descent. The Berbers seem to have been the aboriginal family of Northern Africa.

5. *The Copts* are believed to be the modern representatives of the ancient Egyptians. They are found in Egypt, where they make 5 or 6 per cent of the population. They are of medium size, dark complexion, with soft, woolly hair, oblique eyes, high cheek-bones, and thin beards. They are Christians of antiquated sects, and are extremely bigoted, sullen, avaricious, and untrustworthy. The Coptic language is now dead, being understood by few and replaced by Arabic. Other Hamitic languages are found along the Red Sea E. of Abyssinia, and in the inland Galla region. Several of the Sudan tribes are suspected of being more or less purely Hamitic.

6. *The Arabs* have undoubtedly exercised influence in Northeastern Africa from the earliest times, but the first historical wave of invasion occurred in the first century after the Hegira. In 640 Amru, a Mahomedan general, invaded Egypt, and by 706 the whole of North Africa, from Egypt to the Atlantic, had been conquered. This has been followed by wave after wave of Arab invasion, or Mohammedan religious revival, until Africa N. of 10° N. lat. is now Mohammedan. At the same time the rest of Africa has offered a favorable field of trade for the Arabs, who have extended their influence in the eastern half of Africa as far S. as the Zambesi river.

7. Of the *many other races* which are found on African soil little need be said. The Carthaginians have left hardly a trace, and the same is true of the Gothic tribes who once controlled parts of the northern coast. The Dutch are now numerous in inland South Africa, where they are known as Boers. The British occupy Cape Colony and Natal, and control some neighboring states. The Portuguese and Spaniards have occupied some of the islands and the Portuguese large areas on the mainland. The French have passed in great numbers over to Algeria, especially since the Franco-Prussian war, and the recent colonial revival has brought

many of these and other Europeans sparsely into other parts of the continent. The Jews have also spread in Africa, and at one time a Jewish dynasty ruled Abyssinia. On the east and south coasts are many Hindus.

All forms of government and all stages of civilization may be found on this continent. The feudal type still exists here in entire purity in many places. Cannibalism is practiced by many tribes—some of relatively high development, as the Fans—often as a ceremonial observance, but very often too as a means of obtaining food.

POLITICAL DIVISIONS.—As the native political divisions of Africa were for the most part unknown, the earlier divisions used by writers were geographical. These are still quite generally employed, but are gradually being replaced by the colonial designations which have followed the partition of Africa among the European nations. Among the geographical divisions such names as the Sahara, the Cape (of Good Hope) region, the Niger, Congo, and Mozambique regions, the Delagoa and other bay districts, and Guinea coast need no explanation. The Sudan is the district S. of the Sahara and N. of lat. 5° N., extending from the upper Niger to the middle Nile; the Lake district is that containing the principal great lakes of inner Africa; the Grain, Ivory, Gold, and Slave coasts are the divisions of the coast in order from Sierra Leone to the Niger delta; the Gaboon is the region about and to the S. of the Gaboon river; the Horn of Africa is the eastern Somali extension, terminating in Cape Guardafui. The names given by travelers for interior districts are often the names of chiefs or tribes, and are so often changed that the next traveler is likely to give quite a different set.

The following are the divisions recognized on the authoritative maps (1897): In the districts assigned to different colonies, as British East Africa, Portuguese Angola and others, the territory covered is that recognized in treaties between European nations, but not necessarily by the natives actually included. The foreign influence is only in small part that of an effective government, but mostly that of a protectorate or "sphere of influence." It is probably true that in many cases the natives are yet unaware that they are in such protectorates or spheres of influence.

Egypt is on the lower Nile, and extends up to Old Dongola. Before the Mahdist rebellion Egypt had been extended over Nubia and much of the upper Nile, the latter forming the "Equatorial Province" of which Emin Pasha had charge. Nubia is in large part under Egyptian control, while the Equatorial Province is a part of British East Africa.

Abyssinia occupies the northeastern angle of the great plateau, and is separated from the Red Sea by the Italian colony of *Eritrea*, which is in part a colonial government, in part a protectorate. Abyssinia is an independent government. Inland from Abyssinia to Lake Chad are, in order, *Darfur*, *Wadai*, and *Bagirmi*, which are independent sultanates.

The *Eastern Horn* is under French and British protection along the most of its north coast, and Italian elsewhere. The protection is only nominal even along most of the coast. S. of this, along the coast from the river Juba to near lat. 5° N., and extending inland past Victoria Nyanza nearly to Kordofan and Darfur, is *British East Africa*; S. of it, to the Rovuma river on the S. and Lake Tanganyika on the W., is *German East Africa*; S. of this and extending along the coast to about lat. 26° 30' S. (just beyond Delagoa bay) is Portuguese territory, the part N. of the Zambesi being called *Mozambique*, that S., *Gazaland* or *Lourenço Marques*. Mozambique is bounded on the W. by a somewhat irregular line, of which Lakes Nyassa and Shirwa form part. Gazaland is bounded on the W. by an irregular line, which begins on the Zambesi near where the meridian of 30° E. crosses it, and ends near the coast in about lat. 26° 30' S. To the S. and along the coast come *Amatongaland* and *Zululand*, under British protection; then the larger *Natal*, a British colony, just N. of Cape Colony. W. of Natal is the native *Basutoland*, in the mountains, a British crown colony. Inland from the coast states, from Gazaland to Natal, are the two Boer republics called the *Transvaal*, or *South African Republic*, and the *Orange Free State*. S. of Natal, Basutoland, and the Orange river is *Cape Colony*, which has a large British population. Inland, from the Orange river northeastward to Lake Tanganyika, is an enormous territory claimed by Great Britain, and known as *British Bechuanaland*. It extends from the N. boundary of Cape Colony to the Zambesi, and from the Transvaal and

Matabeleland on the E. to the confines of German S. W. Africa on the W., and is administered by the British South Africa Company. N. of the Zambesi, but S. and W. of Lake Nyassa, lies the British Central Africa Protectorate.

On the Atlantic coast, passing northward, the first district is *Damaraland*, claimed by the Germans, beginning on the coast at the mouth of the Orange river, and extending northward to the mouth of the Kunene river. It is bounded on the E. by Bechuanaland and the Chartered Company, the latter boundary being for the most part on meridian 21° E.; the northern boundary is near the parallel of 17° 30' S. Next comes Portuguese *Angola*, which extends on the coast to the mouth of the Congo, and eastward nearly to the meridian of 25° E. The *Congo Free State* occupies an enormous territory in the interior of equatorial Africa, and reaches the Atlantic coast by a narrow strip about 100 miles wide and 200 miles long, near the parallel of 5° S. It includes most of the basin of the Congo to the point where it is joined by the Ubangi. The northwestern boundary is formed by the Ubangi and Congo rivers. It was formed by a European agreement and placed under the patronage of the King of the Belgians, who willed his rights to Belgium. N. and W. of the Congo Free State is *French Congo*. It extends from the coast to the Ubangi and behind the Cameroons, along the Shari to Lake Chad. N. of this is the German *Cameroons*. Its coast-line extends along the Bight of Biafra to the point where the coast turns westward. From here the boundary runs northeastward, and a narrow neck of it extends to Lake Chad.

The *British Niger Territory* extends along the coast from the Cameroons to the colony of Lagos. Inland it occupies the lower Niger basin nearly to the Sahara, and northeastward to the large independent kingdom of *Bornu*, which lies S. W. of Lake Chad. Then westward comes *Dahomey*, under French protectorate, a N. and S. strip about 200 miles wide; then German *Togoland*, with a narrow strip of coast; then the *Gold Coast*, a British crown colony, and the Ivory Coast which forms the *French colony of the Gold Coast*. Liberia occupies the southwestern angle of the western extension of Africa. It extends along the "Grain" or "Pepper" coast, and inland for about 200 miles. N. W. and adjacent is the British *Sierra Leone*, extending along the coast about 200 miles, and inland about as far. The *Bisagos* islands, with the adjacent coast and interior, are claimed by Portugal. The territory along the Gambia river for about 200 miles forms *British Gambia*. The remainder of this coast to Cape Blanco, and inland over the basins of the Senegambia and Senegal rivers and that of the upper Niger, is claimed by France. She also claims a protectorate over the Western Sahara from lon. 13° E. to 8° W., except in the N. W., where it is claimed by Morocco. By this area of desert territory her enormous possessions in Southwest Africa are connected with Algeria, and French Africa surpasses British Africa in size.

From Cape Blanco to Cape Juby, Spain claims the Saharan coast, and inland to the French line. For some years Great Britain claimed the territory around Cape Juby where some of her subjects settled, but they were harassed by the desert nomads, gave up the experiment, and the British now assert no interests there.

The kingdom of *Morocco* occupies the northwestern angle of Africa. Her coast-line extends from about lat. 29° N. to Tangier, and hence eastward on the Mediterranean to about lon. 2° W. Her eastern boundary runs irregularly S. S. E. from this point, while the southern is in the Sahara and indefinite. Next E. is French *Algeria*, extending on the coast to about lon. 8° E., then *Tunis*, under French protection, occupying the angle of which Cape Bon is the apex, and extending southward nearly to lat. 30° N. Between Tunis and Egypt, on the coast, are the Turkish provinces of *Tripoli* and *Barca*, and S. of the former is Turkish *Fezzan*. South of Barca is the Libyan desert, the very sparse population of which is nominally under Turkish rule, but actually independent.

Of the islands, Zanzibar, Pemba, Socotra, and Mauritius are British; Madagascar, the Comoro islands, and Réunion are French; Madeira, Cape Verde islands, St. Thomas, and Prince's island are Portuguese; and the Canaries, Fernando Po, and Annobon are Spanish.

AREA AND POPULATION.—The table in the next column gives the estimate of area and population by Ravenstein, an acknowledged authority on this subject. The figures should be viewed simply as the nearest approximations possible with our present knowledge.

ESTIMATE OF AREA AND POPULATION.

COUNTRIES.	Area in sq. miles.	Population.	Inhabitants to a sq. mile.
British Africa.....	2,570,926	40,764,100	16
French Africa.....	2,902,624	23,788,000	8
Portuguese Africa.....	841,025	5,416,000	6
Spanish Africa.....	203,767	437,000	2
German Africa.....	822,000	5,950,000	7
Italian Africa.....	602,000	6,300,000	10
Congo State (Belgium).....	865,400	15,600,000	18
Boer republics.....	162,640	888,000	5
Swaziland.....	6,370	61,000	10
Liberia.....	37,000	1,000,000	27
Turkish (Egypt and Tripoli).....	836,000	7,980,000	10
Unappropriated.....	1,584,398	*22,000,900	14
Great lakes.....	80,350
Total.....	11,514,500	130,185,000	11

* Unappropriated Africa includes Morocco (219,000 sq. miles, 5,000,000 inhabitants), Bornu, with Kanem (80,000 sq. miles, 5,100,000 inhabitants), Wadai (172,000 sq. miles, 2,600,000 inhabitants), Bagirmi (71,000 sq. miles, 1,500,000 inhabitants), etc.

The opening of trade and preparation for supremacy by the aid of great corporations, as was done by the East India Company for India, is also practiced in Africa. The British East Africa Protectorate was controlled by the Imperial British East Africa Company, which gave to it the name "Ibea," from its initials, until July 1, 1895. The most of the Niger territory is under the Royal Niger Company. The immense territory of Nyassaland, now officially known as the British Central Africa Protectorate, is under the control of the South Africa Company, with the exception of the eastern portion immediately about Lake Nyassa, which is administered directly by the imperial Government. Damaraland is under the German Southwest Africa Colonial Company, and German East Africa under an imperial company of the same name. There are also some great companies which are auxiliary, but not trusted with governmental powers. Such is the *Deutsche Plantagengesellschaft* in the Cameroons.

COMMERCE.—Agriculture is imperfectly carried on in Africa, except in the extreme N. and S., so that the export products of the continent are largely natural ones. Slaves have from time immemorial been the chief product, but the slave trade is now nearly suppressed. The next best known and most characteristic product is ivory, and this still reaches the coast in the equatorial regions in great quantities. Among the natural products are also palm-oil and palm-kernels, ostrich feathers (from the south), caoutchouc, rubber, gums, sesame seeds, cloves, orchilla, skins, and ebony and other woods. The agricultural products from South Africa are cattle, hides, wool, cereals, including maize, while sugar is exported from both North and South Africa, from the Mascarene islands and from Liberia. Coffee is a very promising production of Liberia and the adjacent regions. This republic also produces cocoa, attempts at the production of which, as well as of bananas, are being tried in the Cameroons and elsewhere, in plantations on an extensive scale. Wines are furnished by Algeria, Tunis, and Cape Colony. Olive oil is produced on the Mediterranean coast. Algeria produces large quantities of cereals and wool. Tunis has a considerable production of sponges. Egypt is a leading producer of cotton and cottonseed.

MINERALS.—The mineral products are relatively small. The best known is the diamond in the Kimberley district in Northern Cape Colony, close to the boundary of the Orange Free State, which is one of extraordinary richness. In 1895 over \$23,000,000 worth of diamonds were exported from Cape Colony. The total of the officially known exports from the discovery of the field in 1867, to 1890 amounted to \$262,000,000. Cape Colony mines much copper, and exported \$3,500,000 worth of the ore in 1890. Gold is found in many places, and is extensively mined in the gold-fields of the South African Republic, which are fully described in the article WITWATERSRAND in the Appendix to the eighth volume of this cyclopædia. The product of these fields naturally makes its way to the coast through Natal and Cape Colony, from which \$45,335,760 worth was exported in 1894. Coal is extensively mined in the Orange Free State, and to some extent in the South African Republic, and has been found in many other places.

The imports into Africa are almost entirely manufactured products, and include textile fabrics, hardware, machinery, iron and copper wire, beads and trinkets; also large amounts of spirits and other drinks.

There is considerable interior trade, considering the means

of communication. Ivory makes its way from the depths of the interior to the coast, usually on men's backs. The trade along the southern edge of the Sahara is particularly brisk, and some of the races of Western Sudan adjacent to the desert have developed considerable manufacturing capacity, especially in cotton and other fabrics, and leather and saddlery. Salt is an active object of interior trade, being abundant in a few places, but generally wanting. It is in some parts so highly prized that it is used for money. Ivory tusks and cowry shells also serve for large and small change. European coins are not valued generally except on the coast, but the Maria Theresa dollar, an Austrian coin, has gained general confidence throughout Central and Northern Africa. It was first struck in 1780, and, to retain the African faith in it, its coinage is continued without change.

COMMUNICATION.—Modern means of communication are rapidly developing. In 1894 Cape Colony had 2,253 miles of railway; Algeria, 1,961; Egypt, 1,170; Natal, 340; and shorter lines were in existence elsewhere, while many long ones were projected. The British East Africa Company is surveying one from the coast to the former Equatorial Province of Egypt, and the coastal part is now (1897) constructed. Another is under construction, 270 miles in length, from Matadi, on the Congo, to Stanley Pool. Cape Colony had 5,973 miles of telegraph in 1894; Algeria, 4,443; and Egypt, 3,168. Regular communication is kept up by steam and sailing vessels on the lower Nile, the lower Niger, and the lower and upper Congo. The African Lakes Company of Scotland keeps a regular line of steamers on the Zambesi and the Shiré, and another on Lake Nyassa. Exploring and mission steamers occasionally navigate Tanganyika and Victoria Nyassa.

HISTORY AND EXPLORATION.—Egypt was ancient in the time of the Roman and even in that of the Greek classical authors. The beginning of its historical era is uncertain, but probably dates at about 5000 B. C., or earlier. In Egyptian pictures the Negro face and figure can be found, and are not essentially different from those known to-day. About 1000 B. C. the Phœnicians established colonies on the Mediterranean coast of Africa, and Carthage had time to rise, flourish, and fall before Rome reached her zenith. Necho or Neku II. (611–595 B. C.) is said by Herodotus to have sent his Phœnician sailors to circumnavigate Africa, a task of which they asserted, on their return, the accomplishment. If true, it has left no other traces to modern times. Perhaps fifty years later, Hanno, a Carthaginian, is said to have fitted out a large expedition, which coasted the western coast of Africa from the Straits of Gibraltar to a point southward, variously assigned from Sierra Leone to the Bight of Benin. The Carthaginians have left us no knowledge of the interior of Africa. In 525 B. C. Cambyses conquered Egypt. The allusions and second-hand tales of the classical authors give occasion to believe that the Egyptians were acquainted with the upper Nile, but they have themselves left nothing behind them on this subject. Egypt was conquered by Alexander the Great in 321 B. C., but though his successors in Egypt—the Macedonian dynasty—were intelligent patrons of the arts and sciences, they have left no indications of additions to the knowledge of Africa. When, however, the Romans came into possession of this country, explorations were extended to Fezzan on the W., and to Abyssinia and the upper Nile on the S.; and before the time of the geographer Ptolemy they had a fair knowledge of the east coast of Africa as far S. as Zanzibar.

Ethiopia, now Abyssinia, at least in part, was also a very ancient country, perhaps as ancient as Egypt. The Queen of Sheba, who visited Solomon about 1000 B. C., is claimed by the Abyssinians as one of their sovereigns. About the time of the Captivity many Jews took refuge in this country, where they acquired great power at one time, and their descendants remain to the present day. About the beginning of the Christian era this kingdom, then known as Auxume, became one of great power, culminating a century or two later.

The modern knowledge of Africa begins with the irruption of the Arabs in the first century after the Hegira. They conquered the entire Mediterranean coast and Abyssinia, and they explored the west coast as far as the mouth of the Gambia, and the east to Sofala in about lat. 20° S. In the fifteenth century the Portuguese, under the enlightened patronage of Prince Henry the Navigator, explored the western coast of Africa, pushing farther and farther S., until in 1486 (and after Prince Henry's death) Diaz rounded the Cape of Good Hope, and in 1497–98 Vasco da Gama completed the circumnavigation of Africa. Accounts of a Christian ruler

named Prester John stimulated discovery in the direction of Abyssinia, and Covilham entered it in 1490. The discovery of America created the slave-trade of the west coast of Africa, and gave rise to a familiar acquaintance of, and some settlements on, the coast from the Gambia to the Gaboon.

Here African exploration practically rested until the formation of an association for the exploration of inner Africa, which was founded in London in 1788. The coast was then known throughout its whole extent, but of the interior only Egypt; Abyssinia, Tunis, Morocco, Senegambia, the Gold Coast, and the Cape were known; and here acquaintance extended over only a strip on the coast less than 150 miles wide, except in the case of the first two. The first scientific journey, properly speaking, had been that of James Bruce (1768–73), who had travelled from Massowah to the upper waters of the Blue Nile, thence to Sennar, thence back to Egypt. The African Association undertook the work of systematic observation. In 1831 it broadened its field by becoming the Royal Geographical Society.

The first problem of which the solution was undertaken was that of the Niger, and connected with that was the discovery of a famous but mysterious Timbuctoo. In 1795–97 Mungo Park entered the Niger district by way of the Gambia, reached the upper course of the Niger, descended it some distance, and returned. In 1805 he again entered this country, and embarked on the Niger to descend it to its mouth, but was killed by the natives at Bussa, below Timbuctoo. Several travelers afterward reached the Niger, Timbuctoo, or Lake Chad, some of whom lost their lives, and it was not until 1830 that the two brothers Lander added to the knowledge of the river by tracing it to its mouth. It was not until Lieut. Hourst floated down the Niger from Timbuctoo to its mouth (1896) that the whole course of the river was revealed and surveyed.

In 1830 France began the conquest of Algeria, and she has continued to push to lower latitudes until its southern boundary has reached the Gulf of Guinea. In 1845–46 Richardson journeyed through the Libyan desert and Tripoli, with the view of opening a trade route over the desert to the mid-Sudan. Barth followed (1850–55) with extensive journeys through the Sudan itself, exploring the regions E., S., and W. of Lake Chad, and extending his journey to Timbuctoo, returning safely to carefully edit his collection of facts concerning this unknown center of Africa. He was followed by Vogel (1853–56), Rohlfs (1865–67), and Nachtigal, who was sent in 1869 on a diplomatic mission to Bornu.

The Egyptian expedition of Napoleon Bonaparte (1798–1801) was a noteworthy beginning of the modern investigation of the Nile basin. The French savants were especially devoted to archaeological research, but geography was not overlooked. The eyes of the world were once more turned to the land of the Pharaohs. The impulse continued under the intelligent Mehemet Ali (1805–48), Khedive of Egypt. He not only invited the learned men of Europe to continue their Egyptian work, but also pushed his conquests through Nubia and Sennar, opening the road for the merchant and missionary, and taking with him European scientists. Cailliaud and Letorzek, who accompanied his army in the conquest of Sennar, were the first Europeans to see the junction of the Blue and White Nile (1821–22).

The development of an exact knowledge of the Abyssinian branches of the Nile (the Atbara and Blue Nile) is due to many different explorers, among whom stand pre-eminent Salt, who accompanied the British Abyssinian expedition of 1810, Burckhardt (1814), Lefebvre (1839–42), Beke (1840–43), Raffray (1873–74, 1881), and Rohlfs (1868, 1880–81). It is, however, the exploration of the White Nile, or main river, which has attracted the most interest and given its results with the greatest difficulty. Linant de Bellefonds was sent out in 1827 by the African Association to explore the upper Nile, but did not get farther S. than lat. 13° N. After other failures, Mehemet Ali conceived the idea of increasing the glory of his reign by rediscovering the sources of the Nile. He sent out two expeditions; the one in 1840 reached 6° 30' N. lat.; that of 1841, 4° 42' N. Petherick discovered the Bahr-el-Ghazal, the chief western branch of the Nile, in 1858, and in 1860 Miani followed the main river up to 3° 34' N. lat. This ended the advance from the N. until after the discovery was made from the S.

The lakes of Central Africa seem to have been known to the ancients. In 1518 the report was brought from Mozambique that a great lake existed to the westward of that place. Cooley collected these reports carefully from 1835, in order to fix the lake with all possible exactitude on his

charts (1845, 1853), and to him is due the introduction of the name Nyassa. On succeeding maps this lake was increased somewhat in size, when the discovery in 1849 of Mt. Kilimanjaro, by Reimann, and Mt. Kenia, by Krappf, led to renewed attention to that region, and brought news of a Lake Ukerewe (now called Victoria Nyanza). Spurred by these reports, Burton and Speke in 1858 struck westward from the Zanzibar coast. Both reached Tanganyika, Speke alone the Ukerewe. In 1862 Speke perfected his work of the previous expedition, and was able to announce that the outflow of the Ukerewe was through the Nile. In 1864 Baker added the Albert Nyanza to the group. Later Stanley discovered the Albert Edward Nyanza, and this is now known to belong to the same group. The Tanganyika has been found to be independent of the Nile, with occasional overflow into the Congo. In 1859 Livingstone discovered the Nyassa and Shirwa lakes of the Zambesi basin. In 1867 he found the Moero, and in 1868 the Bangweolo, lakes of the Congo system. With these discoveries the Central African system of lakes was fully laid open.

In South Africa the Portuguese made no permanent settlement after the discoveries of Diaz and Vasco da Gama. The Dutch followed the Portuguese in the E., and in 1652 the Dutch East India Company formed a colony at the Cape. The colony was weak, but it had some additions to its numbers from other European nations from time to time, notably, in 1686, French Protestant refugees after the revocation of the Edict of Nantes. From 1795 the colonists attempted to gain their independence, but their insurrections were suppressed by the aid of Great Britain, to whom the territory was formally ceded in 1815. In 1835-36 the love of independence among the Boers had become so great that they migrated in a body beyond the limits of the colony, to the N. of the Orange river, and later spread eastward to the coast, in what is now Natal. In 1842 the latter were reduced under British rule, which in 1848 was extended over the Orange Free State. Again the more independent of the Boers journeyed to the wilderness to find independence, and crossing the Vaal to the northward they founded the Transvaal Republic. In 1852-54 Great Britain yielded her claims to sovereignty over the sturdy republicans of both the Orange Free State and the Transvaal. In 1877, however, she took the occasion of disastrous wars between the Boers and natives to announce the annexation of the Transvaal. This was followed by a revolt of the Boers so serious and well sustained that in 1884 the Transvaal was again recognized as independent.

The South African War.—A conference held at Bloemfontein, May 31, 1899, between Sir Alfred Milner and the presidents of the two Dutch republics, to consider the grievances of the outlanders, adjourned without coming to an agreement. Negotiations were continued throughout the following summer, Great Britain urging upon the Transvaal the propriety of granting to the foreign-born residents such privileges as she asserted were due to them as a matter of common justice, that certain monopolies that pressed heavily upon the miners in the Rand be abolished, and that the suzerainty of Great Britain over the Transvaal receive some official recognition. The suzerainty proposition President Kruger flatly rejected as inconsistent with the treaty of 1884, by which Great Britain relinquished her right to interfere in the internal affairs of the republic, and at the same time he offered to submit the other demands to arbitration. Meanwhile, the Orange Free State decided to support her sister republic in the outcome of the dispute. In the latter part of September, while negotiations were still pending, the British Government called out the reserves; troops were sent from England and India; and the troops already in South Africa were massed on the Natal border at Ladysmith and Glencoe. In answer to this, a part of the burgher militia was called out, and on Oct. 9 President Kruger sent his ultimatum to the British Government, demanding the withdrawal of troops from the borders, the removal of all re-enforcements that had arrived since June 1, and that British troops then on the high seas should not be landed in South Africa. An affirmative answer was demanded within forty-eight hours; otherwise, the action of the British Government would be considered a virtual declaration of war. The British Government replied that the conditions were such as they deemed impossible to discuss.

The war actually began at 5 p. m. Oct. 11. The following day the Boer army was in motion. Commander-in-chief Piet Joubert moved with the Transvaal forces into Natal, and Gen. Cronje directed operations in the west. After

serious engagements at Glencoe, Oct. 20, Elandsplaagte, Oct. 21, and Rietfontein, Oct. 24, the British under Gen. White were forced to fall back upon their base of supplies at Ladysmith, where, after an ineffectual sortie, Oct. 30, they were surrounded and their communications cut off by the Boers under Joubert, Nov. 2.

Meanwhile, the London War Office was hurrying an army corps to Cape Town under Sir Redvers Buller as commander-in-chief. The first transports reached Cape Town Nov. 9. The investiture of Kimberley and Mafeking, both garrisoned by small British forces, was complete by Oct. 15, and commandoes of the Free-State Boers crossed Orange river into Cape Colony. Early in November Lord Methuen, with 10,000 infantry and 1,000 cavalry, moved to the relief of Kimberley. He drove the Boers from strong intrenchments at Belmont, Nov. 23, and at Enslin (Gras Pan), Nov. 25, and on Nov. 28, after a bloody fight, forced the passage of Modder river. On Dec. 10-11 he lost more than 1,000 men in an unsuccessful attempt to dislodge the Boers, now re-enforced and heavily intrenched at Magersfontein. Coincident with this disaster, Dec. 10, came the repulse of Gen. Gatacre, who was drawn into an ambuscade at Stormberg, in northern Cape Colony, and only by a masterly retreat saved his command from annihilation. Dec. 15, Gen. Buller, with 22,000 men, moving to the relief of Ladysmith, met with a serious defeat in his attempt to cross the Tugela river at Colenso, losing eleven guns and more than 1,000 men. Dec. 18 Lord Roberts was ordered to assume supreme command in South Africa, and he chose Lord Kitchener as his chief-of-staff, and arrangements were made to increase the field force to nearly 200,000 men. Lord Roberts reached Cape Town Jan. 6, 1900, and Feb. 12 the invasion of the Free State was begun. Meantime the Boers were repelled in a general attack on Ladysmith, Jan. 6, and Buller had made two more unsuccessful attempts to cross the Tugela: Jan. 23-25 taking and abandoning Spion Kop, and Feb. 5-9 executing a similar movement on the Val Krantz Hills; finding both positions untenable after he had occupied them. Gen. Roberts directed his movements against Cronje at Modder river, moving directly on Bloemfontein and Pretoria. Gen. French relieved Kimberley Feb. 15, and on Feb. 20 Cronje and the rear guard of the retreating Boers were surrounded at Paardeberg, where, re-enforcements being unable to reach them, they surrendered, Feb. 27. The withdrawal of troops to the assistance of Cronje enabled Buller to force his way into Ladysmith, Feb. 28. On Mar. 27 Gen. Joubert died. The siege of Mafeking was raised May 16. The relief of Kimberley and Ladysmith, and the surrender of Cronje and his deportation to St. Helena, were the beginning of the end. Lord Roberts occupied Bloemfontein Mar. 13, and after reorganizing his transport moved on Pretoria May 3. At the request of the Transvaal Government, May 10, the United States offered to act as mediator, but the offer was declined by the British Government. Kronstadt, the temporary capital of the Free State, was occupied May 13, Johannesburg May 31, and Pretoria June 5, all after very little resistance. President Kruger sailed for Europe on a Dutch cruiser from Lorenzo Marques. Throughout the year Boer commandoes under Generals Botha and De Wet carried on guerrilla warfare with a great degree of success. Lord Roberts proclaimed the Free State, May 28, and the Transvaal, Sept. 1, colonies of the British Empire, and on Dec. 14 Sir Alfred Milner was appointed to their administration. Lord Roberts sailed from Cape Town Dec. 12, leaving Lord Kitchener in full command. The British losses to Mar. 1, 1901, were: killed and died from wounds, 14,728; missing, 775; unfitted for service, 2,189.

The development of our knowledge of the Congo basin is the most recent of the great events in the history of African exploration. Cameron (1873-75), in his journey across the continent from E. to W., was able to show the outflow of Tanganyika to the westward, but he left uncertain the relations of the Congo to the numerous northward-trending streams he crossed on his new path to Benguela. Numerous explorations followed, but the thread with which to unravel the Congo system was not found until Stanley's journey of 1874-77, when he succeeded in defining the sources of the Nile, and in showing that the upper Congo was to be found in the Luapula, which connects the lakes Bangweolo and Moero. With the discovery, by Grenfell (1884-85), of the identity of the previously known tropical and interior river, the Welle Makua, with the Ubangi, the principal northern tributary of the Congo, the delimitation of the Congo basin was complete in general outlines.

The exploration of the Congo system was accompanied by a remarkable series of political events. In 1876 the International African Association was founded under the presidency of the King of the Belgians, Leopold II., and the International Association of the Congo in 1878. The latter, in 1879, founded two stations on the Congo, and in 1881 a third. In 1884 the association was recognized as an independent territorial government, and in 1885 an international conference gave limits to the Independent State of the Congo, and affirmed its permanent neutrality, the freedom of its commerce, and the abolition of the slave-trade within its borders. The new state covers the most of the Congo basin.

Another political episode, originating in a different quarter, has given occasion for further exploration of the Congo basin. A Mohammedan revival in upper Egypt, called the Mahdist rebellion, culminating in the fall of Khartum in 1884, disorganized the government of this region, and left the more southern Equatorial Province cut off from the civilized world. Its governor was a German scientist, there called Emin Pasha. The attention of Europe was eventually directed toward his relief, and an expedition for this purpose was headed by Stanley in 1887. After an adventurous journey from the west coast and through the Congo basin, Stanley succeeded in finding Emin, returning in 1889.

With the international conference in 1885, the partition of interior Africa was begun. The various possessions on the coast had been already delimited, at least approximately, and the limitations to be decided on were the interior ones. This has steadily proceeded, until in 1897 it is complete for Southern Africa to the equator, and for much of Western Africa. Elsewhere the interior lines are still indefinite. In general, it may be said that in 1897 heathen Africa had been partitioned, while Arab Africa was almost completely assigned. The divisions have been made by international agreement and are usually undisputed, but in unassigned districts an occasional clash occurs, as, in 1892, in Uganda to the N. of the Ukerewe. A result of the partition is to be found in the remarkably increased activity in exploration since 1885.

MARK W. HARRINGTON.

African Languages: The languages spoken in Africa may be arranged in six families or groups,* viz.: the Semitic, the Hamitic, the Nuba-Fulah, the Negro, the Bantu and the Hottentot-Bushman. The Semitic family occupies the western third of the Sahara and a strip of about 500 miles wide along the north coast and up the west bank of the Nile to the Negro field 300 miles above Khartum. The Hamitic occupies the Somali peninsula, most of the region E. of the Nile, more than a third of the Sahara (in the central part), and overlaps the Semitic family in Northwest Africa. For a description of Semitic and Hamitic languages, see EGYPTIAN, BERBER, ETHIOPIC, COPTIC, etc.

The Nuba-Fulah group is found in the territories of the Kwafi and Masai, E. of Lake Nyanza, each larger than Ohio; several extended areas in the upper Nile basin, especially in Kordofan and Darfur; 250,000 sq. miles in the northern part of the Congo basin (Nyam-Nyam, Krej, and Monbutto languages); and several smaller isolated areas in the Lake Chad, Niger, and Senegal basins.

The Negro group occupies (1) the Sudan (Senegal, Niger, and Lake Chad basins), an area extending 2,500 miles E. and W., and 700 miles N. and S.; (2) most of the upper Nile basin (500 miles square); (3) the eastern third of the Sahara (800 miles square). There seems to be considerable phonetic unity, such consonantal combinations as *kp* and *gb*, for instance, occurring in languages scattered through all parts of the Negro field. But in vocabulary there appears thus far to be utter diversity. The words for "one" and "I" appear in Dinka (upper Nile), Kanuri (Lake Chad), Efik (lower Niger), Grebo (on coast W. of Niger), and Bullom (extreme west coast), respectively, as follows: *tok, ghén; lasqe, wu; kiet, ami; dō, mò; bull, yang*. Nor do any of the other numerals or pronouns show resemblance. The Negro languages are mostly "agglutinative" but no structural unity can be affirmed, nor can families be decided upon till the grammars already appeared and fast appearing are carefully compared. Relation to Bantu, however remote, seems already completely disproved. The vast, fertile, and populous basins of the Nile, Lake Chad, and Niger promise to make these languages of great importance to trade and missions (though the Negroes have now become Mohammedans), and hence give the many linguistic problems offered a more than

theoretical interest. Koelle describes the Kanuri, the language of the great Bornu empire, around Lake Chad, as very rich, especially in verbal forms, and possessed of a fully developed and far-reaching system of euphonic laws. Abstract nouns are formed from all concrete ones, and from all adjectives and verbs. There are 5 cases, 2 numbers, no grammatical gender, 6 personal pronouns, 3 demonstratives, 4 interrogatives, 6 possessives, and 18 indefinite pronouns. Various agglutinative suffixes applied to both nouns and verbs give rise to (1) possessive and (2) participial adjectives; to adjectives of (3) nationality, (4) occupation and productivity, (5) agent, and (6) rank and office; to (7) patronymies, (8) personal adjectives, and (9) adjectives meaning "pertaining to," "applied to," etc. Numerals are (1) cardinal, (2) ordinal, (3) multiplicative, (4) adverbial, (5) indefinite. Counting is carried beyond 1,000,000,000,000. Verbs can be derived from substantives, adjectives, or other verbs, and include (1) denominatives, (2) causatives, and (3) frequentatives or intensives. Voices are (1) radical (or simple), (2) relative (or applied), (3) reflective (or middle), (4) causative, (5) relative-reflective. "Tenses" are, first, indefinite (or timeless), including (1) the durative or frequentative, (2) the momentary or solitive; second, time tenses, including (1) aorist, (2) perfect, (3) future. Moods are (1) indicative, (2) imperative, (3) negative, (4) conjunctive, (5) participial, (6) infinitive. Transitive verbs superpose an objective pronominal inflection upon all the above inflections, showing by the form of the verb the person of the object. Adverbs, besides fifty that are original, are formed from the nominative, instrumental, locative, and dative cases of substantives, from adjective pronouns, from the dative of numerals, by composition, and sparingly from the verbs and the four postpositions. There are many conjunctions, both original (which may be simple, compound, or correlative) and derived, but only four interjections. Different varieties of clauses, etc., are used, as in English. As to syntax, the uses of the various cases, moods, tenses, suffixes, etc., are very fully developed.

The Bantu family of languages is for trade and missions the most important in Africa, because the area in which these languages are spoken is, on the whole, greatest in natural resources, and the people speaking them are superior in natural endowment. Cust divides the family into three branches and eight sub-branches, but this classification, while very useful as a point of departure, is purely geographical; e. g. Kongo in the western branch, Zulu in the southern, and Swahili in the eastern, resemble one another more than Zulu resembles Chuana in the same branch. The Bantu field occupies all of Africa S. of the Negro and Nuba-Fulah fields (excluding, of course, the Hottentot field), an area of some 2,500 miles square. Its remarkable linguistic unity was first announced by Liechtenstein at the beginning of the present century, and has since been established by numberless proofs. For instance, the words for "one," "five," "I," "son," and "man," are in Kongo, *-mosi, -tanu, -ami, mv-ana, mu-ntu*; Mpongwe, *-mâri, -tyanu, -am, onw-ana, ono-mi*; Mbundu, *-mosi, -tanu, -ami, mona, mu-tu*; Herero, *-mue, -tano, -ami, omu-na, omu-ndu*; Kikulu, *-omo, -tanu, -emi, bo-ana, bo-ntu*; Ganda, *e-mu, -tano, -ange, mv-ana, mu-ntu*; Swahili, *-moja, -tano, -angu, mv-ana, m-tu*; Yao, *-mo, m-sanu, -angu, mv-ana-che, mu-ndu*; Chinyanja, *-modzi, -sanu, -anga, mv-ana, mu-ntu*; Chuana, *ñue, faev, -me, ñu-ana, mo-thu*; Suto, *-mong (ngue), tlanō, -na, ngu-ana, mo-thō*; Zulu, *-nye, -hlanu, -na (-ami), ndod-ana, umu-ntu*; Xosa, *-nye, -hlanu, -am, uny-ana, um-ntu*.

These languages are remarkable for their far-reaching euphony, perfect regularity, compass, flexibility, and power. Their dialectic divergencies clearly conform to the "wave theory" which has been applied to Indo-European. Since they are in grammatical structure even more homogeneous than in vocabulary, an account of the Kongo may serve for all. Bentley's *Kongo Dictionary and Grammar* (from which the following abstract is mainly taken) defines 10,000 words, excluding most derivatives. Every syllable consists either of a vowel alone, or of one consonant (which may be preceded by a nasal) followed by one vowel. The result is absolute freedom in composition, and regularity in inflection. The language is agglutinative—i. e. every inflectional element retains everywhere its own distinct form and meaning. The case system of Indo-European languages is more than replaced by the alliterative concord, which prefixes to nouns nineteen classes of singular and plural prefixes, and attaches the noun prefix to all the adjectives, nouns, verbs, prepositions, and phrases that belong to it, so that the reference of every word is perfectly unambiguous. There are twenty

* The word group is used where the languages classed together are not known to be generally related to each other.

classes of derivative nouns representing actor (active and middle), agent, instrument, means, recipient, place, action (active, middle, and passive), manner or accessory circumstance, cause or occasion, process, essential quality, accidental quality, diminutives, collectives, "anti-collectives," and accompaniments. Both prefixes and suffixes are used in forming these derivatives, but the prefixes alone concern sentence structure. Adjective forms are (1) primary (attributive and predicate), (2) secondary (absolute), (3) verbal excessives, (4) participial. Adjective phrases and clauses and possessive nouns are treated with the noun prefix, like the ordinary adjective. The native numerals go to 1,000,000, and are (1) cardinal, (2) ordinal, (3) partitive or distributive, (4) alternative, (5) multiplicative. Pronouns are (1) personal, (2) emphatic personal, (3) possessive, (4) interrogative, (5) demonstrative, (6) emphatic demonstrative, (7) relative, (8) indefinite, (9) adverbial, prepositional, and conjunctive, (10) locative. Adverbs are (1) original, and also formed from (2) locatives, (3) pronouns, (4) nouns (a large number), (5) verbs, (6) adjectives. Prepositions are simple and compound, but few in number, since the prepositional idea is usually included in the meaning of verbs. Conjunctions are some fifty in number, besides compounds of these. A large proportion of these are particles like the Greek *ὄμως*, *δήπου*, etc.

Verbs.—Suffixes indicate voice, "form," and "aspect." Voices are (1) active, (2) passive, (3) middle, (4) passive middle. Forms (superposed on each of the voices) are (1) simple, (2) applied (e. g. Eng. *strike for*, *with*, *at*, etc., are applied forms of *strike*), which may be single, double, triple, quadruple, etc., (3) causative, (4) indirect causative, (5) reciprocal, (6) repetitive, (7) persistent repetitive, (8) reverse, (9) potential, and about thirty-five combinations of these. Aspects (superposed both upon voices and forms) are (1) indefinite, (2) continuative, (3) perfect, (4) perfect continuative. (These aspects are the *timeless* distinctions found in Greek participles.) There still remain a considerable number of verbs having *apparent* suffixes with no definite shade of meaning. Doubtless others like these formerly furnished the raw materials for the magnificent voice and form system of the Kongo verb.

Prefixes indicate moods, tenses, person of the subject and person of the object. The infinitive mood is in aspect either simple or continuative, but has no tense. The indicative has ten tenses (counting aspect modifications of tenses as separate tenses), the subjunctive four (all different from those found in the indicative), the imperative two, and the participle three. Both for subject and object prefixes there are four "persons"—first, second, third and neuter.

In addition to the above verb system, there are twenty-four auxiliary verbs. These include such words as *φθάνω* and *τυγχάνω* in Greek; *venir de* and *se mettre à* in French; *can*, *let*, and *keep on* in English.

The subject must always be the most important topic in the sentence, which requires as free a use of the passive and middle voices as of the active. The sentence has a regular order—subject, its attributes, verb, and its attributes—but this is without ambiguity freely departed from for purposes of emphasis. By the use of the prefixes appropriate, any part of speech may become any other part of speech where thought admits of the change—adjectives, verbs, and clauses may become nouns, nouns and adjectives may become verbs, etc.

The Hottentot-Bushman family extends from Cape Town and Port Elizabeth in a strip 500 miles wide for 1,000 miles along the west coast, and mingles at 20° S. lat. with Herero (Bantu). Wallmann speaks of Hottentot and Coptic as closely allied. Bleek gives a comparative view of the pronouns in the two languages, which shows a remarkable similarity throughout. This family includes Khoi-Khoi, Bushman, Namaqua, Koranna, Griqua. Cust also reckons in various subjugated or fugitive remnants of tribes occupying small, isolated areas to 5° N. lat., and speaking languages totally distinct from those of their conquerors. Chief among these tribes are the pygmies of the upper Congo, spoken of by Stanley. Hottentot has grammatical gender, uses suffixes and postpositions, and four clicks and three tones. The clicks are used mostly as consonants, and resemble smacking, elucking, chirruping, and audible swallowing. These languages are being replaced, at least in the south, by Dutch.

Besides the languages above described, some non-African languages have been brought into Africa, and have in many quarters influenced native dialects. They are: Arabic (though this has now practically become African), in the

Sudan, on the Nile, and along the east coast; Portuguese, in Mozambique and Angola; Dutch (corrupted), in South Africa; Hindustani and Gujarati, on the east coast; Malagasi (Malayo-Polynesian), spoken in Madagascar; English, spoken in Liberia, and used for trade on and near the Niger and in South Africa; French, in Algeria, Tunisia, Egypt, and Senegambia.

For a complete bibliography of African languages up to 1883, see Cust's *Modern Languages of Africa* (Lond. 1883), which gives the best general account of these languages, and to which the writer is much indebted. For works appearing between 1883 and 1891, see De Guirandon's *African Linguistics since 1883* in the *Asiatic Quarterly Review* for July, 1891. Bibles and portions are published in many of the African languages by the various Bible societies.

ROBERT J. KELLOGG.

African Methodist Episcopal Church: organized in 1816 by colored Methodists who down to that date had been under the care of the Methodist Episcopal Church. They elected Rev. Richard Allen their first bishop in 1816. Their doctrines are substantially the same as those of the parent church. They report (1900) 5,245 ministers and 663,906 members. They have four high academies, one university, and two weekly journals. Steps for the union of this body with the African Methodist Episcopal Zion Church have been taken. See METHODISM.

African Methodist Episcopal Zion Church: formed in 1820 by a secession of African Methodists from a congregation of the Methodist Episcopal Church in New York city. They held their first annual conference in 1821; it consisted of twenty-two preachers, and reported 1,426 church members. In 1838 the conference elected Rev. Christopher Rush its first bishop, with the title of superintendent. Its superintendents are elected quadrennially by the general conference. They report (1900) 2,908 ministers and 528,406 church members. Their doctrines and ecclesiastical system are mostly copied from those of the Methodist Episcopal Church. Measures have been taken for union with the African Methodist Episcopal Church. See METHODISM.

Africa'nus, SEXTUS JULIUS: a Christian writer eminent for his learning; d. about 232 A. D. He wrote a general chronology of the world from the creation to 221 A. D., in which he fixes the date of the creation at 5499 B. C. See H. Gelzer, *S. J. A. und die byzantische Chronographie* (Leipzig, 1880-85, 2 parts).

Afterglows: unusual and brilliant twilight colors after sunset; those before sunrise are called foreglows; the red colors are predominant, but others are seen. Afterglows usually occur after great volcanic eruptions, and spread from the volcano with great speed and to great distances. After the eruption in 1883 of Krakatoa in the Straits of Sunda (the greatest known to history), the remarkable fore and after glows spread around the earth within six months (from August to January), and recurred for several succeeding autumns with decreasing splendor. They are supposed to be due to an immense number of very minute solid particles remaining suspended in the air. See *Report of the Krakatoa Committee of the Royal Society* (1888). M. W. H.

Afton: a town of Union co., Ia. (for location of county, see map of Iowa, ref. 7-F); on railroad junction, 180 miles W. of Burlington and 50 miles S. W. of Des Moines. It has a fine normal and business college, splendid city schools, opera-house, and electric lights. Pop. (1880) 1,231; (1890) 1,045; (1900) 1,178. EDITOR OF "ENTERPRISE."

Afze'lius, ADAM: Swedish naturalist; b. at Larf, West Gothland, Oct. 7, 1750; became tutor in the University of Upsala, 1799; Professor Extraordinary of Materia Medica, 1812; d. in Upsala, Jan. 20, 1837. He edited the autobiography of Linnæus (Upsala, 1823). Several species of plants called Afzelia are named after him.

Afzelius, ARVID AUGUST: Swedish scholar and man of letters; b. at Fjellåker, May 6, 1785; pastor at Enköping, 1821; d. there Sept. 25, 1871. His translation of the Poetic Edda (1818), his collection of popular ballads, *Svenska Folkvisor från Forntiden*, edited by Geijer and Afzelius (4 vols., 1814-16; new ed. 1880), and his Swedish history, *Svenska Folkets Sago-Häfder* (1839), etc., did much to promote the romantic and national feeling in Swedish literature.

G. L. KITTREDGE.

Ag'ades, Ag'adez, or Ag'dez: a city of Central Africa; capital of the kingdom of Asben; in an oasis of the Sahara; lat. 16° 30' N., lon. 8° 12' E. (see map of Africa, ref. 3-D). It formerly had a population of about 50,000, which is now greatly reduced. It is visited by merchants from the Sudan, and others from Northern Africa. Pop. about 7,000.

Agamem'non (Gr. Ἀγαμέμνων): the son of Atreus, King of Mycenæ; a brother of Menelaus. He had the chief command of the Greeks at the siege of Troy, where he quarreled with Achilles. He, as well as his brother, was often called Atri'des (i. e. son or descendant of Atreus). After his return from Troy to his own kingdom he was murdered by his wife Clytemnestra and Ægisthus. He was the father of Iphigenia, Electra, and Orestes.

Ag'ami: a South American bird, the *Pso'phia crepitans*, called the trumpeter, from a peculiar sound which it utters. It is as large as a large pheasant, but has longer legs and neck. It can be perfectly domesticated.

Agamo'binum: the asexual generation of those animals or plants which exhibit alternation of generations. See ALTER-NATION OF GENERATIONS.

Agamogen'esis [from Gr. ἄγαμος, unmarried + γένεσις, birth]: any form of reproduction that occurs without conjugation of the opposite sexes, as by division or budding, the common method with the Protozoa and not rare with many higher forms. In many forms the ova even may thus develop asexually, or they may develop by being fertilized (sexually), and the form thus produced may reproduce itself

organically for a certain number of generations, when the last of the series will produce ova to be fertilized. See ALTERNATION OF GENERATIONS and PARTHENOGENESIS for examples.

DAVID S. JORDAN.

Ag'apæ [Gr. ἀγάπαι, love-feasts, from ἀγάπη, brotherly love]: love-feasts, or feasts of charity, in use among the early Christians. After the celebration of the communion, the oblations which had been made in the church, consisting of meat and bread, which the rich had brought from their houses, were consumed at a common feast. Abuses having crept in, the two services were separated, and the love-feasts disappeared in the eighth century. A modification of them exists among the Moravians and Methodists, but they are not meals, only religious services at which bread and water are distributed.

Revised by S. M. JACKSON.

Agapem'one [from Gr. ἀγάπη, brotherly love, and μονή, abode]: a community of fanatics and free-lovers formed in 1849 at Charlynch, in Somersetshire, England, by Henry James Prince, who was previously a clergyman of the Anglican Church. His disciples, known as "Lampeter Brethren," or "Family of Love," hold their property in common, live in splendid style, and pass their time in voluptuous ease. Mr. Prince makes extravagant pretensions as an apostle or reformer in religion, and it is said that he is styled "God incarnate" by his followers, who are sometimes called Princeites. See *The Newbery House Magazine* (Lond.), Nov., 1891.

Agape'tæ (Gr. ἀγαπηταί, beloved women): those virgins and widows among the primitive Christians who lived in a state of "spiritual love" with monks and other celibates. This practice was condemned by the Lateran Council in 1139.

Agapetus: name of two popes. I. Became pope in 535, when already an old man; was sent as legate to Constantinople by Theodahad, the Gothic king; there d. April 21, 536. II. Became pope 946; died Nov., 955.

A'gardh, KARL ADOLPH: Swedish botanist; b. in Scania, Jan. 23, 1785; ordained a priest in 1816. He wrote, besides other works, *Species of Seaweeds* (Species Algarum, 1820-28) and *Systematic Arrangement of Seaweeds* (Systema Algarum, 1824). D. Jan. 18, 1859, and was succeeded by his son, T. G. Agardh, an equally distinguished algologist.

Ag'aric [Lat. *Agaricum*, from Gr. ἀγαρικόν]: a fungus belonging to the genus *Agaricus*, the species of which are very numerous. True agarics have radiant gills, while *Boleti* have tubes beneath the cap or pileus. The *Agaricus campestris* or common mushroom and some others are delicate articles of food; the *Agaricus muscarius* and other species are dangerous poisons; many of the species are popularly called toad-stools; numerous small ephemeral species appear to be harmless. The *Agaricus olearius* is remarkable for being phosphorescent. The common mushroom is frequently cultivated, both in the open garden and in sheds. See FUNGI.

Aga'sias of Eph'esus: a Greek sculptor; supposed to have lived about 400 B. C. The fine statue called "The Gladiator" or "Borghese Fighter," or, by modern archaeologists, the "Runner in the Hoplitodromos," one of the finest pieces of ancient sculpture and one of the great ornaments of the Louvre Museum, is by him. See HOPLITODROMOS.

Revised by RUSSELL STURGIS.

Agassiz, aag'a-see, or aä-gaäs'ëe, ALEXANDER, LL. D.: scientist; son of Louis Agassiz; b. at Neuchâtel, Switzerland, Dec. 17, 1835; graduated at Harvard College, 1855; received the degree of Bachelor of Science from the Lawrence Scientific School, 1857; went to California, 1859, as an assistant on the Coast Survey; was an assistant in the Museum of Comparative Zoölogy, 1860-65. In 1865 he made a venture in coal-mining in Pennsylvania, and this led to the great venture of his life—the developing of the two richest copper mines in the world, the Calumet and the Hecla mines of native copper on the shores of Lake Superior. He spent the years of 1869-70 in Europe, visiting different museums, and upon his return resumed the duties of assistant curator of the Museum of Comparative Zoölogy. After the death of his father (1873) he was appointed curator, a position which he held until 1885, when he resigned on account of ill health, in the meantime doing much to develop the museum both by his wealth and by his experience. His winters have been spent in deep-sea dredging in connection with the Coast Survey. He has written many papers upon scientific subjects; among the more important are *Marine Animals of Massachusetts Bay*, by A. Agassiz and Elizabeth Agassiz

(1871); *North American Acalephæ* (1865); *Revision of the Echini* (1872); *North American Starfishes* (1877); *Report on the Echini of the Challenger Expedition*; and several extensive monographs on the deep-sea animals collected by the Coast Survey steamers.

Agassiz Association: a society first organized in 1879 by Harlan H. Ballard, principal of Lenox (Mass.) Academy, for the purpose of stimulating scientific interest among his own students, and named in honor of the great scientist, Louis Agassiz. In 1880 a general association was organized, which has spread over a large part of the world, and includes among its numbers not only young persons, but also many distinguished scientists who recognize the educational value of the movement. The local divisions are called chapters, and must consist of not less than four members. Persons not connected with a chapter may, on payment of a small fee, become corresponding members, and enjoy all the advantages of the association, which include free instruction by correspondence on scientific questions, exchange of specimens, etc. The badge worn by members is a Swiss cross, bearing the letters "A. A." and the number of the chapter. The association offers prizes for original researches. The number of chapters is about 1,000 and of members about 10,000.

C. H. THURBER.

Agassiz, LAKE: the name given by Upham to an extinct Pleistocene lake of the last glacial epoch, occupying the plain of the Red River of the North, in Minnesota and North Dakota, and thence N. into Canada, where its boundary has not been yet fully determined. Its area, as indicated by well-marked shore-lines and deltas, measured from 30 to 100 miles E. and W., and 400 or more miles N. and S. Its depth was from 200 to 400 feet. According to the studies of Upham and others, Lake Agassiz was held up on the N. by the retreating ice-sheet of the last glacial invasion. Its level was determined by the height of the lowest pass in the inclosing slopes of land to the S., where a channel 50 or more feet deep, 50 miles long, and a mile or more wide may be plainly seen, through which the overflow of the lake reached the Minnesota river, whose valley it enlarged on the way to the Mississippi. A number of shore-lines may be traced from 100 to 400 miles N. from the outlet, all rising at gentle but unequal slopes of half a foot to a foot or more in a mile; hence it is inferred that while the waters of the lake beat on the shore and received the deltas of inflowing rivers, the land was gradually rising from a depressed condition below its present altitude in the N. The deltas formed by the Buffalo, Pembina, Assiniboine, and other rivers now form sandy plains many square miles in extent, trenched by the rivers that built them. The plain of the lake bed is remarkably level, descending northward about a foot to a mile. The Red river and its branches have only cut narrow and shallow channels in the plain, few and far between. Other similar expanses of fresh water, marginal to the retreating ice-sheet, occurred in Michigan, Ohio, and Western New York. W. M. DAVIS.

Agassiz, LOUIS JOHN RUDOLPH, M. D., Ph. D., LL. D.: Swiss naturalist and geologist; b. in the parish of Motier, near Lake Neuchâtel, May 28, 1807; son of a Protestant minister. He studied the medical sciences at Zurich, Heidelberg, and Munich, where he graduated. His first work was a Latin description of the fishes which Martius and Spix brought from Brazil, published in 1829-31. He devoted much time to the study of fossil fishes, and was appointed Professor of Natural History at Neuchâtel in 1832. During a visit to Paris he formed friendships with Cuvier and Humboldt. His reputation was increased by a great work in French, entitled *Researches on Fossil Fishes* (5 vols., 1832-42, with more than 300 plates), in which he made important improvements in the classification of fishes. Having passed many summers among the Alps in researches on glaciers, he propounded some new and interesting ideas on geology and the agency of glaciers in his *Études sur les Glaciers* (1840) and his *Système Glaciaire* (1847), which are among his principal works.

In 1846 he crossed the Atlantic on a scientific excursion to the U. S., in which he took up his permanent residence. He accepted, about the beginning of 1848, a chair of zoölogy and geology at Harvard; he explored the natural history of the U. S. at different times, and gave a new impulse to the study of nature in the U. S. He rejected the Darwinian theory of organic development. In 1865 he conducted an expedition to Brazil, and explored the lower Amazon and its tributaries, in which it is stated that he discovered more than 1,800 new species of fishes. He became in 1868 a non-resident

Professor of Natural History at Cornell University, Ithaca, N. Y. Early in Dec., 1871, he accompanied the Hassler expedition, under Prof. Pierce, to the South Atlantic and Pacific oceans and the western coast of America. Among his important works are *Outlines of Comparative Physiology* (1848); a *Journey to Brazil* (chiefly written by his wife, 1868); and *Contributions to the Natural History of the United States*, an expensive work which was to extend to ten vols. 4to, of which the first four volumes appeared 1857-62. Probably no one except Hugh Miller did more to popularize science in our time than Agassiz, and no other teacher trained so many young and rising naturalists. Yet it may be observed that some of his favorite opinions (e. g. of the absolute immutability of species) are not now held by many living naturalists. More, however, than almost any other leader in modern science, Agassiz insisted upon a theistic view of creation, as opposed to the idea of the self-evolution of uncreated nature. "He is not merely a scientific thinker," says Whipple, "he is a scientific force; and no small portion of the immense influence he exerts is due to the energy, intensity, and geniality which distinguish the nature of the man. In personal intercourse he inspires as well as performs, communicates not only knowledge, but the love of knowledge." D. at Cambridge, Mass., Dec. 14, 1873.

Revised by G. K. GILBERT.

Ag'ate [Fr. *agate*, Ital. *agatha*, from Lat. *acha'tes* = Gr. *ἀχάτης*, the agate, whence directly Eng. *achate*]: a mineral much used for ornamental purposes; a variety of quartz marked with veins or layers, which are different in color and often concentric. This structure is due to the mode of formation, in successive layers on the walls of cavities, usually in volcanic rocks. Agates are found in all countries, and are much used for ornaments and utensils, such as seals, ring and pin stones, vases, cups, mortars, etc. Many of the polished agates are very beautiful, and their preparation has created an important industry at Oberstein, in Germany. Here great skill is displayed in cutting and polishing agates, and still more in coloring them. A large part of the Oberstein agates come originally from South America. See CHALCEDONY.

Ag'atha, SAINT: a Sicilian virgin and martyr, who was put to death at Catania, in Sicily, by torture administered by Quintianus, a Roman judge, in revenge for her resistance to his attacks upon her virtue, Feb. 5, 251 A. D. She is the patron saint of Malta, and her veil carried in procession, it is said, has frequently averted eruptions of Mt. Etna. See Butler's *Lives of the Saints*.

Aga'thias (surnamed ASIAXUS): Greek historian and poet; b. about 536 A. D. at Myrina, in Asia Minor; became an advocate in Constantinople, and d. there 582. A history of contemporary events is extant, and some 100 poems of his are preserved in the Greek anthology. See edition by L. Dindorf (vol. ii. *Hist. Græc. minor*), Leipzig, 1871.

Agath'ocles (Gr. Ἀγαθοκλῆς): tyrant of Syracuse; b. in Sicily, 361 B. C.; originally a potter, he raised himself by his talents to a high military rank, and also distinguished himself as an orator. Having massacred a large number of the prominent and respectable men of Syracuse, he obtained the supreme power in 317 B. C. He afterward waged war against the Carthaginians, over whom he gained several victories in Africa, but was subsequently defeated by them. In 306 B. C. a peace was made, which secured to both parties their former possessions. D. in 289 B. C. His death is ascribed to a poisoned toothpick given to him at the instigation of his grandson Archagathus. See his life by Rud. Schubert, Breslau, 1887.

Ag'athon, or A'gatho (Ἀγάθων): tragic poet; b. at Athens about 450 A. D.; a friend of Euripides and a butt of Aristophanes in the *Thesmophoriazusa*. He gained the prize in 416, and the banquet which he gave on that occasion furnished the setting for Plato's *Symposium*. Dainty and dandified in his art as in his person, he did not fall far short of genius, and the scant fragments of his tragedies still bear witness to his antithetic style and his epigrammatic wit. Ed. by Nauck, *Fragmenta Tragicorum Græcorum*, 2 ed. pp. 763-69. D. at Pella, about 400 A. D.

B. L. GILDERSLEEVE.

Agatized Wood: See CHALCEDONY.

Aga've [Lat. form of Gr. Ἀγавή, prop. name meaning noble]: a genus of 138 species of plants of the family *Amaryllidaceæ*; mostly natives of tropical America. The most remarkable species is the *Agave americana*, the maguey

of the Mexicans, etc., commonly called American aloe or century plant. The latter name originated in an incorrect opinion that it bears no flowers until it has attained the age of 100 years. This age, or near it, is sometimes attained in temperate climates, but in hotter regions it often blossoms when less than ten years old. When this takes place a bud rises from the crown of thick and fleshy spiny-toothed leaves, which lengthens at first at the rate of a foot or two a day into a scape from 20 to 30 feet high, bearing a panicle of greenish-yellow flowers, sometimes as many as 4,000 in number. After flowering and maturing seed, the plant dies. Just when the flower stalk is ready to appear, the Mexicans cut away the bud and scoop out the center; into this a sweet sap, which would have supported the rapid growth, is abundantly poured. This is evaporated into sirup or sugar, or fermented into a kind of beer or cider called *pulque*, the favorite beverage in Mexico. From the pulque a strong ardent spirit (mescal) is obtained by distillation. The leaves yield strong and useful fibers (pita thread, sisal hemp), the latter from *Agave rigida*. Other species are cultivated among tender succulent plants. A small one is a native of Virginia, Illinois, etc. Revised by CHARLES E. BESSEY.

Agde (anc. *Ag'atha*): town of France; department of Hérault; on the river Hérault and Canal du Midi, or Languedoc Canal; 2 miles from the Mediterranean, and 18 by rail E. of Béziers (see map of France, ref. 9-G). In the vicinity is an extinct volcano. The town is mostly built of black basalt, and is popularly called the Black Town. Here are a fine old Gothic cathedral and a college, and a school of navigation. Soap and verdigris are manufactured, and the town has an active trade in wine, oil, silk, grain, etc. Its harbor is in lat. 43° 17' N., lon. 3° 28' E., at the mouth of the Hérault river, is accessible to ships of 200 tons, and is defended by a fort. It is on the Canal du Midi. Pop. (1896) 8,478.

Age: (1) the whole duration of the life of a man or other creature; (2) a certain portion or period of human life, which, according to Shakspeare, is divided into seven ages; (3) the time when a person is authorized by law to act for himself, and is released from the control of his parents or guardians. According to the laws of Great Britain and the U. S., a person becomes of age when he or she is 21 years old. Before this age one can not vote or make a valid will. In the U. S., to be President a citizen must have reached the age of 35; Senator, 30; and Representative, 25. In Great Britain men are eligible to Parliament at 21. The natural divisions of human life are infancy, childhood, boyhood (or girlhood), adolescence, manhood (or womanhood), and old age. The age of puberty is 14 or 15. The 63d year is called the grand climacteric. Some trees are believed to live to an age of 4,000 years or more. The average life of a horse is from 25 to 30 years; of an elephant, probably about 200; of a dog, from 12 to 15. Fishes are remarkable for longevity, and a carp, it is said, has been known to live 200 years.

AGE, in chronology and history, is sometimes used as synonymous with century, and sometimes also with a generation. Writers differ in respect to the period included under what is called the *Middle Ages*, but they are commonly understood to begin about the time of Charlemagne, and to extend to the fifteenth century.

AGE, in literature, is a period usually bearing the name of some powerful person who flourished during that time. Among the most memorable of these are the age of Pericles, the Augustan age, the age of Leo X., and the age of Elizabeth (or Elizabethan age).

AGE is also used to designate one of the successive epochs or stages of civilization in universal history or mythology. The Greek and Roman poets imagined a series of four ages—the Golden, the Silver, the Brazen, and the Iron. An ancient and widespread tradition commemorates the pristine innocence, peace, and happiness of the primeval Golden Age under the reign of Saturn. The other three were regarded as successive degrees of declension from that primitive state. The *prehistoric* ages in modern anthropology are usually called the older and newer stone ages (Paleolithic and Neolithic ages) and the age of bronze.

Revised by R. LILLEY.

Agen, *ā-zhaan'* (anc. *Agin'num*): capital of the department of Lot-et-Garonne, France; on the right bank of the Garonne, 85 miles by rail S. E. of Bordeaux (see map of France, ref. 8-E). It is pleasantly situated in a fertile country, and has an active trade in brandy, prunes, leather, wine, madder, and other articles. Here are a college and a public

library; also manufactures of serge, cotton prints, and linen goods. It is the seat of a bishop and a high court of justice. Joseph Scaliger was born in the vicinity of Agen. Pop. (1896) 22,730.

Agen'da [neuter plural of *agendus*, gerundive of *a'gere*, do]: things to be done; applied by theologians to practical duties as distinguished from the *credenda* (things to be believed), or doctrines that must be accepted as articles of faith. In the ancient church it signified, first, divine service in general; and, second, the mass in particular. It is also applied to church books giving the order of church services. The service-books of the Lutheran Church are called *agenda*.

Agénois, *ā'zhā'nwāā'*: a former district of France, in GUIENNE (*q. v.*); area about 1,080 sq. miles. It is now comprised in the department of Lot-et-Garonne.

Age'nor (Gr. *'Αγήνωρ*): in classic mythology, a king of Phœnicia and a son of Neptune; was the father of Cadmus, Phœnix, and Europa.

A'gent [Lat. *agens*, *-tis*; pres. partic. of *a'gere*, act]: in law, one who acts for another. This is an extensive topic, and must be treated with a brevity scarcely admitting even a sketch of its rules. Many of its principles closely resemble the corresponding topic in the Roman law (*mandat*), so that they are of quite general application in the jurisprudence of civilized countries. Agency may be created by express words or by implication. There are cases in which an express authority in writing is necessary by statutory law. It is a general rule that when an act is to be done under seal the agent's authority must be of the same grade. Should a person act as agent without authority, the subsequent ratification of the act will make it valid and binding on the person for whom it was done, in the same manner as if he had originally directed it. An agency is often implied from the course of business. A wife who sells goods in her husband's shop, or receives payment of a debt due him with his knowledge and without objection, may be deemed to be his agent, and may bind him in subsequent transactions of a similar kind. An agency is in general revocable either by the principal's own act, executed with sufficient notoriety, or by some event which renders the performance of the act impracticable. Thus the death of the principal, in general, causes an instantaneous revocation. There is a class of powers, termed "powers coupled with an interest," which in their nature are irrevocable. There must be in this case an interest on the part of the agent in the property over which the power is to be exercised. An illustration is the pledge of goods for a debt, with a power to sell in default of payment. The leading points in agency are the relations of principals to third persons, those of the agent to third persons, and the mutual relations between the principal and agent.

I. The Relations of the Principal to Third Persons.—It is a rule that when an agent acts within the scope of his employment he may bind his principal. This is on the principle of identity. There is another class of cases where the agent is not acting within the scope of his employment, but the principal has given him the *appearance* of authority, and the third person with whom he deals has no adequate means of distinguishing between his apparent and actual authority. In this case the principal is liable under a rule that where one of two innocent persons must suffer, that one should sustain the loss who has put it in the power of the wrongdoer to commit the wrong. It is in substance the doctrine of **ESTOPPEL IN PAIS** (*q. v.*). Under this doctrine usage has great effect upon the power of agents to bind their principals. There is a large number of agents who have known and recognized functions, such as factors, brokers, and cashiers of banks. It is the well-settled rule that these persons, acting within the usage of their business, may bind their principals, notwithstanding instructions to the contrary, unless these restrictions are brought to the knowledge of the persons with whom they deal. It is a general rule that when a power is conferred upon an agent, he has by implication such incidental authority as is necessary to carry his power into effect. An authority created by writing must be followed, and an act in excess of it is unauthorized and not binding on the principal. The mode of execution deserves notice. The agent should purport to bind his principal. This rule is particularly applicable to sealed instruments. Should an agent have a so-called power of attorney to execute a conveyance of land, the deed should purport to be the act of the principal by the agent, and should be subscribed in that manner; otherwise it would be

at most the agent's deed, and not that of the principal. Where there is no technical rule in the way, a principal may be liable even though undiscovered, as he must be deemed to be identified with the agent. On the general principles of the law of contracts, the principal can take advantage of a contract made in his behalf with a third person, and enforce it by action in his own name, even though he were not at the time disclosed, subject to the qualification that the rights of the other party to the contract are not prejudiced. A principal is liable for the fraudulent or wrongful acts of his agent acting within his employment. He can not take the benefit of the agent's acts and avoid their burdens. So complete is the identification of these parties that notice to an agent on the subject of his employment is legally notice to the principal, although it be not in fact communicated. This rule often operates with great severity upon innocent principals, imputing legal fraud when none has been in fact committed.

II. *The Relations of the Agent to Third Persons.*—If the agent having power to bind his principal does so expressly, he is not liable. But if he exceeds his authority, or, acting within it, fails to disclose his principal, he becomes personally responsible. In the case first supposed he is deemed to have entered into an implied contract that he has the necessary authority, and is liable accordingly. In the other case, the third person, on discovering the principal, has an election either to charge the agent or the principal. This doctrine may perhaps be qualified if the agent contracts in writing, on account of the rule that parol evidence is inadmissible to alter a written instrument. The agent, in turn, may have a right of action upon a contract made in his own name with a third person, though in fact made for the benefit of his principal. It is a general rule that an action does not lie against an agent to test the right of the principal to a fund, but the action should be brought against the principal himself. But in the case of duress of goods (see *DURESS*), if payment is made to an agent under protest, an action may be brought against him to recover back the money. This doctrine assumes much importance in its application to duties collected upon imports; so that a law of Congress regulates the mode in which the protest should be made.

III. *The Relation of Principal and Agent as between Themselves.*—The rules governing this relation are quite different. The agent is bound to obey the instructions of the principal. If in violating them he binds the principal to third persons, he is personally liable to make compensation for his breach of duty. His relation is a fiduciary one. He is subject to the rule that he can not deal in his principal's affairs for his own benefit. When directed to sell, he can not become a purchaser; when ordered to buy, he can not become a seller. This rule springs from the relation, and is applied with as much rigor to agents who act gratuitously as to those who receive compensation. An agent having discretion to exercise can not delegate his authority; he can not substitute another in his place. Where the business requires it, he may employ subordinates in the execution of his duties. It is not uncommon to insert a clause in a written delegation of agency (power of attorney) allowing substitution; this is valid. An agent should keep separate accounts, and distinguish his principal's money from his own; otherwise he might become personally responsible for its loss. The measure of his liability ordinarily is reasonable care, which is determined by that diligence which prudent men usually exercise in the conduct of their own affairs. For his services he is in general entitled to a reasonable compensation. He is sometimes paid by commissions; this is usual in the case of a broker. He has earned his commissions when he has brought the purchaser and seller together. He can not be deprived of them by a failure on the part of his employer, through wantonness or caprice, to enter into the contract which he has succeeded in negotiating for him.

The law of agency underlies, to a considerable extent, the law of partnership. The rules whereby one partner can bind his associates by contracts within the scope of their business are but applications of the doctrines of agency to this special branch of the law. See *ATTORNEY, BROKER, FACTOR, PARTNERSHIP*, etc. T. W. DWIGHT.

Agésila'us II.: Spartan general and king; son of King Archidamus II. He began to reign at the death of his brother Agis in 398 B. C., two years after which war was renewed between the Spartans and the King of Persia. Agésilaus commanded the army which invaded Asia Minor,

and gained several victories, but in the meantime the Athenians, Thebans, and other Greek peoples had formed a coalition against Sparta, to defend which the king was recalled by the ephori in 394 or 395 B. C. He maintained his reputation in this war, which was ended by a treaty of peace in 378. Sparta was again involved in a war with the Thebans, who, under Epaminondas, gained a decisive victory at the great battle of Leuctra, 371 B. C., at which, however, Agésilaus was not present. He afterward defended the city of Sparta with success when it was besieged by Epaminondas. D. about 360 B. C., aged eighty-four years.

Agglu'tinate Languages [Lat. *agglutina're*, fasten with glue; *ad*, to + *glutina're*, glue]: in comparative philology, those languages which are in a certain state of development intermediate between those which are strictly monosyllabic, like the Chinese, and those which are inflectional, like the Greek or Latin. Examples of languages in the agglutinated state are found among the Indian languages of America and the Turanian languages of Asia. In the Aryan languages conjugation and declension are doubtless to a certain extent the result of *gluing on* pronouns to verbs and nouns; but in them these terminations have coalesced, so as to form practically a single word, and the primitive parts have therefore, in a greater or less degree, lost their original and independent force. In the Turanian languages, however, the declension and conjugation can still be taken to pieces, and the affixes are seen to be distinct from the roots to which they are appended, as in Turkish, etc. See Max Müller's *Lectures on the Science of Language* (first series, lect. viii.); Von der Gabelentz, *Die Sprachwissenschaft*, pp. 330 ff. (1891).

Agh'mat: a fortified town of Morocco, on the W. declivity of Mt. Atlas, 24 miles S. of Morocco. Pop. about 6,000.

Aghrim, or **Aughrim**, aw'grim, or aweh'rim: a parish of Galway, Ireland; 15 miles N. E. of Loughrea (see map of Ireland, ref. 9-E). Here the army of William III. gained a decisive victory over that of James II., July 12, 1691.

Agincourt, aǎ'zhǎn'koor', or **Azincourt**, aǎ'zhǎn'koor': a village of France; department of Pas de Calais; 18 miles E. of Montreuil, and 10 N. W. of St.-Pol (see map of France, ref. 2-F). Near this place the English king, Henry V., who had about 15,000 men, gained a complete victory over the French army of about 60,000 on Oct. 25, 1415.

A'gio [Ital. *agio*, *aggio*, case]: the difference between the real and nominal values of money, or the percentage difference between the values of the current and standard money of a place. The premium or discount on foreign bills of exchange is sometimes called *agio*.

Agis IV.: King of Sparta; b. about 264 B. C.; a wise and meritorious ruler. He began to reign conjointly with Leonidas in 244 B. C., when Sparta was in a degenerate condition. He attempted to restore the old Spartan institutions and to reform the corrupted morals of the people. He also proposed to improve the condition of the poorer citizens by an agrarian law. Condemned by the ephori on a charge of subverting the laws, he was strangled in 240 B. C.

Agnadello, aǎn-yaǎ-del'lo: a village of Northern Italy; 10 miles E. of Lodi (see map of Italy, ref. 3-C). Here the French Duke of Vendôme defeated Prince Eugène, Aug. 16, 1705, and Louis XII. of France the Venetians, May 14, 1509. Pop. about 1,600.

Agnano, aǎn-yaǎ'no: a lake of Italy, 3 miles W. of Naples; is about half a mile in diameter. It occupies the crater of an extinct volcano. It is a bathing resort. The Grotta del Cane is near by.

Ag'nate [Lat. *agna'tus*, relative by father's side; *ad*, to + *gna'sci*, be born]: In Roman law, *agnates* are those who descend through males from a common ancestor, in opposition to *cognates*—i. e. all the descendants of a common ancestor, whether through males or females.

Ag'nes, SAINT: a Roman virgin; said to have suffered martyrdom under Diocletian, Jan. 21, 303 A. D. See Butler's *Lives of the Saints*.

Agnes Sorel: mistress of King Charles VII. of France; b. 1409; became in 1431 lady of honor to the Duchess of Anjou, and so fascinated the king by her beauty that he appointed her lady of honor to the queen. She exercised in some respects a most beneficial influence over the king, whom she stimulated to action against the English, who then invaded France. She died Feb. 9, 1450—it is supposed by poison administered by the dauphin.

Ag'new, CORNELIUS REA, M. D.: eye and ear specialist; b. in New York city, Aug. 8, 1830; graduated at Columbia College, 1849; received his diploma in 1852 from the College of Physicians and Surgeons; became house surgeon to New York Hospital and its curator, and afterward surgeon to the Eye and Ear Infirmary; studied in Dublin, London, and Paris; member of many medical and scientific societies, and made valuable contributions to medical literature. He was noted for his public spirit, and was equally prominent in Christian work. D. in New York city, Apr. 18, 1888.

Agnew, DANIEL HAYES, M. D.: physician; b. in Lancaster co., Pa., Nov. 24, 1818; practiced medicine there for several years; filled the chair of surgery in the University of Pennsylvania; attained a great reputation by his surgical inventions and medical writings; author of *Principles and Practice of Surgery, Hydrocele, Handbook of Practical Anatomy*, etc. D. in Philadelphia, Mar. 22, 1892.

Ag'ni, or **Ag'nis** [Sanskrit. *agni*'-s, fire, god of fire; Lat. *ignis*; O. Bulg. *ogni*; Lith. *ugnis*]: in Hindu mythology, the god of fire. He was a deity of great importance among the early Aryans, but after the rise of the gods of the Hindu triad he sank into a very subordinate position. He is sometimes represented with two faces, three legs, and seven arms, with his head surrounded by flames, and is generally painted of a deep-red color. By some he has been made to correspond to the Vulcan of classic mythology, but he does not anywhere appear as an artificer, like that deity. His principal characters are those of a purifier and bearer of incense to heaven, thus being made a mediator between man and the gods. His two faces are supposed to be a type of fire in its two characters—beneficent (or creative) and destructive—and his seven arms to indicate the seven prismatic colors.

Revised by R. LILLEY.

Agnoë'tæ [Gr. *ἀγνοῦνταί*, from *ἀγνοεῖν*, to be ignorant]: in ecclesiastical history, a sect in the sixth century who maintained that Christ in his human nature was ignorant of many things, particularly of the day of judgment. An earlier sect of this name denied God's omniscience, maintaining that God knows the past only by memory, and the future only by inference from the present.

Revised by R. LILLEY.

Agno'men [from the Lat. *ad*, to + *no'men*, a name]: a fourth name, derived from some illustrious action or remarkable event, given by the Romans to a person in addition to his prænomen, nomen, and cognomen (*qq. v.*). Thus two Scipios had the name Africanus given them on account of their victories over the Carthaginians in Africa. The younger of these celebrated generals had a second agnomen—viz. Æmilianus—because he was the son of L. Paulus Æmilianus, and adopted into the family of the Scipios. Fabius *Cunctator* (i. e. Fabius the delayer) was so called because by his prudent delays he alone, of all the Roman generals, could oppose Hannibal successfully at the height of the latter's career.

Revised by R. LILLEY.

Agnos'ticism [inaccurately formed from Gr. *ἄγνωστος*, unknown, unknowing; *ἀ-*, not + *γνῶναι*, know]: the doctrine that human knowledge is limited to experience, and that therefore we can neither affirm nor deny the existence of God, or know anything of the ultimate nature of things. *Philosophically*, it is an exposition of the bounds of human thought and knowledge, and upholds the impossibility of knowledge of the Infinite, in opposition to the theory of restricted but true knowledge of the First Cause as infinite and absolute. *Theologically*, it is by inference an exposition of limits of the Infinite and restrictions on the Absolute, implying that God can not reveal himself to created intelligence. The term agnostic, taken from Paul's mention of the altar to the "Unknown God," was first suggested by Prof. Huxley in 1869. Agnosticism is of recent growth, and is traceable to Kant's theory of knowledge.

Ag'nus De'i: the fifth and last section of the Roman Catholic mass, beginning with the words "Agnus Dei, qui tollis peccata mundi" (i. e. Lamb of God, who takest away the sins of the world). The singing of the Agnus Dei at the communion was retained by Luther in his reformation of the Church service, and is extensively practiced in the Lutheran Church. The name *Agnus Dei* is also applied to the figure of a lamb bearing a cross, which is often worn by Roman Catholics.

Agobard': b. in 779, of Gallic parents settled in Spain; ordained a priest in 804 by Archbishop Leidrad of Lyons; became his coadjutor in 813, his successor in 816. D. at

Lyons, June 6, 840. He may be characterized as one of the men of Charlemagne, as representative of his ideas politically and theologically. His writings, which were collected and published in Paris by Masson, in 1605, and by Baluze in 1666, were directed against the idea of the verbal inspiration of the Bible, against the worship of images, against the belief that hail and thunder storms were raised by sorcerers, against ordeals, and against adoptianism, etc. A treatise by him against the Jews was translated into German, 1852. See Hundeshagen's monograph on the *Life and Writings of Agobard* (1831). The best edition of his works is that of Baluze (Paris, 2 vols., 1666).

Agon'ic Line [from Gr. *ἄγωνος*, without angle; *ἄ-*, not + *γωνία*, angle]: the line which joins all the places at which the magnetic needle points due N. and S. The plane of the *magnetic meridian* of a place, which is the vertical plane passing through the two poles of a magnetic needle freely suspended at that place, does not, generally speaking, coincide with that of the geographical meridian, a vertical plane passing through the place and the N. and S. terrestrial poles. The angle formed by these planes is termed the *magnetic declination*. At certain places these planes coincide, and such places are called places of *no declination*. The line which joins all these places is termed the *line of no declination*, or the *agonic line*. A line of this kind passes through the eastern part of South America to Hudson's Bay, thence toward the North Pole to the White Sea; passing southward, it cuts Arabia, and, after traversing the Indian Ocean and the eastern portion of Australia, goes through or near the South Pole to join itself again. It is not fixed in position, but is at present moving slowly westward on the American continent. There is a second agonic line which has been observed near China and Japan.

Agonis'tici: an ascetic sect of Christians who lived in Northern Africa in the fourth century. They renounced labor and matrimony. Their name, derived from the Greek *ἀγωνιστής* (*agonis'tes*), a "wrestler," appears to have been given in allusion to their wrestling with "the world, the flesh, and the devil."

Agos'ta, or **Angus'ta**: a seaport of Sicily; in the province of Siracusa; on the Mediterranean; 14 miles N. of Syracuse (see map of Italy, ref. 10-G). It is built on the peninsula of San Croce, and is connected with the mainland by a narrow causeway; is supposed to occupy the site of the ancient *Megara Hyblæa*. The harbor is difficult of access, but when entered is commodious, and is fortified. In 1693 the town and one-third of its people were destroyed by an earthquake. Pop. 13,867.

Agoult', aa-goo', MARIE CATHERINE SOPHIE, Countess d': b. Dec. 31, 1805, at Frankfort, whither her father, Count de Flavigny, had emigrated during the Revolution; was educated in Paris, and married in 1827 Count d'Agoult, who died in 1856. Under the pseudonym of "Daniel Stern" she wrote a number of novels and literary reviews, a volume of moral and political aphorisms, *Esquisses morales* (1849), and *Histoire de la Révolution de 1848* (2 vols., 1851). D. in Paris, Mar. 5, 1876.

Agouti, aa-goo'tee [Fr. form of native Indian name *aguti*]: a rodent mammal of the genus *Dasyprocta*, related to the porcupines. The common agouti (*Dasyprocta agouti*) is a native of Brazil and neighboring countries. Formerly in these districts it existed in great numbers, but from its frequent ravages on the sugar-cane, potatoes, and yams, it has in many parts been hunted out and almost exterminated. It is about the size of a rabbit, has long hind legs, round ears, bright black eyes, and a short, stumpy tail, which, as well as the rump and thighs, is covered with long, coarse, bristly hair, whence the name *Dasyprocta* (from the Gr. *δασύς*, rough, and *πρωκτός*, hinder parts). The agouti is an omnivorous animal, eating almost all kinds of vegetables, fruits, roots, meats, etc. Its habits are all quick and active, and even while eating it continually turns its head from side to side, in order to guard against danger. The animal is easily domesticated, but, as it is specially fond of using its teeth on all kinds of furniture, it is but little valued as a pet. It gnaws with great rapidity, taking but a few minutes to cut

Black agouti.

its way through an ordinary door. In some countries its flesh is eaten, but a prejudice generally prevails against it.

There are several other species, inhabiting Central and South America, one of which, the black agouti (*Dasyprocta cristata*), extends into the West Indies. This species is said to have been the largest mammal inhabiting the West India islands at the time of their discovery.

Revised by DAVID S. JORDAN.

A'gra, or Akbarâbâd': a city of the Northwest Provinces, British India, and capital of the division of the same name, is on the right bank of the river Jumna, 134 miles by rail S. S. E. of Delhi, and 754 miles by rail N. N. E. of Bombay; lat. 27° 11' N., lon. 78° E. (see map of N. India, ref. 6-E). It was the capital of the Mogul and Mohammedan Emperors of India from 1504 to 1647, and was once a large and splendid city, but a great part of it is now in a ruinous state. The houses are mostly built of red sandstone. Here are several magnificent edifices, the most celebrated of which is the Tâj Mahal, a mausoleum erected by the Emperor Shah Jehan (1627-66) in honor of his favorite queen. This edifice, the finest in India, and perhaps in the world, is built of white marble, surmounted with a dome 70 feet in diameter, and adorned internally with exquisite mosaics of cornelian, lapis lazuli, and jasper. It cost above \$15,000,000. Among the articles exported from Agra are cotton, sugar, salt, and indigo. Many houses in Agra were destroyed by the Sepoys during the mutiny of 1857. Pop. (1891) 168,710.

Ag'ram, or Zag'rab: a royal free city and the capital of Croatia, on the left bank of the Save, 172 miles S. of Vienna (see map of Austria-Hungary, ref. 8-E). It is the seat of a Roman Catholic archbishop, and has 2 gymnasia, 2 Real-schulen, 2 normal schools, and other institutions of learning. Six annual fairs are held here. Pop. (1890) 37,400.

Agrarianism: See the Appendix.

Agra'rian Law [Lat. *agrarius*, pertaining to the field (*ager*)]: in the ancient republic of Rome, a law enacted to distribute or regulate the public land, *ager publicus*. Such laws were opposed by the patricians, who had appropriated to their own use the lands acquired by conquest, and who had long enjoyed the privilege of occupying them as tenants, on the condition of paying to the state a tithe of the produce. The consul Spurius Cassius first proposed to divide a portion of public land among the poor citizens, but the measure was defeated by the aristocrats. In 367 B. C. an agrarian law was originated by Licinius Stolo, ordaining that no man should possess more than 500 *jugera* (330 acres) of the public domain, and that such public land as any man occupied in excess of 500 *jugera* should be distributed among the poor citizens. Tiberius Gracchus was the author of an important agrarian law. These and later agrarian laws were never executed. In Sparta the attempt of King Agis IV. to enforce an agrarian law led to his murder by the ephori (240 B. C.).

Agreement: See CONTRACT.

Agrie'ola, CNEIUS JULIUS: Roman general and statesman; b. at Forum Julii (Fréjus), in Gaul, June 13, 37 A. D. He was appointed Governor of Aquitania by Vespasian in 73, and became consul in 77. About a year later he was sent as governor to Britain, which he conquered, and governed with much ability and moderation. By a wise and humane policy he promoted the civilization and prosperity of the natives. He erected a chain of forts from the Clyde to the Frith of Forth. He was recalled about 85 A. D. by Domitian, who was jealous of him. D. in Rome, Aug. 23, 93 A. D. He was the father-in-law of the historian Tacitus, who wrote a *Life of Agricola*.

Agricola, JOHANN (originally *Schneider* or *Schnitter*): German theologian; b. at Eisleben, Apr. 10, 1492; studied at Wittenberg, and became a friend of Luther, with whom he was afterward involved in a doctrinal controversy. He became a lecturer at Wittenberg in 1536, and court preacher at Berlin, 1540. Agricola and his followers were called Antinomians. (See ANTINOMIANS.) He was one of the authors of the *Interim* (1548), wrote some practical works, and published a valuable collection of German proverbs. D. in Berlin, Sept. 22, 1566.

Revised by HENRY E. JACOBS.

Agricola, RUDOLPHUS: humanist; b. 1443, at Baflo, Friesland, his name properly being Rolof Huysmann; studied in the chief universities of Europe; was a teacher in Italy, but returned in 1483 to Heidelberg and Worms. D. at Heidelberg, Oct. 28, 1485. He was instrumental in introducing

into Germany the taste for literature, just reviving in Italy. His writings were published by Alard (2 vols., Cologne, 1539). He was a painter and musician.

C. H. T.

Agricultural Chemistry: the study of the chemical relations of those substances which compose the products of the farm. Since the chemistry of these substances is most intimately connected with their physical, geological, and physiological aspects, the term agricultural chemistry, as commonly understood, embraces a wide range of natural science in its applications to vegetable and animal production. The object of agriculture is to develop from seed and soil the largest possible value of useful plants and useful animals at the smallest cost. Nothing is plainer than that the farmer should accurately understand the nature of those materials and agencies which build up his crops and increase his herds. He should know whence the materials of his crops may be drawn, what ones are placed at his disposal naturally in surplus, and what must be provided by his own care. He should know how to control or work in harmony with the energies whose action is essential to his success. Agricultural chemistry inquires, first of all, what the plant and animal are made of. It finds that both, when living, consist largely of water, to the extent of 40 to 90 per cent., which is indispensable to their existence as a vehicle for the process of circulation or transfer of nutriment. The dry plant or animal may be divided into matter volatile by heat, 90 to 99 per cent., and 1 to 10 per cent. of ash. The volatile or combustible matter is either organized—i. e. possesses a structure, or is a tissue of organs, imitable by the art of man, through whose mechanism the principle of vitality operates—or else it consists of substances which are the direct results of chemical changes in the organized matter. Muscle-fiber and wood-fiber are of the former, sugar and urea are of the latter kind. The volatile matters are thence termed organic; they consist of carbon compounds, most of which are highly complex in their atomic constitution.

The most important organic matters of our staple field crops are few in number—being, 1. The amyloids, compounds of carbon with hydrogen and oxygen, the last two being in the proportions in which they exist in water—viz. cellulose or wood-fiber, starch, the sugars, and the gums; 2. The pectoids, also compounds of carbon, hydrogen, and oxygen, comprising pectose—the hard pulp of fruits and roots—and pectine, pectose, and pectic acids—the gummy or gelatinous matters of ripe and cooked fruits; 3. The fats and fixed oils; 4. The organic acids, oxalic, malic, citric, and tartaric; 5. The albuminoids, albumen, casein, fibrin, and their analogues, which, besides carbon, hydrogen, and oxygen, contain 15 to 18 per cent. of nitrogen, with $\frac{1}{2}$ to 1 per cent. of sulphur. The ash of the plant consists of phosphates, sulphates, chlorides, silicates, and carbonates of potassium, sodium, calcium, magnesium, and iron.

The growth of a plant is the development of a germ or seed when acted upon by the solar ray, with access of water, air, and soil. The organic matters above enumerated as constituents of crops are exclusively generated and organized by the plant. Carbonic acid gas supplies carbon, water furnishes hydrogen and oxygen, while nitrogen is derived partially from minute quantities of ammonia mingled with the air. Nitrogen is, however, chiefly obtained from the nitrates of the soil. All the ash elements come exclusively from the soil. The agriculturist can not aid the nourishment of his crops except through the soil, and there he can only influence the supplies of water, of nitrogen, and of ash elements. Carbon, the most abundant ingredient of all crops, making up 44 to 48 per cent. of the dry matter, is furnished so fully by the atmospheric carbonic acid that additional supplies from the soil are not directly advantageous. The atmosphere contains, it is true, but a very small proportion of this gas— $\frac{1}{25000}$ of its bulk—but this is considerably in excess of the wants of the most luxuriant growth.

The fertility of the soil depends, chemically—1. upon the presence in it of all the ash elements and of nitrates in proper quantity; and, 2. on their occurrence there in such states of combination as give a constant and regulated supply. Numerous experiments have demonstrated that a soil destitute of any one of the following substances—viz. phosphoric acid, sulphuric acid, potash, lime, magnesia, oxide of iron—is absolutely barren by virtue of such deficiency. It is also certain that a soil which contains the usual amount of potash, but only in the form of feldspar, or of phosphoric acid, but only as apatite, or of magnesia, but only as serpentine, is infertile, because these substances do not yield their elements

to the solvent agencies of the soil or plant rapidly enough to serve as plant-food. Alumina is an abundant element of soils, but it is mostly absent from agricultural plants; and recent investigations also appear to show that silica, which is present in many plants, is an accidental ingredient, and in no manner essential to their growth or perfection. Soda likewise appears to be unessential to most of the vegetative processes; for, although it is perhaps never entirely absent from cultivated plants, it often occurs in them in extremely minute quantity, so that the soda which is indispensable to the blood and milk of animals must be obtained, in part at least, directly from mineral sources.

Nitrates and ammonia salts—which are the natural supplies of nitrogen to crops—rarely are, and never need be, present in the soil in more than the minutest proportion. It is only requisite that they be generated or gathered there as rapidly as crops remove them. The process of nitrification, whereby inert or inassimilable nitrogen existing in the soil or in the air is converted into nitric acid, is one of the utmost agricultural importance, though still largely involved in mystery.

The great bulk of any soil is chemically indifferent in the nourishment of the present crop. The weight of an average loamy soil is about 4,000,000 lb. per acre for each foot of depth. A crop of grain of 33 bush. removes but 140 lb. of ash elements—viz. 40 lb. in the seed and 100 lb. in the straw. A hay crop of 2 tons carries off but 260 lb. of ash ingredients. These quantities, if assumed to come from 2 feet of depth, are respectively but $\frac{1}{30000}$ and $\frac{1}{87000}$ of the entire mass of soil. Hellriegel's experiments give results which warrant us in concluding that 55 lb. of potash, 17 of soda, 17 of magnesia, 23 of lime, 55 of phosphoric acid, 11 of sulphuric acid, 8 of chlorine, and 54 of nitrogen (in the form of nitrates), are all that need be present, in soluble condition, in 1,000,000 lb. of soil, in order to establish there a temporary fertility equal to the production of 33 bush. of barley grain and 2,000 lb. of straw per acre. In other words, the 140 lb. of ash elements may be taken from 1,000,000 lb. of a soil in which but 186 lb. exist in soluble condition, and in which, therefore, the proportion of real plant-food—nitrogen, but not water, included—is but $\frac{1}{4000}$. Good soil, in the practical sense, however, yields, and may contain, a larger proportion of immediately available plant food than one part in 4,000, but rarely more perhaps than ten times that amount.

As cropping removes these substances from the soil, they are replaced more or less rapidly and completely by weathering, whereby, under the influence of moisture, carbonic acid, and oxygen, aided by heat and by the alternations of heat and cold, the rock dust of the soil is gradually fluxed into soluble pabulum, and charged with nitrates.

The soil is endowed with absorptive qualities which enable it to retain in a state of comparative insolubility certain ash elements, especially those which are in general the least abundant—viz. phosphoric acid and potash—even when applied to it from external sources in the most soluble form and in large quantity. This absorption of plant-food by the soil is accompanied by a corresponding liberation of other substances, especially of lime and sulphuric acid. The impalpable matter of the soil, consisting largely of aluminous and ferruginous silicates, is mainly the seat of these absorptions; sand, silica, carbonate of lime, humus, and even pure clay (kaolinite), being destitute of the power in question.

Soils may be fully supplied with all the nutritive elements in proper quantity and form, and yet be infertile. This may happen on account of faults in physical condition, whereby they are rendered uncongenial to plants. A certain medium porosity, admitting of access and efflux of water, and a quality of being suitably warmed by the sun, and of carrying heat through the cool of the night, are no less indispensable to high productive power than an appropriate chemical condition.

Manures improve the soil by supplying one or several of those ingredients required by plants which are deficient either by reason of yearly removal of crops or from original poverty of composition. Practice has taught that phosphates and nitrogen in assimilable form are most commonly the substances which strikingly benefit land, and chemical analysis shows that of these the former is ordinarily the least abundant ingredient of soils, and the latter is one which is not only not abundant, but one which rapidly wastes by solution in rain-water, being daily carried off in immense quantities, through springs and rivers, into the sea.

The action of fertilizers is not, however, fully explained by their affording a direct supply of lacking nutritive ele-

ments; manures operate indirectly to feed crops, by their chemical effects upon the soil. It has been abundantly demonstrated that common salt, gypsum, and other saline matters may react on the soil to convert potash and magnesia, for instance, into soluble forms, and thus to give the same result as would follow an immediate application of the last-named substances.

Certain manures which are used in large doses, such as stable dung, peat, marl, and lime, also influence the fertility of the soil, by amending its texture or otherwise modifying its physical characters.

It is theoretically possible to produce a maximum crop of any given kind, continuously and perpetually, upon the same plat of land. In practice, however, it is far easier, and therefore far cheaper, to alternate or rotate crops. A hoed crop implies surface tillage, several times repeated during the growing season, thus effectually exposing the upper soil to the oxidizing influence of the air. A field put into grass or clover is to some extent under opposite conditions. In the one case, organic matters waste rapidly; in the other, they accumulate in the soil. In the first instance, the surface soil tends to lose that porosity and attractiveness for moisture due to the presence of humus, which is a quality of the utmost significance in climates subject to drouth. In the second instance, the soil gains in these respects. On the other hand, the lower soil, which under hoed crops is yearly broken up by repeated plowing, may settle down to injurious compactness in a pasture or meadow. Deep-rooted crops affect the soil very differently from those whose radication is confined to near the surface. The reasons for rotation thus become, to some extent, apparent. Agricultural chemistry is competent to show, further, that some plants while occupying the soil enrich it, and, though yielding the farmer a large and valuable harvest, yet actually manure the land for a subsequent crop. Clover has long been known as a plant of this kind. A good clover crop, when made into hay, removes from the soil twice or thrice the ash elements and nitrogen that are contained in a good wheat crop, and yet the good clover crop will develop in a soil where the good wheat crop can only be raised by help of manure. More than this, the good clover crop not only grows on the unaided soil, but likewise fertilizes that soil, so that it can subsequently make the good wheat crop. The enriching effects of clover are absolute in respect of nitrogen. The clover plant is able, in a given time and on a given surface, to assimilate nitrogen much more rapidly, or to a much greater amount, than the wheat plant can. It therefore flourishes better on a limited supply, or gives a full crop, where wheat would make perhaps but half a crop; and, besides, leaves in the soil where it has grown more nitrogen in its roots and stubble than an entire wheat crop contains. In respect of ash elements, the clover plant can add nothing to the soil in the way of quantity, but it strongly influences their quality. It transmutes the insoluble matters into soluble, and collects largely, by its deep-penetrating roots, from stores of food which the wheat plant can scarcely reach. When its roots decay, these substances remain where a succeeding wheat crop can at once utilize them. This enriching process has again its narrow limits. If we keep land in clover, it becomes "clover sick," probably from exhaustion of the deep-lying plant-food, and this disease is hard to cure, because of the inaccessibility of the subsoil to fertilizing applications.

By judicious rotation of crops a soil of moderate quality may be made to yield fair harvests without the loss of productive power. In order thus to economize in the fullest degree the resources of soil and crop, the farmer needs an accurate knowledge of their nature, such as can only be obtained by encouraging the study of agricultural chemistry.

In studying the utilization of vegetable products for obtaining the various animal matters which are employed as food, etc., agricultural chemistry enters into a higher and more difficult field. Here it has been obliged, by numerous experiments, to test much of the empirical knowledge which agricultural practice had too vaguely supplied, and also finds itself under the necessity of investigating the most purely scientific questions of physiology. Although many useful practical results have been obtained, this department of our knowledge is extremely incomplete, and, save in technical details, is too closely allied to the general subject of animal nutrition to require notice in these pages.

Of useful books on agricultural chemistry, those of Liebig and Boussingault take pre-eminence; the former by their

brilliant suggestiveness, the latter by their accurate experimental study of many points of the highest practical interest. See Liebig, *Agricultural Chemistry* (1841); *Modern Agriculture* (1859); *Natural Laws of Husbandry* (1863), etc.; Bonssingault, *Économie Rurale* (1851); *Mémoires de Chimie Agricole* (1854); *Agronomie, Chimie Agricole*, etc. (1860-68); Wolff, *Naturlgesetzliche Grundlagen des Ackerbaues* (1856); *Landwirthschaftliche Fütterungslehre* (1861); Heiden, *Düngerlehre* (1868); Knop, *Lehrbuch der Agricultur Chemie* (1868); Meyer, *Agricultur Chemie* (1886); Johnston, *Lectures on Agricultural Chemistry and Geology* (1847); Johnson, *How Crops Grow* (1890); *How Crops Feed* (1870); Armsby, *Manual of Cattle Feeding* (1880); Sachsse, *Lehrbuch der Agrikultur Chemie* (1888); F. H. Storer, *Agriculture in Some of its Relations to Chemistry* (2 vols., 1888); R. Warington, *Chemistry of the Farm* (1891). S. W. JOHNSON.

Agricultural Colleges: institutions of learning, established and carried on for the promotion and dissemination of knowledge in the various arts and sciences connected with agriculture. Agricultural colleges are a product of the nineteenth century. The first and still the most prominent institution of this kind established in England was the Royal Agricultural College, near Cirencester, where a company of noblemen headed by Prince Albert in 1845 erected a stately Gothic structure to be used as a college, and procured a charter authorizing them to give appropriate instruction. Provision was made for six resident professors besides the principal. In 1880 the institution received an additional impulse with the name The Royal Agricultural College of England. There is no endowment fund, the support of the institution depending wholly on the patronage of friends and the fees of students. The purpose of the school, as set forth in the charter, is to train scientific and practical agriculturists. It is adapted especially to meet the needs of three classes: future land-owners, future land-agents, surveyors and managers of estates, and future colonists and employes in Indian agriculture. Besides the technical and special opportunities afforded for these purposes, the college supplies the advantages of a liberal course of intellectual and moral training for the duties of a country gentleman. The entire government and control, both of faculty and students, is in the hands of the principal, who appoints and removes professors, determines the time and numbers of the lectures, and settles all questions respecting the work of the faculty. Students who live in the college building pay an annual fee of \$675. The fee for instruction alone is \$375. Instruction is by lecture and by personal assistance in the laboratory and the field. The subjects taught are chemistry, physics, bookkeeping, zoölogy, agricultural law, and all the phases of practical and theoretical agriculture, including animal industry and veterinary science. The laboratories and museums are admirably equipped. In 1880 the Agricultural College at Downton, near Salisbury, was established on a similar plan. It has five professors, occupying chairs of dairy farming, chemistry, natural history, estate management, and veterinary medicines. The principal has charge of the agricultural department. The fees are a trifle smaller than those at Cirencester, and the work is designed to be of a somewhat more practical nature. The aim of the school is to fit young men for being superintendents, surveyors, and farmers. Of similar character is the Aspatria Agricultural College, near Carlisle, which was established for the better accommodation of those living in Northern England. What is known as Minto House, at Edinburgh, has also a similar object. At Oxford and Cambridge no agricultural colleges have been founded, though lectures on agriculture are given at both of those seats of learning.

Agricultural schools were established on the continent of Europe early in the nineteenth century. But it was not until the chemist Liebig, in 1840, published his celebrated work, *Die Chemie in ihrer Anwendung auf Agricultur und Physiologie*, that any considerable impulse was given to agricultural schools. This eminent chemist showed that, however great the draft upon the soil, fertility may be fully maintained, and even increased, by restoring the mineral and organic matter taken from it by the harvest. He further demonstrated that the proportions and quantities of the ingredients taken up by the crop are so variable that nothing less than a careful and scientific study of soils will enable the farmer to restore those ingredients in the most efficient and economical proportions. These truths naturally made the deepest impression on the people of Germany. It was accordingly held by the governmental authorities that, for

the encouragement of such studies, schools of agriculture should be multiplied. Under the impulse thus begun, the number, as well as the efficiency, of the agricultural schools among the Germans has steadily increased down to the present day. In 1892 Prussia alone had 4 agricultural colleges of the first grade, with some 80 professorships, besides as many as 40 lesser schools, all having model farms. In the same kingdom there are also 5 special schools for the cultivation of meadows and the scientific study of methods of irrigation, 1 special school for the teaching of those who desire to reclaim swamp-lands, 2 special schools for teaching the growing of fruit-trees in industrial nurseries, a school for teaching horseshoeing, 1 for teaching silk raising, 1 for the raising of bees, and 1 for the cultivation of fish. There are also 20 schools for the education of gardeners, and 15 for the training of grape-growers. Agricultural schools have met with similar encouragement in the other German states. Bavaria has 26 agricultural colleges, besides more than two hundred agricultural associations. Würtemberg has 16 colleges of different grades, and 76 associations. Baden has 14 colleges and 4 schools for gardening and forestry. Saxony has 4 colleges of the highest grade, and 20 agricultural schools of secondary rank, besides a veterinary college, and a department of agriculture with 20 professors at the University of Leipzig. Saxe-Weimar has 3 agricultural colleges, and an agricultural department with 15 professorships at the University of Jena. Similar schools have also been established in large numbers in France and in most of the other countries of Europe. The benefits that have been derived from these schools and colleges are universally conceded to be very great. While in the U. S. the crops per acre under the American system of tillage are almost everywhere growing annually less, in those European countries where scientific agriculture has been most thoroughly taught the yield per acre has been steadily increasing. In many parts of England and Germany, Belgium and France, the yield per acre is fully twice what it was one hundred years ago.

The first agricultural colleges in the U. S. were founded before the middle of the nineteenth century. The development of these institutions was slow, however, until the passage of what is known as the Land Grant Act of 1862. By this act every State and Territory in the Union received a gift from Congress of land scrip representing 30,000 acres for each Senator and Representative. The purpose of the act was to provide for the establishment of one or more institutions in each State, "the leading object of which should be, without excluding other scientific and classical studies, and including military tactics, to teach such branches of learning as are related to agriculture and the mechanic arts, in such manner as the legislatures of the States may respectively prescribe, in order to promote the liberal and practical education of the industrial classes in the several pursuits and professions of life." In those States which no longer had any land subject to purchase under U. S. law, it was necessary to sell the scrip at the market price, and the fund received by such sale was devoted to the establishment and endowment of colleges of agriculture and the mechanic arts. In States still having lands subject to entry under U. S. law, purchases could be made with the scrip, and the increase in the value of lands so purchased could be applied to the educational purposes intended. The freedom granted to the several States in the management of these lands has led to a great variety of results. The following table, compiled in 1890 by S. D. Halliday, for the most part from official sources, and published in his *History of the Agricultural Land Grant of July 2, 1862*, shows the number of acres received by each State, the rate at which the land has been disposed of, and the amount of the endowment realized. From the States not represented, no response to inquiries could be procured:

STATE.	Number of acres.	Amount realized per acre.	Total amount realized.
Alabama.....	240,000	\$1 06 +	\$253,500 00
Arkansas.....	150,000	90	135,000 00
California.....	150,000	5 14 +	771,686 86
Colorado.....	90,000	1 25	112,500 00
Connecticut.....	180,000	75	135,000 00
Delaware.....	90,000	92 +	83,000 00
Florida.....	90,000	1 73 +	155,800 00
Georgia.....	270,000	90	243,000 00
Illinois.....	450,000	1 00	450,000 00
Indiana.....	390,000	87 +	340,000 00
Iowa.....	240,000	2 70 +	649,396 16
Kansas.....	90,000	5 57 +	501,426 33

STATE.	Number of acres.	Amount realized per acre.	Total amount realized.
Kentucky	330,000	\$0 60 +	\$200,000 00
Louisiana	210,000	1 00	210,000 00
Maine	210,000	56 +	118,300 00

Totals	9,597,840	\$1 65 +	\$15,866,371 00

In 1890 the act of 1862 was supplemented by a Congressional law giving to each State for the further endowment of the colleges established under the act of 1862 the sum of \$15,000 for the first year, \$16,000 for the second, and thereafter an amount increasing by \$1,000 a year until at the end of nine years the sum shall annually amount to \$25,000. This sum is thereafter to be the annual appropriation. The liberal provisions thus made in the acts of 1862 and 1890 by the Federal Government for education in agriculture have been supplemented by numerous grants in several of the States. The number of agricultural colleges in the U. S. in 1892 was 48. According to the report of the Commissioner of Education for 1888-89, the income of the 32 colleges from which reports had been received was \$1,407,242, of which 37.04 per cent. was derived from State and municipal appropriations, 40.95 per cent. from productive funds, and 15.98 per cent. from tuition fees, leaving a small portion unaccounted for. In the 32 colleges reported, the number of professors and instructors was 670. The colleges of agriculture are generally, though not invariably, associated with similar institutions for giving instruction in the mechanic arts. In Massachusetts, for example, the Institute of Technology, at Boston, receives a part of the income from the land grant of 1862, while a part goes to the Agricultural College at Amherst. In the agricultural colleges tuition is usually free, while in the technological schools the charges for instruction vary, according to location, from \$50 to \$200 a year.

The instruction given in the agricultural colleges in the U. S. is both theoretical and practical. Embracing a period of four years, the curriculum aims to give a general as well as a technical education. In many of the States the training provided for seems to be intended for the sons of farmers, irrespective of the consideration whether the pupils intend to pursue agriculture or some other vocation. Hence studies in language and literature, as well as in history and in general science, make up no small part of the curriculum. In all of this class of schools, however, particular attention is paid to those studies which relate directly or indirectly to the interests of the farming community. Foremost among these branches may be mentioned chemistry, geology, botany, zoölogy, entomology, horticulture, veterinary science, and the various interests more directly associated with theoretical and applied agriculture. These colleges are all connected with experimental farms, on which students have the opportunity of observing carefully conducted experiments in the rotation of crops, the effect on different crops of the several kinds of fertilizers and manures, the breeding and care of domestic animals, the making of butter and cheese, and, indeed, in all the interests associated with the successful pursuit of agriculture. Each of the agricultural colleges issues an annual catalogue or register which contains carefully prepared information concerning the courses of study, and which will be sent gratuitously to any applicant.

C. K. ADAMS.

Agricultural Experiment Station: an establishment founded and carried on for the purpose of obtaining and disseminating information that will be useful to the farming

population. Farming must necessarily be an experimental science, because it is not ordinarily practicable to know either the exact constituents of the soils, or the way in which growing crops will be affected by climatic and other indeterminate peculiarities. The best farming therefore is a constant process of carrying on experiments, and observing carefully their results. The application of different fertilizers to different soils and for different crops; the determination of the most profitable rotation of crops; the uses to which different soils may most advantageously be put; the quantity and quality of the rations that under differing circumstances should be fed to animals; the conditions under which milk, butter, and cheese are most advantageously produced; the way in which different plants and fruits can best be protected from the ravages of pests—these are questions upon the answers to which depend the results of the farmer's efforts. It was for the purpose of assisting in reaching the proper conclusions on questions like these that agricultural experiment stations were established. The work of such stations is carried on in the laboratory, the field, the stable, the dairy, the garden, the orchard, the nursery, and the greenhouse. By systematic experiments, under advantageous circumstances, many questions too abstract and difficult for the practical agriculturist may be definitely settled in the experiment station. For example, what are the effects of the different kinds of fodder, as hay, bran, corn meal, and roots, on the quantity and quality of milk, butter, and cheese? What is the result of giving milch cows warm water instead of cold? What is the most economical food for fattening steers, for fattening hogs, and for working horses? How are the quantity and the quality of manure affected by the nature of the food? It is to obtain answers to such questions as these that experiments are carried on in the agricultural experiment stations.

The work of scientific experimentation may be said to have begun with the establishment in 1843 of the experiment station of Mr. John Lawes, known as Rothamsted, on his estate at Harpenden, England, about 40 miles N. of London. Mr. Lawes, afterward Sir John Lawes, associated with him a very eminent scholar, Prof. Joseph H. Gilbert; and the special object of Lawes and Gilbert was to carry on systematic experiments for the purpose of ascertaining the peculiarities and capabilities of the soils of Rothamsted, and the effect upon these soils of different manures and fertilizers. The most important of the experiments were devoted to testing the capacity of different soils for bearing the same crops year after year. From 1852 down to the present time the policy upon a considerable portion of the estate has been to raise the same crops without interruption, some without fertilizers of any kind, some treated systematically with the same kind of manure, and some treated with commercial fertilizers. An interesting peculiarity of this method of experimentation is the fact that each parcel of ground has been treated in precisely the same way year after year, and has borne precisely the same species of crops every year for nearly forty years. Very striking results have been secured. The plots of ground receiving no manure have uninterruptedly declined in fertility, until the average product of wheat is reported to be less than 10 bush. per acre; while the plots treated with artificial manures have come to yield during the past ten years about 35 bush. per acre; and the plots treated with farm-yard manure have come to yield about 40 bush. per acre. The comparative values of the different commercial fertilizers were also subjected to the same systematic tests. The results of these and kindred experiments, as published from year to year, have been received with great interest by all the more intelligent farmers of Great Britain. The influence of the station has been fruitful in securing most important results throughout the kingdom. While in 1840 the normal yield of wheat in England was not more than about 13 bush. per acre, the average yield between 1870 and 1880 was 29.3% bush. per acre. In 1885 it was 31.3% bush. per acre. In a similar way fields which, without systematic fertilizing, could be made to produce only about 2,300 lb. of hay per acre, were brought up to an average of 6,400 lb. per acre. These results were reached upon fields that have borne grass continuously since the days of Queen Elizabeth. By the experiments of Lawes and Gilbert it has been clearly demonstrated that lands under proper treatment may bear the same crops for at least forty years, and steadily increase in fertility.

But it is in Germany that the results of scientific experimentation have been most completely shown. The first agricultural experiment station proper was established at

Moeckern, a small village near the city of Leipzig, in 1851. A little later this humble beginning received governmental assistance, and became a permanent branch of agricultural instruction. The seed thus sown brought forth abundant fruit, and now there are in Europe more than 100 stations, in each of which from 2 to 15 investigators are at work.

The first agricultural experiment station in the U. S. was established at Middletown, Conn., in 1875. The success of Prof. W. O. Atwater in conducting this station soon led to the establishment of other stations in different parts of the country. In 1880 there were 4 in operation, and in 1887, 17. In that year the Congress of the U. S. made an appropriation of \$15,000 per annum to each of the States and Territories that had established agricultural colleges, for the purpose of founding new experiment stations or improving those already in existence. Under the encouraging influence of this law every State has at least one station, while several have more than one. In 1892 there were 53 fully equipped agricultural experiment stations, employing in all about 400 trained specialists for conducting scientific investigations. The appropriation for these stations by the General Government is about \$715,000 a year, and this is supplemented by about \$135,000 from the legislatures of the different States. In the U. S., as in Europe, the work of the different stations varies according to the special needs of the localities in which the stations are placed. In Germany, 27 stations exercise control over commercial fertilizers by analyzing and publishing the constituents of each, while 29 perform a similar service by the examination of feeding-stuffs. Fifteen are devoted mainly to investigations in vegetable physiology and 7 to animal physiology, including the most economical nutrition of plants and animals; 3 to dairy industry; 4 to sugar-beet culture; and 3 to the cultivation of fruits and vines. In the U. S. the division of work has been somewhat less symmetrically carried on; but the tendency is everywhere in the direction of specialization. Some stations are endeavoring to show how worn-out lands can best be restored; some are making a specialty of determining the value of the numerous commercial fertilizers; some are dealing with the vegetable and animal pests that afflict our fields and orchards; some are studying the influence of various foods on the fattening of cattle and on the production of milk, butter, and cheese; some are devoting themselves to the problem of sugar-making, and others to the problem of irrigation. All the stations in the U. S. are required by law to publish the results of their experiments; and, accordingly, bulletins are issued at least four times a year, and are distributed gratuitously to all such members of the farming community as may apply for them.

The following table gives the name, location, and certain other data of the several stations in the U. S.:

STATE.	Name and location of station.	Date of establishment.	Staff.	Income.
Alabama	Agricultural Experiment Station of the Agricultural and Mechanical College of Alabama, Auburn. Branch stations at Athens and Abbeville.	1883	10	\$23,000
Alabama	Canebrake Agricultural Experiment Station, Uniontown.	1885	2	4,500
Arizona (Ter.) ...	Arizona Agricultural Experiment Station, Tucson.	1890	..	15,000
Arkansas	Arkansas Agricultural Experiment Station, Fayetteville. Sub-stations at Pine Bluff, Newport, and Texarkana.	1888	10	15,000
California	Agricultural Experiment Station of University of California, Berkeley. Outlying stations at Paso Robles, Tulare, Jackson, Cupertino, Fresno, and Missiou San José.	1876	16	28,000
Colorado	Agricultural Experiment Station of Colorado, Fort Collins. Sub-stations at Del Norte and Rocky Ford.	1888	12	15,000
Connecticut	Connecticut Agricultural Experiment Station. First established in Middletown; reorganized in New Haven in 1877.	1875	9	18,600
Connecticut	Storrs School Agricultural Experiment Station, Storrs.	1888	5	7,500
Delaware	Delaware College Agricultural Experiment Station, Newark.	1888	5	15,000
Florida	Agricultural Experiment Station of Florida, Lake City.	1888	..	15,000
Georgia.....	Georgia Agricultural Experiment Station. Experiment near Griffin.	1888	7	\$15,000
Illinois.....	Agricultural Experiment Station of University of Illinois, Champaign.	1887	9	15,000
Indiana.....	Agricultural Experiment Station of Indiana, La Fayette.	1887	9	17,000
Iowa.....	Iowa Agricultural Experiment Station, Ames.	1888	11	15,000
Kansas	Kansas Agricultural Experiment Station, Manhattan.	1888	12	15,000
Kentucky.....	Kentucky Agricultural Experiment Station, Lexington.	1885	8	16,500
Louisiana.....	Sugar Experiment Station, Audubon Park, New Orleans.	1885	7	18,400
Louisiana.....	State Experiment Station, Baton Rouge.	1886	4	8,400
Louisiana.....	North Louisiana Experiment Station, Calhoun.	1888	2	12,000
Maine.....	Maine State College Agricultural Experiment Station, Orono.	1885	10	15,000
Maryland.....	Maryland Agricultural Experiment Station, College Park.	1888	6	15,000
Massachusetts...	Massachusetts State Agricultural Experiment Station, Amherst.	1882	7	10,000
Massachusetts...	Hatch Experiment Station of Massachusetts Agricultural College, Amherst.	1888	8	15,000
Michigan	Experiment Station of Michigan Agricultural College, Agricultural College P. O.	1888	18	15,000
Minnesota	Agricultural Experiment Station of University of Minnesota, St. Anthony Park.	1888	12	15,000
Mississippi.....	Mississippi Agricultural Experiment Station, Agricultural College P. O.	1888	10	15,000
Missouri	Missouri Agricultural College Experiment Station, Columbia.	1888	9	15,000
Nebraska.....	Agricultural Experiment Station of Nebraska, Lincoln.	1887	9	15,000
Nevada.....	Nevada State Agricultural Station, Reno.	1888	5	15,000
New Hampshire.	New Hampshire Agricultural Experiment Station, Hanover.	1888	9	15,000
New Jersey.....	New Jersey State Agricultural Experiment Station, New Brunswick.	1880	5	11,000
New Jersey.....	New Jersey State Agricultural College Experiment Station, New Brunswick.	1888	5	15,000
New Mexico(Ter.)	New Mexico Agricultural Experiment Station, Las Cruces.	1889	..	15,000
New York	New York Agricultural Experiment Station, Geneva.	1882	7	20,000
New York	Coruell University Agricultural Experiment Station, Ithaca.	1879	13	15,000
North Carolina..	North Carolina Agricultural Experiment Station, Raleigh.	1877	9	17,200

Agricultural Geology: geology applied to agriculture embraces whatever can be learned in regard to the nature of the sub-structure of any district with reference to drainage and water-supply, the origin, physical structure, and mineral constituents of soils, the distribution and properties of mineral fertilizers, etc. With present imperfect knowledge of the essential properties of soils, geology is chiefly valuable in showing their distribution. The sub-soil is in general derived from the underlying rock, and the soil is derived from the sub-soil; so that for the most part the rock indicates the soil. The relations of the various type soils of a region to the geological formations of the region having been ascertained, their distribution is shown by a geological map; and the results of experimentation or other experience as to the soil of any locality are thus intelligently applied to the remainder of the tract underlain by the same formation.

Revised by G. K. GILBERT.

Agricultural System: a theory of political economy invented by F. Quesnay (physician to Louis XV.), who taught that those only increase the wealth of a country who develop the resources of the earth, such as the products of the vegetable and mineral kingdoms.

Agriculture [Lat. *agricultura*; from *ager*, *agri*, field + *colere*, *cultum*, till]: primarily the tillage of land; now understood to comprise all those special industries which are connected with the rearing of plants and animals for economic purposes. It deals, therefore, with all those branches of science which have to do with the improvement of soils, with the breeding and development of domesticated animals, and the amelioration of the vegetable kingdom, as well as with the various enemies and diseases of animals and plants; and it is also an art which rests upon the combined experience of all previous generations. The field in which agriculture operates is the farm, and farming in its broadest sense is therefore synonymous with agriculture. Because of the rapid development of special industries in recent years, however, there is now a tendency to restrict the term agriculture to those operations which are concerned with the raising of stock and grains, with the crops incident thereto; while all that portion which has to do with fruits, garden vegetables, and flowers is denominated horticulture. In this classification there are still some industries which fall outside either division, as apiculture, pisciculture or fish-breeding, and forestry. This classification is only one of convenience, however, for, speaking exactly, agriculture must be held to include all rural industries.

The energy expended in the operations of the farm to be at all effective must be carried on agreeably with the laws which govern tillage and the growth of plants and animals. Many of these laws are now known; some are concisely and systematically arranged, forming a true science; and some of them are capable of such definite application that they may be classed among the exact sciences. The production of butter from milk has been reduced to a science almost as exact as has the determination of the solids in milk by chemical analysis. Within the last quarter of a century the wall which divided science from practice has been broken down, though not entirely obliterated. So long as agriculture was considered and practiced as an art little permanent progress was made, but wherever or whenever it has been studied as both a science and an art advancement has been rapid and permanent. Nearly all of the improvements in agriculture which have been made in the last century have been due to the discovery and application of laws before unknown or unapplied, rather than to improvements in the mere art of farming. Bakewell in 1785 discovered and applied the primary laws which govern the art of improving domestic animals. Anciently the breeding of animals was practiced as an art alone; hence little improvement was made, and what advancement accrued was often lost in a single generation. For three-quarters of a century after Bakewell's time rural science suffered in reputation, because the scientists were ignorant of the art of agriculture, and those who knew the art would have none of the science. It is only within a score of years that science and art have consented to act together as a unit for the common good.

The primary or fundamental science and art of agriculture are those connected with maintaining or increasing the fertility of the soil. There has always existed much anxiety in the minds of the most thoughtful agriculturists lest cultivated soils should some day become depleted or exhausted, and profitable tillage of the land become im-

possible. But the experiences of the oldest civilized countries emphatically contradict this apprehension; and the researches of Sir Humphry Davy and Von Liebig, early in the nineteenth century, into the chemistry of the soil gave assurance that careful management of the land and the judicious application of manures can not only maintain but even augment the fertility of the soil. Thorough and frequent light tillage, when the land is neither very wet nor very dry, is of itself a conservator of fertility, from the fact that it aids in unlocking certain fertilizing elements which exist in an unavailable condition in all good soils. The application of concentrated fertilizers and farm manures is now governed by definite precepts, for which the reader is referred to the articles on FERTILIZERS and MANURES. Definite successions or rotations of crops were urged by Liebig and others for the purpose of conserving fertility, largely upon the supposition that plants excrete certain substances which are injurious to themselves, but which are innocuous or even beneficial to other species of plants. Although the original conceptions as to the reasons for maintaining rotations are largely given up, it nevertheless remains a fact that such rotations are exceedingly important in any well-considered scheme of farming.

Rotation of crops may be defined to be the arrangement of a certain regular succession of plants of different species with a view to economize the fertility of the land, prevent the growth of certain species of weeds, economize labor, and to distribute it, so far as possible, through the entire year. It is a well-known fact that some crops require that their food shall be abundant and readily soluble, while others are able to thrive well on nourishment drawn from less tractable substances. This is supposed to be due to the greater power of the roots in some species to excrete the solvents which assist in setting plant-food free. The difference in amounts of inorganic matter abstracted from the soil by different species of cultivated plants is so small that no account is taken of them in fixing a rotation. There are four conditions—climate, soil, local position, and economy of labor—which should be observed in fixing upon any given rotation. A common rotation is two years of grass or clover, one of corn, one of oats or barley, and one of wheat. Where wheat and potatoes both thrive, a three-years rotation—clover, potatoes, and wheat—is often adopted. The exudations of the roots of plants do not, as was formerly supposed, poison the soil; both wheat and corn have been raised continuously on the same land for more than twenty years without diminution of yield, though, from obvious reasons, continuous cropping with one species of plants does not give the best results. Save in exceptional cases, a rotation should be planned so as to secure the largest net returns, while maintaining, or even increasing, the productive power of the land.

The fears that soils necessarily become more or less exhausted after many years of cropping have been the exciting cause of much of the instability in agriculture in the U. S. The fertile and cheap lands of the interior country, offered by the Government and by railroads, have attracted much of the population from the older soils of New England, and have been the means of creating a most unwholesome feeling of unrest in the agriculture of all the Eastern States. The exodus from the East has been so great that many of the hill-farms of New England have been abandoned, and this circumstance is often cited as evidence that agriculture can not thrive in these States. But much or even most of the land which is thus abandoned is really unfit for farming purposes, and ought never to have been cleared. Its uses for forestry are greater than its value for tillage; and much of it is adapted to grazing, for which it is now largely employed. The remaining and really valuable lands in New England are now being devoted more and more to special styles of farming, and, being relieved from some of the neighboring competition, are perhaps as profitable as they ever were, while the best of them are very prosperous. As a rule, therefore, the so-called abandonment of Eastern farms does not call for apprehension; and the fact that the available Western lands are largely taken up is conducing to a more settled and hopeful feeling among our Eastern farmers.

LIVE-STOCK INTERESTS.—The fundamental problems regarding the fertility of the soil are now giving place in a measure to the scientific principles which underlie the improvement of animals and plants. This is well shown in the live-stock interests. While Spain was overrun with valuable sheep, and Great Britain had great numbers of improved horses and cattle, no advantage was taken of these facts

until about the beginning of the nineteenth century. A few English sheep had been imported into the U. S., but they were used only for the purpose of making a little homespun cloth, and it was not until 1809-11 that William Jarvis and others imported about 8,000 Spanish merinos. The commercial difficulties with Great Britain and France in 1807 caused unwashed wool to reach the fabulous price in 1810 of \$2 a pound, and during the war of 1812 it reached \$2.50. Many merino lambs sold for \$1,000 apiece, and from that day to the present the merinos have been bred in large numbers from the Atlantic to the Pacific.

Sheep.—These early prices exerted a powerful influence upon the sheep industry in improving the different breeds; for, while the former prices are now seldom obtained, the total value of the sheep products has wonderfully increased. The low price of wool within the decade 1880-90, and the high price of early lambs, has tended to bring about a change from sheep of intensely fine wool to those of mixed blood, or to the medium-wooled mutton sheep of the British islands. The total number of sheep of all kinds in the U. S. in 1892 was 44,938,365, valued at \$116,121,270, and the total product of wool for 1891 was 285,000,000 lb. The combined effect of all the influences which are now shaping the sheep industry is to make it more apparent that the ideal sheep for the farmer of the U. S. is one of medium size, compact build, quick growth, and rotund form.

Cattle.—It was not until 1830 to 1840 that serious attempts were made to improve the cattle of the U. S. These attempts were inspired by the remarkable success of Robert Bakewell, Charles Colling, Thomas Bates, Booth Brothers, and others in England in improving the shorthorns by careful selection and judicious crossing. Large importations were made from the Bates and Booth herds, and one family of shorthorns—known as the Duchess—early attracted unusual attention in this country. In 1867 J. O. Sheldon, of Geneva, N. Y., sold forty head of this family for \$42,300 to Wolcott and Campbell, of Utica, N. Y. In 1873 this herd was dispersed at public auction by Samuel Campbell. At the sale the eighth Duchess of Geneva was sold to R. Pavin Davies for \$40,600, the tenth Duchess of Geneva to Earl Bective for \$35,000, and the first Duchess of Oneida sold for \$30,600. The tenth Duchess of Oneida, an eight-months calf, sold for \$27,000. The effect of these almost fabulous prices was at once to draw the attention of farmers everywhere to the breeding and selection of cattle. So far as possible within his means nearly every herd-owner obtained the services of an improved bull. Grade shorthorn stock became common, and its effect upon the stock of the country was marked. It was but a step from this improved breeding to a careful study of every animal in the flock, with the result that the poor or unprofitable individuals were not allowed to breed, or are not now even allowed to remain in the herd. Attention was then attracted to the breeding of animals for particular purposes. The shorthorns are essentially a beef breed, and the result of American breeding was such that many judges contend that the herds in the U. S. exceed those of Great Britain in average value of individual animals. In 1850 John A. Taintor imported the Jersey, one of the best of the dairy breeds. Although this breed had been produced in a comparatively warm climate, and did not always adapt itself at first to the severities of the Northern States, it has been improved so much in hardness, quality, and size that it now stands second to no other breed of dairy cattle in the U. S. In 1857 W. W. Chenery, of Belmont, Mass., imported some cattle from North Holland. This importation was soon followed by others, and the animals became known as the Holstein-Friesian breed. This large breed has been handled with such skill in this country that its records for milk and butter astonish the world. Several cows have a record of 20,000 lb. and upward of milk per year, and one has a record of 31,000 lb.; while another has produced 1,153 lb. of butter in 365 days. From these small and recent beginnings, with comparatively little clover and almost no turnips, the stock interest of the U. S. has grown, until in 1891 there were 16,000,000 milk cows, valued at \$346,397,900. The total annual milk production is estimated at 20,000,000 tons, and the average annual production of milk per cow in the Eastern States is 3,000 lb. While, therefore, the prices for individual fancy animals have fallen off, the average value of the stock and dairy interest to the farmers of the country has greatly increased. See CATTLE, BUTTER, CHEESE, and MILK.

Horses.—Probably no animal has shown such quick re-

sponse to the ideals of the breeder as the horse, especially in the trotting horse. Horses from a very early period attracted wide attention, and the thoroughbred or running horse was imported into Great Britain and the U. S. at a very early date. As early as 1854 West Australia ran 2 miles and 4 furlongs in 4:27, or a mile in 1:47. Little progress has been made in the speed of this class of horses, as in 1890 the lowest running record was by Salvator, a mile in 1:35½. From the mixed blood horse of the country on one side and the hot-blooded Oriental, or thoroughbred, on the other, has been developed a distinct type of animal which for speed and endurance is unexcelled. The first trotting record below 2:30 was made less than fifty years ago by Lady Suffolk, in 2:26½, while at the present time there are in the U. S. several thousand horses which have trotted a mile in that time, or less. The first horse to make 2:10 was Jay Eye Sec, in 1884; now at least eight horses have equaled or lowered that time. The best stallion record is by Palo Alto, 2:08¾; the best team record by Belle Hamlin and Justina, 2:13; the best three abreast record by Belle Hamlin, Justina, and Globe, 2:14; the fastest pacing record is held by Direct, 2:06; while the queen of the trotters is Nancy Hanks, 2:04. The best records for different ages are: for yearlings, Frou-Frou, 2:25¼; for two-year-olds, Arion, 2:10¾; for three and four year olds, Sunol, 2:10½. It is no uncommon thing for some of the best bred trotting animals to bring from \$50,000 to \$120,000 each. The trotting horse is a remarkable development. The Puritans believed that a race-course was demoralizing and horse-racing wicked, and so the breeders of fast horses in New England, in deference to this idea, trained to secure trotters. The trotter, in turn, had a marked and positive influence on the character of all light wagons, and soon there appeared many styles of pleasure-carriages and road-wagons unrivaled for lightness and beauty; and they in turn produced lightness, durability, and lines of beauty in every class of farm implements and machinery, team wagons being lighter, and painted and decorated more elaborately than the carriages of the aristocracy of Europe. The South had no such scruples about horse-racing, and so, from the earliest history of the country, running horses have been fashionable there. See HORSE-RACING.

According to the census of 1890 there were in the U. S. on June 1, 1890, 14,976,017 horses and 2,246,936 mules, the average value of the horses being \$67 each, and of the mules \$77.88 each. See HORSE.

Swine.—Among swine there has also appeared a peculiar American breed, the Poland-China, produced in the corn-growing regions of Ohio from the crosses of several of the improved English breeds. Three-fourths of all the swine which arrive at the great pork-markets of the country are of this breed. The enormous corn crops of the country have stimulated the swine industry, until in 1891 there were in the U. S. 201,193,923 animals, at an average value of \$4.15 each, and there were slaughtered 8,200,000,000 lb., as against 8,800,000,000 lb. of beef and 1,000,000,000 lb. of mutton. See SWINE.

Poultry have also responded in a wonderful manner to good care and selection. In 1880 there were 102,000,000 fowls. In the middle of the nineteenth century there were not above half a dozen breeds; now there are over one hundred. Fine birds sell from \$25 to \$225 each. The annual egg product is worth upward of \$200,000,000, and the entire poultry product is estimated at \$700,000,000. Formerly 75 eggs per hen every year was considered a large yield; now many large flocks produce an average of 175 eggs per hen. This improvement, like many others of domestic animals, has been secured by original methods, discovered and put in practice in the U. S. See POULTRY.

Bees.—Marked progress has been made in the management of bees. Extractors, foundation comb, and adjustable hives have enormously increased the total product. The annual honey produced is estimated at 20,000,000 lb.; the number of colonies at 3,000,000. See APICULTURE and BEE.

CROPS.—In most of the older grain-growing sections of the U. S. the yield per acre has decreased since the first crops were taken from the land, and this circumstance has occasioned some alarm among farmers. But such a result is to be expected when we consider the careless methods pursued in pioneer farming. Crop after crop is taken from the virgin soil, rich in plant-foods accumulated during ages, and there is not only little or no attempt to supply the materials consumed, but the management of the land is hasty and often reckless. But it is an encouraging fact that the so-called depleted soils of some sections of the Eastern States are now

giving, under careful management, greater returns than they did in the early days. This is well shown in the wheat crop, of which the yield per acre averages, for the U. S., 15 bush., while many of the old farms in the Eastern States give an annual crop of 35 to 40 bush.; and it is significant that in England, where the land has been cultivated for centuries, the yield per acre is 32 bush. This productiveness of old lands is not due to excessive fertilizing, but to the moderate use of fertilizers in connection with thorough and careful tillage and underdraining. The fertility of virgin soil is really in a measure fictitious; that is, it is not an accurate measure of the intrinsic value of the land, but is rather an index of how much extraneous food material has been deposited upon it. The true science of agriculture finds its best and most permanent usefulness when it considers the management of old soils. A system of agriculture is successful only when it augments the productiveness of the land at the same time that it maintains or increases the product. The cereals now produced in the U. S. are enormous in quantity. In 1891 there were 78,000,000 acres of corn, which yielded 2,060,000,000 bush., worth \$836,439,228, with an additional valuation of stalks of \$156,000,000. Large areas were also grown for ensilage. See ENSILAGE. The wheat occupied 39,916,897 acres, giving 611,780,000 bush., worth \$513,472,711. There were consumed in this country 301,000,000 bush.; 206,000,000 were exported; 56,000,000 bush. were used for seed; the balance was in original hands and not accounted for. Oats covered 25,581,861 acres; produced 738,394,300 bush.; and had an estimated value of \$232,312,267, having increased in total amount over 50 per cent. during the decade. Hay production increased 240 per cent. from 1840 to 1880. At the present time more than 40,000,000 tons are cut annually. From 1791 to 1801 cotton production increased from 2,000,000 to 48,000,000 lb.; in 1891 it was 4,000,000,000 lb. If two pounds of seed are produced for every pound of clean lint, this would give 4,000,000 tons of seed. A ton of seed reginned produces 10 lb. of cotton, 35 gal. of oil, 750 lb. of meal, and 500 lb. of hulls. Less than one-third of the seed is manufactured; two-thirds is wasted or applied direct to the land as a fertilizer. See special articles on the various crops for more particular information. For fruit and kindred interests, see HORTICULTURE, FLORICULTURE, POMOLOGY, OLERICULTURE, and FORESTRY.

LANDS.—The extent of public lands in the U. S. and Territories in 1880 was 1,814,504,147 acres. Up to 1890 88,000,000 acres had been settled under the Timber and Homestead acts, 896,000,000 acres remained unoccupied, and the amount taken up by farms was 536,081,835 acres. During the decade from 1870 to 1880 the number of farms containing from 50 to 100 acres increased 37 per cent.; those from 100 to 500 acres trebled; those from 500 to 1,000 quintupled; while those containing 1,000 acres and above were eight times as many. In 1883 18,000,000 acres were owned by eight proprietors, and the railroad companies held 200,000,000 acres.

In 1892 1,000,000 sq. miles were unsettled, 80,000,000 acres were timber, 70,000,000 coal and other mineral lands, and 500,000,000 wild grazing and desert lands; not more than 25,000,000 acres of good arable lands, capable of profitable cultivation without irrigation or other artificial means, remained. The reckless devastation of forests during the pioneer days in the U. S. is without parallel in the history of nations. The axe and the firebrand preceded the march of population westward, stripping the rich valleys and the hill-sides of their natural covering, leaving vast areas to seorch in the burning sun and to quickly conduct away the melting snows, flooding valleys and inundating enormous tracts of country along the great rivers. Wise timber laws for the protection and extension of forest areas, such as are in existence in Germany and France, are not found in the U. S. Twenty-five billion cubic feet of wood are consumed annually in the U. S., which is equal to the annual wood-growth of 500,000,000 acres of forest, or more than the forests of the U. S. produce. See FORESTRY.

ROADS.—The wars of the U. S. have not made great military highways necessary, and the rapid settlement of new territory and the extension of railroads have tended to discourage a systematic knowledge and practice of road-construction. The number of miles of railroad in operation in the U. S. in 1891 was 170,601. The number of miles constructed during that year was 3,898. Early in railroad building in the U. S. a simple invention made it possible for trains to round short curves safely; this cheapened the cost of constructing them in the U. S. over that of the United Kingdom

by more than 20 per cent. Freight-cars carrying from 20 to 40 tons each have been substituted for the small 5-ton cars which were first used, and locomotives have doubled in size and weight. These are the three great factors which have made it possible to transport a bushel of wheat 2,000 miles by rail to the seaboard market for less than it can be transported 20 miles by wagon carriage. As the population of the country increases, however, there is an increased demand for wagon roads, and this subject is now undergoing great agitation, especially in the East. Undoubtedly the first requisite to a good road system is some sort of State control, by which competent engineers and superintendents can be employed; and it will then be found that proper engineering will make it possible to dispense with many or most of the expensive road-beds which are now advocated. See HIGHWAY, ROADS, and PAVEMENTS.

MACHINERY.—The rapid settlement of Government land brought into cultivation vast areas of productive virgin soil, and the rich rewards for agricultural products and the high price for human labor stimulated the invention of labor-saving machinery; while the universal use of steam-power, the general popularity of the printing-press, together with the discovery of the electric telegraph and telephone, added new impetus to manufacturing. Increased manufactures called for additional agricultural production to supply raw materials; this in turn stimulated invention of labor-saving devices, so that to-day the U. S. is remarkable for the value and number of its farm implements. Nearly every operation of the farm has been made less burdensome, and many methods of agriculture have been completely overturned. The Babcock tester for fat in milk and the milk-separator have revolutionized the dairy interests; seed-sowers and corn-harvesters, self-binders and steam-threshers, have made it possible for one man to accomplish the work which it would have required twenty men to perform a generation ago. In fact, it would be impossible to grow the annual agricultural product of the U. S. with our present population were it not for the farm machinery. There are sold annually about 125,000 self-binders in the U. S., valued at \$15,000,000, and 175,000 mowers, valued at \$8,000,000.

EDUCATION.—Agricultural education received its first great impulse when Congress passed the Morrill Land Grant Act in 1862, giving to every State public lands for the purpose of founding institutions where "such branches of learning as are related to agriculture and the mechanic arts" should be taught. In 1890 additional aid was given to the colleges established under the supplementary Morrill grant of \$15,000 per annum, to be increased each year by \$1,000 until the total annual appropriation shall have reached \$25,000. There were 46 agricultural colleges in operation in 1892, with an aggregate attendance of from 5,000 to 6,000 students. (See AGRICULTURAL COLLEGES.) The national Department of Agriculture at Washington is thoroughly and systematically organized, having for its head a Secretary of Agriculture, who is a member of the President's Cabinet. There are fifteen sub-departments, viz., the departments of statistics, botany, animal industry, plant pathology, gardens and grounds, records and editing, seeds, weather bureau, chemistry, forestry, entomology, mammalogy, microscopy, pomology, and experiment stations. Much valuable scientific work has been done, which is published in the form of bulletins and an annual report for free distribution. The department seeks to introduce new varieties of plants and animals, to foster new industries, to combat pests and diseases, to inspect agricultural exports and imports, to report upon the condition and prospect of crops in this and other countries, to preserve the forest areas, to prevent the adulteration of food products, to report upon the freight rates of transportation companies, and in general to look after the interests of the farmer, and to aid him in every way possible.

Previous to the year 1887 scientific agricultural research had been carried on in the U. S. to a limited extent by special State appropriations or by individual enterprise. At this time Congress passed the Hatch Act, giving to every State \$15,000 annually for the establishment of an agricultural experiment station. During 1891 the stations published 49 annual reports, 255 bulletins, with a total number of 40,000,000 distributed pages, and an aggregate mailing list of 350,000. The number of stations in operation in 1892 was 49 (see AGRICULTURAL EXPERIMENT STATION), employing 473 persons. Not a little of the progress in agriculture is due to the information placed before the farmer in the station bulletins. Great demand for agricultural knowledge has led not less than 30 States, including Canada, to make

an aggregate appropriation of \$85,000 for the holding of farmers' institutes. These institutes assumed definite shape nearly twenty years ago. In 1842 the New York State Agricultural Society provided by resolution for addresses at suitable times at the county agricultural societies. Massachusetts provided for holding farmers' institutes as early as 1859; Michigan in 1861; in 1869-70 farmers' institutes were held in Iowa. From this time on they increased in number and usefulness. (See FARMERS' INSTITUTES.) These farmers' meetings have marked a new era of agricultural education. Of various organizations, many of which receive State aid, there are between 3,000 and 4,000, such as agricultural societies, dairymen's associations, horticultural societies, poultry societies, and miscellaneous organizations. Sir John Lawes has provided by an ample endowment for an American biennial course of lectures on the agricultural investigations conducted at Rothamsted, to be delivered under the auspices of the Society of Agricultural Colleges and Experiment Stations. Upward of sixty villages in Kent, England, have courses of six lectures on botany, entomology, and other subjects relating to agriculture.

LITERATURE.—The literature of agriculture is very voluminous, though to a large extent out of date and unreliable, because of the constant discovery of new laws, methods, and principles. The best works which give us an idea of the agriculture of ancient times are those of Columella, who wrote *De Re Rustica*, and of Vergil, who wrote *The Georgics*. Cato, Varro, Pliny, and Palladius also contributed extensively to contemporaneous literature. The principal writer in Italy for the same period was Creseentius; in Spain, Herrera; in France, Oliver de Serres; in Germany, Hershbachius. Of later times, *The Booke of Husbandrie*, by Sir Anthony Fitzherbert; *Five Hundred Points of Good Husbandrie*, by Thomas Tusser; *The Whole Art of Husbandrie*, by Barnaby Googe; *The Jewel House of Art and Nature*, by Sir Hugh Platt; *The English Improver*, by Walter Blithe; *Husbandry of Brabant in Flanders*, by Richard Weston, are the best books of reference. The most reliable writers at the beginning of the nineteenth century were Fallipo Re, in Italy; Mayer, in Germany; and Marshall, in Great Britain. Still later works covering the general field of agriculture are Loudon's *Encyclopædia of Agriculture*; Stephens's *Book of the Farm*; Morton's *Cyclopædia of Agriculture*; and Wilson's *British Farming*. Later books are *Elements of Agriculture*, by Waring; *Talks on Manures*, by Harris; *Feeding Animals*, by Stewart; *Farm Drainage*, by French; *American Dairying*, by Arnold; *Practical Shepherd*, by Randall; *Swine Husbandry*, by Coburn; *Cattle Breeding*, by Warfield; *How Crops Grow and How Crops Feed*, by Johnson; *Horticulturist's Rule Book*, by Bailey; *Manual of the Apiary*, by Cook; *Animals and Plants under Domestication*, by Darwin; *Insects Injurious to Vegetation*, by Harris; *Farmer's Veterinary Adviser*, by Law; *Agriculture*, by Storer; *The Poultry Book*, by Wright; *Horses, Cattle, Sheep, and Swine*, by Curtis; *Horse Breeding*, by Sanders; *Gardening for Profit*, by Henderson; *Fruit Culture*, by Thomas; and *Fruits and Fruit-Trees of America*, by Downing. In 1884 there were 305 agricultural periodicals published in North America, as against 546 in all the rest of the world. Among the most valuable are the *Rural New Yorker*, *Country Gentleman*, *American Agriculturist*, *New England Homestead*, and *Pacific Rural Press*. Those covering special branches of agriculture are *The Breeder's Gazette*, *Hoard's Dairyman*, *The Dairy World*, *The Poultry Keeper*, *The Poultry World*, *American Gardening*, *Garden and Forest*, *Swine Breeder's Journal*, *American Horse Breeder*, *American Sheep Breeder*, and *Gleanings in Bee Culture*.

I. P. ROBERTS.

Agriculture, Department of: a commissionership of the U. S. Government established by Congress in 1862 in Washington, D. C., changed in 1889 to a department of the Government, with a cabinet officer or "secretary" at its head. By means of annual and monthly reports it diffuses information deemed advantageous to the agricultural interests of the country. It purchases and propagates seeds and plants, which are distributed to the people of the U. S. It has a fine building, which stands W. of the grounds of the Smithsonian Institution. Among its constituent parts are two bureaus (Animal Industry and Weather Bureau), many divisions, an office of experiment stations, a herbarium, a museum, chemical laboratory, propagating-gardens, and a library. Its monthly reports of the prospects of the staple crops are especially valuable. At the propagating-gardens

plants received by exchange from foreign governments and botanic gardens are tested, with a view to introducing new and useful plants in the U. S.

Agrirentum: an ancient city of Sicily, now called Girgenti (*q. v.*).

Ag'rimony: any herbaceous plant of the genus *Agrimonia* and family *Rosaceæ*. The *Agrimonia eupatoria*, a native of Europe and the U. S., has been used in medicine. Several species grow in the Southern U. S.

Agrip'pa, King: See HEROD AGRIPPA.

Agrippa, HENRY CORNELIUS, of Nettesheim: German physician, philosopher, and astrologer; b. at Cologne, Sept. 14, 1486. He cultivated many departments of knowledge, and engaged in various pursuits in many countries of Europe. He acquired fame by his talents and his supposed skill in occult science, but he was regarded as an impostor and heretic by some of his contemporaries. He lectured on theology at Cologne and other places, and practiced medicine in France. Among his works is a satire *On the Vanity of the Sciences* (in Latin, 1530). D. at Grenoble, France, Feb. 18, 1535. See his life by H. Morley (2 vols., Lond. 1856).

Agrippa, MARCUS VIPSANIUS: Roman statesman and general; b. in 63 B. C. He became in his youth a friend of Octavius (afterward the Emperor Augustus), to whom he rendered important military services, especially at the battle of Actium, where he commanded the fleet, in 31 B. C. Agrippa and Mæenas were the principal ministers and advisers of Augustus after he had obtained the supreme power. He married Julia, the daughter of Augustus, about 21 B. C., and had several sons, two of whom were adopted by the emperor. Agrippa wrote a memoir of his life, now lost, and projected a detailed map of the world, for which he had collected much material, which was deposited in the public archives and afterward used by Strabo, Pomponius Mela, and Pliny the Elder. After his death, Augustus executed the map, copies of which were sent to the provinces. D. in Mar., 12 B. C. Revised by M. WARREN.

Agrippi'na I.: a Roman lady; daughter of M. Vipsanius Agrippa and his wife Julia; married to the famous Germanicus. Her virtue is highly commended, and was the cause of her banishment in 29 A. D. to the island of Pandateria, near Naples, by the Emperor Tiberius, who hated her. There she died, Oct. 18, 33.

Agrippina II.: a daughter of the preceding; b. at Cologne, 16 A. D. She was the mother of the Emperor Nero, by Domitius Ahenobarbus, and was notorious for her profligacy and her crimes. Her second husband was Passienus Crispus; her third was the Emperor Claudius, whom she killed by poison. She was put to death by her son Nero in 60 A. D. See her life by A. Stahr (Berlin, 1867; 2d ed. 1880).

Agrostis: a genus of grasses containing about 100 species, which are widely distributed, especially in the north temperate zone. *A. vulgam* (redtop) and other species are valuable for pasture and hay. CHARLES E. BESSEY.

Ag'telek: a village near which is *Bar'adla*, one of the largest and most remarkable stalactitic caverns of Europe; is in the county of Gömör, in Hungary. Here is a labyrinth of caverns, one of which is 96 feet high, 90 feet wide, and extends about 900 feet in a direct line.

A'gna, VOLCAN DE (i. e. volcano of water): a mountain of Central America, in the state of Guatemala, situated about 25 miles S. W. of Guatemala; so called from the fact that it sometimes pours forth torrents of water. The old town of Guatemala has been twice destroyed by it. Its crater is 15,000 feet above the sea-level.

A'gnas Calien'tes (i. e. warm springs): a state of Mexico; bounded N. E. and W. by Zacatecas, and S. by Jalisco. Area, 2,950 sq. m. The soil is very fertile, but poor in minerals. Pop. (1890) 140,180. Capital, Aguas Calientes.

Agnas Calientes: a town of Mexico; the capital of state of same name; on a plain or table-land 6,000 feet above the sea, and 250 miles N. W. of the city of Mexico (see map of Mexico, ref. 6-F). It has numerous churches and three convents, and is surrounded by gardens and orchards of olives, pears, figs, etc. Hot springs occur in the vicinity. Pop. 35,000.

Agne [O. Fr. *ague*, sharp < Lat. *acutâ* (sc. *febris*, fever), fem. of adj. *acutus*, sharp]: the common name for the intermittent fever (*q. v.*). See also CHILL.

Aguilar, aã-gē-laar', GRACE: a Jewish authoress of Spanish extraction; b. at Hackney, near London, June 2, 1816. Among her numerous works are *Women of Israel*; *Home Scenes and Heart Studies*; and *Home Influence, a Tale*. D. at Frankfort, Sept. 16, 1847.

Aguilar' de la Fronte'ra: a town of Spain; on the Cabra, 22 m. S. S. E. of Cordova; noted for the whiteness of its houses and the cleanness of its streets (see map of Spain, ref. 19-E). It has several fine public squares, a town-hall, and a dismantled Moorish castle. Pop. 12,300.

Aguinaldo, EMILIO: Filipino leader; b. in Imus, province of Cavité, Luzon, in 1870. A Chinese mestizo (of Chinese and Tagalog parentage). Educated at the College of St. Jean de Lateran and the University of St. Tomas, in Manila. Afterward, as the protégé of a Jesuit priest, he was for a time a student in the medical department of the Pontifical University of Manila. In 1888 he went to Hongkong, and there studied the English, French, and Chinese languages, and became interested in military affairs, for which he showed a great aptitude. His education, shrewdness, and great personal magnetism made him a commanding figure in the outbreak against the Spanish authority in 1896. At the head of the diplomatic commission he made the terms with the Spanish Government, whereby they paid a large sum of money to the Filipino leaders to lay down their arms. In Hongkong, Aguinaldo quarrelled with his associates over the division of this money, and went to Singapore. At the beginning of the Spanish-American war, Admiral Dewey, on the representations of the American consul at Singapore, sent for Aguinaldo. Aguinaldo arrived at Cavité a few days after the battle of Manila Bay, and at once began the organization of Filipino troops. No promises were made to him, and the insurgents never were officially recognized by the Americans. June 12, 1898, he organized his so-called Filipino Republic, with himself as President, and a few days later proclaimed himself dictator. He protested against the treaty of peace ceding the Philippines to the U. S., and late in the year planned a gigantic massacre in Manila, which was discovered by the authorities and prevented. Feb. 4, 1899, his troops attacked the American lines in the suburbs of Manila. Aguinaldo made a determined resistance to American occupation, and it was not till early in 1900 that the organized insurrection was broken up, and its leader became a fugitive in the mountains. Fighting was continued under his nominal leadership by the dispersed fragments of his army till Mar. 23, 1901, when he was captured at Casiguiran, Isabella Province, Luzon, by a stratagem executed under the leadership of Gen. Frederick Funston. He was taken to Manila, and on Apr. 2 took the oath of allegiance to the U. S.

Aguirre, LOPE de: See LOPE DE AGUIRRE.

Agul'has, CAPE (the Needles): the most southern point of Africa; about 100 miles E. of the Cape of Good Hope. A lighthouse was erected on it in 1849; lat. of lighthouse, 34° 49' 46" S., lon. 20° 0' 37" E.

Agusti'na: the "Maid of Saragossa"; d. at Ceuta, Spain, in 1857. For her bravery during the siege of Saragossa by the French in 1809 she was made a lieutenant in the Spanish army and received numerous decorations. Byron extols her in *Childe Harold*, canto i., stanzas 54, 55, 56.

Agyu'ians [from Gr. à-, not + γυνή, woman]: a Gnostic sect of the seventh century who condemned marriage and the use of certain kinds of meat.

A'hab (Heb. *Ahab*): seventh King of Israel, B. C. 918-896 (Ussher). His wife was Jezebel, daughter of Ethbaal, the usurping King of Tyre. He dwelt at Jezreel, which he adorned with splendid buildings. The story of his weakness, his idolatry, and the stern opposition of the prophet Elijah is related in the first book of Kings. Ahab was killed in battle with Benhadad, King of Damascus.

Ahasuer'us: the name of one Median and of two Persian kings mentioned in the Old Testament. The Ahasuerus of Esther was probably Xerxes, the invader of Greece, who reigned from 486 to 465 B. C. He invaded Greece in 480, and is supposed to have married Esther the year after.

A'haz (Heb. *Ahaz*, possessor): eleventh King of Judah after its secession from Israel; reigned B. C. 741-725. His reign was greatly disturbed by the attacks of Rezin, King of Damascus, and Pekah, King of Israel, as well as those of the Edomites and Philistines. Ahaz called to his aid the powerful Tiglath-Pileser, King of Assyria, who overthrew

the enemies of Judah, but made Ahaz his vassal, and carried off rich treasures from the temple and palaces of Jerusalem. Ahaz was an idolater. His history is given in 2 Kings xvi.; 2 Chron. xxviii. A statement in 2 Kings xvi. 2 as to his accession would make his son and successor, Hezekiah, to have been born when he was eleven years old, but this must be a transcriber's error or the date of a viceroyship.

Ahazi'ah: eighth King of Israel; succeeded his father Ahab, and ruled under the direction of Jezebel, his mother, B. C. 897-896.—Also the name of the fifth King of Judah, B. C. 885-884. A famous error of some transcriber (2 Chron. xxii. 2; xxi. 5, 20) makes him older than his father.

Ahith'ophel (Heb. *Ahithophel*, foolish): a Hebrew politician and counselor of David. He took the side of Absalom in his rebellion, but, foreseeing the failure of the enterprise, went home and hanged himself. See 2 Sam. xvi., xvii.

Ah'quist, AUGUST ENGELBERT: Finnish philologist: b. at Kuopio, Finland, Aug. 7, 1826; made the Finnish language his especial study, and endeavored to raise it to the rank of a written language, and to create a national Finnish literature. For this purpose he traveled with great hardship through Northern Russia and Siberia. He was elected Professor of Finnish Language and Literature in the University of Helsingfors (1862). His chief works are *An Attempt at a Moksha-Mordwinian Grammar* (1862); a *Grammar of the Wotish Language*, and a description of his travels in Siberia (1853-58); *The Structure of the Finnish Language* (in Finnish), 1877. He has also written many poems in the Finnish language, and made several translations from the German of Schiller. D. at Helsingfors, Nov. 20, 1889.

Ah'madabad' (i. e. the abode of Ahmed): a city of British India; in the presidency of Bombay; on the river Sabarmati; 160 miles by rail N. N. W. of Surat; lat. 23° 1' N., lon. 72° 48' E. (see map of S. India, ref. 1-C). It was formerly a large and magnificent capital, but is now much decayed. Here are several beautiful mosques and other remains of its ancient splendor. It was founded by Ahmed Shah in 1412. Pop. (1891) 145,990.

Ahmadna'gar (i. e. the fort of Ahmed): a city and fortress of British India; in the presidency of Bombay; on the Seena; 162 miles by rail E. of Bombay (see map of S. India, ref. 3-C). It was founded by Ahmed Nizam Shah in 1493, and became a capital of the kingdom of the same name. It was taken by Gen. Wellesley in Aug., 1803, and the fortress is now held by a British garrison. Pop. 37,500.

Ah'med IV., sometimes called **Abd'ul-Hamid**: a Turkish sultan; b. in 1725; succeeded to the throne in 1773. His reign is chiefly notable on account of the two disastrous wars with Russia, in which Turkey lost the Crimea, a portion of Circassia, with some other territories, and a number of important fortresses. D. in 1789.

Ahn, JOHANN FRANZ: German writer; author of a new method of learning foreign languages; b. at Aix-la-Chapelle, Dec. 15, 1796; published a *Practical Course for the Quick and Easy Acquisition of the French Language* (Cologne, 1834; 167th ed. 1870), and other similar works, which have found an immense circulation. His method has been imitated by many other writers in the different civilized lands. From 1843 to 1863 he taught at Neuss, retired in the latter year, and died there, Aug. 21, 1865.

Ahnapee: city, Kewaunee co., Wis.; on Lake Michigan; 32 miles E. of Green Bay (see map of Wisconsin, ref. 4-F); has saw and grist mills, and trade in grain, bark, and ties. Pop. (1880) 948; (1890) 1,384; (1900) 1,196.

Ah'rens, HEINRICH: German jurist; b. at Kniestedt, Hanover, July 14, 1808; educated at Göttingen. On account of his participation in the political upheavals in 1830 he fled to Paris, where he lectured in 1833 on the history of German philosophy; became in 1834 Professor of Philosophy in Brussels; in 1850, Professor of Law and Political Economy at Graz; in 1859, of Practical Philosophy and Political Science at Leipzig. His principal works are *Cours de droit naturel* (Paris, 1838; 7th ed. 1875), in German under the title *Philosophie des Rechts* (2 vols., 6th ed. 1870); *Juristische Encycl.* (1855-57). D. at Salzgitter, Aug. 4, 1874.

Ah'riman: Among the ancient Persians the principle of evil. See ORMAZD.

Ah'tena: See ATHAPASCAN INDIANS.

Ah'waz: a small town of Persia; 100 miles N. E. of Basorah; was once an important city. The ruins of the ancient city extend 12 miles on the bank of the Karun.

Ai, aa'i: common name given to the three-toed sloths, edentate mammals of South America, several species of which have been confounded under the Linnæan name of *Bradypus tridactylus*. It takes its name from the loud cry which it makes while moving in the forests.

Revised by D. S. JORDAN.

A'i (i. e. a ruin): a city of Palestine (Gen. xii. 8; xiii. 3), which was destroyed by Joshua (Josh. vii. 2-5; viii. 1-29). Its site is not positively known; also a city of Ammon, destroyed by the Babylonians.

Aid'an, SAINT: first Bishop of Lindisfarne; b. in Ireland, and sent as a missionary bishop to Northumbria by the Bishop of Iona about 635 A. D. He was successful in establishing Christianity, being aided by the king and nobles. His life was adorned by charity, humility, and all the Christian virtues. The Venerable Bede (*Eccles. History* iii. c. c. 5, 17) gives an interesting account of his excellent characteristics and his apostolic labors. D. at Bamborough, opposite Lindisfarne, Aug. 31, 651. See his life by A. C. Fryer (Lond. 1884).

Aidé, HAMILTON: English poet, novelist, and army officer; b. at Paris in 1830 of Armenian parentage, and educated at Bonn. He has published some dozen of novels, including *Carr of Carlyon* (1862); *Poet and Peer* (1880); and *Passages in the Life of a Lady* (1887). Also several volumes of poems: *Eleanore* (1856); *The Romance of the Scarlet Leaf* (1865); *Songs Without Music* (1882), etc. Some of his songs have been set to music.

HENRY A. BEERS.

Aides-de-Camp: confidential officers selected by general officers to assist them in their military duties, are *ex-officio* assistant adjutants-general (act Mar. 2, 1821). They are in the U. S. service attached to the person of the general, and receive orders only from him. Their functions are difficult and delicate. Often enjoying the full confidence of the general, they are employed in representing him, in writing orders, in carrying them in person if necessary, in communicating them verbally upon battle fields and other fields of maneuver. It is important that aides-de-camp should know well the position of troops, routes, posts, quarters of generals, composition of columns, and orders of corps. It is necessary that their knowledge should be sufficiently comprehensive to understand the object and purpose of all orders, and also to judge in the varying circumstances of a battle-field whether it is not necessary to modify an order when carried in person, or if there be time to return for new instructions. (*Scott's Military Dictionary*.) The existing law of the U. S. allows 6 aides-de-camp (colonels) to the general; 2 and a military secretary (lieutenant-colonels) to the lieutenant-generals; 3 (captains or lieutenants) to a major-general; and 2 (lieutenants) to a brigadier-general. The singular is *aide-de-camp*.

Aidin', or **Guzel-Hissar** (anc. *Tral'les*): a town of Asiatic Turkey, in Anatolia, on the river Mender (Meander); about 68 m. S. E. of Smyrna, with which it is connected by railroad (see map of Turkey, ref. 6-D). It has a large trade, being next to Smyrna in commercial importance, and is the residence of a pasha. Here are several fine mosques and synagogues, and a flourishing Protestant mission. The ruins of the ancient *Tralles* are in the vicinity. Aidin is noted for its figs, great quantities of which are produced in the neighborhood, and many are exported. Pop. 30,000.

Aigne Belle, äg'bel': a small town of France in Savoy; on the left bank of the Arc and on the Mont Cenis R. R.; 15 miles E. of Chambéry (see map of France, ref. 6-I). Pop. about 1,100. Here the combined French and Spanish armies defeated Duke Charles Emmanuel III. of Savoy, in 1742. The road built by Napoleon over Mont Cenis commences near Aigne Belle.

Aigne Belle, PAUL ALEXANDRE NEVEUE, d': a French naval officer in the service of China; b. Jan. 7, 1831. He took part with the Franco-Chinese corps against the Tai-Pings, and took in 1864 the important city of Hang-Chow-Foo. He entered the Chinese service, was created a mandarin of the first rank, organized an important military arsenal at Fuh-Chow-Foo, and in June, 1869, he launched the first man-of-war of the new navy built on the European plan. He was then made grand admiral of the Chinese fleets, which title was expressly created for him.

Aignes-Mortes: a town of France; department of Gard; 19 miles from Nîmes (see map of France, ref. 8-G). Pop. about 4,000. The large saline works of Peccais are in the neighborhood. An interview between Francis I. of France

and the Emperor Charles V. took place here in 1538. Louis IX. embarked from this place on the seventh crusade, Aug. 25, 1248, and on July 4, 1270, on the eighth and last crusade.

Aiguillon, ARMAND VIGNEROT DUPLESSIS RICHELIEU, Duke of: French statesman; b. in 1720; was Governor of Alsace, and afterward of Brittany. He gained the favor of the king's mistress, Madame du Barry, and through her influence was made prime minister. Upon the accession of Louis XVI. he was removed from office and banished from court, and d. in 1782.

Aiguillon, ARMAND DE VIGNEROT DUPLESSIS RICHELIEU, Duc: son of the preceding; earnestly supported the popular cause in the States-General of 1789. He commanded one of the armies in 1792, but was proscribed by the ruling party the same year, and escaped by flight. D. in 1800.

Aijalon: See AJALON.

Aiken, ä'ken: capital of Aiken co., S. C. (for location of county, see map of South Carolina, ref. 6-D); on the South Carolina R. R., 120 miles W. by N. of Charleston; noted as a resort for invalids, especially those suffering from pulmonary complaints. Being situated on a plateau 600 feet above the level of the sea and 400 feet higher than the city of Augusta, which is 17 miles distant, and the soil being sandy and porous, the system of natural drainage is almost perfect, rendering the atmosphere peculiarly dry and elastic. The dew-point is invariably low. The climate is a mean between the dry, cold region of Minnesota and the moist, temperate section of Florida, and has proved efficacious in restoring health to thousands of invalids. Here are Aiken Institute, a classical school for white students, and the Schofield Normal School and the Immanuel Training and High School for the colored race. Pop. (1880) 1,817; (1890) 2,362; (1900) 3,414.

EDITORS OF "JOURNAL AND REVIEW."

Aiken, CHARLES AUGUSTUS, D. D., LL. D.: b. at Manchester, Vt., Oct. 30, 1827; graduated at Dartmouth College in 1846, and at Andover Theological Seminary in 1853; was pastor of a Congregational church in Yarmouth, Me., from 1854 to 1859; Professor of the Latin Language and Literature at Dartmouth from 1859 to 1866; Professor of Latin in the College of New Jersey from 1866 to 1869; president of Union College from 1869 to 1871; and became Professor of Christian Ethics and Apologetics in the Princeton Theological Seminary. He was one of the O. T. Company of Revisers of the A. V. of the Bible. He translated and edited the book of Proverbs in the American edition of Lange's *Commentary*, and published several articles in the *Bibliotheca Sacra* and *Princeton Review*, besides numerous critical notices of books. D. Jan. 14, 1892. Revised by GEORGE P. FISHER.

Aiken, WILLIAM: b. in Charleston, S. C., in 1806, graduated at South Carolina College in 1825. He was prominent in public affairs, was Governor of South Carolina (1844-46), and a Democratic member of Congress (1851-57). He was a man of great wealth, and owned Jehossee island, where he formerly employed 1,000 slaves in rice culture. He was noted while in public life for his wisdom and moderate views, and contributed largely to the cause of education and to benevolent objects. While in Congress (Feb., 1856) he lacked but three votes of becoming Speaker of the House of Representatives. D. Sept. 7, 1887.

Aikin, JOHN, M. D.: an English writer; b. in Leicestershire, Jan. 15, 1747. He produced, conjointly with his sister, Mrs. Barbauld, an instructive juvenile book called *Evenings at Home* (1792-95), which had great popularity. He practiced medicine in London and other places. Among his numerous works is a biographical dictionary, entitled *General Biography* (10 vols. 4to, 1815). He edited the *Monthly Magazine* (1796-1806). D. Dec. 7, 1822.

Aikin, LUCY: a daughter of John Aikin; b. Nov. 6, 1781; wrote, besides other works, a memoir of her father (1823), and *Life of Joseph Addison* (1843). D. Jan. 29, 1864.

Aikins, JAMES COX: Canadian statesman; b. in township of Toronto, Ont., Mar. 30, 1823; educated at Victoria College, Cobourg. Entering public life, he represented the county of Peel in the Canadian Assembly, 1854-61; was a member of the Legislative Council of Canada, 1862-67; became a member of the Privy Council in 1869; and was Secretary of State from that date till the resignation of the Macdonald Ministry, Nov. 5, 1873. He was reappointed to the same office, Oct. 19, 1878; became Minister of Inland Revenue, Nov. 8, 1880, which portfolio he resigned May 23, 1882. He was proclaimed a member of the Dominion Sen-

ate, May, 1867, and appointed Lieutenant-Governor of Manitoba and Keewatin, Dec. 22, 1882, an office he held until July 1, 1888.
NEIL MACDONALD.

Ailan'tus [Malay name said to mean tree of heaven]: a tree of the genus *Ailantus*, a native of China, having remarkably large pinnate leaves. It grows rapidly, and is often planted as an ornamental or shade tree in the cities of Europe and the U. S. The foliage is handsome, but it causes much annoyance by the rapid spread of suckers from the parent tree. The staminate flowers, which are borne on distinct trees, have an offensive odor that often produces headache and nausea. The female plants are free from this objection, and the clusters of winged fruit which they bear are quite ornamental, so that they should always be chosen for shade trees. Besides the above (*Ailantus glandulosus*), there are several other species, chiefly tropical. They belong to the family *Simarubaceæ*.

Ailantus Silkworm: the *Attacus cyn'phia*; so named from its feeding on the leaves of the ailantus tree. The silk obtained from this worm is extensively used in China. The eggs are hatched in a manner similar to that in which the eggs of the common silkworm are hatched, and the larvæ, after being fed through their first moult with picked leaves, are transferred to the trees and there left.

Ailantus silkworm.

vaulx, Yorkshire; b. at Hexham, in England, in 1109; educated in Scotland. He wrote numerous sermons, histories, and other works, part of which were edited by Twisden (1652), by Camerarius (1631), and by one Gibbon (Douai, 1631). D. Jan. 12, 1166.

Ail'sa Craig: an islet in the estuary of the Clyde, 10 miles from the coast of Ayrshire, Scotland (see map of Scotland, ref. 14-E). It is a crag of trap-rock of a somewhat columnar character. It is 1,139 feet high, and is not inhabited except by a rabbit catcher and the lighthouse keeper. It gives title to the Marquis of Ailsa, its proprietor.

Ailu'rus ["having a waving tail," like that of a cat; from Gr. *αἶλος*, quickly moving or waving, and *οὐρά*, a tail]: a genus of carnivorous animals of the family *Procyonidæ*. The *Ailurus fulgens*, allied to the raccoon, is found in the mountains of Nepal. By the inhabitants of that country it

Ailurus fulgens.

is termed *panda*, *chitwa*, and *wah*, the last name having been given it on account of its peculiar cry. It is about the size of a large cat, and is remarkable for its singularly rich and beautiful fur, which is mostly of a bright chestnut brown, but deepens into a fine rich black on the chest and outside of the legs. It has a short head and a thick muzzle. The head is of a whitish fawn color, with a ruddy chestnut spot under each eye. The tail is of the same color as the body, being marked with a series of dark rings. "The coat of the panda is not only handsome in appearance, but is very thick, fine, and warm in texture, being composed of a double set of hairs—the one forming a thick, woolly covering to the skin, and the other composed of long, glistening hairs that pierce

through the wool and give the exquisitely rich coloring to the surface of the fur." Cuvier regarded the panda as the most beautiful of known quadrupeds. These animals live among rocks and trees at a considerable elevation in the Himalaya mountains. Their food is chiefly fruit and other vegetable substances.
Revised by D. S. JORDAN.

Aimard, ay-maar', GUSTAVE: French novelist; b. Sept. 13, 1818; came to the U. S. at an early age, and after a stay of ten years went through Southern Europe and Eastern Asia. Among his works are *Les Trappeurs de l'Arkansas*; *Les Aventuriers*; *L'Araucan*, etc. D. Apr. 30, 1883.

Aimorés, or **Aymorés**: See BOTOCUDOS.

Ain, añ: a department of Eastern France; bounded N. by the departments of Saône-et-Loire and Jura, E. by Haute Savoie, on the S. by Isère, and W. by Rhône and Saône-et-Loire. Area, 2,239 sq. miles. The department is watered by the Rhône and the Saône, which flow along its boundaries, and by the Ain. The western part consists of a large plateau, which is very fertile. In the E. large mountain ranges prevail, which contain iron, asphaltum, and the best lithographic stones in France. Pop. (1896) 351,569. Chief town, Bourg-in-Bresse.

Ain-müller, MAXIMILIAN EMANUEL: German painter; b. at Munich, Feb. 14, 1807; noted as the restorer of the art of painting on glass. Among his works are the windows of the cathedrals of Ratisbon and Cologne. D. Dec. 8, 1870.

Ainos, ī'nōz: the aboriginal inhabitants of Japan, now found only in Yezo, Saghalin, and the Kurile islands, whither they have been driven by the advance of the Japanese, who seem to have entered the country from the S. W. Though mentioned in Japanese history as "barbarians," they are of a mild and amiable disposition. Their chief occupations are hunting and fishing. They have Caucasian features, are low of stature but strongly built, and are in general very hairy. They are fetishists, and are in a low state of civilization. In Yezo, however, they are being gradually civilized by Japanese schools and arts; their number is less than 15,000. Very complete vocabularies of their language (which is quite distinct from Japanese) have been compiled, but the affinities of the language have not been determined. See Miss Bird's *Unbeaten Tracks in Japan* (1880); Chamberlain's *Aino Studies*; Batchelor, *The Ainu of Japan; Religion, Superstitions, and General History of the Hairy Aborigines of Japan* (1892).
R. LILLEY.

Ainsworth, ROBERT: an English classical scholar; b. near Manchester in 1660; taught school in London. He published a well-known Latin dictionary (1736). D. April 4, 1743.

Ainsworth, WILLIAM HARRISON: English novelist; b. in Manchester, Feb. 4, 1805. He published *Rookwood* (1834) and *Jack Sheppard* (1839), the latter of which had an extraordinary success; *The Tower of London* (1840), etc. In 1845 he became the proprietor of the *New Monthly Magazine*. His numerous stories, largely historical in subject, have had great popularity. D. Jan. 3, 1882.

Aintab, in-taab': a town of Asiatic Turkey; on the south slope of Mt. Taurus or Alma-Dagh; about 60 miles N. of Aleppo and 92 miles N. E. of Antioch (see map of Turkey, ref. 6-H). It is well built, and has manufactures of leather, woolen cloths, etc. A flourishing mission among the Armenians of this town has been maintained for years by Protestant missionaries from the U. S. Pop. estimated at 20,000.

Air [O. Fr. *air* < Lat. *aer*, -is, from Gr. *ἀήρ*]: considered an element by the ancient philosophers, but now known to be a mixture of oxygen and nitrogen with some other gases. See ACOUSTICS, ATMOSPHERE, BAROMETER, PNEUMATICS, METEOROLOGY, NITROGEN, etc.

Air (in painting): See AËRIAL PERSPECTIVE.

Air: an oasis in the Sahara. See ASBEN.

Air-Bladder, or **Swim-Bladder**: an organ in fishes consisting of a large sac filled with air, which enables them to modify their specific gravity by increasing or diminishing the volume of air in the bladder. This air is largely composed of nitrogen, and is obtained by secretion from the walls of the bladder. It is the homologue of the lungs of air-breathing animals. Both air-bladder and lungs are supposed to be derived from the cellular air-bladder found in the more generalized ganoid fishes. Many fishes are destitute of air-bladders. In others the organ has a highly complex structure.
Revised by D. S. JORDAN.

Air-Cells: in birds, are closed sacs connected with the lungs and distributed over the inside of the chest and abdomen. The bones also contain air-spaces communicating with the air-sacs, the arrangement serving to lessen the weight of the body and adapt the bird for flight. Air-cells in plants are spaces in the cellular tissue, containing air. They occur chiefly in aquatic plants. Revised by D. S. JORDAN.

Airdrie, ā'r'dri: a market-town and parliamentary borough of Lanarkshire, Scotland, 11 miles E. by N. of Glasgow, with which it is connected by railway (see map of Scotland, ref. 12-G). It is well built and lighted with gas. Mines of iron and coal are worked in the vicinity. Pop. 16,335.

Air-Engine: See HOT-AIR ENGINE.

Aire-sur-l'Adour, ā'r'-sūr-la-door': an old French town in Landes, on the river Adour; 20 miles S. E. of Mont de Marsan (see map of France, ref. 8-D); the seat of a bishop, has a cathedral and a college. It was once the capital of the Visigoth kings. Pop. about 5,000.

Air-Gun: an instrument for projecting bullets or other missiles by means of the elastic force of condensed air. A strong reservoir of metal is constructed into which air is forced by a condensing-syringe. The reservoir may be of any form, but it is most conveniently disposed of by placing it within the stock. The bullet should fit the barrel very exactly, so as to leave no windage. On pulling the trigger, the condensed air escapes through the valve and rushes with violence into the barrel, propelling the bullet before it; and the instant the finger is withdrawn from the trigger the valve is closed by the pressure of the air in the magazine, which remains in a somewhat less condensed state for the next discharge. Thus the same supply of air in the magazine will serve for several successive discharges, but the force becomes weaker and weaker after each. The force with which a projectile is propelled from an air-gun is commonly much less than that produced by an ordinary discharge of gunpowder, but they may be so made as to be very formidable weapons.

Airlie, ā'r'li, EARLS OF: Barons Ogilvy of Airlie (1491), Barons Ogilvy of Alyth and Lintrathen (1639, in the Scotch peerage), a prominent family of Great Britain. The first Earl of Airlie was created in 1639.—DAVID GRAHAM DRUMMOND OGILVY, the tenth earl, was born May 4, 1826, and succeeded his father in 1849.

Air-Plants: certain epiphytic tropical plants, which hang in festoons from forest trees, and are able to live suspended in the air. The family of *Orchidaceæ* furnishes many beautiful specimens of air-plants. Air-plants must be distinguished from parasites, like the mistletoe, which feed on and not merely grow on trees, etc. Revised by C. E. BESSEY.

Air-Pump: a machine for the production of a vacuum, or sometimes for the compression of a gas. The vacuum-pump was invented by Otto von Guericke, about 1650. The essential parts of the ordinary air-pump are similar to those of suction-pumps for water (see PUMP), but the capacity of the cylinder is relatively larger, and the valves are constructed with special reference to delicacy of action. All air-pumps with valves cease working before the vacuum is complete. Even where leakage is successfully eliminated, a point is reached at which the valves become inactive. The vacuum attained by means of mechanical pumps is probably rarely as good as $\frac{1}{1000}$ of an atmosphere. By means of various forms of the mercurial air-pump, however (see VACUUM), it has been found possible to reduce the pressure to less than $\frac{1}{100000}$, and, by means of extraordinary precautions, to about $\frac{1}{20000000}$ of an atmosphere. (See PNEUMATICS.) For detailed descriptions of various types of the mechanical air-pump, see Deschanel's *Natural Philosophy*, Part I., pp. 179-203. E. L. NICHOLS.

Air'y, Sir GEORGE BIDDELL, K. C. B., LL. D., D. C. L., F. R. S.: astronomer and physicist; b. at Alnwick, Northumberland, June 27, 1801; educated privately, and at the Colchester Grammar School; entered Trinity College, 1819; elected a fellow, 1822; and graduated B. A. in 1824, being senior wrangler. In 1826 he became Lucasian Professor of Philosophy, and in 1828 Plumian Professor of Astronomy. In 1835 he was appointed astronomer-royal, and was in charge of the Greenwich Observatory until Sept., 1881, when he retired with a pension of £1,100 per annum. Dr. Airy attained a very high rank as an astronomer and physicist, and wrote much upon weights, measures, coinage, railways, and other kindred subjects. He made important improvements in astronomical and philosophical instruments.

He devised the system now in common use for the correction, by means of magnets, of the disturbances of the compass in iron-built ships. He wrote the article *Gravitation* in the *Penny Cyclopædia*, and *Trigonometry, Figure of the Earth*, and *Tides and Waves* in the *Encyclopædia Metropolitana*; also *Mathematical Tracts*; *Ipswich Lectures on Astronomy*; *Errors of Observation*; treatises on *Sound, Magnetism*, etc.; besides very numerous and important monographs and papers for periodicals. He conducted the astronomical operation connected with the definition of the boundary between the U. S. and Canada, and was employed in tracing the Oregon boundary. From the universities of Edinburgh, Cambridge, and Oxford he received the honorary degrees of D. C. L. and LL. D.; was a Fellow of the Royal Society, and its president for two years; and was made a Knight Commander of the Bath, July 30, 1872. D. in London Jan. 4, 1892. R. LILLEY.

Aisne, ān: a river of the N. part of France; rises in the department of Meuse; flows nearly westward, passes by Soissons, and enters the Oise near Compiègne. Length about 85 miles; navigable 44 miles. The canal of Ardennes connects it with the Meuse.

Aisne: a department in the north of France; bounded N. by the Nord department, E. by Ardennes and Marne, S. by Seine-et-Marne, and W. by Oise and Somme. Area, 2,839 sq. miles. It is traversed by the Oise, the Aisne, and the Marne rivers. The soil is fertile, and the manufacturing industry in this department is very large. Wheat and hay are among the staple productions. It is subdivided into 5 arrondissements, 37 cantons, and 841 communes. Chief town, Laon. Pop. (1881) 556,891; (1891) 545,493; (1896) 541,613.

Aist, DIETMAR, von: one of the earliest German minnesingers. An Austrian by birth, whose name is mentioned during the years 1143-70. Few of his beautiful songs were preserved. See *Des Minnesangs Frühling*, Lachmann u. Haupt. JULIUS GOEBEL.

Aitken, Sir WILLIAM, M. D., LL. D., F. R. S.: physician; b. Apr. 23, 1825, in Dundee, Scotland; M. D., University of Edinburgh, 1848; Demonstrator of Anatomy, University of Glasgow, 1848-55; volunteered for hospital service in Turkey during the Crimean war; appointed Professor of Pathology in the Army Medical School, 1860; knighted at the Queen's Jubilee, 1887. Author of numerous published papers on pathology and the science of medicine. C. H. THURBER.

Aitken, Rev. WILLIAM HAY MACDOWALL HUNTER: Church of England "missioner"; b. in Liverpool, Sept. 21, 1841; educated at Oxford; ordained in 1867. After a brief incumbency in Liverpool, Mr. Aitken has devoted himself to the superintendency of the Church of England Parochial Mission Society, which he founded in 1877 to supply trained mission preachers for evangelistic work. He conducted a successful "mission" in New York city in the winter of 1885. He has published *Mission Sermons* (3 vols., 1875-76); *Newness of Life* (1877); *What is your Life?* (1878); *The School of Grace* (1879); *The Highway of Holiness* (1883); also, *Difficulties of the Soul* (1879); *God's Everlasting "Yea"* (1881); *The Glory of the Gospel* (1884); *Around the Cross* (1884); *The Revealer Revealed* (1885); *The Love of the Father* (1887); *Eastertide* (1889). W. S. P.

Aiton, WILLIAM: botanist; b. in Scotland in 1731; director of botanical garden at Kew, England, 1759-93; published *Hortus Kewensis*, a catalogue of plants in the Royal Botanical Garden at Kew. D. in 1793.

Aitze'ma, LIEUWE, van: Dutch historian; b. at Docum in 1600; served for many years in the Dutch diplomatic service; wrote a *History of the Netherlands from 1621 to 1668*. D. in 1669.

Aix, āks (anc. *A'quæ Sextiæ*): a city in the S. E. part of France; department of Bouches-du-Rhône; 33 miles by rail N. of Marseilles (see map of France, ref. 8-H). It was formerly the capital of Provence, and was a celebrated seat of learning in the Middle Ages. It is the seat of an archbishop, has a fine cathedral, a city hall (hôtel de ville), a museum, a royal college, and a public library containing about 100,000 volumes. Here are manufactures of silk and cotton, and warm mineral springs, from which it derived its ancient name. Pop. (1881) 29,257; (1896) 28,913.

Aix-la-Chapelle, āks-la-sha-pel' (in Lat. *A'quis Granum*; Ger. *A'chen*): a city of Rhenish Prussia; on the frontier of Belgium; and on the railway which connects Liège and Cologne, 44 miles by rail W. S. W. of the latter

(see map of German Empire, ref. 5-C). It was once famous, and the capital of the empire of Charlemagne, who made it his favorite residence. It is a well-built, handsome city, with a cathedral founded in 796 A. D., a large town-hall, an elegant theater, a public library, and several hospitals. Here are celebrated mineral springs, the temperature of which is about 112° F. They are considered efficacious for the cure of the gout, rheumatism, and cutaneous diseases. This city has important manufactures of fine broadcloths, needles, and pins. The cathedral contains the tomb of Charlemagne and a collection of relics, which attract a multitude of visitors. The successors of Charlemagne and the Emperors of Germany were crowned here from the ninth century until 1531. Pop. (1895) 110,551.

Aix-la-Chapelle, CONGRESS OF: a congress held in 1818 for settling the affairs of Europe after the war of 1815. The King of Prussia and the Emperors of Russia and Austria were present in person. The different representatives were Metternich, Wellington, Castlereagh, Hardenberg, Bernstorff, Nesselrode, and Capo d'Istrias, with Richelieu on behalf of France. Their deliberations resulted in the withdrawal from French territory of the army of occupation, and prepared the way for what was afterward known as the "HOLY ALLIANCE" (q. v.).

Aix-la-Chapelle, TREATIES OF: I. *Treaty of 1668*. This treaty was concluded May 2, 1668, between Louis XIV. of France on the one side and the "Triple Alliance," including England, Sweden, and Holland, on the other. At the death of Philip IV., Louis laid claim, in the name of his wife and under the laws of succession of Brabant and Namur, to a large portion of the Spanish Netherlands. He had already seized several strongholds and fortresses, when Holland, becoming alarmed at his rapid progress, concluded the triple alliance with England and Sweden. Louis, rather than resort to a war against so powerful a league, determined to accept mediation; and a treaty of peace was concluded at Aix-la-Chapelle, by which France retained possession of Charleroi, Valenciennes, and other strong towns, which she had already seized.

II. *Treaty of 1748*. This treaty ended, in 1748, the Austrian war of succession, in which all the great powers of Europe were, either on one side or the other, engaged. Several German princes had disputed the claim of Maria Theresa to the throne of Austria, and from this cause the war arose. It lasted with various success for eight years (from 1740 to 1748), at the end of which time a peace was concluded which left the different states with nearly the same possessions as before.

Aix-les-Bains, āks'lā-bān': an attractive and fashionable bathing-resort in Savoy, France. It is in the mountains, about a mile from the picturesque Lake Bourget, 90 feet above the lake and 823 above the sea (see map of France, ref. 6-H). It is easy of access, and the accommodations are good. The season is from May to September. The climate is usually mild, but it is sometimes very hot in summer. About 25,000 people underwent treatment here in 1883. The springs are sulphurous; their temperatures range from 113° to 115° F.; and they yield 1,320,000 or more gallons daily. The diseases treated are rheumatism, gout, eczema, neuralgia, catarrh, throat diseases, constitutional syphilis, and scrofula. The waters are administered internally and externally. Pop. (1896) 8,328.

Aizani, ī-zaa'nee: an ancient town of Asia Minor, now in ruins. Among its ruins, the theater, with accommodations for over 12,000 spectators, is in a fine state of preservation.

Ajaccio, a-yaat'chō, or **Ajazzo**, a-yaāt'sō: a seaport; capital of Corsica; on the west coast; lat. 41° 54' N., lon. 8° 44' E. (see map of France, ref. 2-J). It has a good port defended by a citadel. It has also a cathedral and a library of 18,000 volumes. Wine and olive oil are exported from this town. Napoleon Bonaparte was born here on Aug. 15, 1769. A magnificent monument, representing the Emperor Napoleon I., surrounded by his four brothers, was finished in 1865. Pop. (1886) 17,576; (1896) 20,561.

Ajalon: a town of Palestine belonging to the Levites, in the land of Dan. It was probably on the spot now occupied by the village of Yālo. Over the valley in which this town was situated the moon stood still while Joshua pursued the five kings.

A'jax (Gr. *Aias*): surnamed THE GREATER; the son of Telamon, a Grecian hero; was King of Salamis. He acted a

prominent part at the siege of Troy, and exceeded the other Greek warriors in strength and stature. Having been defeated by Ulysses in a competition for the armor of Achilles, he became insane and killed himself.

Ajax: the son of Oileus; surnamed THE LESSER, to distinguish him from Ajax the son of Telamon; was King of Locris. He was one of the Greek heroes that fought at the siege of Troy, and excelled all the Greeks in swiftness, except Achilles. For offending Minerva by his impiety, he was drowned on his homeward voyage from Troy.

Ajmir, or **Ajmere**, aj'neer', or **Rajputana**: a city of British India; capital of a division and a district of the same name; 220 miles S. W. of Delhi, and situated in a picturesque valley (see map of N. India, ref. 6-C). It contains several massive temples and mosques; also an English and Oriental school. Pop. (1891) 67,880.

Ak'abah: a fortified village of Arabia, near the north extremity of the Gulf of Akabah. See ELATH.

Akabah, GULF OF (anc. *Sinus Elanites*): portion of the Red Sea, lying in the northwest part of Arabia; bounded W. by the peninsula of Sinai. It is about 100 miles long, from 12 to 17 miles wide, has high and steep shores and numerous coral reefs.

Ak'bar, or **Ak'ber** (written also ACBAR and ACKBAR), **Mohammed**, surnamed JALĀL-ED-DEEN: a famous and excellent Mogul emperor; b. at Amerkote, in the valley of the Indus, in 1542. He was a son of Humāyun, whom he succeeded in 1556. He displayed great military talents and political wisdom, and extended his dominions by the conquest of Bengal and part of the Deccan. Under his reign the Christians and Jews were tolerated and protected. He encouraged literature and promoted commerce. He ordered a complete survey and census of his empire, the result of which, with minutely detailed statistics, was recorded in a book called *Ayin Akbery* (institutes of Akbar), which is very celebrated. Akbar was greatly distinguished for his justice, humanity, and magnanimity. He died in 1605, and was succeeded by his son Selim, surnamed Jehāngir.

Aken, aa'ken: a town of Prussia; province of Saxony, on the left bank of the Elbe; 24 miles S. E. of Magdeburg; has factories of beet-sugar and chemicals (see map of German Empire, ref. 4-F). Pop. 5,571.

A'kenside, MARK, M. D.: English didactic poet; b. at Newcastle-on-Tyne, Nov. 9, 1721; studied medical sciences at Edinburgh, graduated as M. D. at Leyden in 1744, and practiced in London, where he settled in 1748. His reputation is founded chiefly on *The Pleasures of the Imagination*, in blank verse (1744), which was received with great favor. He wrote several shorter poems and medical treatises. His *Treatise on Dysentery* (in Latin, 1764) proved him to be an excellent classical scholar. He was appointed a physician to the queen in 1760. D. June 23, 1770.

Akerblad, JOHAN, DAVID: Swedish antiquary and Orientalist; b. in 1760. He visited Jerusalem in 1792, and the Troad in 1797; gained distinction by deciphering the demotic writing of ancient Egypt; and wrote a *Letter on the Egyptian Inscription of Rosetta* (1802). D. Feb. 8, 1819.

Ak'erman, AMOS TAPPAN: attorney-general of the U. S. (1870-72) under Gen. Grant; b. in New Hampshire, Feb. 23, 1821, but for fourteen or fifteen years previous to his appointment had been a citizen and practicing lawyer of Georgia. He sided with the Confederates in the civil war, but after the surrender of the Southern arms he advocated the sanction of the reconstruction measures of Congress; was a member of the State convention of 1867-68, and acted a prominent part in shaping the new Constitution formed by that body. D. Dec. 22, 1880.

Akers, BENJAMIN PAUL, commonly known as *Paul Akers*: sculptor; b. at Saearappa, Me., July 10, 1825; studied in Boston and at Florence (1852), and spent some years in Italy, where some of his works were executed, but generally lived and practiced his art in the U. S., most of his work being portrait busts and medallions. D. May 21, 1861.

Akhaltikh, Akalzik, āā-kaāl-tseek', or **Akis'ka**: city of Asiatic Russia; in Georgia; on an affluent of the Koor, about 92 miles W. of Tiflis (see map of Russia, ref. 12-F). It contains a mosque and several churches, and has some trade in silk and honey. Many of the inhabitants are Armenians. The Russians defeated the Turks near this place in 1828, and it was ceded to Russia in 1829. Pop. 18,270.

Ak-Hissar, *āk'his-saar'* (i. e. white castle), written also **Ek-Hissar** (the ancient *Thyat'ira*): a town of Asia Minor; in Anatolia, 53 miles N. E. of Smyrna (see map of Turkey, ref. 5-D). It contains no ancient buildings, the houses being mostly of mud. Pop. about 10,000, two-thirds of whom are Turks.

Akhlāt': a town of Armenia, in Asiatic Turkey; on the N. W. shore of Lake Van; 203 miles S. E. of Trebizond. It was formerly the seat of the Armenian kings, and is at present the seat of an Armenian bishop (see map of Turkey, ref. 5-I). Pop. about 4,000.

Ak'iba, BEN JOSEPH: Jewish rabbi, of great learning and influence; president of the school of Bene Barak in the second century A. D. Having joined the rebellion of Barchochebas, he was flayed and burned by the Romans in the year 135 A. D.

Ak'ka: a dwarf race of Central Africa. See PYGMY.

Akkadians: See SUMERIANS.

Ak'kerman: fortified town of Bessarabia; on the right bank of the Dniester; about 4 miles from the Black Sea, and 28 miles S. W. of Odessa. Lat. $46^{\circ} 12' N.$, lon. $30^{\circ} 22' E.$ (see map of Russia, ref. 10-C). It has a port, several mosques and Greek and Armenian churches, numerous factories, and an extensive trade in salt, etc. A treaty concluded at Akkerman on Sept. 4, 1826, exempted the Danubian provinces from all but a nominal dependence on Turkey. Pop. (1887) 41,178.

Ak'kra, or **Ae'era**: town of Africa; capital of the British Gold Coast colony; situated in about lat. $5^{\circ} 30' N.$ and lon. $0^{\circ} 12' W.$ (for location, see map of Africa, ref. 5-C). It has a population of 16,276, and is one of the most healthful points on the coast.

Akmol'insk: a province of Russia; in Central Asia; S. of the government of Tobolsk. Area, 229,609 sq. miles. It consists of a plateau, in the N. level, and in the S. mountainous, having very little rain. It is frequently visited by heavy snow-storms. Pop. (1897) 683,721. Chief town, Ak-molinsk.

Akragas: the Greek name of the city called by the Romans Agrigentum. See GIRGENTI.

Akron: village (incorporated in 1850) in Erie co., N. Y. (for location of county, see map of New York, ref. 4-C); situated on the West Shore R. R., and on B. and T. branch of N. Y. C. and H. R. R. R.; 25 miles from Buffalo. It has 6 churches, a public school with an academic department, 2 hydraulic cement works, a flouring-mill, a stave and heading mill, and a saw and planing mill. Pop. (1880) 1,036; (1890) 1,492; (1900) 1,585.

EDITOR OF "BREEZE."

Akron: city; railroad center, and capital of Summit co., O. (for location of county, see map of Ohio, ref. 3-H); on the Ohio Canal, 36 miles S. of Cleveland, on the highest point of land between Lake Erie and the Ohio river. It has a variety of manufactures, employing 6,500 hands; annual value of products, \$15,000,000; a beautiful cemetery, a public library, a high school, water-works, electric light, street-cars, etc., and is the seat of Buchtel College. Pop. (1870) 10,006; (1880) 16,512; (1890) 27,601; (1900) 42,728.

EDITOR OF "DAILY BEACON."

Akshehr' (i. e. white city): a city of Asiatic Turkey; in the vilayet of Konia. It is on the route from Constantinople to Syria, and has an important trade. Pop. 15,000. It is the ancient *Philomelion* of Strabo.

Ak'su: a town of East Turkestan, on a river and in a province of its own name; 250 miles N. E. of Yarkand (see map of Asia, ref. 5-E). It has manufactures of woolen stuffs and jasper, and is visited by many caravans from all parts of Central Asia. Pop. 60,000 or more.

Akyab': a town of Burma, at the mouth of the Aracan river; 550 miles S. E. of Calcutta. Its situation is healthful and very advantageous for commerce, with a commodious and safe harbor. It has a large trade, especially in rice, large quantities of which are exported hence (see map of S. India, ref. 2-K). Pop. 34,000, mostly Bengalese and Chinese. Here is a Protestant missionary station.

Al: the Arabic definite article, forms a prefix to many Oriental names, as Al-Mansur, the victorious; Al-Amin, the faithful, etc., and found in English in many words of Arabic origin: e. g. *algebra*, *alcohol*, *almanac*, etc.

A'la, wing: a Roman military term, denoting the wing of an army. At first, when the whole legion consisted of Roman citizens, it was applied to the body of horsemen who served with the foot-soldiers, but after the admission of *socii*, whether Latini or Itali, it was applied to the troops of the allies, both horse and foot, which were stationed on the wings. At a still later time the *alæ* were composed of foreign troops serving with the Roman armies; while under the empire the term was given to bodies of horsemen raised generally in the provinces, and serving apart from the legion. See WING.

Alaba'ma: a river of the U. S.; formed by the Coosa and the Tallapoosa, which unite about 10 miles above Montgomery, in Alabama. It flows nearly westward to Selma, and afterward in a general S. W. direction, and unites with the Tombigbee to form the Mobile river. It is navigable for large steamboats through its whole extent, which is about 300 miles. It traverses a fertile region, of which cotton and maize are the staple products.

Alabama (signifying, in the Creek language, Here we rest): one of the S. or Gulf States of the U. S., lying between the parallels of $30^{\circ} 15'$ and $35^{\circ} N.$ lat., and the meridians of $84^{\circ} 56'$ and $88^{\circ} 48' W.$ lon. from Greenwich. Length from N. to S., 336 miles; breadth, from 148 to 200 miles. Bounded on the N. by Tennessee, E. by Georgia and Florida, S. by Florida and the Gulf of Mexico, W. by Mississippi. Area, 52,250 sq. miles, or 33,440,000 acres.

Alabama, by census of 1900, ranked seventeenth among the States in population, sixteenth in value of agricultural products, and the value of manufactures was greatly increased.

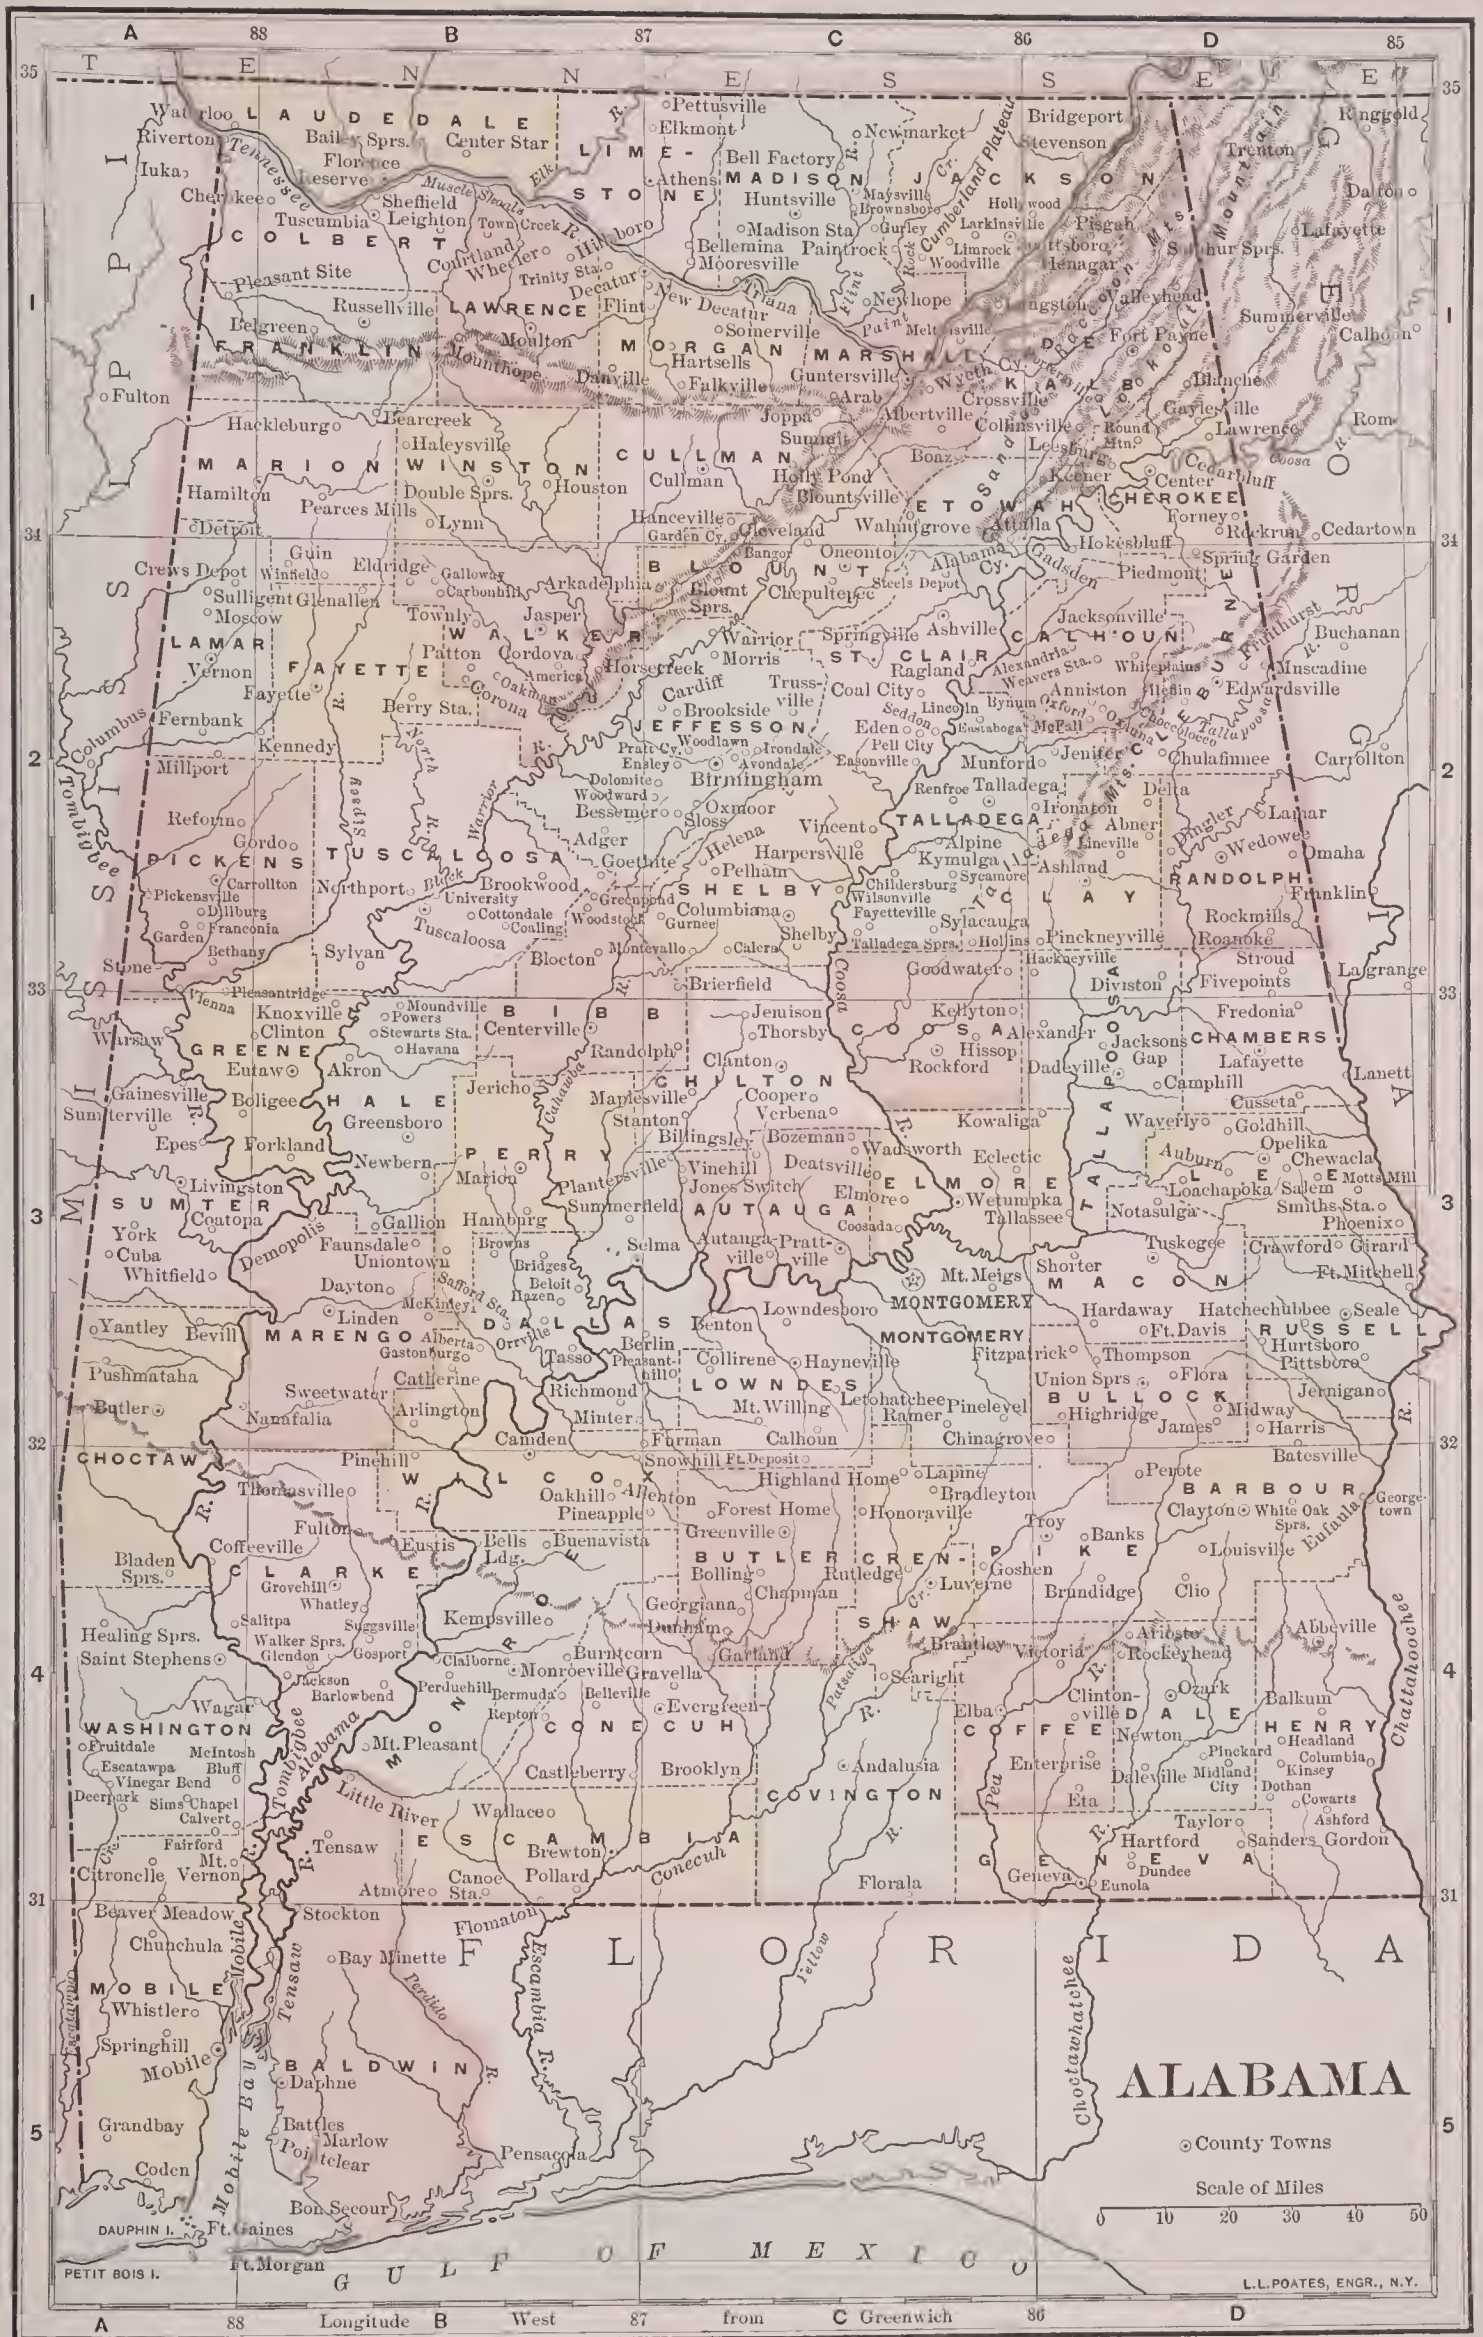

Surface, Rivers, etc.—In the N. broken and hilly, from outlying hills of the Blue Ridge; S. of this almost level, but gently declining to the Gulf. Principal rivers are Tennessee, near N. line of the State, Mobile, Tombigbee, Alabama, Coosa, Black Warrior, Tensaw, Perdido, and Chattahoochee, and their affluents. Of these, the Tennessee, Tombigbee, Black Warrior, Alabama, Tensaw, Chattahoochee, and Perdido are navigable. Mobile bay is the principal bay of the State, Grand, Bonsecours, and Perdido bays being shallow.

Soil.—The soil is divisible into three belts or sections—viz. 1. The S. section, one-fifth of the State, a light but productive alluvial and diluvial soil, yielding moderate crops of corn, cotton, and fruits, with considerable forests of yellow pine. 2. The cotton belt, limestone and chalk lands, mostly prairie, producing good cotton and corn. 3. The N. section, a mineral region, yielding gold, coal, iron, etc., some of it poor and hilly land, but healthy and with good water-power. In this region also is the great Tennessee valley, with fine fertile side valleys yielding cotton, corn, cereals, and fruits, while the hillsides are well adapted to grazing.

Minerals.—Of gold discovered in Randolph County, 1836, there had been deposited in the Mint to June, 1891, \$235,335. There are also mined in the State silver, copper, lead, iron ores of various kinds, and excellent bituminous coal; 7,593,416 tons of coal were mined in 1899; 2,662,943 tons of iron ore were mined in 1899, Alabama ranking as third in amount of production in the U. S. There are many rarer minerals, mineral earths, building-stones, and also mineral springs.

Vegetation.—The forests in the N. belong to the temperate, in the S. to the semi-tropical, zone. Five species of oak, hickory, chestnut, poplar, cedar, elm, mulberry, and white pine in the N. are replaced in the S. by cypress, live-oak, yellow pine, magnolia, and loblolly, with brake or American bamboo, saw-palmetto, etc. The apple, pear, plum, and hardy peach give place to the fig, pomegranate, olive, apricot, scuppernong grape, and orange.

ALABAMA

County Towns

Scale of Miles

L.L. POTATES, ENGR., N.Y.

A 88 Longitude B West 87 from C Greenwich 86 D

Zoölogy.—The wild animals common to the W. and S. W. are found here. The alligator inhabits the rivers and bayous, and there are lizards, some venomous snakes, terrapin, turtles, and excellent fish, and most game-birds, also birds of prey, songsters, and birds of exquisite plumage.

Climate.—Temperature in Northern Alabama delightful, frosts rare, and no intense heat. In Central Alabama, greater heat, but cool nights; occasional frosts. In the S., protracted heat, but good breezes, cool nights, and heavy dew. Rain-fall from 48 to 54 inches. Water in the N. excellent; in the S. poor.

Agricultural Productions.—Cotton is the largest crop, the State ranking, in 1899, fourth in cotton production, and fourth in number of acres cultivated. Alabama was eighth among Southern States in production of corn, but other cereal crops were small. Some cane-sugar and molasses, and more sorghum sirup, are made. Ramie is grown in the S. counties. Average wages of farm labor, 1890, \$14, or with board, \$9.85 per month. The number of farms has doubled in the last decade, but nearly half are rented. Of the farms, eight-tenths are under 100 acres. The crop returns of 1899 exhibit a product of 1,176,042 bales of cotton; corn 33,015,120 bush.; wheat, 431,186 bush.; oats, 3,012,070 bush.; hay, 82,746 tons; other agricultural products were of minor importance.

*Farm Animals.**—In 1899 there were reported 133,546 horses, 132,321 mules, 279,278 cattle, 171,799 sheep, and 231,802 milch cows.

Manufactures are now large, and increasing; lumber, iron, steel, machinery, and cotton goods are the principal articles produced. The production of pig-iron in 1899 was 1,083,905 tons. The census of 1880 reported 2,070 manufacturing establishments, employing 10,019 persons, and that of 1890 reported 2,977 establishments, with \$46,122,571 capital.

Railroads.—In 1886 there were 2,105 miles of railroad in the State, and in 1899 4,023.82 miles. The recent growth of the railway system has been rapid and important.

Finances.—State debt, \$9,249,900, at 4 and 5 per cent. Taxable property assessed for the year 1900, \$266,243,170. Amount raised by taxation for State purposes, \$1,469,676.29. The receipts for the seven months ending Apr. 30, 1900, were \$2,243,191.53, and the disbursements \$1,428,179.28.

Commerce.—Mobile is the only port of entry. Imports for the seven months ending Jan., 1901, \$1,584,164; exports, mostly cotton, \$7,187,165. The number of vessels entering the port was 182; tonnage, 47,376 tons. The number which cleared was 209; tonnage, 36,445.

Banks and Insurance.—There were, Sept. 5, 1900, 28 national banks in operation; capital, \$3,480,000; surplus and undivided profits, \$1,393,640.52; deposits, \$10,938,390.23; outstanding circulation, \$1,717,210. June 30, 1900, there were 20 State banks; capital, \$1,546,500; surplus and profits, \$393,384; deposits, \$4,588,607. Total banking capital, \$5,026,500; total deposits, \$15,526,997.23. The insurance, both life and fire, is mostly in the hands of foreign companies.

Education.—The total expenditure for school purposes in 1898-99 was \$800,273; revenue, \$916,450; value of school property, \$1,500,000. There were 7,058 schools; 7,303 teachers—2,262 male, 5,041 female; average monthly salaries: male, \$32.04; female, \$25.35. There were 634,061 children of school age; enrolled in public schools, 433,733; average daily attendance, 341,138; enrolled in private schools, 26,722. Average number of days school was held, 100; average expenditure per pupil, based on daily attendance, \$3.59. There were 6 universities and colleges with 1,441 students; 41 seminaries, academies, and schools of secondary instruction, with 5,336 students. There were 7 public normal schools, with 77 instructors and 975 students. There were 3 schools of theology, 1 of law, and 1 of medicine, and a State agricultural and mechanical college.

Libraries and Newspapers.—There are 41 public libraries of over 300 volumes, aggregating 95,303 volumes in all, numerous college and school libraries, and many private libraries, having in all nearly 600,000 volumes. In 1900 there were in Alabama 238 newspapers and periodicals, including 19 dailies.

Churches.—The Baptists are the leading denomination, but are followed by the others in the following order: Methodists, Presbyterians, Episcopalians, Disciples or Christians, Roman Catholics, Congregationalists, and minor denominations.

Population of Alabama in 1820 was 127,901; (1830) 309,527; (1840) 590,756; (1850) 771,623; (1860) 964,201; (1870) 996,992; (1880) 1,262,505; (1890) 1,513,017; and (1900) 1,828,697.

Principal Towns and Population, 1900.—Montgomery, the capital, 30,346; Mobile, 38,469; Birmingham, 38,415; Anniston, 9,695; Selma, 8,713; Huntsville, 8,068; Florence, 6,478; Bessemer, 6,358; Tuscaloosa, 5,094; Eufaula, 4,532; New Decatur, 4,437; Gadsden, 4,282; Opelika, 4,245; Phoenix, 4,163; Troy, 4,097; Pratt City, 3,485; and Sheffield, 3,333.

History.—First settlement in 1702, by Bienville; Mobile planted in 1711-13; territory N. of 31° ceded by France to Great Britain in 1763, and in 1783 transferred to U. S.; first attached to Georgia and South Carolina, but in 1802 organized as Mississippi Territory; region S. of 31° belonged to Spain, but in the war of 1812 seized and annexed to Mississippi Territory; this region and Florida purchased from Spain in 1819; Creek war in 1813-14—480 whites killed, 400 wounded, and 1,617 Indians killed; Gen. Jackson defeats the Creeks, who make peace and give up three-quarters of their territory; immigration increases; Mississippi set off as a State in 1817, and Alabama admitted to the Union in 1819. Alabama took an active part in removal of Indians to Indian Territory; as one of the largest slave-holding States in the Union uniformly acted up to what were considered the interests of its section, taking strong ground in favor of the annexation of Texas, resisting all measures for the restriction of slave territory, and opposing with great vehemence what its political leaders

characterized as Northern aggressions; in 1860-61 one of the first of the Southern States to declare for secession and a Southern confederacy; convention of all the Southern States held at Montgomery, Feb. 4, 1861, to organize a Southern confederacy; provisional government organized; Jefferson Davis elected President, and Montgomery made capital of Confederacy; Gov. Moore seized in Jan., 1861, U. S. arsenal, arms, forts, and revenue cutter; July, 1861, capital removed to Richmond, Va. In the progress of the war Alabama took an active part, though the northern portion of the State contained a strong Union party. Several severe battles were fought within the limits of the State—notably the naval actions and the capture of the forts in Mobile bay in Aug., 1864, the siege and capture of Mobile in Mar. and April, 1865, and the capture of Selma and other towns by Gen. Wilson in April, 1865. There were also minor conflicts at Athens, Montevallo, Scottsboro, Talladega, and Tusculumbia. *Reconstruction Measures*: Provisional government appointed June 21, 1865, and State temporarily under military control; State convention met Sept. 25, 1865, and annulled ordinance of secession; military government very lenient; State convention called by Gen. Pope to meet Nov. 5, 1867, to form a new constitution and State government; constitution submitted to people Feb. 4, 1868. There was much opposition to it, and many of those opposed stayed away from the polls; the result was that, though the constitution received a majority of the votes cast, it did not receive a majority of those registered, and hence was deemed to have been rejected. Most of its provisions have, however, been engrafted on the present Constitution of 1875. The State was admitted to a representation in Congress by an act passed over the President's veto June 25, 1868. With the return of financial prosperity, and the development of the mineral, agricultural, manufacturing, and commercial resources of the State by the aid of the great railroad lines now traversing it, Alabama entered on a new era of rapid advancement. The material wealth of the State has been prodigiously increased, and capital has developed the iron and coal industries, which are among the richest in the Union.

Revised by A. R. SPOFFORD.

Alabama Claims: The claims made by the Government of the U. S. in favor of certain of its citizens and on its own behalf upon the Government of Great Britain, on account of the acts of certain warlike vessels, thirteen in number with their tenders, which sailed from British ports in the interest or employ of the Confederate States during the war of the rebellion in the U. S. The treaty of Washington describes them as "differences [which] have arisen between" [the two governments], "and still exist, growing out of the acts committed by the several vessels which have given rise to the claims generically known as the Alabama claims." The Confederate cruisers in respect of which the U. S. made any reclamations before the tribunal of arbitration at Geneva should be separated into two classes; first, those which were substantially fitted out and adapted to warlike use in Great Britain, so that they actually commenced their hostile careers by sailing from a British port; and, secondly, those which commenced their hostile careers in the Confederate service within other territorial jurisdictions.

First Class.—The Florida was an iron srew gunboat. The contract for her was made in 1861 by Bullock, the Confederate agent in England, with Laird & Son, of Birkenhead. Her object and destination were well known at that place, but the formal pretense was kept up that she was designed for the Italian navy. She cleared for the Mediterranean on Mar. 22, 1862, with a crew of fifty-two men, all British except three or four, of whom only one was a citizen of the U. S. Her actual destination proved to be Nassau. She was in every respect a man-of-war, except that no guns were on board. While she was preparing to sail, shot, shells, etc., were sent by river from Liverpool to Hartlepool, and there

shipped on board the steamer Bahama, which left for Nassau, and there joined the Florida. All these facts were from time to time diligently brought to the attention of the British authorities by Mr. Adams, the U. S. minister, and by Mr. Dudley, the U. S. consul at Liverpool. At Nassau certain abortive proceedings against the Florida were undertaken by the colonial government. She sailed from Nassau on the 8th of August, having cleared for St. John, New Brunswick. At the same time a schooner laden with shot, shell, and other munitions of war sailed from Nassau, and met her at a neighboring island, where the transfer was made. But her British crew had refused to serve longer, alleging deviation of voyage, and the Florida after shipping her armament found herself too short handed to cruise. Failing to enlist a crew in Cuba, she accordingly ran the blockade into Mobile and there lay some months. Escaping early in 1863, she cruised for twenty months. Her career ended at Bahia, where she was cut out by the U. S. steamer Wachusett in glaring defiance of Brazilian sovereignty. Three of her captures, the Clarence, the Tacony, and the Archer, were fitted out and armed as tenders, and aided in the work of destruction. During her cruises she was repeatedly received into British ports, and permitted to repair and to take in full supplies of provisions and coals. She and her tenders captured and destroyed U. S. merchant vessels and cargoes amounting in value to many millions of dollars.

The Alabama was a companion ship to the Florida, and was manned by British subjects. She was a wooden steam sloop of about 1,040 tons register, built for the Confederate States by Laird & Son at Birkenhead, in England, and was called "No. 290," from her number in the list of steamers constructed by that firm. She was barque rigged, was furnished with two engines of 350 horse-power each, and was pierced for twelve guns. Strict precautions were taken to keep her destination a secret, but the suspicions of the agents of the U. S. having been excited before she was quite finished, the minister of the U. S. requested the British Government to detain her. The British ministers consulted the Crown lawyers, and after some delay, caused by the illness of the queen's advocate, an opinion was given in favor of detaining her. In the meantime the "No. 290" had escaped under a pretext of a trial trip, near the end of July, 1862. She was not equipped with guns and warlike stores when she left the Mersey, but received them at Terceira, whither they were conveyed by two other vessels. In August, 1862, Capt. Semmes took command of the steamer, which he named the Alabama, and began his cruise with a crew of eighty. He burned most of the merchant vessels which he captured, being unable to take them into any port of the Confederate States in consequence of the blockade. The Alabama never entered any port that was possessed by the Confederate States.

It is stated that she captured sixty-five vessels, and destroyed property valued at \$6,000,000. Much greater than this amount was the damage inflicted on ship-owners of the U. S. by the heavy insurance for war risks to which they were subjected, and by the difficulty in obtaining freight for their vessels.

After a long cruise in the Pacific Ocean, she returned to Europe, and entered the port of Cherbourg to refit and obtain a supply of stores, June 11, 1864. There the Kearsarge, Capt. Winslow, found her and offered battle. Though hardly in fighting trim, the Alabama came boldly out and was speedily sent to the bottom by her antagonist.

The Georgia was built for the Confederates on the Clyde. She sailed early in 1863, and proceeded to a point off the French coast, where she met the steamer Alar, which had been sent from Liverpool with her arms, ammunition, etc. Some steps were taken by the British Government to prevent her escape, but they were too late. After a warlike career of about a year she returned to Liverpool, and was there sold by the Confederate agents, Mr. Adams remonstrating in vain against this proceeding. Shortly after the sale she left the port, and was captured by the U. S. cruiser Niagara.

The Second Class.—The Sumpter, the Nashville, the Retribution, the Tallahassee, the Chickamauga. These were all armed and equipped in and sailed from Confederate ports. The claims made in respect of them were based upon allegations that they were received into British ports, and permitted to ship coal and supplies, in excess of the maximum amount permitted by the queen's proclamation of neutrality; and also in respect of the Retribution, that she was permitted to take captured cargo into one of the Bahamas, and there sell or dispose of it without any judicial

process. The case of the Shenandoah was quite different. She was originally a British steamer, called the Sea King, and had been engaged in the East India trade. She sailed Oct. 8, 1864, for Bombay in ballast, with a crew of forty-seven. She was not then armed and equipped or fitted out as a man-of-war. On the same day another steamer, the Laurel, sailed from Liverpool, ostensibly for Nassau, having on board a number of Confederates and a quantity of guns, gun-carriages, and other munitions of war. These steamers met at Funchal, in the island of Madeira, where the transfer was made. Here she was taken command of by Capt. Waddell, of the Confederate service, and manned. A small part only of the original crew consented to remain with her, and she sailed with less than one-half of her regular force of men. On the 25th of Jan., 1865, she arrived at Melbourne, where she was permitted to repair and to coal. She also at the same place enlisted a large number of men, augmenting her crew by forty-five new enlistments. This was done so openly that it was the common talk of the town, and was freely commented upon by the local papers. The U. S. consul at Melbourne appealed to no fewer than five different officials to stop the enlistment and detain the ship, but without avail. The tribunal of arbitration decided that the colonial authorities did not exercise due diligence in preventing these enlistments. Leaving Melbourne, she proceeded to the Arctic regions, and there, beyond the reach of any U. S. cruisers, she made great havoc among the U. S. whaling ships. This was continued for several months after the complete overthrow of the Confederacy. She finally arrived at Liverpool on the 6th of Nov., 1865, and was surrendered to the British Government, and by it delivered over to the U. S.

A diplomatic correspondence arose at once from the foregoing events. We can only state in the briefest manner the points which were urged by either side. It should be carefully borne in mind that the protracted negotiations growing out of the recognition of the Southern States as belligerents by the queen's proclamation of neutrality on the 13th of May, 1861, had no necessary connection with the Alabama claims. Although the two alleged causes of complaint were often mingled, and perhaps deemed inseparable, in popular opinion in the U. S., yet they were entirely distinct, and were finally and definitively held to be so by the treaty of Washington. During the war the immediate object of all communications made on the part of the U. S. was to induce the British Government to interfere and prevent the escape of the Confederate cruisers; the remote object of the same communications, and the sole purpose of those made after the war, was to present and urge a demand for compensation.

Mr. Secretary Seward and Mr. Adams placed themselves upon the fundamental position that a neutral nation is bound by the principles and doctrines of the international law, independent of any mere municipal regulations, to use all the means in its power to prevent its territory from being made the base of military operations by one belligerent against the other. "If your neutrality laws are sufficient," they said, "enforce them; if insufficient, amend them." The British Government took issue with this position; they denied all international duty antecedent to or beyond the existing statute; this statute, they claimed, was the limit of their power and responsibility. The statute referred to, known as the Foreign Enlistment Act, was passed in 1819. In substance it provides "that if any person within any part of the United Kingdom shall . . . equip, furnish, fit out, or arm" any vessel, or attempt to equip, etc., any vessel, or procure any vessel to be equipped, etc., or knowingly aid in equipping, etc., any vessel, with intent that it may be employed in the service of one belligerent, he shall be guilty of a misdemeanor, and shall be fined and imprisoned, and the vessel, with its arms, etc., shall be forfeited. Lord Russell refused to go beyond this statute, and declared that the executive as such could not act, and that all proceedings under it must be judicial. To this end he demanded from Mr. Adams such preliminary technical proofs as would warrant a conviction by the courts. There was thus thrown upon Mr. Adams and Mr. Dudley the duty of acting as police agents and detectives for the British Government in obtaining the evidence which the local officials did not busy themselves with discovering. At last a construction was given to this statute by the English courts in the case of the Alexandra which made the Foreign Enlistment Act a dead letter. Like the Florida and the Alabama, she was constructed for the Confederates, in every respect a man-of-war ready for action, except that her guns and ammunition were not on

board. She was proceeded against under the statute, which makes it an offense "to equip, furnish, fit out, or arm any vessel." The judge at the trial held that these acts must all be proved coincidentally, and, as the Alexandra was not actually armed in a British port, the law was not violated. This ruling was sustained on appeal by the higher court. As the Government had denied all international obligation, so this decision removed all municipal duty to interfere with the operations of the Confederate agents. Such was the course of the negotiations during the war.

In the year 1868 a change in the sentiments of British statesmen was apparent. They saw what a dangerous precedent they were laying down. Accordingly, a convention was signed on the 14th of Jan., 1869. It provided for a settlement through commissioners or by arbitration of all claims of citizens of either country against the other. The national claims of this country were not taken up. This convention the Senate rejected.

Then negotiations were resumed by Mr. Secretary Fish which ended in the treaty of Washington of 1871. This treaty referred the fishery dispute to arbitration as well as the Alabama claims. See FISHERY RELATIONS. It was the work of a joint high commission, consisting of five men from each country. In the deliberations leading up to it the U. S. commissioners claimed compensation for *direct losses* in the destruction of vessels and cargoes, and in national expenditure in the pursuit of the Confederate cruisers, and for *indirect injury* in the transfer of U. S. shipping to the British flag, in the enhanced rates of insurance, in the prolongation of the war, and in the addition to the cost of the war; they proposed that Great Britain should pay a lump sum, to be agreed upon, for all these claims. The British commissioners in answer proposed arbitration. The U. S. commissioners would not agree to arbitration "unless the principles which should govern the arbitrators were first agreed upon." Finally the latter suggestion was accepted; arbitration was adopted, and the rules which should govern the arbitrators were agreed upon. Articles I. to XI. of the treaty relate to the Alabama claims. The first describes, as has been shown, the matters submitted for decision; the others describe the constitution of the tribunal, its procedure, and the form of its decision. The seventh contains the important three rules, as follows:

First. That a neutral government is bound, first, to use due diligence to prevent the fitting out, arming, or equipping, within its jurisdiction, of any vessel which it has reason to believe is intended to cruise or carry on war against a power with which it is at peace; and also to use like diligence to prevent the departure from its jurisdiction of any vessel intended to cruise or carry on war as above, such vessel having been specially adapted in whole or in part within such jurisdiction to warlike use. *Secondly.* Not to permit or suffer either belligerent to make use of its ports or waters as the base of naval operations against the other, or for the purpose of the renewal or augmentation of military supplies or arms, or the recruitment of men. *Thirdly.* To exercise due diligence in its own ports or waters, and, as to all persons within its jurisdiction, to prevent any violation of the foregoing obligations and duties; it being a condition of this undertaking that these obligations should in future be held to be binding internationally between the two countries.

These rules Great Britain denies to have been parts of the international law when the acts complained of were done, but for reasons of comity only consents that they retroact and apply to those acts, and be made the basis of decision. The article concludes as follows: "The high contracting parties agree to observe these rules as between themselves in future, and to bring them to the knowledge of other maritime powers, and to invite them to accede to them." It may be here remarked that an acceptance of these rules by other powers has never been secured, nor is there any general agreement as to their interpretation. In pursuance of the treaty the following persons constituted the tribunal of arbitration: Count Edward Sclopis, named by the King of Italy; Mr. Jacob Staempfli, named by the President of the Swiss Confederation; Viscount d'Itajuba, named by the Emperor of Brazil; Mr. Charles Francis Adams, named by the President of the U. S.; and Sir Alexander E. Cockburn, named by the Queen of Great Britain. The case for the U. S. was separated into six parts; it gave a minute history of the acts of the British Government toward the U. S. during the rebellion, and of the fitting out and subsequent operations of each Confederate cruiser; and discussed the

questions of international law involved in the controversy, and concluded with a demand of the compensation to be awarded. The British case was separated into ten parts, and covers a similar ground to that of the U. S., though from a different point of view. Both were supplemented by many volumes of evidence. Two very distinct questions arose upon these papers: (1) What matters were submitted by the treaty to the arbitrators? and (2) By what rules and principles of law were the arbitrators to be guided in deciding the matters submitted to them? The consideration of the first and preliminary one of these questions gave rise to a controversy which for a while threatened to interrupt the whole scheme of arbitration. In Part VI. of the U. S. case the U. S. presented the items of damage to which it claimed to be entitled. Quoting the language used by the U. S. high commissioners, the case described claims for "direct" losses or damages, and other claims for "indirect" losses. The "direct" were said to include "losses growing out of the destruction of vessels and their cargoes by the insurgent cruisers, and the national expenditures in pursuit of those cruisers." The "indirect" were said to embrace "the loss in the transfer of the U. S. commercial marine to the British flag," "the enhanced payments of insurance," "the prolongation of the war," and the "addition to the cost of the war." The presentation of these so-called indirect claims caused a great opposition in Great Britain. The Government denied that they were included, or intended to be included, in the terms of the treaty. Fresh negotiations were opened; a supplemental treaty was proposed; the controversy was continued after the meeting of the tribunal; and for a while it seemed possible that the whole proceeding would be a failure. The British agent asked for an adjournment of the tribunal for eight months, to allow formal negotiations. Finally, June 19, Count Sclopis, president of the tribunal, announced that the arbitrators, without deciding the question whether these claims were included in the treaty, "had arrived, collectively and individually, at the conclusion that these claims do not constitute, upon the principles of international law applicable to such cases, good foundation for an award of compensation or computation of damages between nations." The difficulty was then ended, and the arbitration went on.

The argument upon the merits which was presented by the litigant nations to this high tribunal was most able and exhaustive. There is not space to present it even in the briefest outline. It turned mainly upon the true meaning of the phrase "due diligence" used in the three rules. The counsel on the part of Great Britain was Sir Roundell Palmer, then the acknowledged leader of the English bar, and afterward made Lord High Chancellor, with the title of Lord Selborne. The counsel on the part of the U. S. were William M. Evarts, Caleb Cushing, and Morrison R. Waite. The final decision of the tribunal was announced Sept. 14. The arbitrators decided unanimously in favor of Great Britain in respect of the Georgia, Sumpter, Nashville, Tallahassee, and Chickamauga, and similarly in respect of the Retribution, by a vote of three to two. They all decided (Sir Alexander Cockburn for reasons peculiar to himself) that Great Britain was liable for the original fitting out and escape of the Alabama, and for her subsequent free admission into British ports. The same conclusion was reached in respect to the Florida, Sir Alexander Cockburn alone dissenting. The ruling as to these vessels applied also to their tenders. The tribunal was unanimous that no liability arose in respect of the Shenandoah prior to her arrival at Melbourne; but three of the arbitrators, Count Sclopis, Mr. Staempfli, and Mr. Adams, held that the colonial authorities failed to exercise due diligence to prevent the enlistment of men at that port, and that Great Britain was liable for captures made after her departure thence. The tribunal, in making their award, formulated and announced the following general principles, a portion of which lie at the basis of the whole decision, while a portion apply only to the estimate of the quantum of damages: "Due diligence should be exercised by neutral governments in exact proportion to the risks to which either one of the belligerents may be exposed by failure to fulfill the obligations of neutrality on their part." The effects of a violation of neutrality, as committed by the Alabama and other such cruisers, were not done away with by a commission subsequently issued by the Confederate Government. "The Government of Great Britain can not justify itself for its failure in due diligence on the plea of the insufficiency of the legal means of action which it possessed." The claim of the U. S. for the national cost of

pursuing the Confederate cruisers can not be distinguished from the general expenses of the war, and is therefore an indirect loss which can not be allowed. Prospective injuries to shippers and ship-owners, such as loss of future profits, are equally uncertain and indirect. All double claims for the same losses are rejected, but interest is allowed. Upon these principles the tribunal awarded, for actual losses of ships and cargoes and interest, the sum of \$15,500,000. It is thus seen that the tribunal wholly overruled the position maintained by Great Britain from the beginning, that its statute was the sole criterion of its power and duty. In like manner the tribunal brushed away all claims by the U. S. for indirect and national losses, and strictly confined its judgment to the compensation of private citizens of the U. S. for losses of ships, cargoes, freight, and wages.

Revised by T. S. WOOLSEY.

Alabama Indians: See MUSKHOGEAN INDIANS.

Alabaster [Lat. *alaba'ster*, from Gr. *ἀλάβαστρος*]: one of two kinds of white mineral substances, similar in appearance, but different in composition. Alabaster proper is a fine-grained variety of gypsum or sulphate of lime; the finest quality of this is found near Volterra, in Tuscany. It is manufactured into various ornamental forms in Florence, Italy, which is the center of the alabaster trade. The other is a translucent carbonate of lime, and is harder than the first. Both are manufactured into ornaments.

Considerable deposits of alabaster of the gypsum variety are found in England, chiefly in Derbyshire and Staffordshire. It is used there to form the plaster molds of the potters, and is hence called "potter's stone." The fine blocks are used by the turners. A yellow variety found at Sienna is called *alabastra agatato*.

Alabaster, WILLIAM, D. D.: b. at Hadleigh, Suffolk, England, about 1567; educated at Westminster School and at Trinity College, Cambridge; was incorporated at Oxford in 1592; became fellow of Trinity; was chaplain to Robert, Earl of Essex; was converted to Roman Catholicism in France in his twenty-fourth year, but did not long remain a Roman Catholic. He was enticed to Rome and imprisoned, but escaped at the peril of his life. On his return to England he became prebendary of St. Paul's and rector of Hatfield, and was a famous Hebraist. D. about 1640.

Alabaster Cave: a remarkable cavern in Placer co., California; 8 miles S. E. of Auburn, and a mile from the North Fork of the American River. This cave contains beautiful chambers incrustated with alabaster of various tints. It also contains a lake of undetermined extent.

Alabas'trum (in Gr. *ἀλάβαστρον*): a small jar, vase, or bottle, used for holding unguents and liquids. The vessel mentioned in Matt. xxvi. 7, called "alabaster box" in the Authorized Version, and "alabaster cruse" in the Revised Version, is an *alabastrum*.

Alacran'es (i. e. the scorpions): a group of small islands and coral reefs (cays); 80 miles N. of the coast of Yucatan in the Gulf of Mexico. Cay Perez is in lat. 22° 24' N., lon. 89° 42' W. (see map of Mexico, ref. 6-K). They are dangerous to navigation, but have a secure harbor on the south side.

Alago'as: a maritime state of Brazil; between 9° and 10° S. lat.; bounded N. and W. by Pernambuco, E. by the Atlantic, and S. by Sergipe and the river San Francisco. Area, 22,583 sq. miles. The surface is partly mountainous; and the soil of the valleys and lowlands is fertile, and produces cotton, sugar, maize, etc. Capital, Maceio. Pop. (1890) 511,440.

Alagoas (Port., the lakes): a town of Brazil; state of the same name; on the Lake Maysuaba; until 1839 the capital of the province. It was formerly a large and important city, but since the change of the seat of government it has declined very much (see map of South America, ref. 5-H). It has a considerable trade in tobacco. Pop. 15,000.

Alagon': a river of Spain; enters the Tagus about 2 miles N. E. of Alcántara. Length, about 120 miles. It is noted for its fine trout and other fish.

Alain de Lille (Lat. *Ala'nus ab In'sulis*): the *Doctor Universalis*; flourished in the twelfth century; was a Cistercian monk, and wrote a great number of books, theological, philosophical, and poetical. See Dupuy's *Alain de Lille* (1859).

Alais, aã'lay' (anc. *Al'esia*): a town of Southern France; in Gard, on the Gardon, and at the foot of the Cevennes; 31 miles by rail N. W. of Nîmes, with which it is connected by

a railway (see map of France, ref. 8-G). It is in a productive coal-field, and has several manufactories, a college, and a school of mines. Alais was a stronghold of the French Protestants in the seventeenth century, and was captured in 1629 by Louis XIII. It has a citadel built by Louis XIV., and a fine Gothic church. The cold mineral springs in its vicinity are visited by great numbers in the summer season. Pop. (1886) 22,514; (1896) 24,382.

Alajuela, ã-la-hwã'la: a city of Costa Rica, Central America, capital of a province of same name; 23 miles W. N. W. of Cartago (see map of Central America, ref. 8-J), has considerable trade through the port of Puntas Arenas on the Pacific Ocean. Pop. of city, 9,000; of province, 53,087.

Alakul, ã-la-kool': a lake in Northeast Turkestan, Russian Asia; lat. 46° N., lon. 81° 30' E.; 50 miles long, 20 broad; area, 790 sq. miles; 2,559 feet above sea-level. It receives the drainage of a large basin, and is connected by a chain of small lakes with the smaller Sissikul lying a short distance N. W.

Alameda: city, Alameda co., Cal. (for location of county, see map of California, ref. 7-C); on the Southern and Central Pacific R. R. Pop. of township (1870) 1,557; (1880) 5,708; (1890) 11,165; (1900) 16,464.

Alamgir: See AURUNGZEBE.

Alamo, The [*Alamo* is the Sp. for poplar-tree]: a celebrated fort at San Antonio, Tex. A band of 140 Texans here bravely resisted a Mexican force of ten times their number from Feb. 23 to March 6, 1836, and nearly all perished rather than surrender. The six who finally surrendered were murdered by the Mexicans. In consequence of this heroic defense, Alamo is styled the "Thermopylæ of America." "Remember the Alamo!" became the war-cry of the Texans in their struggle for independence.

Alamos, Los: a city of Sonora, Mexico, 110 miles N. W. of Sinaloa; has rich silver mines in the vicinity (see map of Mexico, ref. 3-D). Pop. fluctuating, about 10,000.

Åland Islands, or **Aaland**: a numerous group of small islands in the S. part of the Gulf of Bothnia, near the Baltic, belong to the Grand Duchy of Finland, government of Åbo (see map of Russia, ref. 5-B). About eighty are inhabited. Pop. 18,500; total area, 550 sq. miles. They were ceded to Russia by Sweden in 1809. The Russian fortifications here were destroyed by the British and French troops in 1854; and by a separate convention annexed to the treaty of Paris (April, 1856), the Emperor of Russia agreed "that the Åland Isles should not be fortified," etc.

Ala'ni: an ancient warlike tribe of unknown origin, who made incursions into the Roman empire as allies of the Goths and Vandals. They invaded Asia Minor in the reign of Aurelian, and co-operated with the Vandals in the invasion of Gaul in 406 A. D.

Alarcón, PEDRO ANTONIO, de: Spanish novelist and poet; b. in 1833; began his literary career as a journalist and satiric writer. He took part in the war of 1859 against Morocco, in the capacity of historiographer, and wrote his *Diario de un testigo de la guerra de África* (1860). In subsequent years he wrote, first, a number of successful short sketches, then novels of a more serious character, among them *El sombrero de tres picos* (1868); *La Alpujarra* (1870); *El Escándalo* (1875). The last of these, strongly Catholic in tone, and sharply opposed to the scientific and realistic tendencies in contemporary Spanish literature, was especially successful. D. July 20, 1891. A. R. MARSH.

Alarcón y Mendo'za, DON JUAN RUIZ, de: Spanish poet and dramatist; b. in Mexico about 1590. He became a resident of Spain in 1622, after which he obtained the office of reporter of the royal council of the Indies. A volume of his dramas was published in 1628. Among his works, which present a faithful delineation of Spanish manners, and are commended for elevation of sentiment, are *Las Paredes Oyen* (Walls have Ears), and *La Verdad Sospechosa* (Suspicious Truth), which Corneille imitated in his *Menteur*. D. Aug. 4, 1639. The best edition of his works is by Hartzenbusch (Madrid, 1857). A. R. MARSH.

Alarie: a celebrated conqueror; a Visigoth; b. about 350 A. D. Soon after the accession of Arcadius as Emperor of the East, Alarie invaded Thrace, Macedonia, and other provinces, in 395 A. D. He took Athens and entered the Peloponnesus, from which he was driven out by Stilicho. Hostilities were then suspended by a treaty, and Arcadius appointed Alarie governor of Illyria in 396. He invaded

Northern Italy in 402, but was defeated by Stilicho at Polentia and Verona. Stilicho having been killed in 408, Alarie renewed the invasion of Italy, which the Emperor Honorius was unable to defend. The army of the Visigoths invested Rome, but they were induced to retire by the payment of 5,000 lb. of gold and 30,000 lb. of silver. After unsuccessful efforts to negotiate, Honorius rejected the terms of Alarie, who in 410 took Rome, and permitted his soldiers to pillage it for six days. He was marching to Sicily when he died at Cosenza, in 410 A. D. See Simonis, *Kritische Untersuchungen über die Geschichte Alarich's* (1858).

Alarie II.: King of the Visigoths; began to reign in 484 A. D., on the death of his father, Euric. His dominions included parts of Spain and of Gaul. He was killed in battle by the hand of Clovis, King of the Franks, in 507.

A Las'co, **Alas'co**, or **Alas'ko**, JOHN (in Polish, Lascki): a Polish nobleman; b. in 1499; a great traveler in his early life, who, while at Zurich, imbibed the doctrines of Zwingli. At Basel, in 1525, he became the friend of Erasmus, who bequeathed to him his library. On the invitation of Cranmer he removed from Embden, in East Friesland, to London in 1551, where he became superintendent of the congregations of foreign exiles who had embraced the reformed faith. The Church of the Austin Friars, in Broad Street, was assigned to him, and here he established a Presbyterian form of church government with a service-book from which all the sacerdotal and sacramental principles of the English Prayer-Book of 1549 were carefully eliminated, and sitting at the communion and the disuse of ecclesiastical vestments were enjoined. On the accession of Queen Mary, in 1553, A Lasco and his congregation were banished. In 1556 he returned to Poland, where he died Jan. 13, 1560. A Lasco wrote a number of theological treatises, chiefly in defense of the sacramental views of the Swiss Reformers, and was one of the eighteen divines who prepared the Polish version of the Bible which was published in 1563. W. S. PERRY.

Ala Shehr (the ancient *Philadelphia*, founded about 200 B. C. by Attalus Philadelphia): a walled city of Asia Minor, at the N. E. base of Mt. Tmolus, 93 miles E. of Smyrna (see map of Turkey, ref. 5-E). Here are five Christian churches and numerous ancient ruins. Pop. about 15,000.

Alas'ka: formerly Russian America; a Territory of the U. S., comprising the northwestern part of America, purchased from Russia in 1867 for \$7,200,000. Its eastern boundary starts at lat. 54° 40' N., in the Portland channel, and ascends this channel to where the fifty-sixth meridian crosses the coast of the mainland. From here it passes inland to the summits of the mountains parallel to the coast, or lacking mountains to ten marine leagues from the coast, northward to the meridian of 141° W. From this point, which proves to be very near the apex of Mt. St. Elias, it passes northward to the "Frozen Ocean." The western limit comes southward from the "Frozen Ocean" to the middle of Bering Straits, thence southwesterly in such a way as to pass between Attu (the most westerly of the Aleutian islands) and the Commander islands off Kamchatka. It thus includes not only an enormous tract of mainland, but Prince of Wales island, the King George or Alexander archipelago to the northward, the Kadiak islands, the Aleutians, Pribyloff, and St. Lawrence island in Bering Straits.

Topography.—The coast-line of Alaska is greater than that of the Atlantic seaboard of the U. S. The chief inlets are Prince William Sound and Cook Inlet, on the northern extension of the Pacific called the Bay of Alaska; Bristol bay and Norton Sound on Bering Sea; and Kotzebue Sound on the Arctic Ocean. Point Barrow (lat. 71° 23' N.) is the northernmost point of Alaska. The principal river is the Yukon, which rises in British Columbia less than 200 miles N. N. E. of Sitka, strikes a broad arc of a circle more than 2,000 miles long, and enters Bering Sea on the S. side of Norton Sound through an extensive delta. At 600 miles from the coast it is over a mile wide, and the volume of its water is so great as to freshen the water 10 miles off shore from its principal mouth. The next largest river is the Kuskokwim, which rises on the northern slopes of the Alaskan range of mountains to the eastward of the meridian of 150° W., and empties into Kuskokwim Bay, Bering Sea, in about lat. 60° N. Like the following, it is but little known. Next in order of size are the Colville, flowing into the Arctic Ocean E. of Point Barrow; the Copper, flowing southward from the Alaska Mountains, and emptying into the Bay of Alaska in about long. 145° W.; the Suschitno, and several Arctic

streams. The Rocky Mountains turn westward in about lat. 63° N. and pass into the Alaska Mountains, a range which runs first W., then S. W., and is finally prolonged into the peninsula of Alaska and the Aleutian islands, the peaks in the two latter being often volcanic. This range apparently culminates in Mt. Wrangel, in about lon. 145° W., lat. 62° 30' N.; height, 17,500 feet. Near the coast is a less continuous range, which culminates in Mt. Logan (lat. 60° 30' N.), altitude 19,500 feet, thus overtopping Mt. Elias (18,100 feet), which is situated at the point where the U. S. boundary makes a turn from westward to northward, and which was long regarded as the highest peak N. of Mexico. Among these coast mountains is Mt. Cook (in British territory), 15,750 feet, and Mt. Fairweather (U. S.), 15,500 feet. Glaciers are frequent among these mountains, and one from Mt. Elias dips its nose into salt water at Icy Bay.

Natural Divisions.—The Territory falls naturally into six divisions: (1) The Arctic division, including the entire area that drains into the Arctic Ocean. It is a treeless district, diversified by ranges of hills, almost entirely within the Arctic circle, with no population except the Esquimaux along the coast. The area is 125,245 sq. miles, and the population barely surpasses 3,000. (2) The Yukon basin. This district has an area of 176,715 sq. miles. It has extensive forests, except near the coast. The population is Esquimaux on the coast (numbering about 4,500) and Indians in the interior (about 2,500). Fishing is the chief means of subsistence. (3) The Kuskokwim district. This includes the Kuskokwim basin and the remainder of the area between the Alaska range and the Yukon basin. Its character is much like that of the Yukon district, but it is more mountainous. Area, 114,975 sq. miles. Pop. 8,000 Esquimaux, less than 1,000 Indians, and a few whites. (4) The Aleutian district, comprising the Aleutian islands from the peninsula of Alaska westward. The islands are without trees, but the climate is relatively mild, the rainfall considerable, and the herbaceous growths are luxuriant. Fishing and sealing are the chief means of support. Area, 14,610 sq. miles. Pop. about 2,500; mostly Aleuts, but now much mixed with Russian blood. (5) The Kadiak district, including the mainland and islands S. of the Alaskan range, W. of meridian 141° W., and E. of the central ridge of the peninsula of Alaska. This region is but little known, except near the coast. It is believed to have considerable mineral wealth. Area, 70,884 sq. miles. Pop. about 2,000 Esquimaux, 1,200 Indians, and 1,000 whites and half-breeds. (6) The Sitka district, which includes the archipelago and strip of coast extending southward, W. of British Columbia. It has abundant forests containing magnificent tree trunks for masts and spars. The climate is relatively mild and the rainfall heavy. There is considerable mineral wealth, especially to the N. Area, 28,980 sq. miles. Pop. (1880) 523 whites and half-breeds, 7,225 Indians; (1890) 1,880 whites, 5,432 Indians, 324 Chinese. Total area, 531,409 sq. miles. The most valuable of the export products of the industries of Alaska consists of the furs of seals, bears, foxes, otters, martens, beavers, minks, and some other animals. Next in importance is that of the fishing industry. The center of the salmon-canning industry is at the islands of the Kadiak district, the output for 1890 (over 200,000 cases) being almost two-thirds of the total output of Alaska. Gold is mined in several places, bullion to the value of about \$5,459,500 being shipped in 1899. There are unworked deposits of lignite and copper.

Population.—The population for the whole Territory in 1880 was 33,426, of whom 17,617 were Esquimaux, 11,478 Indians, 2,145 Aleuts, 1,756 half-breeds, and 430 whites. In 1890 the census enumeration (necessarily largely an estimate), gave 4,416 whites, 82 blacks, 1,568 half-breeds, 13,735 natives not Esquimaux, 2,125 Chinese, 8,400 Esquimaux; total, 30,326. The recent census (1900) gives a total population of 63,592. The Esquimaux, or Inuit, are confined to the coast and are found along almost the entire coast of the mainland. They are less gentle than those of the Atlantic side. The Aleuts are a gentle, genial, and fairly industrious people, formerly celebrated as whale-hunters, now contented to live without such dangerous pursuits. They are now gradually dying out. They appear to be more nearly related to the Esquimaux than to the Indians. Among the Indians the Thlinkets are the most numerous (about half).

History.—The coast of this part of America was discovered by a Russian expedition under Bering, in 1741. Settlements were gradually made, and the coast was at one time claimed as far S. as San Francisco. In 1799 the Territory was granted to a Russo-American fur company by the

Emperor Paul VIII., and the charter was renewed in 1839. New Archangel, now Sitka, was the principal settlement. The privileges of the company expired in 1863, and the Territory was purchased by the U. S. in 1867. Portions of the Territory were soon after explored by employees of the Russo-American Telegraph Company in surveying a route for an overland telegraph line to Europe. Explorations of the coast have since been continued by the Coast and Geodetic Survey. The Yukon has been explored by Dall and Schwatka, and Mt. Elias by several parties, the most successful of which was that of Russell in 1891. From Sept. 8, 1881, to Aug. 29, 1883, a well-equipped meteorological station of the U. S. Signal Service was kept at Point Barrow. In 1884 a district government was created by Congress, with a governor and a district court. The latter sits alternately at Sitka and Wrangel. The laws are those of Oregon. Sitka is the capital and has a land-office. The farming of the Pribylof or Fur Seal islands in Bering Sea was at first granted to the Alaska Commercial Company at a rental amounting to about \$300,000 annually. On the expiration of their lease in 1890, the right was acquired by the North American Commercial Company. In 1886 three Canadian sealers were seized by a U. S. revenue cutter while sealing in Bering Sea, their captains and crews tried for illegal sealing, fined, and imprisoned. In 1887 five were similarly seized and tried. In 1888 a Russian steamer seized a Canadian schooner sealing in Russian waters. In 1889 four schooners were seized by the U. S. revenue cutter and a fifth warned to leave. In 1890 and 1891 there were no seizures, but negotiations in the latter year were going on to settle the status of the question of foreign sealing. See *BERING SEA CONTROVERSY*.

Boundary Dispute.—A treaty was signed by the Secretary of State and the British Ambassador in Washington on Jan. 30, 1897, providing for the demarcation of so much of the boundary between Alaska and Canada as lies along the 141st meridian. The remainder of the question was left to the joint high commission appointed to attempt the settlement of all questions at issue between the U. S. and Canada, which first met in Quebec, Aug. 28, 1898, with the following delegates: Great Britain—Lord Herschell, chairman of the conference; Canada—Sir Wilfrid Laurier, Sir R. Cartwright, Sir Louis Davies, Hon. John Charlton; Newfoundland—Sir James Winter, Hon. A. B. Morine; U. S.—Gen. John W. Foster, Hon. George Gray, Hon. C. W. Fairbanks, Hon. John A. Kasson, Hon. Nelson Dingley, T. Jefferson Coolidge. No agreement having been reached, on Oct. 20, 1899, a *modus vivendi* was agreed to by Great Britain and the U. S., fixing a provisional boundary "such as should be without prejudice to the claims of either party in the permanent adjustment of the international boundary"; and officers were appointed by both governments to mark this temporary line.

MARK W. HARRINGTON.

Alas'sio: a charming health resort in the Riviera, Liguria, Italy; 56 miles W. of Genoa. It is on the Mediterranean, and is protected toward the N. by picturesque and wooded mountains (see map of Italy, ref. 4-B). It has been frequently visited by the Italian royal family and by Garibaldi, and is becoming a favorite English resort in winter. Pop. 6,000.

Ala'tri: a town of Italy; province of Rome; 45 miles E. S. E. of Rome (see map of Italy, ref. 6-E). The ancient city which occupied the site of Alatri was called *Alatrium*, or *Aletrium*, and was one of the principal cities of the Hernician League. Here are some of the finest and best-preserved cyclopean or polygonal walls in Italy. They were part of the defenses of the ancient city, and were built of immense polygonal blocks of stone, without cement. Pop. 13,596.

Alatyr': a town of Simbirsk, Russia; at junction of Alatyr and Sura rivers (see map of Russia, ref. 7-G). The principal industries are glass-making and dyeing. Pop. 15,000.

Alau'didæ: the larks; a family of passerine birds, the best known of which is the skylark (*Alau'da arven'sis*), after the nightingale the most celebrated song-bird of Europe. It mounts to a great height in the air, singing vigorously as it rises, and at the end of its song it drops suddenly to the ground, where it skulks among grass and weeds. The beau-

tiful *Alauda cristata*, or crested lark, is another common bird of Europe. The shore-lark (*Otocoris alpestris*) is widely diffused in the cooler parts of Europe, Asia, and North America, and is the only one of the family common on this continent. The larks are largely terrestrial in habit, feeding on insects and the like. Among related birds, they are distinguished by the long straight claw of the hind toe, and by the absence of a sharp ridge on the posterior edge of the tarsus.

Revised by DAVID S. JORDAN.

Alaux, JEAN: historical and decorative painter; b. at Bordeaux, Jan. 15, 1786. Pupil of Vincent and Guérin. Director of the French Academy in Rome, 1846-53; member of the Institute, 1851; Legion of Honor, 1841. Notable pictures and decorations at the Museum of Versailles. D. in Paris, Mar. 2, 1864.

W. A. C.

Al'ava: one of the Basque provinces in Spain; bounded N. by Biscay and Guipuzcoa, E. by Navarre, S. by Logroño, and W. by Burgos. Area, 1,205 sq. miles. The country is mountainous, but fertile, especially along the shores of the Ebro. The chief products are fruit, wine, grain, and hemp. Here are also several mineral springs. Chief town, Vitoria. Pop. (1887) 92,893.

Alb [Lat. *alba* (sc. vestis), fem. of adj. *albus*, white]: a long white linen vestment worn by those in sacred orders in the Roman Catholic Church at the more solemn functions. It symbolizes the purity which the wearer should bring to the discharge of his office.

Al'ba, DUKE OF: See ALVA.

Alba (anc. *Alba Pompeia*): a town of Italy, province of Cuneo, on the Tanaro, 30 miles S. E. of Turin (see map of Italy, ref. 3-B). Wine, silk, grain, cheese, and oil are the staple productions of the district, in which are also quarries of marble and rock salt. It has a cathedral founded in 1486, and is the seat of a bishop. Pop. of the commune, 12,259.

Albace'te: province of Spain; comprises the N. part of the kingdom of Murcia and a portion of New Castile; bounded N. by Cuenca, E. by Valencia, S. by Murcia, and W. by Ciudad Real. Area, 5,972 sq. miles. It has on the N. W. the Sierra de Alcaraz, and the surface is diversified by mountains, hills, and fertile valleys. It is drained by the river Segura, which rises within its limits. Among its staple products are grain, wine, tobacco, oil, cattle, and sheep. Capital, Albacete. Pop. (1887) 229,492.

Albacete: a town of Spain; capital of a province of the same name: 172 miles by rail S. E. of Madrid (see map of Spain, ref. 17-G). It has manufactures of knives and other steel goods, and considerable trade. Large cattle fairs are held here in September. Pop. (1887) 20,533.

Albacore: See the Appendix.

Alba Lon'ga: a very ancient city of Latium, in Italy; founded, according to tradition, by Ascanius, son of Æneas, several centuries before the foundation of Rome. It was situated near the Alban lake, about 16 miles S. E. from Rome. Its remains have been discovered.

Al'ban, SAINT: one of three Christian martyrs who are said to have suffered in England about 286 A. D., during the Diocletian persecution. St. Alban was the protomartyr of Britain. Bede gives his story in his *Eccles. History*, bk. i. c. 7.

Albanen'ses [from *Alba*, a town of Piedmont]: that division of the Catharists who believed in absolute dualism. They taught that the world was created by the evil spirit. See CATHARI.

Alba'ni, ALESSANDRO: Italian cardinal, a nephew of Pope Clement XI.; b. at Urbino in 1692. He made a rich and celebrated collection of statues and other works of art at Rome. D. in 1779.

Albani, MARIE EMMA (Lajeunesse): singer; b. at Chambly, near Montreal, Canada, in 1851. In 1864 she sang in the cathedral in Albany, N. Y.; studied two years in Paris, and made her *début* as an opera singer in Messina in 1870; called herself Albani, out of compliment to the city of Albany, N. Y. Sang in Florence in the winter of 1871-72. She made a great success in Ambrose Thomas's *Mignon*. She sang in St. Petersburg, in London, in Paris, and in the U. S. In 1878 she married Ernest Gye, the operatic manager, and made a tour of the U. S. in 1883. B. B. VALLENTINE.

Alba'nia: the ancient name of a country bounded on the E. by the Caspian Sea, and comprising the modern Daghestan and Shirvan. Its inhabitants were often defeated, but never conquered, by Rome.

VOL. I.—7

Albania [called *Shkiperi* by the natives, and *Arnaoutlik* by the Turks]: the southwestern part of European Turkey; lies between lat. 39° and 43° N., and is bounded on the W. by the Adriatic and Ionian seas. Its length N. and S. is about 290 miles, and its width varies from 40 to 90. It nearly coincides with the ancient Epirus. The surface is mountainous, being occupied with nine ridges that are nearly parallel. The highest peaks rise about 8,000 feet above the level of the sea. Among the remarkable features of Albania are its subterranean rivers and its beautiful lakes. The chief articles of export are wool, horses, timber, and maize. The Albanians are rude and warlike mountaineers, more addicted to robbery than industry. They are probably descended from the ancient Illyrians and Epirotes. Their language belongs to the Indo-European family, and has several strongly marked dialects. The inhabitants are often called *Arnaoots* or *Arnavuts*, and *Skipetar*. Their dress resembles that of the Highlanders of Scotland. Pop. estimated at 1,400,000. Besides these, a large number of Albanians live in Greece and other parts of the Levant.

Albanian Language: the language of the Albanians, spoken in a variety of dialects in Albania proper, in various parts of Greece, in Southeastern Italy, and Sicily. The dialects of Albania divide themselves into two main groups: the northern or Gegan (north of river Scumb); and the southern or Toscan. The old idea that Albanian is a debased offshoot of the Greek has now been thoroughly disproved; it is an independent branch of the Indo-European stock, and leans in its characteristics rather toward the Slavic family of languages than the Greek. (See Meyer, G., in *Bezenberger's Beiträge*, vol. viii. 185.) Thus it resembles the Slavic languages in developing medials out of the Indo-European medial aspirates: cf. *biér*, carry, Lat. *fero*, Sanskrit *bhárāmi*; *derg*, door, Gr. *θύρα*, Lat. *fores*; also in its treatment of the two *k* series; the velar *k* is represented in Albanian by *k*, the palatal by *s*. Contrast *katër*, four, Lat. *quattuor*, Skr. *catvāras*, etc., with *vise*, places, Lat. *vicus*, Gr. *οἶκος*, etc. The investigation of the language and the determination of its position have been rendered peculiarly difficult by the great masses of loan-material from Latin, Slavic, Turkish, and modern Greek sources which have almost buried the original elements out of sight. Of the 5,140 caption-words in Meyer's etymological dictionary of the language, 1,420 prove to be of Latin origin, 1,180 Turkish, 840 Greek, 540 Slavic, and only about 400 inherited from Indo-European. During the Roman occupation of Illyria, in the days of the empire, the Albanian barely escaped the fate of the languages of Spain and Gaul. Not only words but formative and inflexional elements were adopted from the Latin to such an extent that the language became half Romance in character. For instance, Latin suffixes like *-arius* (Alban. *-ár*), *-imen* (Alban. *-ím*), *-tór* (Alban. *-tore*) become a vital possession of the language, and are applied to other than Latin words. The Latin endings of the imperfect *-ābam*, *-ēbam*, *-ībam*, appear as *-ova*, *-eva*, *-iva*. The form of the optative is derived exclusively from the Latin pluperfect subjunctive in *-vissem*. Even pronouns, conjunctions, prepositions, and adverbs are among the borrowed material; thus, *e = et*, *a = aut*, *kuš = quis*, etc. The influence of Greek, the Slavic languages, and Turkish is later and much less far-reaching, being limited to the vocabulary.

For practical introduction to the language, the best book is Gustav Meyer's *Kurzgefasste Albanesische Grammatik* (1888), which contains also reading exercises and a vocabulary. For the scientific study of the language the following works by the same author are important: *Etymologisches Wörterbuch der Alban. Sprache* (1891); *Albanesische Studien* (2 pts., 1883-84); *Die lateinischen Elemente im Albanesischen*, Gröber's *Grundriss*, i. 804 ff.; *Ueber Sprache und Literatur der Alban.*; *Essays und Studien*, 49 ff.; *Einfluss des Lat. auf die Alban. Formenlehre*; *Miscell. di filologia e linguistica* (Flor. 1886). Also, Miklosich, *Albanesische Forschungen* (3 vols., 1870-71); Schuchhardt, *Albanesisches und Romanisches*, Kuhn's *Zeitschr.*, xx. 241; Von Hahn, *Alban. Studien* (1854); and Reinhold, *Noctes pelagicae* (1855).

BENJ. IDE WHEELER.

Alba'no: a lake and mountain in Italy; about 14 miles S. E. of Rome. The lake, which is 6 miles in circumference, occupies the crater of an extinct volcano, and is 1,000 feet deep or more. The lake has no natural outlet, but discharges its waters through an artificial tunnel cut through tufaceous rock. This tunnel or "emissary" was undertaken by the Romans in 397 B. C. It is one of the most remarkable re-

mains of ancient Roman engineering. It is 6,000 feet long. Alba Longa stood on the N. E. margin. From the east shore of this lake rises Mt. Albano or Monte Cavo, which is over 3,000 feet high, and commands an extensive and magnificent prospect. On its summit are the ruins of the temple of Jupiter Latialis.

Albano (anc. *Alba'num*): a city of Italy, on or near Lake Albano, and on the Via Appia, 18 miles by rail S. E. of Rome (see map of Italy, ref. 6-E). It occupies the site of Pompey's villa, is celebrated for beauty of scenery, and is a favorite summer residence of the wealthy citizens of Rome. Here is a museum of antiquities and a large convent. Pop. 7,364.

Al'bany, or **Al'bainn**: an ancient name of the Highlands of Scotland. It is supposed that Albany or Albion (*q. v.*) was the original name given to the whole island by its Celtic inhabitants, and that it was afterward restricted to the northwestern part of Scotland, when the Celts had retired from the other parts of Britain. The title of Duke of Albany was given to the second sons of several kings of Scotland and England.

Albany: a small maritime division of the southeastern province of Cape Colony, South Africa; about 450 miles E. of Cape Town; area, 1,685 sq. miles. It is traversed by Great Fish river. The soil produces maize, barley, cotton, and other commodities. Capital, Grahamstown. Albany sends two representatives to the House of Assembly. Pop. (1891) 9,359 whites, 13,976 blacks.

Albany: town, railroad junction and capital of Dougherty co., Ga. (for location of county, see map of Georgia, ref. 6-G); on the right bank of Flint river, 106 miles S. S. W. of Macon. It is in the center of a district raising sugar-cane, rice, corn, and cotton. Large quantities of cotton are here shipped by rail. The Flint river is navigable to this point only at high water. Pop. (1870) 2,101; (1880) 3,216; (1890) 4,008; (1900) 4,606.

Albany: town, railroad junction and capital of Gentry co., Mo. (for location of county, see map of Missouri, ref. 1-D); on Grand river, 52 miles N. E. of St. Joseph. It has manufactures of furniture, brooms, wagons, harnesses, lumber, etc., graded schools, a grist-mill, a foundry, and a machine-shop. Pop. (1880) 979; (1890) 1,334; (1900) 2,025.

Albany: city, important railroad and commercial center; capital of New York and seat of government of Albany County (for location of county, see map of New York, ref. 5-J); on the west bank of the Hudson, 145 miles N. of New York city, and 164 miles (or 201 by railroad) W. of Boston, in lat. 42° 39' 49" N., lon. 73° 44' 33" W.

Original Site.—The place was first occupied by the Dutch in 1614 as a trading-post, but an actual settlement was not effected till May, 1624, on the arrival of eighteen Walloon families. During the same year a small fort (called Fort Orange, or Aurania) of logs and earth was built. In 1626 a war between the Mohawks on the west and the Mohegans on the east broke up the settlement, and the families were transferred to New Amsterdam, at the mouth of the river. Settlement was resumed in 1630 by Dutch families under the patron system, the settlers renting their lands of the patroon or lord of the manor. The village was called Beverwyck, then Williamstadt, and in 1664 it was called Albany, after the Duke of York and Albany, afterward James II. Till the Revolution it was the center of a large Indian trade. The colony continued to be inhabited by the Dutch, brought over largely by the Van Rensselaer family, who secured, in 1629, 24 miles square on both sides of the river, and leased the lands to settlers. Feudal tenure was abolished in 1787. After the Anti-rent war in 1846 the State prohibited leases of agricultural land for a longer period than twelve years. It was incorporated as the city of Albany in 1686, and became the capital of New York in 1797.

Modern Changes.—The city, which has a river-frontage of 4 miles, extends back over an alluvial plain up the sides of the hills to and upon the table-land 150 feet high, about 5 miles W. The view of the city from the east bank of the river is picturesque and imposing, from the full exposure of the public edifices, with their domes and steeples, the Helderberg and Catskill Mountains being visible in the S. W.

Streets, Public Buildings, and Institutions.—The principal streets are Broadway and Pearl Street, which run parallel with the river, and State Street, which ascends the hill to the Capitol, and thence to the limits of the city proper westward. Washington Avenue runs parallel to it, W. on the N. side of the Capitol, beginning at the City Hall, and

joins Central Avenue, which continues to W. boundary of the city. There are 81 miles of paved streets, of which 69 miles are of granite block, brick, asphalt, and macadam.

The chief public edifices and institutions are the Capitol, of which the cornerstone was laid in 1871, built of drilled granite, 4 stories high, 300 feet wide and 400 long, and occupies a prominence 155 feet above the level of the Hudson. It contains halls for the Assembly, the Senate, the Court of Appeals, the State Library, and rooms for the State officers (cost, including \$543,179 for the site, \$23,721,903.14); the marble State-hall (1842) also contains State departments; the new City Hall, of granite and red sandstone, with a picturesque tower (1882); U. S. Custom-House and Post-Office (1882); 5 hospitals, 3 free dispensaries, Dudley Astronomical Observatory, State Museum of Natural History (1797); State armory (10th battalion, N. G. N. Y.), theaters, and public halls. There are 73 churches, the largest and most imposing being the cathedral of the Immaculate Conception (R. C.), and the cathedral of All Saints (P. E.).

The penitentiary, opened in 1848, receives annually, mostly for short terms, over 1,000 prisoners, and has usually been self-supporting. Washington Park contains 90 acres, with a lake 1,700 feet long, and carriage-drives of 5½ miles. Beaver Park, on the south side, occupying the extensive and picturesque ravines about Martinville, contains 78 acres. Entire city park system contains 305 acres. The charitable institutions are numerous. The beautiful Rural Cemetery, about 4 miles from the city northward, contains 281 acres. Adjoining are St. Agnes (R. C.), containing 112 acres, and Beth Emeth (Hebrew), 25 acres.

Education.—Albany has a high school for both sexes; 21 public schools; 3 boys' academies and 5 for girls; a medical college, a law school and a college of pharmacy, departments of Union University, and a State normal college. There are 13,134 pupils in the public schools and 4,500 in other schools. The Albany Institute is a society formed in 1791 for the advancement of science. It was merged with the Historical and Art Society (1901) under the style of Albany Institute and Historical and Art Society. The Dana Natural History Society (women), organized in 1868, is oldest of its class in U. S. The State Library has, with the law department (1901), 448,488 vols., 250,000 manuscripts, and 166,869 pamphlets; the 9 other public libraries, 59,020 vols.

Albany city has 3 state and 6 national banks, with a combined capital stock of \$2,150,000; surplus and undivided profits, \$2,782,609; individual deposits, \$9,478,735; loans and discounts, \$13,843,281. There are 7 savings banks, with \$52,514,632 in deposits; surplus, \$4,707,357; open accounts, 77,354. There are 9 shirt factories, 4 stove foundries, with an output in 1900 of 50,000 stoves valued at \$750,000; 4 knit-goods factories, 2 piano manufactories, a gas-meter works, one of the largest in the country; one billiard ball company, manufacturer of the celluloid billiard ball; the Albany perforated wrapping-paper company, the embossing company, the largest manufactory of dominoes and alphabet blocks in the U. S.; 2 cracker bakeries; 10 breweries, 12 iron foundries, and 3 candy manufactories. The lumber trade of 1900 amounted to \$8,000,000.

Albany is the center of a large industrial territory. There are 122 passenger and 250 freight trains sent from its Union railway depot daily.

There are 2 joint-stock and one mutual fire-insurance companies—The Albany Ins. Co., \$250,000, and Commerce Ins. Co., \$200,000 capital, and Mutual Fire Ins. Co., \$209,810 assets—one trust company, and one safe deposit company. Total mail matter handled (1900) 31,412,276.

The city is supplied with water from an artificial lake in the sand plains W. of the city, and also by pumping water from the river into elevated reservoirs after it has undergone thorough sand filtration. The fire department has 11 steam-engines, 3 trucks, 7 chemical engines, and a fire-alarm telegraph system. Pop. (1790) 3,506; (1870 with extended limits) 76,216; (1880) 90,758; (1890) 94,923; (1900) 94,151.

Revised by JAMES H. MANNING.

Albany: city: at junction of three railroads; capital of Linn co., Or. (for location of county, see map of Oregon, ref. 3-C); on the Willamette river, at the mouth of the Calapooia. Steamboats can ascend to this point for eight months in the year. Albany has a collegiate institute, Roman Catholic academy, woolen mills, electric lights, and is a manufacturing center. Pop. (1880) 1,867; (1890) 3,079; (1900) 3,149.

Albany, LOUISA MARIA CAROLINE, Countess of: b. at Mons, Sept. 27, 1753; daughter of Gustavus Adolphus,

Prince of Stolberg Gedern. On Mar. 28, 1772, in Paris, she married by proxy, and on Apr. 17 (Good Friday), 1772, at Ancona in person, the Young Pretender, Charles Edward Stuart, a grandson of James II. of England, then 52 years old and a habitual sot. The Young Pretender was called in Italy the Count of Albany, hence her title. After keeping up the wretched relationship for eight years she eloped with the poet Vittorio Alfieri, and lived with him openly as his mistress till his death in 1803. The Pretender had died in 1788, but she and Alfieri did not marry. She was received into the highest society, nevertheless, even in England. After Alfieri's death she lived with a young French artist named Fabre, and to him she bequeathed the curiosities given her by the Young Pretender and by Alfieri, together with other treasures, and these form the foundation of the notable Musée Fabre at Montpellier. D. at Florence, Jan. 29, 1824. See ALFIERI. See her life by Von Reumont (Berlin, 1860).

Albatross: a web-footed bird of the sub-family *Diomedinae*, allied to the petrels; remarkable for their great size and powers of flight. The wandering albatross (*Diomedea exulans*) is the largest of all oceanic birds, having wings which measure 12 feet or more from tip to tip, but

Albatross.

are narrow in proportion to their length. They wander over the open oceans, and often follow ships for days without resting. "Sometimes for a whole hour together," says the Duke of Argyll, "this splendid bird will sail or wheel round a ship in every possible variety of direction, without requiring to give a single stroke to its pinions." The wandering albatross is mostly confined to southern seas, rarely occurring as far north as the Tropics of Capricorn, although stragglers have reached Europe. Besides the above, there are the sooty albatross, *Diomedea fuliginosa*, of Eastern Asia, and the *Diomedea chlororhynchus*; and still other species are described, several of which are found in the North Pacific, but none on the Atlantic of the U. S. Revised by DAVID S. JORDAN.

Albay: a town in Luzon, one of the Philippine islands, 258 miles S. E. of Manila; the capital of a province (see map of East Indies, ref. 3-H). Pop. 19,546. Pop. of the province, 257,533.

Albemarle: a town of France. See AUMALE.

Albemarle, GEORGE MONK, Duke of: a famous English general, chiefly known to history as the principal agent in the restoration of the Stuarts in 1660, generally known in his own time as "Old Monk," and described by Guizot as a "person capable of doing great things, though himself not a great man." He was born of an ancient Devonshire family, at Potheridge, the residence of his father, Sir Thomas Monk, near Torrington, Dec. 6, 1608. He joined the army in order to escape punishment for mishandling a sheriff who was about to arrest his father for debt. In 1625 he engaged in the expedition against Spain, the unsuccessful attempt to capture Cadiz, made by a relative of his, Sir Richard Greenville, took part in the following year in the attack upon the isle of Rhé, and served ten years in the Netherlands, and afterward in England, first on the king's, then on Cromwell's side. After the defeat of the royalist cause Cromwell appointed Monk a lieutenant-general and chief of artillery, in which capacity he did such service at the battle of Dunbar that Cromwell made him general-in-chief of the army in Scotland. In 1652 he took part in the commission which drew up a pact of union between England and Scotland, and went to Scotland as governor in 1654; in which position he had great difficulties in maintaining his rule against the Presbyterians. The royalists had already some hopes of his support, and Charles sent him secret overtures in 1655. Monk delivered this letter up to Cromwell. After the death of the dictator, Monk declared in favor of Richard Cromwell, and assumed the authority of a defender of public order only when Lambert threatened to establish a military despotism. On the 1st of Jan., 1660, he marched over the border with 6,000 men, joining Fairfax at York, and marched into London on the 3d of Feb., without drawing sword from scabbard. At first he kept every one in

the dark as to his intentions. On Feb. 21 he recalled the Presbyterian members expelled from Parliament in 1648, thus creating a majority for the king. He held negotiations with Charles, and Parliament declared the latter king on the 8th of May. Charles gave Monk the offices of privy councilor, chamberlain, and Lord-Lieutenant of Devon and Middlesex, besides creating him Duke of Albemarle. In 1666 the Duke of Albemarle commanded the naval expedition against Holland, was beaten by De Ruyter in the three days' conflict at Dunkirk, but defeated the Dutch admiral at the North Foreland. D. in England, of the dropsy, Dec. 3, 1669. Revised by C. K. ADAMS.

Albemarle Sound: in the N. E. part of North Carolina, extends from the mouth of the Roanoke river 60 miles eastward to a narrow island which separates it from the Atlantic. Its average width N. and S. is about 12 miles. It communicates by narrow inlets with Pamlico and Currituck sounds. The water in it is nearly fresh. Its greatest depth is 24 feet; average depth, 20 feet.

Alberic I.: a ruler of Rome; b. in the beginning of the tenth century; son of a Lombardian noble. He became margrave of Camerino, and, through his marriage with the celebrated Marozia, ruler of Rome. He was banished by John X. from Rome, and was murdered at Orta in 925. His son, Alberic II., was a powerful and wise ruler, and died in 954, after a reign of twenty-three years. He was succeeded by his son, Ottaviano, who was elected pope under the name of John XII. in 956.

Alberoni, GIULIO, Cardinal: an ambitious Italian; b. at Fiorenzuola, near Piacenza, May 31, 1664. He began his public career as envoy of the Duke of Parma to the court of Madrid, and, having gained the favor of Philip V., became prime minister of Spain in 1715, and a cardinal in 1717. His foreign policy was so audacious and violent that nearly all the powers of Europe combined against Spain. Among his offensive acts was the invasion of Sardinia in time of peace. He was removed from office in 1719, and banished from Spain. D. at Piacenza, June 26, 1752. See Bersani, *Storia del Cardinale Giulio Alberoni* (1862).

Albers, JOHANN FRIEDRICH HERMANN: German physician; b. at Dorsten, Prussia, Nov. 14, 1805; became in 1831 Professor of Pathology in Bonn, established a celebrated asylum for insane and nervously affected persons in Bonn, and in 1856 became director of the pharmacological cabinet of the university. D. at Bonn, May 12, 1867. He published, among other works, *Handbuch der allgemeinen Pathologie* (2 vols., 1842-44); *Lehrbuch der allgemeinen Arzneimittellehre* (1853); and *Die Spermatorrhöe* (1862).

Albert: a French revolutionist and mechanic, whose original name was ALEXANDRE MARTIN; b. at Bury (Oise), Apr. 27, 1815. He founded in Paris in 1840 a journal called *L'Atelier* (The Workshop), and was a member of the provisional government formed in Feb., 1848, and was prominent in the defense of Paris in 1870.

Albert: Archbishop of Magdeburg and Elector of Mentz; b. at Brandenburg, June 28, 1490; created cardinal, 1518; and d. at Aschaffenburg, Sept. 24, 1545. Being granted by the pope the privilege of selling indulgences in his diocese, he employed the Dominican Tetzl in that service, and the shameless manner in which the latter conducted it called forth Luther's famous ninety-five theses. See his life by J. May (Munich, 1868-75, 2 vols.). See LUTHER, MARTIN.

Albert I.: King of Saxony; b. April 23, 1828; eldest son of King Johann I. and of Queen Amalie, daughter of King Maximilian I. of Bavaria. As crown prince he took part in the campaign in Schleswig-Holstein in 1849, was made lieutenant-general in 1853, and general in 1857, commanded the Saxon army in the war against Prussia in 1866, received the command of the twelfth army corps after the admission of Saxony into the North German Union, took part in the battles of Rezonville, Gravelotte, and Sedan in the Franco-German war of 1870, and received the command of the fourth army (of the Meuse). In July, 1871, he was created field-marshal of the empire, and soon after field-marshal of Russia. King Albert succeeded to the throne, at the death of his father, Oct. 29, 1873. He married, June 18, 1853, Queen Caroline, b. Aug. 5, 1833, daughter of Prince Gustav of Vasa. He has a civil list of 2,940,000 marks per annum, or about \$700,000; but the royal domains, consisting chiefly in extensive forests and some rich mines, became the property of the state in 1830.

Albert I.: Archduke of Austria; b. in 1248; son of the Emperor Rudolph of Habsburg. He was elected Emperor of Germany in 1298, but his title was contested by Adolphus of Nassau, who had occupied the throne. These rivals fought a battle, in which Adolphus was killed. Albert, who was noted for his cruelty and avarice, was assassinated at Windisch, May 1, 1308, by his nephew, John the Parricide. See his life by Mücke (Gotha, 1866).

Albert I.: Margrave of Brandenburg; surnamed THE BEAR; b. at Ballenstädt about 1106. He was the founder of the House of Brandenburg. D. Nov. 18, 1170.

Albert V.: a son of Albert IV.; b. Aug. 10, 1397; became Duke of Austria in 1404. He was chosen King of Hungary in 1437, and Emperor of Germany in 1438. His title as emperor was Albert II. D. near Vienna, Oct. 27, 1439.

Albert VII.: Archduke of Austria; son of the Emperor Maximilian II.; b. Nov. 13, 1559. He was appointed governor of the Netherlands in 1596 by Philip II. of Spain, whose daughter Isabella he married April 18, 1599. In 1600 he was defeated by Maurice of Nassau, who fought for the Dutch republic. The war was suspended in 1609 by a long truce. D. in July, 1621.

Albert (OF BRANDENBURG): first Duke of Prussia, a grandson of the preceding; b. at Ansbach, May 16, 1490. He was elected grand master of the Teutonic Order 1511, and was the last who held that office. In 1525 he became a Protestant and Duke of Prussia, which he held as a fief of the King of Poland. D. at Königsberg, Mar. 20, 1568.

Albert Edward: See EDWARD VII.

Albert Edward Nyanza: an African lake; one of the sources of the Nile; discovered by Stanley; lat. 1° S., lon. 30° E. It is about 40 miles across, and lies in a crescent, open northward, and about 50 miles from point to point. It is 100 miles N. W. of Victoria Nyanza, on the line between the Congo Free State and British East Africa. It drains by the Semliki river into the Albert Nyanza, and between these two lakes lie the Ruwenzori Mountains, which reach an altitude of 18,000 feet, and which Stanley believes to be the ancient "Mountains of the Moon." The lake was named after Albert Edward, Prince of Wales, in recognition of his interest in African geography. M. W. H.

Albert, EUGEN, d': pianist; b. in Glasgow, April 10, 1864; pupil of E. Pauer in London, and later of Liszt; author of overtures, concert pieces for the piano, an opera, *The Ruby*, etc.; is classed as a performer with Rubinstein and Liszt.

Albert Francis Augustus Charles Emmanuel, better known as *Prince Albert*: Prince of Saxe-Coburg-Gotha and consort of Queen Victoria; b. at Rosenau, near Coburg, Aug. 26, 1819. He was a son of Duke Ernest I. His marriage with Victoria was celebrated Feb. 10, 1840, soon after which he obtained the rank of field-marshal in the British army. He patronized science and art, was a liberal promoter of benevolent institutions, and acquired great influence in public affairs as the prudent and trusted adviser of the queen. In 1857 he received the title of prince consort. D. in London, Dec. 14, 1861. His death was lamented as a national loss. Compare Morton, *The Prince Consort's Farms* (1863); Grey, *The Early Years of the Prince Consort* (1867); *Leaves from the Journal of Our Life in the Highlands from 1848-61*; Theodore Martin, *Life of the Prince Consort* (Lond. 1875-80, 5 vols.).

Albert, FREDERICK RODOLPHE: Archduke of Austria; eldest son of Archduke Charles and Princess Henrietta of Nassau; b. Aug. 3, 1817. He married, in 1844, Princess Hildegard of Bavaria; d. April 2, 1864. He entered the army at the age of twenty; served in Hungary, Moldavia, and Silesia, and commanded a division in Italy, in 1849; fought with great distinction in the battles of Mortara and Movara. He was military and civil governor of Hungary from 1851 till 1860. He assumed the command of the 8th Army-corps at Vincenza in Oct., 1860, and on his appointment as field-marshal, April, 1863, was placed in command of the Austrian army during a leave of absence given to Field-Marshal Benedek. June 24, 1866, he won the brilliant victory at Custozza, and, returning to Austria, raised a new army of 200,000 men to repel the Prussian invasion of Bohemia. To him is due a great part of the credit for the terms secured from Prussia in the peace of 1866. July 13, 1866, he was made commander-in-chief of the Austrian army. He retained the title till Mar., 1869, when he exchanged it for that of inspector-general. D. in Arco, Aus-

tria, Feb. 18, 1895. Published *Responsibility in War* (1869), translated into French, and in English included in W. J. Wyatt's *Reflections on the Formation of Armies* (1869).

Albert Nyanza: a lake of Central Africa; head-waters of the White Nile: lat. 2° N., lon. 31° E.; about 100 miles long by 25 miles broad; 2,400 feet above sea-level. It receives the Semliki river from the Albert Edward Nyanza at the southern end and the Somerset river from Victoria Nyanza at the northern; a short distance from the mouth of the Somerset the waters of the lake empty into the White Nile. This lake was discovered in 1864 by Baker, who partially explored it, but erred in confounding its southwestern extremity with Albert Edward Nyanza and making it about 300 miles long, an error perpetuated on the maps for a quarter of a century. Later discoveries have shown that a group of lofty mountains, the Ruwenzori, lie between the two lakes.

M. W. H.

Albert, PAUL: French critic and literary historian; b. at Thionville, Dec. 14, 1827; made Professor of Literature in the Collège de France in Oct., 1878. His thesis for the doctor's degree in 1858 (*Saint Jean Chrysostome considéré comme orateur populaire*) was crowned by the French Academy. He has published *l'Histoire de la littérature romaine* (1871); *La littérature française depuis ses origines jusqu'à la fin du 18^e siècle* (3 t., 1872-79). Since his death two volumes, entitled *La littérature française au 19^e siècle*, have been brought out by his son. D. in Paris, June 21, 1880.

A. R. MARSH.

Alber'ta [named after the Princess Louise (more fully, Louise Caroline Alberta), Marchioness of Lorne]: a district of the Northwest Territories, and a future province of the Dominion of Canada. It lies E. of the Rocky Mountains and N. of the U. S. boundary, with Assiniboia and Saskatchewan on the E., Athabasca on the N., and British Columbia on the W. Area, 106,500 sq. miles. Pop. (1885) 15,533, of whom 2,855 were English, Scotch, and Welsh; 924 Irish, 831 French, 109 German, 9,418 Indian, and 1,237 half-breeds. The Athabasca and Saskatchewan rise in this district, while the extreme N. drains into the Peace river, and the extreme S. into the Missouri. The country consists of great plains gradually rising toward the W. from 2,000 to 4,000 feet, interrupted by occasional hills, and culminating in the backbone of the Rocky Mountains—here not very high. It is a great grazing country, except that severe cold occurs in winter, and stock must be protected and fed. The blizzard and chinook (*qq. v.*) are characteristic features of the winter climate.

The Canadian Pacific R. R. crosses Alberta from E. to W. near the southern border, and surmounts the Rocky Mountains at Kicking Horse Pass (5,323 feet). Capital, Calgary; chief towns, Edmonton, Lethbridge, Banff, the latter a health resort at the foot of the mountains. The production in pelts is large, but decreasing. It includes musk rat, deer, beaver, martin, mink, lynx, and wolf. Very little timber is produced. The fishing and mineral products are small. In 1885 the district contained 13,500 horses, 61,000 cattle, 17,000 sheep, and 4,000 swine. Pop. (1891) 25,277. M. W. H.

Alber'ti, JEAN: b. at Assen, Holland, Mar. 6, 1698; became minister at Harlem, and afterward Professor of Theology in Leyden; wrote theological works, and edited first volume of Hesychius's *Lexicon*. D. at Leyden, Aug. 13, 1762.

Alberti, LEON BATTISTA: Italian architect, poet, and writer on art; b. at Venice (or, as some say, at Florence), Feb. 18, 1404. He was employed as an architect by Pope Nicholas V.; completed the Pitti Palace at Florence, and built the church of St. Francis at Rimini, and the larger church of St. Andrea in Mantua. He was one of the two men (see BRUNELLESCHI) who introduced the classical style of design into Italy. He was a famous organist. His *Treatise on Architecture* (*De Re Ædificatoria*, 1485) is highly commended. D. in Rome, April, 1484 (others say 1472). See his life by Mancini (Florence, 1882).

Albertinell'i, MARIOTTO: Italian painter; b. in Florence, Oct. 13, 1474; was a pupil of Roselli, and a friend and imitator of Fra Bartolommeo, with whom he painted several pictures. Among his most celebrated paintings are the *Visitation of Mary and Elizabeth*, in Florence; *The Virgin Mary with Saint Domenico*, in the Academy at Florence; *Saint Catherine* and the *Virgin Mary with the Child*, in the Louvre. D. in Florence, Nov. 15, 1515.

Al'bertite: an asphaltic mineral found in Albert co., New Brunswick. The veins now remaining are small and

of little value. For a number of years prior to 1865 it was imported into Portland and Boston, and used in the preparation of illuminating oils—a use from which it was finally displaced by the discovery of petroleum. It occurs in veins nearly vertical that intersect the Albert shales, which are very rich in fossil remains of fish. It is a brilliant black mineral resembling jet, but softer, being easily cut with a knife. Subjected to distillation it yields a distillate composed mainly of the marsh gas or paraffine series of hydrocarbons. It is not at present of commercial importance. See ASPHALT and BITUMEN.

S. F. PECKHAM.

Albert Lea: city and railroad junction; capital of Freeborn co., Minn. (for location of county, see map of Minnesota, ref. 11-E); 128 miles W. of the Mississippi river, 108 miles S. of Minneapolis. It is beautifully situated between two lakes, one of which bears its name, and the surrounding country of undulating prairie and timber is charmingly picturesque. An abundance of game has made it a popular resort. It has a public park, library association, 16 churches, a young woman's college, a Lutheran academy, a high school, and 15 manufactories; numerous artesian wells yielding chalybeate waters, water-works, and electric lights. Pop. (1880) 1,966; (1885) 3,365; (1890) 3,305; (1900) 4,500.

EDITOR OF "STANDARD."

Albert Memorial: a large and costly monument erected in Hyde Park, London, in memory of Prince Albert, shortly after his death, from the designs of Sir George Gilbert Scott.

Alber'tus Mag'nus (i. e. Albert the Great), sometimes called *Albert von Bollstätt*: b. at Lauingen, Suabia, 1193; became a Dominican 1223; lectured for many years at Cologne and at Paris, and wrote numerous works on theology, logic, philosophy, and other subjects. In 1254 he was chosen provincial of the Dominican Order, and in 1260 became Bishop of Ratisbon. The episcopal office, however, was very uncongenial to him, and after the lapse of two years he was allowed to resign and retire to Cologne. He was reputed one of the most learned men of the Middle Ages, hence called by his contemporaries "Doctor Universalis," and was regarded as a magician by some of his contemporaries, for in the estimation of that superstitious period extraordinary ability implied a league with the devil. The great scientific exploit which made his name celebrated was the introduction of the complete system of Aristotle to the understanding of his age, which he effected by a kind of paraphrasing or loose reproduction, not of the Greek originals, but of the Arabic versions and commentaries, *De Prædicamentis, Super Octo Libros Physicorum*, etc. D. at Cologne, Nov. 25, 1280. Thomas Aquinas was one of his disciples. (See PHILOSOPHY.) Cf. his life, by J. Sighart (Regensburg, 1857; Eng. trans., Lond. 1876). His works, edited by Jammy, appeared at Lyons, 1651, 21 vols.; n. e. more complete, in 36 vols., by Borgnet (Paris, 1890, *sqq.*).

Al'bi, or **Al'by** (Lat. *Albi'ga*): an old city of France; capital of the department of Tarn; seat of an archbishop; on the river Tarn, and on a hill 42 miles N. E. of Toulouse (see map of France, ref. 8-F). It has a museum of natural history, a college, a normal school, a cathedral, a public library, and a theater; also manufactures of coarse linens, tablecloths, and cotton goods. The Albigenes derived their name from this town, which suffered much in the religious wars of France. Pop. (1881) 20,379; (1897) 21,490.

Albia: city; capital of Monroe co., Ia. (for location of county, see map of Iowa, ref. 7-H); 100 miles by rail N. W. of Burlington, and about 65 miles S. E. of Des Moines. The county is mostly underlaid with coal of a good quality, and mines have been opened in numerous places. Pop. (1880) 2,435; (1885) 2,142; (1890) 2,359; (1895) 2,588; (1900) 2,889.

Albigen'ses [from *Albi'ga*, the Latin name of Albi, a town of France, which was their starting-place]: an anti-sacerdotal sect in the south of France, allied to the Catharists. They derived their creed from the PAULICIANS (*q. v.*), but exactly what it was is now impossible of statement, as we have only the exaggerated and perverted statements of their foes to go upon. The one fact which led to their extinction was their opposition to the Church of Rome. They were apparently moral and orderly, and their opposition sprang from their belief in that Church's spiritual degeneracy. In the middle of the twelfth century they took possession of the church buildings, drove the Roman Catholic priests away, elected priests and bishops of their own, and finally held a great synod at Lombers, near Albi, 1165, in order to perfect their organization. The Roman *curia* was

startled at these proceedings. They were condemned by Councils held in 1165, 1176, 1178, 1179, but more vigorous measures were then taken. In 1208 Pope Innocent III. proclaimed a crusade against these reformers and against Raymond VI., Count of Toulouse, one of their principal leaders. A large army was led against them by Count Simon de Montfort. The war was carried on with great bitterness of feeling on both sides, and with little intermission, till 1229, when a treaty between the contending parties was concluded at Paris. Many of the Albigenes emigrated to other countries, while others perished in the Inquisition, which was established about the same time that the pope proclaimed his crusade. The name gradually disappears in the early part of the fourteenth century. See Faber's *Inquiry into the History and Theology of the Ancient Vallenses and Albigenes* (Lond. 1838); Hefele's *Conciliengeschichte*, v.; and N. Peyrat, *Histoire des Albigois* (2 vols., Paris, 1880-82).

Albi'na: a former city of Multnomah co., Or. (for location of county, see map of Oregon, ref. 1-C); on Union Pacific R. R. and Willamette river, opposite PORTLAND (*q. v.*), with which it was consolidated in 1891.

Albi'no [Port., from the Lat. *albus*, white]: a person who has congenitally a great deficiency or an absence of pigment in the hair, skin, and eyes. The complexion is very light, the hair often snowy white, the eyes red. Albinism in the human species may be observed in white and black races, and in the Negro is sometimes partial, patches of the skin having the normal color. Such patches of white skin may occur as an acquired disease, in which case the term vitiligo is applied. Interesting examples of albinism were those known as the Cape May albinos, where Negro parents had six children—three albinos, and the other three black. Albinism is frequent among Zuñi Indians and other tribes in Arizona. A degree of nyctalopia (day-blindness) is common among albinos. Elephants, birds, mice, and other animals sometimes exhibit the phenomena of albinism, which is often hereditary.

Revised by WILLIAM PEPPER.

Al'bian: the ancient Celtic name of Great Britain. The name, said to signify "white island," is supposed by some, though without good reason, to have been given on account of the chalky cliffs of Kent.

Albion: on railroad; capital of Noble co., Ind. (see map of Indiana, ref. 2-F, for location of county); about 26 miles N. W. of Fort Wayne; is situated in a farming country. Pop. (1870) 476; (1880) 926; (1890) 1,229; (1900) 1,324.

Albion: city and railroad center of Calhoun co., Mich. (for location, see map of Michigan, ref. 8-I); on the Kalamazoo river; 37 miles S. of Lansing, 96 miles W. of Detroit, and 20 miles W. of Jackson; on the Michigan Central, Lake Shore and Michigan Southern R. R. It is the seat of Albion College, under the control of the Methodist Episcopal Church. The city has fine primary-school buildings, besides an excellent central school, large flouring and other mills, door, sash, and blind factories, a tannery, and extensive agricultural tool manufactory, malleable-iron works, carriage-factory, harness-factory, machine shop and furnace, and a library. Pop. (1880) 2,716; (1890) 3,763; (1900) 4,519.

EDITOR OF "RECORDER."

Albion: capital of Orleans co., N. Y. (for location of county, see map of New York, ref. 4-D); on the New York Central R. R. and Erie Canal; 30 miles W. of Rochester; has a brick court-house, a jail, public parks, a free library, 7 schools, 8 churches, 5 newspapers, fine opera-house, electric lights, grain and fruit warehouses, and several important manufactories of mowing-machines, plows, carriages, shoes, soap, etc. Pop. (1880) 5,147; (1890) 5,773; (1900) 5,749.

EDITOR OF "HERALD."

Albion, Dane co., Wis. (for location of county, see map of Wisconsin, ref. 7-D); is situated in an important tobacco-growing region. Albion Centre is the seat of Albion Academy, under the patronage of the Seventh-Day Baptist denomination. Pop. of township in 1870, 1,142; (1880) 1,351; (1885) 1,518; (1890) 1,516; (1900) 1,590.

Albistan', or **El Bostan'** (i. e. the garden): a town of Asiatic Turkey, pashalic of Marash; in a plain; on the river Sihun, near the northern base of Mt. Taurus; 32 miles N. N. W. of Marash (see map of Turkey, ref. 5-II). It has several mosques, and a trade in wheat. Pop. 9,000. Here the Egyptian Sultan Bibars defeated the united Turks and Mongolians in a great battle on April 16, 1277.

Al'bite [from the Lat. *al'bus*, white]: a silicate of alumina and soda, sometimes called soda felspar. It is a constituent of granite, being associated with true felspar, from which it may be distinguished by its greater whiteness and translucency. It also occurs in syenite and greenstone.

Albo, JOSEPH: Jewish scholar of Spain; d. 1428. He took part in the public discussion between Jews and Christians held before Benedict XIII. in 1412. He continued the work of Maimonides (*q. v.*). According to him, the fundamental dogmas of Judaism are the existence of God, the law of Moses, and the future life. C. H. TOY.

Al'boin: the founder of the Lombard kingdom in Italy; was a son of Alduin, whom he succeeded in 543 A. D. He conducted an army of Longobards into Italy in 568, and conquered the northern provinces. He married Rosamund, a daughter of King Cunimund, King of the Gepidae, whom he had killed, and whose skull was made into a drinking-cup from which Alboin forced Rosamund to drink, June 8, 573 A. D. Rosamund in revenge had him assassinated that day.

Albo'ni, MARIETTA: opera singer; the most celebrated contralto of the nineteenth century; b. at Cesena, Romagna, Italy, Mar. 10, 1823; studied under Mme. Bertolotti in Bologna, and later under Rossini; made her first appearance at La Scala, Milan, 1843, and sang with great success in Europe and in the U. S. She married Count Pepoli, after whose death, in 1863, she retired from the stage. She afterward married Capt. Charles Zieger. She sang in Rossini's mass in 1871, and also on the celebration of Rossini's centenary, Feb. 29, 1892, when she declared that she would never sing again, even in her own home. D. in Paris, June 23, 1894. D. E. HERVEY.

Al Borâk' (i. e. the lightning, so called on account of its fleetness): the name of the fabulous milk-white creature on which Mohammed is said to have made journeys to the celestial regions.

Albornoz', GIL ALVAREZ CARILLO, or **Ægid'ius de Albornoz'**: a Spanish cardinal; b. at Cuenca, 1310. He was appointed (1339) Archbishop of Toledo by Alfonso XI. of Castile, whose life he saved in a battle against the Moors, and made cardinal 1350. In 1353 Pope Innocent VI. sent him as legate to Italy, where he distinguished himself by his military and political talents, and restored the authority of the pope over many cities. D. at Viterbo, Aug. 24, 1367.

Al'brecht: the name of many German princes and others. See ALBERT.

Al'brechtsberger, JOHANN GEORG: a learned contrapuntist; b. at Klosternenburg, near Vienna, Feb. 3, 1736; became director of the choir of the Carmelites in Vienna; organist to the court in 1772; musical director at St. Stephen's cathedral in Vienna in 1792, and died Mar. 7, 1809. He published *Gründliche Anweisung zur Composition* (1790; 3d ed. 1821). He was the instructor of Beethoven and other eminent musicians.

Albret, JEANNE, d', zhaan dal'brā: Queen of Navarre; b. at Pau, Jan. 7, 1528; daughter of Henry II. of Navarre, and Margaret, sister of Francis I.; married Antoine de Bourbon (1548); was celebrated for personal beauty and strength of character; embraced Calvinism and succeeded in retaining her kingdom; declared Protestantism established in her dominions, 1567; with her children, Henry and Catharine, and a small band of Huguenots, joined Coligny at La Rochelle, 1569; was regarded after the assassination of Condé as the only remaining support of the Huguenots; wrote both in prose and verse, some of her sonnets having been published. D. in Paris, June 9, 1572. C. H. THURBER.

Al'bright, JACOB: divine of the Lutheran Church; b. near Pottstown, Montgomery co., Pa., May 1, 1759. He founded, in 1808, the EVANGELICAL ASSOCIATION (*q. v.*). D. at Mühlbach, Lebanon co., Pa., in May, 1808.

Albuera, La, laa-aäl-bwā'ra: a village of Spain; in Estremadura; on a small river of its own name; 13 miles S. E. of Badajoz (see map of Spain, ref. 17-C). Here on May 16, 1811, the British under General Beresford defeated the French under Marshal Soult, who lost nearly 9,000 men. The allies lost about 7,000. Pop. about 600.

Albufera, al'-boō-fa'y'ra: a coast lagoon near Valencia, Spain; abounding with fish and fowl, its banks studded with rice plantations; owes its fame to the defeat (1811) of the Spanish by MARSHAL SUCHET (*q. v.*). The lake and domain were conferred on him by Napoleon, with title of Duc d'Albufera.

Albu'men, or **Albumin** [Lat. *albu'men*, the white of an egg, from *albus*, white]: in chemistry, an organic compound of great importance, which, besides being the characteristic ingredient in the white of an egg, abounds in the serum of the blood, in chyle, lymph, the juice of flesh, and forms an important part of the skin, muscles, and brain. In Bright's disease it is found in considerable quantity in the urine. "It is obvious," says Liebig, "that albumen is the foundation, the starting-point, of the whole series of peculiar tissues which constitute those organs which are the seat of all vital actions." Albumen is also found in small quantities in most vegetable juices.

When heated to a temperature from 140° to 160°, albumen coagulates and becomes insoluble in water. It is also coagulated by alcohol and most of the acids. It contains the elements carbon, hydrogen, oxygen, nitrogen, and sulphur, and has a very complex composition. The fibrine of the muscles and the albumen of blood contain the same elements in about the same proportion.

Egg albumen differs from serum albumen by being precipitated by ether.

Coagulated albumen is white, opaque, and elastic. It dries to a brittle, translucent, horny mass, which when placed in cold water swells up to its original form.

The white of an egg is recommended as an antidote to corrosive sublimate, mercuric chloride, as it forms mercuric albuminate, which is insoluble in water. As it is, however, slightly soluble in saline solutions, the physician should also secure vomiting, to remove the mercury from the stomach. Albumen is much used for clarifying sirups and other liquids. When boiled with them, it coagulates to flocks, entangling the suspended impurities, and carrying them either to the surface as a scum or to the bottom as a sediment. In cooking, the white of egg is employed; in sugar-refining, bullock's blood. Albumen is also used for preparing the surface of paper for photographic printing, and for making a cement with lime.

Egg and serum albumen are now manufactured in large quantities by simply drying the natural fluids in thin layers in warm air, taking care that the temperature shall not be so high as to coagulate the albumen, and thus render it insoluble. The chief application of this albumen in the arts is in calico-printing. It is employed in fastening certain colors upon the fibers of cotton cloth, especially pigments such as ultramarine, chrome yellows and oranges, Guignet's green, etc., and also the aniline colors. The pigments or colors are simply mixed with a solution of albumen, printed on the cloth, and fixed by steaming, which coagulates the albumen and renders it insoluble. A dark-colored, inferior quality of serum albumen, sold under the name of "dried blood," is used by sugar-refiners to clear the solutions of raw sugar.

All albuminoids found in animals owe their origin to processes that take place in plants. See ALBUMINOIDS.

Revised by IRA REMSEN.

Albumen: the old name for the food stored up in the seed of the young plant. See ENDOSPERM.

Albumin: See ALBUMEN.

Albu'minoids, or **Proteids**: an extensive class of organic bodies found in animals and plants. They form the chief constituents of blood, muscles, nerves, glands, and other organs of animals; and though present in plants in much smaller proportions than cellulose, starch, sugar, etc., they still play a most important part in plant-life. Their exact constitution has not been determined. Analysis shows them to contain—

Carbon,	50-55 per cent.
Hydrogen,	6.9-7.5 "
Nitrogen,	15-18 "
Oxygen,	20-24 "
Sulphur,	0.3-2.0 "

They are amorphous, more or less soluble in water, insoluble or nearly so in alcohol, insoluble in ether, soluble in excess of strong acetic acid, soluble in alkalies, and soluble in strong mineral acids. From their solutions they are precipitated by excess of mineral acids, by potassic ferrocyanide with acetic or hydrochloric acid, by acetic acid in presence of a considerable quantity of alkaline or alkaline earthy salt, gum-arabic or dextrine, by mercuric nitrate, Millon's re-agent.

They have been classified as follows:

I. Albumens, soluble in water: 1. Serum albumen; 2. Egg albumen.

II. Globulins, insoluble in water, soluble in very dilute acids and alkalies, soluble in dilute solutions of sodic chlo-

ride and other neutral salts: 1. Myosin; 2. Globulin; 3. Fibrinogen; 4. Vitellin.

III. Derived albumens, insoluble in water and in solutions of sodic chloride; soluble in dilute acids and alkalies: 1. Acid albumen; 2. Alkali albumen, or albuminate casein.

IV. Fibrin, insoluble in water, sparingly soluble in dilute acids and alkalies, and in neutral saline solutions.

V. Coagulated albuminoids.

VI. Amyloid substance, or lardacein.

VII. Peptones, produced by the action of the gastric juice on all albuminoids.

For further information on this important class of bodies see Hoppe-Seyler, *Handbuch der physiologisch-chemischen Analyse*; the *Handwörterbuch der Chemie*, 2t. Auf. II., p. 124; and *A Dictionary of Applied Chemistry*, T. E. Thorpe.

Revised by IRA REMSEN.

Albuminuria, ăl-byu-mi-nyu'ri-a [from *albumin-* and the Lat. *urina* (from Gr. *οὔρον*) urine]; the condition in which albumin occurs in the urine, and a most important symptom of disease. This condition was first recognized by one Nicholas Cotunius in 1770, and by him described as "coagulable urine." Later the relation to forms of dropsy and then to Bright's disease was determined. The connection between Bright's disease and albuminuria is of the greatest importance, but it is to be remembered that this symptom may occur in a variety of other conditions and in health. Of particular interest are those cases of "cyclic albuminuria" in which albumin appears in the urine at definite periods of the day or at longer intervals. These cases occur in boys at the age of adolescence, more rarely in girls, and their nature is obscure. After persisting for some length of time the albumin disappears from the urine and no further symptoms are noted. Again in certain persons there may be periodical albuminuria coincident with attacks of indigestion. In others exercise, cold bathing or a variety of causes bring about the temporary appearance of this symptom. It has been found by experiment that tying the emulgent veins of the kidneys in lower animals causes albuminuria by obstructing the flow of blood; and a similar explanation may be offered for the occurrence of the symptom in man in heart disease, tumors in the abdomen, or some cases of pregnancy, in all of which the outflow of blood from the kidneys is impeded. Besides the above a great variety of conditions may be accompanied by albuminuria, independent of kidney disease. The explanation of the occurrence in Bright's disease itself is not entirely settled. In some cases it may be due to disease changes which cause obstruction of the blood-vessels within the kidney; in other cases it may be disease of the vessels themselves which permits a ready escape of albumin from the blood; in still other cases degeneration of the epithelium lining the renal tubules may be the cause of the transudation. The loss of the albumin, however it occur, is doubtless of itself partly the cause of some of the other symptoms of Bright's disease, such as progressive weakness and anæmia. In certain rare cases of the disease albuminuria may be so slight as to escape detection by our ordinary tests. In others the amount of albumin is so great that on boiling the urine in a test-tube a solid coagulum results which remains in the tube on inverting it.

Besides the ordinary form of albuminuria, in which serum albumin and globulin, the albumins of the blood, appear in the urine, there are various modified forms, in which other albumins occur. In the cases due to indigestion egg albumin is sometimes found in the urine. Again peptones, hemialbumose, and various other forms occur, but are as yet little understood and require special tests for their detection.

Albuminuria is recognized by various tests, of which the two following are most useful: (1) On boiling the urine, mildly acidified with nitric or acetic acid if not already acid in reaction, a coagulation of greater or less distinctness is manifest. The test is made more delicate if the upper portion of the fluid in the test-tube is heated. The contrast of the coagulated with the non-coagulated portion is easily detected. (2) If strong nitric acid be poured into a test-tube, and on the surface of this from a pipette held in an almost horizontal direction a little of the urine, a ring of coagulated albumin will appear at the junction of the two liquids.

The treatment of albuminuria depends entirely upon the condition which causes it. In all cases hygienic measures are of prime importance.

WILLIAM PEPPER.

Albuquerque, al-boo-ker'kay: a town of Spain; province of Badajoz, 26 miles N. of Badajoz (see map of Spain, ref.

17-C). It is 9 miles from the frontier of Portugal, is built on high ground, and is defended by a very strong fortress situated on a mountain. The town was taken in 1705 by the allies of Charles, who was a claimant of the Spanish throne; but it was restored to Spain in 1715. It has a castle and manufactures of cotton and wool. Pop. 7,214.

Albuquerque: town; capital of Bernalillo co., N. M. (for location of county, see map of New Mexico, ref. 10-R); on the Rio Grande, and the Atch., Top. and S. Fé and the Atlantic and Pac. railways; 75 miles S. W. of Santa Fé, the capital of the Territory; at an elevation of 5,000 feet above sea-level. It is in a gold, silver, iron, and coal mining region; has an extensive trade in wool, hides, grain, and wine; is substantially built; and has improved water-works, gas and electric light plants, street-railway, a national bank with capital of \$150,000, a territorial bank with capital of \$75,000, and 3 daily and 3 weekly newspapers. Pop. (1880) 2,315; (1890) 3,785; (1900) 6,238. EDITOR "MORNING DEMOCRAT."

Albuquerque, or **Alboquerque**, AFFONSO, de (surnamed THE GREAT and THE PORTUGUESE MARS): a celebrated general; b. at Alhandra, near Lisbon, in 1452, was related to the royal family. After he had distinguished himself in several expeditions to Africa and the East Indies, he was appointed viceroy of the Indies in 1509. He took the city of Goa in 1510, and conquered Malacca, in which he obtained booty of great value, in 1511. In 1513 his fleet entered the Red Sea, which had never before been navigated by Europeans. He captured the rich emporium of Ormuz in 1515. Having been removed from command, he died at Goa Dec. 16 of that year. He is said to have been eminent for justice and other virtues, which, combined with his military skill, greatly increased the power of Portugal in India.—BRAS AFFONSO ALBOQUERQUE, a natural son of the preceding, was born at Alhandra in 1500. He was a naval officer, noted for his integrity and public spirit. He wrote a narrative of his father's campaigns, *Commentarios do grande Affonso d'Albuquerque*. D. in 1580. English translation by the Hakluyt Society (Lond. 1875-83), and letters which were published in Lisbon, 1884.

Albuquerque, JERONYMO, de: Portuguese soldier; b. about 1514; emigrated to Pernambuco about 1535, and took part in various wars between the colonists and the Indians. On Jan. 2, 1548, he was captured by the Cahatés, but succeeded in gaining their friendship, married the daughter of their chief, and finally brought about the pacification of this powerful tribe. D. at Olinda, near Pernambuco, Feb. 26, 1594. H. H. SMITH.

Albuquerque Maranhão, JERONYMO, de: Brazilian soldier; son of Jeronymo de Albuquerque and the Indian Maria do Espirito Santo, daughter of the Cahaté chief Arco Verde; b. in Pernambuco in 1548. He early accompanied his white father or Indian grandfather in war expeditions, and became an adept in predatory warfare; as leader of an incursion from Pernambuco he conquered Rio Grande do Norte in 1598-99; passed to Ceará in 1613; recovered Maranhão from the French (June 17, 1614), and was soon after made captain-general of that province. D. at Maranhão, Feb. 11, 1618. See Macedo, *Anno Biographico Brasileiro*, tome i, p. 177; Porto Seguro, *Historia Geral do Brazil*; Denis, *Introduct.* to his edition of *Yves d'Evreux*, etc. H. H. SMITH.

Albur'num [from Lat. *albus*, white], or **Sapwood**: that part of the wood of exogenous trees which is most recently formed and is contiguous to the bark. It is of a white or pale color, whence its name is derived. It gradually hardens with age, and is converted into duramen or heart-wood, which is more valuable than alburnum.

Alcæus (Ἀλκαῖος): one of the nine lyric poets of the Alexandrian canon; b. at Mytilene about 600 B. C. A man of war, a bitter partisan, a hearty hater, a thorough aristocrat, he was a sworn foe of the tyrant Myrsilus and of the wise and moderate stadtholder Pittacus. He composed in the fiery Æolic dialect, and the alcaic meter, which bears his name, is full of movement. Even the scant fragments, one of which is addressed to Sappho, breathe passion and energy. To Horace he was a paragon, and in some of Horace's best known odes we have reflexes of Alcæus. Fragments in Bergk's *Poete Lyrici Græci*. B. L. GILDERSLEEVE.

Alca'ic Me'ter: in Greek and Latin poetry, a logæedic (see LOGÆDIC) measure, named after Alcæus. The greater alcaic consists of a preliminary syllable, a trochaic dipody, an irrational dactyl (see DACTYL), and a catalectic trochaic

dipody; the lesser alcaic of two irrational dactyls followed by a trochaic dipody.

1. For | tē's cre | a'ntur | fo'rtibus | e't bo | nī's.
2. De'deco | ra'nt bene | na'ta | cu'pæ.

Alcaide: See **ALCAYDE**.

Alcala' de Hena' res: a city of Spain; in the province of Madrid; on the river Henares; 21 miles by rail E. of Madrid (see map of Spain, ref. 15-F); built in 1083 near the site of the ancient Complutum. It was the seat of a celebrated university founded by Ximenes, which has been removed to Madrid. After this removal Alcalá (which had 22,000 inhabitants in 1768) rapidly declined. Cervantes was born here in 1547. The celebrated Complutensian Bible was printed at Alcalá in 1514. Pop. 12,317.

Alcala' la Real': a city of Spain; in the province of Jaen; stands in an elevated glen about 2,700 feet above the sea, and 24 miles S. W. of Jaen (see map of Spain, ref. 19-E). It has a court-house, several convents, a hospital, etc. Pop. 15,901.

Alcal'de [Span. adaptation of Arab. *al-gā-dī*, the judge]: the title given by the Moors, Spaniards, and Spanish-American nations to a judicial or administrative officer; is sometimes erroneously confounded with *alcayde*. *Alcalde pedáneo* signifies justice of the peace.

Alcarnenes, al-kam'e-neez: sculptor of the fifth century B. C. Ancient writers have great praise for his work, and it has been assumed that he was a pupil of Phidias. Since the discovery of the sculptures at Olympia, which are stated by Pausanias to be his work, it is thought rather that he was a contemporary and rival of Phidias. The Olympia sculptures, indeed, are earlier in style and more nearly archaic in character than those of the Parthenon. These sculptures, which were a part of the temple of Zeus, are extremely powerful and vigorous; the western pediment contained the battle of the Centaurs and Lapithæ, and the metopes are of varied subject connected with the labors of Hercules.

RUSSELL STURGIS.

Al'camo: a town on the island of Sicily, in the province of Trapani, 24 miles S. W. of Palermo; has a college and picturesque ruins of an old castle (see map of Italy, ref. 9-E). Pop. 39,016.

Alcántara (i. e. the bridge): a town of Spain; province of Cáceres; on the left bank of the Tagus, near the Portuguese boundary (see map of Spain, ref. 16-C). Here are ruins of a grand bridge built by the Emperor Trajan in 103 A. D., of which a triumphal arch 40 feet high still remains. The Duke of Alba here defeated the Portuguese in a great battle on Aug. 25, 1580. Pop. 3,300.

Alcántara, Order of, also called the **Order of Saint Julian**: a religious order of Spanish knighthood, founded in 1156 at Alcántara for the defense of the Christians against the Moors. In 1495 the office of grand master of this order was united to the Spanish crown; in 1835 it was changed from an ecclesiastical to a court order. Their crest was a pear-tree.

Alcatraz' (or Alcatrazes) Island, sometimes called Pelican Island: in the bay, 2½ miles N. of San Francisco, Cal. Length, 1,650 feet; height, 130 feet. It is fortified, and commands the entrance of the Golden Gate. On its summit is a lighthouse 36 feet high, in lat. 37° 49' 27" N., lon. 122° 24' 19" W.

Alcava'la, or Alcaba'la [Span. adaptation of Arab. *al-gabālah*, the tax; cf. Fr. *gabelle*]: a tax formerly imposed in Spain and her colonies on all property sold, and payable as often as it changed hands. This tax, which was at first 10 and afterward 14 per cent. *ad valorem*, was very injurious to the prosperity of the country.

Alcayde [Span. adaptation of Arab. *al-gā'id*, the captain]: a jailer or inferior magistrate among the Spaniards, Portuguese, and Moors.

Alca'zar Kebîr' (the great castle): a decayed city of Morocco; 83 miles N. W. of Fez (see map of Africa, ref. 2-B). Pop. in 1864 about 25,000; now only about 6,000. Near it is a bridge (*Alcántara*) where Sebastian, King of Portugal, was defeated and killed, Aug. 4, 1578.

Alces'tis: in classic mythology, a daughter of Pelias and the wife of Admetus, King of Thessaly. The poets feigned that she prolonged the life of her husband by suffering voluntary death as his substitute, and was rescued from Hades by Hercules. The story of her devotion is the subject of one of the tragedies of Euripides.

Al'chemy [from Arab. *al-kīmīā*: *al*, the + *kīmīā*, loanword from Gr. *χημία*, art of transmuting metals, probably so called from native name of Egypt, *Khami*]: the occult science or art of transmuting the baser metals into gold. Some writers suppose that alchemy originated in Egypt, the ancient name of which was *Chem* (dark, mysterious), and that it was introduced into Europe by the Arabs. The origin of alchemy seems to be connected with the widespread notion that the manifold forms of matter have a common basis, and that the individual properties of material bodies are due to formative force separable in thought, if not in fact, from this common substratum. Hence it followed that if this first matter could be dissolved or separated from all special formative forces, and the special "form" of gold or other precious substance discovered and got under control, these or any material body could be produced at will. From this point of view we may understand the reason of the alchemists' search for the "universal solvent" and for the special "forms" of things. The union of the *materia prima* and the "form" of gold would produce the actual metal. In like manner, if the vital principle or form of the bodily organization could be found and controlled, the tendencies to disease and decay in the bodily organization could be resisted. Hence the search after the elixir of life and the philosopher's stone. It was this search after "forms" and the *materia prima* which so vitiated the method of the Middle Age investigators. It was a reaction against this false analysis of Aristotle which led to the bitter opposition to his name and doctrines which marked the rise of modern science in Europe. When belief in the reality of the Aristotelian analysis passed away, alchemy ceased.

In the Middle Ages the alchemists expended immense labor and time in experiments, the object of which was to discover the philosopher's stone and an elixir vitæ (the elixir of life) which could cure all diseases and restore old people to youth. Many useful discoveries were the results of these visionary pursuits, in which the most eminent men of those times took part. Roger Bacon (1214-92) was a believer in the doctrine that base metals can be transmuted into gold. The works which he wrote on alchemy are the oldest extant European writings on that subject. Among the other famous alchemists were Basil Valentine, R. Lully, and Paracelsus. As late as the sixteenth century many men of superior intellect devoted their time and money to alchemy, and hoped to discover the grand arcanum. According to Liebig, "The great (Francis) Bacon, Luther, Benedict Spinosa, and Leibnitz believed in the philosopher's stone, and in the possibility of the transmutation of metals." (*Familiar Letters on Chemistry*.) The same writer affirms that "alchemy was never at any time anything different from chemistry. It is utterly unjust to confound it, as is generally done, with the gold-making of the sixteenth and seventeenth centuries. Among the alchemists there was always to be found a nucleus of genuine philosophers, who were often deceived in their theoretical views; whereas, the gold-makers, properly so called, knowingly deceived both themselves and others." See **CHEMISTRY**.

Alcia'ti, ANDREA: Italian lawyer; b. at Alzato near Milan, May 8, 1492. He lectured on law at Bourges from 1528 to 1532, after which he was Professor of Law at Bologna, Pavia, and Ferrara. He wrote, besides other works, *Commentaries on the Digest*, and a book of emblems. D. in Pavia, Jan. 12, 1550. Erasmus said of him, as Cicero said of Scævola, "He was the most jurisprudent of orators, and the most eloquent of lawyers." His complete works appeared, Basel, 1546-49, 6 vols., and were several times reprinted.

Alcibiades, al-si-bi'a-deez, or al-si-bee'a-deez: famous Athenian general and politician; b. of a noble family about 450 B. C.; son of Cleinias. He was educated at the house of his mother's second cousin, the illustrious Pericles, and inherited a large estate. From nature he received great personal beauty and transcendent abilities, with strong passions and proclivities to licentious habits. As a favorite pupil and companion of Socrates, he enjoyed in his youth great advantages for the cultivation of his mind. (See **SOCRATES**.) In 421 B. C. he began his political career as the leader of the democratic party and an opponent of Nicias, who advocated peace with Sparta. Having induced the Athenians to send a great expedition (in 415 B. C.) against Syracuse, the ally of Sparta, he was chosen to command it, in conjunction with Nicias and Lamachus. Soon after the fleet had reached Sicily, Alcibiades was recalled to defend himself against a charge of sacrilege, but he escaped to

Sparta, and in his absence was condemned to death by the people of Athens. He acquired much influence with the Spartans, whom he aided in their operations against his native country, but several jealous Spartan leaders having conspired against him, he fled to the Persian satrap Tissaphernes, and again changed sides. The next scene in the drama of his eventful and wayward career presents him as the commander of the Athenian fleet in 412 B. C. He defeated the Spartans at Abydos in 411, and at Cyzicus in 410 B. C. Having by these and other victories restored the naval supremacy of Athens, he returned in triumph to the capital in 407, and regained his popularity. He was removed from the command in 406, in consequence of a reverse which his fleet suffered in his absence, and he again went into exile. He sought refuge in Phrygia, where he was assassinated by night in 404 B. C. See Plutarch's *Life of Alcibiades*; Grote's *History of Greece*, vol. viii.; Thirlwall's *History of Greece*.

Alcidamas (Ἀλκιδάμας): pupil of Gorgias and rival of Isocrates. Of the two declamations attributed to him, the one *Against the Sophists* is clever and interesting. Text in Blass's second edition of *Antiphon*, p. 193. See F. Blass, *Attische Beredsamkeit*, ii. 345-63.

Alciphron (Ἀλκιφρων): a Greek epistolary writer, about 180-200 A. D., of whom we have 118 fictitious letters representing the manners and opinions of various classes of society. The material is drawn largely from the New Comedy; the style is pure for the period. Valuable edition by Bergler, reproduced with additions by Seiler (1856).

Revised by B. L. GILDERSLEEVE.

Alcira, aal-thee'ra: an ancient walled town of Spain; on an island in the river Jucar; in the province of Valencia; 25 miles S. of Valencia (see map of Spain, ref. 17-I), has two fine stone bridges, besides an iron railway-bridge. Near it is a curious cavern. Pop. 16,146.

Alcmæon'idæ, THE: one of the most prominent families of ancient Athens; expelled from the city in 596 B. C., their chief, Megacles, having committed sacrilege by allowing Cylon and his partisans to be massacred, though they had sought refuge in the temple of the Eumenides. The family went to Phocis, but its immense wealth and connections with some of the most powerful families in Greece enabled it to return to Athens after an exile of about thirty years. Then followed the long and turbulent contest with Pisistratus, in which the Alcmæonidæ were once more driven from Athens. During this their second exile they spent a great deal of their wealth in rebuilding the temple of Apollo in Delphi, which was burnt down in 548 B. C., and the magnificence with which they accomplished this great undertaking made them so popular throughout all Greece that the Spartans finally restored them by armed force. Among the famous members of the family were Clisthenes, Pericles, and Alcibiades.

Alcman (Ἀλκμάν): Spartan lyric poet; b. at Sardis; was originally a slave. He flourished about 650 B. C., and became a free citizen of Sparta. He wrote songs called *Parthenia*, also bridal hymns and other erotic poems which were greatly admired. The small fragments of his works increased by recent discoveries are contained in Bergk's *Poetæ Lyrici*.

Alcme'ne (Gr. Ἀλκμήνη): a daughter of Electryon and Anaxo, the daughter of Alcæus. She is said to have been the mother of Heracles by Zeus. Hera, jealous of Alceme, delayed the birth of Heracles for seven days, that Eurystheus might be born first, and thus be entitled to greater rights, according to a vow which Zeus had made. There are different accounts of her death. According to Plutarch, Agesilaus opened her tomb at Haliartus in Bœotia, and carried her remains to Sparta.

Alcock, Sir RUTHERFORD, K. C. B., D. C. L., F. R. C. S.: British consul and minister; b. in London in 1809; was a surgeon in the navy in Portugal, 1833-34; inspector of hospitals under Sir de Lacy Evans in Spain, 1835-37; auditor of accounts of the English-Spanish legion, 1839-44; became British consul at Foo-Chow, 1844; at Shanghai, 1848; and at Canton, 1858. In 1859 he was transferred to the diplomatic service and became minister to Japan, whence he was transferred to China, 1865, where he remained until 1871. He was the author of *Notes on the Medical History of the British Legion in Spain* (1838); *Capital of the Tycoon* (2 vols., Lond., 1863); *Art and Art Industries in Japan* (1878), etc. He was created a K. C. B. in 1862. D. Nov. 2, 1897. R. L.

Alcohol [from Arab. *al-koh'l*; *al*, the + *koh'l*, fine powder for coloring the eyelids, etc. Term extended in early Euro-

pean chemistry to any very fine powder, and later applied to fluids as the quintessence, spirit]: a limpid, colorless liquid which has a hot, pungent taste, and is the essential principle of all spirituous liquors and intoxicating drinks. It is the product of the fermentation of sugar or saccharine substances, and is extracted by distillation from spirituous liquors, such as whisky and brandy, which contain nearly 50 per cent. of water. Pure alcohol is very inflammable, has a strong affinity for water, is a powerful solvent, boils at 173° F., and has been congealed at an extremely low temperature (about 200° F. below zero). It is composed of carbon, oxygen, and hydrogen, its composition being expressed by the formula C₂H₆O. In medicine, alcohol is used as a stimulant or excitant, mostly in the form of wine, brandy, or whisky. In pharmacy, alcohol is extensively used as a solvent; its solutions are called tinctures. The strongest alcohol that can be procured is termed absolute alcohol or anhydrous alcohol; it is prepared by removing the last few per cent. of water by quicklime.

Alcohol can be built up from its elements in the laboratory by starting with acetylene, which can be made by passing a powerful electric current between carbon poles surrounded by hydrogen. Acetylene, which has the composition C₂H₂, takes up hydrogen and forms ethylene, C₂H₄. This unites with sulphuric acid to form ethyl-sulphuric acid, which, when distilled with water, yields alcohol and sulphuric acid.

The alcohol of commerce varies in strength from *proof spirits*, which contain 50 per cent. by volume, to *cologne spirits*, which contain from 93 to 95 per cent. It is manufactured from a variety of materials which contain either sugar or starch, such as molasses, beets, potatoes, Indian corn, etc. See WHISKY.

Intoxicating beverages owe their peculiar effects on the system chiefly to the alcohol they contain. They are divided into fermented liquors and distilled liquors or spirits. Fermented liquors include (1) *wine* made from saccharine fruits, such as the grape, apple, and pear; and (2) *beer* made from materials which contain starch, usually barley. Distilled liquors are made from the refuse of the grape—*brandy*; or from molasses—*rum*; or from cereals or potatoes—*whisky*. *Gin* is alcohol flavored with juniper berries. See FERMEN-TATION, WINE, CIDER, BEER, RUM, BRANDY, WHISKY, and GIN.

Revised by IRA REMSEN.

Alcoholism: See INTOXICATION.

Alcoholom'etry [from *alcohol*, and the Gr. μέτρον, a measure]: the method of estimating or ascertaining the amount of absolute alcohol in a given quantity of spirits. This may be done—(1) by determining the specific gravity of the spirits, provided they contain nothing besides water and alcohol. The specific gravity of water being 1, that of pure or absolute alcohol is 0.7938 at 60° F. Tables have been carefully prepared showing the percentage of alcohol corresponding to different gravities between these extremes. (See GRAVITY, SPECIFIC.) If the spirits contain sugar, etc., they must be purified by distillation before determining the gravity. (2) The percentage of alcohol may be determined by observing the boiling-point. Water boils at 212° F., absolute alcohol at 173° F. (3) By observing the tension of the vapor. The first method is always employed in practice.

Alcohols: compounds that have the same general properties as ordinary alcohol or "spirits of wine." The most familiar example is a compound obtained by heating wood, and hence known as "wood spirit." Its chemical name is methyl alcohol. Ordinary glycerin also belongs to this class, and fusel oil is a mixture of alcohols, all of which are more complex than ordinary alcohol. The alcohols differ very much from one another in their properties. Thus some are liquid, others are solids; some act upon the system in the same general way as ordinary alcohol, others do not; some are good solvents for organic compounds, others are not. But in their chemical behavior they are much alike. Their reactions are such as to show that they are closely related to water, in the same way that ordinary alcohol is. Water consists of hydrogen and oxygen in the proportion represented in the formula H₂O. If half the hydrogen is replaced by a group consisting of carbon and hydrogen, the product is an alcohol; thus ordinary or ethyl alcohol is represented by the formula C₂H₅.OH, methyl alcohol by CH₃.OH, etc. The group represented by the formula OH is the same as that contained in water. There are much more complex alcohols than those represented above, but the general statements hold good for all.

IRA REMSEN.

Alcoran: See KORAN.

Alcorn, JAMES LUSK: See the Appendix.

Alcott, AMOS BRONSON: transcendental philosopher; formerly one of the principal contributors to *The Dial*; b. at Wolcott, Conn., Nov. 29, 1799; removed to Boston in 1828, and finally settled at Concord, Mass. He acquired some reputation as an educational reformer, but became chiefly distinguished for his conversational powers. He held formal "conversations" on a wide range of speculative and practical themes in the principal cities of the U. S. Published *Conversations with Children on the Gospels* (1836); *Tablets* (1868); *Concord Days* (1872); *Table Talk* (1877); *New Connecticut* (1881); *Sonnets and Canzonets* (1882); *Ralph Waldo Emerson, his Character and Genius* (1882). D. Mar. 4, 1888.

Alcott, LOUISA MAY: daughter of the preceding; b. at Germantown, Pa., Nov. 29, 1832. In early life she was a teacher; during the civil war a hospital nurse. She published her first book, *Flower Fables*, in 1855, but it was not till 1868, when her *Little Women* appeared, that she attracted much attention. In *Little Men* (1871), *Joe's Boys* (1886), and her later stories, as a delineator of American child-life, she achieved great popularity. D. at Boston, Mass., Mar. 6, 1888. See her *Life* (1889). S. M. J.

Alcove [Fr. *alcôve*, viâ Span., from Arab. *al-gobbah*; *al*, the + *gobbah*, vaulted space]: in architecture, a recess in an apartment, separated by an estrade or partition of columns, and occupied by a bed of state; a recess in a library or a lateral apartment for books.

Alcoy: a city of Spain; in the province of Alicante, 30 miles N. of Alicante (see map of Spain, ref. 17-I). It is built on uneven ground among the hills, and has manufactories of paper and woolen goods. About 200,000 reams of paper are made here annually. A large part of this paper is consumed in the form of cigars (*papelitos*). Pop. about 35,000.

Alcuin, Ælwin [called by himself *Albinus*, and by his friends *Flaccus*]: b. at York, England, about 735. He studied in the famous Cathedral School of York under Archbishop Egbert, and particularly Aelbert, Egbert's relative, and the real head of the school. He thus acquired the best culture of his time, becoming familiar both with the Latin classics and with the Christian Fathers. In 766, when Egbert died and Aelbert became archbishop, Alcuin became virtual head of the school; in 778, on Aelbert's resignation, he was made titular head. In 781, being on his way home from Rome, he met Charlemagne, and was invited by him to become the head of the famous Schola Palatina (School of the Palace), the peripatetic school, made up of the royal family and the courtiers—and frequently attended by Charlemagne himself, who asked very keen questions. He accepted, and was thenceforth the intimate friend and adviser of Charlemagne, teaching in his school, attending closely to the ecclesiastical policy of the empire, and having a large influence upon the grandiose plans which make memorable the reign of Charlemagne. In 790 he visited England, remaining two years; in 801 he retired to the abbey of St. Martin, at Tours, where he lived and taught until his death, May 19, 804. He was a constant writer, producing various theological treatises, school-books, poems, and letters (of great importance for the history of Charlemagne's reign). Though not a man of striking originality, his influence upon the intellectual development of Europe can hardly be overestimated. From him and his school may almost be dated the educational development of the modern world. See *B. Flacci Albini seu Alcuini opera cura et stud. Frobenii* (2 tom. in 4 vols., 1777); Lorentz, *Alcuin's Leben* (1829, Eng. trans. by Slee, 1837); Monnier, *Alcuin et Charlemagne* (1863); Werner, *Alcuin und sein Jahrhundert* (1876); A. Ebert, *Geschichte der Literatur des Mittelalters* (vol. ii. 1880); J. B. Mullinger, *The Schools of Charles the Great and the Restoration of Education in the Ninth Century* (Cambridge, 1877); A. F. West, *Alcuin and the Rise of Christian Schools* (N. Y., 1892). A. R. MARSH.

Aleyona'ria: an order of coral-polyps, including the fan-corals, the red coral of commerce, the sea-pens, organ corals, etc., characterized by the possession of eight branched tentacles around the mouth, and the same number of uncalcified mesenteries or partitions of the body cavity. The skeletons formed by this group of corals vary greatly. They usually consist of an axial stem either horny or calcareous and simple or much branched, surrounded by a thinner

crust which is fleshy or friable. In the organ-pipe coral, the skeleton consists of parallel hollow tubes joined by thin horizontal plates. DAVID S. JORDAN.

Aley'one, or **Haley'one** (Gr. Ἀλκωνη): in classic mythology, a daughter of Æolus and the wife of Ceyx. She was so inconsolable for the death of her husband that she threw herself into the sea. Tradition adds that Ceyx and Aleyone were changed into kingfishers to reward their mutual devotion.

Aleyo'nium [Gr. ἀλκωνειον, from ἀλκων, kingfisher, so called from supposed resemblance to nest of kingfisher]: a genus of zoöphytes belonging to the order *Aleyonaria*, presents a curious polyp mass and star-like pores, through which polyps protrude themselves. The *Aleyonium digitatum* abounds on the shores of Great Britain. The *Aleyonium carneum* is found along the American coast from Cape Cod northward.

Aldan': a river of Siberia; the largest tributary of the Lena; rises in the Yablonoi mountains, near the frontier of the Chinese empire. Flowing northeastward and afterward in a N. W. direction, it enters the Lena about lat. 63° N., and nearly 60 miles below Yakutsk. Length about 400 miles, in considerable part navigable.

Ald'borough: a town of England; in the West Riding of Yorkshire; about 16 miles N. W. of York (see map of England, ref. 6-H). It occupies the site of the town of *Isurium* of the Romans, and is noted for its ancient remains, consisting of interesting ruins of aqueducts, extensive buildings, tessellated pavements, etc. Pop. 2,265.

Aldeb'aran [from the Arabic *al*, the, and *dabarân*, following, i. e. the Pleiades]: a star of the first magnitude in the constellation of Taurus, otherwise called α Tauri. It is the brightest star of a group called the Hyades.

Al'degonde, SAINT: See MARNIX.

Al'degre'ver, or **Aldegraef**, HEINRICH: German painter and engraver; b. probably at Paderborn in 1502; became a citizen of Soest and decided adherent of the Reformation; was a pupil and imitator of Albert Dürer. Among his numerous engravings are *The Labors of Hercules* and a portrait of Luther. Specimens of his painting are very rare, the only undoubted one being a portrait in the gallery at Berlin. D. at Soest after 1555.

Al'dehyde [from *al*, first syllable of *alcohol*, and *dehyd*, first two syllables of *de-hydrogenatus*, deprived of hydrogen]: a compound formed by abstracting hydrogen from alcohol. The change is effected by the action of oxygen, this element uniting with a part of the hydrogen of the alcohol to form water, and leaving aldehyde. In purifying alcohol it is passed through filters of bone-black. The air contained in the pores of these filters oxidizes a part of the alcohol that first passes through, and therefore the "first runnings" contain aldehyde. Large quantities of aldehyde were at one time obtained in this way. It is a volatile liquid of a marked and characteristic odor. It is easily changed to a substance of the same composition, known as *paraldehyde*, which finds application in medicine. IRA REMSEN.

Al'den, EDMUND KIMBALL, D. D.: Congregationalist; b. at Randolph, Mass., Apr. 11, 1825; graduated at Amherst College, 1844, and at Andover Theological Seminary, 1848; He was pastor at Yarmouth, Me., 1850, at Lenox, Mass., 1854, at South Boston, 1859, and secretary of the American Board of Commissioners of Foreign Missions from 1876. D. Apr. 30, 1896. GEORGE P. FISHER.

Alden, JAMES: rear-admiral, U. S. N.; b. at Portland, Me., Mar. 31, 1810; entered the navy as a midshipman, Apr. 1, 1828. In command of the steamer South Carolina, he engaged the batteries off Galveston, Tex., Aug. 3, 1861, and commanded the steamer Richmond in the engagement with Forts St. Philip and Jackson, and at the capture of New Orleans, Apr. 24, 1862, and during the passage up and down the Mississippi river by Vicksburg, June 28 and July 15, 1862; in the engagement at Port Hudson, Mar. 14, 1863; commanded the Brooklyn at the great victory over forts, rams, and gunboats in Mobile bay, Aug. 5, 1864, and in both the Fort Fisher fights, Dec., 1864, and Jan., 1865. In 1869 he was appointed chief of the Bureau of Navigation, and in 1871 to the command of the European station. He retired from active service in 1873. D. at San Francisco, Cal., Feb. 6, 1877.

Alden. JOSEPH. D. D., LL. D.: b. at Cairo, N. Y., Jan. 4, 1807, and graduated at Brown University, 1828; studied theology at Princeton, and was ordained pastor of a Congregational church at Williamstown, Mass. (1834); was a professor in Williams College (1835-52), in Lafayette College, Pa. (1853-57), president of Jefferson College (1857-67), and principal of the New York State Normal School at Albany (1867-82). He was a voluminous writer, especially on educational topics. D. in New York, Aug. 30, 1885.

Alden. WILLIAM LIVINGSTON: author: b. Oct. 9, 1837; educated at Lafayette and Jefferson colleges; founder of New York Canoe Club; introduced canoeing into the U. S.; author of *Canoe and Flying Proa* (1880); *The Moral Pirates* (1881); *Life of Columbus* (1882); *The Cruise of the Canoe Club* (1883), etc.

Al'denhoven: market-town of Prussia; in the Rhine province (see map of German Empire, ref. 5-C). Here the Austrians defeated the French on Mar. 1, 1793, and the French defeated the Austrians on Oct. 2, 1794. Pop. 1,100.

Al'der [O. Eng. *alor*, Germ. *erle*, O. Nor. *öltr*, related Lat. *alnus*, O. Bulg. *jelicha*]: a tree or shrub of the genus *Alnus* and family *Betulaceæ* or *Cupuliferae*. The alders are natives of the temperate parts of Europe and North America. The wood of the common alder of Europe (*Alnus glutinosa*) is used by turners and joiners, affords good charcoal for the manufacture of gunpowder, and is valuable for mill-wheels and the piles of bridges. The alder is prized as an ornamental tree in landscapes. The *Alnus cordifolia*, a native of Italy, is a large and beautiful tree. The alders of the Eastern U. S. are shrubs or small trees, but *Alnus oregona* of the west coast grows to the height of 60 to 70 feet. For the black alder, see WINTERBERRY. C. E. B.

Alderman [O. Eng. *aldormann*, *aldor*, parent, patriarch, chief (subst. from *ald*, old) + *mann*, i. e. the *man* holding a patriarch's position]: the title of a municipal officer or magistrate in the corporations of England and the U. S. Aldermen were first appointed in 1242. The London court of aldermen exercises judicial and legislative authority in the corporation. In New York city the term is applied to the members of the city council, who are elected by the people. In some cities they are magistrates, in others councilors.

Alderney, awl'dér-ni, or **Aurigny**: an island in the English Channel, 7 or 8 miles from Cape la Hague, France (see map of France, ref. 2-C). It belongs to Great Britain, and is about 4 miles long; area, 3 sq. miles. Guernsey, another of the Channel islands, is about 15 miles from this place. The people of Alderney are mostly of French extraction. This island produces a celebrated breed of small cows. It is separated from France by the Race of Alderney, a dangerous strait about 8 miles wide. It is politically a dependency of Jersey. Pop. (1861) 4,932; (1871) 2,738; (1881) 2,048; (1891) 1,843.

Al'dershot Camp: a permanent camp formed in 1855 for the improvement of the British army in tactics and in evolutions on a large scale. It is situated on Aldershot Heath, on the confines of Surrey, Hampshire, and Berkshire. The area of ground appropriated to this purpose is 7,063 acres. A thriving town has naturally sprung up near the camp. Pop. 20,000 (7,000 military).

Al'dine Editions: See MANCIUS ALDUS.

Al'drich. NELSON WILMARTH: b. at Foster, R. I., Nov. 6, 1841; received an academic education; president Providence (R. I.) common council 1872; member Rhode Island General Assembly 1875-76, and was Speaker of its House of Representatives in 1876; was member of the Forty-sixth Congress, and re-elected; was elected, Oct. 5, 1881, U. S. Senator; re-elected in 1887 and again in 1893.

Aldrich. THOMAS BAILEY: poet and story writer; b. at Portsmouth, N. H., Nov. 11, 1836. Lived in his youth in Louisiana, then in New York, where he was for a time a clerk, then a proof-reader, and afterward attained eminence as a writer and editor. Wrote for the *Home Journal*, *Atlantic Monthly*, and other periodicals, and has published *The Ballad of Babie Bell* (1856); *Cloth of Gold* (1874), and several other volumes of verse; besides *The Story of a Bad Boy* (1870); *Marjorie Daw* (1873), etc., in prose. He was editor of the *Atlantic Monthly* from 1881 till 1892.

Revised by HENRY A. BEERS.

Al'dridge. IRA: a Negro tragedian; b. in Maryland about 1810; was in his youth a personal attendant of Edmund Kean. He performed with success in Great Britain and

other countries of Europe. He received medals or tokens of honor from the King of Prussia and the Emperor of Austria. D. at Lodez, Poland, Aug. 7, 1867. He was called the "African Roscius."

Aldrovan'dus. ULYSSES: Italian naturalist; b. at Bologna, Sept. 11, 1522. He graduated as doctor of medicine in 1553, and became Professor of Natural History at Bologna in 1560. Having expended much time and money in collecting specimens and in the study of nature, he began in 1599 the publication of his *Natural History* (13 vols.), of which three volumes on birds and one on insects appeared during his life. The other volumes were edited by several persons after his death. His *Natural History* is a laborious and ill-digested compilation. D. at Bologna, Nov. 10, 1607.

Ale: a sort of beer; a fermented liquor produced from malt. Ale contains more alcohol than common beer, and is a favorite beverage of the British. Scotch ale and Burton ale have a high reputation. There are three varieties of malt liquor in general use in this country—ale, porter, and lager beer. All are prepared from malt, which is barley that has been allowed to germinate (sprout), and has then been dried by artificial heat. Hops are added to give the aromatic bitter flavor. The lower the temperature at which the malt is dried the lighter will be the color of the malt and the beverage. Ale and lager beer are made from light, porter from dark-colored malt. Ale and porter are fermented at temperatures of from 65° to 90° F., while lager beer is fermented at from 46° to 50° F.

In the manufacture of ale the first fermentation is checked at such a point as to leave a considerable quantity of saccharine matter in the liquor. By the subsequent fermentation in the barrels or bottles this is changed to alcohol and carbonic acid, the latter substance causing the characteristic effervescence. See BEER.

Aleander. HIERONYMUS, or, in Italian form, *Girolamo Aleandro*: a learned Italian cardinal; b. at Motta, Feb. 13, 1480. He was appointed librarian of the Vatican in 1517, and was sent by Leo X. as papal nuncio to Germany in 1520, to counteract the influence of Luther, and to him is mainly due the condemnation of Luther at the Diet of Worms. His own report of the Diet is an important source. See Brieger, *Aleander und Luther* (Gotha, 1884). In 1538 he was made a cardinal by Paul III., when he took the title of St. Chrysostom. D. at Rome, Jan. 31, 1542. S. M. J.

Alecsandrescu. GRIGORIE: Roumanian poet; b. at Tirgovesti, Wallachia, in 1812; was sent in consequence of political agitations to a convent, where he wrote his most celebrated work, *The Year 1840*, in which he gives expression to the hopes of his party. In 1859 he was for a few months Minister of Finance, afterward acting with the Liberal opposition, which he effectively aided with his poems and fables. A second edition of his collected works appeared in 1863, about which time his mind became affected and nothing more appeared from his pen. D. at Bucharest, 1886.

Revised by E. S. SHELDON.

Alecsandri. VASILE: Roumanian poet; b. in Northern Moldavia in 1821; took part in the Liberal movement of 1848; was Minister of Foreign Affairs for a few months in 1859-60; and later resided partly in Jassy and partly in Paris. Among his writings are *Doine și lacrimioare* (Elegies and Laments, 1853), dramatic works, and, most important of all, his collections of the popular songs of Roumania, of which a first series appeared in 1852, a second in 1853, the whole being published under the title *Poesii populare ale Românilor* (Bucharest, 1866). Three volumes of his *Poesii* were published at Bucharest in 1876, and a short poem, *Cantul gintei latine* (The Song of the Latin Race), appeared in 1878, with translations into French and Italian. Several of his poems have been translated into English, French, and German. He was Roumanian minister at Paris from 1885 to 1890. D. at Mircești, Moldavia, Sept. 4, 1890.

E. S. SHELDON.

Alectorides. al-ek-tor'i-deez [Gr. ἀλέκτωρ, a cock]: an order of birds containing the cranes, rails, and their allies, the trumpeters, sun-bitterns, kagu, carriama, and bustards (see these headings for details). The last four are often omitted, being transferred to other orders. The group corresponds very nearly to the *Geranomorphæ* of Huxley. Its members are characterized by a schizognathous palate, truncate posterior end of mandible, tufted oil-gland, and absence of powder-down patches. The narial openings are schizorhinal in the cranes, holorhinal in the rails. The sternum

is typically long and narrow, posteriorly entire or two-notched. The young are born downy and are soon able to run. The name is unfortunate, both from its etymology and from the fact that the birds considered as typical by Nitzsch are, as stated, usually placed elsewhere. *Paludicola* is a better term for the group. F. A. LUCAS.

Ale'do: on railroad; capital of Mercer co., Ill. (for location of county, see map of Illinois, ref. 4-B). It is the seat of a college. Coal, stock, and grain are the principal shipments. Pop. (1880) 1,492; (1890) 1,601; (1900) 2,081.

Aleman'ni (i. e. all men): certain German tribes who formed a confederacy against the Romans about 200 A. D., and at that time lived on the Main. They invaded Gaul in the reign of Julian the Apostate, who gained a victory over them in 357 A. D. Having been defeated by Clovis in 496, their confederacy was dissolved. From this word is derived the French *Allemand*, signifying German.

Alembert, JEAN LE ROND, d', daǎ'laǎn'bār': French geometer and philosopher; b. in Paris, Nov. 16, 1717; an illegitimate son of M. Destouches-Canon and Madame de Tencin. Having been abandoned by his mother in the street, he was nursed by the wife of a glazier, and continued to live with her for about forty years. He received from his father an annual pension of 1,200 livres, and was educated in the Mazarin College, which he entered in 1730. His favorite study was mathematics. In 1741 he was admitted into the Academy of Sciences, and in 1743 produced his celebrated *Treatise on Dynamics*, which opened a new epoch in mechanical philosophy, by the demonstration of the principle "that there is an absolute equality at all times between the entire amount of force applied and the sum total of the effects produced." His treatise *On the Theory of the Winds* gained the prize of the Academy of Berlin in 1746. In 1752 Frederick the Great offered him the presidency of the Royal Academy of Berlin, which he declined. D'Alembert was associated with Diderot as joint editor of the famous *Encyclopédie*, for which he wrote an admirable "Preliminary Discourse," and many mathematical articles. He was admitted into the French Academy in 1754. He formed a *liaison* with the accomplished Mademoiselle l'Espinasse, who lived with him twelve years. He showed his independence and indifference to riches by refusing, in 1762, the invitation of Catherine II. of Russia, who offered him a salary of 100,000 francs to direct the education of her son. In 1772 he was elected secretary of the French Academy. He was an intimate friend of Voltaire, and assumed toward Christianity the attitude of a skeptic—i. e. a doubter and candid inquirer—while he openly avowed his hostility to the Church of Rome. His moral character is generally represented as noble and benevolent. Among his works are *Researches on some Important Points of the System of the Universe* (3 vols., 1754-56); *Mélanges of Literature and Philosophy*; *Elements of Philosophy* (1759); and eulogies on the members of the French Academy who died between 1700 and 1772. He died in Paris on the 29th of Oct., 1783. An edition of his works was published by Bossange in 5 vols., 8vo, 1821. "His literary works," says Lacroix, "constantly directed to the perfection of reason and the propagation of correct ideas, were highly appreciated by all good judges. They are all remarkable for a pure diction, a neat style, and strong or pithy thought."

Alemte'jo (i. e. beyond the Tagus): ancient administrative province of Portugal; bounded N. by Beira, E. by Spain, S. by Algarve, and W. by Estremadura and the Atlantic. Area, 9,431 sq. miles. It is intersected by the Gaudiana river, and is washed by the Tagus, which forms part of the northern boundary. The climate is hot and dry, the surface is hilly, and the soil of the northern and eastern valleys is fertile. The chief productions are wheat, maize, barley, grapes, rice, and figs. Capital, Evora. Pop. (1881) 367,169.

Alenear', JOSÉ MARTINIANO, de: Brazilian jurist and novelist; b. in Ceará, May 1, 1829; d. at Rio de Janeiro, Dec. 12, 1877. He is best known by his numerous romances of Indians and colonial life, which have given him, rather undeservedly, the title of the "Brazilian Cooper"; among the best of these are *O Guarany*, *Iracema*, *O Sertanejo*, and *As Minas de Prata*. Under the cognomen G. M. he published *Diva*, *Luciola*, and *Senhora*, romances of society life in Rio de Janeiro, which are much the best of his works. H. H. SMITH.

Aleuçon, ǎ'laǎn'sōn': city of France; capital of the department of Orne; situated on the Sarthe and in a plain, 65 miles by rail W. S. W. of Paris (see map of France, ref. 4-D). It is well built and handsome, has a cathedral, a public library, and a church about 1,000 years old. Here are manufactures of various articles, including muslin, leather, and a celebrated lace called point d'Aleuçon. Pop. (1881) 17,237; (1886) 17,550.

Alep'po, called by the Arabs **Ha'leb** [anc. *Chal'ybon* and *Beræ'a*]: an important city of Syria, and one of the chief emporiums of the Ottoman empire; on the Kowek, about 55 miles E. of Antioch; lat. 36° 11' N., lon. 37° 10' E.; 1,300 feet above the sea (see map of Turkey, ref. 6-11). It is surrounded by limestone hills, and presents a picturesque appearance. The houses are well built of stone, mostly in the Saracenic style, with richly ornamented walls and ceilings. In the environs are celebrated gardens about 12 miles in extent. Aleppo has a castle, a Mohammedan college, and many Christian churches. It has an extensive trade in cotton and silk stuffs, tobacco, wine, oil, indigo, etc., and is visited by large caravans from Bagdad, Diarbekir, Mosul, and Armenia. It was a great emporium of trade during or before the Middle Ages. Its prosperity was greatly injured by the earthquake of 1822, which destroyed a large part of the city and about two-thirds of the inhabitants. The population, which before that event was more than 200,000, was about 70,000 in 1880; in 1892, estimated at 120,000.

Alesandrian Codex: See CODEX ALESANDRINUS.

Ale'sia (Gr. Ἀλεσία): the fortified capital of the Gallic tribe Mandubii; built, according to a legend, by Hercules. Here the last desperate battle for freedom was fought by the Gauls, under Vercingetorix, against the Romans, under Julius Cæsar, in 52 B. C. The Gauls were completely defeated and the city destroyed. Alesia was rebuilt, and again destroyed by the Northmen in 864. It was on the present Mont Auxois, at the foot of which the modern town of Alise is situated.

Ale'sius [Gr. ἄλη, roaming]: the name given, probably by Melanchthon, to Alexander Alane; b. in Edinburgh, Scotland, Apr. 23, 1500; was Canon of St. Andrews, became Protestant, went to Germany in 1532, and again in 1540; was made professor at Leipzig, and died there Mar. 17, 1565. He was active in the negotiations between the Lutherans and Anglican theologians in 1536, and translated the Book of Common Prayer into Latin.

Alessan'dria: a province of Northern Italy; bounded N. by Novara, E. by Pavia, S. by Genoa, and W. by Cuneo and Torino. Area, 1,976 sq. miles. The country consists partly of large fertile plains and partly mountains, and is traversed by the Tanaro, the Scrivia, and the Bormida. Chief town, Alessandria. Pop. (1890) 778,137.

Alessandria (sometimes called *del'la Pa'ghia*, from its first houses having been roofed with straw): a fortified city of Italy; the capital of the province of the same name; on a plain on the river Tanaro, and on the railway from Turin to Genoa; 46 miles E. S. E. of Turin (see map of Italy, ref. 3-B). It was built by the Lombard league in 1168 to serve as a bulwark against Frederick Barbarossa. Its present name was given to it in honor of Pope Alexander III. It was called Cesarea for a time, and was unsuccessfully besieged in 1174 by Frederick Barbarossa. By the peace of Utrecht it was ceded to Savoy, having belonged at different times to the houses of Montferrat and Milan. Bonaparte greatly enlarged and strengthened its fortifications during the French occupation (1800-14). The citadel of Alessandria was taken in 1849 by the Austrians after the battle of Novara. The town is well built, has a cathedral, a royal college, several hospitals, and about fourteen churches. Here are manufactures of silk, linen, and woolen goods, and other articles. Two miles S. E. of this place is the village and battle-field of Marengo, where Napoleon defeated the Austrians in 1800. The citadel is regarded as one of the largest and strongest fortresses in Europe. Pop. 31,000.

Aleurone, a-lyu'rōn: a nitrogenous substance found in the cells of many seeds. In the pea and bean it is mingled with starch, while in the wheat grain it fills a layer of cells constituting the inner bean. It is often called "gluten," and is highly nutritious. C. E. B.

Aleu'tian (or **Aleu'tan**) **Islands**: a group of 150 or more islands, sometimes called the **Catharine Archipelago**; in the North Pacific, extending in a row from the peninsula of Alaska toward the S. point of Kamchatka (see map of Alaska,

ref. 5-B). They were discovered in 1728 by Bering, and were carefully explored by Capt. Krenitzin in 1760. In 1878 Capt. Cook surveyed the E. part of the group. They are rocky and volcanic, having some active volcanoes, and are inhabited by rude natives, who subsist by fishing and hunting. The rock is covered only with a thin layer of argillaceous soil. The vegetation is very insignificant, and agriculture is almost completely unknown. The climate is harsh, subject to sudden changes, and very unfavorable to cultivation. Few trees are found on the islands; only some stunted shrubs of birch, willow, and alder. The inhabitants are of a race essentially Esquimaux. They are small, but well shaped, with swarthy faces, black eyes, and straight black hair. By Russian missionaries they have been converted to Christianity, but their religious and moral ideas are very little developed. They are described as unchaste, unreliable, and entirely destitute of self-control. These islands are part of Alaska, and belong to the U. S. They are divided into three groups—the Aleutian, nearest to Kamchatka, the Andreanof or Andreanofian, the middle group, and the Fox islands, nearest to Alaska. Unimak, the largest of the Fox islands, is about 50 miles long. The seal, the sea-otter, and the Arctic fox are the chief prizes of the chase. Pop. about 2,500.

Ale'wife [Folk etym. corruption of *aloof*, possibly the native American name]: the *Clupea pseudoharengus*, a species of American fish belonging to the family of *Clupeidæ*, and nearly allied to the herring and the shad. It abounds in the Chesapeake bay, and is found along the Atlantic coast of the U. S. from North Carolina to Cape Cod. In the spring the alewives ascend the rivers to deposit their eggs. They are often wrongly confounded with the true herring (*Clupea harengus*), which they much resemble.

Alexan'der, surnamed THE GREAT: third Macedonian king of the name, the most famous of all military heroes; son of Philip, the celebrated King of Macedon, and Olympias, the daughter of the King of Epirus, who claimed descent from Achilles. At the age of fifteen Alexander was placed under the instruction of Aristotle, and soon distinguished himself by his rare intellectual powers, and by his rapid advancement in every kind of knowledge. His descent from Achilles, for whose character and achievements he cherished an enthusiastic and misplaced admiration, appears to have given his mind an early direction toward military glory. Among all books the *Iliad* was his favorite, and we are told that every night a copy of that poem was placed, along with his sword, under his pillow. King Philip had such confidence in his son's courage and capacity that he left him, although only sixteen years of age, the regent of his kingdom during his expedition against Byzantium. At the age of eighteen years Alexander greatly distinguished himself in the battle of Chæronea, and the victory won by the Macedonians on that occasion was due in no small measure to the valor of the young prince. On the death of Philip, in 336 B. C., Alexander, not yet twenty years of age, succeeded to the throne. Several of the states which his father had subjugated deemed this a favorable opportunity for recovering their liberty, but the courage and celerity of Alexander defeated all their schemes. While, however, the young king was engaged in reducing the Triballi, the Thebans raised the standard of revolt. He instantly directed his march toward Bœotia; Thebes was taken by storm, the houses were leveled to the ground, and the citizens who had escaped slaughter in the assault sold as slaves, excepting only the posterity of Pindar, the celebrated Theban poet, and those who had opposed the rebellion. Not long after, at an assembly of the Grecian states held at Corinth, Alexander was chosen generalissimo of the Greek and Macedonian troops destined for the invasion of Persia. Early in the spring of 334 B. C. he entered Asia with an army of about 35,000 men, including 4,500 cavalry. At the river Granicus the Persians sought to prevent his passage. The Macedonians, though fighting at a great disadvantage, gained a signal victory. At Gordium he attempted to untie the famous knot, for he had been told that the empire of the world had been prophesied to him who should succeed in this attempt. But having for some time tried in vain, he at last drew his sword and cut it, saying that this was the only way to untie it. It is said that those whose office it was to decide upon the interpretation of the prophecy, either sincerely or from motives of policy, declared that the Macedonian king had fulfilled it. Having received reinforcements in 333 B. C., he engaged Darius, the Persian king, who commanded at the river Issus an army of 600,000 men. The

Persians were defeated with immense slaughter; the mother, wife, and two daughters of Darius were taken captive, but were treated with the greatest respect and kindness by the conqueror. After this great success scarcely any of the cities of Asia presumed to offer resistance to his victorious arms. But Tyre, then a powerful maritime and commercial city, had the courage or temerity to oppose his progress. The city was taken after a most determined resistance, which lasted seven months, but the conqueror fixed an indelible stain upon his reputation by his merciless cruelty toward the conquered Tyrians, thousands of whom were cruelly slaughtered, and the rest, numbering nearly 30,000, were sold into slavery. Gaza soon after met with a similar fate. Alexander then advanced into Egypt, where the people, weary of the Persian domination, welcomed him as a liberator. In Egypt, on one of the principal mouths of the Nile, he founded a city called Alexandria.

He next visited the temple of Jupiter Ammon, situated on an oasis in the desert of Libya, with the hope, it is said, that the god would acknowledge him to be his son. This having been done through the priest of the temple, he again turned his thoughts to the invasion of Persia, where Darius had succeeded in collecting another army of more than a million men, with not less than 40,000 cavalry. Alexander had scarcely more than 40,000 infantry and 7,000 horse. The opposing armies met at Gaugamela, not far from Arbela, in 331 B. C. The Persians were defeated with prodigious slaughter. Not long afterward Darius was murdered by Bessus, one of his satraps. As the dying king, covered with wounds, lay extended in his chariot, Alexander came up; at the tragic spectacle the conqueror could not restrain his tears. He caused the body of Darius to be taken to Persepolis, where it was interred in the tombs of the Persian kings. Bessus having been taken and put to death, Alexander carried his victorious banners beyond the Jaxartes (now called the Sihon, or the Sir Daria), subdued Sogdiana, and married Roxana, the daughter of a Bactrian prince whom he had conquered. After this he turned his thoughts to the invasion of India. He crossed the Indus 327 B. C., formed an alliance with Taxiles (or Taxilus, as the name is sometimes written), an Indian king, and advanced to the banks of the Hydaspes (now the Jhyum), where he encountered Porus at the head of an immense army, accompanied by a multitude of elephants. After a sanguinary battle the Indian king was totally defeated and taken prisoner. Alexander's favorite horse, Bucephalus, having been mortally wounded in this battle, the conqueror founded a town on the spot where he was buried, which he called Bucephala. Taking one city after another, he had advanced as far as the Hyphasis (now called Gharra), when his troops, alike uninfluenced by his menaces and his entreaties, positively refused to go any farther. Being thus under the necessity of returning, he committed the fleet which he had ordered to be built on the Hydaspes to Nearchus, while he himself proceeded by land through what is now Baluchistan to Susa. His army encountered in this march incredible hardships and suffering, so that many soldiers perished from thirst and hunger. Having arrived at Susa, he married as his second wife a daughter of Darius. As he was forming schemes for the extension and improvement of his empire, he died, June, 323 B. C., at Babylon, in the thirty-third year of his age.

It would be unjust to Alexander to regard him merely as a great and successful military hero. He possessed some moral qualities of a high order, especially generosity and magnanimity. Many of his views of state policy were liberal and enlightened. But all that was most excellent and admirable in his character was impaired and vitiated by mistaken ideas of the dignity and glory which belonged to a great king. As his passions were stronger than his intellect, extraordinary as the latter undoubtedly was, they gradually acquired, during his long career of uninterrupted success, an almost unlimited ascendancy over him. His uniform prosperity may be said to have been his greatest misfortune. Being a stranger to the "sweet uses of adversity," it was impossible for him to see his own character and conduct in their true light. After his unparalleled successes had turned his brain, regarding himself as little less than a god, he could not brook the slightest freedom of speech, even from his most faithful and most meritorious officers. In a paroxysm of ungovernable rage he slew his friend and foster-brother Clitus, who had once saved his life; after which a grief, scarcely less violent than his anger had been, took possession of his soul, so that if he had not been restrained he would probably have taken his own life.

Pope (in *The Temple of Fame*) sums up his career and character in one short line :

The youth who all things but himself subdued.

See Arrian's *History of Alexander's Expeditions*; Quintus Curtius's *Life of Alexander*; Williams's *Life and Actions of Alexander the Great* (1829); Droysen's *Geschichte Alexanders des Grossen von Macedonien* (1833); Geier's *Alexandri Magni historiarum scriptores aetate supparet*, containing the fragments of contemporaneous historians (1844); Holm's *Griechische Geschichte*, vol. iii. (1891).

Alexander I., pope: a Roman by birth, became Bishop of Rome in 109 A. D. D. at Rome in 119.—**ALEXANDER II.** (ANSELMO BADAGIO) was elected pope in 1061. He declared William the Conqueror the true heir to the English crown. D. at Rome in 1073.—**ALEXANDER III.** (ROLANDO RANUCCIO BANDINELLI), one of the ablest men that ever sat on a papal throne, was a native of Sienna. He was elected pope in 1159. He was involved in a long contest with Frederick Barbarossa, and with the anti-popes who were supported by that emperor. Having been twice compelled by his enemies to leave Rome, he was in 1163 acknowledged pope by a council at Tours. The emperor, whom he had excommunicated in 1167, made his submission soon after the battle of Legnano, and was absolved. Thomas à Becket, who had been encouraged by Alexander in his resistance to Henry II. of England, was, after his assassination, canonized by the pope. According to Voltaire, Alexander proclaimed that no Christian should be held as a slave. He is said to have been the first who reserved to the Holy See the right of canonization. D. at Civita Castellano, Aug. 30, 1181. (See Reuter's *Geschichte Alexanders III. und der Kirche seiner Zeit.* (1860, 2 vols.).)—**ALEXANDER IV.** (RINALDO DI ANAGNI) became pope in 1254. D. at Viterbo, May 12, 1261.—**ALEXANDER V.** (PIETRO FILARGI) was chosen pope in 1409. D. at Bologna, May 3, 1410.—**ALEXANDER VI.** (RODRIGO LENZUOLI BORGIA), b. at Jativa, in Valencia, in Spain, in 1431; was a nephew of Pope Calixtus III. He became a cardinal in 1456, and was chosen pope in 1492. Before his election to the papacy he had several illegitimate children, among whom were the infamous Cæsar and Lucretia Borgia. Among the events of his pontificate were the introduction of the index of prohibited books and the burning at the stake of Savonarola. D. at Rome, Aug. 18, 1503. His character was an infamous compound of cruelty, treachery, licentiousness, and other vices.—**ALEXANDER VII.** (FABIO CHIGI) was b. at Sienna, Feb. 13, 1599, and became pope in 1655. He embellished Rome with architectural works. D. at Rome, May 22, 1667.—**ALEXANDER VIII.** (PIETRO OTTOBONI) was b. in Venice, April 19, 1610, and elected pope in 1689. He assisted the Venetians in a war against the Turks. D. at Rome, Feb. 1, 1691.

Revised by S. M. JACKSON.

Alexander I.: King of Scotland; younger son of Malcolm Canmore; began to reign in 1107. He was an able ruler. He died at Stirling, April 27, 1124; was succeeded by his brother, David I.—**ALEXANDER II.**, b. at Haddington, Aug. 24, 1198, succeeded his father, William the Lion, in 1214. He married a sister of Henry III. of England in 1221. He is said to have been a wise and able prince. D. on the island of Kerrera, opposite Oban, July 8, 1249.—**ALEXANDER III.**, of Scotland, b. in 1241, was a son of the preceding, and became king in 1249. He married, in 1251, Margaret, a daughter of Henry III. of England. His reign was peaceful and prosperous. He fell with his horse over a precipice between Burntisland and Kinghorn, and was killed, Mar. 16, 1286.

Alexander I. (or **Alexander Pau'lovitch**): Emperor of Russia; son of Paul I. and Maria, a princess of Würtemberg; b. at St. Petersburg, Dec. 23, 1777. He married, in 1793, Elizabeth, a daughter of the Crown Prince of Baden, and succeeded his father, who was assassinated Mar. 24, 1801. He promoted civilization, education, industry, and trade. His foreign policy was pacific until he joined a coalition against Napoleon in 1805. In December of that year the Russian and Austrian armies were defeated at Austerlitz. After the Russian armies had sustained several other defeats, the war was ended by the treaty of Tilsit in 1807. Alexander then became the friend and ally of Napoleon, and declared war against England. But, alarmed by the insatiable ambition of Napoleon, he resolved upon a change of policy, and formed an alliance with England and Sweden.

Russia was invaded in 1812 by Napoleon, who took Moscow, but his army was soon compelled to retreat, and nearly all perished with cold and hunger or were taken prisoners. After the abdication of Napoleon, Alexander entered Paris with the victorious armies in 1814, and exhibited more generosity and clemency toward the French than the other allies showed. He again entered Paris in triumph in July, 1815, and in the same year formed, with the Emperor of Austria and the King of Prussia, a coalition called "the Holy Alliance," the tendency of which was reactionary and hostile to the cause of liberty. The professed object of this alliance was to promote religion and peace. As he advanced in years he became more contracted and less liberal, a prey to hypochondria and suspicion. His projects of reform were abandoned, a rigid censorship of the press was maintained, and all liberal or progressive tendencies were repressed. He died without issue at Taganrog, Dec. 1, 1825, and was succeeded by his brother Nicholas. See RUSSIA.

Alexander II., **ALEXANDER NIKOLAI EWITCH ROMANOFF**: Emperor of Russia; the fourteenth sovereign of the reigning dynasty, the eldest of the Czar Nicholas's four sons, was b. on the 29th of April, 1818. His education was intrusted, under the czar's own close inspection, almost exclusively to native Russians, foremost among whom stood the poet Joukovski, the generals Kavelin and Fredericks, and, before traveling abroad, the prince was sent on a progress through European Russia in order to acquaint himself with the country. He subsequently visited Germany, Italy, and Great Britain, and on his return, bringing back with him a host of new impressions, he was admitted, only a lad of eighteen, to the czar's conferences with his native ministers and foreign envoys. Five years later, on the 28th of April, 1841, at the age of twenty-three, he married the Grand Duchess of Hesse-Darmstadt, called by the Russians Maria Alexandrowna ("Mary, the daughter of Alexander").

Alexander II. ascended the throne on the 2d of March, 1855, during the Crimean war, which France, Great Britain, and Turkey had waged against Russia. He ended the war as soon as possible, but several years were required to restore the empire to its normal condition. In 1861 followed the serf emancipation, which prominently brought the new czar before the world and earned him his popular title of "the Liberator"; in 1863 followed the Polish rebellion, which was put down with wanton cruelty, the czar placing the destiny of the Polish people in the hands of men equally devoid of mercy and of justice—the Count de Berg and Mouravieff, the latter known by the nickname of "the hangman." But, with this single exception of the Polish war, the nine years which elapsed after the abolition of serfdom became the brightest in the Russian history of the nineteenth century. Military colonies, oppressive statutes, all kinds of crippling restrictions, were abolished. The press began to make itself heard. Immigration was encouraged, agriculture developed, foreign inventions were adopted, foreign authors and institutions studied. Female education received a sudden impetus, and the senseless restrictions on travel were removed. On the 27th of Sept., 1866, Princess Dagmar of Denmark, the bride-elect of the hereditary grand duke, landed, and in 1867 the czar himself appeared at the Paris Exhibition. Meanwhile the works of national reform followed each other—the redistribution of land, the development of the railway system, the establishment of trial by jury, the abridgment of military service, and many others.

But reaction was not slow to appear. The revolutionary attitude of the five great universities of St. Petersburg, Moscow, Kieff, Dorpat, and Kazan, and the ill-timed petition of Moscow for free trade and the liberty of the press, startled the Government into the belief that it had gone too far. At the same moment, the terror of victorious Germany from without, and that of the Nihilist conspirators from within, appeared to necessitate an immediate increase of strength, and in an instant all was changed.

But even this violent change could not deprive Russia of the substantial progress which she had already made. At the Czar's accession in 1855 she possessed only 419 miles of railway; in 1870 she could count 7,123. In 1855 the total number of factories in European Russia was 17,536, representing a yearly value of 350,000,000 rubles (\$262,500,000); the estimates for 1870 gave 23,721 factories, producing annually 500,000,000 rubles. In 1855 Russia's export trade averaged \$30,000,000; in 1870 \$256,500,000. The term of military service extended in 1855 over the enormous space of twenty-

five years, while in 1870 it was limited to ten years. The press, the bar, the local administration, had all been considerably remodeled, and the village schools began to raise the 49,000,000 Russian peasants from mere soulless beasts of burden into thinking and reasoning men.

Only for a time the newly awakened spirit of the country was diverted from the channel of home reform into that of foreign conquest. On Oct. 31, 1870, when neither Great Britain, France, nor Turkey was able to resist, Prince Gortschakoff informed the various cabinets that Russia felt compelled to deviate from the stipulations of the Treaty of Paris and keep a fleet of sufficient capacity in the Black Sea. The Khiva expedition of 1873 completed the conquest of Central Asia, and the Montenegro troubles of 1874, the Herzegovinian insurrection of 1875, were appeals to Russia to gird herself for a fresh crusade against the Crescent. In April, 1877, the war of liberation began. The czar returned to St. Petersburg in triumph, but a triumph which was not unalloyed. The war burdens were enormous. Russia was compelled to make considerable modifications of her first programme, and Austria's complete occupation of Bosnia irritated the Pan-slavists. Thus all things combined to produce a fresh explosion of the spirit of Nihilism, and a season of uprisings, assassinations, and terror ensued. Several attempts were made by Nihilists on the emperor's life. The fifth one was successful. On Mar. 13, 1881, while he was returning from a parade at about two o'clock in the afternoon, two bombs were thrown at the sleigh, one of which exploded at the emperor's feet, inflicting wounds from which an hour and a half later he expired in the imperial palace. See Nihilism.

Revised by C. K. ADAMS.

Alexander III.: Emperor of Russia; b. Feb. 26 (Mar. 10, new style) 1845; second son of Emperor Alexander II. After the death of his elder brother, Nicholas, in 1865, he became the heir-apparent to the throne, and married, on Nov. 9, 1866, the Princess Maria Dagmar (on her rebaptism into the Eastern Church called Maria Feodorovna), daughter of Christian IX., King of Denmark. In 1877 he was in command of the army of Biela, but in that capacity he did nothing of note, and was finally superseded. Toward the end of 1879 he came to an open rupture with his father on account of his opposition to the reactionary policy of the latter. On the assassination of Alexander II., in 1881, he shut himself up in Gatschina, and was not crowned till May 27, 1883; the excesses of the Nihilists resulted in making his rule like that of his father. His reign was conservative, and, although vigorous in consolidating and extending his empire, his policy was one of peace. He sternly repressed Nihilism, and many attempts were made on his life. In support of the Greek Church he was all but fanatical; in 1890-91 thousands of Jews were expelled from Southern Russia. His bravery, sincerity, and uprightness were unquestioned. D. at his estate, Livadia, in the Crimea, Nov. 1 (new style), 1894, and was succeeded by his eldest son, Nicholas.

Alexander, ARCHIBALD, D. D.: divine; b. near Lexington, Rockbridge co., Va., Apr. 17, 1772. He became president of Hampden-Sidney College in 1796, and pastor of the Pine Street Presbyterian church in Philadelphia in 1807. In 1812 he was chosen the first Professor of the Theological Seminary of Princeton, N. J., then just founded. He was distinguished as a pulpit orator and as a writer on theology. Among his works are *Outlines of the Evidences of Christianity* (1824); a *Pocket Dictionary of the Bible* (1829); and *Outlines of Moral Science* (1852). The first of these works has been translated into several languages. He married, in 1802, Janet Waddell, a daughter of a well-known blind preacher. D. at Princeton, N. J., Oct. 22, 1851.

Alexander, GEORGE, D. D.: Presbyterian minister; b. at West Charlton, N. Y., Oct. 12, 1843; was educated at Charlton Academy, Union College, and Princeton Seminary. He was pastor of the East Avenue Presbyterian church, Schenectady, N. Y., 1870-83, and during the last six years of that time was Professor of Logic and Rhetoric in Union College. In 1884 he became pastor of the University Place Presbyterian church, New York city, and leader in an important missionary work in the tenement-house district further S. in the city.

W. J. BEECHER.

Alexander, JAMES WADDELL, D. D.: divine; eldest son of Archibald Alexander; b. near Gordonsville, in Louisa co., Va., Mar. 13, 1804; graduated at Princeton, 1820; and became in 1833 Professor of Rhetoric at the College of New Jersey (Princeton). From 1844 to 1849 he was pastor of the Duane Street Presbyterian church in New York. From 1849

to 1851 he was Professor of Church History in the Princeton Theological Seminary. In 1851 he took charge of the Fifth Avenue Presbyterian church in New York city. D. at Red Sweet Springs, Va., July 31, 1859. He was a man of various culture, and had uncommon unction and power as a preacher. He wrote the life of his father (1854), published numerous articles in the *Princeton Review*, and a number of volumes, such as *Discourses on Christian Faith and Practice*, and *Sacramental Discourses*.

S. M. J.

Alexander, JOHN HENRY: b. at Annapolis, Md., June 26, 1812; published a *Treatise of Mathematical Instruments* (1835); *Contributions to the History of Iron* (1840); *Introits* (1844); *Dictionary of Weights and Measures* (1850); *International Coinage* (Oxford, 1857), and other works. D. at Baltimore, Mar. 2, 1867. See his life by W. Pinkney, 1867.

Alexander, JOSEPH ADDISON, D. D.: son of Archibald Alexander; b. in Philadelphia, Apr. 24, 1809; graduated at the College of New Jersey (Princeton) 1826, in which he was adjunct Professor of Ancient Languages 1830-33. In 1838 he went into the Theological Seminary in the same town as associate Professor of Oriental and Biblical Literature, and in one chair and another continued to serve the institution till his death at Princeton, Jan. 28, 1860. He made extraordinary attainments in the Semitic and other languages. He wrote much for the *Princeton Review*. His most important works are commentaries: *Isaiah* (2 vols., 1846); *Psalms* (3 vols., 1850); *Acts* (1 vol., 1857); *Mark* (1858). *Matthew* was published posthumously in 1860. See his life by H. C. Alexander (1869).

Alexander, WILLIAM, D. D., D. C. L.: Archbishop of Armagh and Primate of All Ireland; b. at Londonderry, Ireland, Apr. 13, 1824; educated at Oxford; became Bishop of Derry and Raphoe in 1867, and archbishop in 1896. Besides several volumes of poems: *The Waters of Babylon* (1869); *St. Augustine's Holiday* (1886); and sermons: *The Great Question* (1887), he has published: *The Divinity of our Lord* (1890); *Leading Ideas of the Gospels* (1871); *Witness of the Psalms to Christ and Christianity* (1877); commentaries on Colossians, Thessalonians, Philemon, and the Epistles of John in the *Speaker's Commentary*; and on the last named in the *Expositor's Bible* series (1889). He was Bampton lecturer in 1876, and in 1892 delivered a series of lectures in Columbia College, New York. The See of Derry was permanently endowed by him with £2,000 a year and the see house.—His wife (born Cecil Frances Humphreys) is the author of *Moral Songs, Hymns for Children, and Poems on Old Testament Subjects*, among which is the celebrated poem *The Burial of Moses*. She died Oct. 12, 1895.

Alexander, WILLIAM LINDSAY, D. D.: b. at Edinburgh, Scotland, Aug. 24, 1808; educated at the universities of Edinburgh and St. Andrews; became classical tutor in Blackburn Theological Seminary, and subsequently (1835) a Congregational minister at Edinburgh; Professor of Theology in the Congregational Theological College, Edinburgh, 1854, and a member of the Old Testament Revision Company, 1870. He was the author of several doctrinal and miscellaneous works, including *The Connection and Harmony of the Old and New Testament* (2d ed. 1853); a *Life of Dr. Wardlaw* (1856); *Christian Thought and Work* (1862); *Zechariah* (1885); *Biblical Theology* (1891). He was the editor of the 3d ed. of Dr. Kitto's *Biblical Cyclopaedia* (3 vols., 1862-66). D. in Edinburgh, Dec. 22, 1884. See his *Life* by Ross (1887).

Revised by GEORGE P. FISHER.

Alexander Æt'olus: learned scholar and poetic experimenter of the Alexandrian period; flourished about 280 B. C. (see GREEK LITERATURE); a star of the Alexandrian tragic Pleiad. Of his elegiac poems we have not inconsiderable fragments, which show his learning, elegance, and false ingenuity. The fragments are in Bergk's *Poetae Lyrici*. See Couat's *La Poésie Alexandrine*, p. 105.

Alexander Ba'las: usurper of the throne of Syria; was a person of low origin, and lived in the second century B. C. He pretended to be the son of Antiochus Epiphanes, and, with the aid of Rome and several Greek princes, defeated his rival Demetrius Soter in 150 B. C., and Demetrius was killed in the flight. After a short reign he was defeated by his father-in-law, and in 146 B. C. was murdered by an Arabian emir with whom he had taken refuge.

Alexander Jannæus: King of the Jews 104-78 B. C.; was the third son of John Hyrcanus, and received from his subjects the surname Thracides ("as cruel as a Thracian"). His reign was an almost uninterrupted series of revolts and

massacres: and when once, in despair, he asked the people what he should do to please them, he was answered, "Kill yourself." His wife, Alexandra, succeeded him, and reigned, by the aid of the Pharisees, in peace.

Alexander John I.: Prince of Roumania; b. Mar. 20, 1820; elected in 1858 to the assembly of Moldavia, became in the same year Minister of War of the united principalities, was elected in 1859 first Prince of Moldavia, and then Prince of Wallachia, in both cases by a unanimous vote, but had to pledge himself to complete the union of the two principalities, and then resign in favor of some European prince. But he was not recognized by Turkey until Dec. 23, 1861, as prince of both principalities, on which day the union of the two principalities under the name of Roumania was proclaimed. But, in consequence of several unpopular measures, the most prominent men of Roumania planned a revolution, and in the night of Feb. 23, 1866, entered his apartments and forced him to sign his resignation. After that time he lived in Vienna as a private citizen. He died at Heidelberg, May 15, 1873.

Alexander Karageorgevitch, kaã'raã-jor'je-vich': Prince of Servia; son of Czerny George (*q. v.*), the first Prince of Servia; b. at Topola, Oct. 11, 1806. After the death of his father he lived for several years in a kind of exile in Wallachia, but finally obtained permission from Prince Michael Obrenovitch to return to Servia, and was even appointed his aide-de-camp. After Prince Michael's deposition he was elected Prince of Servia in 1842. Russia protested against his election, but Mar. 27, 1843, he was again elected, and this time by a unanimous vote. The policy he pursued was one of peace. In spite of Russian and Austrian intrigues he succeeded in keeping clear of any serious embroilment; even in 1853 he preserved neutrality, in spite of the internal excitement prevailing in the country. Meanwhile, a complete system of primary education was established; the finances of the state were brought in order; good roads were built, giving access to new markets; and in ten years the exportation of the country more than doubled. In consequence, however, of his peace policy toward the foreign powers, he became obnoxious to the people, and was deposed Dec. 11, 1858. In 1868 he was accused of complicity in the murder of Prince Michael, his successor, and was sentenced in 1871 by the authorities of Austria, where he had resided since his deposition, to eight years' imprisonment and the costs. D. at Temesvar, Hungary, May 2, 1885.

Alexander Nev'ski (or **Nev'skoi**): Russian prince and hero; b. at Vladimir in 1219; was a son of the Grand Duke Yaroslaf II. He gained in 1240 a signal victory over the Swedes on the Neva; hence his surname. On the death of his father, about 1246, he became Grand Duke of Vladimir. D. at Gorodetz, Nov. 14, 1263. By the Russians he is regarded as a saint. In his honor Peter the Great, in 1712, built the Alexander Nevski monastery in St. Petersburg, on the spot where the hero and saint is said to have gained his great victory. The monastery is one of the greatest and richest institutions of the kind, forming a whole city by itself, and having nine churches, a theological seminary for 1,000 scholars, the residence of the metropoliite of St. Petersburg, etc.

Alexander of Aphrodis'ias: celebrated Greek commentator on Aristotle; lived at about the close of the second century after Christ. Like his masters, Herminius and Aristotle the Messenian, he tried to free the Peripatetic philosophy from the syncretism of Ammonius and others, and to restore the true interpretation of Aristotle's works. He contended that the human soul does not survive the death of the body, but is absorbed into the world-soul. This led to new commentaries on the part of the great Schoolmen in the twelfth and thirteenth centuries.

Alexander, JOSEPH, OF BATTENBERG: ex-Prince of Bulgaria; son of Prince Alexander of Battenberg (Hesse); brother of the late Empress of Russia; b. Apr. 5, 1857; served with the Russian army during the war with Turkey; elected hereditary Prince of Bulgaria by the Assembly of Notables at Tirnova, Apr. 29, 1879; invested with extraordinary legislative powers by a vote of the Grand National Assembly, July 13, 1881. In 1885 war was declared against Bulgaria by King Milan of Servia, and although the Bulgarian army was inexperienced and the smaller, Prince Alexander, by his personal bravery and strategic skill, won several victories, and King Milan was finally forced to sign a treaty of peace at Bucharest. Aug. 20, 1886, part of his

army, induced by Russian intrigue, revolted and forced Prince Alexander to sign his abdication. He was carried as a prisoner to Russian territory, but soon returned, and was greeted with great popular enthusiasm. He decided, however, that he could not make way against his Russian enemies, and abdicated. Jan. 11, 1889, the prince formally took the name of Comte de Hartenau, and in the month following married Fräulein Amalia Loisinger, an actress, and retired to his estate at Gratz, in Styria. D. at Gratz, Nov. 17, 1893.

Alexander of Hales (surnamed *Doctor Irrefragabilis*, *Doctor Doctorum*, and *Fons Vitæ*): one of the greatest of the Schoolmen (*q. v.*), and the first of them to study Aristotle as a whole in the light of Arabian commentary and bring to bear on each passage the light of all others. He was born in Gloucestershire, England; studied and taught in Paris, where he died in 1245. His *Summa Theologiæ* is based on the sentences of Peter the Lombard. W. T. HARRIS.

Alexander Seve'rus: Roman emperor; b. about 205 A. D. His original name was Alexianus Bassianus, but when, upon his removal to Rome, he was created cæsar, pontiff, consul, and *princeps juvenis* elect by his cousin, the Emperor Elagabalus, he assumed the name Marcus Aurelius Alexander, and added Severus afterward. In 222 A. D., upon the death of his cousin, Alexander was proclaimed emperor by the prætorians and confirmed by the senate. From 231 to 233 he waged war against the Persians; in 234 he marched into Gaul against the Germans, but was waylaid and murdered by some mutinous soldiers near Mayence, 235.

Alexan'dra, CAROLINE MARIE CHARLOTTE LOUISE JULIE: Queen of England; daughter of Christian IX., King of Denmark; b. Dec. 1, 1844. She was married Mar. 10, 1863, to Albert Edward, Prince of Wales, and became queen upon his accession as Edward VII. in 1901.

Alexan'dria [classical accentuation, *Alexandri'a*; Gr. *Ἀλεξάνδρεια*; Turk. and Arab. *Iskanderieh*]: an ancient and celebrated city and seaport of Lower Egypt, named from Alexander the Great, by whom it was founded in 332 B. C. (see map of Africa, ref. 2-E). It was situated on a low and narrow tract which separates Lake Mareotis from the Mediterranean, near the western mouth of the Nile, and 117 miles N. W. of Cairo. Lat. of Pharos, the Alexandria lighthouse, 31° 12' 9" N., lon. 29° 53' E. Soon after its foundation it became the capital of the Grecian kings who reigned in Egypt, and one of the most populous and magnificent cities in the world. It was a great emporium of commerce, for which its position between Europe and India was very advantageous. Before, as well as after, the Christian era this city was a celebrated seat of learning and philosophy. Here was founded by the Ptolemies, about 296 B. C., the celebrated museum, to which was attached the greatest library of antiquity, known as the *Alexandrian Library* (see MUSEUM and ALEXANDRIAN LIBRARY). Among the principal edifices was the Serapeion, or temple of Serapis. In front of the city stood a famous lighthouse called Pharos, on an island of the same name. It is supposed that during its greatest prosperity Alexandria had 600,000 inhabitants, a majority of whom were Greeks and Jews. Even after Egypt had been conquered by the Romans this city was second only to Rome in size and importance. About the period 300-640 A. D. it was a great focus of Christian theology and sectarianism. It was captured by the Saracen caliph Omâr about 640, and then its prosperity declined. The discovery of a passage to India by the Cape of Good Hope (1497) aided in its ruin, and the population in 1778 was only 6,000. The chief remains of its ancient grandeur are: a granite monolith erroneously called Pompey's Pillar; the Catacombs; and two obelisks named Cleopatra's Needles—one of these obelisks was taken to London, England, in 1877-78, and set up on the Thames embankment; the other was presented to the U. S. by Ismail Pasha, and was taken to New York city in 1880.

The modern city, which again became populous and important, is built near the site of the ancient, and on a mole or isthmus connecting the mainland with the island of Pharos. It is connected with Cairo by a canal and railway, and with Suez by a railway, which is continued from Cairo. In consequence of steam navigation, Alexandria again became a great emporium of the commerce between Europe and India. The chief articles of export are grain, sugar, drugs, cotton, gums, rice, dates, and hides. Steamers ply regularly between this port and Brindisi, Malta, and Constantinople. Newspapers are published here in the Italian, Greek, and French languages. Pop. (1897) 319,766, of whom some 50,000 are Greeks, Italians, French, Germans, and Swiss,

and other foreigners. Its new artificial harbor, with a break-water 2 miles long, begun in 1871, is one of the most important works of the kind in the Mediterranean. In consequence of the Egyptian revolution headed by Arabi Pasha, which broke out during the summer of 1882, culminating in the most revolting cruelties against the Christians, Alexandria was bombarded by the British, under Admiral Seymour, July 11 and 12, 1882. The forts defending the harbor were dismantled, and on July 13 the greater part of the city was practically a mass of ruins. Revised by C. K. ADAMS.

Alexandria: town, Glengarry co., Ontario, Canada (for location, see map of Ontario, ref. 2-1); on Canada Atlantic R. R.; has grist-mills, 3 saw-mills, 2 sash and door factories, furniture-factory, 2 carriage-factories, cheese-box factory, 2 newspapers, 5 Roman Catholic churches and a convent, a Presbyterian church. Pop. (1881) 1,200; (1891) 1,614; (1892) estimated 1,850. EDITOR OF "GLENGARRIAN."

Alexandria: town and railroad center; the capital of Rapides parish, La. (for location of parish, see map of Louisiana, ref. 9-C); on railroad and south bank of the Red river, 196 miles by railroad and 350 miles by water N. W. of New Orleans. It has a convent of the Sisters of Mercy and four prosperous institutions of learning, also a large trade in cotton, sugar, molasses, and hides, etc. Pop. (1870) 1,218; (1880) 1,800; (1890) 2,861; (1900) 5,648.

Alexandria: capital of Douglas co., Minn. (for location, see map of Minnesota, ref. 7-B); on railroad, 142 miles W. N. W. of St. Paul. It has a U. S. land-office, fine high school, 8 churches, and 3 newspapers. Has furniture, plow, and cutlery manufactories; and steam, grist, and saw mills. It is pleasantly situated amid beautiful lakes, and is surrounded by fine wheat-growing country, the wheat of this neighborhood taking first premium in 1891. Pop. (1880) 1,355; (1890) 2,118; (1900) 2,681. EDITOR OF "POST."

Alexandria: Jefferson co., N. Y. (for location of county, see map of New York, ref. 2-G); in a township of its own name, on the St. Lawrence river, 25 miles N. by E. of Watertown. Alexandria Bay (P. O. name) is a port which is visited by steamboats. It has a lighthouse. The township embraces a part of the Thousand isles, and is a great summer resort. It contains a glass-factory. Pop. of Alexandria Bay (1880) 587; (1890) 1,123; (1900) 1,511.

Alexandria: city; important railroad center; port of entry, and capital of Alexandria co., Va. (for location of county, see map of Virginia, ref. 4-I); pleasantly situated on the right bank of the Potomac, 6 miles below Washington. The river is here a mile wide, and forms a good harbor for the largest ships. An extensive shoe-factory has been in operation for a number of years, with flouring-mills, machine-shops, plaster-mills, and other industries. The city is noted for the number and excellence of its institutions of learning. Pop. (1880) 13,659; (1890) 14,339; (1900) 14,528.

Alexandrian Library: the largest and most celebrated library of antiquity; founded by Ptolemy Philadelphus, King of Egypt, about 275 B. C. He purchased many books at Athens, Rome, and other places. This library is said to have been partially destroyed by fanatical Christians about 395 A. D. According to some authorities, it was burned in 642 A. D. by order of the caliph Omār, who argued that if books agree with the Koran they are unnecessary; if they differ they should be destroyed. See Ritschl, *Die Alexandrinischen Bibliotheken* (1838).

Alexandrian Manuscript: See CODEX ALEXANDRINUS.

Alexandrian Period: See GREEK LITERATURE.

Alexandrian (or Alexandrine) School: a certain type of thought and culture which began to prevail in Egypt about 300 B. C., and which exercised a palpable influence on Christianity, added a new chapter to the history of Greek philosophy, and produced even a hitherto unknown form of Judaism. In Alexandria the East and West met for the first time peaceably, and even amicably, with each other, and compromises, often of the most curious description, were the natural results. All these various compromises—between the fantastic asceticism of India, the prophetic inspirations of Judaism, the imaginative reasoning of Greece, the positivism of the Romans, not to speak of the numerous minor peculiarities of spiritual character—had a certain character in common, which justly took its name after the place where it originated. But beyond this—an amalgamation of different civilizations, with the natural stimulus inherent in such a process—the Alexandrian school can hardly be said to have gone. It

produced no new ideas; its ideas it always borrowed. But it tried new combinations, and the results were often very surprising; and the style in which it presented its thoughts was new and long-enduring. The intercourse of the Jewish and Greek colonists who had previously settled in that country had given rise to a blending of the peculiar religious ideas of each. The Gnostics, whose system was a mingling of Oriental with Christian thought, originated chiefly in Alexandria; and Philo-Judaus, the foremost representative of the Jewish-Alexandrian philosophy, was also a native of that city, and his writings powerfully influenced the Christian teachers, like Athanasius, Gregory of Nazianzus, and other eminent Christian Fathers. This school was likewise renowned for the culture of mathematics and physical science, and numbered among its disciples Euclid, Aristarchus of Samos, and, according to some writers, Archimedes. The celebrated critic Aristarchus is said to have passed the greater part of his life in Alexandria, where he founded a school. With regard to correctness and elegance of expression the Alexandrian writers were highly distinguished, but they were deficient in life and spirit. In a school where imitation and rule took the place of inspiration, each generation became more artificial and lifeless than its predecessor, and both prose and poetry often became labored affectation. Special works on the history of the Alexandrian School have been written by Matter (2 vols., 2d. ed. 1840-44); Barthélemy St.-Hilaire (1845); Simon (2 vols., 1844-45); and Bigg's *Christian Platonists of Alexandria* (1887).

Revised by S. M. JACKSON.

Alexandrine: a poetical line or verse formed of six iambs; so called from an old French poem of the twelfth century on Alexander the Great, or, with less probability, from Alexander de Bernay, one of the authors of the poem. The last line of the Spenserian stanza is an Alexandrine. See Byron's *Childe Harold*. See also Vergil's *Georgics*, iii. 424. Drayton's *Polyolbion* (1612-22) is the only poem in English written wholly in Alexandrines.

Alexandrine Age: a period during which Alexandria was the principal center of literature and science in the world. It extended from about 300 B. C. to 600 A. D., and was represented by many eminent grammarians and critics, who excelled in correctness and elegance of style, but were deficient in genius and originality.

Alexandrite [named by Nordenskiöld after Alexander II. of Russia]: a variety of chrysoberyl, of a chrome or grass-green by day, but changing to a columbine or raspberry color by artificial light. It is found in gems up to 65 carats in weight, and valued up to \$2,000 each, in Kandy, Ceylon, and originally in large crystals at Takowaja, in the Ural mountains. See CHRYSOBERYL. G. F. KUNZ.

Alexandrof: town of Central Russia; in the government of Vladimir; 70 miles W. N. W. of the city of Vladimir. It contains a convent founded by Ivan IV., who is said to have also established here the first printing-press in Russia. Pop. 6,915.

Alexandro'pol (formerly *Gumri*): fortified town of the Caucasus; in the government of Erivan; on the Arpa-Chai river, 85 miles S. W. of Tiflis. The fort, which lies about 2,000 feet from the city, 300 feet above the level of the river, commands the entire vicinity, and can hold 10,000 men. Alexandropol is an important strategical point, as it is the key to Armenia. Pop. (1897) 30,735.

Alex'is, or Alex'ins: the name of several emperors who reigned at Trebizond (Trapezus) in the thirteenth, fourteenth, and fifteenth centuries. They belonged to the Comnenus family. See COMNENUS.

Alexis, or Alexins I.: Emperor of Constantinople; b. in 1048. Having distinguished himself by his military talents he was proclaimed emperor by his soldiers about 1080, in place of Nicephorus, who was then deposed. He showed himself an able and a crafty ruler. Some writers censure him for his failure to support the operations of the first crusade, which occurred in his reign. He died Aug. 5, 1118, and was succeeded by his son John.

Alexis Alexandrovitch: Grand Duke of Russia; younger son of the Emperor Alexander II.; b. in Jan., 1850. He visited the U. S., making an extensive tour in 1872, and meeting nearly everywhere a warm reception among the Americans.

Alexis Michaelovitch: Emperor of Russia; b. Mar. 10, 1629; succeeded his father Michael in 1645. He promoted

civilization and improved the laws. He was the father of Peter the Great. D. Jan. 29, 1676.

Alexis Petrovitch, or Petrewitsch: a Russian prince; son of Peter the Great; b. at Moscow, Feb. 28, 1690. He showed such a hostility to the reforms of his father that the latter resolved to exclude him from the throne. While Peter was traveling in Western Europe in 1717, Alexis fled to Vienna and Naples. He was soon brought back, and condemned to death on the charge of treason or rebellion. He died in prison, July 7, 1718. His son Peter became emperor in 1727.

Alexis, WILLIBALD: See HÄRING, WILHELM.

Alex'ishad: a watering-place of Germany; in the Harz Mountains, 9 miles from Ballenstädt (see map of German Empire, ref. 4-F); was established as a watering-place by the Duke of Anhalt-Bernburg in 1810. It has two springs—the Selke spring, which contains no carbonates, and very little carbonic acid gas, but large quantities of chloride and sulphate of iron, and is only used for bathing; and the Alexis spring, containing carbonate of iron, which is used for drinking. The scenery in the neighborhood is beautiful.

Alexis of Thuri: Greek comic poet; b. B. C. 392; one of the most important and prolific writers of the Middle Attic Comedy (see GREEK LITERATURE), though living as he did to the age of 106 he reached far into the period of the New Attic Comedy. The part of the parasite was considered his special invention. Fragments in Meineke, *Fragmenta comicorum Græcorum*, iii. 382 ff.; Kock, iii. 297 ff. (345 numbers).

Alfalfa: See LUCERNE.

Alfie'ri, VITTORIO, Count: Italian poet; b. at Asti, in Piedmont, Jan. 17, 1749, and inherited a large fortune. He was sent to the Academy of Turin, in which he learned little, and which he quitted about 1764. Recoiling with disgust and resentment from the stupid pedantry and tyranny of his teachers, he plunged into dissipation and neglected the cultivation of his mind. He passed many years in travel, for which he had a strong passion, and visited nearly all the countries of Europe, impelled by morbid unrest and love of excitement, rather than a rational resolution to complete his education. He began his literary career by the drama of *Cleopatra*, which was performed with applause in 1775. About this time he entered a more regular course of life, and devoted himself with passionate ardor to study and composition. It is stated that he commenced the study of Greek after he was forty years old. His literary success was promoted, as he affirms, by the influence of the Countess of Albany, the wife of the Young Pretender, Charles Edward Stuart. (See ALBANY, COUNTESS OF.) He passed many years in her society at Florence and Rome, and in France. He composed numerous tragedies, comedies, satires, and lyrical poems. His reputation is founded chiefly on his tragedies, among which we notice *Virginia*, *Filippo II.*, *Orestes*, *Abel*, *Mary Stuart*, *Myrrha*, *Octavia*, and *Saul*. His dramas, which display great energy of language and intensity of passion, and abound in noble sentiments, were well adapted to reform the national literature, which had become effete, insipid, and destitute of manly vigor. "The aim of his works," says Madame de Staël, "is so noble, the sentiments which the author expresses accord so well with his personal conduct, that his tragedies ought always to be praised as actions, even when they may be criticised as literary works." (*Corinne*.) Alfieri was liberal in politics, and ardently desired to improve the political and social condition of Italy by his writings. Among his works are an *Essay on Tyranny*, five odes on the American Revolution, and his interesting autobiography. He died at Florence, Oct. 8, 1803. His complete works were published at Pisa in 22 vols. 4to, 1808. A new edition of his dramatic works was published by Milanese (1855, 2 vols.). His life was written by Teza (1861). See also Tedeschi, *Studi sulle tragedie di Alfieri* (1869).
Revised by A. R. MARSH.

Alfon'sine (or Alphon'sine) Tables: the astronomical tables prepared by the order of Alfonso X. of Castile and Leon, at a cost of 400,000 gold ducats—about \$800,000. They were published in 1252.

Alfonso I. of Castile (or Alfonso VI. of Leon), surnamed THE BRAVE: son of Fernando I.; became King of Leon in 1065, and of Castile in 1073. Aided by the famous Cid, he defeated the Moors in several battles. He died in 1109.—ALFONSO VIII. of Castile (sometimes called ALFONSO III.), was born about 1155, and became king in 1158. He defeated the Sultan Mohammed An-Nâsir in a great battle in 1212.

D. in 1214.—ALFONSO XI. of Castile, b. in 1311; succeeded his father, Fernando IV., in 1312. He gained a great victory over the Sultan Aboul-Hassan at Tarifa in 1340. D. at Gibraltar in 1350.

Alfonso I.: King of Naples and Sicily; b. about 1385; was a son of Fernando I. of Aragon, whom he succeeded in 1416. On the death of Joanna II., Queen of Naples (1435), that kingdom was claimed by Alfonso and René of Anjou. After a long war between these rivals, Alfonso obtained the throne of Naples in 1442. He died June 27, 1458, and was succeeded by his son, Ferdinand I.

Alfonso I.: King of Navarre and Aragon; came to the throne in 1104; married the daughter of Alfonso I. of Castile, and proclaimed himself "Emperor of all Spain" in 1109; won many battles against the Moors, taking Saragossa in 1118. He also crossed the Pyrenees and captured Bordeaux in 1130, and Bayonne in 1131. D. in the cloister of San Juan de la Pegna, Valencia, Sept. 15, 1134. C. H. T.

Alfonso I.: first King of Portugal; b. about 1100; a son of Henry of Burgundy. Having gained a great victory over the Moors at Ourique in 1139, he assumed the title of king. He afterward took Lisbon, and became master of all Portugal. He died at Coimbra, Dec. 6, 1185, and left the throne to his son, Sancho I.

Alfon'so III. of Asturias, surnamed THE GREAT: began to reign in 866 A. D. He enlarged his dominions by victories over the infidels of Spain. D. at Zamora in 901.

Alfonso V.: King of Portugal; b. in 1432; was successful in wars against the Moors in Africa, and surnamed *Africano* on that account; but failed in his attempt to add Castile and Leon to his dominions. D. at Cintra, Aug. 28, 1481.

Alfonso VI.: King of Portugal; b. 1643; succeeded his father in 1656; on account of his vices was dethroned by his wife and brother in 1667; and d. in imprisonment at Cintra, Sept. 12, 1683.

Alfonso X.: called *El Sabio*, "The Learned"; b. Nov. 23, 1221; succeeded to the throne of Castile and Leon in 1252. He abandoned the warlike policy of his father, Ferdinand III., and it was chiefly owing to him that a favorable opportunity was lost for driving the Arabs from Spain. Having been elected German emperor by a faction of the German princes in 1257, his desire to maintain a splendid court forced him to resort to unjust and disastrous financial measures, which estranged his subjects from him and helped to prepare the way for the usurpation of his throne by his second son, Sancho, in 1282. He died as a fugitive in Seville, April 4, 1284. It is not to his capacity as a ruler, but to his extensive learning and literary activity, that Alfonso X. owes a distinguished position in Spanish history. His great interest in astronomy and natural science is attested by such compilations as the *Astronomical Tables*; his *Book of the Treasure*; in law, by *The Mirror of all Laws*, and especially by his well-known code named *Las Siete Partidas* (The Seven Divisions), which is, however, rather a series of essays on legislation, moral and religious, than a legislative monument such as the great statutes of Edward I. While in the *Chronicles*, which he caused to be written in Castilian, he laid the cornerstone of a national historiography, and in the translation of the Bible into Castilian, made under his direction, he greatly contributed toward making the Castilian dialect the language of the whole kingdom, he has also the great merit of having perfected and firmly established by the above-mentioned works the character of Castilian prose. Alfonso X. was also the warm friend of the Provençal troubadours, whose poetic forms he imitated in a number of lyric compositions still extant. In this lyric court-poetry, as well as in his 401 songs in honor of the Virgin Mary (published by the Spanish Academy in 1889), he did not employ the Castilian, but the Galician dialect, then in common use among all the troubadours of Western Spain. HENRY R. LANG.

Alfonso XII.: King of Spain; b. Nov. 28, 1857; son of Queen Isabel and of the Infante Francisco; educated at the Military Academy of Woolwich, England; on Dec. 31, 1874, Gen. Martinez Campos proclaimed him king; on Jan. 9, 1875, he landed at Barcelona and took command of the army; Jan. 23, 1878, he married Princess Maria de las Mercedes, b. June 24, 1860, youngest daughter of the Duke of Montpensier; became a widower June 26, 1878, and married, in second nuptials, Nov. 29, 1879, Archduchess Maria Christina of Austria, b. July 21, 1858. King Alfonso XII. died at Madrid, Nov. 25, 1885.

Alfonso XIII.: King of Spain under the regency of his mother, Maria Christina; the son of Alfonso XII.; b. May 17, 1886, after his father's death.

Alford, CHARLES RICHARD, D. D.: Anglican divine; b. 1816, at West Quantoxhead, Somersetshire, England; educated at Trinity College, Cambridge; ordained in 1840; principal Metropolitan Church of England Training College, 1854-64; Bishop of Victoria, Hongkong, 1867-72; author of *First Principles of the Oracles of God*; a charge on *China and Japan*; and numerous sermons and pamphlets.

Alford, HENRY, D. D.: poet, preacher, painter, scholar, critic, philologist, and theologian; b. in London, England, Oct. 7, 1810. He became a fellow of Trinity College, Cambridge, in 1834; incumbent of Quebec Street chapel, London, in 1853, and Dean of Canterbury in 1856. His most popular poetical work is *The School of the Heart, and other Poems* (1835), which was highly commended by the *Edinburgh Review* for Jan., 1836. He gained a high reputation as a biblical critic by his edition of the Greek New Testament (1844-52), in which he made much more use than his predecessors of the treasures of German learning, and thereby created an epoch in New Testament study. A revised edition of it appeared in 4 vols. (1859 *et seq.*). The *Contemporary Review* was inaugurated under his editorship, and was conducted by him from Jan., 1866, to Aug., 1870. Seven volumes of sermons preached in Quebec Street chapel were published at intervals of his busy life; also two volumes of *Hulsean Lectures*, delivered before the University of Cambridge. He published also a small volume entitled *The Queen's English*, which attracted no little attention. D. at Canterbury, Jan. 12, 1871. Revised by W. S. PERRY.

Alfred, surnamed THE GREAT; written also **Ælfred**, **Alured**, or **Alvred** (in Lat. *Ælfre'dus*): King of the West Saxons in England; b. in Berkshire in 848 or 849 A. D. He was a younger son of Ethelwolf, and succeeded his brother Ethelred in 871, when he found the country in a miserable condition. In the preceding reign the kingdom had been invaded and ravaged by an army of Danes, whom the Saxons were unable to resist. After the accession of Alfred these piratical incursions were continued or renewed, and nearly all of the kingdom was conquered by the Danes. Alfred was forced to flee from his court and conceal himself in the hut of a cowherd. Having by furtive measures raised a small army, he attacked and routed the Danes at Eddington in 878. Soon after this battle the Danish King Guthrum surrendered himself, was converted to Christianity, and remained a peaceable subject of Alfred, who now directed his attention to civil affairs. He founded or improved the British navy, rebuilt cities and forts, established schools, compiled a code of laws, and reformed the administration of justice. In that age of ignorance he was distinguished as a scholar, as well as a patron of learning. He translated several works from the Latin into Anglo-Saxon. About 893 he was recognized as the sovereign of all England. His kingdom was again invaded in 894 by an army of Northmen under Hastings, who is said to have had a fleet of 300 ships. Alfred defeated them in several battles, and finally drove them out of the island. He died at Winchester, Oct. 28, 901, and was succeeded by his son, Edward the Elder. Alfred is regarded as the wisest and greatest of all the kings of England. He was, says Freeman, "a saint without superstition, a scholar without ostentation, a conqueror whose hands were never stained with cruelty, a prince never cast down by adversity, never lifted up to insolence in the day of triumph." See Sharon Turner's *History of the Anglo-Saxons*, and Hughes's *Alfred the Great* (1878).

Alfred, ERNEST ALBERT: Duke of Edinburgh; second son of Queen Victoria of England; b. in Windsor Castle, Aug. 6, 1844; entered the royal navy Aug. 31, 1858; was married Jan. 23, 1874, to Grand Duchess Marie of Russia, the only daughter of Emperor Alexander II.

Alfred (or **Alured**) of **Beverley**: an English priest and historian; b. about 1100. He wrote a history of Britain in Latin, an abridgment of Geoffrey of Monmouth.

Alfred Centre, Allegany co., N. Y. (for location of county, see map of New York, ref. 6-D); 2 miles from Alfred station on the Erie R. R.; has an academy, and is the seat of Alfred University, a Seventh-Day Baptist institution. Pop. (1880) 513; (1890) 786; (1900) 756.

Alfreton: a market-town and parish of Derbyshire, England; 12 miles N. N. E. of Derby (see map of England, ref.

8-H). It is supposed to have been named in honor of Alfred the Great. Pop. 4,492.

Al'gæ [plu. of Lat. *alga*, a seaweed]: the general name of the seaweeds, etc., comprising many species which grow in salt or fresh water, and are greatly diversified in form, size, and structure. Some are too small to be seen by the naked eye, while the stem of the "giant kelp" of the west coast of America sometimes attain a length of from 1,000 to 1,500 feet. Having no true roots, they usually adhere to rocks or the sea bottom, and sometimes they float on the surface. Navigators frequently meet with masses of gulfweed (*Sargassum*) many miles in extent. An area of this kind in the Atlantic is said by Maury to be as large as the Mississippi valley. There are several such areas in the ocean, called SARGASSO SEAS (*q. v.*). Al'gæ are cellular in structure, are useful as manure, and some species, like Irish moss, are used as food. Kelp or barilla, made by burning seaweeds and other marine plants, yields soda and iodine. See VEGETABLE KINGDOM.

Revised by CHARLES E. BESSEY.

Algar'di, ALESSANDRO: Italian sculptor and architect; b. at Bologna about 1600; studied design under the Caraeci. His masterpiece in sculpture is a colossal work in relief in St. Peter's church, Rome, the subject of which is Pope Leo forbidding Attila to enter Rome. Among his works are statues of S. Filippo Neri and Innocent X. D. in Bologna, June 10, 1654.

Algarovil'la: an astringent substance procured from a tree called *Juga marthæ*, found in New Carthage, South America. It is a powerful agent for tanning leather.

Algar've (i. e. the western land), or **Faro**: the southernmost province of Portugal; bounded N. by Alemtejo, E. by Spain, and S. and W. by the Atlantic Ocean. Area, 1,872 sq. miles. The surface is mostly mountainous. The main exports are wine, salt, dates, and other fruits. The chief towns are Faro and Lagos. Pop. (1878) 205,901; (1881) 204,031.

Al-Gazza'li, or **Al-Ghazza'li**, ABU HAMED MOHAMMED: b. at Tus, Persia, in 1058; taught both in Nishapoor and in Bagdad; lived a while in Syria; visited Egypt; spent the latter part of his life in Tus, where he died in 1111. He was one of the most prominent of the Moslem theologians and philosophers, and a very prolific writer. See Lewes's *Biographical History of Philosophy*. J. R. J.

Al'gebra [mediev. Lat. (or Ital.) form of Arab. *aljebr*; *al*, the + *jebr*, reuniting, to *jabara*, restore]: an important branch of mathematics, sometimes called universal arithmetic, but it may be more properly described as a calculus of symbols. The symbols it employs are of three kinds: (1) those of quantity, known or unknown, which consist of ordinary numbers and letters of the alphabet; (2) those of operation, among which are +, -, ×, ÷, √, etc.; and (3) mere abbreviations for ordinary words. (See SIGN.) The combination of these symbols according to fixed laws leads to algebraical expressions or formulæ, in which actual computations are indicated rather than performed. The universality of algebra as compared with arithmetic consists in the fact that in the latter, computations being effected as they arise, all traces of the intermediate steps are obliterated, and the result is applicable to a single case only; whereas in algebra the formulæ contain implicitly the answers to an unlimited number of questions. Again, to the equivalence of two algebraical formulæ always corresponds a general theorem, which arithmetic can only *verify* in particular cases. Thus from the algebraical identity

$$(a+b)(a-b) = a^2 - b^2$$

we learn that the "product which results from multiplying the sum by the difference of *any* two numbers is equal to the difference of their squares."

The systematic notation, to which algebra owes its chief power as an instrument of research, has been of very gradual growth, and is still being extended. In the first known treatises on the subject, by Diophantus, who probably lived in about the fourth century of our era, the few symbols employed are mere abbreviations for ordinary words. The Arabians, who obtained their algebra from the Hindus, did little or nothing toward its extension, though their treatises, after being carried into Italy by a merchant of Pisa, Leonardo Bonacci (1202 A. D.), gave rise to important improvements. Scipio Ferreus, of Bononia, is said to have first solved the equation of the third degree (1505); but it was Tartaglia, or rather Cardan, who first gave the general solution of a cubic equation, and employed letters to denote the unknown quantities, the known ones being still mere num-

bers. Without extending algebraic notation, Ferrari, a disciple of Cardan, discovered the general solution of a biquadratic equation, and thus, unknown to himself, reached the barrier which, as has since been proved, will ever remain impassable to the searcher for *general* solutions of equations of the fifth and higher degrees. (See EQUATIONS.) Toward the middle of the sixteenth century algebra was introduced into Germany, France, and England, by Stifelius, Peletarius, and Robert Recorde, respectively. In doing so, the latter also invented the very convenient symbol of abbreviation =, and Stifelius the far more important symbols of operation +, -, $\sqrt{\quad}$. In the same century, through her far-famed son Vieta, France contributed still more to the progress of the science. Vieta introduced letters as symbols for known as well as for unknown quantities, and by the increased power thus acquired he laid the foundation of the general theory of equations. In this direction he was followed by Girard, Harriot, Descartes, and others; in short, the science now advanced rapidly toward its present state of perfection. It would be fruitless here to attempt to trace its progress. The reader may consult with advantage Hutton's *Mathematical Tracts*, vol. ii.; Bonnycastle's translation of Bossut's *Histoire des Mathématiques*; or the works of Montucla. See DETERMINANTS.

Revised by S. NEWCOMB.

Algeciras, aal'khaÿ-thee'ras (i. e. the Peninsula): a seaport of Spain: in the province of Cadiz; 6 miles W. of Gibraltar, from which it is separated by the Bay of Gibraltar; lat. 36° 8' N., lon. 5° 26' 5" W. (see map of Spain, ref. 20-D). Pop. about 14,000. Leather and charcoal are exported from this port. Here occurred a naval battle between the English and French in July, 1801.

Alger, HORATIO, JR.: Unitarian minister; b. at N. Chelsea (now Revere), Mass., Jan. 13, 1834; graduated at Harvard in 1852; studied divinity at Cambridge; was ordained over the Unitarian church at Brewster, Mass., in 1864; and settled in New York in 1866. He published *Bertha's Christmas Vision* (1855); *Paul Preston's Charge* (1865); *Do and Dare* (1884), etc. D. in Natick, Mass., July 18, 1899.

Alger, RUSSELL ALEXANDER: politician; b. at Lafayette, O., Feb. 27, 1836; admitted to the bar 1859; entered the Union army as a private; was breveted major-general of volunteers June, 1865; Governor of Michigan 1884; candidate for President in Republican National Convention 1888; elected commander-in-chief of the G. A. R. 1889; Secretary of War in McKinley's administration 1897. Resigned July 19, 1899.

Alger, WILLIAM ROUNSEVILLE: clergyman and author; b. at Freetown, Mass., Dec. 30, 1822; graduated at Harvard Theological School in 1847. Besides his most important work, *A Critical History of the Doctrine of a Future Life*, with the remarkable bibliography by Ezra Abbot, *Literature of the Doctrine of the Future Life* (1863), his *Genius of Solitude* (1865) and *Friendships of Women* (1867) have been admired. He has also translated Oriental poetry from the German. He has been since 1875 pastor of Unitarian churches in New York, Denver, and Boston.

Alge'ria (Fr. *L'Algérie*): a French colony in Northern Africa: between the Mediterranean and about lat. 37° N., and the meridians of 2° W. and 10° E. Area, 184,474 sq. miles. Boundaries: Mediterranean on the N., Tunis and Tripoli on the E., Sahara S., Morocco W. A protectorate is claimed over an enormous desert area to the S., extending to about lat. 15° N., and from meridian 8° W. to 13° E.

Topography.—Coast high and steep, with few good harbors; near the coast, Little Atlas Mountains; mountainous region, with coast streams and deep, fertile valleys. Back of these mountains an extensive arid plateau 2,000 to 3,000 feet high, declining toward the Sahara. Between this plateau and the desert, main Atlas chain, with wooded slopes. No large rivers.

Climate.—The climate is dry; the rainy season lasts from September to April, but the rains are not constant. The summer is almost rainless. The heat is not as intense as in some countries, but is protracted. The winters are pleasantly cold, making the colony an agreeable winter resort.

Soil and Vegetation.—The soil of the valleys and the Metidjah, or northern plain, is very fertile. Near the coast market vegetables are grown largely and exported to Europe. The valleys and plain produce wheat, barley, and tropical fruits. The grasses and reeds of the Shott or great plateau afford rich pasture to the Arab or Berber horses, cattle, asses and mules, and sheep. The esparto grass, extensively used in paper-making in France and Great Britain, grows

all over this plateau. The forests are of different species of palm, cedar, and cork-oak. The date-palm ripens its fruit in the S. The wild beasts, except the hyæna and jackal, are mostly exterminated. The minerals are iron, lead, copper, marble, sulphur, and salt.

Commerce.—In 1890 the imports were \$47,000,000, and the exports about \$52,000,000. The exports from and imports to France were nearly equal—viz., \$42,000,000. In 1891 there were 1,910 miles of railway in operation, including the Tunisian extension of 140 miles. In 1890 the telegraph lines, including branches into Tunis, were 4,310 miles in length, with 10,000 miles of wire.

Weights and Measures.—(1) Length: The metric system is established by law. The former unit of length was the (so-called) Turkish pik = 25.197 inches = 640 mm., which is not, however, that of Constantinople, nor equivalent to any of the various piks in use in the Levant. The so-called Moorish or Arabian pik = $\frac{3}{4}$ of the foregoing = 18.898 inches = 480 mm., was also used; but this is not the pik used in Morocco or in Arabia. Sub-multiple, the robi = $\frac{1}{8}$ pik.

(2) Volume: For liquid capacity the khoullé = 4.4027 gal. = 16.675 liters. For dry measure, the tarrie = 0.56295 U. S. bush. = 19.84 liters. Multiple, 16 tarries = 1 eaffiso. The saâ is a little less than 3 tarries; it is = 1.646 bush. = 58.0 liters.

(3) Weights: The rotl or rottolo is the unit, and has different values for different commodities. The rotl-kébir (large rotl), for honey, butter, oil, dates, and soap = 1.806 lb. avoirdupois = 0.81912 kilog.; the rotl-ghredouri, for fruits and leguminous vegetables = 1.34543 lb. av. = 0.61434 kilog.; the rotl-feudi, for precious metals and gems = 1.0968 lb. av. = 0.49743 kilog.; and the rotl-attari, for drugs and commodities generally = 1.20403 lb. av. = 0.54608 kilog. The rotl-feudi and the rotl-attari are subdivided into 16 ounces each, the rotl-ghredouri into 18 ounces, and the rotl-kébir into 24 ounces. The rotl-attari has a multiple by 100, called the kantar-attari, for commodities generally; a multiple by 110 for cheese, almonds, cotton, and some other things, called the kantar-fromage; a multiple by 166 for honey, butter, oil, soap, etc., called the kantar-beurre; and a multiple, called the kantar de lin, of 200 rotl-attari. There are a kantar-ghredouri and a kantar-kébir, each of 100 times the corresponding rotl. The kharouba or karob is a small weight for pearls and jewels = 3 grains = 0.1944 gramme; multiple, 24 karobs = 1 métiéal.

History.—The Numidians and Moors, who inhabited this region, soon came under the control of Carthage. On the fall of Carthage, 146 B. C., Algeria became a Roman colony, and enjoyed a great degree of prosperity till its conquest by the Vandals, in the middle of the fifth century. Two centuries later the Saracens became masters of the country, and the people gradually sank into a state of barbarism. In 1516 the ameer called in the pirates of Barbarossa to his help against the Spaniards, and they became masters of the country and acknowledged the suzerainty of Turkey. For three centuries the Algerine pirates were the terror of Southern Europe and the Mediterranean. In 1705 they renounced allegiance to Turkey, and their piracies grew more audacious for the next hundred years. Partially checked by Napoleon I., they returned to their bloody deeds after the peace, but in 1815 were compelled to sue for peace by a U. S. squadron. After a time they became bolder than ever, and France resolved to chastise them. After a three-years blockade of the ports of Algeria, the French bombarded and captured Algiers, July 5, 1830. The country was under French military control for forty years, and there was constant fighting with the Arabs and Kabyles. It was generally believed that the French rule had been a failure, and that the colony had cost much more than France would ever receive for it; but in 1871, after the suppression of a serious rebellion, Algeria was put under a civil administration. There has been since that time some trouble with the native tribes, but as a whole the civil administration has proved a success. A standing army is still maintained there of 60,000 men, but half of them are native troops. In 1881 a war commenced with the native tribes of Tunis, which resulted in the establishment of a protectorate over that country by France. After the Franco-Prussian war homes were offered to Alsatians who preferred to remain with France. Many took advantage of the offer, and the colony has since been prosperous.

Administration.—A civil governor-general now administers affairs, and Algeria is looked on rather as a part of France than as a colony. Military administration is now limited to the outlying parts in the Sahara. The laws are made by the French Chambers, and each Algerian depart-

ment sends 1 senator and 2 deputies to the National Assembly. The departments are 3 in number—Algiers in the middle, Constantine on the E., and Oran in the W. Education is well cared for. There is an academy at the city of Algiers with 223 students (1888), and there are 8 communal colleges and 1 college for girls. Order is well maintained, and crime is not more common than in France. The population is largely agricultural. Wheat, barley, grapes, tobacco, and alfa are the common crops.

Population.—The total population in 1891 was—in the civil districts, 3,636,967; in the military districts, 487,765; total, 4,124,732, or 22 to the sq. mile. The civil territory is being constantly increased by taking in parts of the military territory. Of the above population, 272,662 were of French extraction, 47,667 were naturalized Jews, and 3,567,223 were French indigenous subjects, besides foreigners, properly so called. In 1876 the population of Algiers (capital of the colony and of the department of Algiers) was 74,792; Oran (capital of Oran department), 67,681; Constantine (capital of Constantine department), 44,960; Bona, 29,640; Tlemçen, 28,204; Philippeville, 22,177; Blidah, 24,304; Sidibël-Abbès, 21,595.

Besides the Europeans there are eight different races found in Algeria. (1) The Kabyles, a race representing the ancient Berbers, probably the aborigines and possibly Aryan. They form a large part of the population, especially in the mountains. (2) The Arabs, common especially in the S. They are Bedouins or nomadic Arabs and are turbulent. (3) The Moors, a mixed race, common in towns near the seacoast. (4) The Jews, generally engaged in commerce in the towns. (5) The Turks; long dominant but never numerous, they have now about disappeared. (6) Kolougis, half-breed Turks by native women, not uncommon in the cities. (7) Negroes who were brought originally as slaves. (8) The Mozabites, an African race furnishing laborers for the coast towns.

WORKS OF REFERENCE.—Faidherbe, *L'Avenir du Sahara et du Soudan* (1866); Maltzan, *Drei Jahre im Nordwesten von Afrika* (1869); Fillias, *L'Algérie ancienne et moderne* (1875); Gaffarel, *L'Algérie, histoire, conquête, colonisation* (1883); Playfair's Murray's *Handbook of Algeria and Tunis* (1887); Playfair's *Bibliography of Algeria*, published by the Royal Geographical Society (1888); and numerous official publications by the French Government.

Revised by MARK W. HARRINGTON.

Alghero, or Algheri: a fortified town and seaport of Sardinia; 15 miles S. W. of Sassari (see map of Italy, ref. 7-B). It has a cathedral and several convents. Wine, grain, tobacco, coral, etc., are exported from it. Pop. of commune, 10,532.

Algiers' (Arab. *Al-Jezair'*, Fr. *Alger*): a seaport and city of North Africa; on the Mediterranean; lat. 36° 47' 3" N., lon. 3° 4' 5" E. (see map of Africa, ref. 1-C). It was formerly the capital of the Dey of Algiers, but since 1830 has been the capital of the French colony of Algeria. Built on the slope of a steep hill, which rises to the height of 500 feet, it presents from the sea an imposing appearance, which is partly owing to the whiteness of the houses. The old streets are mostly narrow and crooked, but several straight and elegant streets have been made since the French became masters of the city. The houses are built of stone and brick, have flat roofs, and are annually whitewashed. Among the public buildings are numerous mosques, several Roman Catholic churches, a fine cathedral and exchange, and a public library. The beauty and prosperity of the city have been much improved by the French, and its commerce has been greatly increased. Among the articles of export are wheat, coral, animal skins, and olive oil. Steam-vessels ply frequently between Algiers and Toulon and Marseilles. This city was for three centuries the rendezvous of the Algerine pirates, who, though few in number, defied the power of the greatest nations of Europe. It was bombarded by the English admiral Lord Exmouth in July, 1816, when a large part of the city was reduced to ruins, and was taken by the French in July, 1830. Pop. (1881) 64,714, exclusive of the military; (1886) 74,792.

Algo'a Bay: on the south coast of Africa; in Cape Colony, about 425 miles E. of the Cape of Good Hope. Here are a good harbor and a flourishing seaport called Port Elizabeth, situated at the mouth of the Zwartkops river. It was at Algoa Bay that the first immigrants landed in South Africa.

Algol: the star which in the ordinary nomenclature is known as β Persei (R. A., 3 h. 1 m.; Decl., 40° 33'). In recent times it has become the subject of some most remarkable discoveries. For more than a hundred years it has figured as a variable star, because at certain regular intervals, a little less than three days, its light gradually faded out during about four hours, until it was reduced from the second to the fourth magnitude. During the following four hours its light would be recovered, and the magnitude of the star would then remain unchanged for about two and a half days. It was long ago suggested that these variations might be due to the partial eclipse of the star by a dark body revolving around it, and passing between the earth and the star at every revolution. But the testing of this hypothesis seemed hopeless until the system of measuring the motion of stars in the line of sight, originally introduced by Dr. Huggins, of London, was brought to extreme perfection by Dr. Vogel, of Potsdam. The latter found by repeated measurement that before each eclipse the star was moving away from the earth, and after the eclipse toward the earth. Such an alternation of motion pointed directly to the action of a dark body revolving around it, the eclipse occurring as the body passes between the earth and the star. The time and amount of the eclipse, the time of revolution, and the velocity of the star as it receded and approached, led to the following approximate elements of motion:

Diameter of Algol.....	1,060,000 miles.
Diameter of satellite....	830,000 miles.
Distance of the bodies...	3,200,000 miles.
Orbital velocity.....	55 miles per second.
Masses.....	$\frac{1}{4}$ and $\frac{2}{3}$ of the sun's mass.

It thus appears that Algol is about as large as our sun, and, what is yet more remarkable, the eclipsing planet is nearly as large as the star itself; it may be regarded as certain that the volume of this invisible planet is thousands of times that of our earth, and, indeed, hundreds of times that of Jupiter.

Dr. Vogel's discovery has been supplemented by another, made by Mr. S. C. Chandler, of Cambridge. For some time it has been known that the period between two eclipses of the star is not uniform. It occurred to Mr. Chandler that this variation of the period might be explained by supposing that both Algol and its invisible satellite were revolving around a third dark body. When by moving in this orbit Algol was coming toward us, the period between two eclipses would be shortened, because the star would partly overtake the light by which we see it. When moving away from us, the period between the eclipses would be longer, because the light would have farther to travel after each eclipse. He therefore investigated the question whether observations on the position of the star showed an irregularity of proper motion which would be caused by such an orbital revolution. By discussing all the observations from 1750 till the present time, such a change was very strongly made out; yet it is so slight that the quantity of it can not be regarded as exactly measured. But the remarkable agreement between the parallax found by Mr. Chandler and the parallax we should expect a star of the second magnitude to have, were it equal to our sun in brilliancy, seems to leave no doubt of the correctness of the conclusion. The period of the revolution of Algol around the third body was fixed by Mr. Chandler at 130 years, but this is probably too short; indeed, until the star is observed through more than a complete revolution, it will be impossible to fix the length of the period with certainty.

We have thus acquired a knowledge of two immense dark bodies, not only forever invisible to human eyes, but incapable of producing any motion that can be detected by the ordinary telescopic measurement; yet the effect of whose attraction is shown by the spectroscope and by the laws of the motion of light. See *Astronomische Nachrichten*, vol. cxxiii.; and the *Astronomical Journal*, vols. vii. and xi.

S. NEWCOMB.

Algo'ma: a district of Ontario, Canada; formerly occupying the entire northwestern extremity from about lon. 81° westward, now extending only to 85° W., and from the North Channel, Lake Huron, to the Albany river on the N. It is well wooded and watered and rich in minerals, but has few inhabitants, except a sparse Indian population, and in the eastern part a sprinkling of farmers. Two branches of the Canadian Pacific Railway cross the district. M. W. H.

Algotometer: See RECORDING APPARATUS, PSYCHOLOGICAL, in the Appendix.

Algo'na: capital of Kossuth co., Ia. (for location of county, see map of Iowa, ref 2-F); on the East Fork of the Des Moines river, about 120 miles N. by W. of Des Moines; has Northern Iowa Normal school and is a wagon-manufacturing point and dairying center; it has two steam flouring-mills, a steam butter-tub factory, and a brick and tile factory. Pop. (1870) 860; (1880) 1,359; (1890) 2,068; (1900) 2,911.

EDITOR OF "COURIER."

Algon'kian Period: a division of geologic time preceding the Cambrian and preceded by the Archean. The name refers to a district in and about Canada, originally inhabited by Algonkins (*q. v.*). The Algonkian differs from all later periods in that it is not characterized by a fossil fauna. In its rocks have been found a few obscure fossils, besides tracks resembling those of marine worms; and presumptive evidence of abundant life exists in the presence of carbonaceous and calcareous deposits; but these indications do not suffice for the discrimination and classification of its rocks. The differentiation of life forms had progressed so far in the Cambrian period, immediately following, and some Cambrian species were so highly organized, that the evolutionist is unwilling to believe the history of life before that date shorter than its subsequent history. So, while there can be no hope of completely tracing the early development of life by means of vestiges preserved in the rocks, it is yet possible, or even probable, that faunas belonging to the Algonkian will be discovered. The Algonkian rocks have a thickness of many thousands of feet and are locally divided by unconformities into several distinct series. Consideration of the magnitude of the deposits and of the extent of intervening epochs of erosion, demonstrated by the unconformities between the series, leads to the belief that the Algonkian period may have equaled in duration the sum of several later periods, or even the whole time that has since elapsed. Certain of the series consist of sedimentary rocks in their ordinary condition, as sandstone, shale, limestone, etc.; others exhibit metamorphism in various degrees, and the same series may be unaltered in one region and metamorphic in another. Volcanic rocks are extensively interbedded in some districts, showing that igneous agencies were no less active then than now.

The type locality for Algonkian rocks is the Lake Superior region, where their title to a category separate from Archean was first demonstrated by R. D. Irving. (See ARCHEAN.) They comprise there three series—the Lower Huronian, 5,000 feet; the Upper Huronian, 12,000 feet; and the Keweenawan, 25,000 feet, each limited above and below by a great unconformity. Rocks of this period occupy great areas in Canada and the Hudson Bay country; they occur at many localities in our western mountains, in Texas, in the Black Hills, in the Adirondacks, and they probably occur in New England and in the Appalachian region. To this period are to be referred also rocks described in Great Britain, Scandinavia, France, Bavaria, etc. The literature of the subject is epitomized for America by C. R. Van Hise in *Archean and Algonkian*, Bulletin 86, U. S. Geological Survey (1892). See GEOLOGY, HISTORIC. G. K. GILBERT.

Algon'kins: one of the two great families of Indians that formerly occupied the valley of the Mississippi and the regions east of it. The Indians of New England belonged to the same linguistic stock. See Parkman's *The Jesuits in North America*; Baldwin's *Ancient America* (1872). See the articles on the ALGONQUIAN INDIANS and INDIANS OF NORTH AMERICA.

Algonquian Indians: the most widely extended of all the North American linguistic stocks, its territory stretching along the Atlantic coast from Labrador to Pamlico Sound, and westward from Newfoundland to the Rocky Mountains, with one or two tribes in the prairies farther to the S. In a general way the people of this stock had the Eskimauan and Athapasean tribes on their N., the Siouan tribes on their W., the Muskogean and eastern Siouan tribes on their S., with the Iroquoian tribes forming a linguistic island in their center. (See map under INDIANS OF NORTH AMERICA.) They were divided into a large number of tribes and bands, speaking about forty distinct languages and innumerable dialects.

The name Algonquin or Algommequin is derived, according to Trumbull, from *A'goumek*, "on the other side" (of the river), a term originally used to designate the Indians of the Ottawa river by their neighbors lower down on the St. Lawrence. Another form of the word occurs in Accomack, Virginia.

Divisions.—The principal Algonquian tribes and confederacies may be grouped as follows: *North Atlantic*—Micmac, Malecite, Abnaki (including Penobscot, Norridgewock and Arosaguntacook), Pennacook, Massachusetts, Wampanoag, Narraganset, Nipmuc, Pequot, Mohegan, Mahican (including Stockbridge), Metoac (including Montauk and Shinnecock), Wappinger. *South Atlantic*—Munsi, Leni-Lenape or Delaware, Shawano, Nanticoke, Conoy, Powhatan (including Mattaponi and Pamunkey), Mattamuskeet. *Interior*—Nascapi, Montagnais, Algonquin and Ottawa, Maskegon, Cree, Ojibwa, Misisaga, Miami, Piankishaw, Illinois (including Peoria and Kaskaskia), Sac, Fox, Kickapoo, Pottawatomi, Menomini. *Western*—Siksika or Blackfoot, Atsina, Arapaho, Cheyenne.

Early Migrations.—It is impossible to decide upon the original home and the early migrations of the Algonquian family, but the consensus of tradition shows that they regarded the North Atlantic coast region, from about the mouth of the St. Lawrence to the mouth of the Delaware, as their most ancient territory.

The westward movement of the Ojibwas, Crees, Ottawas, and Pottawatomis from the neighborhood of the Ottawa river to the upper lakes, the sources of the Mississippi and the Saskatchewan, has been chiefly within the historic period, and was due largely to the inroads of the Iroquois about the middle of the seventeenth century. Within the same period they have driven the Eskimo hundreds of miles to the N. along the shores of Labrador and Hudson Bay, and seem also to have pressed the Cherokees farther to the S. The advance of the Blackfeet, Cheyennes, and Arapahos into the prairies is comparatively recent, as they still retain distinct traditions of a time when they lived in a timber country and cultivated the soil.

History.—From their position along the eastern seaboard the Algonquian tribes were among the earliest to encounter the white immigration. Settlements were made almost simultaneously at widely separated points within their territory by French, Dutch, and English colonists. The result may be briefly stated. The contact with the whites, whether as allies or enemies, always brought about destruction or expatriation to the free warriors, and degradation to the few who remained behind. The early wars—the Pequot and King Philip's war in New England, the war between the Dutch and the tribes about Manhattan, and the long and merciless struggle between the Virginia colonists and the Powhatans—were carried on by the native proprietors of the soil, without aid or instigation from the outside, in the hope and expectation of driving the white intruder from the land. The result was that the coast tribes were dismembered and almost annihilated, and the remnants compelled to seek safety beyond the mountains. Then began another series of Indian wars, but under different auspices. France and Great Britain contended for the mastery in the New World, and the Indians, no longer able to stand alone, became the allies and tools of one or the other, according as interest or vengeance prompted. The Algonquian tribes, which had been driven from the seacoast into the western wilderness, ranged themselves almost to a man under the French banner.

Before the close of the French and Indian war the Algonquians had been driven from the seaboard across the Alleghanies. Their joining the British side in the Revolution resulted in their being driven across the Ohio, and Wayne's treaty in 1795 forced them still farther to the W. The war of 1812, in which again they joined the British against the U. S., left the broken and dispirited tribes unable to withstand the continued pressure. Under a systematic "plan of removal" the Government inaugurated a series of treaties, by which, before the year 1840, most of the native tribes were transported beyond the Mississippi. Among these were the Shawanos, Delawares, Miamis, Weas, Piankishaws, Kickapoos, Sacs, Foxes, Pottawatomis, the remnants of the Illinois, and others, leaving of the Algonquian tribes of the U. S. only the Ojibwas, Ottawas, Menomins, and portions of the Abnakis and Miamis in their old homes. The Algonquians of Canada have never been removed in such systematic style, but were simply assigned to limited reservations within their ancient territories, and have diminished but little, if any, in numbers since the advent of Europeans. Those in the U. S., however, have been reduced by war, disease, and successive removals, and whole tribes and confederacies have been swept out of existence. The present number of the Algonquians is about 100,000, of whom 37,000 are in the U. S. and 63,000 in Canada. The largest tribes are the Ojibwa and the Cree.

Tribal Histories.—The Micmacs of Nova Scotia, with the Malecites or Echemins of New Brunswick and the Abnakis of Maine, acted always in the colonial period as the firm allies of the French against the English, with whom it may be said they were constantly at war until the fall of Quebec. Long before that time, however, the southern Abnakis, with the remnants of the Pennacooks and others, abandoned the vicinity of the English settlements and removed in a body to the St. Francis river below Montreal. The others made treaties by which they were permitted to remain in their old homes, where they have since maintained themselves with a fair degree of prosperity. Those in Maine now number about 600.

The Southern New England tribes—Massachusetts, Wampanoags, Nipmucs, Narragansets, Pequots, Mohegans and Mahicans—are practically extinct, and will be remembered in history chiefly in connection with the Pequot and King Philip's wars. It was among these tribes that the first English settlements were made. Eliot translated the Bible into the Massachusetts dialect, and gathered a few hundred into "praying-towns," until the outbreak of King Philip's war in 1675 once more scattered them. War, emigration, and deportation as slaves to Bermuda and the West Indies rapidly depleted their numbers. In the eighteenth century another effort was made to convert the remnant, and a new mission was established at Stockbridge in Western Massachusetts. As a result of missionary work continued through two centuries the aborigines of Massachusetts have been reduced to a handful of mixed bloods along the coast and about 200 souls near Green Bay, Wis., 1,000 miles to the W. The Mohegans still have a small organization near Groton, Conn., while the Metoacs and Wappingers are extinct. A few mixed bloods, however, live along the east end of Long Island, at Gay Head on Nantucket, and about Narragansett bay.

The Munsis and Delawares, who formerly owned all New Jersey and the Delaware basin, began to settle on the Ohio before the opening of the French and Indian war. Here they were joined by the remnants of the Nanticokes and Conoys from Maryland, the Mahicans from the Hudson, and the Shawanos, who had originally lived in Tennessee and on the Savannah river, but moved north to be near their kindred. At the close of the Revolution the combined tribes were in possession of a large portion of Ohio and Indiana, which by successive treaties rapidly passed out of their hands. The main body of the Delawares and Shawanos, numbering together about 1,500, is now incorporated with the Cherokees in the Indian Territory. There are also a considerable number of Delawares and Munsis in Ontario, Canada. The Nanticokes and Conoys have disappeared.

The Powhatans of Virginia carried on unceasing war against the English colonists for forty years, until they were completely broken, and the final blow came in repelling the inroad of a mountain tribe, probably the Cherokees, about 1654, in which their chief and nearly all their remaining warriors were slain. A few mixed bloods, with more of the Negro than of the Indian element, still keep up organizations under the name of Pamunkeys and Mattaponies about 20 miles from Richmond, Va. The tribes about Albemarle Sound, among whom Raleigh made his first attempts at colonization, seem to have possessed but little stamina, and disappeared almost unnoticed. The Mattamuskeets were about the last to keep up a tribal form, but the Tuscarora war of 1712 completed their destruction.

The Miamis, Weas, Piankishaws and Illinois are nearly extinct. A few mixed bloods retain the names in the Indian Territory, and about 300 Miamis, more or less mixed, yet live in Indiana. The extinction of the Illinois is due largely to the war waged upon them by the lake tribes in revenge for the murder of Pontiac.

The Pottawatomis, Kickapoos, Sacs, and Foxes, formerly in Michigan, Illinois, and Southern Wisconsin, are now chiefly in Oklahoma, and still have a considerable population. A portion of the Kickapoos at one time drifted down into Mexico, but were brought back about twenty years ago.

The Menominis, Ottawas, and Ojibwas or Chippewas of the upper lakes have never been removed, but still retain about their original numbers on numerous reservations in Michigan, Wisconsin, and Minnesota. The same may be said of the Canadian Ojibwas, Crees, and Maskegons north and northwest of the Great Lakes, and the Montagnais and Nascapis of the lower St. Lawrence. As the country is still but thinly settled, they have remained almost undisturbed and undiminished within their original limits.

The prairie tribes of the Algonquian race—the Blackfeet, or Siksika (including the Piegans), Atsina, Arapahos, and Cheyennes—have suffered from wars and smallpox, but still retain strong organizations. The most numerous are the Blackfeet, who with the Atsina number about 8,000, of whom 2,000 are in Montana and the rest on the Canadian side of the boundary. A portion of the Cheyennes also live in Montana, but the main body is in Oklahoma. The Arapahos also are in two bodies, part living in Wyoming and the rest with their old allies, the Cheyennes, in Oklahoma. The two tribes, north and south, number together about 5,000. Those in Oklahoma sold their reservation in 1891, and have now taken lands in severalty. See INDIANS OF NORTH AMERICA.

Food Supplies.—The Algonquian tribes were mainly sedentary and to some extent tillers of the soil, with the exception of the Ojibwas, Crees, and others in the extreme north, and the Blackfeet, Cheyennes, and Arapahos on the prairies. These latter also, however, according to their own traditions, at one time cultivated the ground, although from the first European acquaintance with them they have subsisted entirely by the chase. The coast tribes planted their fields in the spring, and then retired into the interior to hunt the deer and other animals—including the buffalo, which once abounded in the prairies north of the Ohio—until their crops were ripe in the fall. The winter was usually spent in their villages, with occasional short hunting excursions into the neighboring forest. In the Ohio valley and the lake region the early spring was employed in collecting the sweet sap of the maple to make sugar. The tribes along the shores of the Chesapeake and Albemarle Sound depended largely upon fish, which they took in weirs of elaborate construction. Fish also formed an important part of the food supply along the lakes.

Corn was the main agricultural staple, and the Powhatan tribes raised enough to supply not only their own wants but also those of the Virginia colonists for several years after the founding of Jamestown, while in 1794 Wayne's army found one continuous plantation extending along the entire length of the Maumee. From the Algonquian tribes the whites learned to make hominy and johnny-cake, as well as maple-sugar. They also raised beans, pumpkins, etc., and used manure, it being the common practice along the coast to put a dead fish into each corn hill when planting.

House-building.—In their permanent villages the houses were oblong, and built to accommodate several families. In the North they were frequently made of logs, while in the South and West they were generally constructed of saplings bent over at the top to form an arched roof, and covered with bark or mats of rushes. About the upper lakes and farther to the North and West the lodge was of the style of the prairie tipi and covered with bark or skins. Along the Atlantic coast the villages were more compactly built, and sometimes strongly fortified with palisades, from which construction they were often called forts or castles. The temporary summer encampments were light coverings of bark on a framework of poles.

Character.—The Algonquian tribes were, perhaps, equal to the Iroquoian in bravery, intelligence, and physical powers, but seem to have lacked their constancy of purpose and solidity of character. Their failure in concerted action, however, was doubtless due in part to the great diversity of languages and the wide extent of their territory, as compared with the Iroquois, who, by reason of their narrower limits and mutually intelligible dialects, were better able to keep up a compact organization. Many individual Algonquian tribes, as the Pequots and Powhatans, displayed indomitable resolution in defending their homes, stubbornly contesting every foot of ground until they were practically exterminated.

JAMES MOONEY.

Algonquin, al-gon'kwīn: a post-township of McHenry co., Ill. (for location of county, see map of Illinois, ref. 1-F). It contains the villages of Algonquin, Cary, and Crystal Lake. The first is noted as a milk-shipping station, also for its fine water-power and flouring-mills and its mineral spring. Crystal Lake is a railroad junction and a fine summer resort; the lake of the same name is a beautiful sheet of water, from which ice is harvested for the Chicago market. Pop. (1880) 2,321; (1890) 2,512; (1900) 3,048.

Algorism, or **Algorithm** [viā mediæval Lat. from Arab. *al-Khowārazmī*, name of the Arabic mathematician through whose works the Arabic notation became known in Europe. The form *algorilm* is due to a false association with the Gr. *ἀριθμος*, number]: the art of computing in reference to some particular subject, or in some particular way, as the *algorilm* of numbers, of surds, etc.; generally any system of notation by means of algebraic symbols.

Alguazil', or **Alguacil'** [Span. from Arab. *al-wazīr*; *al*, the + *wazīr*, vizier, minister; from *wazara*, carry on]: the name given in Spain to an inferior officer appointed to execute the law, corresponding to a constable, bailiff, or policeman.

Al-Hak'em-Ibn-At'tâ (called **Al-Moken'na**, -**Mokanna**, or -**Mukanna**, i. e. the veiled one): an impostor who in 774 A. D. announced himself as a prophet and lawgiver in Khorassan. Having been attacked by the troops of the Caliph Mahdi in 780, he set fire to his castle and consumed himself to ashes. His story is the subject of Moore's *Veiled Prophet of Khorassan*.

Alha'ma de Grana'da (i. e. the bath of Granada): bathing-resort of great popularity; near Granada and Malaga, Spain (see map of Spain, ref. 19-E). The spring is about 8 inches in diameter, and furnishes warm (110° F.) magnesian waters, abounding in sulphuretted hydrogen. The season is from April to October; the climate healthy and mild; the diseases benefited are those of the mucous membranes and skin, nervous debility, rheumatism, and sluggish sores. The baths were much frequented by the Saracens, and the Caliph of Granada is said to have received in some years as much as 500,000 ducats of revenue from these baths. Pop. 8,000.

Alham'bra [from Arab. *al*, the + *hamrā*, red, sc. house]: famous palace and citadel of the Moorish Kings of Granada; built 1248-1314 in a suburb of the city of Granada. It is surrounded by beautiful gardens and groves of aromatic trees. The interior of the palace is exceedingly gorgeous, and richly decorated with painted and glazed tiles, and plaster ornaments in relief, richly painted and gilded. Among the portions now standing are the Court of the Lions and the Court of the Fish-pond. The former is named from a fountain in its center supported by twelve lions, and surrounded by a gallery resting on columns and arches which are admirably light and elegant. This place capitulated to the Spaniards in 1491, and was entered in triumph by Ferdinand and Isabella in 1492. See Irving, *The Alhambra* (1832).

A'li, or **A'li-Ibn-A'bi-Tâ'lib** (surnamed **THE LION OF GOD**): Arabian caliph; a cousin-german of the prophet

Mohammed; b. at Mecca about 602 A. D. He married Fâtimah, a daughter of Mohammed, whose doctrines he adopted and enforced with great ardor and courage. Mohammed died in 632, but it was not till 656 that Ali became caliph, he having been preceded in this office by Abu Bekr, Omâr, and Othman. His troubled rule of less than five years was ended at Kufa by the dagger of the assassin in 661. Ali was a brave and high-minded man, but lacked many of the qualities essential for the successful government of a large empire. He is said to have been the author of many maxims and proverbs. A collection of sentences bearing his name was published in an English translation (Lond. 1832), and the original by H. L. Fleischer (Leipzig, 1837); a new edition of his *Divan* (lyrical poems) was published at Boulâk, near Cairo, in 1840. See **SUITES**. Revised by J. R. JEWETT.

Alibamu Indians: See **MUSKHOGEAN INDIANS**.

Ali-Bey, al'i-bâ: chief of the Mamelukes; b. in Abkhasia in 1728. He was taken to Egypt at an early age, and raised himself from a servile condition by his ability; became Bey of the Mamelukes; and in 1757 Bey of Egypt; and succeeded in becoming independent of Turkey. He attempted to restore the ancient Egyptian empire, and had almost conquered Syria, when his chief general, his adopted son, was bribed by the Turks, and drove him from Egypt. He succeeded in getting up another army, but after a few victories was again defeated and captured, and died a few days after, Apr., 1773.

Alibert, JEAN LOUIS: French medical writer; b. in Aveyron, May 12, 1775. He became first physician-in-ordinary to Louis XVIII., 1818. He wrote, besides other able works, a *Description of the Diseases of the Skin* (1806-27), which is commended for its style and other merits. D. in Paris, Feb. 6, 1837.

Al'ibi [Lat., elsewhere]: in law, the absence of a person accused of crime from the place where the offense is charged to have been committed. If established, it is a defense to the accusation.

Alicante, al-i-kan'tâ: province in the southeastern part of Spain; bounded N. by Valencia, E. by the Mediterranean, S. and W. by Murcia. Area, 2,098 sq. miles. The country consists partly of fertile plains and partly sterile mountains. Pop. (1887) 432,335.

Alicante (anc. *Lucen'tum*): fortified city and seaport of Spain, the capital of the above province; is on the Mediterranean Sea; lat. 38° 20' N., lon. 0° 26' W. (see map of Spain, ref. 18-I). It is well built, with high and substantial stone houses, and contains several hospitals, one college, and a theater. Wine, grain, soda, oil, oranges, etc., are exported from this place, which is the chief seaport of Valencia. Pop. (1877) 34,926; (1887) 39,638.

Alica'ta: See **LICATA**.

A'lien [from Lat. *alie'nus*, belonging to another (place or person)]: by English law a person born out of the allegiance of the king. In the U. S. one born out of the jurisdiction of the U. S., who has not been naturalized or made a citizen under their laws. By the common law the children of public ministers born abroad are citizens, for their fathers owe allegiance to no foreign power. By the laws of Congress, children born abroad are citizens of the U. S. if their fathers were citizens of the U. S. and had resided in the U. S. (See **CITIZEN**.) It has been claimed that, independent of this statute, such children are citizens of the U. S. (The arguments against this view are stated with great cogency and learning by Horace Binney in an article upon *The Alienage of the United States*.) Aliens are subject to certain disabilities affecting their exercise of political rights. After naturalization they are ineligible to the office of President and Vice-President of the U. S. The principal disability affecting aliens concerns the acquisition of the title to real estate. There are two general modes of acquisition—by purchase and by descent. An alien may acquire title by purchase (including conveyance and devise) in the absence of statutes to the contrary, and can hold it subject to a proceeding by the State termed "office found." This is in substance an inquiry through an authorized officer into the fact of alienage; and if that be found, the land is adjudged to belong to the State. An alien can convey no better title to a citizen than he himself possesses. This defect in the title can be cured by a private act of the State Legislature. In the case of descent no title at all passes to the alien, and no inquest of office is necessary. A citizen brother can inherit from a brother, though their father be an alien, owing to the

common-law rule that inheritances never ascend, and it is accordingly not necessary to trace title through the alien father. This disability is wholly removed in a number of the U. S., and modified in others. Where the disability is not removed, legislation is almost universal in favor of resident aliens, allowing them, if they intend to become citizens, to acquire land for a limited period, and to dispose of it and to transmit it to heirs. Aliens are capable of acquiring, holding, and transmitting personal property in the same manner as citizens, and may freely resort to courts of justice to maintain and protect their rights. Under the laws of Congress they are not, however, entitled to take out a copy-right. Aliens have been distinguished in time of war into friends and enemies. An alien enemy can not make a contract with a citizen. It is illegal in its inception, and can not be enforced even after peace. Nor can such an alien prosecute actions of any kind while the war lasts, though, if there be no illegality in the claim, the right to sue revives in time of peace. An alien becomes a citizen through naturalization. The difficulties growing out of this subject have led to the negotiation of various treaties between the U. S. and foreign powers. See NATURALIZATION. T. W. DWIGHT.

Aligarh, al'-i-gūr: district, fort, and city of the Meerut division, Northwestern Provinces, British India; lying between the Ganges and Jumna (see map of N. India, ref. 5-E). It has an area of 1,955 sq. miles, with a population of over 1,000,000. The fort is in lat. 27° 56' N., lon. 78° 8' E., on the railway from Calcutta to Delhi. It was captured from the Mahrattas in 1806, and has since been much strengthened and improved. A short distance S. of the fort is the city, called Aligarh by foreigners, Koel by natives. Pop. (1891) 60,560.

Alimentary Canal: the cavity in the body of an animal in which food enters to be digested before it is conveyed by the nutritive vessels into the system. In some animals it is a simple cavity, with only one opening; in others it is a proper canal, with an outlet or anus distinct from the inlet or mouth, and is a continuous passage of variable dimensions from the mouth to the anus. The principal portions of the alimentary canal of mammalia are the œsophagus, a duct or tube leading from the mouth to the stomach; the more expanded cavity of the stomach; the small intestines, which are long and convoluted; and the large intestines. The canal is lined throughout its whole length with mucous membrane. Its entire length in man is about 30 feet.

Alimony [Lat. *alimonia*, nutriment, from *alere*, nourish]: in law, an allowance granted by a court to a wife from the husband's estate, either during a litigation between them or at its termination. Originally it was only granted in suits for separation, but now by statute it is usual to make the allowance in proceedings for divorce dissolving the bonds of matrimony. In England the ecclesiastical court had jurisdiction of this subject until 1857, when it was vested in a court of divorce. In this country the jurisdiction is conferred in general on courts of equity. Alimony is of two sorts—*pendente lite* and permanent. (1) The object of the first is to enable the wife to carry on a litigation with her husband, or to sustain herself during its pendency. It is immaterial whether the proceedings be instituted by or against her. Should the wife have sufficient means of her own, no allowance of this kind will be made. The amount rests in the sound discretion of the court, and is subject to increase or diminution. (2) *Permanent Alimony*.—This is a periodical allowance given from the husband's estate as the result of the litigation in the wife's favor. No allowance is made when the proceedings terminate unfavorably to her. The amount varies with the husband's wealth and position, and is commonly from one-third to one-half of his income. It is subject from time to time to variation by the action of the court, depending upon the circumstances of the case. The court has ample power to make its decree effectual, and may have recourse to the writ of *ne exeat* to prevent the husband's withdrawal from the State without proper security for its payment. Should the husband depart to another State, the parties might become "citizens of different States," within the view of the U. S. Constitution; so that she could enforce her claim to alimony in the Federal courts. The ordinary rule that the domicile of the wife follows that of the husband would not be applicable to this case, even though the case were one of judicial separation rather than of total divorce. T. W. DWIGHT.

Alisma'ceæ [from the Gr. *άλισμα*, name of a water-plant]: a natural order of endogenous plants, natives of temperate

climates. They are herbaceous, and usually grow in swamps or shallow waters. Among the genera of this order are *Alisma* and *Sagittaria* (arrowhead).

Alison, ARCHIBALD: Scottish writer; b. in Edinburgh, Nov. 13, 1757, and educated at Oxford. He took orders in the Church of England in 1778, and became curate of Kenley, in Shropshire, in 1790. In 1800 he removed to Edinburgh, where he preached for many years. His chief works are *Essays on the Nature and Principles of Taste* (1784), and two volumes of sermons (1814). D. in Edinburgh, May 17, 1839.

Alison, Sir ARCHIBALD, Bart., D. C. L.: son of the preceding; b. at Kenley, in Shropshire, England, Dec. 29, 1792. He graduated in the University of Edinburgh, studied law, and was called to the bar in 1814. In 1832 he published his *Principles of Criminal Law*, a work of standard authority. His chief work is a *History of Europe during the French Revolution* (10 vols. 8vo., 1833-42), which comes down to 1815, and has had a great popularity. "Its merits," says the *Edinburgh Review* for Oct., 1842, "are minuteness and honesty—qualities which may well excuse a faulty style, gross political prejudices, and a fondness for exaggerated and frothy declamation." He wrote a continuation of this history to the year 1852, and a *Life of John, Duke of Marlborough* (1847). In politics he was ultra-Conservative. D. in Glasgow, May 23, 1867.

Alison, Sir ARCHIBALD, Jr., Bart.: son of Sir Archibald, the eminent historian; b. at Edinburgh, Jan. 21, 1826; educated in the universities of Glasgow and Edinburgh; entered the army; served in the Crimea and in India, where he was military secretary to Lord Clyde; lost an arm at Lucknow; and distinguished himself as brigadier-general, second in command of the Ashantee expedition of 1873-74. He succeeded to the baronetcy 1867, and became deputy adjutant-general in Ireland, Oct., 1874. He distinguished himself in the war of 1882 in Egypt, and became lieutenant-general in November of that year. After Arabi's surrender, General Alison commanded the British army of occupation in Egypt.

Alizarin [from Arab *al*, the + *azārah*, juice, extract; *alizeri* is the commercial name of madder in the Levant]: the coloring-matter of madder (*Rubia tinctorum*). Alizarin was discovered in 1824 by Robiquet and Colin, by treating madder with strong sulphuric acid, producing a black mass, which they called *charbon de garance*. On heating this, it yielded a sublimate of alizarin crystals.

Alizarin is largely sold to the calico-printers in the form of a yellowish brown paste, under the name of "madder extract"; also in the form of a dry powder. It may be crystallized from solution in red prisms or by sublimation in yellow needles.

It is soluble in caustic alkalies and alkaline carbonates, forming a violet solution, from which it is precipitated by acids. Alkaline solutions of alizarin form, with soluble lime and baryta salts, precipitates of a beautiful purple color; with alumina salts, a red; with iron salts, a purple precipitate. If a piece of cotton cloth which has been printed with the common alumina and iron mordants is placed in water holding a little alizarin in suspension, it will be found on heating the whole that the cotton will become permanently dyed in shades of red and purple. Alizarin is a feeble acid, forming, as above shown, soluble salts with the alkaline metals, and insoluble colored salts with most other metals. Turkey-red, madder-pink, and the various shades of purple and chocolate on calico, are compounds of alizarin with metallic bases.

Artificial Alizarin.—One of the greatest triumphs of modern chemistry was the production by Graebe and Liebermann in 1869 of artificial alizarin.

By passing the vapor of alizarin from madder over heated zinc dust they obtained the compound anthracene, C₁₄H₁₀. Further investigation showed that alizarin is more directly related to anthraquinone, a compound of the composition C₁₄H₈O₂, which is formed by oxidizing anthracene. When anthraquinone is treated with bromine it is converted into dibrom-anthraquinone, C₁₄H₆Br₂O₂, and this when melted with caustic potash, KOH, is converted into the potassium salt of alizarin, from which the acid was precipitated by hydrochloric acid as a yellow powder identical with the alizarin derived from madder. The practical importance of this discovery attracted to it the attention of numerous chemists, and simpler processes, avoiding the use of the expensive bromine, were soon devised. An abundant supply

of anthracene is obtained from the refuse coal-tar of gas-works, and in a few months anthracene, which had never been seen except as a chemical curiosity, became a regular article of commerce. See ANTHRACENE.

The process now employed for making alizarin consists in converting the anthraquinone into a mono-sulpho acid and fusing the soda salt of this with caustic soda, with a small addition of potassic chlorate. In executing this process it is found that two di-sulpho acids are formed in large quantities, which yield with soda two new isomeric coloring-matters of great importance, $C_{14}H_8O_5$: flavo-purpurine from the *a* acid, which produces yellowish reds, and anthra or iso purpurine from the *b* acid, which produces pure fiery reds. Alizarin produces bluish reds. By separating the mono and the two di sulpho acids, each may be made to yield its own coloring-matter on fusion with soda, or by operating upon various mixtures of them dyestuffs producing the greatest variety of shades may be obtained.

The following new dyestuffs have been prepared from alizarin:

Alizarin carmine, which is the sodium salt of mono-sulpho alizarin and the two purpurines. It is used on wool as a substitute for cochineal.

Alizarin orange is nitro-alizarin.

Alizarin blue is produced by heating nitro-alizarin with glycerin and sulphuric acid.

Alizarin blue S. is a compound of the blue with acid sulphite of sodium.

The annual consumption of madder in dyeing and calico-printing exceeded \$10,000,000. Large tracts in Holland, Alsace, Italy, and the Levant were devoted to its culture. It not only supplied dyestuffs, but in Alsace it yielded a large proportion of the alcohol of commerce; the root containing sugar, which was extracted and subjected to fermentation.

The brilliant discovery of Graebe and Liebermann has effected a very serious change in the agricultural system of people as remote from each other as the shores of the North Sea and Asia Minor. Theoretically, 1 lb. of alizarin would require 0.60 lb. anthracene, which would be obtained from 30 lb. of coal-tar, requiring 660 lb. of coal. In practice, the yield is less than half this amount. For further details, consult *Die Farbstoffe*, von P. Schützenberger, uebersetzt von Dr. H. Schroeder (Berlin, 1873); *The History of Alizarin*, by W. H. Perkin (I. Soc. Arts, 1879); *Die Chemie des Steinkohlentheers*, von G. Schultz (Braunschweig, 2 Auf., 1886); *Dictionary of Applied Chemistry*, T. E. Thorpe (Lond., vol. i., 1890).

C. F. CHANDLER. Revised by IRA REMSEN.

Alkali [from Arab. *al*, the + *qalī*, calcined ashes of the plant glass-wort (*Salicornia*), from *qalay*, fry]: one of an important class of bases which combine with acids to form salts, turn vegetable yellows to brown, and vegetable blues to green, and act upon oil or fat to form soap. The proper alkalies are potash, soda, lithia, cæsia, rubidia, and ammonia, which are extremely caustic. Potash is called vegetable alkali, soda is called mineral alkali, and ammonia, volatile alkali. Lime, magnesia, baryta, and strontia, having some properties of alkalies, are called *alkaline earths*. The alkalies and alkaline earths are metallic oxides, except AMMONIA (*q. v.*). When an alkali and an acid combine, they are said to neutralize each other; they really produce metallic salts:

See ACID.

Alkali Flat: See PLAYA.

Alkalim'eter [from *alkali* + Gr. μέτρον, a measure]: an instrument used to ascertain the proportion of pure potassium or sodium carbonate in a commercial sample of those articles, and to test the strength and purity of soda-ash, potash, etc. It consists of a graduated glass tube divided into 100 degrees (numbering from the top), and filled with diluted sulphuric acid, poured into a given quantity of the solution of the alkali until it is neutralized. If this process empties the tube to the eightieth degree, it shows that the article contains 80 per cent. of pure alkali. This process is called alkalimetry. The same instrument is also used to test the strength of acids, by filling the tube with a solution of alkali and reversing the process. See the article ANALYSIS, VOLUMETRIC.

Alkalimetry: See ALKALIMETER and ANALYSIS, VOLUMETRIC.

Alkaloids [from *alkali* + ending *-oid*, from Gr. εἶδος, form, shape]: compounds of vegetable origin, generally of complex composition and capable of producing marked effects upon animals. They all contain nitrogen, and all have certain properties in common with ammonia, more especially the power of combining directly with acids to form salts. They belong to the general class of organic bases. On account of their poisonous and medicinal properties, they have long attracted the attention of chemists. They are extracted from the plants by treating with dilute acids, and, from the solutions thus obtained, they are precipitated by ammonia. Among the most important alkaloids are: Aconitine, from *Aconitum napellus*; atropine, hyoscyne, and belladonnine, from *atropa*; quinine and cinchonine, from *cinchona*; cocaine, from *coca-leaves*; caffeine, from *coffee-berries*; coniine, from *conium*; nicotine, from *Nicotiana tabacum*; morphine and narcotine, from *opium*; strychnine and brucine, from *Strychnos*; and veratrine, from *veratrum*. It sometimes becomes a matter of importance to determine whether alkaloids are present or not, as, for example, in cases of suspected poisoning. Chemists can now determine this with absolute certainty. I. R.

Alkanet [from Span. *alcana*, from Arab. *al-hennā*, the shrub henna]: a herbaceous plant found in Europe belonging to the genus *Anchusa* and family *Boraginaceæ*. They have five stamens. Some of the species are cultivated for the beauty of the flowers. The root of the *Anchusa tinctoria* affords a resinous red coloring-matter, and is used to color pomades, lip-salves, hair-oils, etc.

Al-Kindi, or **Alchindus**: a very prolific Arabian writer on medicine and philosophy; b. at Bassorah; flourished in the middle of the ninth century. Several of his works, translated into Latin, were much read during the Middle Ages; the most celebrated was *De Theoria Magicarum Artium*.

Alkmaar': an old and important town of Holland; province of North Holland; 20 miles N. N. W. of Amsterdam, and 5 miles from the ocean (see map of Holland and Belgium, ref. 4-E). It is well built, and is traversed by several canals, by which it carries on an active trade in butter and cheese. It is said to be the greatest mart for cheese in the world. Here are manufactures of soap, leather, sail-cloth, etc. This town was defended with success against the Spaniards in a long siege which began in 1573. Pop. (1879) 13,304; (1890) 15,833.

Alkmaar, HENDRIK, van: a Low German poet who wrote about 1475-1491. He was the translator of a very popular satiric poem entitled *Reinke de Vos* (Reynard the Fox), which he published in Low German at Lübeck in 1498. See REYNARD THE FOX.

Alkoran: See KORAN.

Al'lah: the Arabic name of the Supreme Being, the only true God, as distinguished from the deities worshiped by idolaters.

Al'lahabad' (i. e. the city of God): a division (district and city) of the Northwestern Provinces, British India; on the Ganges and Jumna, between Benares and Oudh (see map of N. India, ref. 7-F). The division contains 13,746 sq. miles. Pop. (1891) 5,942,900. Allahabad district is the territory around the junction of the Ganges and Jumna, and contains 2,833 sq. miles. The city is at the junction of these rivers, and is the capital of the Northwestern Provinces. Lat. 25° 26' N., lon. 81° 55' E. It is one of the most noted resorts of Hindu pilgrimage, and owes its sanctity to its being at the confluence of three sacred rivers—the two above mentioned and the Saraswati. The latter, however, does not now reach the city, being lost in the sands 400 miles to the N. W.; but the Hindus assert that the junction occurs underground. A great annual fair is held at Allahabad. The most conspicuous feature of the city is a fort, which rises directly from the banks of the confluent rivers, and completely commands the navigation of both streams. Within it are the remains of a splendid palace erected by the Emperor Akbar, and his favorite residence. Next in interest is a great mosque, once occupied by the English, but afterward returned to the Mohammedans, who have since refused to use it as a place of worship because of its desecration.

The city was taken by the British in 1765 from the Vezir of Oudh, and assigned to the titular Emperor of Delhi. When he joined the Mahrattas it was transferred to the Nawab of Oudh, but was finally ceded to the British in 1801.

It is growing rapidly in commerce and in population, and is now a railway center. The population was 72,098 in 1853, 144,464 in 1872, and 176,870 in 1891.

MARK W. HARRINGTON.

Allan, DAVID: a Scottish painter of domestic and humorous subjects; called the "Scottish Hogarth"; b. at Alloa, Feb. 13, 1744. He studied and worked for many years in Rome, whither he went in 1764. Among his works are *The Origin of Painting*, which represents a Corinthian maiden drawing her lover's profile on the wall, and illustrations of Allan Ramsay's *Gentle Shepherd*. D. in Edinburgh, Aug. 6, 1796.

Allan, GEORGE WILLIAM, D. C. L., F. R. G. S.: Canadian Senator; b. in Toronto, Jan. 9, 1822; educated at Upper Canada College; admitted to the bar in 1846; represented York county in the Conservative interest in the Legislative Council of Canada, 1858-67; became a member of the Senate in May of the latter year, and appointed Speaker of that body March 17, 1888. He is Chancellor of the University of Trinity College; president of the Ontario Society of Artists, and of the Historical Society of Ontario; chief commissioner of the Canada Company; president of the Western Canada Loan and Savings Company; and is prominently connected with other institutions—learned, industrial, etc. He is a lieutenant-colonel of militia, and was at one time mayor of Toronto.

NEIL MACDONALD.

Allan, Sir HUGH: Canadian ship-owner; b. at Saltcoats, Scotland, Sept. 29, 1810. After completing his school education he was for some time employed as a clerk, and in 1824 removed to Canada. He served in the rebellion of 1837, and attained the rank of captain. In 1838 he became a partner in the firm of Edmonston & Allan, who in 1853 began the construction of iron screw steamships. From this the Allan line of steamships has developed. He was knighted in 1871. Sir Hugh attained some prominence in Canadian politics in consequence of his connection with the Canadian Pacific Railway scandal. He died in Edinburgh, Dec. 8, 1882.

NEIL MACDONALD.

Allan, Sir WILLIAM: a Scotch portrait and figure painter; b. in Edinburgh in 1782; elected a Royal Academician, 1835; and was president of the Royal Scottish Academy, 1838-50. D. in Edinburgh, Feb. 23, 1850.

WILLIAM A. COFFIN.

Allan-Kardee', HIPPOLYTE LÉON DENIZARD: b. at Lyons, Oct. 3, 1803; was the representative of the spiritualistic movement in France, and wrote *Le Livre des Esprits* (1857); *Le Livre des Médiams*; and *L'Imitation de l'Évangile selon le Spiritualisme* (1864). He also founded the *Revue spirite* (1858). D. in Paris Apr. 1, 1869.

Allantois, a-lan'tō-is [false sing. of quasi-plur. *allantoi'des* = Gr. *ἀλλαντοειδής*, sing. sausage-shaped, *ἀλλās*, sausage + *ειδος*, shape]: a thin membranous sac developed during incubation in the eggs of birds and reptiles, and in the embryo of viviparous animals during gestation. For its development and uses, see EMBRYOLOGY.

Alla'tius, LEO [Latinized form of Leone Allacci]: b. of Greek parents in the island of Chios in 1586. He was taken when nine years old to Calabria in Italy, and thence in 1600 to Rome to complete his studies; was employed in 1622 by Pope Gregory XV. to superintend the transfer to Rome and the incorporation in the Vatican of the Heidelberg library, which had been given to the pontiff by the Elector of Bavaria; was appointed by Pope Alexander VII. in 1661 librarian of the Vatican, which office he held till his death in 1669. Leo was a prolific writer; his works were partly editions and elucidations of the classic and ecclesiastic writers and notices of authors, and partly treatises on the history and doctrines of the Roman Church and on the differences between the Eastern and Western churches. Though the son of Greek parents, he was an extreme partisan of the Roman Church. A complete list of his productions (fifty enumerated by Fabricius) is added to his *Exercitatio de Mensura Temporum Antiquorum* (Cologne, 1645), and is also given by Fabricius in his *Bibliotheca Græca*, vol. xi. 437, sqq., ed. Harles. See Creuzer, *Zur Gesch. der Class. Philologie*. H. DRISLER.

Allatoona: on railroad, Bartow co., Ga. (for location of county, see map of Georgia, ref. 2-F); 40 miles N. W. of Atlanta. Gen. J. E. Johnston, when pursued by Gen. Sherman, made a stand in the strong position of Allatoona Pass, in May, 1864, until his flank was turned. General Corse defended this place with success against the assault of a superior force in Oct., 1864, while Gen. Sherman, from the top of Kennesaw Mountain, signaled that he should hold out to the last.

This incident furnished the theme for Ira D. Sankey's famous religious song, "Hold the Fort, for I am Coming."

Al'legan: railroad junction; capital of Allegan co., Mich. (for location of county, see map of Michigan, ref. 7-II); on the Kalamazoo river; has electric lights, the Holly water-works, foundries, car-works, and other manufactories using water and steam-power; an academy; and the library of the Allegan Literary and Library Association. Pop. (1880) 2,305; (1890) 2,669; (1900) 2,667.

EDITOR OF "JOURNAL."

Allegha'ny: a river which rises in Potter co., Pa., makes a short circuit in New York, and returns into the former State. Flowing afterward in a S. S. W. direction through the hilly oil-regions, it unites with the Monongahela at Pittsburg, forming the Ohio. It is navigable for small steamboats 150 miles or more above Pittsburg, is over 400 miles long, and its waters are remarkably clear and pure. Among the principal towns on its banks are Warren, Franklin, and Kittanning.

Alleghany Mountains, or Alleghanies: the Appalachian system of mountains. (See APPALACHIAN MOUNTAINS.) In a more limited sense the name is applied to parallel ranges which traverse Pennsylvania, Maryland, and Virginia W. of the great valley. The general direction of these ridges is nearly N. E. and S. W., and their mean height about 2,500 feet. These ridges are remarkable for the parallelism of their direction and the uniformity of their outline and altitude, and inclose several beautiful and fertile valleys. The rocks of the Alleghanies are shales, sandstones, and limestones of Silurian, Devonian, and carboniferous age, and include in the upper series the most important store of coal in the Eastern States.

Alleghany Springs: Montgomery co., Va. (for location of county, see map of Virginia, ref. 7-D); 3 miles from Shawsville, on the Norfolk and Western R. R., and 77 miles S. W. of Lynchburg; a popular resort for invalids and others. The springs are highly saline, and produce laxative, tonic, or alterative effects, according to the method of use. They are especially recommended for dyspeptics. Eight miles distant are the sublime Puncheon Run Falls.

Allegheny: city; Allegheny co., Pa. (for location of county, see map of Pennsylvania, ref. 5-A); separated from Pittsburg by the Allegheny river, here crossed by nine fine bridges. For map, see PITTSBURG.

Allegheny is the terminus of the West Pennsylvania R. R., the Pittsburg and Western R. R., and is on the Pittsburg, Fort Wayne and Chicago R. R. and the Cleveland and Pittsburg R. R. The city covers an area of 5,925 acres; the ground is hilly, the elevation above low-water mark ranging from 20 to 671 feet; it has a river-front on the Ohio river of 19,000 feet and on the Allegheny river of 14,500 feet; 76 miles of paved streets, 40 miles of sewers, 86 miles of water-pipes, and many miles of gas-pipe for conveying natural gas, which is used as fuel.

The town of Allegheny was laid out in 1788, created a borough in 1828, and incorporated as a city in 1840.

The municipal government is similar to that of Pittsburg, both cities being in the second class. It is composed of a recorder, auditor, controller, treasurer (the last three chosen by councils), with city councils in two branches, styled respectively select and common. These are elected by the people. The recorder appoints the administrative officials to take charge of the police, health, and fire departments, assessments and public works. The total assessed valuation of the city of Allegheny for purposes of taxation is \$82,582,800, on which a revenue is collected, for all purposes, of \$1,268,158; the bonded indebtedness of the city is \$5,535,470, with a sinking fund of \$1,171,143.

The city contains extensive iron and steel rolling-mills, locomotive-works, cotton and woolen mills, foundries, machine-shops, tanneries, flour-mills, salt-works, white-lead works, etc. According to the census of 1890 the number of manufactories was 616, with a capital of \$14,441,916, employing on the average 9,210 persons, who receive during the year \$5,020,188, the total value of the product for the year being \$19,297,003.

The Western University of Pennsylvania, 3 theological seminaries, numerous benevolent and reformatory institutions, and the Western Penitentiary are located in Allegheny. It has 24 ward schools with 340 teachers, and 20,500 pupils in attendance. The high school, 22 teachers and 570 pupils. Besides the public schools there is a large number of

others, including the parochial schools of the Roman Catholic Church.

The Western University and Allegheny Observatory are located on a high hill in the northern part of the city. There are two free public libraries—one founded by Col. James Anderson and maintained by the Board of School Controllers, for use of teachers, pupils of the public schools, and citizens of Allegheny; the other founded by Andrew Carnegie. The city has two parks, containing 315 acres.

Allegheny holds the same relation commercially and socially to Pittsburg as Brooklyn does to New York, and may justly be termed a city of churches, including, as it does, eighty churches of all religious denominations, as well as many benevolent and eleemosynary institutions, among which may be mentioned the Allegheny Orphan Asylum, Home of the Friendless, etc. Pop. (1890) 105,287; (1901) 129,896.

JOHN B. KENNEDY.

Allegheny College: organized at Meadville, Pa., by citizens of the village, in 1815. Its first president was Rev. Timothy Alden, D. D., a Presbyterian. Incorporated in 1817, it came under the control of the Methodist Church in 1833. The three buildings of the college are pleasantly located and well equipped; the library numbers 12,500 volumes; and the productive endowment is \$160,000. Three courses lead to the degree of A. B., and one to that of C. E. In 1900 there were 17 professors and tutors, 326 students in the college, and 116 in the preparatory school. Nearly a fifth of the students are ladies. The president is (1901) William H. Crawford, D. D., and the college is under the joint control of the Pittsburg, Erie, East Ohio, and West Virginia conferences of the M. E. Church. C. H. THURBER.

Alle'giance [Eng. prefix *a-* + M. Eng. *ligeance*, a derivative of *lige* = Mod. Eng. *liege*, faithful; Fr. *allégeance* is adopted from Eng.]: in law, the tie or obligation which binds a citizen or subject to a state. The common law distinguishes between natural and local allegiance. The former is that which a citizen owes to the state of which he is a member; the latter is due from a person who is not bound by the rules of natural allegiance, but who is temporarily subject to the laws of the state by which the allegiance is claimed. Under this theory a foreigner temporarily residing in a country is subject to its laws. Under such circumstances, should he conspire to overturn the government he may be guilty of treason. When he departs his allegiance is at an end. Natural allegiance, on the other hand, can only be shaken off by a formal act on the part of the citizen; this is called naturalization, following emigration. Should he abandon the country to which he belongs, and engage in war on the part of a foreign state against it, he might in strictness, if taken prisoner before naturalization, be treated as a traitor. Such a treatment would, under some circumstances, be extremely harsh, as where the state had encouraged emigration, and the consequent assumption by an emigrant of relations naturally leading to a duty to take sides in a controversy with an adopted country. The doctrines of allegiance are of feudal origin, and it has been found difficult to reconcile them with the requirements of modern times. The U. S. in their legislation upon naturalization have proceeded upon the theory that a citizen of a foreign country might, at his will, shake off his allegiance and become a citizen here. The European nations formerly denied that there was any such rule of public law, Great Britain until 1870 even maintaining a right to the indelible allegiance of her subjects. But now, through a series of treaties negotiated about twenty years ago with Great Britain and many of the continental states, a complete transfer of allegiance in favor of the U. S. on the part of these subjects is permitted. Allegiance to one state remains until superseded by the acquisition of a new allegiance to another. See NATURALIZATION.

T. W. DWIGHT.

Revised by T. S. WOOLSEY.

Allegret'to [Ital.; a diminutive of *allegro*, brisk]: in music a movement or time quicker than *andante*, but not so quick as *allegro*.

Alle'gri, ANTONIO: See CORREGGIO.

Alle'gri, GREGORIO: Italian composer of sacred music; b. in Rome about 1580. He was a singer in the pope's chapel, and a pupil of Nanini. His masterpiece is the *Miserere*, which is annually performed in the pontifical chapel during Passion Week. D. in Rome, Feb. 18, 1652.

Alle'gro [Ital. brisk < Lat. *a'lacer*]: in music, one of the principal degrees of movement; a term which signifies that

the piece to which it is prefixed is to be performed in a brisk and lively manner. The word is sometimes used as a substantive, and a name of an entire musical composition.

Al'lein, or **Al'leine**, JOSEPH: an English Nonconformist minister and writer; b. at Devizes in 1634; educated at Oxford. He was ejected from a curacy at Taunton in 1662, after which he was persecuted by imprisonment in Herester jail, and was fined for preaching. His death was hastened by ill treatment, and he died Nov. 17, 1668. Among his works is an *Alarm to the Unconverted* (1672), which is highly esteemed. See his life by Stanford (1861).

Allen, ALEXANDER VIETS GRISWOLD, D. D.: professor in the Episcopal Theological School, Cambridge, Mass.; b. at Otis, Berkshire co., Mass., May 4, 1841; graduated at Kenyon College, Gambier, O., 1862, and at Andover Theological Seminary 1865; was rector of St. John's, Lawrence, 1865-67, when he was appointed to the chair of ecclesiastical history at the Cambridge school. Besides review articles and other minor publications he has issued *The Continuity of Christian Thought, a Study of Modern Theology in the Light of its History*, the Bohlen lectures for 1883, and a life of *Jonathan Edwards* (1889).

W. S. P.

Allen, CHARLES, LL. D.: jurist; b. at Worcester, Mass., Aug. 9, 1797; admitted to the bar in 1818: a judge of various State courts of Massachusetts between 1842 and 1859, and Chief Justice of the Massachusetts Superior Court (1859-67). From 1849 to 1853 he was a Free-Soil member of Congress. He was a delegate to the Peace Congress of 1861. D. at Worcester, Mass., Aug. 6, 1869.

Allen, ELISHA HUNT: b. at New Salem, Mass., Jan. 28, 1804; graduated at Williams College; was admitted to the bar; removed to Brattleboro, Vt., and in 1830 to Bangor, Me.; member of Maine Legislature, 1836-41 and 1846; in 1838 was Speaker; member of Congress from Maine, 1841-43; removed to Boston in 1847, and was elected to the Massachusetts Legislature in 1849; U. S. consul at Honolulu, 1852-56, then became Hawaiian Minister of Finance, and from 1857 was Chief Justice and Chancellor of Sandwich islands, holding that office twenty years, during which period he was several times minister plenipotentiary of Sandwich islands to the U. S. He was resident minister of Sandwich islands at Washington from 1876 till his death, at Washington, D. C., Jan. 1, 1883.

Allen, ELIZABETH (*Akers*): poet; known as "Florence Percy"; b. at Strong, Me., Oct. 9, 1832. Her maiden name was Elizabeth Chase; her first husband was the sculptor Akers, and she afterward became the wife of E. M. Allen, of New York. She published in 1866 a volume of poems, and in 1886 *The Silver Bridge and other Poems*, and has contributed much to periodical literature. Her most popular poem is the song *Rock Me to Sleep, Mother*.

Allen, ETHAN: general: b. at Litchfield, Conn., Jan. 10, 1737. He became an owner of iron-works at Salisbury, Conn., and in 1766 removed to Vermont, where he became a leader in the popular resistance to the claims of New York. The province of New York declared Allen an outlaw, and offered £150 for his arrest. On the outbreak of the Revolution, Allen heartily joined the movement, and on the 10th of May, 1775, he surprised and captured the fort at Ticonderoga, summoning its astonished commander to surrender "in the name of the great Jehovah and the Continental Congress." This capture gave the army a valuable supply of artillery and stores. He had but eighty-three men under him, among whom was Benedict Arnold. On Sept. 25, 1775, he attacked Montreal with a small force, but was captured and sent to England as a prisoner. He was treated with great cruelty, and was not exchanged till 1778. The British authorities tried in vain to bribe him to induce the Vermonters to join their cause, but he skillfully contrived by his negotiations to keep the British troops out of Vermont. He published pamphlets against the New York domination, a narrative of his captivity (1799); a *Vindication of Vermont* (1779); and *Allen's Theology, or the Oracles of Reason* (1784), an attack upon the Christian religion. He professed to believe in the transmigration of souls. D. near Burlington, Vt., Feb. 12, 1789. See his life by Hugh Moore (1834), by H. W. de Puy (1853), and by H. Hall (1892).

Allen, FREDERICK DE FOREST, Ph. D.: classical scholar; b. at Oberlin, O., 1844; graduated at Oberlin College, 1863; studied at University of Leipzig; professor in University of Tennessee, Knoxville, Tenn., 1866-68 and 1870-73; tutor at Harvard, 1873-74; professor in University of Cincinnati,

1874-79; professor at Yale, 1879-80; Professor of Classical Philology, Harvard University, 1880; author of an edition of the *Medea* of Euripides, 1876; *Remnants of Early Latin*, 1880; *Greek Versification in Inscriptions*, 1888. D. Aug. 5, 1897.

Allen, GRANT: See the Appendix.

Allen, HARRISON, M. D.: surgeon; b. in Philadelphia, Pa., Apr. 17, 1841; M. D., University of Pennsylvania, 1861; assistant surgeon U. S. army, 1862-65; Professor of Comparative Anatomy, University of Pennsylvania, 1865-78, and later of Physiology. In the same year he was elected Professor of Anatomy and Surgery in the Philadelphia Dental College, and in 1870 surgeon to the Philadelphia Hospital. Author of *Outlines of Comparative Anatomy* (1867); *System of Human Anatomy* (1880). D. Nov. 14, 1897.

Allen, HEMAN, LL. D.: b. at Poultney, Vt., Feb. 23, 1779; graduated at Dartmouth, 1795; became a lawyer; was chief justice of a Vermont State court (1811-14); member of Congress (1817-18); U. S. minister to Chili (1823-28); and held various other important positions. He was a nephew of Ethan Allen. D. at Highgate, Vt., April 9, 1852.

Allen, HENRY: an enthusiast; b. at Newport, R. I., June 14, 1748; founder of the "Allenites." He maintained that Adam and Eve before the fall had no corporeal bodies, and denied the resurrection of the body. He preached in Nova Scotia, and published some hymns and religious treatises. D. at Northampton, N. H., Feb. 2, 1784.

Allen, HORATIO: civil engineer; b. at Schenectady, N. Y., in 1802; graduated at Columbia College in 1823, and at once engaged in civil engineering. In 1828 he went to Great Britain to purchase locomotives for the Delaware and Hudson Canal Co., and on Aug. 9, 1829, he operated at Honesdale, Pa., "the Stourbridge Lion," the first locomotive ever run in America. Soon after he was appointed chief engineer of the South Carolina R. R., on which the first continuous 100 miles of track ever built was opened. Later he became connected with the Croton aqueduct as principal assistant engineer, and had particular charge of the Forty-second Street reservoir in New York city, and of High Bridge over the Harlem river. He was president of the New York and Erie R. R. on its first formation, and during 1872 and 1873 was president of the American Society of Civil Engineers. He died Dec. 31, 1889. See RAILWAYS.

Allen, IRA: general; a younger brother of Ethan Allen; b. in Cornwall, Conn., May 1, 1751. Emigrating in 1772 to Vermont, he became a prominent and public-spirited citizen. While he was colonel of militia, his regiment did good service at the battle of Bennington. He bore a prominent part in settling the early difficulties of Vermont with the neighboring States. In 1795 he went to France to purchase arms for his State, but was taken on the voyage home, carried to England, and there sustained with success an eight-years' lawsuit on the charge of attempting to supply the Irish with arms. For a time he was imprisoned in France. He wrote a *Natural and Political History of Vermont* (1798), and other works. D. in Philadelphia, Jan. 4, 1814.

Allen, JEROME, Ph. D.: b. at Westminster West, Vt., July 17, 1830; educated in Amherst College; principal of Maquoketa (Ia.) Academy, 1853-55; Professor of Natural Sciences in Alexander College, Dubuque, 1855-59; principal of Bowen Collegiate Institute, Hopkinton, 1859-67; superintendent of schools, Monticello, 1867-71; Professor of Natural Sciences in the State Normal School, Geneseo, N. Y., 1874; president of the State Normal School at St. Cloud, Ia., 1885; Professor of Pedagogy, University of New York; dean of the School of Pedagogy, 1889; author of *A Handbook of Experimental Chemistry for Laboratory Use*; *Methods for Teachers in Grammar*; *Manual of Map-drawing*; *Mind Studies for Young Teachers*; *Temperament in Education*. D. in Brooklyn, N. Y., May 26, 1894. C. H. T.

Allen, JOEL ASAPH: b. at Springfield, Mass., July 19, 1838; entered the Lawrence Scientific School at Cambridge, Mass., as a special student in zoölogy (1862); from 1865-69 was a member of various scientific expeditions to Brazil, the Rocky Mountains, and Florida, the scientific results being given in a series of papers on the birds and mammals of the different regions. In 1873 he was appointed chief of a scientific party to accompany the Northern Pacific R. R. surveying expedition, and a *Report of the Natural History of the region traversed* was published in the Proc. Bost. Soc. Nat. Hist.; elected (1870) assistant in ornithology at the Museum of Compara-

tive Zoölogy in Cambridge; author of *Monographs of North American Rodentia* (with Elliott Coues, 1877); *History of North American Pinnipeds* (1880). He has edited the *Bulletin of the Nttal Ornithological Club* (.876-80), and became editor of *The Auk*. RALPH S. TARR.

Allen, JOSEPH HENRY, D. D.: Unitarian scholar and preacher; b. at Northboro, Mass., Aug. 21, 1821; educated at home and at Harvard University; settled as minister at Jamaica Plain (Roxbury), Mass., 1843-47, Washington, D. C., 1847-50, Bangor, Me., 1850-57; taught a boys' school and preached in his native town, 1857-67; removed to Cambridge, taught, and edited the Allen and Greenough series of Latin classics (16 vols.), 1867-77; lectured on ecclesiastical history in Harvard University, 1875-82; editor of the *Unitarian Review*, 1887-91; author of *Ten Discourses on Orthodoxy* (1849; 2d ed. 1889); *Memorial of H. Withington* (1849); *Manual of Devotions* (1852); *Hebrew Men and Times* (1861; 2d ed. 1879); *Christian History in its Three Great Periods* (1883, 3 vols.); *Outline of Christian History* (1884); *Our Liberal Movement in Theology* (1889); *Positive Religion: Essays, Fragments, and Hints* (1891); senior editor of the *History of Unitarianism*. D. in Cambridge, Mass., Mar. 29, 1898. JOHN W. CHADWICK.

Allen, PAUL: journalist; b. at Providence, R. I., Feb. 15, 1775; graduated at Brown University in 1796; studied law and removed to Philadelphia, where he engaged in journalism, serving as editor and as correspondent to various journals. He published a volume of poems (1801); *Lewis and Clark's Travels* (1814); *Life of Alexander I.* (1818), etc. His *History of the Revolution* (1819) was written by John Neal and others. He was for a time insane. D. at Baltimore (where he was an editor of the *Morning Chronicle*), Aug. 18, 1826.

Allen, PHILIP: b. in Providence, R. I., Sept. 1, 1785; graduated at Rhode Island College (now Brown University) in 1803. He was an extensive cotton-manufacturer, and built the first Watt steam-engine ever made in Providence; was Governor of Rhode Island (1851-53), and U. S. Senator (1853-59). D. in Providence, Dec. 16, 1865.

Allen, RICHARD: first bishop of the African Methodist Episcopal Church in the U. S. He was originally a preacher in the Methodist Episcopal Church, and was ordained deacon by Bishop Asbury in 1799. He was elected bishop of the African Methodist Episcopal Church in 1816. D. in Philadelphia, Mar. 26, 1831.

Allen, RICHARD L.: b. in Hampden co., Mass., Oct., 1803. Was a merchant in Buffalo, N. Y., in 1834, residing later at Allenwood, his farm, on the Niagara river. With his brother, A. B. Allen, he established the *American Agriculturist* in the city of New York, in 1842, which became a very successful paper. He was the author of the *American Farm-book* and the *Diseases of Domestic Animals* (1845). D. at Stockholm, Sweden, Sept. 22, 1869.

Allen, STEPHEN, D. D.: divine and educator of the Methodist Episcopal Church; b. in Maine in 1810; graduated at Bowdoin College in 1835; entered the ministry in the Maine Conference in 1839; and devoted much of his life to education in his native State, particularly as principal of Maine Wesleyan Seminary. D. July 3, 1888.

Allen, THOMAS: animal and landscape painter; b. in St. Louis, Mo., 1849; pupil of the Düsseldorf Academy; associate member National Academy of Design; member of the Society of American Artists (1880). Two of his best works are *Maplehurst at Noon*, a herd of Jersey cattle at rest under the trees, and a landscape of an effect at early evening called *O'er all the Hilltops is Rest*. Studio in Boston. W. A. C.

Allen, WILLIAM, F. R. S.: English chemist and philanthropist; b. in London, Aug. 29, 1770; was a friend of Sir H. Davy. In conjunction with W. H. Pepys he made researches on respiration, etc. He devoted much time to benevolent enterprises, and as an eminent minister of the Society of Friends traveled in France, Germany, and Russia. He had interviews with the Emperor Alexander in 1814 and 1822, first in England, next in Vienna. In 1825 he founded two manual-labor schools at Lindfield in Sussex, where he died Dec. 30, 1843.

Allen, WILLIAM, D. D.: b. at Pittsfield, Mass., Jan. 2, 1784; graduated at Harvard in 1802; was licensed to preach in 1804; in 1810 succeeded his father as pastor in Pittsfield; was chosen president of Dartmouth University in 1817, and

was president of Bowdoin College from 1820 to 1839. His last days were spent at Northampton, Mass., where he died July 16, 1868. He published numerous volumes, both of prose and of poetry. His best known work is an *American Biographical and Historical Dictionary* (1809; 3d ed. 1857).

Allen, WILLIAM: cardinal; b. in Lancashire, England, 1532; a zealous defender of the Roman Catholic faith in the latter half of the sixteenth century; founded the English College at Douay, in France, 1568; was made cardinal in 1587. D. at Rome, Oct. 16, 1594. Author of a number of polemical and apologetic works. See Gillow's *Bibliographical Dictionary of English Catholics* (Lond. 1885).

JOHN J. KEANE.

Allen, WILLIAM FRANCIS: historian and essayist; b. at Northborough, Mass., Sept. 5, 1830; graduated at Harvard 1851; studied at Berlin, Göttingen, and Rome 1854-56; Professor of Ancient Languages at Antioch College, O., 1866-67; Professor of Latin and History in the University of Wisconsin 1867-89. He published numerous works on classical and historical subjects, evincing varied, broad, and exact scholarship. The list of his publications given in his collected *Monographs and Essays* covers thirty 12mo pp. D. Dec. 9, 1889.

C. K. ADAMS.

Allen, WILLIAM HENRY, M. D., LL. D.: b. at Readfield, Me., Mar. 27, 1808; educated at Bowdoin College, Me., 1833; was Professor of Latin and Greek in the Cazenovia Methodist Seminary, N. Y., from 1833 to 1835; Professor of Chemistry and Natural Philosophy in Dickinson College, Carlisle, Pa., from 1836 to 1846; Professor of Philosophy and English Literature at the same institution from 1846 to the close of 1849; president of Girard College, Philadelphia, from 1850 to 1863; president of the Agricultural College of Pennsylvania during 1865 and 1866, and was reappointed president of Girard College in 1867. In 1872 he was elected president of the American Bible Society. He was author of *A Manual of Devotion for Girard College Orphans*, and of numerous and able addresses, reviews, etc. D. Aug. 29, 1882.

Allen, WILLIAM SULLIVANT VANDERBILT: a figure painter who was one of the first of American artists to adopt the methods of the "impressionists" in painting; b. in New York, Oct. 8, 1860. He is well known, also, as an illustrator, and is a talented draughtsman in pen and ink. Pupil of Gérôme and Puvis de Chavannes, Paris, and of Claude Monet at Givernay, France. Member of the Society of American Artists (1887); third-class medal, Paris Exposition (1889). Studio in New York.

W. A. C.

Allen'de: the name of two towns in Mexico. (1) SAN MIGUEL DE ALLENDE, or simply *Allende*, is in the state of Guanajuato, a few miles E. of the city of the same name, on the Mexican National R. R., 34 miles N. of Celaya (see map of Mexico, ref. 6-G). It is a pretty town, situated on the declivity of a high hill, and has well-paved streets and a college. Pop. 15,000. (2) EL VALLE DE ALLENDE, in Southern Chihuahua, S. E. of Parral and W. of the Mexican Central R. R. It is said to contain 12,000 inhabitants.

Allende, JUAN RAFAEL: Chilean poet and dramatist; b. in Santiago in 1850; began writing for the press in 1869. In 1875 he published studies in local customs in the journal called *El Padre Bobos*. In 1884 he founded the paper *El Padre Padillo*, which has made him famous. In 1872 his first piece was given in a theater, being entitled *El Qué Dirán*. He has since written several successful comedies. During the war between Chili and Peru he published six volumes of verse, entitled *Poesías del Pequén*. The Chilean Minister of War had 10,000 copies of these popular and intensely patriotic poems printed for the use of the army.

A. R. MARSH.

Allentown: city; an important railroad center; capital of Lehigh co., Pa. (for location, see map of Pennsylvania, ref. 5-I); on the right bank of the Lehigh river, 60 miles N. by W. of Philadelphia. The town was first incorporated as Northampton in 1811. In 1836 the name was changed to Allentown by act of the Legislature. There are many blast furnaces at this place, large rolling-mills, foundries, and machine-shops, tanneries, shoe-manufactories, tube-works, woolen-mills, fire-brick works, etc. According to the census of 1890 there were 376 manufacturing establishments, representing 74 different industries, with an aggregate capital of \$6,479,860, and employing 5,805 persons. The wages paid during the year amounted to \$2,302,638; and the total value of the products to \$8,826,273. There is a fine court-house, and a prison costing \$250,000. It is the seat of Muhlenberg

College, and other institutions of learning. Pop. (1870) 13,884; (1880) 18,063; (1890) 25,228, including suburbs: (1900) 35,416. FRANK J. SHERER, CITY EDITOR OF "CHRONICLE."

Alleppi', or Aleppi': the chief port of the native state of Travancore; on the west coast of the southern extremity of Hindustan; lat. 9° 20' N., lon. 76° 25' E. (see map of S. India, ref. 7-D). A canal connects it with a large coast lake called the Backwater. There is a large trade in teak, cardamoms, and pepper. The name of this town is very variously spelled, including such forms as Alipee, Aulapolay, and Alipalli. Pop. about 30,000.

Al'ler: a river of Germany, an affluent of the Weser, rises near Magdeburg and flows northwestward. It is about 150 miles long.

All Fools' Day: See APRIL FOOL'S DAY.

All-Hal'lows [*hallows*, plural of *hallow*: O. Eng. *hālga*, saint]: the old English name for All Saints' Day (the 1st of November).

Alli'ance: city and railroad junction: Stark co., O. (for location of county, see map of Ohio, ref. 4-I); has many extensive manufactories of horseshoes, reapers, pumps, terracotta ware, steam-hammers, tin-presses, besides rolling-mills, white-lead works, etc. It has excellent public schools, a college, and good libraries. Pop. (1880) 4,636; (1890) 7,607; (1900) 8,974.

EDITOR OF "REVIEW."

Alliance, Evangelical: See EVANGELICAL ALLIANCE.

Alliance, Holy: See HOLY ALLIANCE.

Alliance Israélite Universelle: a league established in Paris in 1860 by a number of distinguished Israelites for the protection of their co-religionists against the oppressions which crushed them, and for their social elevation. It has spread all over the world wherever Jews are found, and has been of great service. Local committees are formed which keep up communication with the central committee in Paris. By the munificence of Baron Hirsch, who in 1873 put one million francs at its disposal, and by other donations and contributions, the Alliance supports trade schools in Turkey, in Palestine (one for agriculture at Jaffa), and in Africa. The girls are taught in self-supporting arts and vocations.

S. M. J.

Alliance of the Reformed Churches THROUGHOUT THE WORLD HOLDING THE PRESBYTERIAN SYSTEM (popularly called the PRESBYTERIAN ALLIANCE): a voluntary organization for the promotion of brotherly feeling and co-operation among the members of the widely scattered religious bodies bearing different names but agreeing in Reformed theology and Presbyterian form of government. The alliance owes its origin to the advocacy of the Rev. Dr. James McCosh, ex-president of the College of New Jersey, who in 1862 first called attention to the need for one. Other persons made suggestions on the subject, prominent among whom was the Rev. Dr. W. G. Blaikie, professor in New (Free Church) College, Edinburgh, whose articles on the subject powerfully influenced the Scotch Presbyterians. But in reality the project was a revival of a scheme as old as Presbyterianism itself, for we find that Calvin in his letter to Cranmer in 1552, replying to an invitation to attend a conference at London for the promotion of unity in doctrine, suggests that the Reformed churches should be brought into one. So, later, the authors of the *Second Book of Discipline*, in Scotland, and also Théodore Beza in 1561. But the times were not favorable for this, any more than for the wider union proposed by Henry of Navarre in 1583. The union in 1820 between the Burgher and Anti-Burgher churches, making the United Secession Church, and other events of similar nature, set Presbyterians thinking on the desirability of more intimate relations with those who agreed with them in theology and polity. The General Assembly of the Irish Presbyterian Church and of the Presbyterian Church of the U. S. (North) resolved in 1873 to open up correspondence "with other churches holding by the Westminster Confession of Faith, with a view of bringing about an œcumenical council of such churches, to consider subjects of common interest to all, and especially to promote harmony of action in the mission fields at home and abroad." Advantage was taken of the meetings of the Evangelical Alliance in New York city that autumn to convene a gathering of Presbyterian (including Reformed) ministers and elders. Other conferences were held in different countries, and finally the movement took shape in the conference held in London, July 21 and 22, 1875, which settled on a constitution and arranged for the first General Council,

which convened in Edinburgh, July 3-10, 1877. The invitation given by the London conference was accepted by almost every Presbyterian organization through its highest court, and delegates were appointed. The roll of the first council showed that there were actually present 249 delegates, representing 40 different communions. The platform on which they met was thus expressed in their constitution: "Any church organized on Presbyterian principles, which holds the supreme authority of the Scriptures of the Old and New Testaments in matters of faith and morals, and whose creed is in harmony with the consensus of the Reformed churches, shall be eligible for admission into the alliance." The council is made up of delegates, both ministerial and lay in equal number, regularly commissioned by their respective communions; considers questions of general interest to the Presbyterian community, but is expressly forbidden to "interfere with the existing creed or constitution of any Church in the alliance, or with its internal order or external relations."

The second General Council was held in Philadelphia, Sept. 23-Oct. 2, 1880, and was attended by 220 delegates, representing 28 different communions; the third in Belfast, June 24-July 3, 1884, with 238 delegates from 35 communions; the fourth in London, July 3-12, 1888, with 275 delegates from 44 communions; the fifth in Toronto, Sept. 21-30, 1892, with 279 delegates from 25 communions; the sixth in Glasgow, Scotland, June 17, 1896; and the seventh in Washington, D. C., Sept. 27, 1899. On the roll of the council there are altogether 61 different bodies, but as many of them are in the mission field they can not be regularly represented. The papers and proceedings of these different councils have been published, and are on sale in London at the office of the general secretary of the alliance, Rev. Dr. G. D. Matthews. They contain much valuable matter. The alliance has been of great service in cementing union among the Reformed Churches.

Allibone, SAMUEL AUSTIN, LL. D.: author and librarian; b. in Philadelphia, Apr. 17, 1816. His principal work is a *Critical Dictionary of English Literature and Authors* (1859-70); also a *Dictionary of Poetical Quotations* (1872), etc. Became librarian of Lenox Library, New York, in 1880; resigned in 1888. D. at Lucerne, Switzerland, Sept. 2, 1889. A continuation of his *Dictionary of English Literature and Authors*, prepared by J. Foster Kirk, was published in 1891.

Allier, aäl'lée-ā': a river of France; the most important affluent of the Loire. It rises in the south of France, near the source of the Loire, flows nearly N., and enters that river at Nevers. Its entire length is about 260 miles.

Allier: a department of France; bounded N. by Cher and Nièvre, E. by Saône-et-Loire, S. by Puy-de-Dôme, and W. by Creuse and Cher. Area, 2,822 sq. miles. It is intersected by the Allier, and bounded on the N. E. by the Loire. The soil is fertile. The chief productions are wine, grain, timber, cattle, horses, and sheep. Iron, coal, and marble are found here. It comprises four arrondissements. Chief town, Moulins. Pop. (1881) 416,579; (1891) 424,382; (1896) 424,378.

Alligator [corruption of Span. *al lagarto*, the lizard < Lat. *lacerta* (*lacarta*)]: a genus of American saurian reptiles

Alligator.

(nearly allied to the crocodile) which abound in the rivers and swamps of the Southern U. S. They have broader heads, more numerous teeth, and more obtuse snouts than crocodiles. Similar reptiles are called caymans in South America. They all hibernate in the winter or dry season, when they bury themselves in the mud. The alligator is about 12 feet long, including the tail, which is a powerful weapon for defense. It is a fierce and voracious animal, and sometimes attacks and kills men in the water, but it can not turn quickly on land. During the heat of the day it is often seen basking in the sun on the dry ground. Its back and sides are defended

by hard mailed plates. The alligator is an oviparous animal, its eggs being small, but numerous. The parent deposits them in the sand of the river-side, scratching a hole with her paws, and placing the eggs in a regular layer therein. She then covers these with sand, grass, mud, etc., and deposits another layer on top of them, and so on until she has laid from fifty to sixty eggs. These are hatched by the heat of the sun and the decaying vegetable matter. The name alligator is also frequently applied to the mugger of India. The common alligator of the Southern States is the *Alligator mississippiensis*. Among the so-called alligators of Florida a true crocodile (*Crocodylus americanus*) also occurs. See CROCODILE. Revised by DAVID S. JORDAN.

Alligator Pear: See AVOCADO PEAR.

Allingham, WILLIAM: Anglo-Irish poet, journalist, and playwright; b. at Ballyshannon in 1828. He was at one time editor of *Fraser's Magazine*, and was intimately associated with the Pre-Raphaelites. He published many volumes of poetry, original and selected, including *Day and Night Songs* (1854); *The Music-Master* (1855); *Laurence Bloomfield in Ireland* (1864); *Evil May-Day: a Play* (1882); *Irish Songs and Poems* (1887). His poems were illustrated by D. G. Rossetti, Kate Greenaway, and other eminent designers. His most popular pieces are *Mary Donnelly* and *The Fairies* (1883). D. in London, Nov. 20, 1889. HENRY A. BEERS.

Allio'li, JOSEPH FRANZ: German Catholic theologian; b. at Sulzbach, Aug. 10, 1793. He became Professor of Theology at Munich in 1826, resigned in 1835, and became canon soon after at Ratisbon. His German translation of the Bible (6th ed. 1839-45) was approved by the pope, and had a very wide circulation. He also published a *Manual of Biblical Antiquities* (1841). D. at Augsburg, May 22, 1873.

Allison, JOHN: b. Aug. 5, 1812, at Beaver, Beaver co., Pa., where he was a hatter; took a leading part in the Whig party; was elected to the State Legislature in 1846, 1847, and 1849; served in Congress 1852-54 and 1855-57; was a member of the convention of Pittsburg which instituted the Republican party (1856), and in 1860 he headed the State delegation in the convention at Chicago which nominated Lincoln; served as major and paymaster in the army during the civil war, and register of the U. S. treasury from Apr. 1, 1869, till his death, at Washington, D. C., Mar. 23, 1878.

Allison, WILLIAM B.: b. at Perry, O., Mar. 2, 1829; educated at Western Reserve College, O., studied law and practiced in Ohio until his removal to Iowa in 1857, where he served on the Governor's staff and aided in organizing volunteers at the commencement of the civil war of 1861-65; was representative in Thirty-eighth, Thirty-ninth, Fortieth, and Forty-first Congresses; was elected to U. S. Senate as a Republican, and has held that office since Mar. 4, 1873. He was a delegate from the U. S. to the International Monetary Congress at Brussels, Dec., 1892.

Allium [Lat., etymology unknown]: a genus of herbaceous plants of the natural order *Liliaceae*, natives of the temperate and cold regions of the northern hemisphere, including the garlic, onion, leek, and chive. They have mostly bulbous roots, umbellate flowers, narrow and fistulose leaves, and a peculiar smell and taste called *alliaceous*.

All-mouth: See ANGLER.

All'oa: a seaport and market-town of Scotland, in the county of Clackmannan, on the left (N.) bank of the Forth, and at the head of its frith; 28 miles W. N. W. of Edinburgh (see map of Scotland, ref. 11-G). It has a good harbor and an active trade. Glass, ale, whisky, woolen goods, and leather are manufactured here, and coal is an important article of export. Steamboats ply daily between Alloa and Edinburgh. Pop. 11,638.

Allocu'tion [Lat. *allocu'tio*, from *ad*, to + *loqui*, speak]: a formal address, as by a general-in-chief to his soldiers; in ecclesiastical usage, a speech which the pope addresses to the college of cardinals on some political or ecclesiastical subject. The pope often resorts to this method to define his position or explain his policy. At the opening of the Lambeth Conference of 1888 the Archbishop of Canterbury, Dr. Benson, delivered an "allocation" to the Anglican bishops assembled from all parts of the world, from the patriarchal chair of St. Augustine, Canterbury's first archbishop.

Allo'dium, or Allo'dial Ten'ure [med. Lat. *allo'dium*, from Ger. **alōd*, entire ownership, *all*, entire + *ōd*, property, O. H. G. *ōt*, O. E. *eād*]: in feudal law, freehold estate, land held by an individual in his own absolute right, and free

from feudal tenure or obligation. There is no allodial land or property in England, the laws of which declare that the king is the original proprietor and lord paramount of all the land in the kingdom.

Allon, HENRY, D. D.: Congregationalist; b. at Welton, near Hull, England, Oct. 13, 1818; graduated at Cheshunt College, 1843; minister of Union chapel, Islington, London, from 1844 to his death, Apr. 16, 1892. He was editor of the *British Quarterly Review* for twenty-two years, from 1865. He compiled a popular hymn-book, *The Congregationalist Psalmist*. He published *The Life of James Sherman* (1863) and a volume of sermons (1876); and edited *Binney's Sermons* (1875), with a preliminary memoir. Dr. Allon was one of the ablest and most influential leaders of the Congregationalists in England, and was highly respected beyond the limits of this religious body. GEORGE P. FISHER.

Allo'pathy [from Gr. ἄλλος, other + πάθος, suffering]: a supposed theory of medicine, according to which remedies are used whose effects are opposite to the symptoms of the diseases treated. The term allopathy was formed after that of homœopathy, and both terms were introduced by Hahnemann. The two terms are contrasted, the one teaching that medicines must produce a *similar affection* to the disease itself, the other a *different affection*. The idea of this method of medication is at least as old as Hippocrates, who used the expression, "τὰ ἐναντία τῶν ἐναντίων ἐστὶν ἰήματα"—"opposites are remedies of opposites." It has been contrasted in modern times especially with the maxim of Hahnemann, "*similia similibus curantur*," or "like cures like," which is the fundamental principle of homœopathy—an idea which is also advanced by Hippocrates. It is altogether an error to designate the prevalent and ancient science and practice of medicine as allopathy. The teachers and adherents of this science insist that its scope legitimately embraces all positive truth concerning disease and its treatment; no more to be narrowed down to an exclusive principle such as that of allopathy, than astronomy can be made synonymous with the nebular theory, or zoölogy with the theory of development.

Allori, ALESSANDRO: Italian painter; b. in Florence, May 31, 1535; d. there Sept. 22, 1607; excelled in the science of anatomy. Among his masterpieces are *The Last Judgment* and *Christ Disputing with the Doctors*. His son Christofano (b. 1577, d. 1621) is celebrated for his portraits.

Allotta'va, or abbrev. 8^{va}: in music, a direction to play an octave higher or lower, according as the phrase may be placed above or below the notes in question.

Allotropy, or **Allotropism** [Gr. ἄλλοτροπία, diversity; ἄλλος, other + τροπος, turn, guise]: in chemistry, the diversity of form and properties which some elements exhibit in certain circumstances, as when exposed to a great heat or to an electric discharge. (See ISOMERISM.) Many chemists believe that every element is capable of existing under several allotropic modifications. Among the substances which afford examples of allotropy are sulphur, phosphorus, oxygen, and carbon. If the solid and brittle sulphur be heated to 480° F., and then poured into water, it ceases to be brittle and becomes very elastic. Sulphur in its ordinary state is slightly soluble in turpentine and some fixed oils, but in its elastic condition it becomes insoluble in those oils. Phosphorus affords a remarkable illustration of the same principle. In ordinary circumstances, when freshly prepared, it is a pale yellow solid, resembling wax. In this form it is extremely combustible, requiring to be kept under water to avoid taking fire spontaneously. But if this same substance be excluded from air and kept several days at a temperature of about 450° F., it becomes red, and ceases to be readily combustible, so that it need not be kept under water to prevent its taking fire. Oxygen, which in its common state has no odor, may by an electric discharge through a glass tube or bottle containing air be transformed into ozone, which has a peculiar odor and other new properties. (See OZONE.) The diamond and graphite are allotropic forms of carbon.

Revised by IRA REMSEN.

Alloway Kirk: an old ruined church in the parish of Ayr, near the mouth of the river Doon, Scotland; the scene of Burns's poem *Tam o' Shanter*. A monument has been erected here to the memory of Burns, who was born near the kirk.

Alloy [modif. under influence of Fr. *aloi* of older *alay* < O. Fr. *alay*, from Lat. *attigare*, combine]: a mixture or compound of two or more metals fused together; sometimes a compound of precious metal with a metal of less value; thus, in coinage, the term alloy is applied to a

baser metal mixed with gold or silver in order to make it harder. Chemists apply this term to all combinations obtained by fusing metals together; thus, brass is an alloy of copper and zinc; bronze is an alloy of copper and tin; pewter is an alloy of tin and lead. In many cases the metals do not unite in definite or invariable proportions. The density—or, in other words, the specific gravity—of an alloy is sometimes greater and sometimes less than the mean of its components. Most alloys have greater cohesion than either of the metals of which they are composed, so that a bar of an alloy will bear a greater longitudinal strain than a bar of either metal. British gold coin contains 11 parts of pure gold and 1 of copper; the law of the U. S. requires that in 1,000 parts of coin there must be 900 parts of gold; and the intent of the law is that the alloy shall be of copper only; but, as in parting silver from native gold it has been heretofore impossible to separate the whole, except at an expense too great to be economical, it has been permitted to allow the residual silver to be counted as part of the alloy, provided the proportion of silver be *not greater* than one-half. The more effectual processes introduced of late years into the U. S. assay offices have made it possible to make the parting nearly complete; and it is now provided that the silver shall not exceed *one-tenth* part of the whole alloy. A compound of mercury with another metal is an *amalgam*.

Revised by IRA REMSEN.

All Saints' Day, or **All-Hallows**: a festival of the Roman Catholic, Anglican, Lutheran, and the various Oriental churches, observed on the 1st of November, in honor of the saints in general. The Greeks keep their feast of All Saints on the Sunday after Whit Sunday.

All Souls' Day: a festival of the Roman Catholic Church observed on the 2d of November, when the prayers of the living, offered at the Eucharist, are publicly offered for the faithful departed.

Allspice: pimento, or Jamaica pepper, the dried berry of the *Eugenia pimenta*, which is a native of the West Indies. It is called allspice because it is supposed to combine the flavor of several spices.

Allston, ROBERT FRANCIS WITHERS: soldier and Governor; b. in All Saints' parish, S. C., Apr. 21, 1801; graduated at West Point in 1821; served as lieutenant of artillery on topographical duty till he resigned, Feb. 1, 1822, to become a rice-planter on the Great Pedee river; surveyor-general of South Carolina 1823-27, member of the House of Representatives of South Carolina 1828-32, of the Senate 1832-56, presiding 1847-56, deputy adjutant-general of South Carolina 1831-38, and Governor of South Carolina 1856-58. He was much interested in agriculture and public education, and wrote valuable memoirs upon both subjects. D. April 7, 1864, on his plantation near Georgetown, S. C.

GEORGE W. CULLUM.

Allston, WASHINGTON: painter of historical and religious compositions and of portraits; b. at Waccamaw, S. C., where his father was a planter, Nov. 5, 1779, and d. at Cambridgeport, Mass., July 9, 1843. He became acquainted with Edward Malbone, a miniature painter, while at school in Newport, R. I., and after graduating at Harvard College in the class of 1800 he went to Charleston, S. C., and began to paint, making use of such small opportunities for study as the place afforded. In 1801 he went to London with Malbone and entered the schools of the Royal Academy, and in 1804 he went to Paris to study in the Louvre and soon afterward to Rome, where he spent about four years. He returned to the U. S. in 1809, but shortly returned to London, where in 1812 he won a prize of 200 guineas from the British Institution with a picture entitled *The Dead Man Restored to Life by the Touch of Etisha's Bones*. It was afterward purchased by the Pennsylvania Academy of Fine Arts, and is now in its permanent collection at Philadelphia. Allston's fame grew rapidly in succeeding years, and he was elected an associate of the Royal Academy, London, in 1818. He took a studio in Boston the same year, and began work on his *Elijah* and a large composition, *Belshazzar's Feast*, which, however, he never finished. A sketch of the picture is in the Boston Athenæum. A portrait of Benjamin West is also in the Athenæum Gallery, and a portrait of Coleridge is in the National Portrait Gallery in London. In the gallery of the Fine Arts School of Yale University one of his important pictures may be seen, painted in Boston during the time he passed there from 1818 to 1830. He went to Cambridgeport to live in 1830 and

spent the rest of his life there, devoting himself to literature and painting, but working irregularly and producing little. Allston was a man of refined sensibility and poetic temperament, and was loved and esteemed by his friends and fellow-artists. His reputation as an artist is greater than his achievement in painting warrants on the whole, and in his work there is not much to entitle him to a high rank. His best quality was a good sense of color. His portraits, in spite of only moderate technical skill, are refined, and impress with a sense of personality that is often lacking in better work. Being one of the first in the U. S. to take up the study of the fine arts seriously and devote his life to the profession of painting, he will always remain an interesting and important figure in the history of our art. WILLIAM A. COFFIN.

Allu'vion [viâ Fr. from Lat. *allu'vio*, a washing against; *ad*, to + *lu'ere*, wash]: the soil imperceptibly formed by the constant washing of the waters along the banks of a river or the sea. (See ACCRETION.) It differs from "avulsion," as the latter is not gradual, but sudden and perceptible.

Allu'vium [Lat. neut. of adjec. *allu'vius*, washed against; *ad*, to + *lu'ere*, wash]: gravel, sand, and other matter washed down by rivers and floods, and spread over land that is not permanently submerged. Such deposits often accumulate at the mouths of large rivers and form deltas. (See DELTA.) Streams which issue from mountain gorges upon an adjacent plain usually accumulate alluvium about the mouths of the gorges in sloping plains known as alluvial fans or alluvial cones.

Al'lyn, ROBERT, D. D.: clergyman; educator in the Methodist Episcopal Church; b. at Ledyard, Conn., Jan. 25, 1817; graduated in 1841 at the Wesleyan University, Conn.; mathematical teacher in Wilbraham Academy, Mass., in 1841-43; joined the New England Conference 1842; was elected principal at Wilbraham 1845; principal of the Providence Conference Academy 1848; Commissioner of Public Instruction for Rhode Island 1854; served three terms in the Rhode Island Legislature; appointed Professor of Ancient Languages in Ohio University at Athens 1857; president of the Wesleyan Female College, Cincinnati, O., 1859, and president of McKendree College, Ill., 1863-73. D. Jan. 7, 1894.

Al'ma: a small river of Russia, in the Crimea, flows W. and enters the sea about 20 miles N. of Sevastopol. On its banks the allied armies of England, France, and Turkey defeated the Russians on Sept. 20, 1854. The British forces consisted of 25,000 men and 60 guns, commanded by Lord Raglan. The French had 30,000 men and 68 guns, and also 7,000 Turkish infantry, the French and Turkish forces being all under the command of Marshal St. Arnaud. The Russians had 36,000 men and 122 guns under Prince Menschikoff, and were strongly posted on the left bank of the river, on the heights.

Alma: city (founded in 1865); capital of Wabaunsee co., Kan. (for location of county, see map of Kansas, ref. 5-1); 35 miles W. of Topeka, the State capital; on two railroads; has good water-power and fine stone quarries, a flouring-mill, a creamery, graded public schools, a Lutheran school, 5 churches, and 3 weekly newspapers. Pop. (1880) 300; (1890) 1,125; (1900) 966. EDITOR OF "NEWS."

Alma: town in northeastern part of Gratiot co., Mich. (for location of county, see map of Michigan, ref. 6-1); on Pine river, 32 miles W. of Saginaw, and on the Detroit, Lansing and Northern and Toledo, Ann Arbor and North Michigan R. Rs. A branch of D., L. and N. connects Alma with Ithaca, the county seat, 9 miles south. It is the seat of Alma College (Presbyterian), and has an excellent public school of twelve departments. There are six churches. The leading manufactures are lumber and shingles, hoops, sashes, doors, and blinds, furnishings for buildings, tables, flour, excelsior, barrels, machinery, and woolen goods. Pop. (1880) 456; (1890) 1,655; (1900) 2,047.

EDITOR OF "RECORD."

Alma: city; county seat of Buffalo co., Wis. (for location of county, see map of Wisconsin, ref. 5-B); on the Mississippi river, 60 miles N. of La Crosse, and within 4 miles of the celebrated Beef Slough Booms. It has manufactures of lumber, bricks, wagons, flour, etc., and is surrounded by good farming country. It has a high school with seven departments, and four churches. Pop. (1880) 1,244; (1890) 1,428; (1900) 1,201. EDITOR OF "JOURNAL."

Al'mack's: a suite of assembly-rooms in King Street, St. James, London, was formerly celebrated as a fashionable place of resort for the aristocracy. Annual balls were given

in these rooms, the managers of which were ladies of high rank, who conducted them with great exclusiveness. These rooms were built in 1765 by a person named Almack, an anagram of McCall, his original name. The desire for admission to balls and parties at Almack's was so eager that it is said that votes in Parliament were bought by tickets offered to wives and daughters of members.

Almaden', or **Almaden' del Azo'gue** (i. e. the mines of quicksilver): a town of Spain, in the province of Ciudad Real, 50 miles S. W. of Ciudad Real (see map of Spain, ref. 17-E). Here are mines of quicksilver (cinnabar), which are said to be the richest and most ancient in the world, producing annually about 2,000,000 lb. They were worked by the ancient Spaniards, and afterward by the Romans. Almaden has a practical school of mines and three hospitals. The mines were rented in the sixteenth century by the Fuggers, the famous bankers of Antwerp, and in 1843 the Rothschilds obtained the contract from the Spanish Government. Pop. 8,645.

Almaden': township of Santa Clara co., Cal. (for location of county, see map of California, ref. 8-C); has mines of mercury and mineral springs. Pop. (1870) 1,647; (1880) 2,418; (1890) 1,932; (1900) 1,599.

Almaden Quicksilver Mines (Santa Clara co., Cal.): named after those of Almaden in Spain, the latter being the most important in the known world. The Santa Clara mines are the New Almaden, Providence, Enriquita, and Guadalupe. The first mentioned is 14 miles from San José and 65 miles S. of San Francisco, in a region remarkable for its picturesque scenery. The ore (cinnabar) has from time immemorial been known to the Indians, who used it for making vermilion paint. Some Mexicans having bribed them to disclose the profound secret of its place, a company was formed in 1846, which began to work the mine. The presence of this deposit has been of incalculable benefit to the Pacific coast, since enormous quantities are employed in gold and silver mining. The metallic mercury is separated from the ore by a simple process of distillation. The total production of the California mines from July, 1850, to Jan. 1, 1899, was 967,796 flasks of 76½ lb. each. The maximum was reached in 1865 with 47,194 flasks, the product in 1898 being 5,875 flasks. Revised by C. KIRCHHOFF.

Al'magest [viâ O. Fr. from Arab. *al-majisti*; *al*, the + Gr. *μεγίστη*, fem. greatest (sc. *σύνταξις*): a name given by the Arabs to Ptolemy's celebrated work on astronomy, in which the laws of the celestial motions were developed on the supposition that the earth was the center of the universe. It was the standard work from the time it was written, about A. D. 150, until Copernicus showed that the earth revolves around the sun.

Almagro, al'maa'grō: city of Spain; province of Ciudad Real; 14 miles S. E. of Ciudad Real (see map of Spain, ref. 17-F). It is well built, has a town-hall, two hospitals, and one Latin school. Large quantities of fine black and coarse white lace are made here; also brandy, soap, and earthenware. Pop. 14,000.

Almagro, DIEGO, de: a Spanish soldier of fortune; one of the conquerors of Peru; a founding named after the city in which he was found in 1475. At an early age he went to America, where he is said to have enriched himself by plunder. Pizarro, Almagro, and Luque in 1525 united in an enterprise to conquer Peru, in which they were successful. (See PIZARRO, FRANCISCO.) In 1535 Almagro invaded Chili and gained some victories over the natives, but his progress was hindered by the enmity and perfidy of Pizarro. He returned from Chili in 1536, and took Cuzco, which Pizarro claimed as part of his possessions. In April, 1538, Almagro was defeated in battle and taken prisoner by Pizarro, who put him to death.

Almagro, DIEGO, de: son of the preceding; b. about 1520. He became the leader of a party which was hostile to Pizarro, whom they assassinated in 1541. He then took the title of captain-general of Peru, but he was defeated in battle by the royal army under Vaca de Castro, and was executed in 1542.

Alma'li: a large town of Asiatic Turkey; in the S. part of Anatolia; on the river Myra; 25 miles from the Mediterranean (see map of Turkey, ref. 6-E). It is beautifully situated in a valley, contains several factories and mills, and has a prosperous trade. The appearance of the town is uncommonly picturesque. Pop. variously estimated from 8,000 to 25,000.

Al'ma Ma'ter (Lat., fostering or propitious mother): a name used to express the relationship of a university to its "foster-children" (alumni) who have been educated in it.

Almanac [from a Spanish-Arab. *al-manākh* of uncertain origin]: an annual publication designed to give information respecting times, seasons, the motions and positions of the heavenly bodies, and other celestial phenomena. Frequently, also, the times of high and low tides are added, especially in the case of almanacs intended for use in seaports or on ship-board.

The familiar household almanac is calculated and compiled from a large Government publication, issued in different countries under different names. In the U. S. this publication is known as the *American Ephemeris and Nautical Almanac*; in the United Kingdom as the *Nautical Almanac and Astronomical Ephemeris*, the familiar name of the publication in both countries being simply the *Nautical Almanac*. See EPHEMERIS.

Among the most widely known almanacs of the present time is the *Almanach de Gotha*, which was first published in German in 1763. It is also published in French. It contains the official lists of statistics of all nations, with much political information.

The first American almanac was that of William Pierce, published at Cambridge, Mass., in 1639. In 1733 Franklin first published his celebrated *Poor Richard's Almanac*. The *American Almanac* appeared from 1830 to 1861, and a new publication under the same title, edited by A. R. Spofford, from 1878 to 1889. Over 100 almanacs are published in the U. S., embracing very many subjects—religious, political, agricultural, etc. S. NEWCOMB.

Almanach de Gotha: See GOTHA ALMANAC.

Almandine: See GARNET.

Alman'sa, or **Alman'za**: a town of Spain; province of Albacete; 52 miles by rail E. of Albacete (see map of Spain, ref. 17-H). It has manufactures of linen and cotton fabrics, brandy, leather, and soap. Near this town the French, under the Duke of Berwick, defeated the British and Spanish armies, April 25, 1707. Pop. 7,900.

Al-Mansoor', ABOO JAAFAR: the second caliph of the family of the Abbassides; b. in 712. He ruled from 754-775; persecuted the Christians in Syria and Egypt; founded Bagdad; and promoted arts and sciences.

Alma-Tadema, LAURENZ, al-ma-tad'e-ma: figure painter, principally of Greek and Roman subjects; b. at Dronryp, Friesland, Jan. 8, 1836. Pupil of the Antwerp Academy and of Baron Leys. Has resided for many years in London, and was elected a member of the Royal Academy in 1879. Has received many honors at the principal exhibitions on the Continent and in Great Britain, and is a member of the academies of Amsterdam, Munich, Berlin, Madrid, Stockholm, and Vienna. Officer of the Legion of Honor, 1878; first-class medal, Paris Exposition, 1878; medal of honor, Paris Exposition, 1889. His work is remarkable for archaeological correctness and for technical qualities of a high order. Some of his principal pictures are: *Roman Dance* (1866); *Vintage Festival* (1870); *Sculpture Gallery* (1874); *Picture Gallery* (1874); *The Four Seasons* (1877); *Bacchante* (1877); *In the Tepidarium* (1881); *Anthony and Cleopatra* (1883); and *The Women of Amphissa* (1888). Some excellent examples of his work are owned in the U. S. Studio in London. WILLIAM A. COFFIN.

Al'meh, or **Al'mah**, written also **Almé** (plu. **Awâlim**): a professional female singer of Egypt. The singers are hired to perform in the harems of the rich. The common dancing-girls are a different and less respectable class, and are called Ghawazis (*q. v.*).

Almei'da: a fortified town of Portugal; in Beira; on the Coa, 95 miles N. E. of Coimbra (see map of Spain, ref. 14-C). It is an important stronghold. Here Lord Wellington defeated the French General Massena, Aug. 5, 1811. Pop. 10,125.

Almeida: a town of Brazil; province of Espirito Santo; is on the ocean, about 20 miles N. of Victoria (see map of South America, ref. 6-H). It was founded by the Jesuits in 1580. Pop. about 4,000.

Almeida, DON FRANCISCO, de: a famous Portuguese commander and Viceroy of India; b. in Lisbon about 1450. He was a son of the Count of Abrantes. Having gained distinction in wars against the Moors, he was appointed Viceroy of India in 1505. He built several forts on the Indian coast,

and extended the dominion of Portugal by his conquests. In 1507 Albuquerque was sent to India with a commission to supersede Almeida, but the latter refused to resign. He gained a decisive victory over the Egyptian fleet near Diu in 1508, and resigned his office about the end of that year. As he was returning to Portugal, he was killed by some Kaffirs near the Cape of Good Hope, Mar. 1, 1510.

Almeida-Garrett, JOÃO BAPTISTA, de: a Portuguese poet and politician; b. at Oporto, Feb. 4, 1799; Minister of Public Instruction, 1820-23; was compelled to leave the country in 1823, and again in 1828. In 1832 he landed in Portugal with Dom Pedro, was minister to Belgium in 1834, and member of the Cortes after the revolution of September, 1836. He was raised to the peerage in 1852, and died at Lisbon, Dec. 9, 1854. Inspired by the romantic movement with which he became acquainted during his exile in France since 1823, he was the first to collect the ballads and other forms of the national poetry of the Portuguese people, recognizing in them and in the national traditions the only organic basis upon which to build up a truly national literature, free from the influences of French classicism. Though his efforts to create a modern Portuguese drama were not successful, it is on them that his claim to a place beside Gil Vicente and Camoëns, the two other great poets of Portugal, chiefly rests. The most important of his works are the *Romanceiro* (3 vols.), a collection of Portuguese ballads; the historical novel, *O Arco de Sant' Anna*; the satirical poem, *Dona Brauca*; the epic-lyrical compositions, *Camoëns* and *Adozinha*, and especially the dramas *Auto de Gil Vicente*, *Filippa de Vilhena*, *O Alfageme de Santarem*, and *Frei Luiz de Sousa*. Valuable information in regard to Garrett's life is contained in Francisco Gomes de Amorim's work, *Almeida-Garrett, Memorias biographicas* (1881). HENRY A. LANG.

Almeri'a: a province of Spain; forms the E. part of the former kingdom of Granada. It is bounded N. by Murcia, E. and S. by the Mediterranean, and W. by Granada. Area, 3,302 sq. miles. It contains rich mines of silver and lead. Grain, silk, and wine are the chief productions. Pop. (1887) 339,383.

Almeria: city and port of Spain; on the Mediterranean; 104 miles E. of Málaga; the capital of a province of the same name (see map of Spain, ref. 19-G). Under the reign of the Moorish kings it was one of the richest and most important towns in the kingdom of Granada. It has a safe harbor, defended by two forts, and a fine cathedral. Wine, silk, cochineal, and other articles are exported from this port. It is pretty well built, the architecture of many of the houses still showing its Moorish origin, and has some fine squares. Pop. (1877) 40,323; (1887) 37,241.

Almodo'var, ILDEFONSO DIAZ DE RIBERA, Count: b. in 1777 at Granada; educated at the Military Academy of Segovia, and fought with distinction in the war against the French. By the reactionary Government of Ferdinand VII. he was suspected of liberalism and confined in the dungeons of the Inquisition, but was liberated by the revolution of 1820. In 1823, however, he was compelled to flee to France, and did not return until after the death of Ferdinand, when he at once took rank as one of the leaders of the Liberal party. In the cabinets of Mendizabal, Calatrava, and Espartero he was Minister of War, but retired in 1843 from public life. D. at Valencia, Jan. 26, 1846.

Almohades, al'mō-hadz [Arabie *Al-Mowahidoon*, i. e. the unitarians, or advocates of the unity of God, as taught in its original purity by Mohammed]: a Mohammedan dynasty that reigned in Spain and Northern Africa from 1129 to 1269. It was founded by Abu-Abdillah Mohammed, surnamed AL-MAHDI, "the director." The Almohades were the conquerors and successors of the Almoravides. The first Almohade who took the title of sultan was Abd-el-Mumen.

Almonacid': a town of Spain; province of Toledo; on the Tagus (see map of Spain, ref. 16-F). Here the French under King Joseph defeated the Spaniards under Vanegas on Aug. 11, 1809.

Almond (*Prunus communis*): a fruit closely allied to the peach, and supposed by some to have given rise to the peach through cultivation and selection. It has been in cultivation from time immemorial, and is thought to be native to the Mediterranean basin and Western Asia. The fruit is characterized by a more or less hard and inedible flesh, the marketable product being the pit or stone, the meat or kernel of which is the edible portion. There are a score of varieties, most of which fall readily into one of two groups—the sweet

kernels and the bitter kernels. The thickness and consistence of the shell vary in each group, so that the common terms "soft shell" and "hard shell" express no definite distinctions. The almonds of the shops belong to the sweet kernel group, and the best of them are thin-shelled varieties. Bitter varieties yield the "oil of bitter almonds," and they are used for medicinal and confectionery purposes. Almond leaves are rich in prussic acid. The almond is extensively cultivated in Southern Europe, and lately it is being grown largely in California, where several varieties have originated peculiarly well adapted to certain localities. Several varieties are hardy as far N. as New York and Detroit, but the popular market sorts rarely succeed N. of 38° or 40°. Almonds are cultivated in the same manner as peaches. They are budded upon almond, peach, plum, or apricot, these stocks being named in the order of preference. The fruits are shaken from the tree as soon as the outer flesh is burst open. The hulling is done in this country by simple hand or power machines. When thoroughly dry the stones are bleached with sulphur fumes to improve their appearance.

Flowering or dwarf almonds are bushy plants belonging to the species *Prunus triloba* and *P. nana*. They are propagated by budding upon plum or peach; also by root-cuttings, division, and rarely by cuttings of the branches.

L. H. BAILEY.

Almond'bury: a large village, township, and parish of England, in the West Riding of Yorkshire (see map of England, ref. 7-H). The village is on the Calder, 36 miles S. W. of York, and has cotton and woolen mills. Pop. about 16,000.

Almon'de (sometimes *Alemonda*), PHILIPPUS, van: a Dutch admiral; b. at Briel, Dec. 29, 1646. He was the second in command under De Ruyter when the latter was killed in 1676, and contributed to the victory which Van Tromp gained over the Swedes in 1677. He accompanied William of Orange to England in 1688, and commanded the Dutch fleet which, aided by the English, defeated the French at La Hogue in 1692. D. near Leyden, Jan. 11, 1711.

Almonds, OIL OF: a fixed oil, of a light-yellow color and odorless, obtained by pressure from almonds, both sweet and bitter. It consists chiefly of olein; is soluble in 25 parts of alcohol. It is used in medicine, having a mild laxative property. It is sometimes given to new-born infants, mixed with sirup of roses. One hundred pounds of almonds yield about 50 lb. of oil. Bitter almonds, macerated with cold water and distilled, yield a volatile oil known as the "oil of bitter almonds," or benzoic aldehyde. This does not pre-exist in the almonds, but is produced, together with hydrocyanic or prussic acid, from the glucoside amygdalin under the influence of the ferment emulsin:

It is a colorless, limpid oil, smelling of bitter almonds. When freed from prussic acid it is not poisonous. It oxidizes to benzoic acid, $\text{C}_7\text{H}_6\text{O}_2$. It is regarded as the aldehyde of benzoic acid. It is also produced by the action of manganese dioxide and sulphuric acid on albumen, fibrin, casein, and gelatin. It has been used to a considerable extent for flavoring confectionery and for scenting soap. For the former purpose the prussic acid which it usually contains makes it dangerous. For the latter purpose it has been entirely superseded by the much cheaper nitrobenzene or essence of mirbane ($\text{C}_6\text{H}_5\text{NO}_2$), also called artificial oil of bitter almonds, which possesses the same odor.

Revised by IRA REMSEN.

Al'moner [O. Fr. *almosnier*, from Lat. *elemosynarius*, adjec. from Gr. *ἐλεημοσύνη*, pity]: an officer whose duty is to distribute alms for a king or other person of rank, or for a monastery. The grand almoner of France was a functionary of high rank, and usually a cardinal. This office was abolished during the revolution. In England there is a lord high almoner, who distributes the bounty of the queen twice a year, and whose duties are defined in the constitutions of the royal chapels. All monasteries by the ancient canons were to spend not less than a tenth part of their income in giving alms to the poor. All bishops were required to keep almoners.

Almonte: town in Lanark co., Ontario, Canada (for location, see map of Ontario, ref. 2-H); situated in an agricultural region, on Canadian Pacific Railway, 35 miles S. W. of Ottawa; has good water-power, and manufactures woolen and knit goods. Pop. (1881) 2,684; (1891) 3,071.

Almon'te, DON JUAN NEPOMUCENO: a Mexican general and statesman of Indian descent; b. at Valladolid, Mexico, in 1804; was attached to the embassy in London in 1824 and 1832, Minister of War under Bustamente, and in 1841 minister plenipotentiary at Washington. He distinguished himself in the war against the U. S., was sent to Washington in 1853, and in 1857 to Paris. He went to Mexico with the French expedition in 1862, and was declared President in Juarez's place, but was not able to gain recognition. He entered the capital with the French army June 10, 1863, and was made President of the Government Junta; was sent to Paris as minister extraordinary 1866, and remained there after the fall of Maximilian till his death, Mar. 22, 1869.

Revised by S. M. JACKSON.

Almoravides, al-mō-ra-vids [a corruption of the Arabic *Almorabitun*, signifying those bound or devoted to the service of God]: the name of a Moslem or Arabian dynasty that reigned in Northern Africa and Spain. It was founded by Abdallah-Ibn-Yaseen about 1050, and continued until 1145, when it was succeeded by the Almohades.

Almquist, alm'kvist, CARL JONAS LUDVIG: Swedish writer of the Romantic school; b. at Stockholm, Nov. 28, 1793. After an eccentric attempt to establish a community of the old Scandinavian pattern, he devoted himself to literature, producing books of all sorts—poems, plays, school-books, tales, and romances. In 1851 he fled from Sweden to America, under suspicion of an attempt at murder. He afterward returned to Europe and lived some years under a false name (C. Westermann) in Bremen, where he died Sept. 26, 1866. His most important work is *Törnrosens Bok* (Book of the Thorn-Rose, 17 parts in two series, 1832-51), a collection of miscellanies in prose and verse, among which may be mentioned the short stories *Araminta May* and *Skällnora Quarn*; the semi-dramatic sketch *Colombine*; the dramas *Marjam* and *Isidoros of Tadmor*; and the epic *Arturs Jagt*. Of his long romances, *Amalia Hillner* and *Gabriele Mimanso* are perhaps the best. G. L. KITTEDGE.

Almshouses: See PAUPERISM.

Almucan'tar [from the Arabic *al-muqantarāh*, a horizontal circle on the celestial sphere; from *al*, the + *muqantarāh*, a sun-dial; from *qantarāh*, an arch]: a small circle, immediately around the zenith, or a larger one at any altitude, the largest of all being the great circle of the horizon.

The term has also been applied by Mr. S. C. Chandler to an instrument of his invention, for the very accurate measurement of equal altitudes. It consists essentially of a telescope mounted upon a stand which floats in quicksilver. The eyepiece of the telescope is supplied with one or more horizontal spider-lines. If the stand of the telescope be made to turn as it floats, the axis on which it turns will be truly vertical; and the line of sight of the telescope will therefore describe an almucantar. Thus the equal altitudes of two or more heavenly bodies at given moments can be determined with this instrument with, perhaps, greater precision than any other. But its use requires great care and skill on the part of the observer. An elaborate series of observations and investigations with it will be found in one of the volumes of *Annals of the Harvard College Observatory*. S. NEWCOMB.

Almy, JOHN JAY: See the Appendix.

Alnwick, an'nik: a market-town of England; county of Northumberland; on the river Alne; 32 miles N. of Newcastle (see map of England, ref. 3-H). It is well built of stone, and has a town-hall, a theater, a mechanics' institute, etc. There are remains of the old wall which formerly surrounded the town. Pop. about 8,000.

Alnwick Castle: seat of the Duke of Northumberland; N. W. of the town of Alnwick; one of the most magnificent baronial castles in England. It is supposed to be twelve hundred years old or more, and has belonged to the Percy family since the reign of Edward II. In 1830 it was repaired at a cost of £200,000. Malcolm III., King of Scotland, while besieging this castle in 1093, was killed, with his eldest son, by the Earl of Northumberland. William the Lion of Scotland, having laid siege to it in 1174, was defeated and made prisoner.

Al'oë: a genus of endogenous plants of the order *Liliaceæ*, natives of Africa and other warm regions, and chiefly valuable for their medicinal properties. The drug called aloes is obtained from several species, among which the *Aloe socotrina*, found in the island of Socotra, affords the best quality. See ALOES.

Aloe, American: See AGAVE.

Al'oes: a stimulating, purgative drug having a bitter taste, is the inspissated juice or extract obtained from the leaves of several species of the aloe. It is imported from Bombay, Socotra, the Cape of Good Hope, the West Indies, etc. "Cape aloes" is obtained from the *Al'oe spica'ta*; "Socotrine aloes," from the *Al'oe socotri'na*; and "Barbadoes aloes," from the *Al'oe vulga'ris*. Aloes is much used combined with other cathartics; from its stimulating effect upon the lower bowel it is unsuitable for those suffering from piles. Heated with nitric acid, aloes yields chrysamic acid. See Wood and Bache's *Dispensatory*.

Aloes Wood, or **Agila**, or **Eagle Wood**: the inner part of the trunk of the *Aquila'ria ova'ta* and the *Aquila'ria agal'lochum*, trees which are natives of tropical Asia. It is supposed to be the lign-aloes of the Bible. Aloes wood contains a fragrant resinous substance, which emits a pleasant odor when burned, and is highly prized as a medicine by the Orientals.

Al'ogi: a sect of religionists opposed to the Montanists; formed about 160 A. D. They were styled Alogi, a name of double meaning, signifying their rejection of writings in which the Logos is mentioned, and also that they were without reason.

Aloi'adae (i. e. sons of Aloens): in Greek mythology, Otus and Ephialtes, two giants of extraordinary strength who attempted to storm Olympus, and were condemned to suffer in Tartarus.

Alom'pra: the founder of the last dynasty of Burma, which came to an end early in 1886, when Upper Burma became a province of British India. Alompra was born about 1700. He revolted against the King of Pegu in 1753, was victorious in several battles, and became master of Burma, in which he founded Rangoon. D. May 15, 1760.

Alopecia: See BALDNESS.

Alo'ra: a city of Spain; in the province of Málaga; 17 miles N. W. of Málaga (see map of Spain, ref. 20-E). Soap and oil are manufactured here. A winter resort with mineral waters. Pop. 10,014.

Alosa: See SHAD.

A'lost, or **Aalst**: an ancient town of Belgium, in East Flanders, on the navigable river Dender, midway between Ghent and Brussels (see map of Holland and Belgium, ref. 9-D). It contains the church of St.-Martin, one of the largest and finest in Belgium, a town-hall, a college, and an academy of design. Here are cotton-mills, copper-foundries, distilleries, and manufactures of lace, leather, etc. Alost has an active trade, and exports hops, corn, and oil. It was formerly the capital of Austrian or imperial Flanders. Pop. (1896) 28,137.

Aloysius, SAINT, OF GONZAGA: See GONZAGA.

Alpa'ca: the *Auche'nia pa'cos*; supposed by many zoölogists to be only a domesticated variety of the *guanaco*, a

eated or semi-domesticated state on the high Andes of Peru and Bolivia. It is rather smaller than the llama, and is not used as a beast of burden, being valued only for its wool. The latter varies in color, and is remarkable for its length, fineness, silken texture, and a luster almost metallic. It is longer and straighter than that of sheep. The most extensive manufactures of alpaca cloth are in Great Britain, which imports annually about 3,000,000 lb. of this wool. A great part, however, of the so-called alpaca goods of commerce are made of the wool of the Cotswold, Leicester, and other long-wooled breeds of sheep.

Alp-Arslan' (i. e. strong lion), written also **Alp-Arselan**: a famous Persian sultan of the Seljukian dynasty; b. in Turkestan in 1029. He ascended the throne in 1063, embraced Islamism, and became sole monarch of Persia from the river Tigris to the Oxus. Under the direction of his wise vizier, Nizâm-ul-Mulk, who was one of the most noted statesmen in early Mohammedan history, and ably assisted him in consolidating his empire and subduing contending factions, Persia enjoyed great prosperity, many colleges were founded, justice was well administered, and learning was promoted. In 1071 Alp-Arslan defeated and took prisoner Romanus Diogenes, Emperor of Constantinople, whom he treated with great generosity and kindness. Alp-Arslan was assassinated Dec. 15, 1072.

Alpe'na: city; capital of Alpena co., Mich. (for location of county, see map of Michigan, ref. 4-J): at the head of Thunder Bay. It manufactures about 200,000,000 feet of lumber yearly, and large quantities of shingles and lath. Contains large hemlock-extract factory, a sulphite fibre works, and spool factory, has an excellent harbor, and is situated about 210 miles N. by W. from Detroit on Lake Huron. It has a high school costing \$40,000; another school costing \$12,000; 7 miles paved streets, electric lights, water-works, telephone exchange, etc. Pop. in 1880, 6,153; in 1890, 11,283; (1900) 11,802. H. C. HAMILL, PUBLISHER OF "PIONEER."

Alpes, Basses: See BASSES-ALPES.

Alpes, Hautes: See HAUTES-ALPES.

Alpes-Maritimes, alp-ma-rêe-teem' [i. e. the Maritime Alps]: a department forming the S. E. extremity of France, bordering on Italy. It is bounded N. and E. by Italy, S. by the Mediterranean, W. by Var and Basses-Alpes. Area, 1,482 sq. miles. It is drained by the river Var. The surface is diversified by mountains and fertile valleys. The mild climate along the coast makes it a favorite winter resort for invalids. This department includes the county of Nice, which was ceded by Italy to France in 1860; also the arrondissement of Grasse, detached from the department of Var. It is partly covered with forests of valuable timber. Among its staple products are grapes, olives, oranges, lemons, figs, silk, and flowers for perfumes. The chief towns are Grasse, Antibes, Cannes, and Nice, which is the capital. It is divided into three arrondissements. Pop. (1881) 226,621; (1891) 258,571; (1896) 265,155.

Al'pha and O'mega: the names of the first and last letters of the Greek alphabet, Α. Ω. These words occur in the book of Revelation as a title of the Lord Jesus Christ. The two letters were used by the early Christians as symbols of faith, and were sometimes marked on coins, tombs, ornaments, etc.

Alphabet: this term, formed from the names of the first two Greek letters, *alpha*, *beta*, after the manner of our *a-bee-see'*, and originally applicable to the series of letters by which the Greek language is written, has been extended in application to any such complete set of symbols for the sounds of a language. The modern European alphabets are all ultimately derived from the Greek. The Russian and those of other Slavic countries where the Greek Orthodox Church is dominant are modifications of the Cyrillic alphabet, which is based upon the Greek writing of the ninth century A. D. Our own alphabet is essentially the Roman form of the Greek. The letter J is a late differentiation of I, and W represents the attempt, in the earlier use of the Latin alphabet among Germanic peoples, to indicate the Germanic consonantal *u* (= *w*) by doubling the Roman symbol V, which had assumed, since the third century A. D., the value of a spirant. The symbol &, often appended to our alphabet, is, as well as + (*plus*), a conventionalized degradation of Latin *et* (ε), "and."

The form of the Greek alphabet from which the Roman is derived is that form of the Eubœan which was introduced into Italy by the colonists from Chalcis. The alpha-

Alpaca.

ruminant animal nearly allied to the llama, and belonging to the family *Camelidæ*; occurs in large flocks in a domesti-

bet which we commonly know as Greek is essentially the Ionic. It had its home in the Ionic cities of the Asiatic coast, and from there gradually spread over all Greece, becoming the standard at Athens in 403 B. C., and in Greece generally during the following century. It differed from the Chalcidian in the following points (see table): 1. *Gamma* (3) was angular, not rounded. 2. *So delta*, which was rounded in the Roman source. 3. *Eta* (8) had assumed the value

Order.	Hebrew name.	Moab.	Chalcid.	Ionic.

Non-Phœnician.				Y
				X
				ϕ
				ψ
				Ω

of open *e* in Ionic, where in the dialect the sound *h* was lacking, but Chalcidian, and consequently the Roman, re-

tained it in its older value. 4. *F* was not in use. 5. *Lambda* had its angle at the top. 6. *Koppa* (19) was lost, though preserved in Chalcidian (cf. our Q). 7. *Rho* lacked its queue. 8. *Sigma* was angular, and generally composed of four lines. 9. The letter *X* had the value *ch*, not *ks*, as in Chalcidian. 10. A special symbol for open *o* had been developed (*omega*).

In Roman usage the alphabet suffered the following modifications: (1) C, the Greek *gamma*, was commonly used for both sounds *k* and *g* until by the addition of a diacritical mark G was invented, and put in place of the disused *zeta* (ζ). (2) K was little used. (3) F assumed the value *f* instead of *v*. (4) In the Augustan age *upsilon* (pronounced *ū*) and *zeta* were introduced from the Greek alphabet, primarily to assist in writing Greek words, and were placed at the end of the alphabet. Hence our *y* and *z*. (5) The three aspirates ⊕ ⊙ ⊕ disappear except as numerals; thus ⊕ "1000" survives as CIO, which through influence of *milite* becomes M, and D as one-half of it denotes "500."

All the Greek alphabets are based upon the Phœnician alphabet of twenty-two letters, to which a twenty-third (Y) was directly added. From this series of twenty-three letters all the various systems may be derived. The form of the parent alphabet may be regarded as almost identical with the writing of the Moabite stone (c. 890 B. C.), which is reproduced in the table above. See GREEK LANGUAGE.

The adoption of the Phœnician alphabet by the Greeks occasioned the following changes: (1) As the Phœnician alphabet lacked vowel signs, Nos. 1, 5, 10, and 16, which were otherwise useless, were given the values of *a*, *e*, *i*, *o*, and a variety of No. 6 supplied a symbol for *u*. (2) The four sibilants, Nos. 7, 15, 18, 21, were reduced to two, *zeta* and either *san* (M) or *sigma* (ς). (3) All the alphabets except those of Thera, Melos, and Crete add the symbols ϕ (*ph*) and χ (in some *kh*, in others *ks*).

The order of the letters, as may be inferred from various indications, notably the acrostic Psalms (119, 145), etc., the ancient "*abecedaria*" or written lists of letters, as that of Formello (see Kirchoff, *Studien zur griech. Alphab.* 4 134), and the use of the letters as numerals, is old, and is most rigidly preserved. The original grounds for this arrangement are not entirely clear; it was partly due to likeness of sounds, thus the three sonants *b*, *g*, *d*, and the liquids *t*, *m*, *n*, and partly, doubtless, to the names of the letters; thus Nos. 16, 17, 19, 20 refer to the head or its parts, *ayin*, "eye"; *Pê*, "mouth"; *Q'ôph*, "back of head"; *Rêsh*, "head."

The Greek names of the letters are meaningless echoes of their Semitic originals, which were themselves, however, suggestive of some resemblance in the shape of the letters. Thus *alpha* from *aleph*, "ox" (cf. our *elephant*), because of the resemblance of the letter (ϑ) to the head of an ox; so *gamma* = *gimet*, "camel" (English *camel* is of Semitic origin), probably from the suggestion of a camel's hump (Δ). Kirchoff, *Studien zur Geschichte des griech. Alphabets* (4th edit., 1887); Taylor, *The Alphabet* (2 vols., 1883); Hinrichs, *Mütter's Handbuch d. Alterthumsw.*, i. 331 ff.; Roberts, *Introduction to Greek Epigraphy* (1887); Schlottman, *Riehm's Bibelwörterb.*, ii. 1416 ff. s. v. *Schrift*. See also WRITING.

BENJAMIN IDE WHEELER.

Alphand, al-foñ, JEAN CHARLES ADOLPHE: civil engineer; director of the improvements of Paris, the Expositions of 1867, 1878, and 1889; b. at Grenoble, Oct. 26, 1817; entered the Polytechnic School in 1835 and the School of Ponts et Chaussées in 1837. Graduating in 1843 with the appointment of engineer, he was posted at Bordeaux, where in addition to his duties as engineer he was a member of the municipal council, and of the general council of the canton. In 1854 Baron Haussmann, prefect of the Seine, who had known Alphand when he himself was prefect of Bordeaux, called him to Paris, appointing him chief engineer of the improvements of the city. In 1871 President Thiers appointed him Director of Works of Paris, which included the supervision of all architectural matters. In 1878 he became Director of Water-supply and Drainage, thereupon centralizing in his own person all the technical services of Paris. In the Exposition of 1867 he was in charge of the works of the Champ de Mars, a member of the executive committee of the Exposition of 1878, and director of the works of that of 1889. He was appointed chief engineer of Ponts et Chaussées in 1857, and inspector-general of the first class in 1875. During the war of 1870-71 he was colonel of a corps of engineers, in charge of the continuous line of defense surrounding the city. Chevalier of the Legion of Honor since 1852, and officer since 1862, the

insignia of grand officer were sent to him at the new Hôtel de Ville by the President of the republic on the 13th of July, 1882. Modern Paris is said to owe its existence to Baron Haussmann, but it was Alphand who organized the means by which they were carried out. When the official life of the great prefect terminated with the fall of the empire the work begun by him was continued, and Alphand, having held aloof from politics, maintained his position, and became himself its controlling spirit, not only in the design and execution of the works, but in providing means for carrying them on. He died in harness of an attack of paralysis on the 6th of Dec., 1891, in the seventy-fifth year of his age.

WILLIAM R. HUTTON.

Alphe'us, or **Alphei'us**: the modern Roupbia, a celebrated river of Greece, in the Morea. It rises in the S. E. part of Arcadia, on the frontier of Laconia, flows westward through Arcadia and Elis by Olympia, and empties into the Ionian Sea after a course of about 100 miles. The Alpheus, like some other rivers in Arcadia, disappears more than once in the cavernous limestone mountains, and appears again after flowing some distance underground. In the commencement of its course it is now called the *Saranda*. Below Pegæ, the Alpheus receives the Helisson, and below Heræa the Ladon, after which it is called the Roupbia. In the upper part of its course the Alpheus is generally called the *River of Karitena*. Below the Ladon the Alpheus receives the Erymanthus. A temple and grove of Artemis Alpheionia were at the mouth of the Alpheus, which river is wide and shallow from the Pass of Lavdha to the sea.

Alpheus: in classic mythology, a river-god and a son of Oceanus. According to the poetical legend, he loved the nymph Arethusa, who fled from him to the island of Ortygia, and was transformed into a fountain. Alpheus pursued her under the sea and was united to the fountain.

Alphonso: See ALFONSO.

Alpine Club: a society for the promotion of Alpine discovery; formed in Great Britain in 1858. Three members of this club, Mr. Hudson, Lord Francis Douglas, and Mr. Hadow, perished with their guide in the descent of the Matterhorn in July, 1865. Other Alpine clubs were formed in Austria, Switzerland, Italy, and Germany. In 1873 an Alpine Club was formed in the U. S.

Alpine Plants: those plants which grow at considerable elevations (a mile or so) upon mountains. Primarily, the term was applied to the plants on the Alps, but, inasmuch as the vegetation of all high mountains resembles that of the Alps, the term has come to have a broader significance. It has been observed, also, that as we go N. (in the northern hemisphere) and S. (in the southern hemisphere) the vegetation is Alpine in character at lower and lower levels, so that finally it occurs upon the surface but little above sea-level. The botanist finds many plants in Labrador and other far northerly parts of Canada which occur on the mountains of the U. S. A notable example of this is the *Diapensia lapponica*, which is abundant in Labrador, occurring also on the White Mountains of New England.

Among the more remarkable Alpine plants is the EDELWEISS (*q. v.*) of the higher regions of the Alps. Little less interesting are the gentians, of which many species occur in the Alps (*Gentiana nivalis*, *G. brachyphylla*, *G. bavarica*, *G. excisa*, *G. acaulis*) and in the Rocky Mountains (*G. barbellata*, *G. prostrata*, *G. frigida*, *G. parryi*), while some are common to both regions (*G. amarella*, *G. tenella*). The low catchfly (*Silene acaulis*) occurs on the Alps and the Rocky Mountains, and the same is true of species of forget-me-not (*Myosotis alpestris*), saxifrage (*Saxifraga oppositifolia*, *S. aizoides*), knot-grass (*Polygonum bistorta*), etc.

The woody plants growing at high altitudes are greatly reduced in size—e. g. the Alpine species of willows (*Salix ovata*, *S. retusa*, *S. reticulata*, etc.), which trail upon the ground, and bear small or even minute leaves. At great elevations trees of various kinds are sometimes reduced to mere shrubs. The flowers of Alpine plants are remarkable for the brightness of their colors.

CHARLES E. BESSEY.

Alpi'nus, or **Alpini**, PROSPER, M. D.: a celebrated Italian botanist; b. at Marostica, in the Venetian state, Nov. 23, 1553. Having passed several years in Egypt, he published in Latin a work on *The Plants of Egypt* (1591), and obtained a chair of botany at Padua in 1593. He made important contributions to the science of botany. Among his works is one on *Exotic Plants*. D. at Padua, Feb. 5, 1617.

Alps [Lat. *Alpes*, Fr. *Alpes*, Ger. *Alpen*, etymology uncertain]: the most remarkable system of mountains in Europe as regards both extent and elevation. They may be said to extend from the Mediterranean between Marseilles and Nice irregularly eastward to near 18° E. lon. and 45° 30' N. lat. They form a crescent-shaped chain, and stretching across the country cover a part of France, the greater part of Switzerland, and a considerable portion of Northern Italy and Austria. They culminate in Mont Blanc, and form the watershed or dividing line between the rivers that flow into the Mediterranean and those which discharge their waters into the German Ocean and Black Sea. Several important rivers of Europe take their rise in Alpine valleys: the largest are the Rhine and the Rhône. This system of mountains is included between the parallels of 44° and 48° N. lat. and 6° 40' and 18° E. lon., and covers an area of about 95,700 sq. miles. It is estimated that the Alps, with their various windings, have an extent from W. to E. of about 700 miles, and a breadth varying from 50 to 200 miles. The bases of the northern and the southern sides are encircled by an extensive series of lakes, those on the former side being from 1,200 to 1,500 and those on the latter from 600 to 700 feet above the level of the sea, while in the interior some are found at an elevation of 6,000 feet. The average height of the central chain is 10,000 feet, being in the region of perpetual snow, while several hundred peaks rise above it to 12,000 and 15,000 feet. From these snowy heights descend the destructive avalanches. In the numerous valleys of these lofty regions are collected the immense quantities of snow which form the long streams of ice called glaciers. (See GLACIERS.) The Alps are generally divided into three parts which are distinguished as the East, the West, and the Middle Alps: I. WEST ALPS.—The principal ranges included within these are: 1. The Maritime Alps, commencing not far from Genoa, extend westerly along the coast of the Mediterranean to near Barcelonette in France, and attain in their highest part an elevation of nearly 10,000 feet. 2. The Cottian Alps, culminating in Monte Viso, 12,600 feet high. 3. The Graian Alps, forming the boundary between Savoy and Piedmont, and rising in Mont Iseran to an elevation of 13,272 feet, and in Mont Cenis to 11,785 feet. II. MIDDLE ALPS. *Central Chain*.—1. The Pennine Alps between the plains of Lombardy and the valley of the Rhône. Their most lofty peaks are: Mont Blanc, 15,781 feet high, and Monte Rosa, 15,217 feet high. 2. The Helvetian Alps, extending from the Pass of the Simplon along St. Gothard (10,000 feet) to the Pass of Splügen. 3. The Rætian Alps, between the Inn, the Adda, and the Upper Adige. *Northern Chain*.—1. Bernese Alps, between the Rhône and the Aar. The highest summits are Finsteraarhorn, 14,026 feet; Jungfran, 13,672 feet; and Schreckhorn, 13,393 feet high. *Southern Chain*.—1. Oertler Alps, between the Adda and the Adige, the highest peak being Oertlerspitze, 12,823 feet high. 2. The Tridentine Alps, between the Adige and the Piave. III. EAST ALPS.—The principal chains of these are: 1. The Noric Alps, highest summit Gross-Glockner, 12,957 feet high. 2. The Carnic Alps. 3. The Julian Alps. 4. The Dinaric Alps. Generally speaking, the Alps are lowest where the system is broadest, and highest where the system is narrowest.

The passes over the Alps are called in French, *cols*. They are about sixteen in number, and now most of them can safely be traveled over by carriages. One of the most noteworthy is the Great St. Bernard, connecting the valley of the Rhône with Piedmont. It was crossed by Napoleon in 1800. Its highest summit is about 8,170 feet. The Little St. Bernard connects Geneva, Savoy, and Piedmont. This is the pass by which some suppose Hannibal to have crossed into Italy. Its highest point is about 7,190 feet above the level of the sea, and is now but little used. The Splügen Pass, connecting the sources of the Rhine with the Adda, was used by the Romans in their intercourse with the countries bordering on the Danube and the Rhine, by the Germans in the Middle Ages, as well as by modern tourists. In some places bridges, terraces, and long galleries are constructed of stone to afford protection against the avalanche and whirlwinds. The latter are not only destructive in themselves, but frequently set the former in motion. The Alps, with the exception of Switzerland, are rich in minerals, and offer one of the finest fields in the world for the geologist. It has been shown that the highest central mass, the primary Alps, consists chiefly of the crystalline rocks, gneiss and mica-slate, with a small proportion of granite. Representatives of the carboniferous and Jurassic formation appear among the Central Alps. In the Pennine, Graian,

and Rhaetian Alps are found large masses of serpentine. Quartz-porphry is found in the N. of Piedmont and in the upper valley of the Adige; and in the E. of Piedmont on the N. and S. sides of the chief range extensive deposits of clay-slate and grauwacke, mixed with transition limestone, occur. Precious stones are found in considerable numbers. Among these is the well-known rock crystal of St. Gothard. Most of the mining and smelting is done in the eastern part of the Alps; gold and silver are found in Tyrol, Salzburg, and Carinthia; copper exists in the French Alps, in Tyrol, and in Styria. The amount of iron and lead extracted from the mines of Carinthia and Styria is about 745,000 cwt. per annum. Large quantities of quicksilver are extracted from the mines in Carniola. Salt exists in almost every part. Coal is found in abundance in Switzerland and Savoy, and hot springs are numerous. Many animals inhabit the Alps. Among them are the chamois, the ibex, marmots, wolves, bears, lynxes, wild cats, and various species of birds. Of the domestic animals goats and oxen abound, but horses, sheep, dogs, etc., are found in small numbers. Fish are found in some of the lakes at an elevation of 6,000 feet. The inhabitants of the Alps are industrious and simple hearted, but the spirit and manners of the neighboring plains have penetrated the larger valleys; the true Alpine life has passed away, and the simplicity and characteristic industry of the Alpine farms are now preserved only in the higher valleys.

A. GUYOT.

Alpujarras, al-pōo-char'as: a mountain region or range of Spain; in Granada between the Sierra Nevada and the Mediterranean. The direction of the range is nearly parallel to the seacoast. The highest peaks rise to the altitude of about 7,000 feet. Rich pastures abound on the slopes and in the valleys of the northern side of the range.

Alrau'neu, or **Alru'næ**: a name given by the ancient Germans to certain prophetic women who were employed in sacrificing victims, and were supposed to have magical or supernatural skill. Also applied to small images carved out of mandrake roots, and exhibiting a rude imitation of the human form. These were venerated or superstitiously prized by the Germans and other northern nations.

Alsace, al-saās' [Ger. *Elsass*, i. e. the country of the "Sassen" (settlers) on the Ill; Lat. *Alsatia*]: a part of the German empire, but for centuries a bone of contention between France and Germany, the French always trying to push their eastern frontier to the Rhine as the natural boundary line, and the Germans to prevent them: bounded E. by the Rhine, S. by Switzerland, and W. by the Vosges Mountains, which separate it from France. Area, 3,236 sq. miles. It was ceded to France by the Emperor of Austria in 1648, and became a province of that country. After the division of France into departments, about 1790, it formed the departments of Haut Rhin and Bas Rhin (upper and lower Rhine), which in 1866 contained a population of 1,119,255. Chief towns, Strassburg, Colmar, and Mülhausen. After the German armies had defeated and captured Napoleon III. in 1870, Bismarck and his king insisted on the annexation of Alsace to Germany as one of the conditions of peace. The French therefore continued to fight for it, but at last they were compelled to cede it (with the exception of the fortress Belfort and its *rayon*) by the treaty of May 10, 1871. Pop. (1890) 1,093,114. Revised by C. K. ADAMS.

-Alsace-Lorraine, al-saās' lor-rān' (Ger. *Elsass-Lothringen*): a new division of Germany formed of those portions of Alsace and Lorraine which in 1871 were ceded by France to Germany. It has not been annexed to any particular German state, but it is a Reichsland (imperial land), immediately subject to the emperor. Area, 5,668 sq. miles. It is divided into three districts (Bezirke)—Ober-Elsass, Unter-Elsass, and Lothringen. The first corresponds to the former French department of Haut Rhin, the second to the former French department of Bas Rhin, while the third contains all the territory which has been ceded of the French departments of Moselle, Meurthe, and Vosges. The districts have been subdivided into circles (Kreise), which in extent do not correspond with the former French arrondissements. Ober-Elsass contains six, Unter-Elsass eight, and Lothringen eight circles. Pop. (1890) 1,603,506.

It is estimated that of the population 1,393,000 are of German origin and 210,000 of French origin. Of the latter, 180,000 belong to Lothringen, and 15,000 to Ober-Elsass and Unter-Elsass each. Over 77 per cent. of the population profess the Roman Catholic religion, which in Elsass-Lothringen is more predominant than in any other German

state; Bavaria, the next in order, numbering less than 71 per cent. of Catholics. The legislative functions are exercised by the German Reichstag, in which Elsass-Lothringen is represented by fifteen members. At the head of the administration is the Statthalter, Prince Hohenlohe-Schillingsfürst, appointed by the emperor. The revenue and expenditure for the year ending March 31, 1892, were each estimated at 49,990,732 marks. The public debt is equivalent to 25,799,400 marks. At the time when the country was ceded to Germany 770 km. (1 km. = 0.62 English miles) of railroads were in operation, which, with a few exceptions, belonged to the Société des Chemins de Fer de l'Est, from which the German empire bought them for 325,000,000 francs. In 1891 there were 824 miles of railway, of which all but eleven belonged to the state. The navigable rivers are the Rhine, Ill, Moder, Saar, and Moselle. The soil is fertile and rich in mines of iron, copper, and coal. The chief productions of the soil are grain, wine, beet-root, tobacco, madder, and linseed. Mülhausen (Mulhouse) is the seat of important manufactures of cotton prints, muslins, flowered silk stuffs, linen damasks, etc. Capital, Strassburg. Revised by C. K. ADAMS.

Alsa'tia: a name formerly given to Whitefriars, London, which was used as a sanctuary by criminals in the early part of the seventeenth century. This privilege, owing to disgraceful abuses of it, was abolished by an act passed in 1697. See WHITEFRIARS.

Al Se'gno (Ital. to the sign): in music, a notice to a performer that he must return and commence again that part of the movement to which the sign :S: is prefixed.

Al'sen: an island belonging to the Prussian province of Schleswig-Holstein, in the Baltic, near the coast of Schleswig; 18 miles long, and has an area of 124 sq. miles (see map of German Empire, 1-E). It is remarkable for its picturesque and beautiful scenery, is very fertile, and produces excellent apples. Christian II. of Denmark, who was deposed in 1523, was imprisoned here for nearly seventeen years. Pop. 24,000.

Al Sirat' (literally the road or passage): a bridge as narrow as the edge of a razor, supposed by the Mohammedans to extend from this world over hell to paradise.

Alsop, RICHARD: poet and scholar; b. at Middletown, Conn., Jan. 23, 1761; was versed in Greek, Latin, French, and other languages. In conjunction with Theodore Dwight and others, he edited the *Echo*, a satirical publication, the first number of which was issued at Hartford in 1791. He published a *Monody on the Death of Washington* (1800), and translated from the Spanish Molina's *Natural and Civil History of Chili*. D. at Flatbush, L. I., N. Y., Aug. 20, 1815.

Alstrœme'ria: a genus of plants of the family *Amaryllidaceæ*, natives of Peru and Chili. Several species of this genus have beautiful flowers, and are cultivated in gardens. The tubers of the *Alstrœmeria salsilla* are cultivated for food in the West Indies.

Al'strömer, or **Alstrœmer**, KLAUDIUS or KLAS: Swedish naturalist; b. at Alingsås, Aug. 9, 1736. He was a pupil of Linnaeus, who named in his honor a genus of plants, *Alstrœmeria*. He traveled in Spain and other countries, and published a *Discourse on the Breeding of Fine-wooled Sheep* (1770). D. Mar. 5, 1796.

Altai, aāl-tī': a group of mountains in Central Asia; between Jungaria (Northwest Mongolia) and West Siberia, extending from the T'ien Shan to the Yenisei river, consisting of a series of parallel ranges running nearly E. and W. The principal individual ranges, beginning at the S., are the Alatan, the Tarhagatai, the little Altai, and the Altai proper, the latter continued eastward into Mongolia under the name of the Tannu-ola Mountains. The great Siberian rivers, the Obi, Irtish, and Yenisei, rise on the northern side of these mountains, and, although not very lofty, they are said to be very picturesque. They are rich in mineral products, especially gold, silver, copper, and iron. The area covered by perpetual snow is considerable, and there are many glaciers, which, however, rarely extend beyond the snow-line. M. W. H.

Altamaha': a river of Georgia, formed by the union of the Oconee and Ocmulgee in the central part of the State. Flowing southeastward through sandy plains, it enters the Atlantic 12 miles below Darien, after a course of about 140 miles. It is navigable for vessels of 30 tons.

Altamont: Effingham co., Ill. (for location of county, see map of Illinois, ref. 8-F); at foot of the Mound (old Government signal station); the highest point between Terre Haute and St. Louis; 88 miles from either place; at the crossing of O. and M. and Van lines, and terminus of Wabash and C. and N. O. R. Rs.; was laid out in 1870; is a grain and fruit shipping point; has 5 schools, 7 churches, 10 different factories, 2 flouring-mills, 2 elevators, 4 hotels, creamery, etc. Pop. (1880) 650; (1890) 1,044; (1900) 1,335.

EDITOR OF "NEWS."

Altamu'ra: a handsome cathedral town of Southern Italy; province of Bari; at the foot of the Apennines; 33 miles S. W. of Bari (see map of Italy, ref. 7-G). It is defended by a castle, and has a fine cathedral. It was formerly the seat of a university. Here is the site of the ancient *Lupatia*. Pop. 20,841.

Alt'ar: an elevated place or table on which sacrifice is offered. The first altar mentioned in history was built by Noah immediately after the Flood. Altars were sometimes erected as memorials of some great event by the religious personages of sacred history. The ancient Greeks and Romans used a great number of altars, each of which was dedicated to some particular deity. They were constructed of different materials and in various forms. In the Christian Church the term "altar" is applied to the table-like construction, whether of wood, stone, or marble, upon which the Eucharist is offered. There are wooden altars existing in the churches of St. John Lateran, "the mother of churches," and St. Praxedes at Rome. Pope St. Sixtus II. is said to have erected the first stone altar, A. D. 257. St. Wolstan is believed to have introduced stone altars into England, where before, as in the Eastern Church, they were generally of wood. Of old, as in the Greek Church now, there was but one altar in a church; the addition of others being comparatively of late introduction. In the first Prayer-Book of King Edward VI. the altar was called "God's board." The words "holy table" appear in the place of "altar" in the Prayer-Books of the English and American churches. In fact, in these Prayer-Books the word "altar" is not found at all. It occurs, indeed, in the American "Office of Institution of Ministers into Parishes or Churches," where it includes the whole sanctuary. The Lutheran Church retains the altar. An altar was a sanctuary both among the Jews and the heathen for those who fled to it for refuge.

Revised by W. S. PERRY.

Altaz'imuth: the name given by Prof. Airy, late astronomer-royal of England, to an instrument formerly known as the "altitude and azimuth instrument." Its purpose is to determine both the altitude and the azimuth (*q. v.*) of a heavenly body, and therefore the exact position of the body relative to the horizon, and to a N. and S. line, at any required moment. It consists essentially of a telescope turning upon a horizontal axis, like a meridian circle, having attached to it a vertical, graduated circle. But the base of the instrument, instead of being fixed, turns upon a vertical axis. There is also a horizontal circle, by which the azimuth of the instrument, as it turns on this vertical axis, can be determined. Both circles being read, the horizontal circle shows the azimuth of the body on which the telescope is pointed, and the vertical circle shows its altitude, or zenith distance. It was constructed by Sir George Airy for the purpose of observing the position of the moon when it could not be seen on the meridian. The instrument is not, however, of extensive use in astronomy, since the work of both making and reducing the observations is extremely laborious, and the results not so accurate as those made with an instrument fixed in the meridian.

S. NEWCOMB.

Alt'dorf (i. e. old village), or **Alt'torf:** a town of Bavaria; on the river Schwarzbach; 13 miles E. S. E. of Nuremberg; had a university from 1623 to 1809 (see map of German Empire, ref. 6-E). Pop. 3,106.

Altdorf (Switzerland): See ALTORF.

Alt'dorfer, ALBRECHT: German painter and engraver; a pupil of Albert Dürer; b. at Altdorf, in Bavaria, in 1480. A painting of the victory of Alexander over Darius, now in the Pinakothek at Munich, is called his masterpiece. He left many engravings on copper and on wood. Died at Regensburg, 1538.

Alt'enburg, SAXE, GERMAN DUCHY OF: See SAXE-ALTENBURG.

Altenburg (i. e. old castle): a city of Germany; capital of Saxe-Altenburg; 24 miles by rail S. S. E. of Leip-

zig (see map of German Empire, ref. 5-F). It is the seat of the higher courts, and contains seven churches, one theater, and several hospitals. Linen goods, brandy, porcelain, and optical instruments are made here. Pop. (1880) 26,241; (1890) 31,439.

Altenes'sen (i. e. old Essen): a suburb of Essen, Rhenish Prussia, 2 miles distant (see map of German Empire, ref. 4-C). It has large iron-works, with coal mines near by. Pop. 17,350.

Altengaard: a seaport-town of Norway; capital of the province of Finmark; on the Alten, at the head of a fiord; 53 miles S. of Hammerfest (see map of Norway and Sweden, ref. 2-II).

Alten Oet'ting (i. e. old Oetting), or **Alt'ötting:** a small town of Bavaria; near the river Inn; 42 miles S. W. of Passau (see map of German Empire, ref. 7-G). It is visited by great numbers of Roman Catholic pilgrims, who are attracted thither by an image of the Virgin Mary, called the "Black Virgin." Several German emperors held their court here in the Middle Ages. Pop. 3,202.

Alt'enstein: a castle in Saxe-Meiningen, Germany, near the watering-place Liebenstein (see map of German Empire, ref. 5-E). Near this castle is the beech-tree where Luther was captured and taken to the Wartburg on May 4, 1521.

Altenstein, KARL, Baron von: a Prussian minister of state; b. at Anspach, Oct. 7, 1770. In 1815 he rendered important services to Germany by the recovery of works of art and literature which the French had removed to Paris. He was appointed Minister of Public Instruction and Worship in 1817, and held that office till Dec., 1838. D. in Berlin, May 14, 1840.

Al'teratives [from the Lat. *altera're*, change]: drugs which so act upon the system as to induce healthy action. The same drugs in large doses may act as decided irritants or poisons, as mercury, iodine, and arsenic.

Al'ter E'go (i. e. my other self): a term used in the former kingdom of Naples to signify the king's deputy, who was authorized to perform the functions of royalty during the compulsory absence of the king.

Alternate Currents (in electricity): When the electro-motive force in any electric circuit undergoes periodic changes of direction and intensity, the current generated by this fluctuating electro-motive force is an "alternate current." The simplest and most important case is that of the current generated by the uniform revolution of a ring or coil in a uniform magnetic field. Here the fluctuations of electro-motive force are given by the equation,

$$e = E \sin \frac{2\pi t}{T},$$

where e is the electro-motive force at any time t ; E is a constant depending upon the size of the coil, the strength of the field, and the rate of revolution; while T is the time of one complete revolution of the coil. These are the conditions existing, with a more or less close approximation, in every properly constructed alternating current dynamo. Under these conditions the electro-motive force follows the law of sines, disappearing every half-revolution of the coil, and reaching maximum values, opposite as to direction, at instants midway between the times of disappearance. The character of the fluctuation is shown graphically in Fig. 1.

FIG. 1.—Curve of sines, showing the usual law of fluctuation in an alternate current circuit.

Now, in any circuit (see ELECTRICITY) the current and electro-motive force tend to rise and fall together, and where there is an alternating electro-motive force the current will undergo the same number of reversals per second, although not always following precisely the same law of change as does the electro-motive force. Owing, moreover, to the presence of induced currents in the circuit, which always impede the rise and retard the fall of current strength, the

curve of current fluctuation (except in certain cases where inductance is absent) will lag behind the curve of electro-motive force, as to time.

Fig. 2 shows curves of electro-motive force and current

FIG. 2.—Curves of alternating E. M. F. and current, from measurements by Messrs. Humphrey and Powell.

from actual measurements, by Messrs. Humphrey and Powell. See *Trans. Am. Inst. of Elec. Engineers*, vol. vi.

The curve of current in this illustration lags through a very considerable angle, and it differs in a striking manner from the curve of electro-motive force.

The great importance which alternating currents have attained is due to their remarkable inductive action. In every piece of metal near an alternating current circuit, alternating currents of similar type are induced. By means of modifications of the ordinary induction coil (see TRANSFORMER), actuated by alternate currents, it has been found possible to transfer electrical energy from one closed circuit to another without serious loss. The electro-motive force can at the same time be raised or lowered through almost infinite range, a matter of the utmost importance in the application of electricity. By raising the electro-motive force, for instance, to 20,000 volts, or even to 30,000 volts, it becomes possible to transfer hundreds of horse-power hundreds of miles, over conductors no larger than an ordinary telegraph wire. By reducing the electro-motive force, on the other hand, to small values, enormous currents are obtained and such processes as welding and smelting by electricity become practicable. See ELECTRIC WELDING. See also DYNAMO ELECTRIC MACHINE and ELECTRO-MAGNETIC INDUCTION, under INDUCTION. For a complete analysis of alternate-current phenomena, see Fleming, *Alternate Current Transformers* (2 vols., Lond.). E. L. NICHOLS.

Alternator (in applied electricity): a machine for the generation of alternate currents. See DYNAMO.

Alternation of Generations: a term used in biology to designate the course of development peculiar to certain groups of animals and plants, in which at least two generations of individuals are necessary to complete the life of the species, one reproducing sexually, the other asexually. In such a case one animal produces an egg—the sexual product. This develops into an individual unlike the parent, incapable of producing eggs, and reproducing only by division or budding—the asexual method. The progeny thus formed develop again into the sexual generation, which produces eggs. These alternating generations frequently differ from each other greatly in appearance and structure, and have often been classed in different groups before their relation to each other has been recognized. Sometimes the sexual, sometimes the asexual, generation is the longer-lived and more conspicuous.

Among the hydroids the egg develops into a polyp—a cup-shaped animal attached by the closed end. A much-repeated process of budding now occurs, the individuals thus produced cohering to form a finely branched colony, moss-like or tree-like in appearance, and frequently mistaken for a seaweed. Most of the polyps thus asexually formed remain sterile, but certain ones detach themselves, develop into small, free-swimming medusæ which greatly resemble the larger jellyfishes, finally form and distribute the eggs, and thus complete the cycle. DAVID S. JORDAN.

Alternation of Generations (in plants): In the moss-worts (*Bryophytes*) the thallus, or leafy plant, bears sexual organs; after fertilization of the egg-cell, a new plant-body is produced, in which are eventually developed the spores; from the latter may be produced the thallus, or leafy plant, again, and so on. We have here two generations which alternate with one another, viz. (1) the sexual generation (*gametophyte*), and (2) the asexual generation (*sporophyte*). In the fern-worts (*Pteridophytes*), the thallus (prothallium) bears sexual organs; after fertilization of the egg-cell a new plant-

body is produced, consisting of root, stem, and leaves, the latter eventually producing spores. The two generations are here very sharply defined: (1) the prothallium (sexual generation, or gametophyte), and (2) the leafy plant (asexual generation, or sporophyte). In flowering plants (*Anthophytes*) the gametophytes are much reduced, and are developed within the ovule and stamen of the sporophyte. In *Gymnosperms* an actual prothallium develops, and this in turn produces sexual cells. In *Angiosperms* the prothallium is more reduced, being represented by the endosperm in the ovule and the vegetative nucleus in the pollen cell. The leafy plant in *Anthophytes* is the sporophyte or asexual generation, while the gametophyte is almost suppressed.

CHARLES E. BESSEY.

Althæ'a [from Gr. *ἀλθαία*, marshmallow]: a genus of plants of the family *Malvaceæ*, natives of Europe and naturalized in the U. S. It includes the hollyhock (*Althæ'a rosea*) and marshmallow (*Althæ'a officinalis*), which is used in medicine as a demulcent or emollient. *Althæa*, or shrubby *althæa*, is also a common name of the *Hibiscus syriacus*.

Althen, EHAN or JEAN: a Persian who gained distinction by introducing Turkey madder into France; b. in 1711; taken captive by the Arabs in his youth, and sold as a slave in Smyrna, whence he escaped to France with seeds of madder, 1761. He made successful experiments in the cultivation of that plant, which was afterward extensively cultivated and became very profitable. D. in 1774.

Althorp, LORD: See SPENCER.

Altin' Nor, or **Altyn' Nor** (i. e. sea of gold), or **Teletskoi**: a lake of Siberia, in the S. part, is about 320 miles S. of Tomsk, and is traversed by one of the head-streams of the Obi. It is about 48 miles long and 8 miles in average width, but its size fluctuates much with the season.

Al'titude [Lat. *altitudo*, from *altus*, high]: a synonym for height. In astronomy, it signifies the apparent height of a star or other body above the horizon—that is, the angle which a line from an observer to the star makes with the plane of the horizon. This altitude is expressed in degrees, the greatest possible altitude being ninety degrees. It is measured in observatories by means of a telescope attached to a graduated circle, which is fixed vertically. The altitude of a triangle is measured by a straight line drawn from the vertex perpendicular to the base; that of a cone or pyramid by a straight line drawn from the vertex perpendicular to the plane of the base.

Al'tmühl: a river of Bavaria; rises near the village of Hornau, flows S. E. and E. and enters the Danube at Kelheim, after a course of 100 miles. The Ludwigs Canal connects this river with the Regnitz, and opens communication between the Danube and the Rhine.

Al'to [Ital. high, i. e. the highest male voice]: in music, the part immediately below the treble, and the deepest and lowest kind of musical voice in females and boys. As the word alto signifies *high*, the apparent discrepancy of this musical usage may be explained as follows: The voice-part referred to was originally sung by a species of high tenor, now apparently becoming extinct in the whole world. Therefore this male voice *was singing high*. The word "alto" has been retained, but the fact remains that the female or boy altos sing in their lower range to produce sounds of the pitch required. DUDLEY BUCK.

Al'ton, RICHARD, Count of: b. in Ireland in 1732; became a general in the Austrian service, and commanded in the Low Countries at the commencement of the rebellion in 1789. He was obliged to evacuate Brussels, and died in 1790 during his retreat toward Vienna.

Alton: city and important railroad center and port of entry in Madison co., Ill. (for location of county, see map of Illinois, ref. 8-D); on Mississippi river; 21 miles above St. Louis and 5 miles above the mouth of the Missouri. It stands on a high limestone bluff, and is magnificently picturesque. It has important manufactures. Large quantities of grain, hay, fruit, stone, lime, and flour are exported. It has a female seminary and a large Roman Catholic cathedral; an excellent system of public schools, a large number of factories, foundries, glass-works, public library, opera-house, electric lights, etc. The Burlington R. R. is bridging the Mississippi at Alton, and the city is connected by electric railroad with Upper Alton, 2 miles distant. Upper Alton is the seat of Shurtleff College. Pop. (1880) 8,975; (1890) 10,294; (1900) 14,210. EDITOR OF "SENTINEL DEMOCRAT."

Alto Amazonas: See AMAZONAS.

Al'tona: the most populous and important city of the Prussian province of Schleswig-Holstein; on the right bank of the Elbe; immediately adjoining Hamburg (see map of German Empire, ref. 2-E). It is connected by railroad with Kiel, and has an extensive trade by the Elbe. Many of the merchants of Hamburg reside in Altona, which contains an observatory, a gymnasium, and a library of 12,000 volumes or more. Here are important manufactures of tobacco, soap, chemicals, leather, ropes, etc. Altona is a free port, accessible to large vessels. Pop. (1885) 104,719; (1895) 148,944.

Altoona: city, 1,180 feet above sea-level; on Pennsylvania R. R., in Blair co., Pa. (for location of county, see map of Pennsylvania, ref. 5-D); 237 miles W. of Philadelphia, and 117 E. of Pittsburg, at the E. base of the Alleghany Mountains, which the railroad here crosses. It contains the extensive machine-shops of the Pennsylvania R. R., in which locomotives and cars are manufactured, and in which over 5,000 men are employed; large individual car-works, several extensive planing-mills, one large rolling-mill, partly in the city, extensive water-works, costing over \$300,000, an electric street railway, and a mechanics' library, containing about 14,000 volumes. Pop. (1880) 19,710; (1890) 30,337; (1900) 38,973.

EDITOR OF "TRIBUNE."

Alto Orino'co (i. e. the Upper Orinoco): a territory of Venezuela: covering a very large area in the southwestern part of that country, and claimed in part by Brazil. It is bounded on the N. and N. E. by the state of Bolivar, on the S. E. by Brazilian Guiana, on the S. by the territory of Amazonas, and on the W. by Colombia. Area, 119,780 sq. miles. It is crossed by the Orinoco in a nearly N. and S. direction, and is well watered by it and its branches. Its surface consists in part of savannas, in part of heavily wooded tracts. Its population is very sparse, averaging about one to every 5 sq. miles.

M. W. II.

Alt'orf, or **Alt'dorf** (i. e. old village): a town of Switzerland; capital of the canton of Uri; near the S. extremity of the Lake of Lucerne, and at the foot of the Grunberg (see map of Switzerland, ref. 4-G). Here is an old tower said to mark the place where William Tell shot the apple off his son's head. Pop. 2,901.

Alto-rilievo, al-tō-reel-yā'vō: in sculpture, high relief; that is, such sculpture as consists of figures projecting boldly from the background, having half or more than half, their full roundness. In some cases the figures are almost entirely detached from the background. An excellent instance of this kind of work is found in the metopes of Doric temples, as of the Parthenon of Athens. Compare BAS-RELIEF and RELIEF.

RUSSELL STURGIS.

Altran'städt: a town of Saxony, at which Charles XII. of Sweden concluded a treaty with Augustus, Elector of Saxony, in 1706. A treaty was also signed here in 1714 between the Emperor Charles VI. of Germany and Louis XIV. of France.

Altrices, al-tri'ssez: those birds in which the young are hatched in an immature condition, and are reared in the nest and fed by the parents. The higher birds, as sparrows and thrushes, belong to this group, which is, however, no longer used in classification.

Al'tringham: a market-town of England; in Cheshire; on the Cheshire Midland R. R. and on Bowden Downs, 8 miles by rail S. W. of Manchester (see map of England, ref. 7-G). It has some cotton-factories and is a resort for invalids, because of the salubrity of the air. Pop. about 12,000.

Al'truism: a term applied by the French positivist Comte to denote the benevolent instincts of man as distinguished from *egoism*, or the selfish instincts. In the philosophy of Herbert Spencer, as set forth in the *Data of Ethics*, *altruism* is recognized as an essential element of all organized society. In modern political economy also the same instinct is sometimes presented and urged as an element that necessarily under certain conditions modifies the force of the strict utilitarian doctrines that were formerly considered as the sole basis of that science.

C. K. ADAMS.

Al'udel [from Arabic *al-uthāl*; from *al-*, the + *uthāl* or *ithāl*, pl. of *athla*, a utensil]: one of several pear-shaped glass or earthen vessels used as receivers in the distillation of certain substances, especially mercury and hydrochloric acid. They are generally arranged in the form of a chain on an inclined surface.

Al'um [O. Fr. *alum*, Lat. *alu'men*]: a double salt of great importance, the chemical name of which is aluminium-potas-

sium sulphate. It occurs in colorless octahedral crystals, having a sweet astringent taste. It is a powerful styptic, and is applied sometimes as a mild caustic. Its formula is $AlK(SO_4)_2 + 12H_2O$. Alum is largely manufactured, and is much used in preparing skins, as a mordant in calico-printing, and in glazing paper, and occasionally for the adulteration of bread.

Ammonia alum, $Al(NH_4)(SO_4)_2 + 12H_2O$, containing ammonium in place of potassium, has of late largely replaced potash alum in the arts, owing to the low cost of the ammoniac sulphate prepared from gas-liquor. The term alum is now applied to a class of isomorphous double sulphates resembling ordinary alum very closely. In these, in place of the element aluminium contained in ordinary alum, there may be iron, chromium, manganese, etc., and in place of the potassium there may be sodium, ammonium, lithium, calcium, rubidium, etc. Next to the alums above mentioned, the most common is chrome alum, $CrK(SO_4)_2 + 12H_2O$. Ammonio-ferric alum is used in medicine and the arts.

Revised by IRA REMSEN.

Al'umbagh: a fort in Oude; about 4 miles from Lucknow (see map of N. India, ref. 6-F); was originally a palace surrounded by a fine garden and a park. During the mutiny of 1857 it was used as a fort by the Sepoys, from whom it was taken by the British under Outram and Havelock. It was afterward defended with success by Sir James Outram and a garrison of 3,500 men against the Sepoys.

Alungir, or **Alamgir:** See AURUNGZEBE.

Alu'mina: the oxide of aluminium, the most abundant of all the earths, and the principal constituent of clay. In 100 lb. of alumina there are 52.94 of aluminium and 47.06 of oxygen. Its symbol is Al_2O_3 . In its common state this earth is a soft white powder, without taste, and in the crystalline form it occurs as sapphire and ruby, two of the hardest and most valuable of the precious stones. An impure alumina, which is found in the islands of the Grecian Archipelago, Asia Minor, and Chester, Mass., is the emery used as a polishing-powder for glass and metals, on account of its hardness. The clay of arable land is mostly produced by the disintegration of felspar, which is a compound of alumina, potash, and silica. Alumina has two properties which render it of great importance in the useful arts: one is that its silicate forms with water a plastic material adapted for pottery; the other is its strong affinity for coloring and extractive matter, by which it is useful as a mordant in printing calico and in dyeing.

Aluminium, or **Alu'minum** (chemical symbol Al; atomic weight 27.04): an element; one of the most widely distributed constituents of the earth, occurring in a number of forms of combination. Among the best known minerals which contain it are the *feldspars*, silicates of aluminium and potassium or sodium; *cryolite*, a fluoride of aluminium and sodium; *bauxite*, the oxide together with ferric oxide; *corundum*, *emery*, *sapphire*, and *ruby*, which are forms of the oxide, Al_2O_3 ; *topaz*, a silicate containing silicon fluoride; *garnets*, silicates containing iron, magnesia, lime, etc. It is, however, most abundant in the different varieties of clay in which it is present as silicate.

History.—Wöhler first isolated aluminium in 1827 by decomposing aluminium chloride by potassium, obtaining it in the form of a gray powder. Later, in 1845, he obtained small malleable globules, but it was not until 1854 that H. St. Claire Deville isolated aluminium in a state of almost perfect purity, and determined its properties. Using first potassium as the reducing agent, he produced it in the same year by electric decomposition, employing the galvanic battery. Bunsen having made the latter discovery simultaneously. Toward the middle of 1854 Deville turned to sodium as the reducing agent, and developed the method to such perfection that it changed but little until the perfection of modern dynamos gave the electrolytic process economic pre-eminence. Deville's experiments attracted the attention of Napoleon III., at whose expense industrial work began at Javel. Meanwhile, in 1855, C. and A. Tissier started works at Amfreville-la-mi-Voie, near Rouen. Deville installed a plant at Nanterre, which was subsequently removed to Salindres, finally getting into the hands of Pechiney & Co., who until recent years enjoyed the reputation not only of making the best, but also the largest amount of aluminium produced in the world. In 1856 Alfred Monnier made some aluminium at Camden, N. J., exhibiting the product at the Franklin Institute, Philadelphia. In England the first aluminium works were started at Battersea, near Lon-

don, and in 1860 Bell Bros. began its manufacture at Newcastle-on-Tyne, continuing operations until 1874. Until 1882 the French company at Salindres was the only concern making aluminium, progress until that time being confined to the cheapening of the cost of production by improvement in details of process and apparatus. The price, which was \$28 to \$32 per lb. in 1857, had declined to \$17 per lb. in 1860, and ranged from \$12 per lb. and upward, according to purity, from 1862-87. James Webster in 1882 developed a process for the cheaper production of alumina and its conversion into chloride, with which was coupled a method, invented in 1886 by H. Y. Castner, of New York, for the manufacture of sodium, which lowered the cost of sodium from \$1 per lb. to about 20 or 25 cents. He reduces sodium compounds by means of a carbide of iron. In 1888 a plant was started under the name of the Aluminium Co., Limited, at Oldbury, near Birmingham, England, with a capacity of 100,000 lb. of aluminium annually. Another innovation upon the Deville sodium process was that of the Alliance Aluminium Co., whose works at Wallsend-on-Tyne, England, were also started in 1888. The methods are those of Dr. Netto, who produced metallic sodium cheaply by allowing fused caustic soda to trickle over incandescent charcoal in a vertical retort. He employed the fluoride or the double fluoride of aluminium and sodium as the compound to be reduced instead of the chloride or the double chloride of aluminium. Promising as they were, the modern improvements of the Deville sodium process have given way to the electrolytic methods developed during the past few years as the result of the great advances made in dynamo-electric machinery. Since the experimental work done simultaneously in 1854 by Deville and Bunsen, a series of proposals to produce aluminium by electrolytic methods were made by Le Chatelier in 1861, Monckton in 1862, Gaudin in 1869, Kagenbusch in 1872, Berthaut in 1879, and Grätzel in 1883. Only the last named appears to have been tried on an industrial scale at the Aluminium und Magnesium Fabrik, at Hemelingen, near Bremen, Germany, where it has since been superseded by secret methods devised by Saarburger, the manager of the works, which in 1888 were reputed to be producing at the rate of 12,000 kgr. of the metal annually. In 1886 Dr. Ed. Kleiner brought forward a process for electrolyzing molten cryolite by passing a current between two carbon poles, which was put in operation in an experimental plant at the Hope Mills, Tyldesley, Lancashire. It was experimented with by the Société Métallurgique Suisse, at Neuhausen, near Schaffhausen on the Rhine, but was abandoned in favor of the Heroult process. In the U. S. the first claimant for the honor of having manufactured aluminium on a commercial scale was William Frishmuth, of Philadelphia, who, in 1884, professed to have produced the metal used in the manufacture of the aluminium cap of the Washington monument. An epoch in the aluminium industry was created by the invention in 1885, by E. H. and A. H. Cowles, of Cleveland, of the electric furnace and the process for manufacturing aluminium alloys. A plant was established at Lockport, N. Y., and subsequently at Stoke-on-Trent, England, while the subsequent rolling of the alloys into sheets, wire, and rods is carried out at the Aluminium Brass and Bronze Co., Bridgeport, Conn., organized in 1887. The most notable advance in the production of the pure metal was, however, made by the invention of Charles M. Hall, whose process was established on a manufacturing scale in 1888 by the Pittsburg Reduction Co. In 1891 the same concern built a larger works at Kensington, near Pittsburg, and a branch establishment at Patricroft, Lancashire, England, in 1890. The American Aluminium Co., of Milwaukee, Wis., was formed in 1887 to manufacture by the process of A. J. Rogers, a small experimental plant having been put up in 1888. In a tentative way there has been work also in this country at Bridgeport, Conn., and later at Boonton, N. J., with the Heroult process, which is being used for the manufacture of aluminium alloys on a large scale at Neuhausen, and at Froges, Isère, France. Bernard Bros., at Creil, Oise, France, use the Minet process, which consists in electrolyzing a mixture of sodium chloride with aluminium fluoride, or with the double fluoride of sodium and aluminium. They are putting on the market metal of good quality.

The Manufacture of Aluminium.—Beauxite and cryolite are the minerals most used as raw materials, corundum being so valuable for other purposes that it is not used as an aluminium ore. Clay or kaolin is not available, because the large amount of silica it contains is much more easily reduced than its alumina. Beauxite, $H^6Al^2O^6$, is a mineral

first found near Beaux, large deposits occurring in the departments of Var and Bouches-du-Rhône, France. Important beds have also been discovered at Wochein, Styria; at Freisstritz, Austria; at a number of points in Ireland, and in abundance in the South, in Tennessee, Virginia, North and South Carolina, Georgia, Alabama, and Arkansas. Cryolite ($Al^2F_1^6, 6NaF$) is mined in large quantities by the Pennsylvania Salt Co. at Ivigtuk, on the west coast of Greenland. The beauxite must be purified, to get rid of silica and iron. It is calcined at a low temperature with sufficient sodium carbonate to form sodium aluminate. The incinerated mass is ground and lixiviated in hot water, dissolving the sodium aluminate, and leaving the silica and iron compounds as a residue. From the sodium aluminate solution the alumina is precipitated with carbonic acid gas. From cryolite alumina is obtained by incinerating a finely ground mixture of cryolite with chalk and coke. From the soluble aluminate of soda formed the alumina is precipitated in the same manner. Upon the purity of the alumina thus obtained depends the quality of metal produced by the electrolytic methods now almost exclusively employed.

As described by A. E. Hunt, president of the Pittsburg Reduction Co., the Hall process consists in electrolyzing alumina dissolved in a fused mixture of fluorides of aluminium and sodium, or of fluorides of aluminium and potassium. The mixture of fluoride salts is placed in a row of carbon-lined iron tanks placed in series. The pots, together with their carbon linings and the reduced metal in the bottom of the pots, become the negative electrodes, or cathodes. The positive electrodes, or anodes, are a series of 3-inch diameter carbon cylinders attached to the copper conductors. The current of 5,000 ampères and 50 volts in one series, and of 2,000 ampères and 20 volts in the other series, is turned on, and the mixture is melted by the heat caused by the resistance offered to the current by the fluoride mixture. In less than two hours' time the mixture becomes fluid, and alumina is added. The electrolyte then becomes a much better conductor, the resistance goes down to a normal one of about 8 volts, and the operation of electrolysis commences. The heat is retained in the molten bath by a covering of finely powdered carbon, on top of which the alumina is placed. When the voltmeter attached to each pot shows a rising resistance, more heated ore from the surface of the pot is stirred in. The light metal accumulates in the bottom of the pot, and may be tapped off while the feeding is made continuous. Thus the pots are run for months at a time, the wasting carbons being replaced by fresh ones from time to time.

Properties.—Commercial aluminium is never chemically pure, and displays properties varying more or less from those of the pure metal. The impurities most frequently met with are combined and graphitoid silicon, iron, copper, sodium, and lead. The following table, compiled by A. E. Hunt, gives a series of analyses:

COMPOSITION OF VARIOUS COMMERCIAL ALUMINIUMS.

ALUMINIUM METAL MADE BY THE	Per cent. of aluminium.	Per cent. of combined silicon.	Per cent. of graphitoid silicon.	Per cent. of iron.	Per cent. of copper.	Per cent. of sodium.	Per cent. of lead.

That even greater purity is attainable is shown by the fact that metal with 99.92 per cent. aluminium has been commercially made.

The most striking property of aluminium is its lightness, Deville having determined the specific gravity of the chemically pure metal as 2.60, while Mallet makes it 2.583. John W. Langley ascertained that an aluminium casting $\frac{3}{4}$ inch thick, the metal carrying 98.52 per cent. of aluminium, had a density of 2.587, while the same material, a $\frac{3}{8}$ -inch round rod, had a specific gravity of 2.703. Taking the specific gravity of aluminium as one, soft steel is nearly 2.95 times, copper 3.6 times, ordinary high brass 3.45 times, silver 4 times, lead 4.8 times, and gold 7.7 times as heavy. Many extravagant and erroneous claims have been based on the lightness of aluminium for its use as a structural material, coupled often with assertions relating to very low cost of production. Aluminium is not, section for section, comparatively a very strong metal. It is only about as strong under tensile strain, section for section, as cast iron, and has less than one-half the strength of wrought iron under ordinary conditions. Under compression the metal has a very low elastic limit, although its extreme ductility allows the metal to flow on itself so freely as to make it for special purposes a very safe metal to use in compression. Alfred E. Hunt, John W. Langley, and Charles M. Hall, in a paper read before the American Institute of Mining Engineers, vol. xiii., summarize its mechanical properties as follows:

AVERAGE TENSILE AND COMPRESSION TESTS OF COMMERCIAL ALUMINIUM.

		Pounds.
Elastic limit per square inch in tension,	Castings	6,500
" " " "	Sheet	12,000
" " " "	Wire	16,000-30,000
" " " "	Bars	14,000
Ultimate strength per square inch in tension,	Castings	15,000
" " " "	Sheet	24,000
" " " "	Wire	30,000-65,000
" " " "	Bars	28,000
		Per cent.
Percentage of reduction of area in tension,	Castings	15
" " " "	Sheet	35
" " " "	Wire	60
" " " "	Bars	40
		Pounds.
Elastic limit per square inch under compression in cylinders, with length twice the diameter		3,500
Ultimate strength per square inch under compression in cylinders, with length twice the diameter		12,000
The modulus of elasticity of cast aluminium is about 11,000,000.		
The modulus of elasticity of cold-drawn aluminium wire is about 19,000,000.		
The modulus of elasticity of aluminium sheets and bars is about 13,000,000.		

Under transverse stress aluminium is not a very rigid metal.

Pure aluminium is white with a decided bluish tint, which becomes much more marked upon exposure, when a thin film of white oxide on its surface prevents further tarnishing from the air, but seems to give by contrast to the metal as a background an enhanced bluish tint. The metal fuses at about 1,300° F., but becomes pasty at a temperature of about 1,000° F. The specific heat is 0.2143, and its coefficient of linear expansion is 0.000206 per degree centigrade. Placing the electrical conductivity of silver at 100, commercial aluminium has a conductivity of about 50. It exhibits no appreciable polarity. Annealed aluminium has a thermal conductivity of 38.87, and unannealed of 37.96, referred to silver at 100. It can be welded readily electrically. It has been successfully soldered by the use of pure zinc and Venetian turpentine. Pure aluminium, when properly treated, is a very malleable and ductile metal, being most malleable at between 200° and 300° F. Both malleability and ductility are greatly impaired by the presence of the two common impurities, silicon and iron. Aluminium can readily be rolled into sheets $\frac{1}{10000}$ of an inch thick, can be beaten into leaf nearly as thin as gold-leaf, and can be drawn into the finest wire. In working it must be frequently annealed, which is best accomplished at a temperature of about 800° F. By hardening the metal by rolling, forging, stamping, or drawing, it may be turned out very rigid, and is then suitable for many purposes for which the annealed metal would be too soft or too weak.

Aluminium can be readily cast in dry sand molds without fluxes. It should not be heated much above the melting-point. It flows readily, but shrinks more than brass, the shrinkage being about 2.26 per cent. of the length of the mold.

The metal is not acted upon by carbonic acid, carbonic oxide, or sulphuretted hydrogen. It withstands better than silver the action of organic secretions, and is therefore widely

used for surgical instruments and apparatus. It is less acted upon than tin, copper, or silver, by salt water, and by such solutions in vinegar as the metal is likely to be subjected to in culinary vessels. Hydrochloric acid is the natural solvent, and it is corroded rapidly by the caustic alkalis, chlorine, bromine, iodine, and fluorine.

Aluminium Alloys.—Tissier claims that silver is the metal most useful to improve aluminium, 5 per cent. of silver giving to it increased elasticity and hardness without injuring the malleability of the metal. The alloy is susceptible of a fine polish. While it is predicted that the alloys of silver and aluminium will have a large use in the arts in the future, the most valuable thus far manufactured on a large scale are those of aluminium and copper, the so-called *aluminium-bronzes*. They are alloys of copper containing from 2 to 12 per cent. of aluminium, which possess great strength and ductility, and resist corrosion well. The specific gravity is about 7.7 for 10 per cent. bronze, 8.25 for 5 per cent. bronze, copper being 8.90. The hardness lessens with the percentage of aluminium, while the color changes from a yellowish gold at 10 per cent. to a deep red gold at $2\frac{1}{2}$ per cent. of contained aluminium. The following tests of cast aluminium bronze and brass were made for the U. S. Navy Department by W. H. Harris, chief engineer U. S. N., on specimens 1.87 inches in diameter and 15 inches in length between reference marks:

	APPROXIMATE COMPOSITION.						
	Copper.	Aluminium.	Silicon.	Iron.	Tensile strength, lb. per sq. in.	Elastic limit, lb. per sq. in.	Elongation, per cent.
6½ per cent. cast aluminium-bronze	91.50	6.50	1.75	0.25	60,700	18,000	23.2
Do.....	91.50	6.50	1.75	0.25	67,600	24,000	21.62

Do.....	88.50	9.33	1.66	0.50	69,930	33,000	1.33
Aluminium-brass, cast..	63.00	3.33	0.33	Zinc. 33.33	82,200	60,000	2.33
Do.....	63.00	3.33	0.33	33.33	70,400	70,000	0.4

In forged bars a 10 per cent. aluminium bronze can readily and uniformly be made with 100,000 lb. tensile strength per square inch, an elastic limit of 60,000 lb., and with at least 10 per cent. elongation in 8 inches. The 5 per cent. to 7 per cent. aluminium-bronzes give 70,000 to 80,000 lb. tensile strength, with an elastic limit of over 40,000 lb. per square inch and an elongation of over 30 per cent. in 8 inches. The 5 to 7 per cent. bronzes can be rolled or hammered at a red heat, and can be worked in almost every way that steel can, having the advantage over it of greater combined strength and ductility, and much greater power to withstand corrosion. It is a remarkably rigid metal under transverse strain, and possesses excellent anti-friction qualities. Sound, clean castings of aluminium-bronze can be safely and regularly made, either in sand molds or against chills, if proper precautions are taken.

As a substitute for German silver the Cowles Co. produce what they call "silver-bronze," containing 18 manganese, 1.20 aluminium, 5 silicon, 13 zinc, and 67.5 copper. On small bars it has a tensile strength of about 57,000 lb. and 20 per cent. elongation. Its electrical resistance is about 48 times that of copper and about 37 times that of German silver, considerably greater than that of any other material known which is capable of being drawn into strong, tough wire for resistance coils.

Aluminium in Iron and Steel.—In cast iron, additions of metallic aluminium or of aluminium-iron alloys are occasionally made, the quantity used being from 2 to 5 lb. per ton. It has a similar influence to that of silicon, which is, however, cheaper in the ferro-silicon and high silicon irons used. Additions of aluminium may prove of service where very difficult castings are to be made. The peculiar property of aluminium in reducing the long range of temperature between that at which wrought iron first softens and that at which it becomes fluid has been taken advantage of in the Mitis process of making castings. The widest use of aluminium in the metallurgy of iron is, however, its employ-

ment to improve steel and steel castings, the principal effect being the quieting of the steel in pouring. For open hearth metal the quantity used is 5 to 10 oz. per ton of steel, while for Bessemer metal it should be increased to 7 to 16 oz. It has been found also that aluminium may be made to replace manganesc. The addition of $\frac{1}{4}$ of a lb. of aluminium to 10 tons of spelter in galvanizing has also been found to improve the surface finish of galvanized iron or steel sheets.

LITERATURE.—Joseph W. Richards' *Aluminium, its Properties, Metallurgy, and Alloys* (Phila. 1890); papers by A. E. Hunt, J. W. Langley, T. Sterry Hunt, A. H. Cowles, F. P. Dewey, R. A. Hadfield, and W. J. Keep, in the *Transactions of the American Institute of Mining Engineers*.

CHARLES KIRCHHOFF.

Alum'nus, plu. **Alumni** (fem. sing. **Alum'na**, plu. **Alumnæ**): a Latin word signifying a "foster-child," applied in modern times to the graduates of a university or college, in order to express the relation between them and their ALMA MATER (*g. v.*). In Germany there were at one time institutions called *alumnat*, founded for the gratuitous education of poor boys, termed alumni.

Alum-Root: either of two species of plants, natives of the U. S., the *Gera'nium macula'tum* and the *Heuche'ra america'na*. Their roots are astringent, and are used in medicine. The latter is found in rocky woodlands from Connecticut to Wisconsin and southward.

Alum-Shale, Alum-Slate, or Alum-Schist: a rock consisting of clay, combined with much iron pyrites and some bituminous or carbonaceous matter. From it the alum of commerce is obtained by a double decomposition, induced by burning the alum-schist slowly until its condition is sufficiently changed, leaching, and then adding sulphate of potash or ammonia to the solution.

Al'mnite, or Alum-stone: a mineral found in various localities, which was formerly largely used for the preparation of Roman alum. It is a basic sulphate of aluminium and potassium.

Aln'ta, called also **Alt**: a rapid river of Transylvania, rises in the Carpathian Mountains, flows southward through Wallachia, and enters the Danube at Nicopolis. Length, 341 miles.

Al'va, or Al'ba, FERNANDO ALVAREZ DE TOLEDO, Duke of: Spanish general; b. of a noble Castilian family in 1508. He entered the army in his youth, and accompanied Charles V. in his campaign against the Turks in 1530. In 1547 he gained a decisive victory over the German Protestants at Mühlberg. In 1555-56, as commander-in-chief of the army of Philip II., he defeated the French and papal forces in Italy. As a general he was inclined to pursue a Fabian policy. He was distinguished for cool determination and remorseless cruelty. In 1567 he was sent by Philip II. to the Netherlands with an army of about 10,000 veterans, to suppress the revolt of the Protestants. He established the "Council of Blood," beheaded Count Egmont after a mockery of a trial, and commenced a reign of terror and sanguinary persecutions of persons suspected of heresy. To defend the country against this bloody despotism, William, Prince of Orange, raised an army in 1568, but the Duke of Alva avoided a battle, and by delay compelled William to retire from the contest, because he could not pay his troops. Although Alva defeated or out-generated the Dutch patriots in war, he utterly failed to subdue or pacify them, and he was recalled in 1573. He boasted that he had put to death 18,000 persons in the Netherlands, besides those killed in battle. In 1580 he invaded and conquered Portugal. D. at Thomar, Jan. 12, 1583. See Prescott, *Philip II.* (vol. ii.); Motley, *History of the Dutch Republic*.

Alvarado: city; Johnson co., Tex. (for location of county, see map of Texas, ref. 3-H); on Missouri, Kansas and Texas and Gulf, Colorado and Santa Fé R. Rs., 26 miles S. S. E. of Fort Worth and 40 miles S. W. of Dallas; it has good schools and churches, cotton-gins and mills. It is surrounded by a fine agricultural district; chief staples, corn and cotton. Pop. (1880) 377; (1890) 1,543; (1900) 1,342.

EDITOR OF "BULLETIN."

Alvarado, al'va-raa'tho, ALONZO: a Spanish officer who served under Cortez in Mexico. After its conquest he went to Peru, held high command under Pizarro, and was defeated and taken prisoner by Almagro in 1537. Alvarado was lieutenant-general in the army which subdued Gonzalo Pizarro's rebellion in 1548, and was made captain-general of Peru, but was overcome in 1553 and shortly thereafter died.

Alvara'do, PEDRO, de: a Spanish general and adventurer, b. at Badajos, who removed to America in 1518. He served with distinction under Cortez in the conquest of Mexico, and in 1520 was selected by Cortez to command in the city of Mexico during the absence of his chief, who marched against Narvaez. He conducted a successful expedition against Tehuantepec and Guatemala in 1523, and was appointed Governor of Guatemala. After a voyage to Spain, he led an army across the Andes into the province of Quito, which he found already occupied by Pizarro. This chief induced Alvarado to retire by the payment of a large sum of money. Alvarado was killed in a fight with some natives in New Galicia in 1541.

Alvarenga Peixoto, IGNACIO JOSÉ: Brazilian poet. See PEIXOTO, IGNACIO JOSÉ ALVARENGA.

Alvares de Azevedo, MANOEL ANTONIO: Brazilian poet. See AZEVEDO, MANOEL ANTONIO ALVARES DE.

Alvares, or Alvares Coelho, DIOGO: See CARAMURÚ.

Alvarez, al'va-rez, FRANCISCO: Portuguese priest; b. at Coimbra; went to Abyssinia in 1515 in company with the Portuguese ambassador, Duarte Galvam. He passed about six years in that country, which he explored, and returned to Portugal in 1527. An interesting account of his travels was published in 1540, entitled a *True Account of the Country of Prester John*. D. about 1540.

Alvarez, al'va-reth, Don JOSÉ: Spanish sculptor; b. at Priego, in the province of Córdoba, Apr. 23, 1768. He gained a prize in 1799, after which he pursued his studies in Paris. He removed to Rome, where he passed many years, and was intimate with Canova. Among his works are *Orpheus Sleeping*; *Antilochus and Memnon*; and *Grupo Colossal de Zaragoza*, which represents a scene in the defense of Saragossa. He was appointed court sculptor to Ferdinand VII. D. at Madrid, Nov. 26, 1827.

Alvarez, JUAN: Mexican general; b. in 1790. He was a leader of the insurgents who took arms against Santa Anna in the spring of 1854, and drove him from power in Aug., 1855. Alvarez became President of Mexico in October, but he resigned in December of the same year. During the French invasion of 1863-66 he was one of the most determined opponents of Maximilian and his party. D. in 1863.

Alvarez, Don LUIS: a contemporary genre painter; b. in Spain; pupil of Federico de Madrazo. First-class medal, Paris Exposition, 1889, for his picture *The Chair of Philip II., The Escorial, 1597*. Studios in Paris and Rome.

Alvary, MAX: See the Appendix.

Al'vinczy, or Al'vinzy, JOSEPH, Baron von: an Austrian general; b. in Transylvania, Feb. 1, 1735. He served with distinction in the Seven Years War, and obtained the rank of lieutenant-field-marshal in 1789. In the summer of 1796 he took command of an army of about 55,000 men sent to oppose Bonaparte in Italy. He fought indecisively at Bassano, and was defeated at Arcola Nov. 17, 1796, and at Rivoli Jan. 14, 1797. D. at Ofen, Sept. 25, 1810.

Al'vord, BENJAMIN, A. M.: soldier; b. at Rutland, Vt., Aug. 18, 1813; graduated at West Point 1833; paymaster-general U. S. A. Jan. 1, 1872, and brigadier-general U. S. Vols. April 15, 1862. He served chiefly at frontier posts 1833-34, in the Florida war 1835-37 and 1841-42, engaged at Camp Izard, Olaklikaha, Thlonotosassa, and Big Cypress Swamp, as assistant professor at the Military Academy 1837-39, in Cherokee nation 1839-40, adjutant Fourth Infantry 1840, in military occupation of Texas 1845-46, in the war with Mexico 1846-47, engaged at Palo Alto and Resaca de la Palma (brevet captain), Paso Ovejas, National Bridge, Cerro Gordo (Aug. 15), Las Animas (brevet major), and Huamantla, and, upon being transferred from the infantry to the pay department, as chief paymaster of the department of Oregon 1854-62. In the civil war was in command, as brigadier-general of volunteers, of the district of Oregon. Brevet lieutenant-colonel, colonel, and brigadier-general U. S. A. Aug. 9, 1865, for faithful and meritorious services; then became paymaster in New York city 1865-67, and chief paymaster of the district of Omaha and Nebraska 1867-72; paymaster-general U. S. A., headquarters at Washington, D. C., 1876-80. Author of a memoir on the *Tangencies of Circles and of Spheres* (1855); *The Interpretation of Imaginary Roots in Questions of Maxima and Minima* (1860); and of numerous essays and reviews, 1833-73. Retired June 8, 1880. D. Oct. 17, 1884.

Alvord, HENRY E.: See the Appendix.

Al'war, or **Al'var**: a semi-independent state of India; at the eastern end of Rajputana; S. of Delhi; in lat. 27° and 28° N., and lon. 76° and 77° E. It is of irregular form, and contains about 3,000 sq. miles, with a population of about 800,000. The eastern portion is open and highly cultivated, the western is diversified by hills and peaks which form a continuation of the Aravalli range. These hills are rich in minerals, and abundant iron ore is found close to the surface. Numerous smelting-furnaces give occupation to a large number of people. Copper is also mined, and silver, lead, and sulphur have been found. Capital and principal town, Alwar. Pop. (1891) 52,490. M. W. H.

Alyat'tes: King of Lydia, who ascended the throne about 618 B. C.; the father of Croesus. During a battle between him and Cyaxares of Media an eclipse of the sun occurred, and made such an impression that they ceased fighting and made a treaty of peace. Some astronomers identify this eclipse with that of 610 B. C. D. about 560 B. C.

Al'zei, or **Alzey**: an old city of Germany, in the grand duchy of Hesse, on the Selz; 19 miles S. of Mentz (see map of German Empire, ref. 6-D). It has a Realschule. Alzei and the vicinity form the scene of the events of the *Nibelungenlied*. Pop. 5,922.

Al'zog, **JOHANNES BAPTIST**: German Catholic theologian; b. at Ohlau, in Silesia, in 1808; became in 1853 Professor of Ecclesiastical History at Freiburg, in Germany. His *Manual of Universal Church History* (Handbuch der Universal-kirchengeschichte, Mainz, 1840; 9th ed. 1872, 2 vols.) has been translated into the principal European languages (Eng. trans., Cincinnati, O., 1874-76, 3 vols.). Another important work is his *Patrologie* (Freiburg, 1866, 4th ed. 1888). D. at Freiburg, Feb. 28, 1878.

Amade'us (Ital. *Amedeo* or *Amadeo*): the name of nine counts and dukes of Savoy, the first of whom was a son of Count Humbert, and lived in the eleventh century.—**AMADEUS V.**, the Great, Count of Savoy, a son of Count Thomas II., was b. at Le Bourget, Sept. 4, 1249. He succeeded his uncle Philip in 1285, increased his dominions by marriage, and was the first Prince of Savoy that made any considerable figure in history. D. at Avignon, Oct. 16, 1323.—**AMADEUS VI.**, of Savoy, grandson of the former; b. at Chambéry, Jan. 4, 1334, and became count in 1343. He was an able and successful ruler, defeated the French in battle in 1354, and added a part of Piedmont to his dominions. D. of the plague in Apuleia, Mar. 2, 1383.—**AMADEUS VIII.**, Duke of Savoy; a grandson of the preceding; was b. at Chambéry, Sept. 4, 1383, and succeeded his father in 1391. He received the title of duke from the Emperor Sigismund in 1419. In 1433 he resigned his power to his son Louis, and retired to the monastery of Ripaille. Having a high reputation for wisdom, he was chosen pope by the Council of Basel in 1439, and took the name of Felix V. As Eugenius IV., who had been deposed by that council, was still recognized as pope by a strong party, a schism ensued in the Church. Felix V. resigned the papacy in 1449, and died at Geneva, Jan. 7, 1451.

Amadeus: King of Spain; a son of Victor Emmanuel, King of Italy; was b. May 30, 1845. He received the title of Duke of Aosta, and married, May 30, 1867, Marie Victoire Charlotte, a daughter of the Prince dal Pozzo della Cisterna. On the 16th of Nov., 1870, the Spanish Cortes, by a vote of 191 against 98, elected him King of Spain, the throne of which had been vacant for two years. Amadeus accepted it, and arrived at Madrid Jan. 2, 1871. On Feb. 11, 1873, he abdicated the throne, being unable to maintain order, and the republic was proclaimed. D. at Turin, Jan. 18, 1890.

Am'adis of Gaul (*Amadis de Gaula*): the hero of a celebrated prose romance of chivalry known by the same name. The oldest version extant is the Spanish redaction made by Garcí-Ordoñez de Montalvo about 1470, but some form of the romance was popular in Spain as early as 1350. A Portuguese version by Vasco Lobeira (died about 1400) is lost, and some scholars even deny that it ever existed. In any case, there is no evidence that Montalvo's book is a translation from Lobeira. A French version of Montalvo's redaction, begun by Nicholas de Herberay (died about 1552), greatly extended the popularity of the story. Southey's English translation of Montalvo is judiciously retrenched. The romance had several continuations, and its direct influence on the literature of Europe did not die out till the beginning of the nineteenth century. See E. Binet's *De l'Amadis de Gaule* (Paris, 1873); L. Braunfels's *Kritischer Versuch über Amadis* (Leipzig, 1876). See ROMANCES. G. L. KITTEDGE.

Amador de los Rios. **JOSÉ**: Spanish historian and critic; b. 1818, at Baena; began his serious work with a translation into Spanish of Sismondi's *Littératures du Midi de l'Europe* (1841-42). Established in Madrid, he published his *Estudios políticos y literarios sobre los Judíos de España* (1848). Then, after several critical editions of Spanish authors, he undertook the work for which he is most celebrated, his *Historia crítica de la literatura española*, of which but seven volumes were completed before his death (Madrid, 1861-65). His intention was to give Spain a work like the famous *Histoire littéraire de la France* by the Benedictines. Hence he undertook to trace the literary development of Spain from the earliest times, through the Latin, Gothic, and Saracenic, as well as the Spanish period proper. The task, however, was beyond his strength, or indeed the strength of any single man. Hence the work is, even for the portion completed, too often diffuse and inaccurate. It is, however, still indispensable to students of Spanish literature. He wrote also an *Historia de la villa y corte de Madrid*, and works on the monuments of Seville and Toledo. D. Mar., 1878. A. R. MARSH.

Am'adou, or **German Tinder**: any one of several species of fungi growing on oak and ash trees in Europe. The hard amadou (*Polyporus igniarius*) and the soft amadou (*Polyporus fomentarius*) are used for tinder, and applied to wounds as styptics. Some varieties are prepared for tinder by charging them with saltpeter.

A'mager: a small island of Denmark; adjoining the harbor of Copenhagen; partly occupied by a suburb of that city. Area, 22 sq. miles. Here are gardens which supply that capital with vegetables, and a large chemical factory. Pop. 9,000 (besides suburb Christianshafen), consisting of the descendants of a Dutch colony brought here in 1516, and still retaining many peculiar customs.

Amal'arie; b. in 501; the son of Alaric II., King of the Visigoths; succeeded his father in 507 by the aid of his grandfather Theodoric, King of the Ostrogoths, and married in 527 Clotilde, a daughter of Clovis, King of the Franks, but in order to compel her to embrace Arianism he treated her so cruelly that her brother Childebert came to her rescue with a great army in 531. Amalarie was defeated and slain, and Theudis succeeded him as King of the Visigoths, while Clotilde returned with her brother to the land of the Franks, where she died shortly after.

Amala'rius Fortunatus: Archbishop of Treves; sent by Charlemagne in 811 A. D. to diffuse Christianity among the Saxons, and established the first church at Hamburg. D. in 814 A. D.

Amalason'tha: b. in 498; a daughter of Theodoric the Great, King of the Ostrogoths; married in 515 Eutharic and bore him a son, Athalaric, who, in 526, when only ten years old, succeeded his grandfather as King of Italy under the guardianship of his mother, his father having died in 522. The government of Amalasontha was very successful, but her son grew up a debauched and dissipated drunkard, utterly unfit to reign. He died in 534. Amalasontha then married her cousin Theodatus, in order to strengthen her power, and made him co-regent; but, stung by the contempt with which his wife treated him, and desiring to rule alone, Theodatus imprisoned her and had her strangled in 535. This arbitrary action was the pretext for Justinian's invasion of the East Gothic kingdom, which led to its overthrow.

Am'alek: a grandson of Esau, and one of the chieftains of Edom (Gen. xxxvi. 12, 16). A remnant of his posterity existed in the time of Hezekiah (1 Chron. iv. 43).

Amal'ekites: a nomadic and warlike people, occupying, at the time of the Exodus, the Sinaitic peninsula and the wilderness between Egypt and Palestine. Opposing the march of the Israelites, they were signally defeated at Rephidim (Ex. xvii. 16). Centuries later they were severely punished by Saul (1 Sam. xv.), and finally destroyed by David (1 Sam. xxx.).

Amal'fi: an ancient and decayed city and seaport of Southern Italy; on the Gulf of Salerno; 25 miles S. E. of Naples (see map of Italy, ref. 7-F). During the several centuries of the Middle Ages it was a great commercial emporium and the capital of a republic. It is the seat of an archbishop. Its situation is rocky and very picturesque. Amalfi was the birthplace of Masaniello and of Flavio Gioja, called the inventor of the mariner's compass. Pop. 4,186.

Amal'gam [possibly from Gr. μάλαγμα (μαλάσσειν), an emollient]: a combination or alloy of mercury with another metal. Some amalgams are definite chemical compounds. Glass plates are converted into mirrors or looking-glasses by covering one surface with an amalgam of tin. Gold and silver are dissolved in mercury, and form amalgams which are used in the processes of gilding and plating various objects.

Amalgama'tion: the act or process of combining mercury with another metal; especially the process of separating gold and silver from the quartz-rock in which they are found imbedded. This is effected by shaking the crushed quartz-rock in a barrel in contact with mercury which readily unites with the particles of gold and silver. See GOLD and SILVER.

Amalie, MARIE: wife of Louis Philippe, King of France; daughter of Ferdinand I., King of the Two Sicilies; b. Apr. 26, 1782; married the Duke of Orleans, then a political refugee with no prospect of reaching the throne, Nov. 25, 1809, at Palermo; Queen of France, 1830-48; d. Mar. 24, 1866, at Claremont; distinguished for piety and exemplary domestic life.

Amal'rich of Be'na: a Scholastic philosopher who taught dialectics and the liberal arts at Paris in the twelfth and thirteenth centuries; was b. at Bena (Bène) near Chartres, and attempted to reconcile theology with the Averroistic and materialistic interpretation of Aristotle's metaphysics. He and his book (*Physion*) were condemned by the university and the pope in 1207; and Amalrich, after an enforced recantation, died of grief in Paris in 1209. In 1210 his bones and his books were burned together. His followers (Almericians) appear to have been a pantheistic and mystical sect, finally developed into that of the Brethren of the Free Spirit. Their doctrines, briefly, were (1) God is all; (2) every Christian is a member of Christ's body; (3) those who abide in the love of God can not sin. The last proposition naturally was the occasion and the justification of their excesses. They rejected the Church and the sacraments. They were subjected to severe persecutions.

Revised by S. M. JACKSON.

Amalthe'a, or Amaltheia: in classic mythology, the nurse of Jupiter; supposed to have been a goat, the horn of which, broken off by Jupiter, was endowed by him with magical power, and became famous as the cornucopia, or the "horn of plenty."

Ama'ma, SIXTIVS: b. at Franeker, Netherlands, in 1593; was a Protestant biblical philologist, and Professor of Oriental Languages at Franeker 1618-29, and was author of a critical work on the historical books of the Old Testament and some Latin treatises. D. in 1629.

Amani'ta: a genus of fungi nearly allied to *Agar'icus*, from which is derived a poisonous principle called *amanitine*. The *Amani'ta musca'ria*, a native of Europe, is very poisonous, and is used to kill flies.

Amapa'la: a city and seaport of Honduras; situated on Tigre, the most important island of the bay of Fonseca, which contains a number of excellent harbors (see map of Central America, ref. 5-G). The chief articles of export are tobacco, hides, precious woods, and indigo. Pop. about 1,000.

Amar, J. P.: a French Jacobin, notorious for his cruelty; b. at Grenoble in 1750. He became a member of the Convention in 1792, voted for the death of the king, and in Oct., 1793, presented to the Convention a report which condemned to death twenty-two Girondists. He contributed to the ruin of Robespierre on the 9th Thermidor, 1794. D. in Paris in 1816.

Am'aranth [from Gr. ἀμάραντος, unfading; ἀ-, not + μαρῖνειν, to wither. The final *h* due to false association with ἄνθος, flower]: a plant of the genus *Amarantus* and family *Amarantaceæ*, bearing small but aggregated flowers that are scarious, persistent, and not liable to wither, and which, in some species, are highly colored. The *Amarantus caudatus* ("prince's-feather"), "love-lies-bleeding," and other exotic species, are cultivated in the gardens of the U. S. Several other unsightly species are naturalized as weeds.

Amaranthaceæ: the AMARANTH FAMILY (*q. v.*).

Amaranth Family (Amarantaceæ): mostly herbaceous, apetalous flowering plants, related to the chenopods, buckwheats, pinkworts, etc. About 480 widely distributed species are known.

Amaranthus, or Amarantus: a genus of plants. See AMARANTH.

Am'arapu'ra (i. e. city of the gods): a decayed city of Burma, on the Irrawadi river, about 8 miles N. E. of Ava (see map of N. India, ref. 8-L). It was formerly the capital of Burma, and had at one period a population of about 170,000, but after the seat of government was removed in 1819 it rapidly declined. The houses are mostly of bamboo. Pop. 50,000.

Am'ara-Sing'ha, or -Sin'ha: an eminent Hindu poet and grammarian of unknown period, supposed by some to have lived about 50 B. C. He was a Bûddhist, whose works were all destroyed by the Brahmins, except his *Amara Kosha*, which is a vocabulary of about 10,000 Sanscrit words.

Amargosa Desert: See GREAT BASIN.

Ama'ri, MICHELE: an Italian statesman and Orientalist; b. at Palermo, July 7, 1806. His political life calls for no comment beyond the statement that he was intimately associated with the policy and plans of Garibaldi, and subsequently of Cavour. He is known to scholars by his *Guerra del Vespro siciliano* (1842; 9th ed. 1886; Eng. trans. by Lord Ellesmere); his *Storia dei Musulmani di Sicilia* (1854-68); and his *Diplomi Arabi del Archivio fiorentino* (1863). He translated from the Arabic the *Solwan* of Ibn Djafer (English translation, Lond. 1852). D. in Rome, July 16, 1889.

Amarna, or el-Amarna: ruins of a city on the Nile, midway between Thebes and Memphis, built by Amenophis IV., the great sun-worshiping Pharaoh of the eighteenth Egyptian dynasty. Here were discovered several hundred cuneiform tablets in 1887. See ASSYRIAN EXPLORATION.

D. G. L.

Amaryllida'ceæ: the AMARYLLIS FAMILY (*q. v.*).

Amaryllis: a genus of bulbous-rooted plants of the family *Amaryllidaceæ*, including but one South African species, *A. belladonna*. The name amaryllis is commonly applied to species of several other genera—e. g. *Crinum*, *Nerine*, *Zephyranthes*, etc.

C. E. B.

Amaryllis Family (Amaryllidaceæ): herbaceous, monocotyledonous plants, mostly bulbous, and related to the yams, irises, cannas, bananas, etc. About 650 species are known, mostly in warm climates. *Narcissus*, *Amaryllis*, *Polyanthus*, and *Agave* are important genera.

C. E. B.

Ama'sia, Amasieh, or Amasiyah: a city of Asia Minor; on the Yeshil-Irmak, 355 miles E. of Constantinople (see map of Turkey, ref. 4-G). It contains nearly 4,000 houses, many of which are of stone, a strong citadel, and a fine mosque. Silk is produced here and is exported. Strabo was a native of Amasia, which was formerly the capital of the Kings of Pontus (*q. v.*). Pop. between 20,000 and 25,000.

Ama'sis: a famous King of Egypt, who succeeded Apries about 570 B. C.; was more friendly to the Greeks and other foreigners than his predecessors. Under his reign Egypt enjoyed peace and prosperity. He built magnificent monuments at Memphis, his capital. D. about 525 B. C., and was succeeded by his son, Psammeticus III.

Amat', FELIX DE TORRES: Aragonese ecclesiastic and literary historian; b. at Sallent, Aug. 6, 1772; became Bishop of Astorga, and a senator under the reformed constitution of 1837. In 1808 he was charged by the Government of Spain to prepare and annotate a new Castilian translation of the Bible. Of this work the first edition appeared in 1823, in eight volumes, besides a volume of notes and appendices. In the edition of 1832 the notes are chiefly printed at the foot of the pages. D. at Madrid on Dec. 29, 1840. Amat is best known abroad by his *Memorias para ayudar a formar un Diccionario crítico de los escritores Catalanes* (Barcelona, 1 vol. 8vo, 1836). A supplement to the *Diccionario*, by Juan Corminas, appeared at Burgos in 1 vol. 8vo, in 1849. These works are valuable contributions to the history of Catalan literature, and indispensable to all who wish to become acquainted with that literature and its bibliography.

GEORGE P. MARSH.

Am'athus: an ancient city of Cyprus, especially addicted to the worship of Venus, who was hence called Amathusia. Adonis also was worshiped here.

Ama'ti, ANDREA: an Italian who lived at Cremona about 1550; made excellent violins, which are equal or superior to any made in the present time.—ANTONIO, a son of the preceding, was born about 1565. He was a celebrated maker of

violins. D. 1635.—NICOLÒ, ANTONIO (1550–1635), and GERONIMO, all excelled in the art, but Nicolò, jr. (b. Dec. 3, 1596; d. Aug. 12, 1684), excelled the rest of the family in the number and quality of his violins.

Amatitlan', or **Amatitan'**: a town of Central America, in Guatemala, 19 miles S. W. of the city of Guatemala, near the lake of the same name; lat. 14° 28' 39" N., lon. 90° 37' 50" W. (see map of Central America, ref. 4-D). The houses are made of mud, and are only one story high. Wells of boiling hot water occur in this vicinity. The chief business is the production of cochineal. Pop. about 4,000.

Amaton'galand: an independent native state of South Africa, extending along the coast of the Indian Ocean from Delagoa Bay to St. Lucia Lake, and inland to the Transvaal. Area, 5,300 sq. miles. Pop. estimated at 37,000. The Amatonga people are of Zulu extraction, but are much mixed with Swazi blood. They are governed by a queen, under whom are seventeen feudal chiefs. M. W. H.

Amaurosis: See BLINDNESS.

Amaur'y (or **Amal'ric**) I.: King of Jerusalem; a son of Baldwin II.; b. in 1135. He began to reign at the death of his brother, Baldwin III., in 1162 or 1163. In 1168 he invaded Egypt, from which he was soon forced to retreat by Saladin, who in turn invaded Amaury's dominions in 1170. D. July 11, 1173.

Amaury II., sometimes called **Amaury de Lusignan**: became King of Cyprus as heir of his brother Guy, and on his marriage with Isabella took the title of King of Jerusalem in 1198. His dominions were occupied by the victorious Saracens, so that his reign was only nominal. D. in 1205.

Amaxichi, an-aks-ee'kee, or **Santa Maura**: the capital of the Ionian island of Santa Maura (or Leucadia), is on its east coast. It has a lighthouse, and a harbor adapted for small vessels. It is the residence of a Greek archbishop. Pop. 7,000. Earthquakes often occur here. The remains of cyclopean walls are found in the vicinity.

Amazi'ah: King of Judah (2 Kings, xiv. 1–20), succeeded his father Joash about 837 B. C. He waged war with success against the Edomites, and reigned twenty-eight or twenty-nine years. He was killed by conspirators at Lachish, in 809 B. C.

Am'azon, or **Amazons** [so called from the fabled tribe of female warriors said by the Indians to exist on its banks, and which Orellana imagined he had encountered]: a South American river, and the largest river on the globe, rises among the Andes in Peru. It is formed by the union of several large head-streams called the Beni, Apurimac, Ucayale, and Tunguragua, which last is the most western branch, and is sometimes called the upper Marañon. Geographers have not unanimously decided which of these is the main stream. The Apurimac, the most southern of all the branches, rises about lat. 15° S.

By South Americans this river is known under three different names in different parts of its course: from its mouth to the mouth of the Rio Negro it is called the Amazonas or Amazon; from the mouth of the Rio Negro to Tabatinga, on the borders of Ecuador, it is known as the Solimoens; and from Tabatinga to its source in the Andes it is called the Marañon (corruption of the Tupi-Indian word *paraná*, a great body of water: the name given by them to the whole river). The Amazon, from its junction with the Napo in Ecuador, has a nearly due eastern course, varying therefrom not more than two or three degrees throughout its whole length; it is therefore almost wholly in the same latitude, which is not the case with any other large river on the globe. It is also entirely within the tropics—its average distance from the equator is less than 200 miles—but the climate is not so hot and sickly as might, from this, be supposed, the average temperature being 84°, and the extremes 72° and 94°. The waters of the main river, owing to the clay which they contain, are somewhat turbid, but those tributaries which rise in the woody plains have their waters black or of a dark amber color, and in some cases of a deep green, being dyed by the vegetable matter found so abundantly along their banks. This mighty stream, flowing through Ecuador and the boundless forests of Brazil, and increased to an immense volume by the great tributaries that enter it from the right and from the left, empties itself into the Atlantic Ocean under the equator. Its whole length, including windings, is rather more than 3,000 miles, and the area of the countries which it drains is estimated at 2,500,000 sq. miles. It is said to be 4 miles wide at the mouth of the

Japura, more than 1,000 miles from the sea. The navigation of the upper Marañon is obstructed by rapids. One of the most interesting facts connected with the Amazon is the smallness of its fall; at a distance of 2,500 miles from its mouth the elevation is only 210 feet; the descent is therefore about an inch to the mile. According to Lient. Herndon, the river and its Ucayale branch are navigable for a distance of about 3,300 miles from the ocean, but this is overestimated. The Tunguragua is likewise navigable for many miles above the mouth of the Ucayale. Boats can also be navigated from the Amazon, through the Rio Negro and the Cassiquiari, into the Orinoco, but they are obliged to pass rapids on the Negro, and again on the Orinoco, before they can reach the sea. It is estimated that the Amazon and its affluents open to the ocean 15,000 miles of interior navigation for large vessels. The tide ascends it over 400 miles, and about the time of full moon a great tidal wave rushes into the mouth of the river with such violence that it raises the water nearly 30 feet high. This wave, which is very dangerous to small vessels, is called *bore* in English and *pororoca* by the natives. The river abounds, in some parts, in turtles, whose eggs yield a valuable oil. The principal affluents on the right are the Ucayale, the Yuma, the Purús, the Madeira, and the Tapajós. Those that enter it from the left are the Napo, the Putumayo, the Japurá, and the Rio Negro. The Tocantins is not properly a branch of the Amazon. During the rainy season the Amazon overflows its banks and submerges a large extent of country. It is well supplied with fish, and flows through a region of great fertility, which is densely covered with primeval and almost impassable forests, in which jaguars, pumas, monkeys, tapirs, and other wild animals abound. The river incloses numerous large islands, besides that named Marajó or Joannes, which is 150 miles in diameter. This island separates the mouth of the Amazon from that of the Tocantins, but the two rivers are connected W. and S. of Marajó by channels, through which a small portion of Amazonian water reaches the Tocantins and its mouth, the Pará. The mouth of the Amazon was discovered by Yanez Pinzon in 1500, but the first European who explored the river was Orellana, in 1539. Early maps sometimes name the river Rio de Orellana, after this explorer. Since 1867 the river has been opened for trade to all nations. The dense forest that covers the valley of the upper Amazon is a remarkable feature. See H. W. Bates, *The Naturalist on the Amazon* (1st ed. Lond. 1863; the subsequent ones are somewhat abridged); Orton, *The Andes and the Amazon*; Keller, *The Amazon and Madeira Rivers*; Edwards, *A Voyage up the River Amazon*; Spix and Martius, *Reise in Brasilien*, vol. iii.; C. R. Markham, *Valley of the Amazon*; and the works of Hartt, Wallace, Von den Steinen, Penna, H. H. Smith, Myers, Hassaurek, Maw, Smythe, Herndon, Gibbon, Acuña, Poeppig, Barboza, Rodriguez, and Chandlers.

Revised by H. H. SMITH.

Amazo'nas, or **Al'to Amazo'nas** (i. e. upper Amazon): a state in Northern Brazil; bounded N. by Dutch and British Guiana and Venezuela, E. by the province of Para, S. by Bolivia and Matto Grosso, and W. by the United States of Colombia, Ecuador, and Peru. Area, 732,460 sq. miles. It consists chiefly of forests, inhabited by small independent tribes of Indians. The most important rivers in this province are the Amazon, which is called the Solimoens above Manaos, the Negro, Putumayo, Purús, and Madeira. The entire civilized population amounts to (1888) 80,654. Capital, Manaos (formerly Barra do Rio Negro).

Amazonas: a territory of Venezuela, forming the extreme south of that country, with Brazil on the S. and S. E. and Colombia on the W. It is claimed by Brazil. Area, 90,928 sq. miles. Pop. about 19,000, mostly Indians. It is drained in part by the Orinoco, in part by the Amazon, and within it is the celebrated river Cassiquiari, which connects the Orinoco with the Rio Negro, a branch of the Amazon. See CASSIQUIARI. M. W. H.

Amazonas: a department of Peru; bounded N. by Ecuador, E. by Loreto, S. by Junin, and W. by Cajamarca and Libertad. The soil is fertile, but, owing to thinness of population, very little is done to cultivate it. Straw hats of a superior quality are made here and exported. Chief town, Chachapoyas. Area, 14,129 sq. miles. Pop. 34,245.

Am'azons [from Gr. ἀμαζών. The Gr. explanation from ἀ-, not + μαζός, breast, is no more than a folk-etymology]: female warriors; a semi-fabulous nation of martial women which was celebrated by the ancient Greek poets. They are said to

have cut off their right breasts, so as not to interfere with their aim in shooting. According to tradition, they lived in Asia Minor, and fought against the Greeks at the siege of Troy, where they were commanded by their queen, Penthesilea. Another Queen of the Amazons, named Thalestris, is said to have made amorous overtures to Alexander the Great. The battles of the Amazons were favorite subjects with ancient Greek painters and sculptors. In modern times the African kingdom of Dahomey has been noted for its army of Amazons, distinguished for their bravery.

Ambal'a, or Umballa: a city of India; in the North-western Provinces; capital of a district and division of the same name (see map of Northern India, ref. 4-E). Pop. (1891) 79,270. Here a treaty was concluded between the Governor-General of India, Lord Mayo, and the Emir Shere Ali of Afghanistan in 1869.

Ambale'ma: a town in the republic of Colombia; in the state of Cundinamarca; on the Magdalena, about 50 miles W. of Bogotá (see map of South America, ref. 2-B). Excellent tobacco is produced in the neighborhood. Pop. about 9,700.

Ambarva'lia [Lat. *amb-*, around + *arva*, fields]: a religious festival observed by the ancient Romans in the month of May, in order to propitiate Ceres and invoke her blessing on the coming harvest. It was so called from the victims being carried round the fields by the priests.

Ambas'sador, or Embassador [viâ Fr. *ambassadeur*; Ital. *ambasciatore*, from mediæv. Lat. **ambactia'tor*, deriv. of Lat. *ambac'tus*, retainer. The spelling with *em-* was the commoner two centuries ago, and remains now in *embassy*]: a diplomatic minister of the highest order, sent by a prince or nation to the court of another power to manage special affairs of state. He is expected not only to be the agent of his government, but to represent the power and dignity of his sovereign or his country. (See DIPLOMATIC AGENTS.) The word ambassador is recognized as an official title of the highest rank of the diplomatic service of the U. S. See INTERNATIONAL LAW, Summary of its Principles.

T. S. WOOLSEY.

Amba'to: a town of Ecuador, 65 miles S. S. W. of Quito (see map of South America, ref. 3-B); has an active trade in grain, sugar, and cochineal. It was destroyed in 1698 by an eruption of Cotopaxi, but was soon rebuilt. Pop. 12,000.

Am'ber [Fr. *ambre*, from Arab. *anbar*, ambergris, by confusion extended to the resinous amber (Gr. *ἤλεκτρον*). The French distinguish *ambre gris*, gray amber, ambergris, and *ambre jaune*, yellow amber]: a fossil resin, usually of a pale yellow color, opaque to perfectly transparent. It is found in many parts of the world in deposits of cretaceous or tertiary age, and is now known to be a resinous exudation from several species of extinct coniferous trees, of which one, called *Pinites succinifer*, is supposed to have produced the greater part. Over 800 species of insects have been found preserved in amber, and leaves or other fragments of 163 species of plants. Amber is extensively used for ornaments, and especially for the mouthpieces of pipes, the consumption being greatest in Eastern Europe, Turkey, Persia, etc. The largest mass known is in the Cabinet at Berlin; it weighs 18 lb. and is valued at \$30,000. Most of the amber of commerce was formerly obtained from the shores of the Baltic, between Königsberg and Memel; but now the greater part is systematically dug or mined for near the latter place, at some distance from the sea. Small pieces are frequently found in the green sand of Gay Head and New Jersey, and in the tertiary coals of the far West. Amber was highly prized and much used by the ancients, and was one of the chief articles of commerce among the early Britons, Celts, Romans, etc. It was formerly employed as a charm against witchcraft, etc.; many superstitions as to its fancied virtues are still believed by the credulous. It was an object in many of the voyages of the Phœnicians, and was an article of exchange long anterior to the dawn of history, as we know by its frequent occurrence in the remains of the lake-dwellings of Switzerland.

Amber exhales a fragrant odor when burned, and was formerly in high repute as a medicine. An acid obtained from it (succinic) is a useful agent in chemical operations. When rubbed, amber becomes strongly electro-negative, and the first exhibition of electric force which received intelligent attention was the attraction exerted on light bodies by amber. This force, at first supposed to be possessed by

amber alone, took the name of that substance, *ἤλεκτρον*, from which "electricity" is derived.

Revised by GEO. F. KUNZ.

Amber-fish, or Amber-jack: a large fish of the genus *Seriola* and family *Carangidae*. The amber-fishes are allied to the cavallas and mackerels, and reach a length of from 3 to 5 feet in the tropical seas. They are of fair quality as food.

Am'berg: a walled town of Bavaria; on the river Vils; 39 miles E. of Nuremberg (see map of German Empire, ref. 6-F); was formerly the capital of the Upper Palatinate. It is well built, and has a gymnasium, a normal school, and a large public library; also a royal manufactory of muskets, and several breweries and potteries. The French Republican army under Jourdan was defeated near this town by the Archduke Charles, commanding the Austrians, in 1796. Pop. (1880) 14,583; (1890) 19,098.

Am'bergris [from Fr. *ambre gris*, i. e. gray amber]: a concretion formed in the intestines of the sperm whale (*Physeter macrocephalus*), and found floating on the surface of the seas where this animal occurs. In it are often found embedded the horny beaks of the squids, on which the whale feeds. It was formerly used in medicine, but is now dissolved in alcohol and used as a base in perfumes, rendering them more lasting. The price of it is about \$5 an ounce. It affords about 85 per cent. of a peculiar fatty and crystalline subject called *ambrein*. The specific gravity of ambergris is about 0.8.

Ambergris (so called from the ambergris found on its shores): a barren island at the S. W. angle of Yucatan; is 30 miles long from N. E. to S. W., and 3 miles wide; said to be uninhabited.

Ambi'orix: a famous Gallic chief who ruled over the Belgic tribe of Eburones, and waged war against Julius Cæsar. By insidious measures and stratagem he gained a decisive victory over the Roman Generals Sabinus and Cotta, whose army he annihilated in 54 B. C., during the absence of their commander. He was afterward signally defeated by Cæsar.

Am'bitus [Lat., a going round, i. e. to canvass for votes; from *ambi're*, *amb-*, round + *ire*, to go]: a term used by the ancient Romans to designate the going about and soliciting votes by candidates for office. The practice of offering one's self as a candidate in an open and honorable way was called *ambitus popularis*. Another kind, which was common, but disreputable, consisted in cajolery, bribery, etc.

Ambler: borough (organized in 1888 from parts of Upper Dublin and Gwynedd townships), Montgomery co., Pa. (for location of county, see map of Pennsylvania, ref. 6-J); 16 miles N. of Philadelphia; on the Philadelphia and Reading R. R.; is a manufacturing place, situated in an agricultural district. Pop. (1880) 251; (1890) 1,073; (1900) 1,884.

Ambletense: a decayed seaport of France, on the English Channel, 6 miles N. of Boulogne, and about 25 miles from the English coast (see map of France, ref. 1-E). Here James II. of England landed after his abdication in 1689, and here Napoleon I. erected a granite column in honor of the Grand Army in 1805.

Amblyop'sis [from Gr. *ἀμβλῦς*, dull + *ὄψω-*, see in *ὄψω*, eye, *ὄψωπα*, have seen, *ὀπάζομαι*, look, etc.: *ἀμβλυωπία* suggests the correcter *amblyopia*]: a genus of blind fishes. This genus contains a single species (*Amblyop'sis spelæus*), which is found in the caves of Kentucky and Indiana. The eyes of this fish, though seemingly absent, exist in a rudimentary

Amblyopsis spelæus.

state, hidden beneath the skin. The body is translucent, and partly covered with scales, and reaches a length of about 5 inches. Prof. Cope, describing the habits of these fish, says: "They are easily taken by the hand or net if perfect silence be preserved, for they are unconscious of the presence of an enemy except through the sense of hearing. This sense is, however, evidently very acute, for at any noise they turn suddenly downward and hide beneath stones, etc., on the bottom." Their food consists in a great part of the crayfish found in the cave, but they sometimes feed on other

fish, in the pursuit of which they show remarkable activity, thus proving that the tactile sense is well developed. The genus belongs to the order *Haplomi*, its nearest kindred being mud-minnows, pickerels, and killifishes. The family of *Amblyopsidae* contains three genera, *Amblyopsis* and *Typhlichthys*, which are blind and are confined to the caves, and *Chologaster*, which has well-developed eyes, and is found throughout the swamp region from Virginia southward. From *Chologaster* or some similar type the others are evidently descended. See an account (by F. W. Putnam) of the Blind Fishes of the Mammoth Cave in the *American Naturalist* for Jan., 1872.

Revised by DAVID S. JORDAN.

Amblys'toma [from Gr. ἀμβλός, blunt + στόμα, mouth]: a genus of American salamanders containing many species, the commonest and most widely distributed of which is the tiger salamander, *A. tigrinum*. This large salamander is common over all of North America, and in the West and South its larva is conspicuous in ponds and streams. Its metamorphosis may easily be retarded, and in Mexico seems to take place rarely, the animal propagating in the larval state while retaining its external gills. See AXOLOTL.

DAVID S. JORDAN.

Am'bo [Lat. *ambo*, -o'nis, from Gr. ἄμβων, ridge, reading-desk]: a reading-desk or pulpit which was common in ancient Christian churches, and is still found in Oriental churches. The Gospels and Epistles were read from the ambo.

Amboina: See AMBOYNA.

Amboise, am'-bwaws' (anc. *Ambacia*): an old town of France, in the department Indre-et-Loire, on the railway from Orleans to Tours, 14 miles by rail E. N. E. of Tours (see map of France, ref. 5-E). Here is a splendid château of the time of the Renaissance. It is celebrated as the place of imprisonment of Abd-el-Kader from 1848-52. Here the "Conjuration d'Amboise," a conspiracy of the Huguenots against the Guises, was formed in 1560. It has been the residence of several of the Kings of France. Pop. (1881) 4,167.

Amboise, GEORGES, Cardinal d': French statesman; b. at Chaumont-sur-Loire in 1460. He became Archbishop of Rouen in 1493, and a faithful adherent of the Duke of Orleans, who, on ascending the throne as Louis XII. in 1498, chose him for his prime minister, and in the same year he became a cardinal. He was an able administrator and a prudent counselor. He retained power until his death at Lyons, May 25, 1510.

Am'boy: city; Lee co., Ill. (for location of county, see map of Illinois, ref. 2-E); 94 miles W. of Chicago; at the junction of the C., B. and Q. and Ill. Cent. R. Rs. It has a fine public hall, 4 free-school buildings, 6 churches, 2 newspapers, grain-elevators, and the Illinois Central shops, employing over 400 hands. It was laid out in 1854. Pop. (1870) 2,825; (1880) 2,448; (1890) 2,257; (1900) 1,826.

PUBLISHER OF "NEWS."

Amboy'na (Malay, *Ambun*): the most important, though not the largest, of the Moluccas or Spice islands, situated E. of Booro, in lat. 3° 46' S., lon. about 128° E. (see map of East Indies, ref. 8-I). It is about 30 miles long, and has an area of 264 sq. miles. The surface is mountainous, and granite rock occurs on the summits of some of the mountains. The staple production is cloves, the trade in which was once monopolized by the Dutch. About 500,000 lb. of cloves is the average quantity annually produced here. The aborigines of the island are called Horaforas, but the most of the population are Malays, and the inhabitants are mostly Christians or Mohammedans. The Portuguese were the first Europeans that visited Amboina (1512), and they obtained peaceable possession in 1580; it was taken by the Dutch in 1605. A British settlement was made here about 1615, which was destroyed by the Dutch in 1623. The island was taken by the British in 1796, and restored in 1802; retaken by the British in 1810, and restored again in 1814. Pop. estimated at 30,000.

Amboyna: the capital of the Dutch Government of Amboina, on the island of the same name, and defended by Fort Victoria (see map of East Indies, ref. 8-I). It is regularly built, has a public garden, and a good harbor. Pop. about 13,000.

Ambra'cia: a town of ancient Greece, on the site of the modern Artta; was the capital of Epirus during the reign of King Pyrrhus, who was killed 272 B. C.

Am'briz: formerly a small native kingdom on the west coast of Africa, about the lower part of a river of the same name, now a part of the Portuguese colony of Angola. The name is applied now to a race of natives in this part of Africa, and the river is called Brisho or Loge.

Am'bros, AUGUST WILHELM: German composer; b. at Mauth, Bohemia, Nov. 17, 1816; became in 1869 Professor of Music in the University of Prague. Among his works are overtures to *Genofeva* and *Othello*, and a *History of Music* (Geschichte der Musik, 1862-68). D. in Vienna, June 28, 1876.

Am'brose, SAINT: one of the Latin Fathers of the Church; b. in Gaul about 340 A. D. He was a son of the Roman prefect of Gaul, and is supposed to have been born at Treves. Having studied law, he was appointed Governor of Liguria and Æmilia, with his residence at Milan, about 370, and distinguished himself in that position by his wisdom and moderation. On the death of the Bishop of Milan in 374 A. D., a violent contest ensued between the Catholics and Arians about the choice of his successor. By general consent Ambrose, who was not obnoxious to either party, was elected bishop, although he had never been a priest. He accepted the office with reluctance, but performed its duties with great ability and zeal. Under his preaching Augustine was converted. He favored the Catholics and earnestly opposed Arianism, but he does not appear to have been a violent persecutor. On several occasions he manifested moral courage by denouncing the sins and checking the arrogance of temporal rulers and potentates. The Emperor Theodosius the Great having ordered a massacre of the Thessalonians in 390, Ambrose forbade him to enter the church, and extorted from him the performance of a public penance of eight months, and the promise that thereafter no sentence of death should be executed until thirty days after it was passed. D. at Milan, April 4, 397 A. D. He was the author of a method of singing called the "Ambrosian Chant," and left numerous religious works and letters. He is commended by Villemain as "a man who, amid the turbulence and instability of the empire, never had a foible or a stain on his character, and whose magnanimity was adequate to all trials."

Revised by S. M. JACKSON.

Ambro'sia [from Gr. ἀμβροσία, to ἀμβροτος, immortal; ἀ-, not + βροτός (< *μροτός), mortal]: in classic mythology, "the food of the gods," which was supposed to confer immortal youth. According to a poetical legend, it was sometimes given to mortals who were favorites of the gods, and was used by Jupiter and Venus to anoint their hair. Ambrosia is also the name of a genus of weeds, one species of which, common in the U. S., is known by the name of hogweed or Roman wormwood.

Ambrosian Chant: the choral music of the early Christian Church; derived its name from St. Ambrose, Bishop of Milan, who introduced it into the Western Church about 386 A. D. The style of singing was antiphonal; the musical notation was, no doubt, borrowed from the Greek, and adapted to the church services. The Ambrosian chant is the foundation of ancient church music.

Am'brototype: See PHOTOGRAPHY.

Ambula'era [plur. of Lat. *ambula'crum*, walk, avenue, from *ambula're*, walk]: the series of tube-feet or locomotor organs of the starfishes, sea-urchins, and other echinoderms. In those with hard exoskeleton the feet protrude through perforations in the shell, and are grouped in definite areas, occupying in the starfish grooves along the under side of the arms, and in the sea-urchin forming usually five meridional bands. Each tube-foot consists of a thin extensible tube with muscular walls, provided with a terminal sucker for attachment to foreign bodies. Attachment being made, the tube contracts and draws the animal forward. The tube-feet form a part of the water-vascular system, and are filled with fluid. They are sensory as well as locomotor in function, those nearest the tips of the arms in the starfish being largely used for this purpose. The term ambulacra is also used for the perforated areas of the shell.

DAVID S. JORDAN.

Am'bulance [Fr. for earlier *hôpital ambulant*, movable hospital; Lat. *ambula're*, to walk]: in France, a movable hospital attached to each division of an army, and furnished with apparatus for the relief of the sick and wounded. It was invented or improved by Baron Larrey, and is only intended to afford help of a more or less temporary kind. The name is now commonly given to a covered vehicle by means

of which wounded men are removed from the field of battle. Improvements were made in the construction of ambulances during the civil war in the U. S., 1861-65, the excellence of which was recognized by their use during the Franco-German war of 1870. Ambulances are now attached to the hospitals of many American and European cities.

Ambulance Corps: a body of men employed in the British army in the Crimean war to drive ambulances and attend the sick and wounded. The experiment was not successful, and the ambulance corps was superseded by the land transport corps. In the civil war of the U. S. (1861-65) the officers and men of the ambulance corps were detailed from the line.

Amelan'chier: See JUNE-BERRY.

Ame'lia: See AMERIA.

Amelia Island: in the Atlantic; a part of Nassau County, which forms the N. E. extremity of Florida (for location, see map of Florida, ref. 2-J). It is 16 miles long and 4 miles wide. Amelia island light, in lat. 30° 40' 23" N., lon. 81° 28' 20" W., is at the N. end of the island. The lighthouse is built of brick, 58 feet high, and shows a flashing white light 112 feet above the level of the sea.

Amélie-les-Bains, ä-mäy-lee'lä-bän' (i. e. the baths Amelia): a celebrated bathing-resort in the Eastern Pyrenees, France; 700 feet above sea-level (see map of France, ref. 9-F). The waters are sulphurous saline, with temperatures ranging from 71° to 172° F. They are useful in diseases of the liver and respiratory organs, rheumatism, scrofula, and syphilis. Pop. about 2,000. M. W. H.

Amelot de la Houssaye, äm'lō' de-la-oo'-sä', ABRAHAM NICOLAS: b. at Orléans, France, in 1634; served for some time as secretary to the French embassy at Venice, but devoted himself afterward exclusively to the study of history and literature. D. in Paris, Dec. 8, 1706. He wrote *Histoire du Gouvernement de Venise* (3 vols., 1676); also translated Paoli Sarpi's history of the Council of Trent, and the *Prince* by Macchiavelli.

Amen [Gr. ἀμήν, from Heb. *āmēn*, certainty; as an adv., surely]: in the service of the Christian Church, a response and expression of assent at the end of a prayer. In some passages of the New Testament, at the beginning of an emphatic declaration, it is translated "verily."

Amende Honorable: in French law, a form of infamous penalty to which criminals who offended against public decency or morality were condemned. The simple *amende honorable* consisted of a confession in open court made by a bareheaded and kneeling criminal. The *amende honorable in figuris* was made by a culprit kneeling in his shirt, with a torch in his hand and a rope round his neck. In modern speech the term is applied to a public recantation or apology.

Amend'ment: in law, is the correction of an error committed in any process, or the alteration of the record or of any pleadings in a civil or criminal cause. The deficiency of means of amendment in pleading at common law led to the statutes of amendments and jeofails.

AMENDMENT, in legislation, is an alteration in the words of any bill, motion, or resolution. Any member may move an amendment to a bill or resolution after it has been read twice, and it is usual to take a vote on the amendment first, and next on the main question. An opponent of a bill has a right to move an amendment to it by a motion to strike out all after the enacting clause, and to substitute a contrary principle. Either House of Parliament (or Congress) has a right to amend a bill which has been approved by the other, but such amendments must receive the assent of both Houses before the bill can become a law.

The term amendment is also applied to an alteration of the Constitution of the U. S. To render an amendment valid it must be first proposed by two-thirds of both Houses of Congress, and must be ratified by the Legislatures of three-fourths of the several States. The most recent of these changes in the organic law is the Fifteenth Amendment, which ordains that no man shall be disfranchised on account of color or race. See CONSTITUTION.

Ameno'phis (or Am'enoph) I.: a powerful King of Egypt; the second of the ten kings of the eighteenth dynasty, began to reign about 1500 B. C.

Amenophis (or Amenoph) II.: the sixth king of the eighteenth Egyptian dynasty; regarded by some authors as identical with Memnon, who fought against the Greeks at the siege of Troy. See MEMNON.

Amenophis III.: a grandson of the preceding, and the eighth king of the eighteenth Egyptian dynasty. He ascended the throne about 1400 B. C. His reign was long, and greatly promoted the prosperity of Egypt, which he adorned with many noble monuments. He is supposed to have built the palace of Luxor (El-Ukser) at Thebes, which was his capital. His military exploits are recorded on the obelisk now standing in the Place de la Concorde in Paris. According to Bunsen, Amenoph III. was the king whom the Greeks called Memnon.

Amen'ta, NICCOLO: b. at Naples, Italy, in 1659; was a poet, lawyer, and philologist, and composed popular comedies. Among them are *Constanza, Il Forca,* and *La Carlotta*. He wrote also *Della Lingua nobite d'Italia*. D. in 1719.

Amenta'ceæ [from Lat. *amenta'ceus*, having an amentum or thong]: a name given by Jussieu to a natural order of dicotyledonous trees or shrubs having their flowers arranged in aments or catkins. It included the birch, willow, alder, and other common trees. By many botanists this order has been broken up into the *Betulaceæ, Saticaceæ,* and others. The order (or cohort) *Amentales* of recent botanists includes the families *Cupuliferæ, Juglandaceæ, Myricaceæ, Casuarinaceæ, Salicaceæ, Piperaceæ, Chloranthaceæ,* and *Lacistema-ceæ*.

CHARLES E. BESSEY.

Amentum: same as *Ament*. See CATKIN.

A'merbach, BONIFACE, son of JOHANN AMERBACH: b. at Basel, Switzerland, in 1495; taught civil law at the University of Basel for twenty years, and was intimate with Erasmus, who appointed him his residuary legatee. With his brothers he corrected an edition of St. Jerome (1516-26). D. at Basel in 1562.

Amerbach, JOHANN: b. at Reutlingen, Swabia, in 1443; was a famous printer of Basel, Switzerland, in the fifteenth century. He was the first to use the Roman type instead of Gothic and Italian, and published the first edition of the complete works of St. Augustine, on which he spared no labor or expense. He was rich, learned, and pious, and had previously published the works of St. Ambrose, and afterward undertook to prepare those of St. Jerome, which were published after his death under the direction of his sons. D. at Basel, Dec. 25, 1513.

Amercement, or Amerciament [Anglo-Fr. *amercement*, from vb. *amercier*, deriv. of *à merci*, e. g. in phrase *estre à merci*, to be at mercy of; *estre amercie*, to be fined at discretion; *merci* < Lat. *mer'ces*, -e'dis, wages, gift, favor, mercy]: a pecuniary punishment which is imposed at the discretion of the judge or court. Fines differ from ameracements by growing expressly from some statute, while ameracements are such as are arbitrarily imposed.

Ame'ria: one of the most ancient cities of Umbria, and one of the most important; about 15 miles S. of Tuder and 7 W. of Narni, between the Tiber and the Nar and a few miles above their junction (see map of Italy, ref. 5-E). It is said to have been founded in 1135 B. C., but this date is not historical. Its territory extended to the Tiber and abounded in osiers and fruit-trees. Its lands were divided by Augustus among his veterans. The modern town of *Amelia* retains the ancient site and parts of the ancient wall. It is the see of a bishop, and has a population of 9,000.

Amer'ica [so named from Amerigo Vespucci, who discovered a portion of the continent in 1499]: one of the four great recognized divisions of the globe; first practically made known to Europeans by Columbus in 1492, although parts of it were visited by the Northmen in the eleventh century, but they made no permanent settlements.

Situation and Area.—America appears to be separated into two continents, North and South America, connected by the Isthmus of Panama or Darien. It stretches from Boothia Felix, lat. 71° 55' N., to Cape Horn, 56° S. In its widest parts it measures over 3,000 miles, the extreme E. point being Cape St. Charles, in lat. 55° N., and the farthest W., Point Parina, lon. 81° W. from Greenwich. The narrowest part at the isthmus is 28 miles. The N. boundary is the Arctic Ocean; the E., through its whole extent, the Atlantic; the Southern Ocean washes its coast on the S., and its W. shores are bounded by the Pacific. America is about four times as large as Europe, and one-third larger than Africa. While rather less than Asia in area, it embraces about three-tenths of the land on the earth. In physical features it surpasses all other regions of the globe in the length and volume of its rivers, the area of its lakes, the extent of its valleys, and the number of its mountain-ranges

(inferior in height to the Himalayas alone), while its active volcanoes embrace more than two-thirds of those known to exist. The continent stretches over about 126° of latitude—8,280 miles—being much longer than any other.

The following table, based on the best authorities, gives the principal political divisions of the continent, with their areas and populations:

NAMES OF COUNTRIES.	Sq. miles.	Population.
North America	8,629,790	80,056,538

* Including Alaska and Indians.

NORTH AMERICA.

North America extends from the Arctic Ocean to the Gulf of Mexico and Central America on the S. With the general outline of a triangle, it is deeply indented by inlets, bays, and gulfs, and has a length of about 13,700 miles on the Atlantic, 10,500 on the Pacific, and 3,500 on the Arctic; total, 27,700 miles of coast-line. The continent approaches closely to Asia on the N. W. at Bering Strait, 48 miles wide. In the N. E., Greenland is separated from the continent by Baffin Bay and Davis Strait.

Physical Features.—North America may be roughly stated as presenting—1. In the N. a vast series of plains, bleak and barren and crowded with lakes, extending from about lat. 50° N. to the Frozen Ocean; 2. The region E. of the Appalachian range, consisting of lands mostly of low elevation and diversified soil; 3. The central valley of the Mississippi, reaching from the Alleghanies to the Rocky Mountains, and embracing in its E. region the richest agricultural portion of North America, in its W. the arid and sandy plains of the Great American Desert; 4. The W. plateau, stretching from the Rocky Mountain range to the Pacific, a region rich in minerals, with a varied soil and a generally equable climate; 5. The elevated table-lands of Mexico, with their extensive mountain-ranges, and narrow coast-line of lowlands on the E. and W.

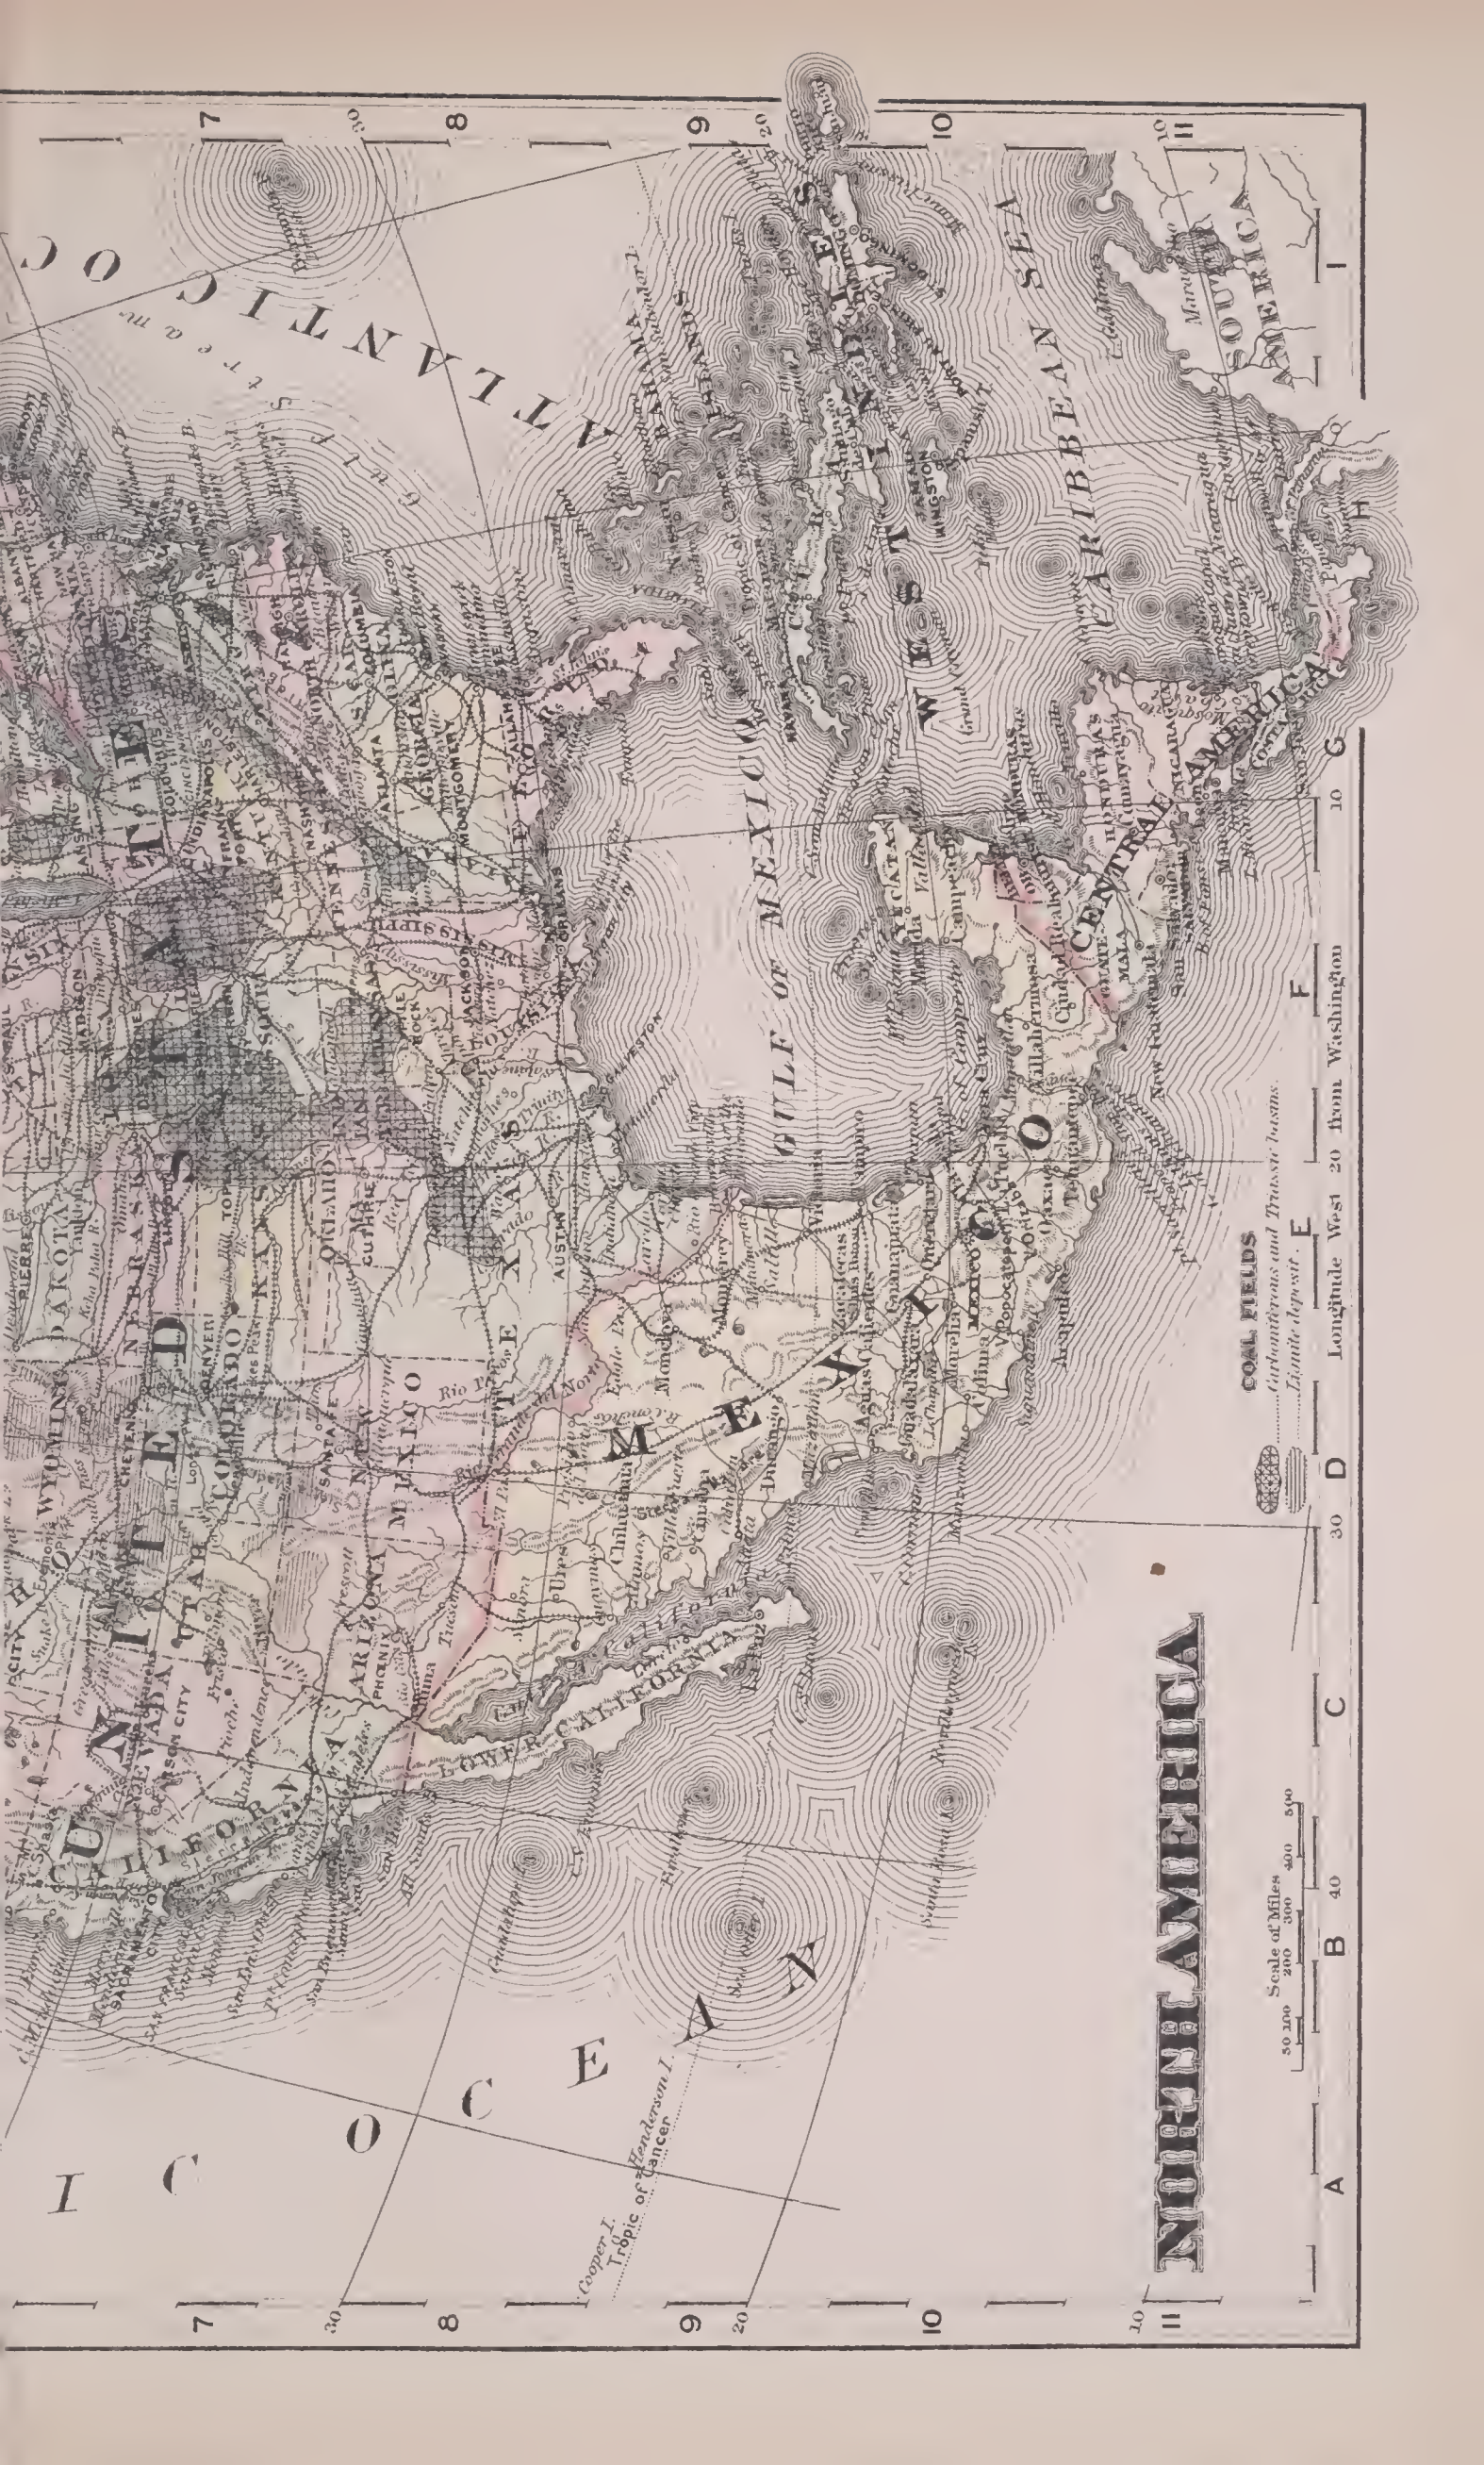

Mountains.—The great characteristic ranges of mountains in North America, creating marked divisions of its watersheds, and with broad valleys between, are the Rocky Mountain range in the W. and the Appalachian (sometimes called the Alleghanies) in the E. The Rocky Mountains (*q. v.*) may be said to begin in British American territory, above lat. 60° N., stretching in a southern direction through Montana, Idaho, Wyoming, and Colorado, until they meet the Sierra Madre range, which runs from New Mexico through the greater part of the Mexican republic. The highest Rocky Mountain peaks are the Holy Cross, Pike's, Long's, and

Torrey's peaks, rising to a height of between 14,000 and 14,400 feet. They are, however, overtopped by Mt. Whitney, in the Sierra Nevada range, California, 14,898 feet high. Numerous collateral ranges, frequently classed as part of the Rocky Mountain system, run in directions generally parallel. These comprise the Cascade Mountains, stretching far northward from S. Oregon into British America, the Coast Range and Sierra Nevada in California, the Wasatch Mountains in Utah, the Wind River Mountains and the Black Hills in Wyoming and Dakota. The Cascade range extends along the coast as far N. as Alaska, its loftiest peak, Mt. Logan, about 60° 30' N., being 19,500 feet high. Southward the mountain-ranges of Mexico have the volcanic peaks of Orizaba, 18,314 feet, and Popocatepetl, 17,887 feet. The Appalachian system stretches from Western North Carolina northward in Virginia and Pennsylvania, terminating in isolated mountains of lesser elevation and the White Mountain range in the New England States. The highest summit of the White Mountains is Mt. Washington, 6,293 feet. The highest Appalachian peak is Mt. Mitchell in the Black Mountains of North Carolina, 6,688 feet. See APPALACHIAN MOUNTAINS.

Rivers.—A marked feature of North America is its navigable rivers, affording means of interior communication to an extent unequalled on the other continents. The Mississippi alone, with its branches, supplies more miles of inland navigation than all Europe possesses. The distance from the mouth of the Mississippi to the farthest point navigable on the head-waters of the Missouri is 3,900 miles, and this great river, with its tributaries, drains twenty States and three Territories. The St. Lawrence affords a water transit (including the lakes with which it communicates) of 2,200 miles. The Mackenzie river in the N. flows through British territory into the Arctic Ocean (about 2,300 miles), and the Saskatchewan (1,200 miles) into Lake Winnipeg, while the Frazer river runs through British Columbia to the Pacific. The Yukon, of Alaska, is about 2,000 miles long. The Columbia rises in the Rocky Mountains, flows through Washington and Oregon, and reaches the Pacific. The Hudson, navigable for 150 miles above New York, is always crowded with commerce. The Rio Grande del Norte flows into the Gulf of Mexico, and the Colorado into the Gulf of California.

Lakes and Bays.—The inland seas of North America comprise Lakes Superior, with an area of 30,829 sq. miles; Erie, 9,900 sq. miles; Ontario, 7,104 sq. miles; Huron, 22,322 sq. miles; and Michigan, 21,729 sq. miles. Lake Champlain lies between New York and Vermont. All these are great avenues of commerce, while Lakes Winnipeg, Athabasca, Great Slave, and Great Bear, lying in the bleak regions of the N., are less navigated. Many lesser lakes are scattered through the Northern U. S. The Gulf of Mexico washes the southern boundary of the U. S.; the Gulf of California is on the W. coast. Baffin Bay and Hudson Bay are large and almost land-locked bodies of water to the N. of Canada; and these, with the Gulf of St. Lawrence, form the most notable of the bays which indent the coast, but the smaller ones are almost innumerable.

Geology and Minerals.—It is impossible to analyze the diversified geological structure of the continent in a brief space. The palæozoic rocks cover the greater portion, consisting of Silurian, Devonian, and carboniferous strata, the latter furnishing great coal-fields in Pennsylvania and other border-lands of the Appalachian chain, in Illinois, Michigan, and in British America. Glacial drift and bowlders are scattered profusely over many regions N. of about 40°. The Atlantic coast develops the cretaceous and tertiary strata, with gneiss beneath it, the latter covered partially by new red sandstone on the east slope of the Alleghanies. Large areas of cretaceous, triassic, and oölitic rocks are found in the W., and in California the secondary strata and tertiary beds are most prominent. British America abounds in the Laurentian and Huronian rocks, being the most ancient yet found, and these extend S. to the Adirondack region in New York. The Rocky Mountains exhibit volcanic rocks and the upheaved strata of granite, slates, and carboniferous rocks. The great plateau running from Mexico to British America, W. of the Rocky Mountains, and bisected by the cañons of the Colorado to the depth of several thousand feet, exhibits specimens of almost all the geological structures. North America, since the middle of the nineteenth century, has been one of the richest parts of the globe in the production of gold and silver. As regards gold, it is now surpassed in richness and production by both South

Africa and Australia (see WITWATERSRAND), but still holds first place as regards silver. Copper is largely mined on the shores of Lake Superior in Michigan, and in Mexico. The upper Mississippi affords lead-ore in abundance, and the Sudbury district of Ontario is rich in nickel. Quicksilver is found in California and Mexico. Iron abounds, salt is distributed widely, and the immense coal-beds, both bituminous and anthracite, afford a practically inexhaustible supply of fuel.

Climate.—All the climates of the globe may be found in North America. The New England regions are colder than the W. in the same parallels of latitude, and 10° or 12° lower than the same latitude in Western Europe. Vast regions N. of the lakes are almost uninhabitable from the intense cold, while in the Southern States and parts of Mexico the climate of the torrid zone prevails during a part of the year. The mean range of temperature for the year is as follows in the regions named: Alaska, 42° F.; Alabama, 66°; Massachusetts, 46°; Washington (city), 56°; Greenland, 13°; Mexico (city), 61°; Nova Scotia, 44°; Quebec, 40°; California, 55°; Minnesota, 42°; Florida, 70°. Extremes of temperature and sudden changes occur in most regions remote from the seaboard. The rainfall is variable. Parts of Mexico and California are dry almost throughout the year. The trade-winds blowing from the Gulf of Mexico carry the moisture of the torrid zone up the Mississippi valley, while the great plains directly E. of the Rocky Mountains present an almost rainless region.

Soil and Productions.—With the exception of the arid region near the Rocky Mountains, the stony or sandy or exhausted lands along the Atlantic coast, and the vast bleak regions lying below the Arctic Ocean, the soil of North America is singularly fertile. The rich alluvium on the banks of the Ohio, Mississippi, and other rivers, is almost inexhaustible. The Western prairies and the wooded regions of the Northern and Southern States have a productive soil. The table-land of Mexico, with parts of California and the Great American Desert, are without forests. Canada is rich in timber; so are some parts of the Northwestern and Southern States. The most valuable forest trees are the oak, maple, hickory, chestnut, pine, ash, beech, poplar, black walnut, tulip, and white cedar. Indian corn, or maize, is the most important grain crop; wheat, oats, rye, and barley come next. The hay crop is of great value; so are potatoes. Cotton ranks among the most important products. Large quantities of tobacco, rice, and sugar-cane are produced, although their area of production is limited. Fruit-trees, including the apple, pear, peach, orange, etc., are widely raised. The grape has of late years become a very important crop.

Zoölogy.—The animals of North America include every important species known in Europe, and there are remains of several extinct mammals and birds. The bisons, or buffaloes, are fast disappearing. The deer family embraces several varieties—reindeer in the Arctic region, the moose in Maine and British America, and the *Cervus americanus* among the forests and mountains of several States. Other wild animals are the bear, panther, lynx, wildcat, wolf, dog, fox, beaver, otter, raccoon, badger, opossum, antelope, squirrel, muskrat, hedgehog, hare, weasel, and gopher. Among domesticated animals, horses, sheep, cattle, and swine are abundant. The birds of North America, elsewhere described, number about 700 species, embracing the turkey, pheasant, buzzard, hawk, pigeon, eagle, vulture, owl, grouse, quail, wild goose, swan, duck, pelican, lark, thrush, mocking-bird, robin, woodpecker, parrot, humming-bird, grosbeak, whip-poor-will, kingfisher, bluebird, jay, oriole, cedar-bird, etc. Serpents are numerous, the rattlesnake being the most venomous. Alligators abound in the Southern rivers, and turtles, toads, and frogs everywhere. Fish are abundant and valuable, including salmon, shad, cod, mackerel, sturgeon, trout, whitefish, herring, sheepshead, bass, perch, bluefish, etc.

Population and Language.—What may have been the origin of the aborigines of North America is a problem still unsolved. There yet remain of the indigenous races between four and five millions, mostly in Mexico. The Esquimaux appear to be a distinct race. All the native races are copper colored, though of a different tinge, with black straight hair. They are in general a stationary, unprogressive race. The number of languages spoken nearly equals that of all the rest of the globe, and all attempts to trace these confused dialects to Eastern originals are more fanciful than scientific. The natives of Alaska are sup-

posed to be of different origin from the other American Indians. (See INDIANS OF NORTH AMERICA.) The African race, originally introduced as slaves, now number over 7,000,000, mostly in the Southern U. S. The white population numbers about 75,000,000, of whom more than three-fourths inhabit the U. S. They are mostly of the Germanic branch of the Caucasian race, those of Latin descent being chiefly in Mexico. The Anglo-Saxon element peoples over two-thirds of the settled regions, and the English language is that of nearly nine-tenths of the population, the one considerable exception being the Mexican use of the Spanish tongue.

Religion, Education, etc.—Protestant Christianity is the more prevalent religious belief in North America. Methodism outnumbers any other, the Baptist coming next, and the Presbyterian third, followed by the Congregational and the Episcopal. The Roman Catholic worship is widely prevalent in the U. S., and in Canada embraces more than one-third of the population. In Mexico the great majority are Roman Catholics. Mormonism's main foothold is in Utah. Education is widely diffused in the U. S. and Canada. The percentage of illiteracy, however, embraces one-fifth of the population of ten years and upward. In Mexico and New Mexico there is a large ignorant native population.

Discovery and Settlement.—As has already been said, Northmen landed in Greenland early in the eleventh century, and undoubtedly went as far S. as what is now Rhode Island. Columbus reached the West India islands in 1492, and subsequently discovered the mainland of South America. The mainland of North America was probably first touched by John Cabot in 1497. In 1500 the Portuguese Cortereal touched at Labrador; in 1513 Balboa crossed the Isthmus of Darien and found the South Sea; in 1519 Cortez invaded Mexico, and finished its conquest in 1521; in 1535 Cartier sailed through the Gulf of St. Lawrence; in 1537 Cortez discovered California, and took possession of it in the name of Spain; in 1578 New Albion was discovered by Sir Francis Drake; in 1587 John Davis found the Cumberland islands and Davis Strait; in 1604 De Monts made the first settlement in Acadie (Nova Scotia). The first permanent English settlement in North America was made in 1607 at Jamestown, Va. In 1608 the French founded Quebec; in 1611 Newfoundland was colonized by the English, and the Dutch settled on the Hudson; in 1614 New York was founded; in 1618 Baffin sailed N. to lat. 78°, and named Baffin Bay. In 1620 took place the settlement at Plymouth of the first English colony in New England. In 1682 William Penn founded a colony in Pennsylvania, and in the same year La Salle took possession of Louisiana in the name of France; in 1683 Georgia was colonized by the English.

History.—The most marked historical events in the history of North America have been—1. The transfer of most of the French colonies to Great Britain after the French war of 1756–63, by the treaty of Paris, in the latter year; 2. The American Revolution, ending in the independence of British rule of the U. S., 1775–83; 3. The independence of Mexico of Spanish rule, accomplished in 1821. The subsequent history of the various countries, the United States, Mexico, and the British colonies will be found under their respective headings.

LITERATURE.—Humboldt, *Examen critique de l'histoire de la géographie du Nouveau Continent* (5 vols., Paris, 1837); Fiske, *The Discovery of America* (2 vols., Boston, 1892); *Narrative and Critical History of America*, ed. by Winsor (8 vols., Boston, 1886–89); Payne, *History of the New World called America* (London, 1892).

A. R. SPOFFORD.

Revised by R. LILLEY.

CENTRAL AMERICA.

CENTRAL AMERICA is an isthmal prolongation of the southern end of North America, joining it to South America, and lying between the Caribbean Sea on the E. and the Pacific Ocean on the W. The name is variously used to include widely different extents of territory. Physically, Central America begins southeastward where the Isthmus of Panama joins South America, and it may be said to extend northward to the Isthmus of Honduras or to that of Tehuantepec, thus including Yucatan and Southern Mexico. With zoölogists and botanists the term now includes the region from Panama through Mexico into Southern Texas, but only part of Northern Mexico. In its early history Panama must be included, while Guatemala and Yucatan are linked rather to Mexico. In its later history Pana-

ma is excluded, and Yucatan, Guatemala, and the Mexican state of Chiapas are taken in. Politically, at the present day (1893) the name Central America is used collectively for the five independent states of Guatemala, Salvador, Honduras, Nicaragua, and Costa Rica; the Isthmus of Panama is ruled by Colombia, and is thus included in South America; Chiapas and Yucatan are joined to Mexico; and Belize is a colony of Great Britain. For convenience, we shall include Belize and the Panama isthmus with the five independent states in our general description.

In this sense, then, Central America is a great isthmus extending from the southern boundary of Mexico, at first southeastward and then in a double curve E. N. E. and E. S. E., until it joins the extreme northwestern angle of South America in about 7° 30' N. lat. and 77° W. long. The whole length, including the curves, is about 1,280 miles. The extreme breadth at the northern end is about 315 miles; the eastern indentation of the Gulf of Honduras narrows it to 160 miles; it widens again to 265 miles across Honduras and Nicaragua, thence narrows rapidly to 70 miles in Costa Rica; and the curved portion is a slender neck nearly 400 miles long and, in parts, less than 30 miles wide. This neck is generally known as the Isthmus of Panama, but that name is used in a more limited sense for the eastern portion. See PANAMA.

From N. W. to S. E., Guatemala, Honduras, Nicaragua, Costa Rica, and Panama (Colombia) form a line, all of them extending from the Caribbean Sea to the Pacific. Salvador is a strip cut out from the southwestern side of Honduras, and leaving only a small extent of Pacific coast to the latter; Belize, on the opposite side, is physically a part of Yucatan, and it nearly cuts off Guatemala from the Caribbean Sea. The whole area, including Panama, is about 207,474 sq. miles, and the population about 3,500,000, of whom probably less than 200,000 are whites. See table given on page 148.

Physical Characters.—From the Mexican frontiers to the eastern curve, Central America may be described as mountainous, with small inland plateaus which are little more than wide valleys and strips of low land along the coasts, principally on the Caribbean side. The highest mountains are near the Pacific coast, and they form a broken chain, either close to the ocean or separated by lower but often very hilly lands which may be 50 or 60 miles wide; the descent on the Pacific side is steep. To the E. the slope is gentler, and there is a network of branches spreading over the country and inclosing numerous valleys and plateaus; the latter, by their succession, sometimes forming a series of terraces to the Caribbean coast. The main chain is a continuation of the Mexican Sierra Madre del Sur, but it has no collective name; northward, in Guatemala, its average height is nearly 7,000 feet, and there are peaks rising to nearly 14,000 feet; southeastward it is generally lower and more central, with many low passes, until it dies into the hills of Panama. In Guatemala some of the plateaus are 4,000 feet above the sea, with mountains about them much higher. The Panama isthmus is hilly rather than mountainous, and in some parts of it the highest elevations hardly exceed 300 feet. Structurally it seems to be rather a spur of the Central American mountains than a part of the main chain, and there is no proof that it forms a connecting link between them and the Andes. So far as our present knowledge goes, the old theory that the Andes and the Rocky Mountains formed a continuous chain through Mexico and Central America must be abandoned.

Depressions, Lakes, and Rivers.—East of the main chain in Nicaragua, Central America is traversed diagonally by a great depression. The bottom of this depression is really below the sea-level, but the waters of the two lakes, Nicaragua and Managua, which fill its deeper portions, are somewhat more than 100 feet above mean tide. There are three low passes from the lakes westward to the Pacific, and to the S. E. Lake Nicaragua discharges its waters by the San Juan river into the Caribbean Sea. The rivers, lakes, and one of these passes form the proposed route for the Nicaragua ship-canal. (See NICARAGUA, PANAMA, ISTHMUS OF, and SHIP-CANALS.) There are numerous other lakes in Central America, but most of them are small and some are nothing more than the flooded craters of volcanoes. The whole country is well watered, nearly all the rivers flowing into the Caribbean Sea. From the narrow extent of country drained, none is very long, and only a few are available for navigation.

Volcanoes and Earthquakes.—Central America is intensely

volcanic; forty active or hardly quiescent peaks are known, and the number of extinct volcanoes is very great. The principal centers of active force are at present (1893) in Nicaragua and Salvador. Belize lies beyond the volcanic belt. Among the great eruptions we may mention that of the Volcan de Agua (1541), which overwhelmed the city of old Guatemala by a deluge of water from its crater; and that of Coseguina in Nicaragua (1835), which, during four days, threw out such a tremendous cloud of ashes and sand that the country for a hundred miles around was in midnight darkness. Earthquakes are very frequent, hardly a month passing without at least a slight tremor.

Geology and Minerals.—Too little is known of the geology to attempt any general description at present. What is known of the structure leads us to suppose that Central America was formed by upheavals of very ancient rocks which now appear as highly altered and inclined strata. Along the eastern side there are beds of limestone, some of them said to be of Jurassic age, and the coast alluviums are tertiary or newer. From the general resemblance of marine life on the Caribbean and Pacific side, it has been surmised that there was an opening through the isthmus, probably not longer ago than the middle tertiary.

Gold and silver are about the only minerals which are regularly mined. This was the first part of America in which the Spaniards obtained considerable quantities of these metals from the Indians; but the mines thus far have not proved very rich. Copper has been mined and is said to be abundant, and promising deposits of lead, zinc, and nickel have been reported; but these are little more than vague rumors, such as are heard in most thinly settled regions. There are rich iron-ores, but they cannot be profitably worked, owing to the lack of coal. Opals are mined to a small extent in Honduras; large beds of lignite are found in that state, and marble is quarried in Guatemala.

Climate and Distribution of Plant-Life.—Central America receives the trade-winds on its eastern side; these strike the mountains and their moisture is precipitated in heavy rains near the coast. In the interior and on the Pacific coast the abundance or scarcity of rains is due mainly to local causes, the vicinity of high mountains, or the extent of plateaus. The trade-winds also appear to cross the low passes of Nicaragua and Costa Rica diagonally, and strike portions of the Pacific coast. Generally, however, it may be said that the western side is considerably drier than the eastern, though never devoid of rain or subject to long droughts. The so-called dry seasons are only marked by less frequent and less abundant showers. Their period varies in different regions; along most of the eastern side the driest and coolest months are February, March, and April. On the Caribbean coasts the climate is unpleasantly warm and in many places insalubrious. The interior plateaus and valleys are temperate and healthful.

The forests follow the rainy belts. They cover the Isthmus of Panama and most of Costa Rica in one luxuriant mass, hardly broken by the scattered towns and plantations. This forest is continued on the eastern side to Yucatan, in a belt varying in width and including the low coast lands and the eastern mountain sides. In the interior the steeper slopes are generally wooded, but the plateaus and valleys embrace large tracts of grass-land or open tracts with scattered bushes and trees. On the higher mountains there are often forests of oak and pine.

Fauna and Flora.—Central America has a rich fauna and flora, closely related to those of tropical South America. The largest mammalia found are the jaguar and a kind of tapir; among peculiar birds may be mentioned the quetzal (*Trogon resplendens*), whose feathers were formerly used as insignia of rank by the Aztec princes. The rivers and coasts abound in fish. Along the eastern coast, especially in Belize, Guatemala, and Honduras, mahogany-cutting is a regular branch of industry, employing many thousands of the poorer classes; logwood and rosewood are cut and exported in smaller quantities. There are many other valuable timbers, but they are unknown to commerce. The Castilloa rubber-tree (*Castilloa elastica*) grows wild near the eastern coasts, and of late years considerable quantities of rubber have been exported. Sarsaparilla and vanilla are at present the only other forest products of commercial importance.

Soil and Agriculture.—The soil of Central America seems to be naturally fertile, and especially over volcanic rocks which have had time to disintegrate. Only small portions are cultivated and that generally in a very slovenly manner. The most important products for export are sugar

CENTRAL AMERICA

Scale of Miles

and coffee, but cacao has latterly come into prominence. Indigo, formerly much cultivated on the Pacific side, has been abandoned, the product being superseded by other dyes. All the tropical fruits grow almost without care, and considerable quantities of oranges, bananas, and coconuts are sent to the New Orleans markets. Beans and maize, with yams, sweet potatoes, and the other common tropical vegetables, are grown for home consumption. Manioc is cultivated principally in Belize, Costa Rica, and Panama. The grazing industry is unimportant, though large districts are well adapted to it.

Ethnology and Archaeology.—At the time of the conquest the dominant race in Guatemala, Yucatan, and southern Mexico was what is now known as the Maya stock. Some of them—notably the Quiches and Cakchiquels in Guatemala—had attained a degree of civilization superior, in some respects, to that of the Aztecs. They are among the few American aborigines who have left us written chronicles, legendary in great part, but extending back at least through several hundred years, and perhaps to the eighth century. Their cities were large and well built, and remains of them may still be seen. (See INDIANS OF CENTRAL AMERICA.) But deep in the forests of this region and southward remains of much older cities have been found, and of these we have no historical record. The ruins are of great extent and covered with elaborately carved figures and symbols. The latter appear to be hieroglyphic, but thus far they have baffled every effort to decipher them. That the builders of these cities were powerful appears certain, and their work indicates stability and some degree, at least, of civilization. Some of the sculptures seem closely allied to those of the Aztecs, and possibly they were related to that race. See CENTRAL AMERICAN ANTIQUITIES.

South of Guatemala, Central America was occupied by small tribes, some of whom were agricultural and others wandering hunters and robbers; none appear to have been raised above the savage state. The Spaniards called some of these Indians Caribs, but it does not appear that any true Caribs were found in Central America. The present Caribs of Eastern Honduras, Guatemala, and Belize are descendants of those brought from the West Indies in 1798. See CARIB.

History.—Columbus on his fourth voyage discovered Honduras (Aug. 14, 1502), and followed the coast to South America. Before that, Bastidas, exploring the northern shore of South America, had reached the site of Darien (1501). It is possible, but not probable, that Central America was visited still earlier by an expedition in which Vespucci was a subordinate. (See VESPUCCI.) Pinzon and Solis explored the eastern coast in 1506. In 1509 the Spanish court commissioned Alonzo de Ojeda and Diego de Nieuesa to colonize these countries. Both failed in their attempts, but their expeditions resulted in the founding of Darien by Martin Fernandez de Eneiso (1510). Vasco Nuñez de Balboa, left in charge of this colony, explored the surrounding country, won the good will of the Indians, and heard of the Pacific, which he at length succeeded in reaching (Sept. 28, 1513). See BALBOA.

Pedro Arias de Avila, better known as Pedrarias, was appointed governor of Darien in 1513; he brought with him large accessions to the colony, and during his administration the whole Panama isthmus and portions of Costa Rica were conquered. In 1519 the seat of government was changed from Darien to Panama, on the other side of the isthmus, the former town being for the time abandoned. Pedrarias, on account of his severity, was much disliked. He quarreled with Balboa, and put him to death on a real or fancied charge of treason. When (1522) Gil Gonzales de Avila explored the western coast and attempted to colonize Nicaragua, Pedrarias claimed the territory and sent Francisco Hernandez de Córdoba to drive him out (1524). Meanwhile Cortez had conquered Mexico, and sent expeditions into Central America. Alvarado had conquered Guatemala for him (1523 and 1524), and Cristobal de Olid had advanced into Honduras. Gil Gonzalez, retreating from Córdoba, was driven north into Honduras; and here the three rival factions met: Olid, sent by Cortez from the N.; Córdoba, acting as lieutenant of Pedrarias and coming from Darien; Gil Gonzalez, who owned allegiance to neither. A desultory but bloody warfare ensued, by which Gil Gonzalez was driven out. The other two coveted the country for themselves. Olid threw off allegiance to Cortez, but was killed by Casas; Córdoba rebelled against Pedrarias, but was captured and executed. In these and subsequent quarrels among rival bodies of Spaniards, not only were the ter-

ritorial rights of the Indians ignored, but they were treated as beings who had no rights at all; great numbers were enslaved, and several hundred thousand perished during a few years.

The struggle for supremacy continued in Honduras. Cortez himself marched overland into that country (1524–25), in one of the most terrible journeys ever recorded. Obligated to return, he left a governor there. Soon after, the Spanish court, probably hoping to end the quarrel, formed the captain-generalcy of Guatemala. This embraced the whole of Central America except Panama, and included a large tract in Southern Mexico, the capital being at Granada, and was divided into provinces, generally ruled by governors. This arrangement, with some changes, continued until the revolution. See GUATEMALA.

In the sixteenth and seventeenth centuries the coasts of Central America were repeatedly attacked by the buccaneers and by English freebooters. In 1665 England assumed a nominal protectorate over a portion of the eastern coast, in Nicaragua and Honduras, inhabited by Mosquito Indians. See MOSQUITOS.

Revolutionary movements began in 1811, supporting those of Mexico, but it was only in 1823 that the five states finally threw off their allegiance to Spain and formed a federal union, embracing all the region we have described except Panama. But the disorders which had lasted through the colonial times continued in the republics, and the union was dissolved in 1833. Since then the five states have continued independent. There have been frequent political revolutions in all of them, and none can be said to have a stable government. The most prosperous are Salvador, Guatemala, and Nicaragua.

In 1850 Great Britain resigned her claim to the Mosquito coast of Honduras; but she retained Belize, which had been colonized by British log-cutters in the eighteenth century.

THE WEST INDIES.

THE WEST INDIES are so called from the belief of the early discoverers that the countries found in the fifteenth century were the western regions of India. They embrace about 900 islands, lying E. of the coast of North and Central America. The name of Antilles is made to embrace all the West Indies except the Bahamas. Another designation divides the West Indies into the Leeward islands, comprising those N. of lat. 15°, and the Windward islands, embracing those S. of that parallel. The Windward islands, or a part of them, were also named the Caribbees, and the sea which they separate from the Atlantic is called the Caribbean. The geological structure of these islands indicates both coral-formation and volcanic origin. The whole submerged region is subject to earthquakes. The rocky

coast of most of the islands abounds in reefs, although there are some good harbors. The Bahama islands embrace the northernmost chain, stretching S. E. from a point near the coast of Florida. On one of this group Columbus made his first landing. The entire West Indies embrace about 90,400 sq. miles, with about 5,500,000 inhabitants. About half the area and population belonged to Spain until 1898. Great Britain holds the dominant share in the remainder, while France, Denmark, and the Netherlands have possessions in this archipelago. Revised by A. R. SPOFFORD.

SOUTH AMERICA.

SOUTH AMERICA, the southern division of the American continent, constitutes an immense peninsula between the South Atlantic and Pacific Oceans, and is joined to the northern division only by the narrow Isthmus of Panama. It is somewhat triangular in form, rather more than 4,500 miles long on a meridian, and about 3,200 in its greatest breadth; the total area is calculated at from 6,500,000 to 7,500,000 sq. miles, divided among ten republics and three colonies. Of this immense area nearly half is included in Brazil, and almost a sixth in the Argentine Republic. For the areas of the various countries, see the table given on page 148. It must be mentioned, however, that nearly all have disputed boundaries, often involving territories of vast extent. As these tracts are very thinly settled, they do not greatly affect the statistics of population given in the table already mentioned. It is proper to state, however, that, with the exception of the Guiana colonies, no South American country has ever had a census that can be relied upon, and most of the official estimates of population are based on old lists. Of the entire population of South America, probably not more than 500,000 belong to independent Indian tribes.

General Topography.—South America has the longest range of mountains, and, next to the Himalayas, the highest peaks in the world, as well as the largest rivers. It may be described as a plateau with a raised edge of mountains; three wide valleys or depressions, meeting above, divide the plateau into three main parts; the rivers flowing from these valleys find an exit through three great gaps in the mountain wall, two to the northeast and the other to the southeast; hence nearly all the drainage is to the Atlantic.

Mountains.—On the W. the Andes follow the coast from Cape Horn almost to the Isthmus of Panama; sometimes close to the Pacific, sometimes separated from it by a strip of low land from 50 to more than 100 miles wide. The mountains themselves vary in width from about 20 miles at the southern end to 250 miles in Bolivia, and 300 or 400 miles in Peru and Ecuador. Generally the main mass is from 8,000 to 12,000 feet high, rising abruptly from the low lands; this is capped by two, three, or more parallel ranges, called Cordilleras, and the latter are often connected by transverse ridges or knots. In these Cordilleras are many peaks rising above 20,000 feet. (See **ANDES**.) Between the Cordilleras there are plains and valleys varying in elevation from 6,000 to 10,000 feet. Quito, in Ecuador, lies in one of these, and is 9,520 feet above the level of the sea. In Bolivia a very extensive inclosed valley is occupied by Lake Titicaca and the Desaguadero river. (See **BOLIVIA** and **TRINCACA**.) In Colombia the Andes divide into three branches. The eastern one crosses Colombia and Venezuela in a nearly northeasterly direction, passes to the S. and E. of Lake Maracaybo, then curves along the whole northern coast of Venezuela to the Boca del Drago, opposite Trinidad. These northern mountains are the Maritime Andes of Venezuela, having an average height of 4,000 to 5,000 feet, but with peaks much higher. On the eastern side of the continent we find another, but much lower, mountain system, that of Brazil, also bordering the coast, but entirely unconnected with the first. It really stretches from the Plata to Cape São Roque, but has a mountainous form only from S. lat. 31° to the river São Francisco. (See **BRAZIL**.) The highest point is Itatiaia, near Rio de Janeiro, about 9,000 feet. A branch runs N. and divides into two, separating the valleys of the São Francisco, Tocantins, and Araguaia, and all three of these from the Paraná. None of the Brazilian mountains are active or recent volcanoes, and none attain the limit of perpetual snow. Guiana and the adjacent parts of Brazil form a table-land, but in the interior there seems to be an E. and W. line of true mountains, with peaks over 6,000 feet high. Humboldt and others supposed that the Guiana highlands were a branch of the Andes, parting from the main range in about N. lat. 3° or 4°, and crossing the Orinoco at the falls of that river; but this has not been proved.

South America is thus surrounded in great part by mountain-ranges, highest on the W. On the eastern side the southern end of the frame is broken between Uruguay and Cape Horn. This gives an outlet to the Paraná river-system. The northeastern side of the continent presents two other great breaks between Cape São Roque and Guiana, and between Guiana and Venezuela; through these breaks flow the Amazon and the Orinoco.

Plateaus.—Within this mountain frame the continent is a great plateau, more or less cut up by river-valleys and divided into three parts by the broad lowlands of the Orinoco, Amazon, Madeira, Paraguay, and lower Paraná. These parts are (1) a strip bordering the eastern slope of the Andes, broadest in Bolivia; it is much broken by spurs of the Andes, and its limits can not be easily defined. (2) The great plateau of Brazil, including most of that country and Paraguay and limited by the lowlands of the Amazon, Madeira, and Paraguay rivers. (3) The Guiana plateau, with its central core of mountains, extending westward to the Rio Negro and Cassiquiari and southward nearly to the Amazon. The average height of all these plateaus is probably about 2,700 feet, but it must not be supposed that they are either level or flat. Commonly they present long slopes or undulating lands; in parts of Bolivia, Brazil, and Guiana they appear to attain nearly 4,000 feet altitude, and in others they sink to only 800 or 1,000 feet. Indeed, the Brazilian plateau where it approaches the Amazon is only 500 feet above the sea. Everywhere they are cut through by the valleys of rivers, and these valleys nearly always have steep or even precipitous sides. The numerous mountain-chains represented on our maps are simply the edges of the plateaus where they abut on the river-valleys. The Brazilian plateau is partly divided by the branch of the coast range already mentioned.

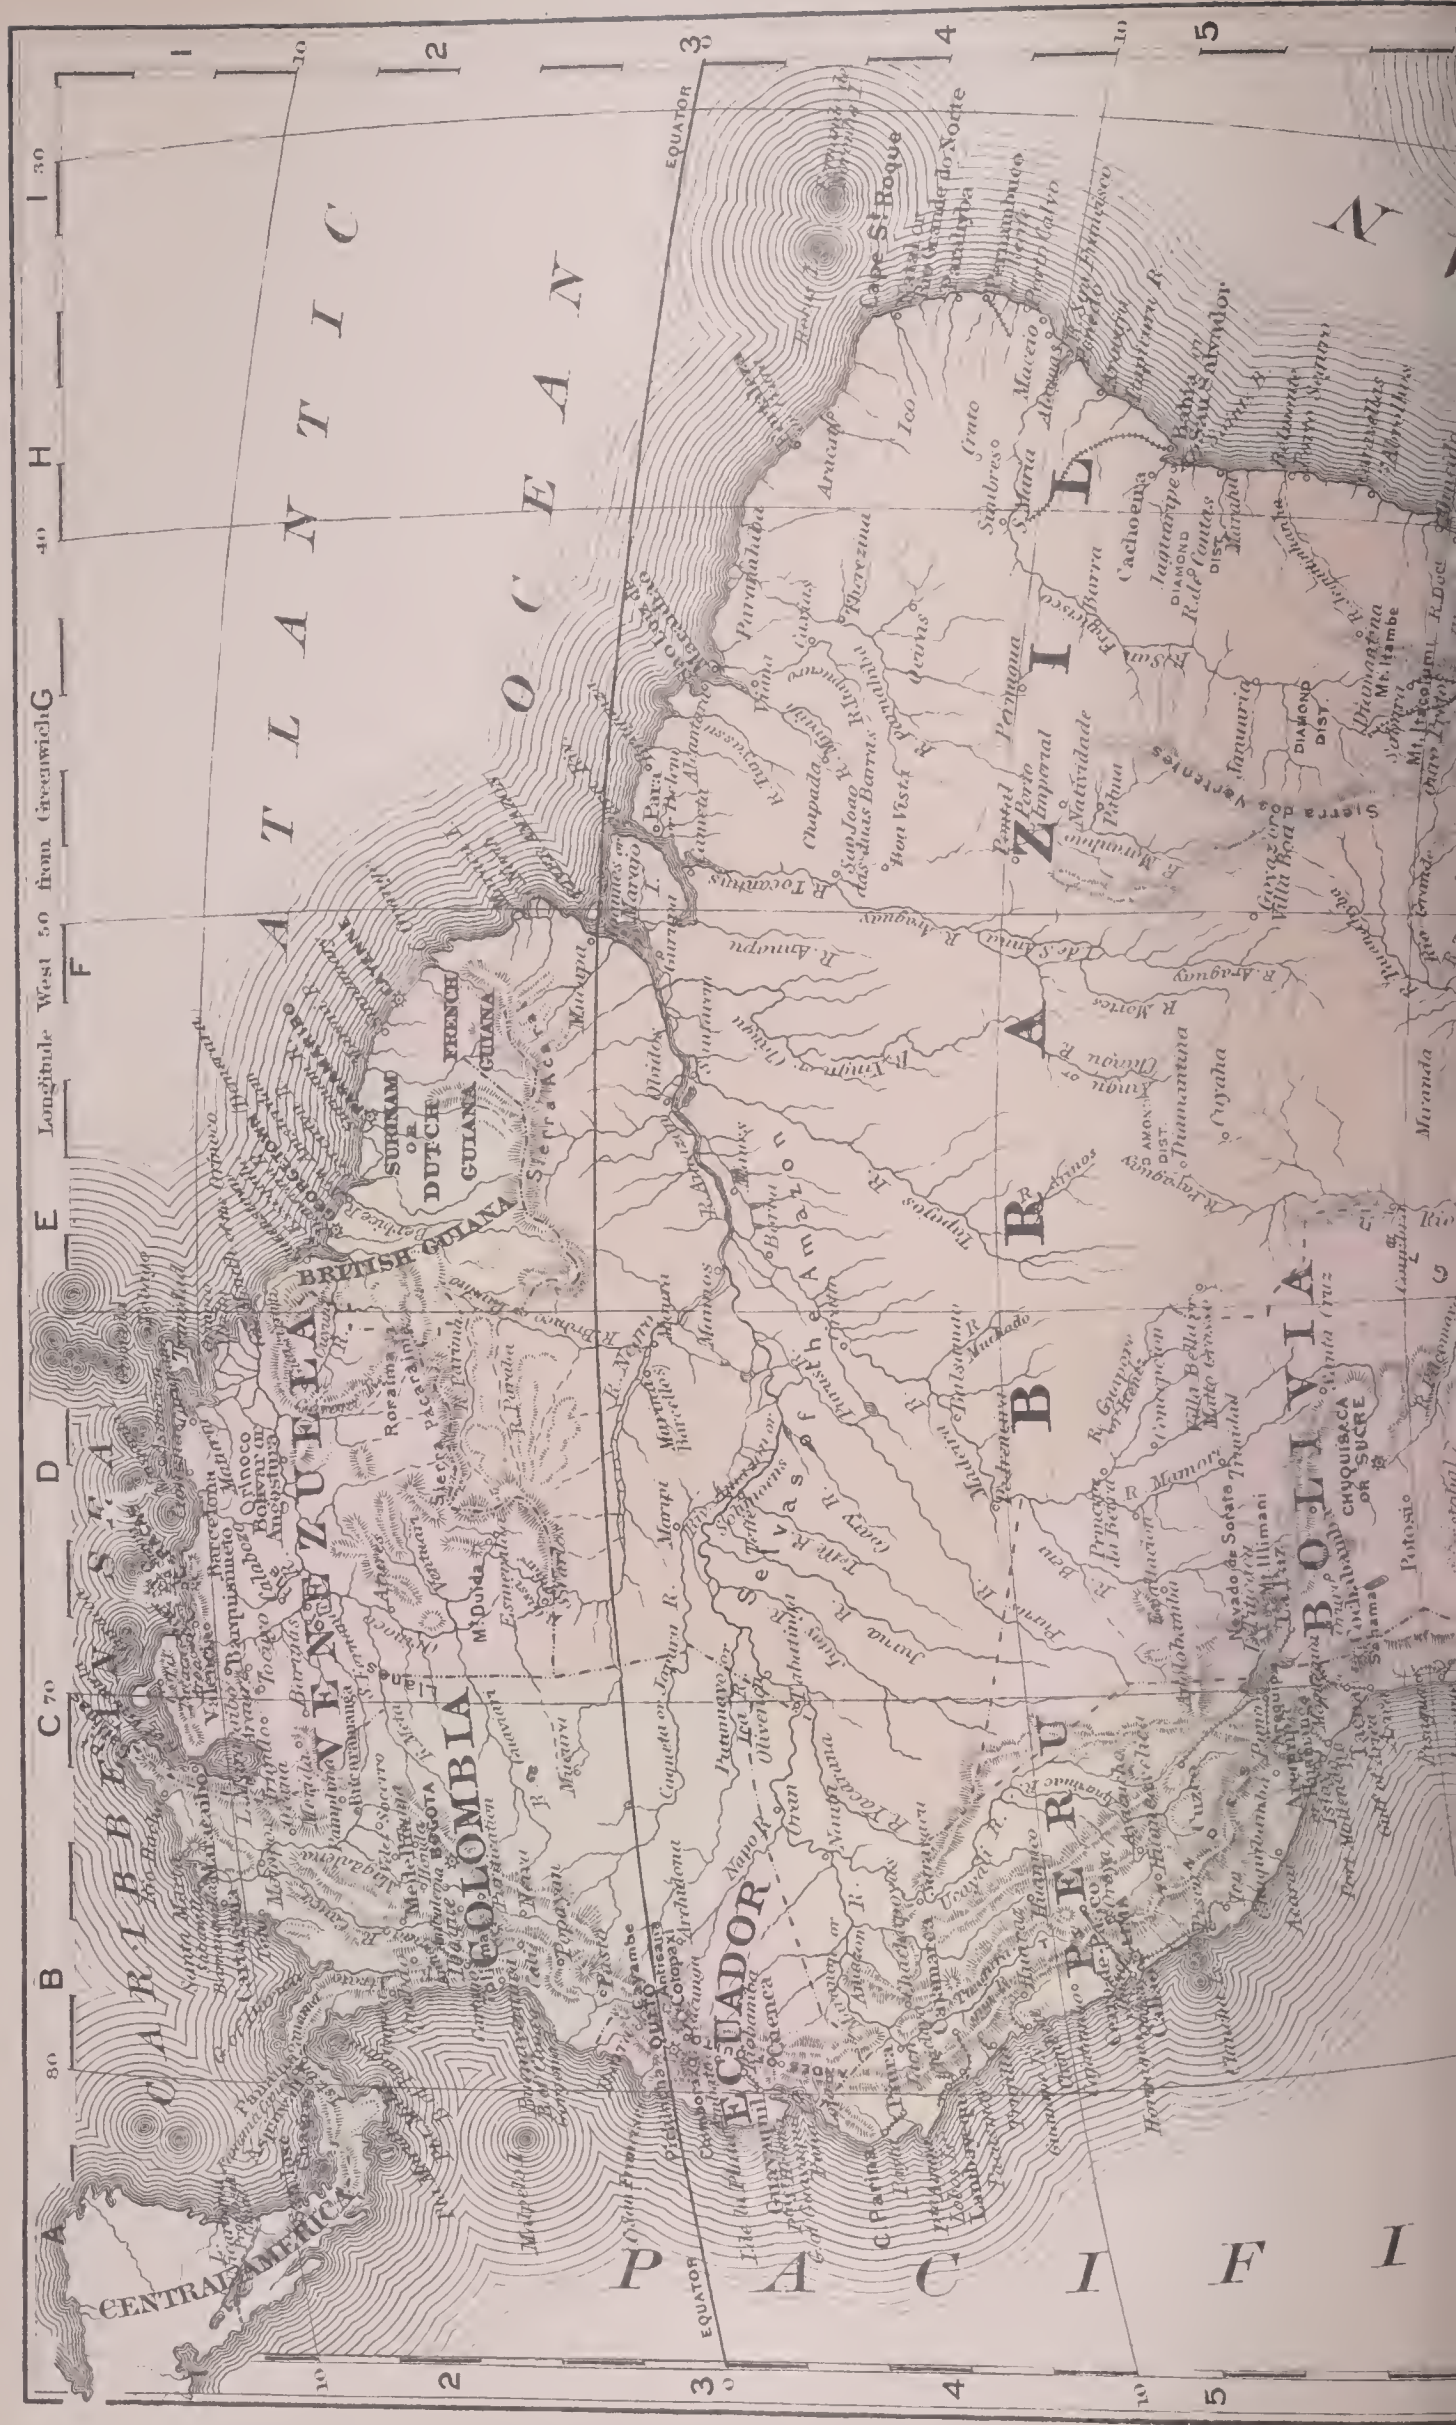

River-plains.—The great river-plains of the Amazon, Paraná, and Orinoco are a distinctive feature of the continent, being vast, level depressions, widest above, where they run into each other; the Amazonian depression is actually joined to the Orinoco by the Rio Negro and Cassiquiari; the Madeira, a branch of the Amazon, is separated from the Paraguay only by a low and narrow ridge. (See **CASSIQUIARI**, **MADEIRA**, and **PARAGUAY**.) The flood-plains, especially of the Amazon and Paraguay, are of vast extent.

The Argentine territory consists mainly of low, flat plains, the pampas, which are physically a part of the Paraná depression. Southward they are open to the Atlantic coast and extend into Patagonia. The llanos of the north are included in the Orinoco depression.

Rivers.—The Amazon, though not the longest river in the world, is by far the largest, the outflow from it being more than double that of the Mississippi; it is navigable for almost its whole length, and with its great tributaries forms an inland waterway of unequalled value. (See **AMAZON**.) The Paraná with the Paraguay—its real continuation—is navigable for 2,500 miles; the Orinoco to about 700, where it is obstructed by falls. The other large South American rivers are properly highland streams, without extensive flood-plains or expanded upper valleys. We may mention here the Uruguay, which meets the Paraná at its mouth, the São Francisco and Paranahyba in Brazil; the Tocantins, generally considered an affluent of the Amazon, but really receiving water from that river and discharging into the sea by a broad estuary, the Pará; and the Magdalena in Colombia. The upper Paraná is properly a branch of the lower Paraná and Paraguay, and is almost entirely a highland river. These, as well as the great affluents of the Amazon, will be described under their respective names.

Lakes.—The largest of these in South America is Lake Titicaca in Bolivia, with an area of about 3,200 sq. miles; it is probably the highest large lake in the world, being 12,600 feet above the sea. The lowlands of the great rivers are dotted with numerous lakes, many of them quite large, but generally shallow. Lake Parima in Guiana, formerly supposed to be very large, is really of insignificant size. Old maps place a lake called Xaraes or Charaes at the head of the Paragnay; this seems to be nothing more than the great plains bordering that river, which are flooded every year. The so-called Lake of Maracaybo in Venezuela is a deep and almost land-locked gulf of the Caribbean Sea.

Islands.—The Straits of Magellan cut off from the southern end of the continent the large island of Tierra del Fuego, and there are numerous smaller islands about Cape Horn. The island of Marajó, at the mouth of the Amazon, is separated from the southern mainland only by a system

of narrow channels. Of the outlying islands, Juan Fernandez and Mas a Fuera belong to Chili, the Galapagos islands are claimed by Ecuador, and on the east Fernando de Noronha is a penal colony of Brazil; all of these are small. The Falkland islands, east of the Straits of Magellan, belong to Great Britain.

Geology.—Our knowledge of the geology of South America is still too fragmentary to permit a clear general view. It seems certain that the oldest mountains are those of the Brazilian coast range; the forces which raised these have long ceased to be felt, but traces of ancient volcanoes have lately been discovered in them, and these probably had a part in their formation. They date from the Silurian at least, and probably from the Eozoic age. The Andes, in great part, have been raised since the palæozoic and probably since the cretaceous period; it may be surmised that the newest portions are about the volcanic group of Ecuador.

The plateaus are composed mainly of horizontal or little inclined strata with local disturbances. Devonian and carboniferous rocks seem to be widely spread, as they are reported from the Amazon, Central and Southern Brazil, Bolivia, Colombia, Venezuela, and Guiana. Cretaceous deposits also seem to be extensive. The pampas are great stretches of clay and sand-rocks, largely fresh-water deposits brought down from the Paraguay and the Paraná; buried in them are remains of the quarternary and tertiary animals of South America, and numerous species have been described from these as well as from the caves of Brazil.

Probably the great valleys of the Orinoco, Amazon, and Paraná were all originally arms of the sea, which have been gradually filled in with detritus. This was certainly the case with the Amazon valley, for deposits of shells of later tertiary age have been found on the river-banks as far up as Peru. Relics of these inland seas are found in the marine character of the river-faunas; porpoises, for example, are common in both the Orinoco and the Amazon, and crabs of marine forms live far above their mouths.

Minerals.—South America is rich in metals, including gold, silver, copper, mercury, platinum, lead, and iron; the first two are the only ones that have been extensively mined. Gold occurs in nearly all parts of the Andes and on the northern coast; in the interior of Brazil rich mines have been worked, but are now mostly abandoned; that country, in fact, has given to the world more gold than California has, though the mining period was much longer. It is probable that further explorations will result in the opening of new and perhaps richer mines. The gold obtained from the Andes was mainly the spoil of the Incas, which they had accumulated during several centuries. Since 1880 rich gold workings have been developed in Guiana, and the metal is mined to some extent in nearly all the other countries. The Andean region has been most productive in silver; the richest mines being those of Potosi in Bolivia, now worked only on a small scale. Copper and mercury have been mined to some extent along the Andes and northern coast. The rich deposits of iron in South America have been almost unused, owing to the lack of coal; a low grade of bituminous coal is mined in Southern Brazil and Uruguay, and beds are reported from the Argentine, Chili, Bolivia, Colombia, and Venezuela. The diamond mines of Brazil were formerly the principal source of the world's supply, but have been nearly abandoned since the discovery of the South African fields; emeralds are mined in Colombia. Rich guano deposits are worked on islands near the Peruvian and Chilian coasts, and beds of phosphate are among the chief riches of those countries.

Climate.—The greater part of South America lies within the tropics, and almost the widest part of it is under the equator, but the heat is much tempered by various causes. The Andes, owing to their great elevation, include almost every variety of climate, from the hot, dry region of the Pacific coast and the steaming plains of the Amazon to the cold valleys and table-lands; and over these a great number of peaks rise far above the limits of perpetual snow. The Brazilian and Venezuelan mountains rise to a temperate climate, but, except at a few isolated points, they are never very cold. The gaps in the mountain-wall, which afford an outlet to the great rivers, also give ingress to the Atlantic winds, and these cool the whole continent. On the lower Amazon the trade-winds blow regularly during a great part of the year; above the junction of the Negro they form an upper current, which is felt even on the eastern slope of the Andes, as was observed by Orton. These trade-winds are surcharged with moisture from the warm South Atlantic;

rising gradually as they advance over the continent, they are cooled, and discharge the vapor in abundant rains; to the W. they mix with cold currents from the Andes, and there the rains are almost constant; 110 inches have been measured in a single year on the upper Amazon, and the climate is so damp that sugar and salt deliquesce in a few hours, gunpowder becomes useless unless kept in sealed cans, and watches are stopped by the rust. Even at the mouth of the river the so-called dry season is varied by heavy showers. Something similar to this is found on the Orinoco, but the temperature and humidity are less influenced there by the trade-winds, because they blow less directly in the course of the valley. Southward the winds which most influence the continent are those which, passing over the plains of Patagonia and the Rio de la Plata, are known as *pamperos*. These blow only at intervals, from May to September, and they are very cold. Entering the great trough of the Paraná valley, they ascend that river and the Paraguay, cross the low divide, and descend the Madeira to the Amazon. Their prevalence is always marked by a sudden lowering of temperature; on the upper Paraguay, in lat. 15°, water sometimes freezes; and even on the Madeira and Amazon fish in the rivers have been known to die of cold. These cold spells generally last two or three days; the Brazilians call them *friagens*.

The great plateaus, besides being influenced by the trade-winds and *pamperos*, are cooled by their elevation, and, westward, by descending currents from the Andes. Their climate is perhaps the most delightful in the world, free alike from the extremes of heat and cold, and watered by abundant rains, at least during a part of the year. Near Cuyabá, in the middle of the continent, the average temperature of the Brazilian plateau is about 70° F., and the extremes observed during two years (excluding the *friagens*) were 90° and 54° F. During the *friagens* there was a fall to 37° or 38°, and rarely, according to reports, the temperature is lowered to the freezing-point.

South of the Amazon valley the period of *friagens* is also the time when other winds blow most regularly, and this is the dry season (May to October), when, over most of the plateau, no rain falls. The rest of the year is characterized by greater, but never excessive, heat, calms and ascending currents and rains, most abundant in December, January, and February. In the eastern part of Brazil the rains are sometimes almost lacking during one, two, or even three or four years; these are the droughts or *seccas* which have desolated that region at intervals.

In and north of the Amazon region the seasons are reversed, but there the dry period (September to February) is much less marked, and is never free from rain. The heat, in most places, is not at all excessive; in the Amazon valley it rarely reaches 93° F., and that only for an hour or two; the nights are always cool and pleasant.

The southern part of the continent, beyond the tropics, has a true winter from May to October; snow falls abundantly on the plains of Patagonia, and even as far north as Southern Brazil.

The eastern winds, passing over the continent, discharge their last rains on the slopes of the Andes. West of that mountain wall the narrow strip of low land is dry, and in parts almost rainless. In Northern Chili and Southern Peru this region is so arid as to be nearly devoid of vegetation; this is the desert of Atacama, of limited extent, and the only true desert land in South America, except some inclosed valleys of the Andes. In Southern Chili the Pacific slope is fairly well watered, and very fertile; under and north of the equator the climate is moist, being influenced by Pacific winds.

The *pamperos* are only felt as severe storms in Patagonia, about the Plata, and northward along the eastern coast, sometimes as far as Rio de Janeiro. Aside from these, South America is singularly free from violent winds; tornadoes and hurricanes are unknown, and thunder-storms seldom do any damage. Generally speaking, the whole of South America is healthy; the exceptions are portions of the great river-valleys and their branches, where intermittent fevers sometimes prevail, and a few of the tropical coast cities, where yellow fever has become endemic; this is generally confined to the warmer months, and is rather the result of poor sanitation than of the climate.

Distribution of Plant-Life: Forests, Pampas, Llanos, and Campos.—With its generally moist climate and abundant rains, South America is well fitted to support a growth of trees; but the extent of its forests has been much overesti-

mated. The largest continuous mass and the largest forest in the world is in the Amazon basin. In the western part of that region it appears to be not less than 1,100 miles wide, and includes the flood-plains. Below the mouths of the Negro and Madeira it narrows rapidly to 100 or 200 miles, principally on the southern side, and the flood-plains of the river itself, with the island of Marajó, are mainly covered here with grass. Strips of forest follow all the branches, and there is a prolongation on the coast to Maranhão. From the Amazonian forest there is a connection along the Rio Negro to that of the Orinoco, where it surrounds the headwaters and extends on the southern side into Guiana, and along the coast to the mouth of the Amazon. Over all this ground the trees form a thick mass, laced together with immense vines, and in parts nearly impassable.

The Brazilian coast range was originally covered with forest nearly everywhere, and much of this remains; it begins in Rio Grande do Sul, is widest about Rio, and narrows rapidly to Bahia. Most of this is true tropical forest, but southward in Paraná, Santa Catharina, and Rio Grande do Sul, the higher mountains are covered with araucaria pines.

The upper Parauá basin, including most of Paraguay and portions of Brazil, has a large tract of forest, which appears to be separated from that of the coast range. Eastern Bolivia has another, skirting the plateaus and cordilleras, and extending in some places to the Paraguay. Southern Patagonia, about the Straits of Magellan, has considerable forests, principally of pine. Finally, there is a long strip on the northern coast mountains from the mouth of the Orinoco to the Isthmus of Panama; it is continuous with the forests of Central America, and on the western coast of South America there is a narrow and broken prolongation at the base of the Andes, extending to the equator. All other forests in South America are of very limited extent.

The general surface of the plateaus is more or less open and has been erroneously called prairie-land; it seems rather to be a kind of degraded forest. Trees are abundant nearly everywhere, but they are generally scattered, small and stunted, with a growth of grass between them; sometimes they are more crowded and higher, forming a kind of dry wood; or they may be almost wanting over considerable tracts. But everywhere the aspect is the same, and as different as possible from the true forest; there are no large vines; palms and other broad-leaved plants are almost wanting; the foliage is of a light green, and the trees shed their leaves during the dry season; caeti are often abundant. The grass is thick enough everywhere to afford pasturage during the rains. In Brazil and Guiana these lands are called *campos* and, where the trees are closer, *cerrados*.

The northern part of the Orinoco depression is occupied by the llanos. In some parts these are true prairies, a level stretch of tall grass without trees; in other places they are broken by bushes and even clumps of woodland. The landscape is described as very monotonous.

The Argentine Republic, except its northern part, is occupied by low, flat prairie-lands, known as pampas; except near the streams and toward the base of the Andes, these are hardly broken, even by bushes. They afford excellent pasturage and are well adapted for cultivation, but many parts are subject to floods and droughts. Southward, in Patagonia, the pampas are arid, but with proper irrigation can be used for agriculture and pasturage. The name pampas has been extended to the grass-lands which cover most of Uruguay and the southern point of Brazil. These are hilly or rolling, except near the Uruguay; they form excellent pastures. Northward, the flat pampas west of the lower Paraguay merge into the Chaco country, which occupies the northern part of the Argentine, Western Paraguay, and Southeastern Bolivia; it is a great plain with a confused mingling of grass-land, bushes, strips of wood, lakes, and swamps. Many parts are alternately flooded during the rains and baked by the sun during the dry season; large portions of it have a thin but very regular growth of tall palms, presenting a most curious appearance. This is one of the least known parts of South America, and is still occupied by roving Indians. To the N., again, the Chaco is continuous with the immense flood-plain of the upper Paraguay, a region of grass-lands which every year are transformed into a great lake.

West of the Andes the lowlands of Chili are devoid of trees, but well watered by streams and very fertile; farther N., in the deserts of Atacama and Peru, they become arid and sterile.

Botany.—The flora of tropical South America must be in-

cluded, with that of Mexico, Central America, and the West Indies, in the Neotropical region. The species are generally peculiar, and they are very numerous, both in the forests and on the open lands. Travelers have always been struck by the immense variety of trees in these tropical forests; nearly two hundred kinds have been counted on a square mile in the Amazon valley, and the list was probably incomplete. Immense vines trail over these trees, and the branches are loaded with air-plants; palms in great variety are most abundant near the rivers. Some of the trees are of immense size, the trunks 40 or 50 feet in circumference, and the tops 200 feet or more from the ground; probably the average level of forest on the Amazon or in the coast range is 110 feet. Among the important forest trees we may mention the Pará rubber-tree, found on the Amazon and its branches and the Orinoco: from it the best rubber is obtained, and the markets of the world are mainly supplied from it. In the same region is the magnificent Brazil-nut tree, 200 feet high, and the allied sapneia nut-tree, the fruit of which is much superior to the Brazil-nut, but seldom enters into commerce. Cinchona trees of several species occur along the eastern flanks of the Andes, in the upper Amazonian forest; they supply the world with Peruvian bark and quinine. Cabinet woods of rich quality and immense variety are found, but the only one extensively exported is rosewood; this occurs in nearly all the forests. Sarsaparilla, the tonka bean, vanilla, ipeacuanha, the Peruvian coea, and various medicinal plants are derived from the forest; of the campo-trees perhaps the most important is that yielding the Ceará rubber, in Eastern Brazil.

Animals.—All of South America, except the southern end, is included with the West Indies, Central America, and the greater part of Mexico in one great zoölogical region—the Neotropical. In other words, the Neotropical region occupies all of tropical America. Throughout this vast extent the animals closely resemble each other. Many species are found from one end to the other; most of the larger genera have representatives in all parts, and with rare exceptions the families are the same everywhere. On the other hand, the assemblage of animals is very peculiar. It has relations, generally distant, with Africa, the Malay Archipelago, India, and Australia; hardly any with North America, except where it has lent a few forms to the latter, such as the puma and the Carolina parrot. Nine families of mammalia, 23 of birds, 5 of reptiles, 4 of batrachia, and 3 of fishes are peculiar to the Neotropical region, and others hardly extend beyond it. South America is the true home of the edentates; in the quaternary period it possessed such immense representatives of them as the *Megatherium*, the *Chlamydothorium*, and the *Myiodon*; three of the five living families—the sloths, ant-eaters, and armadillos—are confined to it, the other two being in tropical Asia and Africa.

The Neotropical region has the richest fauna in the world, but huge quadrupeds, like those of Africa, are wanting. The largest indigenous mammalian is the tapir, with four or five closely related species, occurring from Mexico to Southern Brazil. The only very formidable quadrupeds are the jaguar and the closely related species or variety called the black tiger; the puma, much more common, is very little feared. Other spotted and gray cats are numerous in species, but generally small. Indeed, the idea that South America swarms with savage animals is entirely erroneous. The traveler is rather impressed with the fact that so few animals of any kind are seen; large herds of ruminants, such as the bisons that used to roam over North America, are quite unknown; of terrestrial animals only the peccaries, or wild hogs, go in bands, and on this account are sometimes formidable to hunters. In the great forests what strikes one most is that nearly all the animals seem to be arboreal; monkeys, sloths, the various small tiger-cats, the coatis or South American raccoons, all but one species of ant-eater, and the opossums live in trees; birds and insects, snakes, lizards, and frogs, all keep to the tree-tops. On the open lands the commonest quadrupeds are armadillos and deer; birds are most conspicuous about the river-plains, where the white herons and other waders gather in vast flocks; alligators also abound about the rivers and lakes. Of other animals the llamas of the Andes are remarkable, not only for their relationship to the camels, but because they have been domesticated from the earliest times. (See LLAMA.) The chinchillas of the south temperate region are prized for their skins; and we may mention the Brazilian wolf and a kind of bear (*Ursus spectabilis*) found in the Andes. Among these mountains also is seen the condor, the largest bird that is able to

fly, and exceeded in size only by the terrestrial ostriches. Three species of ostriches roam in small bands on the plateaus and pampas. The water-boas (*Eunectes*) are the largest South American serpents; these are by no means common, but they are formidable, attaining a length of 30 feet or more, and able to swallow a horse. The boa-constrictor and its allies, far from being dangerous, are often kept about houses to kill rats and other vermin. There are innumerable other serpents, some of them poisonous. The shores and rivers swarm with fish, among which we may mention the pirarueú (*Sudis*) of the Amazon, attaining a length of 7 feet, and forming the staple animal food of that region; the cannibal fishes (*Serra salmo*), which often attack and kill bathers; and the strange electric eels. Insects are enormously rich in species; 20,000 have been collected at one place, in a few years; 700 kinds of diurnal butterflies are known from Pará, Brazil. Among noxious species are the termites, ants, and different species of mosquitoes and sand-flies; these latter sometimes swarm in immense numbers, especially along the Paraguay and Orinoco.

Industries and Products.—The chief agricultural products are wheat in Chili and the Argentine, coffee in Brazil, sugar in Brazil and Guiana, cacao or chocolate on the Amazon and Orinoco, and in Colombia and Venezuela; the tropical regions produce corn, fruits, and vegetables abundantly, but they are little exported, and generally agriculture is at a low ebb. The principal center of the grazing industry is about the Plata, in the Argentine, Uruguay, and Southern Brazil; cattle are also bred largely on the llanos of Colombia and Venezuela, and to a less extent in Eastern Brazil, on the lower Amazon, and through the interior. Rubber is the principal export of the Amazon, parts of the product coming from Bolivia, Colombia, and Peru. South America has as yet hardly any important manufactures; the most advanced regions in this respect are the Argentine, Chili, and Southern Brazil.

Means of Communication.—Several thousand miles of railroad have been made in South America, principally in the Argentine Republic, Brazil, and Peru. Hardly any of these have yet paid interest on the capital invested, and, as they are supported directly or indirectly by the states through which they run, the financial burden has been very great. The cause of these troubles is evident. The South American countries do not furnish the heavy freights—coal, lumber, and grain—which largely support North American roads; the countries are thinly inhabited, and only a small portion of the population travel at all; and there is little demand for foreign goods, except at the coast cities. The natural means of communication is by the great rivers. With these and a better system of common roads there will be a natural and healthy growth. Much of the interior commerce is carried on by means of mule-trains, and these are in use even where railroads have been built, because they can successfully compete with the high freight tariffs. It has been proposed to unite North and South America by a grand intercontinental railway.

Ethnology.—Before the arrival of Europeans, South America was peopled by a vast number of Indian tribes, some of them powerful nations, others small agricultural communities, others again mere wandering hordes. The chief of these were the Kechuas, the Araucanians, the Abipones, the Aymaras, the Tupis, etc. See these titles and the articles ARAUCARIA and INDIANS OF SOUTH AMERICA.

History: (1) Discovery and Early Explorations.—Columbus in his third voyage reached the coast of Paria, north of the mouths of the Orinoco, Aug. 2, 1498. This was probably the first discovery of the continent. Ojeda and Alonso Niño visited the same shore soon after, and in 1500 Pinzon and Diego de Lepe explored the coast of Brazil. Shortly after, South America was discovered quite independently in a voyage which would probably have been made had Columbus never existed. The Portuguese navigator, Pedro Alvarez Cabral, was on his way to India by the route around Africa which Vasco da Gama had just opened. For some reason, probably to avoid the calms off the African coast, he chose to keep far out in the Atlantic. This brought him into the longitude of the eastern part of South America, and he struck the coast S. of Bahia, following it for some distance. Within a few years the northern and most of the eastern coast of South America was known; but it was supposed to form a part of Asia until Balboa crossed the isthmus (1513) and discovered the Pacific. (See BALBOA.) Solis and Pinzon discovered the Plata, probably in 1508; and in 1520 Magellan passed the southern point of the continent.

Explorations of the western side began at Panama, and resulted in the conquest of Peru (1527–33) and Northern Chili (1535–46). (See ALMAGRO, CHILI, PERU, and PIZARRO.) Thus by the middle of the sixteenth century the entire coast-line of South America had been explored. The conquest of Peru led to the discovery of the Amazon by Gonzalo Pizarro and its descent (1540–41) by Orellana. (See AMAZON and ORELLANA.) Cabot and Irala explored the Paraná and Paraguay (1528–43), and the latter succeeded in establishing overland communications with Peru.

During the sixteenth and seventeenth centuries many expeditions were made in search of El Dorado, the fabled king of an equally fabulous city, supposed to exist somewhere in the northern part of South America. (See EL DORADO.) These led incidentally to the exploration of large tracts in the interior of New Grenada and Venezuela, and to discoveries on the lower Orinoco. The upper part of that river was known only by vague reports until the voyage of Humboldt (1800), who passed the falls and proved the connection of the Orinoco with the Rio Negro by the Cassiquiari. (See ORINOCO.) Much of our earlier knowledge of the interior of South America is due to the Jesuit and other missionaries, and to the slave-hunting expeditions of the Portuguese and Spaniards.

(2) *Settlement, Conquest, and Colonial Period.*—The part of Brazil discovered by Pedro Alvarez Cabral in 1500 was well to the east of the Tordesillas line (see TORDESILLAS), and it was at once claimed by the Portuguese; their right was never opposed by Spain. All the rest of the coast, eastern, northern, and western, was claimed by the Spanish as lying W. of the line of demarkation. Later, both nations claimed whatever lands they had conquered in advancing inland from the coasts.

Francisco Pizarro landed at Tumbez, Peru, in 1532, and his conquest of that country may be said to have been completed when he entered Cuzco, the Inca capital (Nov. 15, 1533). Cuzco was turned into a Spanish town; Pizarro founded Lima (1535), and made it the capital of his new viceroyalty, which included what are now Ecuador and Northern Bolivia, as well as the modern Peru. Lima soon became the most important city in South America. From Peru Diego de Almagro had marched into Chili (1536), and been appointed governor of that country. Disputes about the limits of their respective territories led to wars and the death of both Almagro and Pizarro. (See PERU.) The conquest of Chili was continued by Pedro de Valdivia until 1547, and it ended in the permanent establishment of Spanish rule in that country as far S. as lat. 37°.

Meanwhile the Plata was invaded by the Spaniards. Buenos Ayres was founded (Feb. 2, 1535), and Asuncion, Paraguay (1536). At first the Platine colonies were weak, but they gained more strength with the government of Cabeza de Vaca (1540–44), and Martinez de Irala (1544–57), who made their capital at Asuncion and established inland communications with Bolivia, or Upper Peru as it was then called.

By the end of the sixteenth century the whole of South America, except Brazil, was nominally under the rule of Spain; but the settlements on the northern coast were still weak, and Guiana and Patagonia were untouched. The whole of this immense territory was under the jurisdiction of the viceroys of Peru at Lima; subordinate to these were various divisions or *audiencias*, ruled by presidents who were sometimes called captains-general or governors. Upper Peru or Bolivia had its audiencia at Chareas (the modern Chuquisaca), established in 1559 and including Paraguay. The audiencia of Chili (established 1568) was at Santiago, with a captain-general at its head. New Grenada had its audiencia after 1564, and Quito, the modern Ecuador, from 1542; that of New Andalusia (Venezuela) was erected later. The governors of Buenos Ayres, after 1580, were almost independent, and after 1777 that district, with Paraguay and Bolivia, was a viceroyalty.

From first to last the Spanish rule in South America was marked by contempt for the rights of the Indians, who were enslaved and oppressed in every possible way, notwithstanding the efforts of the Spanish Government to protect them. The only exception was in the Jesuit missions, where the priests of that order sought to establish a mild, paternal rule, protecting their charges from the rapacity of the civilians and establishing plantations and simple industries. In Paraguay the Jesuits became so powerful that they virtually ruled the country until the expulsion of their order from America in 1767. The system of paternal rule tended to

keep both Indians and whites in a childish condition, and in that respect its evils are still apparent; but it was the means of preventing the still greater evil of the entire destruction of the aborigines.

BRAZIL (*q. v.*) was first settled near Santos (1531). Incursions to the westward led to the discovery of rich mines at Cuyabá and Matto Grosso, and colonies were established there far W. of the Tordesillas line. Portugal and Brazil were subject to Spain from 1582 to 1640.

The only other European nations who attempted settlements in South America were the French, Dutch, and English. The French had short-lived establishments at Rio de Janeiro and Maranhão on the Brazilian coast, and a part of that country was held by the Dutch from 1630 to 1654. (See BRAZIL.) All three nations formed establishments in Guiana during the seventeenth century; that of the English was soon abandoned, but they took the western part of the country from the Dutch in 1796. The colonies of the three nations still exist.

(3) *Period of Revolution and of Modern States.*—As early as 1780 the oppressions of the Spaniards led to the Indian rebellion of Tupac Amarú, near Cuzco. (See TUPAC AMARÚ.) The Spanish Government, through jealousy of other nations, had restricted the commerce of its colonies, and their distance caused much inconvenience and mismanagement. The Inquisition also was a constant source of grievance. The success of the North American and French revolutions led the Spanish-Americans to believe that they also might become independent. There were local rebellions in Peru in 1811 and 1812, and in 1813 the people of Lima rose against the Inquisition and drove its officers from the city. By Napoleon's invasion of Spain and the peninsular wars the government of the American colonies was thrown into confusion; at length a decided revolution broke out in Venezuela (Apr., 1810). From the first Simon Bolívar was its leader. The viceroy was deposed and a republic established, but fresh troops arrived from Spain and the rebellion was quelled (1812), Bolívar escaping to Jamaica. About the same time there were equally unsuccessful rebellions in Chili and Bolivia; but in Buenos Ayres the Spanish officials were driven out and a national government formed (1810-13). This was the first permanently successful revolution in South America. But meanwhile the excitement had spread to all the colonies, and local rebellions were constantly taking place. Bolívar returned to Venezuela (1817), collected a small army on the Orinoco, and was declared president of the country at Angostura (1819). By the battles of Boyaca (Aug. 7, 1819) and Carabobo (June 24, 1821) he freed Venezuela and Colombia from the Spaniards, and the two countries were united as a common republic. In 1822 he freed Quito (now Ecuador), and the country was incorporated with the others under the general name of Colombia. His lieutenant, Gen. Sucre, advanced into Peru, was joined there by Santa Cruz, and the Spaniards were defeated at the battle of Pichincha.

Meanwhile fresh revolts had broken out in Chili and Bolivia, and were supported from Buenos Ayres. San Martín marched from the Argentine across the Chilean Andes (Jan., 1817), took Santiago, and declined the office of supreme dictator of Chili to which he was nominated. By the battle of Maipú (Apr. 5, 1818) the Spaniards were finally driven from Chili. The revolutionists now organized a fleet and advanced northward to aid their party in Peru, the ships being commanded by Lord Cochrane and the army by San Martín. Callao was besieged and its castle taken (Sept., 1821). San Martín drove the Spaniards before him and entered Lima, and Peru was declared independent (July 28, 1821), San Martín being named protector of that country. San Martín and Bolívar met at Guayaquil; soon after the former resigned his office and retired to private life in Europe, honored by every Spanish American.

From Peru an expedition was sent under Gen. Santa Cruz to aid the revolutionists in Bolivia. It suffered two severe reverses, but by the battle of Ayacucho, not far from Cuzco, the power of the Spaniards in South America was finally overthrown (Dec. 9, 1824). The only point which they still held was Callao Castle, which they had retaken by a mutiny of the garrison; but this was surrendered on Jan. 19, 1826.

Bolívar had been declared dictator of Lower and Upper Peru. In 1825 he decreed that Upper Peru should be an independent republic, and it received the name of Bolivia. Peru began its independent existence in 1826. In 1830 the republic of Colombia separated into the three states of

Ecuador, Venezuela, and New Grenada; the latter changed its constitution in 1857, and was thereafter known as the United States of Colombia. Uruguay began its separate existence in 1828, and Paraguay was declared independent from 1811. The subsequent histories of these countries will be treated of under their respective names.

In 1807 the Portuguese court was driven from Lisbon by the armies of Napoleon and took refuge in Brazil, only returning in 1821. The king's son, Dom Pedro, was left as regent, but the revolutionary movement which had long existed ended in the separation of Brazil from Portugal, and the establishment of an empire with the prince at its head as Pedro I. (1822). His successor, Pedro II., was forced to abdicate in 1889, and the country became a federal republic under the name of the United States of Brazil.

Negro slavery was early established in Spanish America, but the number of slaves was not large, and they were freed either during the revolution or soon after. The system was much more prominent in Brazil, where slavery was finally abolished in 1888.

American Association for the Advancement of Science: the most important American scientific society. On April 2, 1840, the Association of American Geologists was organized in Philadelphia. Two years later, at a session held in Boston, its scope was enlarged, and it became the Association of American Geologists and Naturalists. In 1847, likewise at a Boston session, a new organization was effected, embracing all sciences, and the present name was assumed. Any person may become a member, but membership practically includes only citizens of the U. S. and Canada. From the membership are chosen fellows, and the body of fellows choose the officers. There are now about 800 fellows and 1,200 other members. The society is migratory, meeting each summer in some North American city. The meeting occupies a week, the attendance ranging from 300 to 1,000. For the purposes of its scientific sessions, the association is organized in nine sections as follows: Section A. Mathematics and Astronomy; B. Physics; C. Chemistry; D. Mechanical Science; E. Geology and Geography; F. Zoölogy; G. Botany; H. Anthropology; I. Economic Science and Statistics. These meet separately for the hearing and discussion of papers. An annual volume of proceedings is printed at Salem, Mass.

American Institute: a New York institution, the object of which is to encourage and promote domestic industry in New York State and the U. S., in agriculture, commerce, manufactures, and the arts, by bestowing rewards and other benefits on those who shall make improvements therein or excel in any of the said branches. It was organized in 1828 by a few enterprising citizens who met in a small room in Tammany Hall. A charter was granted in 1829 by the Legislature of the State of New York, under the title of The American Institute of the City of New York.

One of the principal means to accomplish its objects was the holding of exhibitions—or, as they were then called, annual fairs—in which inventors, manufacturers, and others could exhibit their various productions, and many modest men who would have remained in obscurity have made fortunes by having their skill and ingenuity brought prominently before the public by the great facilities afforded them by the American Institute. Among the things first shown at these exhibitions may be named Morse's telegraph, Colt's firearms, the sewing-machine, McCormick's reaper, Francis's metallic life-boats and car, Hoe's printing-press, and the telephone.

The first fair was held in 1828 in Masonic Hall, then standing on Broadway, nearly opposite the New York Hospital, at the head of Pearl Street. This was very successful, and after holding six fairs there it was found necessary to secure more ample accommodations. After examining various locations, Niblo's Garden was selected, notwithstanding that great doubts were expressed as to its accessibility, it being deemed by many too far out of town. The fair was, however, well patronized that year, and the exhibitions became very popular until the place was consumed by fire in 1846.

Castle Garden, on the Battery—then a fashionable resort for the citizens of New York—was next selected, and the fairs were held there every fall until 1853.

The exhibition of the industry of all nations was opened in the Crystal Palace in 1854, on Reservoir Square, in Sixth Avenue, between Fortieth and Forty-second Streets. After its close, the American Institute procured it for holding its exhibitions, which were held there in 1855, 1856, 1857, and 1858, when it was destroyed by fire on the afternoon of Oct. 5, 1858, with all its contents. Notwithstanding this disaster, the managers held an exhibition the next year in Palace Garden, in Fourteenth Street, on the site of the present armory of the Twenty-second Regiment. The institute, at great expense, made many improvements in that building, and held fairs in it for several years.

In 1863 the exhibition was held in the Academy of Music, Fourteenth Street and Irving Place.

In 1869 the institute secured the large structure on Third Avenue between Sixty-third and Sixty-fourth Streets. This building had been erected for a skating-rink; to this the institute has added three large buildings, the whole covering forty city lots, extending from Third to Second Avenue.

The exhibitions are held under the direction of a board of managers, elected annually by the members. The articles on exhibition are classified under seven departments, which are again divided into seven groups. The classifications are as follows:

1. Department of Fine Arts and Education.
2. Department of the Dwelling.
3. Department of Dress and Handicraft.
4. Department of Chemistry and Mineralogy.
5. Department of Engines and Machinery.
6. Department of Intercommunication.
7. Department of Agriculture and Horticulture.

In connection with the fairs, the American Institute has held eighteen exhibitions of live stock from 1838 to 1859; the exhibitions of 1857 and 1858 were confined to fat cattle.

The exhibitions were held for some years on the ground on which the Fifth Avenue Hotel now stands; it was then out of town. On this ground stood a famed hostelry known as Madison Cottage, kept by Corporal Thompson; this was the stopping-place for the Broadway stages.

The cattle-shows were also held on Hamilton Square and on Hamilton Park, in Third Avenue.

In addition to its valuable scientific library, consisting of about 14,000 volumes, there are four sections, viz.:

1. The Farmers' Club, under the direction of the committee on agriculture, which meets the first Tuesday of each month, at 2 P. M., at its rooms.

2. The Polytechnic, under the direction of the committee on manufactures and machinery, which discusses scientific subjects, the examination of new inventions, etc.; it meets at the same place on the third Thursday of each month, at 8 P. M.

3. The Photographic Section, under the direction of the committee on chemistry and optics, which discusses all matters in relation to photography and the action of light. This section meets at the same place on the first Tuesday of each month, at 8 P. M.

4. The Electrical Section, under the direction of the electric committee; its objects are advancement of electrical knowledge among its members. The section meets on the second Wednesday of each month, at 8 P. M.

All these meetings are open to the public.

The number of members is about 1,500. The institute is governed by a board of trustees consisting of thirteen members, of which the president, two vice-presidents, and two members are retired and elected annually. Prominent among its early friends were William Few, its first president in 1828-29; John Mason, in 1830-31; Gen. James Tallmadge, until 1846, when Mahlon Dickenson became president, holding office for two years, when Gen. Tallmadge, who had just returned from Europe, was again elected, and served in that capacity until his death in 1853.

The presidents of the institute since that date have been Robert L. Pell, James Renwick, William Hall, Horace Greeley, William B. Ogden, F. A. P. Barnard, Orestes Cleveland, Nathan C. Ely, Cyrus H. Loutrel, Thomas Rutter, and J. Trumbull Smith.

JOHN W. CHAMBERS.

Americanisms: a great and incongruous variety of peculiarities of speech in inflection, syntax, vocabulary, and pronunciation which are found to occur either locally or generally, in either the spoken or written English of the U. S., and which appear to depart from the usage of the standard English of Great Britain. The great mass of these are, however, either survivals from older English, or dialectal peculiarities inherited from the English dialects and still existing in these dialects, though not recognized by the standard language; or, finally, they are so entirely local or individual in their American use as not to be properly styled Americanisms at all, but simply represent caprices of expression, which have never established themselves as elements of a language. It is a recognized weakness of Bartlett's well-known *Dictionary of Americanisms* that it makes no attempt to discriminate between these classes, or to apply any rigid tests in determining what are really "Americanisms."

The term may be limited in one of two ways. It may be made to apply solely to those peculiarities which are the special product of American usage, as *caucus*. The question may, however, on the other hand, be regarded as one purely of standard, and the term be used to cover all those features of common standard usage in U. S. English which depart from the standard English of the British islands. This latter limitation of the term offers the most practical solution, for the question is really one of usage and standard rather than of origins. In determining the existence of a standard and what may belong to that standard, we are in nowise concerned with the *origin* of words or expressions. It is not a question of origin, but one of "good form." The observation that *to guess* in the sense of "opinari" is found in Chaucer and Gower does not prevent its being regarded as an Americanism, if it shall be determined that, while excluded from the English standard, it is in universal and accepted use in the U. S. The word *fall* for *autumn* may, in isolated instances, be found in English writers, and is undoubtedly, with some meaning or other, a good old English word, but the fact is that as a substitute for *autumn* it is not "good form" in Great Britain, and is in the U. S. *Spry*, "nimble," "active," is an Americanism, because, though found in the English dialects, it is a standard word only in the U. S.

The question of standard, it must again be remembered, concerns not what ought to be, but what is the fact. The assertion of certain purists that the usage of the educated classes in London ought to be regarded as the absolute standard for the English of the U. S. also does not alter the fact that usage in the U. S., while following in the main the general standards of Great Britain, feels itself independent within certain limits, and maintains a secondary standard of its own. This is based not upon the usage of any class or any district, but upon the common and universally recognized

usage in the chief centers and along the chief avenues of commercial activity and national life, and corresponds to the rapidly developing consciousness of nationality.

Cases of true Americanisms—i. e. of expressions which are quite universally acceptable in the U. S., at least among speakers whose usage is not recently and consciously affected by contact or instruction, but which are foreign to the standard usage in Great Britain—are the following: Different words for the same idea: Amer. *bureau*, Eng. *dressing-table*; Amer. *elevator*, Eng. *lift*; Amer. *sleigh*, Eng. *sledge*; Amer. *store*, Eng. *shop*; Amer. *fall*, Eng. *autumn* (also Amer.); Amer. *candy*, Eng. *sweets*; Amer. *cracker*, Eng. *biscuit*; Amer. *rare* (of meat), Eng. *under done*; Amer. *straight* (of drinks), Eng. *neat*; Amer. *pants* (regarded as vulgar by cultivated classes in cities), Eng. *trousers*; Amer. *sack-coal*, Eng. *jacket*; Amer. *waist*, Eng. *body*, *bodice*, etc. Especially instructive is it to note how special activities, particularly those of more modern development, have found themselves in Great Britain and the U. S. separate vocabularies; for instance, the language of railroad travel: Amer. *engineer*, Eng. *engine-driver*; Amer. *fireman*, Eng. *stoker*; Amer. *conductor*, Eng. *guard* (only in general comparable, as functions differ); Amer. *baggage-car*, Eng. *luggage-van*; Amer. *railroad*, Eng. *railway*; Amer. *car*, Eng. *carriage*; Amer. *road*, Eng. *tine*; Amer. *switch*, Eng. *points*; Amer. *to switch*, Eng. *to shunt*; Amer. *freight-train*, Eng. *goods-train*; Amer. *baggage*, Eng. *luggage*; Amer. *horse-car*, Eng. *tram-car*, etc.

Political life in the U. S. also has developed a vocabulary of its own, thus: *caucus*, *stump*, *to stump*, *fibbustler*, *federalist*, *senatoriat*, *gubernatorial*, *copperheads*, *knownothings*, *carpet-baggers*, *to gerrymander*, *to toby*, *miteage*, *wire-putter*, etc.

Differences in the use of words common to both: *Tiresome*, Eng. "dull," "annoying," Amer. "fatiguing." *Lumber*, in Great Britain means "cumbersome material"; in the U. S. it means also building material of wood. *To fix*, in Great Britain means "to fasten"; in the U. S. it also means "to repair." *Corn*, in Great Britain denotes "grain"; in the U. S. it is used to designate "maize." *To transpire*, in Great Britain is to "exhale," "become public," etc., as in the U. S., where it also means to "occur."

The subtler differences in turns of expression are even more significant than single words: Amer. *quarter of five*, Eng. *quarter to five*; Amer. *sick abed*, Eng. *itt in bed*; Amer. *back and forth*, Eng. *to and fro*; Amer. *it doesn't amount to anything*, Eng. *come to*; Amer. *fill teeth*, Eng. *stop teeth*; Amer. *have a good time*, Eng. *enjoy one's self* (also Amer.); Amer. *are you through?* Eng. *have you finished?* etc.

The study of the American dialects of English is beset with peculiar difficulty, owing to the freedom of movement and intercourse, and the mixture of population in even the original settlements; but systematic work in this field has been begun under the auspices of the recently (1889) established American Dialect Society (secretary, Prof. E. S. Sheldon, Cambridge, Mass.), which publishes its collections of material in the *Dialect Notes*. A specimen investigation of a local dialect is afforded in O. F. Emerson's *Dialect of Ithaca* (N. Y., 1891); Bartlett, J. R., *Dictionary of Americanisms* (4th ed. 1877); White, R. G., *Words and their Uses*, chap. iii. (1870); *Galaxy*, xxi. 521; xxiv. 376, 681; *Atlantic Monthly*, xli. 495, 656; xlii. 97, 342, 619, 643, and in succeeding volumes; Schele de Vere, M., *Americanisms* (1872); *Southern Review*, ix. 290, 529, (U. S.) *Americanisms*, a Study of Words and Manners; Primer, S., *The Huguenot Element in Charleston's Provincialisms*, *Phonetische Studien*, iii. 139; *The Pronunciation near Fredericksburg, Va.*, *Proceedings Am. Phil. Assoc.* (1889); *Dialectical Studies in West Virginia*, *Colorado College Studies*, vol. i.; Norton, L., *Political Americanisms* (1891); Lowell, J. R., *Biglow Papers* (1848, 1864); Lounsbury, T. R., *The English Language in America*, *International Review*, viii. 472, 596; Smith, C. F., *On Southernisms*, *Transac. Am. Phil. Assoc.*, 1883; Carruth, W. H., *Dialect Word-list*, *Kansas Univ. Quarterly*, i. 95 ff.; Farmer, J. S., *Americanisms, Old and New; a Dictionary of Words, Phrases, and Colloquialisms peculiar to the United States, British America, and the West Indies* (Lond. 1889). BENJ. IDE WHEELER.

American Languages: See INDIAN LANGUAGES OF AMERICA.

American Party: See KNOWNOTHINGS.

American Plants: this term is applied in Great Britain to *Rhododendrons*, *Azateas*, and other related Ericaceous plants. It also includes hardy flowering shrubs growing in peaty soil.

C. E. B.

American River: in the north central part of California, formed by the union of its North and South Forks in the western part of El Dorado County; it flows in a S. W. direction, and empties into the Sacramento river a short distance above Sacramento city. Gold is found along the banks of this river and its forks.

American Sunday-school Union: organized at Philadelphia, May 25, 1824. It was, however, the immediate successor of the Philadelphia Sunday and Adult School Union, which was organized in 1817, and had auxiliary "unions," or branches, in eleven of the States, when, in 1824, it transferred its capital and schools to the new national organization. A still earlier organization, to the work of which the new national society practically succeeded, was the First Day or Sunday-school Society of Philadelphia, started in 1790. The American Sunday-school Union is under the direction of thirty-six managers, of whom at least twenty-four must reside in Philadelphia and its vicinity. All these managers are laymen, and they are selected from various Christian denominations. The union is not a union of denominations, but of individual Christians of different denominations. The object of the union was, at its formation, "to concentrate the efforts of Sabbath-school societies in the different parts of our country, to strengthen the hands of the friends of pious instruction on the Lord's Day, to disseminate useful information, circulate moral and religious publications in every part of the land, and to endeavor to plant a Sunday-school wherever there is a population." Various denominational Sunday-school societies have resulted from the work of the union, but it has continued its operations without interruption, and its aim still is to improve existing Sunday-schools, and to organize new ones. Its plan is to publish books and papers suited to the wants of Sunday-schools, and to send out missionaries, lay and clerical, of various denominations, to organize new Sunday-schools wherever there is a needy population. No Sunday-schools are under the control of the union, but its missionaries watch and help as they have opportunity the pioneer schools they have organized. Many of these schools have proved the foundation of Christian churches. Indeed, a large share of all the Protestant churches organized in the newer States within the past fifty years have had their beginning in Union Sunday-schools. The union has been the parent of most of the distinctive agencies and methods of the American Sunday-school system. Sunday-school libraries, question-books, periodicals, teachers' helps, conventions, plans for teacher-training, schemes of limited lessons uniform throughout the country, were originated by or first gained prominence through the agency of the union or of its officers and managers. Moreover, its work created or stimulated a demand in these departments which has greatly increased the supply in them all. Its list of separate publications exceeds 2,000. The value of these, circulated by sale and donation, up to Mar. 1, 1892, amounts to more than \$10,000,000. Up to the same date its missionaries had organized 89,380 Sunday-schools, including, at the time of their organization, 534,704 teachers and 3,677,709 scholars. In addition to this, its missionaries have visited and helped many thousands of existing schools, including several millions of scholars.

HENRY CLAY TRUMBULL.

American University, THE: a post-graduate institution at Washington, D. C., under the direction of the Methodist Episcopal Church; was chartered in the District of Columbia, May 28, 1891. A site of 90 acres, at the N. W. terminus of Massachusetts Avenue extended, is the gift of the citizens of Washington. Its board of trustees, numbering fifty, includes as *ex-officio* members the President, the Vice-President, the Chief Justice of the Supreme Court of the U. S., and the Speaker of the House of Representatives. The Methodist Episcopal Church, by the action of the General Conference, May 25, 1892, accepted the patronage of this institution. Endowment will be made and faculty organized with distinct purpose to open professional and post-graduate departments for advanced studies and original research. Only those who have taken a degree will be received as students. Bishop John F. Hurst, D. D., LL. D., is chancellor.

A. OSBORN.

Amer'icus: city; capital of Sumter co., Ga. (for location of county, see map of Georgia, ref. 5-G); on railroad: 70 miles S. S. W. of Macon; has a female college and a high school for boys, and is situated in a cotton and sugar-cane raising district. Pop. (1880) 3,635; (1890) 6,398; (1900) 7,674.

Americus Vespuccius: See VESPUCCI.

Ameri'ola: a city of ancient Latium; one of those which were conquered by the elder Tarquin. It was among the "Prisci Latini," and was doubtless one of the thirty cities of the League. Its site is not definitely known.

A'mersfort, or **A'mersfoort**: a town and port of the Netherlands; province of Utrecht; on the river Eem, 12 miles N. E. of Utrecht (see map of Holland and Belgium, ref. 5-G). It has a Jansenist seminary, a Latin school, and manufactures of cotton and woolen stuffs. Tobacco, grain, and dried herrings are exported from this town. It received municipal privileges in 1249, and was taken by the Archduke Maximilian in 1483 and by the French in 1672 and 1695. Pop. (1879) 13,704; (1890) 15,694.

Ames: city; Story co., Ia.; on Chi. and N. W. Ry. (for location, see map of Iowa, ref. 5-G); the seat of the State Agricultural College. Pop. (1880) 1,153; (1890) 1,276; (1900) 2,422.

EDITOR OF "INTELLIGENCER."

Ames, ADELBERT: soldier; b. at Rockland, Me., Oct. 31, 1835; graduated at West Point 1861; lieutenant-colonel Twenty-fourth Infantry July 28, 1866, and brigadier-general U. S. Vols. May 20, 1863. Brevetted major-general Mar. 13, 1865, for gallant and meritorious services in the field. Since the war was made provisional governor of Mississippi June 15, 1868, in command of fourth military district, department of Mississippi, 1869. Resigned Feb. 23, 1870; U. S. Senator from Mississippi 1870-73; Governor of State of Mississippi 1874-76.

Ames, CHARLES GORDON: Unitarian preacher and editor; b. at Dorchester, Mass., Oct. 3, 1828; studied and taught for three years in Grange Seminary, Ohio; was for ten years a Free Baptist preacher at Minneapolis; organized Unitarian churches in Illinois, California, and Pennsylvania; held pastorates at Albany, N. Y., Germantown, Pa., and Boston, Mass., and became in 1889 pastor of the Church of the Disciples, Boston. Was editor of the *Minneapolis Republican*, the first Republican paper in the Northwest, in 1854, and the *Christian Register*, 1877-80; has preached and lectured in twenty States, and published numerous tracts, essays, and articles. His *George Eliot's Two Marriages* ran through four editions. He also edited *The Ethics of George Eliot*, and wrote the introduction to that book. Has been deeply interested in all social and philanthropic questions.

JOHN W. CHADWICK.

Ames, EDWARD RAYMOND, D. D., LL. D.: Bishop of the Methodist Episcopal Church; b. at Athens, O., May 20, 1806. He was educated at Ohio University; was tutor at McKendree College 1823-29; began to preach in 1830, and was appointed a bishop in 1852. From 1861 he resided in Baltimore. D. at Baltimore, Md., April 25, 1879.

Ames, FISHER, LL. D.: orator and statesman; b. at Dedham, Mass., Apr. 9, 1758. He graduated at Harvard College in 1774, after which he studied law in the office of William Tudor, of Boston, and was admitted to the bar in 1781. In several political essays which he wrote for the newspapers of Boston about 1785 he displayed practical wisdom and literary ability of a high order. He was a member of the convention of Massachusetts which in 1788 ratified the Federal Constitution, and he advocated its adoption in an eloquent speech. Having identified himself with the Federal party, he was elected to Congress in 1789 by the voters of the district which included Boston. He supported the administration of Washington, spoke frequently in Congress, and soon acquired a national reputation as an orator of the foremost rank. Among the most memorable of his parliamentary efforts was a powerful speech in support of Jay's treaty with Great Britain, April, 1796, which has been preserved. At the close of this speech an opponent of the treaty moved to postpone the vote on the question, giving as a reason that the members were too much excited to make a just and rational decision. After he had served four terms in Congress he retired to private life in 1797, on account of his delicate health. He married Frances Worthington, of Springfield, in 1792. In 1799 he pronounced a eulogy on Washington before the Legislature of Massachusetts. He was elected president of Harvard College in 1804, but he declined that position. He died at Dedham, Mass., July 4, 1808, leaving several sons. His character was eminently pure and honorable. He was distinguished for his wit, his colloquial powers, and his brilliant imagination. His orations abound in happy metaphors and illustrations. His works, consisting of orations, essays, and letters, were published by his son, Seth Ames, in 2 vols., 1854.

Amesbury: on railroad; Essex co., Mass. (for location of county, see map of Massachusetts, ref. 1-I); 40 miles by rail N. of Boston. There are two electric railroads, one via East Salisbury to Newburyport, 5 miles distant, and another, 5 miles long, to Merrimac. There is also a branch railroad connecting with the Eastern R. R. Here are extensive manufactures of flannels, carriages, boots and shoes, cassimeres, broadcloths, etc. Amesbury was the residence of the poet Whittier. The township has been united since the 1870 census. Pop. of township (1880) 3,355; (1890) 9,798; (1900) 9,473

EDITOR OF "AMESBURY DAILY."

Am'ethyst [Gr. ἀμέθυστος, remedy against drunkenness; ἀ-, not + μέδυσκειν, intoxicate]: a purple variety of rock-crystal or quartz, colored by manganese, so named from its reputed virtue of preventing intoxication. It is found in Brazil, Ceylon, India, and many other places, and is worn in the form of seals and ornamental articles. The Oriental amethyst is a variety of spinel, and is a more valuable gem than the common amethyst.

Amha'ra: the central division of Abyssinia; capital, Gondar. See ABYSSINIA.

Amhar'ic Lan'guage [from the province of Amhara]: the chief language of Abyssinia, since the extinction of the ETHIOPIC LANGUAGE (*q. v.*). It is spoken by the majority of the population in the countries between the rivers Tacazze and Abai, and in Shoa and Argubba, while in the countries in the N. E. of Abyssinia, N. of the Tacazze, the Tigré language predominates. Among the Semitic languages, the Amharic is nearest related, both grammatically and lexicographically, to the Ethiopic, but is by no means a new form of the Ethiopic, but rather a descendant of the Old Amharic, which is closely allied to the Ethiopic. Although the Amharic has retained many peculiarities of the Old Semitic, it still represents a later stage of development of the southern Semitic than does the Ethiopic. In all its phonetic relations the Amharic has degenerated very much, while many of its grammatical forms have been abolished, and have been only in part replaced by new forms. After the Amharic language had been used for many centuries by the people, and after the extinction of the Ethiopic, it became a written language, the Ethiopic alphabet being employed, while for the sounds peculiar to the Amharic new characters were introduced by a modification of the Ethiopic characters. Although the Amharic can not be called a literary language in the true sense of the word, still many works have been written in it within the last three centuries, partly translations and explanations of biblical and other Ethiopic books and vocabularies, partly short historical works, dogmatical and ethical compendia, formulæ for confession, etc., for the people, partly medical and magical treatises, and, recently, translations of European books. In the Ethiopic-Amharic books of the history of the native kings some of the older Amharic poems are given. But of these works very little is known in Europe. Up to the present time only missionary works have been printed. The Amharic has been treated grammatically and lexicographically by Ludolf (1698); more completely by Isenberg (*Lexicon*, 1841; *Grammar*, 1842); and very fully, from the modern linguistic point of view, by Franz Praetorius (*Grammar*, 1879), and Antoine d'Abbadie (*Dictionary*, 1881). For fuller information, see the works of Praetorius and d'Abbadie. See SEMITIC LANGUAGES. Revised by C. H. Toy.

Am'herst: a town and seaport of Burma, capital of a district of the same name, 30 miles S. S. W. of Maulmain (see map of S. India, ref. 4-M). It was founded by the British in 1826, and named in honor of the Governor-General of India, who projected it. Large teak forests abound in its neighborhood, and the timber is exported in considerable quantities. The harbor, though large and deep, is difficult of access, and is exposed to the S. W. monsoon. Pop. about 30,000.

Amherst: capital of Cumberland co., Nova Scotia, Canada (see map of Quebec, ref. 2-B), on Intercolonial R. R., near the N. E. end of the Bay of Fundy; is about midway between Halifax, Nova Scotia, and St. John, New Brunswick, and is in an agricultural, lumber, coal-mining, manufacturing, and ship-building district. Pop. (1881) 2,274; (1891) 3,781.

Amherst: on Central Mass. and New Lond. and N. R. Rs.; in Hampshire co., Mass. (for location of county, see map of Massachusetts, ref. 3-E); 85 miles N. of New London, and 82 miles W. of Boston. It is the seat of Amherst College and of the Massachusetts Agricultural College. (See AMHERST COLLEGE.) The town has excellent schools, including

a high school. It has also paper and planing mills, manufactures of leather, children's wagons, palm-leaf hats, and planes. Amherst is one of the most healthful towns in Massachusetts. The village is situated upon an elevation which affords a beautiful view of the fertile and picturesque valley of the Connecticut and of the surrounding mountains—the Holyoke range to the S. W., and on the N. Mettawampe, Sugar Loaf, and others. Pop. of township (1880) 4,298; (1890) 4,512; (1900) 5,028. EDITOR OF "RECORD."

Amherst, JEFFERY (called **Lord Amherst**): British general; b. at Riverhead, in Kent, Jan. 29, 1717. He entered the army in 1731, and became aide-de-camp to Gen. Ligonier in 1741; served with him in the battles of Dettingen, Fontenoy, and Rocoux. In 1756 he became a colonel of infantry; went to America in 1758, and served against France in the inter-colonial war; commanded the troops at the siege of Louisbourg, a famous fortress built by the French upon the eastern coast of Cape Breton island; the town was destroyed by the bombardment, and, with the garrison and the French fleet, surrendered July 26, 1758; became commander-in-chief of all the forces in America, Sept. 30, 1758; completed the conquest of Canada from the French by the capture of Montreal Sept. 8, 1760; was made Knight of the Bath in 1761; Governor of Virginia in 1763; was dismissed from the army, but restored in 1768; became governor of Guernsey 1770; lieutenant-general of ordnance in 1772; Baron Amherst of Holmesdale 1776; commander-in-chief in England 1778-82; Baron Amherst of Montreal 1788; again commander-in-chief in England in 1793-95; became field marshal 1796. D. at Montreal, his seat in Kent, England, Aug. 3, 1797.

Amherst, WILLIAM PITT, First Earl of: nephew of the preceding; b. in England, Jan. 14, 1773. He was sent as an ambassador extraordinary to China in 1816, and reached Peking, but he failed to effect the object of his mission (which was to improve the commercial relations between that empire and Great Britain), as he refused to comply with the degrading ceremonies which Chinese etiquette prescribed, and was not admitted into the presence of the emperor. He was shipwrecked in Gaspar Strait on his return to England, but escaped by boat to Batavia, and continued his voyage, stopping at the island of St. Helena on his way, where he had a number of interviews with the Emperor Napoleon. He was Governor-General of India in 1823-26, and became an earl in 1826. D. at Knole Park, Kent, Mar. 13, 1857.—His son, WILLIAM PITT (b. 1805, d. 1886), succeeded him as second earl.

Amherstburg: Essex co., Ontario, Canada, on railroad and the Detroit river, 2 miles from its entrance into Lake Erie; 18 miles S. of Detroit, Mich., and 225 miles W. S. W. of Toronto (see map of Ontario, ref. 6-A). It is one of the oldest towns in Ontario, and during the war of 1812 between Great Britain and the U. S. it was dismantled by Gen. Proctor, of the British army, Sept. 26, 1813, and destroyed by Gen. Harrison of the U. S. forces, Oct. 2, 1813. It was named in honor of Lord Amherst, and has a large city-hall, 4 schools, 6 churches, water-works, and electric lights (both owned by the municipality), and some manufactures, and is the principal coaling-station on the Detroit river. Pop. (1881) 2,672; (1891) 2,279. EDITOR OF "ECHO."

Amherst College: one of the leading colleges in the U. S.; in Amherst, Hampshire co., Mass. It was founded in 1821, and in its general catalogue, in 1900, it had 4,000 alumni, of whom 3,000 were supposed to be living. Of the whole number of its graduates, 1,123 were ministers and 111 missionaries in foreign lands; 208 served in the civil war and 28 died in the service. The college edifices, 12 in number, have been erected at a cost of \$400,000. The pecuniary value of the scientific and archaeological collections can not be estimated at less than \$125,000, and the whole property of the institution, including permanent funds, professorships, scholarships, prizes, etc., is nearly \$2,000,000. All this is the gift of private charity and munificence, with the exception of about \$50,000 granted by the State. The donors have been chiefly the Christian men and women of Massachusetts. The Hitchcock Ichnological Cabinet, the Adams Collection in Conchology, the Shepard Meteoric Collection, and the Mather Art Collection, are widely known as of unsurpassed value and excellence. The Pratt Gymnasium, with its accompanying system of exercise and instruction, constitutes a feature peculiar to this institution; all the students, unless excused for special reasons, are required to exercise half an hour daily, chiefly in the light gymnastics, under the direction of a professor who is an educated physi-

cian, and who has charge of their health and physical culture. The Pratt Field for ball-playing and other athletic exercises gives Amherst an equipment for modern outdoor athletics in advance of any other college. The faculty of Amherst College consists of 34 persons, including 1 lecturer, 3 instructors, and a librarian with his assistant. The number of students in 1900, all in four classes of the regular college course, was 397. The annual income is about \$100,000. The presidents have been Rev. Z. Swift Moore, D. D. (1821-23); Rev. Heman Humphrey, D. D. (1823-45); Rev. Edward Hitchcock, D. D., LL. D. (1845-54); Rev. William A. Stearns, D. D., LL. D. (1854-76); Rev. Julius H. Seelye, D. D., LL. D. (1876-90); Merrill E. Gates, LL. D., L. H. D. (1890-99); and George Harris, D. D., LL. D.

The Massachusetts Agricultural College, although the offspring of Amherst College, and situated in the same place for the purpose of securing the advantage of its scientific treasures, has no organic connection with it, having a separate faculty and a distinct board of trustees, elected by the State Legislature. It was opened for students in the fall of 1867, and held its first commencement, with the graduation of its first class, in the summer of 1871. It has three college halls, a fine stone chapel and library building, two boarding-houses, the Durfee Plant-house, a large military building, and a botanic museum, besides the buildings pertaining to the farm, which consists of over 300 acres. The students work on the farm a certain number of hours each week, under the direction of the superintendent and the professor of agriculture. They also receive regular military exercise and drill under the professor of military science and tactics. The real estate of the college cost over \$200,000. Its permanent funds, derived from the sale of lands given by Congress, from grants by the State, and from private donations, amount to half a million. The faculty, as exhibited in the catalogue of 1890, consists of 14 persons, including the president, Henry H. Goodell, LL. D., 11 professors, 1 lecturer on farm law, and a farm superintendent. There were then 160 students—16 resident graduates, 20 seniors, 27 juniors, 35 sophomores, and 62 freshmen. See *History of Amherst College*, by Prof. W. S. Tyler, D. D., LL. D. (1872).

W. S. TYLER.

Amherst, or Tonti Island: an island in the eastern end of Lake Ontario, near the Canadian side, at the mouth of the Bay of Quinte. Pop. about 1,200. Amherst is also the name of one of the Magdalen islands in the Gulf of St. Lawrence; of a group of islands lying W. of the S. W. extremity of Korea; and of some islands off the coast of Arakan, a division of Burma. M. W. II.

Amia: a genus of fishes found in the fresh waters of North America; interesting from their relationship to the ancient fossil fishes, and remarkable for the cellular structure of the air-bladder, which somewhat resembles the lung of a reptile. One species is known (*Amia calva*) as the "dog-fish" or "bow-fin," and is worthless as food.

Amian'thus [Gr. *ἀμιανθος*, free from defilement; *ἀ-*, not + *μιαίνω*, defile. The h is due to false association with *ἄνθος*, flower]: a delicate and fibrous form of serpentine, so called because cloth made of it can be purified by fire. It is sometimes called mountain-flax. The cloths in which the ancients wrapped the bodies that were burned on the funeral pyre were sometimes made of amianthus.

Am'ice, or Amic'tus: an upper garment worn by the Romans over the tunic; also a linen vestment worn over the shoulders of Roman Catholic priests during the celebration of the mass. By the Sarum use (English), not only the higher clergy but those in minor orders were required at special seasons to be vested in both alb and amice. Formerly placed on the monarch's head at the coronation. King Edward VI. was the last to use it on this occasion.

Amici, *ā-mee'ehēe*, GIOVANNI BATTISTA: an Italian optician and savant; b. at Modena, Mar. 25, 1784. He was skillful in the fabrication of mirrors and lenses for telescopes and microscopes. He was for many years director of the Observatory of Florence, where he gained distinction as an observer. He wrote on double stars and other topics of astronomy. The achromatic microscope which he constructed was considered a valuable improvement. D. at Florence, Apr. 10, 1863.

Amicis, *ā-mee'ehēe*, EDMONDO, de: Italian writer; b. at Oneglia, Oct. 21, 1848; educated in the military college at Modena. He took part in expeditions against the Sicilian brigands, and then in the war of 1866 against Austria. His

first literary successes were some military sketches published in 1868 and thereafter, *La Vita Militare* (1869). A little later he traveled extensively, and showed himself a master in the art of describing the life and natural aspects of foreign countries and cities. His works in this manner have been much admired, and translated into many modern languages. They are: *La Spagna* (1873); *Ricordi di Londra* (1874); *Olanda* (1874); *Marocco* (1876); *Ricordi di Parigi* (1878); *Costantinopoli* (1878). In his work *Il Romanzo d'un Maestro* (1889), he has given a striking account of the condition of popular education in Italy.

A. R. MARSH.

Amiel, ämëe-el', HENRI FRÉDÉRIC: Genevese poet and thinker; b. at Geneva, Sept. 27, 1821. Educated in Geneva, he subsequently spent several years in study at Heidelberg and Berlin, and in travel in Italy, Germany, Scandinavia, and Holland. In 1849 he was appointed Professor of Æsthetics and French Literature in the Academy of Geneva; in 1854, Professor of Moral Philosophy. A brilliant career was now expected of him, but to the surprise and regret of his friends his life gradually slipped away with the production of no more than a few essays and slight volumes of poems: *Grains de Mil* (1854); *Il Penseroso* (1858); *La Part du Rêve* (1863); and *Jour à Jour* (1880). When he died, however, it was found that he had left a private journal of enormous extent (17,000 folio pages of manuscript), in which he had written down for years his meditations and experiences. In 1882 the first volume of extracts from this *Journal Intime* was published, and was at once recognized by all Europe as a very remarkable book. Thus after his death Amiel attained to fame—the fame of one of the best interpreters of the spiritual and intellectual doubts and anxieties which vex the noblest minds in our time. In 1884 a second volume of extracts appeared, and deepened this impression. See the *Journal Intime*, translated by Mrs. Humphry Ward (London, 1889); *Henri Frédéric Amiel, étude biographique*, par Berthe Vadier (Paris, 1886). D. at Geneva, May 11, 1881.

A. R. MARSH.

Amiens (anc. *Samarobri'va* and *Ambia'ni*): an ancient and important town of Northern France; capital of the department of Somme, on the river Somme, and on the Paris and Boulogne R. R., 81 miles by rail N. of Paris (see map of France, ref. 2-F). It was once very strongly fortified, and still has a citadel. It is the seat of a bishop, and contains a magnificent Gothic cathedral, 415 feet long, 182 feet wide, which was founded in 1220. This is one of the six or seven most important Gothic cathedrals of France, ranking with both of Chartres, Paris, Bourges, Rouen, and Reims. It contains the most remarkable set of choir-stalls, in carved oak, existing. Among its other fine edifices are the Hôtel de Ville, Château d'Eau, and the library, containing 60,000 volumes. Here are extensive manufactures of cotton velvet, serges, plush, and other cotton and woolen stuffs. The river, which is here divided into many canals, affords water-power for mills and manufactories. Amiens was the native place of Peter the Hermit and of Delambre. An important treaty, called "the Peace of Amiens," was signed here by the French and British in March, 1802. On Nov. 27, 1870, the German General Manteuffel obtained here a great victory over the French army of the Loire, and soon after the Germans took possession of the town. Pop. (1896) 88,731.

Revised by RUSSELL STURGIS.

Amite, am-cet': a river rising in the S. W. part of Mississippi; enters Louisiana, flows southward to Ascension parish, where it turns toward the E. and falls into Lake Maurepas. Length about 100 miles.

Amite City: capital of Tangipahoa parish, La. (for location of parish, see map of Louisiana, ref. 9-F); on the Illinois Central R. R. and the Tangipahoa river, 68 miles N. N. W. of New Orleans; has a court-house, 5 churches, 2 schools, and a weekly newspaper. Extensive truck-farming is carried on in the neighborhood. Pop. (1880) 1,120; (1890) 1,510; (1900) 1,547. EDITOR OF "THE FLORIDA PARISHES."

Amityville: summer resort near Babylon, Suffolk co., N. Y. (for location of county, see map of New York, ref. 8-C); on Long Island R. R., 31 miles E. of New York city, and half a mile from the south shore of Long Island. Pop. (1880) 1,063; (1890) 2,293; (1900) 2,038.

Am'leth, or **Ham'leth**: an ancient Prince of Jutland, who is considered a fabulous personage by some writers. He is said to have lived about 150 B. C. His story is related by Saxo Grammaticus, whose narrative was formerly considered the foundation of Shakspeare's *Hamlet*. But Saxo Gram-

maticus was not translated into English when Shakspeare wrote his play, and the differences between the historical narrative and the tragedy give irrefragable evidence that the writer of the latter has known the former only at second hand—probably through the novel of Belleforest, which just at that time was translated from French into English.

Am'ling, KARL GUSTAV: designer and engraver; b. at Nuremberg, Bavaria, about 1650; worked at Munich, Bavaria; was patronized by Maximilian II., and very successful in portraits. He was considered the best German engraver of his time. D. in 1701.

Amling, WOLFGANG: b. at Minnerstadt, Franconia, in 1542; educated at the universities of Tübingen, Wittenberg, and Jena; became rector of the school of Zerbst in 1566, minister at Koswig in 1573, and soon after minister at St. Nicolai in Zerbst. He strongly opposed the *Formula Concordiæ*, and wrote the *Confessio Anhaltina*. D. May 18, 1606.

Amlweh, am'look: a seaport and parliamentary borough of North Wales; is on the north coast of the island of Anglesey, 15 miles N. W. of Beaumaris (see map of England, ref. 7-D). It owes its prosperity to the Parys and Mona copper mines. Pop. about 5,000.

Am'man, or **Am'mon** (the ancient *Rabbah*, the capital of the Ammonites): a ruined city of Syria, in the pashalic of Damascus; picturesquely situated on the Zurka, an affluent of the Jordan, 55 miles E. N. E. of Jerusalem. Here was an important city in ancient times, originally named Rabbah, which was besieged and taken by the army of King David. (See 2 Sam. xi. and xii.) After it had been once ruined it was rebuilt by Ptolemy Philadelphus, and called Philadelphia. It has extensive ancient remains. As late as 300 A. D. it was a remarkable city, having a magnificent theater and temples. It was one of the cities of the Decapolis.

Amman, JOHANN CONRAD, M. D.: Swiss physician; b. at Schaffhausen in 1669; practiced at Haarlem and Amsterdam in Holland. He acquired distinction by his successful efforts to teach the deaf and dumb to speak, and wrote on that subject an essay called *Surdus Loquens* (the Deaf Speaking, Amsterdam, 1692; Eng. trans. 1694). D. near Leyden, 1724.

Amman, JOST or JUSTUS: Swiss engraver and designer; b. at Zurich in 1539. He removed about 1560 to Nuremberg, where he worked for many years and illustrated numerous books with his designs. He engraved on copper and on wood. Among his works are *Portraits of the Kings of France from Pharamond to Henry III.* (1576), and woodcuts of "Reinecke Fuchs." D. at Nuremberg in 1591. See his biography, by C. Becker (Leipzig, 1854).

Ammana'ti, **Ammana'te**, or **Ammana'to**, BARTOLOMMEO: Italian sculptor and architect; b. at Settignano, near Florence, June 18, 1511; was a pupil of Sansovino. He was patronized by Pope Julius III., who employed him to adorn the Capitol (in Rome) with sculptures. He completed the Pitti palace of Florence. Among his best works are a bridge called Ponte della Trinità at Florence, and three statues which adorn the tomb of Sannazar at Naples. D. in Florence, Apr. 22, 1592.

Am'men, DANIEL: rear-admiral, U. S. N.; b. in Brown co., O., May 15, 1820; entered the navy as a midshipman July 7, 1836. During the latter part of 1861 and all of 1862 he commanded the gunboat Seneea in the South Atlantic blockading squadron; he bore a conspicuous part in the battle of Port Royal, Nov. 7, 1861. He engaged afterward in all the operations of Dupont's command on the coasts of Georgia and Florida; was commanding officer of the monitor Patapseo in the engagement with Fort McAllister, Mar. 3, 1863; in the ironclad attack on Fort Sumter, Apr. 7, 1863; in both attacks on Fort Fisher, Dec., 1864, and Jan., 1865; in 1866 and 1867 a member of the board assembled to examine volunteer officers for admission into the regular navy; in 1869 appointed chief of the bureau of yards and docks, and on Oct. 1, 1871, chief of bureau of navigation; retired June 4, 1878. Author of *Country Homes and their Improvement*; *The Old Navy and the New*, etc. He designed the Ammen life-raft. Congress, by the act of Mar. 2, 1889, authorized the construction of a twin screw, armor-plated, harbor-defense ram (the Katahdin) upon the design of Admiral Ammen. She is 251 feet long, 43.5 feet beam, mean draft 15 feet, displacement 2,183 tons. D. near Baltimore, Md., July 11, 1898.

Ammen, JACOB: soldier and teacher; b. in Botetourt co., Va., Jan. 7, 1808; graduated at West Point 1831; and be-

came, July 16, 1862, brigadier-general U. S. Vols. During the civil war he was captain and lieutenant-colonel of the Twelfth Ohio Vols., colonel of the Twenty-fourth, and brigadier-general U. S. Vols. D. at Lockport, O., Feb. 6, 1894.

Am'mergau Mys'tery (Ger. *Ammergau Passionsspiel*): the representation of our Saviour's Passion which since 1634 has taken place every ten years at the village of Ober-Ammergau (*q. v.*), in Bavaria. The custom originated in a vow made by the inhabitants on their deliverance from the plague to celebrate the Passion tragedy every tenth year. The last representation took place in 1900. The text of the Passion-play is given by W. T. Stead (London, 1890).

Am'meter or **Ampère'meter**: an instrument for the measurement of heavy electric currents. The ammeter is distinguished from the current-meter (see **ELECTRIC-METER**) in that it serves to indicate the amount of current at any given instant, whereas the other sums up total electric quantity for an interval of time. The ammeter indicates the rate of flow in ampères, the current-meter records in ampère-hours, or in other convenient units of electrical quantity. The ammeter is usually a **GALVANOMETER** (*q. v.*), or electro-dynamometer, in the construction of which particular attention has been paid to questions of portability, rapidity of action, legibility, and freedom from outside influences, both magnetic and mechanical. For details concerning the construction of ammeters, of which there are many forms, see Kittler, *Handbuch der Elektrotechnik* (Bd. i. p. 254); *La Lumière électrique*, vols. ii., iii., vi., ix., xi., xiv., etc.; *The Electrician*, vols. xii., xiii.; and various other articles in the electrical journals.

E. L. NICHOLS.

Am'mianus Marell'ianus: an eminent Roman historian; b. at Antioch; was of Greek extraction. He served in the army in his youth (about 350 A. D.), and in the expedition which the Emperor Julian conducted against Persia. Having abandoned the military profession, he settled at Rome, and there composed in Latin his *History of the Roman Empire* in thirty-one books, of which the first thirteen are lost. The entire work comprised the period from 96 A. D. to 378 A. D., the extant portion only the years 353-378. His history is highly prized for its impartiality and other merits. Best edition by V. Gardthausen (Leipzig, 1874-75); English translation of Wagner and Erfurdt ed. by Phil. Holland (London, 1609); also by C. D. Yonge in Bohn's Classical Library (1862). D. about 395 A. D.

Revised by M. WARREN.

Ammira'to, Scipione: Italian historian; b. at Lecce, in the kingdom of Naples, Sept. 27, 1531. He became a resident of Florence in 1569, and was patronized by the Grand Duke Cosimo. In 1596 he obtained a prebend in the cathedral of Florence. He wrote, besides other works, a *Discourse on Cornelius Tacitus* (1594), and a *History of Florence* (*Istorie Fiorentine*, 2 vols., 1600-41), which is regarded by some critics as the most accurate work on that subject. He has been styled the modern Livy. D. in Florence, Jan. 30, 1601.

Ammody'tes [Gr. ἀμμοδύτης, sand-burrower; ἄμμος, sand + δύτης, diver, from δύνειν, get into]: a Linnæan genus of apodal fishes, characterized by a compressed head narrower than the body, and both elongated. The sand-eel is an example of this genus.

Am'mon (or more correctly *Amon*, the concealed): the Egyptian name of the deity whose principal place of worship was Thebes. The Greeks and Romans called him Zeus or Jupiter Ammon (Gr. Ἄμμων). He was sometimes represented in the form of a ram. There was a great temple of Ammon in the oasis of Siwah or Ammonium in the Libyan desert, wherein was a famous oracle, and another at Thebes, which city was called No (Jer. xlvi. 25; Ezek. xxx. 14-16) by the ancient Hebrews. Alexander the Great visited the temple of Ammon in the oasis (B. C. 331), and assumed the title of the son of Ammon. Remains of this temple still exist.

Revised by S. M. JACKSON.

Ammon, Christoph Friedrich, von: German Protestant theologian and pulpit orator; b. at Baireuth, Jan. 16, 1766. He became Professor of Theology at Göttingen in 1794, obtained a chair at Erlangen in 1804, and removed in 1813 to Dresden, where he was appointed court-preacher to the King of Saxony. He was a man of great and varied erudition, and belonged to the Rationalist school in theology. His most important work is *Fortbildung des Christenthums zur Weltreligion* (4 vols., 1833-35; 2d ed. 1836-40). D. at Dresden, May 21, 1850. See his biography (Leipzig, 1850).

Revised by S. M. JACKSON.

Am'monia, or Volatile Alkali: an important chemical compound in the form of a transparent, colorless, and pungent gas, consisting of nitrogen and hydrogen. Its symbol is NH₃. Priestley, who first obtained it in a separate state, called it *alkaline air*. The name *ammonia* is derived from *sal-ammoniac*. This name was first applied to common salt found in the Libyan desert in the neighborhood of the temple of Jupiter Ammon. A confusion of terms afterward led to the application of the name to ammonium chloride. It is now obtained as a by-product by the distillation of bituminous coal in making gas, and from refuse animal matter in preparing bone-black, etc. It combines with acids to form salts. As it supplies to plants the nitrogen they require, it is one of the most important ingredients in manures. (See **GUANO**.) A solution of this gas in water is used in medicine, and is called spirits of hartshorn or *liquor ammonia*. One volume of water will dissolve or absorb 500 volumes of ammonia. Liquid ammonia has been employed as a motive-power by Tellier, and for the production of artificial cold by Carré. (See **ICE**.) This gas can also be liquefied by pressure and cold, and then becomes a colorless liquid, with the properties of ammonia much intensified. The smelling-salt, or volatile salt of hartshorn, used as a restorative in faintness is a carbonate of ammonia. Ammonic sulphate, (NH₄)₂SO₄, is manufactured in large quantities by boiling "gas-liquor" with lime, and conducting the ammoniacal gas which is liberated into sulphuric acid. On evaporating the solution, the sulphate is obtained as a white salt. It is extensively used in the manufacture of alum in place of potassic sulphate, as a constituent of artificial fertilizers, and for the preparation of other ammoniacal salts. Ammonic nitrate is used for the preparation of nitrogen monoxide (N₂O), laughing-gas. Ammonic chloride, NH₄Cl, has long been known as *sal-ammoniac*.

Revised by IRA REMSEN.

Am'moniae: a gum-resin used in medicine. It is imported from Africa and India, and is obtained from the *Dore'ma ammoniacum*, an umbelliferous plant containing a milky juice, which by drying is converted into this gum. It is used as an expectorant, and sometimes applied externally as a plaster.

Ammonites [from *Ammon* + suffix *-ite* (Gr. -ίτης), as in *meteorites, augite*, etc. The fossil was called *cornu Ammonis*, from a supposed resemblance to the horns of Jupiter Ammon]: a genus of extinct mollusks belonging to the order *Cephalopoda*, and one of the most striking features in the fauna of the Mesozoic era. The ammonites were discoid, chambered, spiral shells, sometimes 4 feet in diameter, and often beautifully ornamented exteriorly. The internal structure was similar to that of the *Nautilus*, except that the siphon was external, and the septa (partitions between the chambers) were arched outward, and were convoluted at their margins, so that their intersection with the walls of the shell produced beautiful foliated figures. The ammonites began in the carboniferous period, were immensely multiplied in the Triassic, Jurassic, and Cretaceous ages, and became entirely extinct at the close of the last. More than 500 species have been described, and they are found in the Mesozoic strata of all parts of the world. Beautiful ammonites occur in the cretaceous rocks of the country bordering the upper Missouri, in the Indian Territory, and in Texas. The old genus *Ammonites* has been lately much subdivided by Prof. Alph. Hyatt, Prof. von Hauer, and others. See *Proc. Bost. Soc. Nat. Hist.* (1883), and **AMMONOIDEA**.

Revised by H. S. WILLIAMS.

Am'monites: an ancient Semitic tribe or nation, descendants of Ben-Ammi, a son of Lot (Gen. xix. 38). They inhabited the east side of the Jordan, between the rivers Arnon and Jabbok, and adjoining the northern part of Moab. Their chief city was Rabbah. (See **AMMAN**.) They frequently waged war against the Israelites, and were conquered by Jephthah (Judges xi. 33), and afterward by Saul, David, and other later kings (1 Sam. xi., 2 Sam. xii., 2 Chron. xx., 2 Chron. xxvii.). They opposed the rebuilding of the walls of Jerusalem (Neh. ii. 10). They gradually became absorbed with the general Arab population. About 164 B. C. they were defeated by Judas Maccabæus. They are called "the children of Ammon" in the Old Testament.

Revised by S. M. JACKSON.

Am'monium: a hypothetical metal, (NH₄), which is supposed to exist in the salts of ammonia, and to be composed of one volume of nitrogen and four of hydrogen. It is the analogue of potassium and sodium, but has never been obtained in a separate state; a supposed amalgam of ammoni-

um, however, may be formed by the action of the galvanic battery on a globule of mercury surrounded by a solution of ammonia, and by the action of sodium amalgam on a solution of ammonium chloride.

Ammono'num, or **Am'mon**: the ancient name of an oasis in the Libyan desert, about 300 miles W. S. W. of Cairo. It is now called El Siwah. Here were a celebrated oracle and temple of Jupiter Ammon, in a grove of palms; also royal palaces, and the "Fountain of the Sun," the water of which was cold at noon and warm at midnight. The ruins of the temple may still be seen.

Ammono'nius, surnamed **SACCAS**: a Greek philosopher; b. in Alexandria; was the founder of the school called Neo-Platonic about 193 A. D. He held that the philosophy of Aristotle is substantially the same as that of Plato, a view that came to be indorsed later by the Schoolmen and more recently by the German philosophers. Though born of Christian parents, he went over to paganism. Among his pupils were Longinus, Origen, and Plotinus. He left no writings, and died about 241 A. D. Revised by W. T. HARRIS.

Ammonoidea: a sub-order of extinct cephalopodous mollusca, represented in the latter periods of the Palaeozoic and throughout the Mesozoic ages by numerous genera and families of fossil shells. The nearest living relative of this extinct group is the Nautilus, and it is a comparison of the ammonoid shell with that of the Nautilus which has led naturalists to separate the ammonoids as a distinct sub-order from the Nautiloidea, of which the living Nautilus is the type. In both sub-orders there is developed an external chambered shell, the animal at any particular stage of its growth inhabiting the outer chamber. Behind this, which is called the living or body chamber, is a series of gradually decreasing chambers, the whole series forming an elongated cone, which is either straight or curved, or is spirally coiled to form a helicoidal or discoid shell. The chambers are filled with air or a similar gas, and are connected from the initial to the outer body chamber by a hollow tube called a *siphon* or *siphuncle*. The air-space formed by the chambers is supposed to serve as a float to buoy up the animal in the water. In the Ammonoidea the siphuncle is situated near the outer or inner wall of the shell. In the Nautiloidea the siphuncle is generally central, or nearly so. The partitions forming the chambers are called *septa*; the margins of the septa, where they are attached to the outer wall of the shell, are called *sutures*. These sutures are straight or simply arched in the Nautiloidea; in the Ammonoidea the sutures are variously convoluted. The form of the shell, and of the living-chamber in its various aspects; the surface markings, which are often very complicated and beautiful; the relative size and relations to each other of the separate whorls of the spiral shells; the number and size of the chambers; and particularly the nature and degree of complication of the convolutions of the suture, have furnished palaeontologists with the means of exhaustive study of the successive modification of the Ammonoidea in geological time. Upon the above characters the representatives of the sub-order have been classified into 4,000 species; according to the statistics of Von Sutner (Zittel, *Paleontologie*, vol. i. pt. ii. p. 483), distributed in fifteen families and ninety-four genera, or (if we recognize the genera into which Hyatt subdivides the families *Goniatitidae* and *Clymenidae*) the total number of genera would exceed 130. The shell of most of the Ammonoidea is in the form of a more or less closely coiled discoid spiral; this was characteristic of the earlier forms, and of the genera up to the eretaceous. In the cretaceous, which was the last period of the existence of these organisms, there were several genera which may be described as differing from the typical forms by being unrolled to various degrees. In *Macroscaphites*, the last whorl is straightened out. In *Crioceras*, the whole shell is coiled so that the separate whorls do not touch. In *Ancyloceras*, the whorls are separate, but the last half is straightened out and recurved near the end. In *Hamites*, the tube is recurved two or three times. In *Turritites*, the coils are laterally drawn out, forming a long spiral helicoidal shell. In *Baculites*, the shell is quite straight. This unrolling of the ammonite coil is regarded as evidence of retrograde development; the earlier Palaeozoic Nautiloids are either straight, curved, or loosely coiled forms (*Orthoceras*, *Cyrtoceras*, *Gyroceras*, and *Nautilus*). The details of the sutural convolutions have been minutely studied and classified by palaeontologists. Classifications with definite nomenclature have been proposed by several authors. Those of Von Buch and Sandberger are the best known. It has been

observed that the complexity of the convolutions increases with the development of the individual; that in series of closely related species those occurring later geologically are more completely convoluted; and, in general, the species with simpler sutures were earlier to appear, and their dominance, both in number of individuals and in variety of form, took place at an earlier geological period than that of the forms with more differentiated sutures. On account of the close relationship existing between these progressive modifications of the Ammonoidea and the chronological order of their appearance, this sub-order has been used as a beautiful illustration of the law of evolution. Several definite stages of elaboration of the suture lines may be recognized: (1) The Nautilian type, in which the suture is straight or simply arched (*Nautilus*, *Orthoceras*); (2) the Goniatite type, in which the suture is simply lobed or notched by the oscillation of the line forward and backward—the forward bends are called saddles, the backward bends lobes; (3) secondarily lobed type, as in *Ceratites*, in which the secondary lobation is confined to the "lobes" in *Helicites* where the secondary lobation affects only the "saddles," or in *Mendlicottia* where the whole extent of the primary lobes and saddles is more or less affected by the secondary lobation; (4) the tertiarily lobed type, or Ammonite type, in which the secondary lobes are again lobed, forming an elaborate foliation of the suture—this is the characteristic suture of the Ammonites; (5) the Pinacoceran type, in which tertiary lobes are again indented, forming a quaternary lobation of the suture line. The *Pinacoceras* has the most elaborately convoluted suture of all the Ammonites. It is observed that the first appearance of each of these types of suture lines is chronologically in the order in which they are named above. When the suture line is physically considered, it is seen to consist of the fluted edge of the septum forming the separating partition between the chambers of the shell; and the law expressed in all this elaborate variety of sutures may be simply defined in the following terms: In the successive geological stages the circumferential dimension of the septum is gradually increased in proportion to the diameter, and thus it becomes evident that the observed order of sequence is the only order of sequence which could naturally take place.

H. S. WILLIAMS.

Ammonoosuc, Lower: a river of New Hampshire, rises in Coos County, near Mt. Washington, and flowing southwestward, through Grafton County, enters the Connecticut river. It is about 100 miles long.

Ammonoosuc, Upper: a river of Coos co., N. H., which empties into the Connecticut at Northumberland. It is about 75 miles long.

Ammunition: cannon-balls, shells, bullets, fuses, cartridges, grenades, gunpowder, and all the projectiles and explosive substances used in war. The ammunition of field-artillery consists of shot, loaded shells, ease-shot, shrapnel, cartridges, priming-tubes, matches, and rockets. An infantry soldier generally carries sixty rounds in his cartridge-box.

Amnesia: See MEMORY.

Am'nesty [from Gr. ἀμνηστία, oblivion; ἀ-, not + μνᾶσθαι, remember]: an act of oblivion of past misconduct granted by a government to those who have been guilty of some offense. It is usually granted to whole communities or classes of individuals who have taken part, or are supposed to have participated, in some movement against lawful authority; it may be granted either before or after conviction, and its effect is entirely to efface the crime and cause it to be forgotten by the law. An instance is an act of amnesty in England in 20 Geo. II. c. 52, called "an act for the king's most gracious general and free pardon." This subject has excited much interest in the U. S., owing to a provision in the fourteenth amendment to the Constitution creating certain disqualifications as to holding office by persons who have participated in rebellion, and at the same time allowing their removal by a special vote of the Congress. Such a removal is in the nature of an act of amnesty.

Amœba, a-mee'ba: a genus of one-celled organisms of the branch *Protozoa*. The term is also used as a common name applied to members of the genus *Amœba* and allied forms. An amœba consists of naked protoplasm, and has the power of locomotion by means of a streaming motion of the protoplasm which often forms projections over its surface, called pseudopodia. It can ingest food by means of the same motion, possesses a nucleus, and usually a con-

tractile vacuole. Several species have been described. It is of especial interest from the fact that it is often selected in treatises on biological subjects for illustration of the processes of nutrition, motion, sensation, reproduction, etc., in a very simple form, all performed by a single cell, which is not greatly differentiated and specialized. The organism is found in moist places, ponds, ditch-water, and swamps.

DAVID S. JORDAN.

Amol', or **Amul**: a city of Persia: province of Masanderan; on the river Heraz; about 12 miles from its entrance into the Caspian Sea, and 85 miles N. E. of Teheran (see map of Persia and Arabia, ref. 2-G). A bridge of twelve arches crosses the river here. Pop. estimated at from 35,000 to 40,000.

Amoor: same as AMUR.

Amoret'ti, CARLO: Italian naturalist and writer; b. at Oneghia, near Genoa, Mar. 13, 1741. He produced a good biography of Leonardo da Vinci (1784), and a work on the natural history and geography of Lakes Como, Maggiore, and Lugano, called *A Journey from Milan to the Three Lakes* (1794). In 1797 he became librarian of the Ambrosian Library of Milan. D. at Milan, Mar. 24, 1816.

Amor'gos, or **Amor'go**: a fertile island in the Archipelago, 18 miles S. E. of Naxos; belongs to the kingdom of Greece (for location, see map of Greece, ref. 17-M). It is 13 miles long and 6 miles wide, and contains a small town called Amorgos. The surface is mountainous. The poet Simonides was born here. It has a good harbor; lat. of E. end, 36° 54' N., lon. 26° 6' E. Pop. about 3,700.

Am'orites (i. e. mountaineers): a powerful nation of Canaan that occupied the country on both sides of the Jordan in the time of Moses, and resisted the Israelites in their march toward the Promised Land. Moses defeated their two kings, Sihon and Og, who reigned at Heshbon and Bashan respectively. Og is said to have been the last "remnant of giants" (Deuteronomy iii. 11). The Amorites were afterward subdued by Joshua, and their territory divided between the tribes of Reuben and Gad, but he was not able to exterminate them. They appear to have been long hostile to the Israelites, but in Solomon's time were reduced to a tributary condition.

A'mos: one of the minor Hebrew prophets, who was a contemporary of Isaiah; about 785 B. C. He was originally a herdsman and a gatherer of sycamore fruit in Tekoa, a town 12 miles S. S. E. of Jerusalem. He denounces in vigorous and eloquent terms the prevalent corruption and oppression, using many images taken from rural and pastoral life. His prophecies seem to have all been given in one year, and his plain speaking caused the charge of conspiracy against the government because he alienated the people.

Amo'tion [Lat. *amo'tio*, from *a*, away + *move're*, *mo'tum*, move]: in law, the removal of an officer of a corporation from his office. It differs from disfranchisement, which refers to the removal of a member. Amotion may accordingly take place without disfranchisement.

Amoy, a-moi' [a local pronunciation of *Hia-mun*, the Chinese name]: a seaport-town of China, on an island of the same name, in the province of Fuh-Kien, and on the strait of Formosa; lat. 24° 28' N., lon. 118° 4' E. (see map of China, ref. 8-K). It is situated at the mouth of the river on which stands the large city of Chang-Chow-Foo. Amoy is an open or treaty port and one of the chief commercial towns of China. It was taken by the British in 1841, and has been open to the trade of all nations since 1843. Among the articles of import are cotton, cotton goods, iron, sugar, camphor, and pepper. The chief articles of export are tea, sugar, porcelain, silks, and paper. Pop. 96,000.

Ampel'idæ: See VINE FAMILY.

Ampel'ius, LU'CIUS: a Roman writer of uncertain date, probably of the second or third century, whose brief work, entitled *Liber Memorialis*, is a curious miscellany of astronomy, geography, mythology, and historical events, classified under different heads, often based upon good sources. Best edition by Woelfflin (Leipzig, 1879). M. WARREN.

Ampelop'sis [from the Gr. *ἄμπελος*, a vine + *ᾠψις*, appearance]: a genus of creeping, vine-like, woody plants (of the family *Vitaceæ*), to which the Virginia creeper or American woodbine (*Ampelopsis quinquefolia*) belongs. This is one of the most beautiful of our hardy creeping ornamental plants. It is better adapted to the climate of America than the ivy, and is also more rapid in its growth

and has handsomer foliage. The leaves are deciduous, but they die in a blaze of crimson glory when touched by frost.

Ampère, āñ'pār', ANDRÉ MARIE: French philosopher and mathematician; b. at Lyons, Jan. 22, 1775. He produced in 1802 an interesting essay *On the Mathematical Theory of Games of Chance*. He became inspector-general of the University (1808), Professor of Analysis in the Polytechnic School in Paris (1809), chevalier of the Legion of Honor (1809), a member of the Institute (1814), and Professor of Physics in the College of France (1824). Having made important discoveries in electro-magnetism, he published in 1822 a *Collection of Observations on Electro-Dynamics*, a work which displays remarkable sagacity. "The vast field of physical science," says Arago, "perhaps never presented so brilliant a discovery, conceived, verified, and completed with such rapidity." He further explained his discoveries in this department of science, to which he gave the name of electro-dynamics, in his *Theory of Electro-Dynamic Phenomena Deduced from Experiments* (1826). Among his other works are treatises on optics and an *Essay on the Philosophy of the Sciences*, etc. (1834). He was a man of genial disposition, and noted for simplicity of character. D. in Marseilles, June 10, 1836.

Ampère, JEAN JACQUES ANTOINE: an accomplished scholar and *littérateur*, son of André Marie Ampère; b. at Lyons, Aug. 12, 1800. He enjoyed in his youth the society of Madame Récamier, and devoted much attention to English and German literature. In 1833 he succeeded Andrieux as Professor of French Literature at the College of France. He became a member of the Academy of Inscriptions in 1842, and a member of the French Academy in 1847. He traveled extensively in Egypt, the Levant, Scandinavia, and America. On the establishment of the empire he removed to Italy. His chief works are *Littérature, Voyages et Poésies* (1833); *Grèce, Rome et Dante* (1848); *Promenades en Amérique* (1855); and especially *l'Histoire littéraire de la France avant le XII^e. Siècle* (1839); *l'Introduction à l'histoire de la littérature française au moyen âge* (1841); and *l'Histoire romaine à Rome* (4 t., 1856-64). D. in Pau, Mar. 27, 1864. Revised by A. R. MARSH.

Ampere (in electricity): the practical unit of current-strength; named after André Marie Ampère, the French physicist. It is an exact tenth of the C. G. S. unit of absolute current-strength. The ampère is the amount of current which will be generated in a conductor, the resistance of which is one ohm, when the difference of potential between the ends of the conductor is one volt. Previous to 1881 a practical unit, similarly defined, was in use among electricians, under various names. It was frequently called the "weber." The International Electrical Congress which met at Paris in that year systematized the practical units in electricity, and gave to the unit of current the official name of the ampère. E. L. NICHOLS.

Ampere-me'ter: See AMMETER.

Ampere-turns (in electricity): the product of the amount of current flowing in a coil or helix, measured in ampères, into the number of turns of wire of which the coil is composed. As this product is a factor in the measurement of the magnetic field produced by the coil in question, it is an important and much-used quantity in applied electricity.

Amphib'ia [Gr. *ἀμφίβια*, neut. plur. of *ἀμφίβιος*, living in both; *ἀμφί*, on both sides + *βίος*, life]: a term originally applied to all animals that live both on the land and in the water, and variously used by the earlier systematists. It is now limited to a class of vertebrates intermediate between fishes and reptiles, and including the salamanders, frogs, toads, and their allies. They are cold-blooded animals, having the skin usually without plates or scales, and the young provided with gills during part or all of their lives. In common with fishes, they fail to form during their development the amnion and allantois, the embryonic membranes characteristic of the reptiles, birds, and mammals.

Most amphibians pass through a metamorphosis like that of the frog, which emerges from the egg as a tadpole, when it is fishlike in form and breathes by gills, being truly aquatic; subsequently the tail and gills disappear, legs and lungs are developed, and the mature animal, though perhaps inhabiting the water, is an air-breather. In some amphibians the first or embryonic condition continues unchanged through life, as in *Necturus*, etc., the water-puppy or water-dog of the Western rivers. The largest of these aquatic carnivorous salamanders is *Megalobatrachus*, which inhabits the

lakes of Japan, and attains a length of 3 feet. Though now regarded as dull and disgusting creatures, this latter group of amphibians once stood at the head of all then existing members of the zoölogical series. The amphibians first appeared in the carboniferous age, and the lagoons in the coal-marshes swarmed with aquatic salamanders, some of which were 6 feet in length, very active and predaceous, and the monarchs of the animal world of that age. More than twenty species of amphibians have been obtained by Dr. Newberry from the cannel coal of one mine in Ohio. The amphibians had their golden age in the Trias, when *Labyrinthodon*, with a body as large as that of an ox and teeth 4 inches long, ruled the animal kingdom. In the succeeding age (Jurassic) the scepter passed from the amphibians to the true reptiles.

Revised by DAVID S. JORDAN.

Am'phibole [from Gr. ἀμφίβολος, hitting on both sides, ambiguous; ἀμφί, on both sides + βάλλειν, throw]: a name given by Haüy to hornblende, on account of its resemblance to augite. See HORNBLENDE.

Amphie'tyon (Gr. Ἀμφικτύων): an ancient and perhaps fabulous hero and King of Attica, supposed to have been a son of Deucalion.

Amphietyon'ic Conn'cil: a celebrated congress or politico-religious court of the confederated tribes of ancient Greece, which met twice every year at Thermopylæ. It was composed of the deputies of twelve tribes, viz.: Thessalians, Bœotians, Dorians (or Spartans), Ionians (or Athenians), Locrians, Dolopians, Magnetes, Malians, Achæans, Phocians, Ænians, and Perrhæbians, who each sent one or two members. The predominance of northern and Pelasgic tribes proves the great antiquity of this institution, which in course of time declined, and in the age of Demosthenes had lost its authority. The members of this council bound themselves by an oath that "they would not destroy any Amphietyonic city nor cut off its streams in war or peace." One great object of the council was the protection of the temple at Delphi. See Tittmann's *Ueber den Bund der Amphiktyonen* (1852).

Amphi'on: in Greek mythology, the son of Zeus and Antiope and twin brother of Zethus. The brothers were found and reared by a shepherd, and Amphion became skilled in music by the gift of the gods, and Zethus became a shepherd. Meanwhile Antiope was cruelly treated by their uncle Lycus, King of Thebes, and his wife Dirce, and when the brothers discovered their parentage they marched against the city, put Lycus to death, and bound Dirce to a wild bull. This punishment of Dirce is represented in the group of statuary called the FARNESE BULL (*q. v.*), discovered in the baths of Caracalla, and now in the museum at Naples. According to the poetic legend, he availed himself of his skill in music to build the walls of Thebes, and the stones, attracted by the sound of his lyre, moved and arranged themselves in the proper position. Amphion married NIOBE (*q. v.*), and according to tradition killed himself in grief at the slaying of his children by Apollo and Artemis. F. S. ALLEN.

Amphioxus: See LEPTOCARDII.

Amphip'oda [from Gr. ἀμφί, both + πούς (gen. ποδός), foot]: an order of small crustacea, for the most part marine, the most familiar members of which are the "sand-fleas" and "beach-fleas" found so abundantly among decaying seaweed, or burrowing in the sand of our beaches. Other forms live attached to the skin of whales, and still others are found in the genital pouches of the jellyfishes with which they are commensal. Some European species are very destructive, burrowing in the hulls of ships and in the piles of wharves, in the manner of the teredo. In all, the body is laterally compressed, the abdominal region is elongated, and the anterior and posterior feet are dissimilar, the former being frequently adapted for seizing or swimming, while the latter are directed backward and used in leaping. The gills are attached to the bases of the thoracic legs. DAVID S. JORDAN.

Amphip'olis: an ancient and important city of Thrace or Macedonia, was founded by an Athenian colony about 437 B. C. It was situated at the mouth of the river Strymon, which here enters the *Strymonicus Sin'us*, the modern Gulf of Contessa. The waters of the river are said to have once surrounded the town (whence the name). In the Middle Ages it was called Popolia. Its site is now occupied by a small Turkish town called Yenikeui.

Amphisbæ'nidæ [Gr. ἀμφίσβαινα, from ἀμφί, at both ends + βάλειν, go]: a family of lizards with an elongated serpentiform body and a blunt tail. Limbs are generally absent, a pair of small front legs being found in the genus

Chirotes only. The head and tail are sufficiently similar in appearance to have suggested the name. About two dozen species inhabit the warm portions of both hemispheres.

Amphisbæna fuliginosa.

They burrow in the earth in search of larvæ, and have rudimentary eyes.

Revised by D. S. JORDAN.

Amphis'sa: a town of ancient Greece, in Loeris, was situated 7 miles from Delphi, on the site of the modern town of *Salona*. The town was destroyed B. C. 338 by Philip of Macedon, but was rebuilt. Here was a temple of Athena, containing an image of the goddess.

Amphithe'ater [Lat. *amphitheatrum*, from Gr. ἀμφιθέατρον; ἀμφί, on both sides + θέατρον, theater]: a spacious and uncovered edifice of an elliptical or circular form, in which the ancient Romans witnessed the exhibition of public games and the combats of gladiators and wild beasts. It was constructed so that all the spectators could behold the performance, which was given in an open level space called the arena, surrounded on all sides by tiers of seats, which rose higher as they receded from the arena. The most famous of these edifices was the Flavian Amphitheater, or Colosseum of Rome, which was built by the Emperors Vespasian and Titus, finished about 80 A. D., and is still standing. It is about 620 feet long, 513 feet wide, and 157 feet high. The longest diameter of the arena was 287 feet. It is said to have had seats for 80,000 spectators, and standing-room for 20,000 more. The exterior was adorned by three rows of columns—Doric, Ionic, and Corinthian. The Colosseum is regarded by many as the most august and imposing ruin in the world.

Amphithe'rium [from ἀμφί, on both sides + θηρίον, wild beast]: a genus of fossil insectivorous mammalia found in the oölitic strata in Oxfordshire, England. It presents many points of analogy with the living marsupial genus *Myrmecobius*.

Amphitri'te: in the Greek mythology, a Nereid, a goddess of the sea, the wife of Neptune and the mother of Triton. She is represented sitting in a ear of shells drawn by tritons, or on a dolphin.

Amphit'ryon: in classic mythology, a son of Alcæus. Having accidentally killed his uncle Electryon, he was banished from Mycenæ. He married Alcmena, who was the mother of Hercules.

Am'phora [Lat., from Gr. ἀφορεύς for *ἀμφι-φορεύς; ἀμφί, on both sides + φέρειν, carry, with reference to its two handles]: a vase with two handles which was used by the ancient Greeks and Romans to hold wine and oil. It was also a liquid measure, containing about 8½ gal. among the Greeks and 6 among the Romans.

Am'plitude: in astronomy, is the angular distance of a heavenly body, when it rises or sets, from the E. or W. points of the horizon. The amplitude of a fixed star remains the same all the year, but that of the sun changes daily, and on a given day varies according to the latitude of the observer.

Ampu'dia, PEDRO, de: a Mexican officer who obtained the rank of general in 1840. He fought against the Texans in 1842, and commanded the Mexican troops which defended Monterey in 1846 against Gen. Taylor, to whom he surrendered in September of that year.

Ampul'la: a Roman vessel of glass or earthenware, used for holding oil, wine, etc.; was nearly globular in form. Many of these are preserved in the collections of antiquaries. In the Catholic Church an ampulla is a vessel which contains wine for the sacrament. *Ampulla Remensis* (in Fr. *la Sainte Ampoule*) was a famous vessel of holy oil which, according to tradition, was brought from heaven by a dove, and was used to anoint Clovis when he was crowned at Rheims in 496 A. D.

Ampulla'ria [Lat. *ampullarius*, from *ampulla*, a flask]: a genus of gasteropod mollusks, called apple-shells, idol-

Ampullaria dubia.

shells, pond-snails, etc. Fifty or more species are known, mostly tropical, and all inhabiting fresh water and mud, though some are occasionally found in salt and brackish waters. They are remarkable for their tenacious hold on life, many being able to live away from the water for years. One species is occasionally found alive in hollow logs of mahogany and logwood from Honduras. The *Ampullaria dubia* is brought from the Nile.

Amputa'tion [Lat. *amputatio*; *am-* (*amb-*), about + *puta've*, prune]: in surgery, the removal, by operation, of any part of the body or limbs on account of disease or injury, such as would endanger life if the part were allowed to remain. The term of late denotes more especially such removal of a limb, but is still sometimes used for the excision of a tumor or gland.

Amputations are properly resorted to not only after severe and very dangerous injuries, but in such diseases as gangrene, cancer, etc., which are without rational prospect of cure by other means. In general, cases where the chances of cure will probably be much increased by this operation afford legitimate subjects for its exercise. This rule would include some cases of intractable ulcers of the leg, of aneurism, and of diseased bones and joints. Incurable and unsightly deformities, where they put the patient to great inconvenience, may in some circumstances be removed by the knife. An amputation in which a bone is cut off is said to be "in the continuity." An amputation at a joint, when no bones are divided, is in "the contiguity"; the latter operation is not often performed, though it has had recent advocates. Amputations are chiefly either "flap" or "circular" operations. The "flap" operation, in some of its many modifications, is probably the most frequently employed. One, two, or even three flaps have been employed, the size, shape, and thickness of these flaps of skin and flesh varying with circumstances. In general, they ought to be large enough to cover amply the end of the stump, and not so large as to be redundant after the wound shall have healed. The flap amputation, practiced by certain mediæval surgeons, and revived by Lowdham, of England, nearly 200 years ago, was made general by Liston, and has since his time been variously improved and modified.

"Circular amputation" is performed by first dividing the skin and superficial fascia by a sweep of the knife around the limb, dissecting up the skin for 2 or 3 inches, and at that part dividing the muscles down to the bone. The flesh is removed from the bone to allow the saw to be applied.

The danger attending amputation is generally in proportion to the nearness of the operation to the trunk, as well as

to the size of the limb. Thus amputation at the hip joint is the most doubtful of all in its results; but even this, in some cases, especially in military surgery, may improve the chances of life under severe injury. Amputations at the joints are by most surgeons considered as more serious than in the continuity of the limbs. Of the foot alone several different modes of amputation are in use, as Lisfranc's, Chopart's, Syme's, and Pirogoff's amputations. Revised by WILLIAM PEPPER.

Amri'ta, sometimes incorrectly written **Amreeta** [Sansk. *amṛta-s*, immortal; *a-*, not + *mṛta-s*, dead: Gr. *ἄμβροτος*. The vowel *-i-* represents an earlier method of English transliteration]: in Hindu mythology, the water of immortality, which is said to have been obtained by the churning of the ocean. The term amrita or amrit is sometimes given to the food as well as the drink of the gods, and likewise to any delicious drink.

Amritsar, *ūm-rit'sūr* (i. e. Amrita Saras, fount of immortality): a city of Northern India; capital of a division and district of the same name; and commercial center of the Punjaub. It is on the railroad, 40 miles E. of Lahore, and 330 miles N. W. of Delhi (see map of N. India, ref. 3-D). This city is the center of the Sikh religion and learning. It owes its importance to a reservoir for religious purposes which Ram Das, one of the great spiritual guides of the Sikhs, caused to be made here in 1581, and which has become an object of pilgrimage and veneration. This reservoir still remains, and on an island in its center there is a celebrated temple, supporting a large body of priests. The city also carries on an extensive trade with Central Asia, and manufactures imitations of Kashmir shawls and silks. Pop. (1891) 136,500. The district has an area of 1,574 sq. miles, and a population of 900,000. The division, including this district, Sialkot, and Gurdaspur, extends northward to the Himalayas, and lies between the Chenab and Bias rivers. Area, 5,354 sq. miles. Pop. 2,750,000. It is not well watered, and extensive irrigation is necessary. The population is about one-half Mohammedans, one-fourth Hindu, and only one-eighth Sikhs. M. W. H.

Am'rou Ben el As (more correctly Amr ibn-al 'Assi): a famous Arabian warrior; b. about 600 A. D.; at first opposed Mohammed, but became a zealous proselyte; aided in the conquest of Syria; conquered Egypt, of which he became emir, taking Alexandria in 640 A. D., and Tripoli three years later. He became an opponent of Ali. He was a man of energy and prudence. D., as Governor of Egypt, 664.

Ams'dorf, NIKOLAUS, von: a Reformer; b. in Saxony, probably at Torgau, Dec. 3, 1483. He accompanied Luther to the Diet of Worms in 1521, assisted in the translation of the Old Testament; introduced the Reformation into Magdeburg, where he was pastor, 1524-42; became Bishop of Naumburg, 1542, and Superintendent of Eisenach, 1548. After Luther's death, he was prominent in opposing certain tendencies of Melancthon. (See ADIAPHORITES.) An extravagant expression of Amsdorf, that "good works are injurious to salvation," was the occasion of the discussion in the *Formula of Concord*, Art. iv. D. at Eisenach, May 14, 1565.

Revised by HENRY E. JACOBS.

Ams'ler, SAMUEL: skillful engraver; b. at Schinznach, Switzerland, Dec. 17, 1791. He became Professor of Engraving in the Academy of Fine Arts in Munich. He engraved many of the works of Raphael and Thorwaldsen, and reproduced the former with peculiar fidelity. Among his best works are the *Triumph of Alexander the Great*, after Thorwaldsen; a *Holy Family* and a *Burial of Christ*, both after Raphael; also a *Christ*, after Dannecker. D. at Munich, May 18, 1849.

Am'sterdam, formerly **Amstelredamme**, or **Amstel-damme** (the dike or dam of the Amstel; in Latin, *Amstelodanum*): an important commercial city and capital of the kingdom of Holland; situated at the junction of the Amstel with the Y, and near the Zuyder Zee, through which it has access to the ocean; lat. 52° 29' N., lon. 4° 53' E. (see map of Holland and Belgium, ref. 5-F). It is the largest city of Holland and its constitutional capital, but the royal court is at The Hague. Amsterdam stands on flat, marshy ground, into which piles, 50 feet long, are driven to form a foundation for the houses, which are mostly built of brick. The city is divided into ninety islands by a number of canals, which are crossed by 280 bridges. A part of the old ramparts have been pulled down, and twenty-eight windmills for grinding grain have been erected on the bastions. The principal streets are the Heerengracht, Keizergracht, and Prin-

zensgracht, each of which is about 2 miles long, and describes a semicircle. Canals occupy the middle of these streets, which are scarcely surpassed in elegance by those of any capital in Europe. Among the grand public buildings of this metropolis is the palace or town-hall, a stone edifice 282 feet long and 235 feet wide, resting on 13,659 piles, driven into the ground to the depth of 70 feet. This palace contains a remarkable hall 120 feet long, 60 feet wide, and 100 feet high, lined with white Italian marble. The city has a beautiful justiciary hall, a modern building of Grecian architecture. The most beautiful church of Amsterdam is the Nieuwe Kerk (founded in 1408), 350 feet long and 210 wide. This Nieuwe Kerk and the Oude Kerk, which has a remarkable organ, belong to the Reformed Church. Much of the water-supply of Amsterdam now comes from the sand dunes of the coast. Amsterdam is liberally supplied with hospitals and other charitable institutions. Among the important educational and literary institutions are the Athenæum Illustre, which has a botanic garden, a school of anatomy, and chairs of art, law, medicine, and theology; the city Latin school; the Royal Academy of Fine Arts, founded in 1820; the Arti et Amicitie society of painters; the naval school; the Royal Dutch Institution for science, literature, and art; the antiquarian society; and the society of literature and fine arts, called Felix Meritis. The museum at the Trippenhuis contains the finest collection in Europe of pictures of the Dutch school, among which are the *Banquet of the Arquebussiers*, by Van der Helst, and *The Night Watch*, and the so-called "Syndics," by Rembrandt. There is also an admirable collection of engravings. There are also in the city several smaller collections, public and private, so that this city must be visited by all who wish to study Dutch painting.

The chief manufactures are tobacco, soap, canvas, glass, jewelry, cordage, machinery, steam-engines, etc. Its commerce is more important than its manufactures. That great trade which in the sixteenth century placed Amsterdam at the head of the commercial cities of Europe gradually declined, partly from the rise of other ports, but principally from the difficulties of navigation caused by the silting up of the Zuyder Zee, and, above all, the Pampus Bar. Large vessels were obliged to discharge their cargoes outside, and were then floated over the bar by means of *camels*, which, when the water was pumped out of them, raised the vessel with them. To remedy this, the North Holland Canal was cut to the Helder, a distance of 51 miles. It is 124 feet broad at the surface and 31 feet at the bottom, and is available for vessels drawing 18 feet of water. But even this great highway is now inadequate, and moreover is obstructed in winter by ice. To maintain the rank of Amsterdam as one of the great commercial *entrepôts* of Europe, one of the most remarkable engineering works of modern times was commenced in 1863, and is now completed—the *direct* connection of the port of Amsterdam with the North Sea, 15 miles distant, by a canal terminating in an artificial harbor on that sea. This has made Amsterdam practically a seaport. Diamond-cutting is almost exclusively carried on here. See CANALS.

Amsterdam is the terminus of numerous railways. The chief articles of export are butter, cheese, sugar, coffee, oil, spices, colors, etc.

Amsterdam was founded about 1250, before which it was a mere fishing-village, with a castle, the residence of the lords of Amstel. It was fortified in 1482, and became a part of the United Provinces in 1578, after which its commerce and population rapidly increased. Between 1630 and 1750 it was the foremost commercial city of Europe. Pop. (1867) 267,627; (1885) 372,325; (1891) 417,539.

Revised by MARK W. HARRINGTON.

Amsterdam: city, on Mohawk river, Montgomery co., N. Y. (for location of county, see map of New York, ref. 4-I); on N. Y. Central R. R.; 33 miles N. W. of Albany. It has about 40 manufactories (carpets, knit goods, brooms, steel springs, paper, etc.), 3 daily newspapers, numerous churches, and an electric railroad. Its streets are lighted by electricity, and it has an academy, private schools, Roman Catholic institute, etc. Excellent water-supply, fine system of drainage, and well-paved streets. Pop. (1870) 5,426; (1880) 9,466; (1890) 17,336; (1900) 20,929. EDITOR OF "DEMOCRAT."

Amsterdam Treaty: a treaty concluded by France, Russia, and Prussia, Aug. 4, 1717. The mediation of France was accepted between the Czar and the King of Prussia on one side, and Sweden on the other. Russia also abandoned the

invasion of Mecklenburg, and France agreed not to renew a treaty of subsidies with Sweden.

Amu', or Amu Dar'ya: See OXUS.

Am'ulet: an object worn on the person as a charm, and supposed to have power to protect the wearer against evil spirits, sickness, and other real or imaginary evils. Amulets were worn by the ancient Egyptians, Greeks, and Jews. The Greeks and Romans wore a variety of gems and small figures of heroes, deities, and animals. Amulets were also used by the early Christians, but that form of superstition was condemned by the Council of Laodicea about A. D. 360. They are common among the Turks at the present day. An astrological amulet called a talisman was highly prized by the Arabs.

Amunategui, ää-moo-naa'täy-gëe, MIGUEL LUIS: Chilian publicist and *littérateur*; b. Jan. 11, 1828; educated in the University at Santiago, where he attracted the attention of the eminent Andrés Bello. In 1848 he helped Bello in his *Historia de Grecia y Roma*, and was thenceforth his close friend. Much of his life was passed in writing for Chilian periodicals, but several of his books remain among the most serious productions of his country. Such are *Biografias de Americanos* (1854); *Los Precursores de la Independencia* (1870-72); *Vida de Don Andrés Bello* (1876). D. in 1888. A. R. MARSH.

Amur': a province of Russia; in Eastern Siberia: N. of the Amur river, S. of the Yablonoi and Stanovoi Mountains, and W. of the Coast Province; the boundary between it and the last being about the meridian of 135° E. Westward it extends to the mouth of the Shilka river. It comprises the basin of the Seya and Bureya rivers, with some smaller tributaries of the Amur. Area, 172,848 sq. miles. Pop. (1886) 63,221. In a broader sense, the Amur country includes all the Russian territory from Lake Baikal to the Okhotsk Sea, S. of the Stanovoi Mountains. As thus defined it takes in the Russian provinces of Transbaikal, Amur, the Coast Province, and Saghalien, an area of 1,150,000 sq. miles, with a population of 700,000. In climate and character this country is not unlike New England and Quebec, while the southern end of the Coast Province has about the climate of New Jersey and Pennsylvania. Agriculture is generally possible and in places would be very successful. Minerals abound, and a few Americans have found their way there in search of gold. The settlements at present are mostly penal ones. M. W. H.

Amur River: a river of Eastern Asia: for most of its course the boundary between the Russian and Chinese possessions, formed in about lon. 122° E. by the union of the Shilka and Argun. It soon breaks through the Chingan Mountains and takes a general southeasterly course until lon. 135° is reached, when it turns northward and empties into the Okhotsk Sea opposite the northern end of Saghalien at the town of Nicolayevsk, at which point it forms a considerable delta. The chief tributaries are the Seya, Bureya, and Angun. Length, 2,800 miles; area of basin, 520,000 sq. miles. M. W. H.

Amur'ath, or Mu'rad I.: Sultan of the Turks; b. in 1319; succeeded Orkhan, his father, in 1359; took Adrianople in 1361; and waged with success long and bloody wars, chiefly with the Christians; in what is now European Turkey. He was assassinated June 15, 1389.

Amurath II.: succeeded his father, Mohammed I., in 1421; attacked Constantinople in 1423; contended with varying success for many years against the Hungarians under Hunyady, and against Scanderbeg. He gained a great victory at Kosovo in 1448. D. Feb. 9, 1451.

Amurath III.: one of the most cruel of the sultans; b. in 1545; came to the sultanate in 1574. His reign was marked by long wars with Austria and Persia, and with the janizaries at home. D. Jan. 17, 1595.

Amurath (Murad) IV.: Sultan of Turkey; b. about 1610; succeeded his uncle Mustafa in 1623. He had a passionate temper, which was rendered more violent and dangerous by habitual drunkenness. He amused himself by shooting from his palace windows at passers-by in the streets. The most important event of his reign was the capture of Bagdad by his army in 1638. D. Feb. 9, 1640.

Amussat, ää'moos'saa', JEAN ZULÉMA: French surgeon and writer; b. at St. Maixent, in Deux-Sèvres, Nov. 21, 1796. He invented and improved several surgical instruments, and published some able professional treatises, among which are

Researches into the Nervous System (1825), and a *Memoir on the Torsion of Arteries* (1829), which obtained a prize of the Institute. D. in Paris, May 13, 1856.

Amyclæ: an ancient town of Laconia, on the Eurotas, 20 stadia S. E. of Sparta, in a district noted for the abundance of its trees and its fertility; famous in the heroic or legendary age as the abode of Tyndarus and Leda and Castor and Pollux, who were called *Amyclæi Fratres* (Amyclæan Brothers). This town was conquered by the Spartans about 775 B. C.

Amygdaloid [from Gr. ἀμυγδάλη, almond + εἶδος, form]: having the form of an almond; applied in geology to certain volcanic rocks in which once existed oval cavities or cells now filled with nodules of some crystalline mineral deposited from an infiltrated solution. The nodules are composed of agate, chalcedony, calcareous spar, etc. The cavities they occupy were formed as bubbles by steam or other gas while the rock was in a molten condition.

Amygdalus [from Gr. ἀμύγδαλος, ἀμυγδαλή, almond-tree]: a genus of plants of the order *Rosaceæ*, consists of trees whose fruit is a drupe. It comprises the almond (*Amygdalus communis*) and the peach (*Amygdalus Per'sica*).

Amyl (C₅H₁₁): a compound radical belonging to the alcohol series, exists in amylic alcohol, C₅H₁₁.O.H, or fusel oil. It forms a series of compound ethers (see **ETHERS**), some of which are used as substitutes for the essences of natural fruits. The nitrite of amyl is an ethereal liquid of agreeable odor, which has been recently brought to the attention of medical practitioners on account of its peculiar action on the circulation. A few drops inhaled causes a sudden acceleration of the pulse and flushing of the face.

Amyot, JACQUES: b. at Melun, France, Oct. 30, 1513; taught Latin and Greek at the University of Paris; visited Italy; became tutor to the two youngest sons of Henry II.; was made grand almoner under Charles IX., and finally Bishop of Auxerre, where he died Feb. 6, 1593. He published a number of translations of Greek authors, which are highly esteemed for the excellent French in which they are written. These are the *Theagenes and Chariclea* of Heliodorus (1547); seven books of *Diodorus Siculus* (1554); the *Daphnis and Chloe* of Longus (1559); *Plutarch's Lives* (1559); *Plutarch's Morals* (1574). Of these, incomparably the most famous is the translation of *Plutarch's Lives*, which made Amyot one of the most noted writers of France. The English version of Amyot's French, by Sir Thomas North (1575), was extraordinarily popular among the Elizabethans, and was used by Shakspeare as a source for several of his plays. A. R. MARSH.

Amyot, JOSEPH: French Jesuit missionary; b. at Toulon in 1718. He sailed to China in 1750, was invited to Peking by the emperor, and passed the rest of his life there. He learned the Chinese language, from which he translated several works into French, and compiled a *Mantchoo-Tartar-French Dictionary* (Paris, 3 vols., 1789-90). Few European authors have done so much to illustrate the history and customs of China. He wrote a large portion of the *Memoirs Concerning the History, Sciences, Arts, and Customs of the Chinese* (16 vols., 1776-1814). D. in Peking in 1794.

Anabant'idæ [from Gr. ἀναβάς, -βάντος, partic. of ἀναβαίνειν, go up, climb]: a family of spiny-rayed fishes, with the superior branchials of the gill-arches laminated and developed into a superbranchial organ which retains water sufficient to moisten the gills for a considerable time, and with more or less spines in the dorsal and anal fins. Species are found in Southeastern Asia and Africa. One, the *Anabas scandens*, found in India, etc., is especially remarkable for a limited power of climbing. Unlike the eel, which passes over only moist ground, the anabas takes its journey over hard, dry, and dusty roads, and frequently up steep ascents heated with the burning beams of the noonday sun, and does not seem to feel any serious inconvenience from these. It is even asserted by some writers that this fish is able to climb a tree.

Anabas scandens: climbing perch.

Anabaptists: a widely disseminated religious community that arose in the period of the Protestant Reformation, and

still exists in many parts of Europe and North America under the designation of **MENNONITES** (*q. v.*).

The name, derived from ἀναβαπτίζειν, signifies *rebaptizers*. It was bestowed by their opponents, and was never acknowledged by the brethren of the party. The injustice of the name is now generally conceded. The brotherhood denied that they were chargeable with rebaptizing, on the ground that persons who had received the rite in unconscious infancy had never been baptized at all. Influenced perhaps by the powerful example of Prof. Cornelius, German authorities have now adopted a custom which allows the correctness of the Anabaptist contention. Instead of writing them down as "Wiedertäufer" it has become common to designate them simply as "Täufer," and their church as "die täuferische Kirche." That custom has introduced an amount of confusion among English authorities. The word "Täufer" is frequently translated Baptists, and "täuferische Kirche" as Baptist Church. The two things are distinct and should be held apart. The Mennonites, who are the Anabaptists of modern times, have never failed to insist upon the distinction, and to keep themselves separated from the Baptists. See **BAPTISTS**.

The Reformation period is allowed by all authorities to have been exceedingly unsettled and perilous. Deep and widespread dissatisfaction prevailed in more than one rank of society in Germany. The peasants were in a particularly restless frame of mind. One of several outbreaks that had occurred during the earlier years of the sixteenth century was enacted by them in the year 1525, under the leadership of Thomas Münzer. Almost as a matter of course it ended disastrously. The peasant movement was of a social and political sort. There were no Anabaptists engaged in this movement. Münzer, it is conceded, wrote against infant baptism, but neither himself nor his followers went to the extent of rebaptizing. The Anabaptist movement originated at Zurich, Switzerland, between Jan. 18 and 25, 1525. For more than a year dissatisfaction had been growing against some of the methods and measures of Zwingli, the Reformer of Switzerland. In particular the Anabaptist leaders objected to the use he made of the civil government in carrying forward his work, and to the relations of his Church to the government. Besides, though Zwingli was decidedly more literalistic than Luther in the interpretation of Scripture, he retained infant baptism, for which in their estimation there appeared to be no biblical authority. The matters at issue were brought to trial in a formal discussion held in the presence of the city council on Jan. 18, 1525. Zwingli was successful; the city council ordered the Anabaptists to retract or to leave the canton within seven days. During this period, just before their departure, the brethren took the step which gave them the name they have borne for almost the entire period since the Reformation; at an assembly in the house of Felix Manz they instituted adult baptism, and most of the leaders submitted to it.

The significance of that step can hardly be correctly estimated at this distance of time. In the estimation of their opponents, and possibly of a portion of the brethren, it unchurched and unchristianized both Zwingli and his followers. The Church in Zurich, however, was so closely intertwined with the state that a blow at the Church was at the same moment a blow at the state, and an act of rebellion against all constituted authority. There is no reason to suppose that the leaders intended to assume any such extreme position. Their aims were chiefly religious, not political or social; there is every reason to conclude they were estimable and sober men. But they were the victims of circumstances which it was out of their power, and perhaps of any human power, to control. On the heels of this daring act came the peasants' rebellion and the enormities enacted by Münzer. Suspicion was already active against the brethren as being on the side of anarchy. Even under the most favorable conditions it would have been difficult for them to allay the apprehensions of their opponents and to quiet the public mind. The catastrophe at Frankenhäusen on the 15th of May, in which the peasants were defeated and scattered, robbed all parties of reason. Zwingli and his adherents became unalterably convinced that the brethren were in league with disorder, and that it was the duty of every friend of Church and state to use every resource to put them down.

The form of baptism adopted when the movement was instituted appears to have been by sprinkling or pouring, and with comparatively few exceptions that form was observed wherever the party was established. In Switzerland,

in portions of Swabia, and in Poland there were some who were in favor of immersion; but instances were comparatively infrequent. Sprinkling and pouring had supplanted immersion in every section of Germany, except Pomerania, before this time, and the brethren fell into the current fashion, apparently almost without reflection. It is suggested that what little immersion was observed among them may have been due to the influence of Johann Denck. Sprinkling and pouring are believed to have prevailed without exception among the Melchiorites in Holland and Lower Germany. The Mennonites have never followed any other mode.

The connection between the brethren and older reforming parties that existed before the Reformation has been much discussed. The leaders of the movement in Switzerland were aware of no such connection; it was also the custom of the advocates of adult baptism to speak of these leaders as the "founders of Baptism" for more than a century after their decease. Finally, however, in a work published in 1647, the claim was first advanced that the Waldensians were their progenitors. That claim has been often repeated, but has never been established. The failure to establish it does not prove that it is not true; it is possible that additional information may one day be obtained. It is a significant circumstance, however, that modern Mennonite scholars, notably de Hoop Scheffer of Amsterdam, appear to have decided against the notion of any kind of succession. On the other hand, Dr. Ludwig Keller, of Münster, zealously defends that notion, and has written largely to exhibit the correctness of his position.

The principal leader among the "founders of Baptism" in Switzerland was Conrad Grebel, a person of fine learning, noble family, and, on the whole, of admirable spirit. Worthy to stand at his side was his fellow-townsmen of Zurich, Felix Manz, a competent Hebraist and a splendid character. George Blaurock, formerly a monk, gave the impulse which led to the introduction of adult baptism. William Reublin, a man of good fame and real worth, was another fellow-laborer. He had the honor of procuring the adhesion of Balthazar Hubmeier, the famous pastor of Waldshut, who shortly became one of the leading figures in the movement.

First Stage of the Anabaptist Movement.—Having described the beginnings of the brotherhood in Switzerland, it is now in order to describe the earliest fortunes which it encountered. Zwingli was sensible—perhaps too sensible—of the perils of the situation. He was a man of superb courage, but the example of the peasants under Münzer had disturbed his poise. He sounded the alarm. The anarchists had just showed their hand in Germany; Switzerland was nourishing a party of the same sort, and she might shortly suffer a similar fate. Seriously, there was no real cause for alarm; he was seized with the wild panic which prevailed in so many quarters. In his eyes the mark of adult baptism was nothing better than the red flag. The men who showed that mark were men of peace; one of their leading articles provided against war and the bearing of arms. The reformer could not trust their pretensions. The reflection that they had denied to him and his the blessings of Christianity and of the Church of God led him to fear that they were bent upon the overthrow of every social barrier. It is difficult to predict what might have been the issue of the matter if the brethren had not resorted to adult baptism, deferring the baptism of their adherents until they had attained to adult age, and then baptizing them for the first and only time. Zwingli himself was opposed to infant baptism, until such time as he fancied the standard of revolution was being reared in the land by his opponents. Upon the command of Melchior Hofmann, adult baptism was suspended for a period of almost two years in Holland, during which time the cause advanced greatly.

In the month that succeeded the peasants' overthrow at Frankenhausen, Vadian, of St. Gall, began the attack on the brethren of that city. He, too, did not favor infant baptism; but he attacked rebaptism as disorganizing and politically dangerous. His adversaries were forced to yield. Before the year was out there was scarcely a corner of Switzerland where their presence was not forbidden. But they that were scattered abroad went everywhere preaching the word. During the years 1526 and 1527 the most extraordinary triumphs were achieved. The brotherhood was established in almost every quarter of Germany, from Hesse to Livonia. They penetrated into Austria, Moravia, and Bavaria, and the new evangel spread like wild-fire. This great success, however, brought with it great perils. Many revolu-

tionary and dangerous elements were attracted by the mark of adult baptism, and it was plain the leaders would find it difficult to control them. But besides these dangerous classes were won a number of men who would have adorned any cause or Church—as Sattler, Kautz, and Rinck. The unexampled success of these two years proved a sad misfortune. The wildest alarm was experienced, lest they should swallow up all forms of religion and of social order. The sword of persecution was unsheathed and claimed thousands of victims. In a surprisingly short time all of the leaders were in their graves, and the desolated Church was left a prey to violent and unclean men who had crowded into it. The voice of prophecy began to be heard, and there was none to quench the evil spirit. False doctrine was proclaimed almost without opposition. Mystical enthusiasm rose to an unexampled pitch and turned into shocking uncleanness. Speculative heretics claimed the highest seats in the synagogue. By the beginning of 1529 the cause of the brotherhood was lost—ground to powder between the millstones.

Second Stage of the Anabaptist Movement.—In this hour of their exhaustion Melchior Hofmann appears on the scene. He came to Strassburg as a confessor of Zwinglianism from the Low Countries. The Zwinglian Church there was found to be in a critical situation, and Hofmann, uniting with the party of the brotherhood, hoped to capture Strassburg for the Anabaptists. He shortly returned to the Low Countries to acquaint his old friends of his new doctrine. They received him and it with open arms. From the middle of 1530 the brotherhood had gained a large following in the Netherlands and the regions adjacent. These came to Strassburg, which Hofmann had declared to be the New Jerusalem, in the hope of capturing a stronghold for their faith. Instead of capturing Strassburg, Hofmann was captured by it; the city council put him in prison in 1533 and kept him there ten years.

During his confinement the movement he had instigated fell into the hands of even less worthy leaders among his adherents in Holland. Hofmann's weakest point had been the prophecies, but he always employed his ingenuity in the labor of interpreting those prophecies he found in the Scriptures. Jan Matthys, of Haarlem, who succeeded him, was also a prophet, but he had little use for the Scriptures; his most casual conceits were understood to be inspired of God. The evil spirit which Luther had exorcised from Wittenburg returned with seven spirits worse than itself. In the beginning of 1534 possession was gained of Münster in Westphalia, which thereupon took from Strassburg the honor of being the New Jerusalem. A theocracy was established and Matthys sent forth his apostles to convert the world. The place was shortly besieged by the Bishop of Münster, and Matthys was slain in a sally to which he invited a small company of his friends, with a promise that one should put a thousand and two should put ten thousand to flight. He was succeeded by Jan Beukels, of Leyden, who introduced polygamy and had daily revelations. The enormities which he perpetrated gave a shock to the civilized world. The city was carried by storm in 1535, and the second stage of the movement came to an end.

Third Stage of the Anabaptist Movement.—After the overthrow of the theocracy at Münster, Menno Simons came to the helm. His brother was an Anabaptist, and had been killed in one of the engagements of the party in Holland; but Menno kept his position as pastor of the Catholic church at Witmarsum until Jan., 1536. Becoming identified with the now scattered and persecuted brethren, he spent the remainder of his life in devotion to their interests. In the course of time nearly all the brotherhood in any portion of Europe fell under his influence, and most of them were called by his name. Owing to the persecution which was carried on against them from 1635 to 1710 by the Swiss Government, they were almost exterminated in the country of their birth, where at present not more than ten or twelve of their churches can be found. They are still somewhat numerous in Elsass, the Bavarian Palatinate, Baden, Württemberg, Hesse, Nassau, and on the lower Rhine. Several churches exist in East Frisia, Hamburg, and seventeen in Lithuania. Poland numbers six, Galicia and Bavaria one each. In France they still hold forth the word at various points in the Vosges Mountains. Large numbers are met with in Russia, and about 50,000 in Holland. In the U. S. there are twelve different branches of the brotherhood represented in more than half the States, and numbering 41,541 communicants, according to the census of 1890. The number in Canada is estimated at about 10,000.

Doctrines.—No history of doctrines, as held by the brotherhood, has yet been composed. In general, it appears that their tendency was not toward dogmatical development; their main exertions were given to affairs of practical morality in the departments of ecclesiastical, civil, and social life. The tenet by which they became most widely known was the rejection of infant baptism and the practice of adult baptism. To keep the Church pure they employed strenuous discipline, and often resorted to excommunication. The Lord's Supper was observed; through the influence of Carlstadt they were induced to surrender the Roman Catholic notion touching the bodily presence of Christ in the elements, and to adopt the conception of Zwingli, which in the beginning they had opposed. Their separation from the world was often so strict as to excite the suspicion of their contemporaries. All differences between communicants with regard to property were to be settled by the Church. The notion that this was an invasion of the rights of the state in the interest of a theocracy was encouraged by the circumstance that they refused to bear the sword and to hold any kind of civil office. It was also forbidden to take an oath in courts of justice. In addition to these matters of mainly external concern, it may be said that their general type of doctrine is understood to be Arminian. So far as is known, the brethren all opposed Luther's doctrine of justification by faith, insisted upon the freedom of the will, and denounced predestination. This did not place them in sympathy with the Roman Catholics, however; it was their business to resist the Roman Catholics as strenuously as they set themselves against the reformers. Melchior Hofmann added as much to the creed of the brethren as he received from them; it was he who introduced the notion that our Lord took not his flesh from the Virgin, but that the word became flesh without the co-operation of human agency. This view prevailed in Holland, and as the English Anabaptists came from that country, it may be observed among them.

The Church Constitution was not uniform. In Moravia there was a somewhat elaborate hierarchy; elsewhere they seem to have employed only elders, often called bishops, and deacons. Community of goods, which did not prevail elsewhere, was established in Moravia.

LITERATURE.—*Zwingli's Werke* (Zurich, 1828-42); H. Bulingier, *Der Wiedertäufer Ursprung, Furgang, Secten* (Zurich, 1560); J. H. Ottius, *Annales Anabaptistici* (Basle, 1672); P. Winter, *Geschichte der Bayrischen Wiedertäufer* (Munich, 1809); Krohn, *Die Wiedert. in Niederdeutschland* (Leipzig, 1758); K. von Hase, *Heilige und Propheten (das Reich der Wiedert.)* (Leipzig, 1892); K. Bouterwek, *Zur Literatur und Geschichte der Wiedert.* (Bonn, 1865); H. W. Erbkam, *Geschichte der prot. Sekten im Zeitalter der Ref.* (Hamburg, 1848); Heberle, *Anfänge des Anabaptismus in der Schweiz; Jahrbücher f. D. Theol.*, iii. s. 225-280; Egli, *Die Zürcher Wiedertäufer* (Zurich, 1878); H. S. Burrage, *History of the Anabaptists in Switzerland* (Philadelphia, 1882), based on the two preceding works, with some assistance from the following; C. A. Cornelius, *Geschichte des Münsterischen Auf- rührs, in drei Büchern* (Leipzig, 1855-60); only two books appeared; Ludwig Keller, *Das Reich der Wiedert. zu Münster* (1881), apparently an effort to complete the work of Cornelius; Johann Denck, *Ein Apostel der Wiedert.* (1882); *Die Reformation und die älteren Reformparteien* (1885); de Hoop Scheffer, articles on Menno Simons and the Men- nonites in the second edition of Herzog's *Real-Encycl.*, vol. ix.; W. Roehrich, *Geschichte der Reformation im Elsass* (1830); Egli, *Aktensammlung zur Zürcher Reformationsge- schichte* (Zurich, 1882). WILLIAM H. WHITSITT.

Anaba'ra: a river of Siberia, on the boundary between Yeniseisk and Irkutsk; rises about lat. 69° N., and lon. 107° E., flows northward about 300 miles, and enters the Arctic Ocean in lat. 72° 40' N., lon. 112° 30' E.

Anab'asis [Gr. ἀνάβασις, ascent; ἀνά, up + βαίνειν, go]: a Greek word signifying an "ascent," a march from a lower into a higher region. In medicine it is sometimes applied to the increase of a disease or paroxysm. It is also the title of two Greek historical works: (1) Xenophon's account of the expedition of Cyrus the Younger against his brother Artaxerxes Mnemon, King of Persia, 401 B. C., and of the retreat of the ten thousand Greeks who had served in the army of Cyrus. (2) Arrian's *Anabasis*, in which are recorded the expeditions of Alexander the Great into Persia and India.

An'ableps [from Gr. ἀναβλέπειν, look up; ἀνά, up + βλέπειν, look]: a genus of haplomis fishes, characterized by a remarkable projection of the eyes from the sides of the head,

and by the pupil being incompletely divided into two by a pair of lobes projecting from each side of the iris, which, together with the division of the eye into an upper and lower portion by a band of integument, gives the fish the appearance of having two eyes on each side. Several species are found along the sandy coasts and in the fresh waters of tropical America. Revised by D. S. JORDAN.

Anacanthi'ni [from Gr. ἀνάκανθος, without spine; ἀν-, not + ἄκανθα, thorn]: an order of fishes distinguished by an ossified endoskeleton, the surface covered in some cases with cycloid, in others with ctenoid, scales; fins supported by flexible or jointed rays; ventrals beneath the pectorals, or wanting; swimming-bladder without air-duct. This order includes the cod and many other edible fishes.

Anacardia'ceæ: See SUMACH FAMILY.

Anach'aris canadensis (now called *Elodea canadensis*): a herbaceous plant of the family *Hydrocharidaceæ*; a native of North America, growing in ponds and slow streams, in which it is entirely submerged. It has a much-branched and slender stem, and is remarkable for the rapidity of its growth. It is naturalized in Great Britain, where it suddenly appeared in such abundance as to obstruct the navigation of the Trent, Derwent, and other rivers. It was first observed in Great Britain about 1842. It causes no such trouble in the U. S.

Anachar'sis (Gr. Ἀνάχαρσις): Scythian philosopher who lived about 600 B. C., and was a friend of Solon. He was the only "barbarian" admitted to the privilege of a citizen of Athens, and was by some reckoned among the Seven Wise Men of Greece. On his return to Scythia he was put to death, because he practiced some Greek religious rites. Some of his pithy sayings have been preserved by Diogenes Laertius and others. The name of Anacharsis has been made familiar to modern readers by the popular work of J. J. Barthélemy, whose work entitled *Voyage du jeune Anacharsis en Grèce* (1788) represents the life and customs of the ancient Greeks.

Anach'ronism [Gr. ἀναχρονισμός, from ἀνά, up + χρόνος, time]: an error in chronology; an inversion or disturbance of the order of time. The use of cannon in Shakspeare's *King John* is an anachronism, as cannon were not employed in England until a hundred years or more after his reign. Painters who represent ancient patriarchs in modern costumes are censured for anachronism.

Anacle'tus: an anti-pope, was elected by a party of cardinals in 1130 as a rival pope to Innocent II., who was recognized by the majority of European powers. Anacletus was supported by the Romans. D. in Rome, Jan. 25, 1138.

Anacon'da (*Eunectes murinus*): a large serpent allied to the *Boa constrictor*; a native of tropical America, especially of Brazil and Guiana. It sometimes grows to the length of 30 feet, and is the largest serpent of America. It passes much of the time in the water, preferring the shallow parts of a lake or stream. Among the generic characters that distinguish it from the boa are the small size and position of its nostrils, which open at the upper part of the end of the muzzle, and are directed upward. It is not venomous. Its food consists of lizards and other small animals. The natives make use of its skin for shoes and its flesh for food. See BOA. Revised by D. S. JORDAN.

Anaconda: city, Deer Lodge co., Montana (for location of county, see map of Montana, ref. 6-E); on the Montana Union R. R.; 27 miles from Butte. Has 5 schools, with 21 teachers; 4 churches—Methodist Episcopal, Roman Catholic, Presbyterian, and Christian. There is also preaching in German, Swedish, and Scandinavian. The principal industry is copper smelting, the smelters of the Anaconda Mining Co. being located here, employing about 1,500 men and treating exclusively the ores of the Anaconda group of mines in Butte. The town dates from 1884, when the smelting-works were erected. Pop. (1890) 3,975; (1900) 9,453. EDITOR OF "STANDARD."

Anacor'tes: town, Skagit co., Wash. (for location of county, see map of Washington, ref. 2-C); on Seattle and Northern R. R. and Puget Sound, 15 miles N. of La Couter and 95 miles N. of Seattle; has saw-mills, sash and door factory, and is a shipping-point for coal and iron. It is in an agricultural, lumbering, and fishing district, and wheat, coal, and iron market. Pop. (1890) 1,131; (1900) 1,476.

Anac'reon (Ἀνακρέων): Greek lyric poet; b. at Teos, in Ionia, about 560 B. C. He emigrated from Teos when that

town was taken by the Persians, about 540, and passed many years at the court of Polycrates of Samos. After the death of Polycrates, 522 B. C., he became a resident of Athens, to which he was invited by Hipparchus. Love and wine were his favorite themes; but love and wine do not exhaust the significance of Anacreon, who was capable of vigorous and biting satire. D. in 476 B. C. According to tradition he was choked to death by a grape-stone. Some fragments of his poems are extant (see Bergk's *Poetae Lyrici Græci*), but the character of his own work has been obscured, and his high position as a poet lowered by the *Anacreontea*, light, toying, graceful versicles of a late period.

Revised by B. L. GILDERSLEEVE.

An'adir, or **Anadyr**: a river of Siberia; near the extreme N. E. part of Asia; rises near the Arctic Circle, and after a very winding course enters the Gulf of Anadir. Length about 450 miles. The Gulf of Anadir is in Siberia, near the N. E. extremity of Asia, and is a large inlet of Bering Sea. It is separated from the Arctic Ocean by a peninsula about 150 miles wide.

Anadyom'ene [Gr. *ἀναδυομένη* (sc. Ἀφροδίτη), partic. of *ἀναδύεσθαι*, rise up from; *ἀνά*, up + *δύεσθαι*, enter]: a surname given to Venus; also the name of a masterpiece of Apelles representing Venus rising from the sea and wringing her flowing hair with her fingers. This picture was purchased by the people of Cos, who sold it to the Emperor Augustus for 100 talents, or more than \$100,000 of our money.

Anæmia, a-nee'mi-a [Gr. *ἀναιμία*; *ἀν-*, without + *αἷμα* blood]: a morbid condition in which the blood is lessened in quantity or impoverished in quality. The former is unusual, but may occur, as after profuse bleeding. Even here, however, the quality soon becomes impaired, since the tissues pour their fluids into the depleted vessels and thus dilute the remaining blood. Impoverishment in the quality of the blood consists of decrease in the number of the red corpuscles, or of the coloring-matter or hæmoglobin contained in them (see BLOOD). Anæmias may be classed as of two kinds: secondary or symptomatic, and primary. Secondary anæmias are such as arise in the course of consumption, cancer, suppurations, diseases of the stomach, and the like, in which there is systemic weakening from constant wasting discharges or from interference with the action of important organs. The second class, or primary anæmias, includes such cases as are not dependent upon other diseases, but in which the degradation of the blood seems to result from derangement of the blood-forming organs. Much remains to be learned in regard to these cases. Among these primary anæmias may be named *progressive pernicious anæmia*, a serious form in which the anæmia grows more and more severe until death closes the case, *chlorosis* (q. v.), and *leukæmia*.

The symptoms of anæmia are most diverse, but among the more characteristic may be named pallor, debility, wasting of the tissues, and indigestion. There is tendency to depressing perspiration, urine of low specific gravity, fluttering palpitations of the heart, and many other indications of weakness. In the late stages dropsical swelling of the feet may be noted.

The treatment consists of nourishing diet with treatment directed to the stomach to secure proper assimilation; fresh air, and due exercise. Of medicines, two deserve mention, viz., iron and arsenic. Iron is in many cases of anæmia almost a specific, and in others arsenic is extremely useful.

WILLIAM PEPPER.

Anæsthe'sia [Gr. *ἀναισθησία*, insensibility; *ἀν-*, not + *αἰσθέσθαι*, perceive]: in medical language, when used to designate a symptom, denotes a diminution or a complete loss of the sense of feeling, either general or much more frequently local. In this sense it is opposed to the term hyperæsthesia, which denotes an exaltation or excess of sensibility. Both these conditions are symptoms of disease of the nervous system. When feeling proper is abolished while pain exists, it is called "anæsthesia dolorosa"; when both pain and the sense of touch are absent, it is "analgesia." But of late the term commonly denotes a total or partial, local or general, suspension of all the senses as the result of the application or inhalation of some chemical agent. Local anæsthesia is produced by the rapid evaporation of some highly volatile substance, like ether or rhigolene, and consequent chilling of the part to be affected. The local application of certain drugs, such as aconitine, and notably cocaine, will also produce a degree of anæsthesia. General anæsthesia is, however, by far the most common result of this kind to which the physician directs his efforts. The Chinese have

used preparations of hemp for this purpose for many centuries. The *Arabian Nights* contain numerous allusions to a similar use of this drug. Mandragora, opium, and many other soporifics were used by the ancients as anæsthetics, though such use is dangerous from the profound effects produced. Surgical operations in later times have been successfully performed while the patient was in the mesmeric sleep or condition of "hypnotism." Such a condition is, however, usually regarded as a diseased one, and its production is outside the province of the physician. The anæsthetics generally in use are common or ethylic ether, chloroform, and nitrous oxide gas, each of which is administered by inhalation. There is some reason to believe that the anæsthetic property of ether was not unknown in the sixteenth century, soon after the discovery of this agent by the alchemists. Several physicians in the eighteenth century recommended the use of ether by inhalation for the relief of pain. Sir Humphry Davy in 1800 observed the anæsthetic effect of nitrous oxide, and proposed its use in surgery, but it was not till 1844 that Horace Wells, a dentist of Hartford, Conn., successfully employed this gas for the prevention of pain in removing teeth. The subject, however, fell for the time into undeserved neglect, though at present this gas is extensively employed in dentistry and other surgical operations.

Between 1816 and 1846 several American physicians proposed the use of ether as an anæsthetic. In October of the latter year Dr. W. T. G. Morton, of Boston (who had successfully used ether in dentistry), administered it to a patient in the Massachusetts General Hospital during a surgical operation by the late Dr. Warren. In Nov., 1847, Sir J. Y. Simpson, of Edinburgh, first announced chloroform as an anæsthetic, it having been used for the relief of difficult breathing by Ives, of New Haven, Conn., in 1832, and its anæsthetic effect upon the lower animals having been shown by Flourens ten months before Simpson's experiments. The use of both ether and chloroform has spread rapidly since the above discoveries. Various other agents (amylene, amyl hydride, carbon bichloride, Dutch liquid, methylene bichloride, ethyl bromide, etc.) have been proposed, but for the most part they have turned out to be more dangerous than the older and better known anæsthetics.

With regard to the relative superiority of the various agents used, opinions differ. It is claimed by some that ether is much safer than chloroform, while other practitioners of eminence assert that chloroform is pleasanter, cheaper, and more speedy in its effect, and equally safe if the requisite skill is employed in administration. The principal objections to nitrous oxide are that it is not easily portable, and that its effects are very transitory. Experiments tend to show that ether produces anæsthesia by causing carbonic dioxide poisoning, while chloroform appears to act by producing anæmia of the brain.

Revised by R. PARK.

Anæsthet'ies: certain preparations having the property of producing ANÆSTHESIA (q. v.).

Ana'gni (anc. *Anagnia*): an episcopal town of Italy, situated 37 miles E. S. E. of Rome (see map of Italy, ref. 6-E). It was the birthplace of several popes, among whom were Innocent III., Boniface VIII., and Gregory IX. Anagnia was nearly as old as Rome, was the chief city of the Hernici, and was an important place during the whole period of the ancient Roman history. Vergil mentions it as the wealthy Anagnia. Here are some of the finest cyclopean walls in existence. Pop. 8,156.

An'agram [as if from a Gr. **ἀνάγραμμα*; *ἀνά-*, again, anew + *γράμμα*, writing; cf. *ἀναγραμματίζειν*, transpose letters]: a word or sentence formed by the transposition of the letters of some word, phrase, or sentence. The most perfect or proper anagram, called palindrome, is formed by reading backward—i. e. reversing the order of the letters—as "evil," *live*. The making of anagrams was a fashionable exercise of ingenuity in the sixteenth and seventeenth centuries, as well as in the Dark or Middle Ages. A very curious specimen of anagram is the transmutation of Pilate's question, *Quid est Veritas* (What is truth?) into *Est Vir qui adest* (It is the Man who is present). Dr. Burney made the felicitous discovery that the Latin sentence *Honor est a Nilo* (Honor is (or comes) from the Nile) is concealed in the name of Horatio Nelson. The opponents of the Dutch theologian Jacobus Arminius transformed his name into *Vani Orbis Amicus* (A friend of the vain world). Among recent examples of the anagram are—Florence Nightingale, "Flit on, cheering angel"; Sir Robert Peel, "Terrible poser"; French Revolution, "Violence, run forth."

An'ahem: town: in Orange co., Cal. (for location of county, see map of California, ref. 12-F); on Southern Pacific R. R.: in the center of the largest valley in California. It is 28 miles S. of Los Angeles, is 12 miles from the sea, and is the headquarters of the wine interest of Southern California. It produces over 1,000,000 gal. of wine annually. Pop. (1870) 881; (1880) 833; (1890) 1,273; (1900) 1,456.

Anahnac': a Mexican word used vaguely or in various senses; sometimes applied to the great central table-land or plateau of Mexico, which comprises more than half of the Mexican republic, and lies between lat. 15° and 30° N., and lon. 95° and 110° W. It is elevated from 6,000 to 9,000 feet above the level of the sea, contains several lakes, and is bounded, especially on the W., by chains of high mountains. From this plateau rise several high volcanoes, one of which, Popocatepetl, has an altitude of 17,784 feet.

An'akim: the ancient race of giants who lived in the south of Palestine at the time of the exodus of the Israelites. They are called "the children of Anak" in Num. xiii. 28. "Joshua destroyed them utterly with their cities," but a remnant of them was left in Gaza, in Gath, and in Ashdod (Joshua xi. 21, 22).

Anal'cime, or Anal'cite [from Gr. *ἀν-*, not + *ἄλκιμος*, strong]: a hydrated silicate of soda and alumina, generally occurring in twenty-four-sided crystals, which are sometimes transparent. By friction it becomes *feebly* electrified, whence its name. It is found in the trap-rocks of Ireland, Scotland, Nova Scotia, and Lake Superior.

Analem'ma [Lat. *anatemma*, support of sun-dial, sun-dial, from Gr. *ἀνάλημμα*, prop. to *ἀναλαβεῖν*, restore]: in geometry, the projection of a sphere upon the plane of a meridian, the eye being supposed to be placed at an infinitely distant point of the radius perpendicular to that plane. In this projection (which is also called *orthographic*) all small circles whose planes are parallel to that of projection are represented by concentric circles of the same magnitude as the originals; all circles in planes perpendicular to that of projection are seen as chords or diameters of the meridian circle, and all other circles of the sphere are projected into ellipses.

Anal Glands: in comparative anatomy, organs for secreting substances which, though not always so, are generally repulsive, and are used in some cases by the animal for the purpose of defense. They present every grade of glandular structure, nearly always opening into the termination of the intestine near the anus. The sweet fluid ejected by the aphides, and of which the ants are so fond, is the product of secreting tubules opening on the posterior part of the body; and the singular defensive acrid vapors discharged explosively by the insects called "bombardiers" are likewise the products of anal glands. In the mollusks the most remarkable example of these glands is presented by certain cephalopods, such as the cuttle-fish, in which there is sometimes a single and sometimes a bilobed or trilobed cyst, that secretes an inky fluid which these animals eject to blacken the water around them, for the purpose of concealment in time of danger. In reptiles the anal bags are either single, double, or triple, and in many species, as in frogs and tortoises, are developed to a great size, and serve for aquatic respiration. In birds the anal follicles consist of a single cavity, which is termed the *bursa Fabricii*. In quadrupeds the anal follicles generally consist of two sacciform cavities, each having an opening near the verge of the anus. In the skunk (*Mephitis mephitis*) the secretion of these glands furnishes to the animal its principal means of defense. In the civet (*Viverra civetta*) and the beaver (*Castor fiber*) the secretions from the anal glands have long been an article of commerce; the former is sometimes employed, when combined with other substances, as a perfume; the latter, under the name of castor, is used in medicine.

Revised by D. S. JORDAN.

Anal'ogy: *in language*, a term adopted from the usage of the ancient Greek grammarians, and freely used in the recent literature of language-history, to cover in the widest sense all those changes in the outer form of language which arise from association. All changes in the outer form of language, apart from the borrowing of material from other languages, are to be referred either to the operation of the laws of sound or to the principle of association. The changes by which primitive Germanic *stainaz* appears in Gothic as *stains*, in Old English as *stān*, in English as *stone*, in German as *stein*, are due to the regular operation of phonetic laws.

Every like-conditioned Germanic *ai*, if unhindered or undeflected in its development by the influence of association, will become *ā* in Old English, and *ō* in Modern English. Thus Gothic *haims*, Old English *hām*, Modern English *home*; *aips*—*āp*—*oath*; *draib*—*drāv*—*drove* (pret.); *hlaifs*—*htāf*—*loaf*; *mail*—*māl*—*mole*; *snaiws*—*snāw*—*snow*; *gait̥s*—*gāt*—*goat*, etc.

In striking contrast to this class of changes in word-form stand those which represent the influence of other words of the same idea-group. Consciously or unconsciously all our ideas exist in some connection with other ideas. The natural instinct of speech is to express the like by the like. The action of the laws of sound tends to produce a diversity which the unifying tendency of association continually operates to correct. The laws of sound beget the diversity Lat. *arbos-arboris*, which analogy corrects to *arbor-arboris*. The office of analogy therefore in the development of language is the maintenance and re-establishment of the groups which the phonetic laws tend to disrupt, as well as the formation of new groups. It tends to eliminate purposeless variety. The folk has no use for the wealth of form-material which mixture of dialects and the action of the phonetic laws have produced, and with which tradition offers to endow it. The phenomena of analogy are in the last analysis due to the unconscious effort of the mind in its quest for unity to reduce the apparently incongruous elements of speech to systems and groups, and to put simplicity in the place of complexity. It seeks continually to endow the dead conventionalities of speech-material with life by infusing meaning into them. In this process, however, reflection is not involved; still less the historical sense of the philologist. For example, the French *femelle* would naturally appear in English as **fēmēl*, but the contrast with *male* evidently directed the folk-consciousness to read into the syllable *fē-* the value of a distinguishing element, so that the word-pair *male*: *fe-male* was created. A reference to our common language-sense will probably show that in the word *cutlet* we connect a meaning "little" with the syllable *-let*, and have falsely read into the first syllable the meaning of the verb *to cut*, though the word is really derived from Latin *costa*, "a rib."

The results of the operation of analogy can be understood and consistently classified only on the basis of the psychological activities which produce them. It will be found that the groupings of words which give rise to them always represent some real or supposed affinities of meaning or value, and never occur on the basis merely of outward likeness or resemblance of form.

Thus words of the same general class of meanings are often so grouped that the common idea is gained a representation in some part or element of their outward form. Thus the pronunciation of *February* as *Febryary* betrays a grouping with *January*, which has seized upon a characteristic ending, *-uary*. French *été* was originally feminine (cf. Lat. *astatem*), but grouping with *hiver*, m., and *printemps*, m., has made it masculine. In Sanskrit the word *pāti-s*, "lord," when used in the sense "husband," betrays its grouping with the common words of relationship like *pitár*, "father," *mātár*, "mother," *bhrátár*, "brother," when in some of its ease-endings it follows their standard; thus genit. *patyúr*, like *pitár*, though its regular genitive would be *pátēs*. Latin *ille* for *olle* follows *iste*, *ipse*, *is*.

In the same way a grouping according to likeness of value or function is shown in the leveling between like moods, tenses, cases, etc. Thus the older *sleep*: *slēp*; *weep*: *wēp* has been replaced by the commoner type *steep*: *stēpt*, etc. The influence of the type Latin *tribui*: *tribūtus*; *minui*: *minūtus* changed in vulgar Latin *visus* to **vidūtus*; cf. Italian *veduto* and French *vu*; so *ventus* to **venūtus*, French *venu*; *habitus* to *habūtus* > French *eu*. The older forms survive only in words which have been removed from the stress of the system, and isolated by a special substantive use, as French *dette* < Latin *debīta*, whereas *dū* < **debūtus*; so French *vente* < *vendīta*, but *vendu* < **vendūtus*.

Contrast of signification often forms a tie between words, as when Latin *sinister* becomes *senexter* under influence of *dexter*, and *meridialis* becomes *meridionatis* under influence of *septentrionatis*. English *mīster* (Mr.) for *master* has its *i* from *mīstress*.

Likeness of signification groups together different cases, moods, etc., of the same word, and interposes a resistance to the disintegrating work of the phonetic laws. Thus the older diversity *ἀνέρες*—*ἀνδρῶν* yields to the leveling *ἄνδρες*—*ἀνδρῶν*. While *shelves* is the usual plural of *shelf*, *roofs* is the plural of *roof*. Both *wharfs* and *wharves* are in use.

The preterite *was*—*waren* has become in standard German *war*—*waren*. A similar extension of the *r* from the plural is found in English *wan't* = *wor not* for *was not*. A similar influence is exerted between derivatives and their primitives. Thus the vulgar *threble* has its *th* from *three*; *agréable* has its accent from *agréé*. The vulgar *fur* for *far* is due to *further*.

It is entirely possible for a likeness of form *deceptively* to suggest a likeness of signification, and a grouping made upon the basis of this presumed likeness of meaning or value may bring about a change in the form. The English *belfry* should be *berfry* (Old French *berfroi*), but the first syllable was changed in deference to a supposed connection with *bell*. German *beispiel*, "example," has originally nothing to do with *spiel*, "play." It should be *beispiel* (*spel*, "story," cf. English *gospel*). Such changes as these are called "folk-etymologies." See Palmer, *Folk-Etymology* (London, 1882); Andresen, *Ueber deutsche Volksetymologie* (Heilbronn, 4th ed. 1883); Keller, *Lateinische Volksetymologie und Verwandtes* (Leipzig, 1891).

Graphic analogies, or the merely orthographical effects of analogy, are to be clearly distinguished from the foregoing. They are mostly due to pedantry, and our own language affords an unfortunately large list of examples. Thus the *scissors* (Middle English *sisoures*) is due to learned comparison with Latin *scindere* or its derivatives; *debt* (Middle English *dette*) and *doubt* (Middle English *doute*) have adopted their *b* as a mere decoration from Latin *debere* and *dubitare*; *victuals* has borrowed a false livery from Latin *victus*, but its Middle English form, *vitailles*, has been duly continued in the pronunciation *vittles*; cf. Middle English *battailles* > Modern English *battles*.

Jour. of Philol.*, xii, pp. 1 ff.

BENJ. IDE WHEELER.

Analogy and Homology: in the comparative anatomy and physiology of plants, *analogy* refers to similarity of function, and *homology* to similarity of structure. Thus spores and seeds are analogous, both being functionally reproductive bodies; while leaves and stamens are homologous, both being structurally phyllomes.

C. E. B.

Analysis [in Gr., literally a loosing, from *ἀναλύειν*, to resolve into elements, from *ἀνα*, back, and *λύειν*, to loose]: the resolution of a whole into its parts.

Analysis, Chemical: the identification and separation of the elements of chemical compounds or mixtures of any sort. When conducted simply with reference to determining what elements exist in any substance it is termed *qualitative analysis*. When the absolute or relative quantities of the elements are ascertained it is *quantitative analysis*. The theory of qualitative chemical analysis is to put the substance to be analyzed under such conditions and associations as shall cause all its various elements, one after another, to present certain characteristic phenomena or to enter into certain recognizable combinations, and is based on the grand truth that each chemical element has constant and absolute peculiarities which it carries into its compounds. Thus the fact that silver and mercury are the only elements whose compounds with chlorine are insoluble in dilute nitric acid is taken advantage of to separate these two metals from all others. Any nitric solution of metals which is not made milky or turbid on the addition of hydrochloric acid does not, and can not, contain silver or sub-salts of mercury. Again, any nitric solution wherein hydrochloric acid produces a white milkiness or a white curdy separation, or a fine, dazzling white powder, which neither dilute hydrochloric acid, dilute nitric acid, nor hot water will clear up, must contain either silver or mercury, or both. In case such a white separation—or "precipitate," as the chemist technically terms it—is formed by hydrochloric acid in a solution of metals, the liquid, together with the suspended precipitate, is poured upon a filter (a conical cup folded from a circle of paper specially prepared for the purpose) sustained in a glass funnel. The liquid, which retains all the other elements in solution, passes the pores of the paper, but the precipitate of silver chloride and mercurous chloride remains upon it. The filter is next repeatedly filled with water until the acid liquid has been washed out from the precipitate and the pores of the paper, and we have then all the silver and all the mercury that existed in the form of sub-salts in the filter, and all the

other elements in the "filtrate," as the liquid which has passed through is designated.

The substances which are employed to bring about those chemical changes which serve the purposes of chemical analysis are called *reagents*, and the chemical processes themselves are termed *reactions*, for the reason that at least two substances must always be involved in chemical transformations, and that both act and are reacted upon. Thus the hydrochloric acid employed in our separation of silver and mercury from all other metals is a reagent, and the precipitation is the evidence of a reaction.

Chemical reactions have been known and employed to identify certain bodies from the earliest times. Pliny described the use of paper dyed in nutgalls for detecting iron sulphate when mixed with verdigris as an adulteration. The reaction is a blackening of the paper (formation of ink). In many cases it is easy to recognize a substance by simply applying in this manner a single reagent, which is then called a test. Thus copper in its solutions is tested by a bit of clean iron wire, which precipitates it as a red powder. A clean piece of copper is a test for mercury in solution, the latter metal forming a silvery coating on the former. Lime-water is a test for carbonic acid gas, making with it a white precipitate of carbonate of lime. Hydrochloric acid is a test for ammonia, as the vapors of the two, when brought together, produce a white cloud. But there are circumstances under which such simple tests fail to give unequivocal answers to the chemical inquirer, and it is needful to frame a system of operations which takes account of all possible contingencies, and which enables the analyst not only to prove with certainty that such and such elements exist in any substance he analyzes, but also gives him equal assurance that nothing else is present in it—a system, in short, which can lead him to a complete knowledge of the composition of any body. Such systems of procedure, more or less satisfactory, have been devised out of the collective experience of chemists, and their details are found in our treatises on qualitative chemical analysis. In respect to the elements and compounds of mineral or inorganic chemistry, a very perfect plan has been elaborated, which has received in all essential points the sanction of universal usage.

This system of analysis applies to all the metals and their oxides, and to all their compounds with mineral elements or acids. It supposes that the elements, etc., are in a state of solution either in water or an appropriate acid, and gives directions for obtaining such solutions. The substance is first subjected to a "preliminary examination," which often leads to the detection of some of its ingredients, or demonstrates the absence of certain elements, and furnishes useful hints as to the mode of solution and subsequent procedure. The actual examination begins with the application of four "general reagents," which serve to dissect the substance into six "groups," as regards its bases or metallic oxides.

The solution being in nitric acid, the first reagent is hydrochloric acid, which precipitates the first group—viz., silver and mercury (the latter from mercurous salts). The acid filtrate from these chlorides is submitted to a stream of sulphuretted hydrogen gas, which precipitates the second and third groups, consisting of twelve metals together, as sulphides. These are collected and washed upon a filter, and upon them is poured sulphide of ammonium. This dissolves and carries through the filter the sulphides of the second group—viz., arsenic, antimony, tin, gold, platinum, molybdenum, and tungsten, while the sulphides of mercury (from mercuric salts), lead, bismuth, copper, and cadmium, constituting the third group, remain undissolved.

The filtrate from the precipitate by sulphuretted hydrogen is next taken in hand, made alkaline by ammonia, and sulphide of ammonium is added to it. This throws down, as hydroxides or phosphates, aluminium, chromium, glucinum, and the cerium metals; as phosphates, calcium, barium, strontium, and magnesium; and as sulphides, nickel, cobalt, manganese, zinc, iron, uranium, thallium, and indium—making a fourth group.

To the ammoniacal liquid, separated by a filter from the last precipitate, is added carbonate of ammonium, whereby the fifth group—viz., barium, calcium, and strontium—are precipitated as carbonates.

Lastly, the liquid filtered from the above carbonates may contain the alkalis and magnesium.

The resolution of these groups is accomplished by further application of appropriate reagents. Each group is treated after a certain order which experience has taught. To illus-

trate: the white precipitate obtained by hydrochloric acid, already described, may contain silver chloride or mercurous chloride, or both. To complete its examination we employ the deportment of these chlorides toward ammonia-water, which easily dissolves silver chloride to a clear liquid, but converts white mercurous chloride into a black substance that remains undissolved. It is only needful then to pour dilute ammonia upon the white content of the filter; and if it blacken, the presence of mercury is demonstrated. The ammonia-water that passes the filter is dropped into excess of dilute nitric acid; the separation of a white, curdy substance is evidence of silver.

After thus isolating the two metals we may apply further confirmatory tests. Thus the black mercury compound remaining in the filter may be mixed with carbonate of sodium, dried, introduced into a small glass flask, and heated to redness, when metallic mercury will distil off and gather on the cold part of the vessel in brilliant globules. So, too, the white curds of silver chloride separated by nitric acid from the ammoniacal solution may be gathered and washed on a filter, the latter burned, the precipitate and ashes mixed with moist carbonate of sodium into a pellet, and heated strongly on charcoal by aid of a jeweler's blowpipe. The silver is thus reduced to the metallic state, and may be found, even when present in extremely minute quantity, by cutting out the charcoal to a little depth around the spot where the pellet was placed, grinding it in a smooth mortar of porcelain or agate, and carefully washing away the coal-powder by a gentle flow of water. The flattened silver particles will reveal themselves by their luster.

The detection of acids is accomplished in another portion of the substance by the use of other reagents, after the same general plan.

In quantitative chemical analysis it is needful to convert each element of a substance into some form or compound which will admit of complete separation from all the others, and also of accurate weighing or measuring. In many cases an element must be separated in one form, and converted into another for weighing. Silver may be both separated and weighed as chloride or as metal, while zinc must be separated as carbonate or sulphide, but can only be weighed accurately as oxide. Many of the reactions employed in qualitative analysis also serve in quantitative estimations; the latter branch of analysis has, however, a multitude of processes peculiar to itself.

In many cases the determination of the quantity of an element or ingredient consists in the collection of a precipitate on a filter, washing, drying, burning away the paper at a red heat, and weighing the ignited residue. This requires a delicate balance, accurate weights, vessels of glass, porcelain, and platinum, which are unalterable by acids and by heat, and great nicety of manipulation. It also requires a perfect knowledge of the deportment of the precipitate toward all the reagents and solvents with which it must have contact, and a certainty that it can be obtained of perfectly definite and known chemical composition. Our present stock of this kind of knowledge is the fruit of a multitude of the most painstaking experiments, and every day the labor of skilled investigators is adding to its variety and extent.

To certain branches or general modes of analysis technical names are applied. Thus "blowpipe analysis" designates a system of operations carried on mainly by aid of the blowpipe, which serves for identifying a large share of the elements, and even for quantitatively estimating the precious metals, as well as lead, copper, nickel, and some others. "Spectral analysis," which furnishes the most sensitive tests for the presence of the alkali metals, is based on the fact that the light proceeding from a flame in which the vapor of any substance is intensely heated, manifests, when viewed there by a prism, lines or bands of color whose position and number are characteristic. "Volumetric analysis" is a branch of quantitative analysis, in which measured volumes of solutions of determined strength are employed in reactions whose completion is indicated by some change of color or other marked phenomenon. "Organic analysis" is either ultimate or proximate. The former signifies the estimation of carbon, hydrogen, nitrogen, and the other elements of organic compounds. Proximate organic analysis is the separation of organic compounds from each other, as is done, for example, in determining the proportions of water, oil, starch, etc., in seeds. "Assaying" is the term usually applied to the estimation of the valuable metals, or ingredients of an ore or other commercial article.

Some of the most striking discoveries of science have been

steps in the development of chemical analysis. The recognition of oxygen, chlorine, barium, and manganese were results of Scheele's analysis of the mineral "wad" or pyrolusite. Among the first fruits of quantitative analysis was the discovery of the laws of definite and multiple combining proportions. Those philosophers who, like Bergmann and Dalton, were the first to announce, and those who, like Berzelius, Dumas, and Stas, have done most to establish, these laws have been eminent for their skill in analytical chemistry.

The utility of chemical analysis manifests itself in a multitude of directions. By it the values of bullion, coinage, and plate are established; ores of all the metals are worked and sold on the chemist's report of their analysis. The same is true of a host of commercial articles, such as various alkalies, acids, salts, medicines, dyestuffs, fertilizers, etc. Chemical analysis furnishes the consumers of these and many other articles a protection against the dishonesty or ignorance of producers or dealers. The physician often gathers decisive diagnostic hints from the analysis of urine; the advocate relies upon chemical analysis for the detection of poisons which can be employed in the perpetration of murder.

There are indeed limits to the application of chemical analysis. It is not difficult to make mixtures some of whose constituents no chemist can identify with the knowledge now at his disposal. The composition of a large number of drugs, such as vegetable extracts, is nearly or quite unknown; and the "analysis" of a "compound sirup," or "bitters" containing the virtues of a dozen vegetable remedies is impossible.

The successful pursuit of analytical chemistry requires a long course of the most patient and conscientious experimental work; it is therefore an admirable disciplinary study, and is recognized as such in the higher schools of Europe and this country.

Extended treatises on chemical analysis are Rose's *Handbuch der Analytischen Chemie*; Fresenius's *Qualitative Analysis*, and the same author's *Quantitative Analysis*; Bunsen's *Gasometric Methods*; Hoppe-Seyler's *Handbuch der Physiologisch- und Pathologisch-Chemischen Analyse*; Mohr's *Titrimethode*; Post's *Chemisch-Technische Analyse*. The *Zeitschrift für Analytische Chemie*, edited by Fresenius, and now (1892) in its thirty-first volume, is a nearly complete repertory of all that is currently published on the subject.

S. W. JOHNSON.

Analysis: in *elementary geometry*, a method of finding the demonstration of propositions, and testing their truth, by examining what consequences flow from them and what propositions may lead to them. In the case of a problem, it may first be supposed to be resolved, and then the consequences resulting from that solution may be deduced until we arrive at something known, which may serve as a starting-point for the actual solution. In modern language, the term analysis is applied to that branch of mathematics which treats of continuously variable quantities by the symbolic notation of algebra. It includes, in a general way, both the higher algebra and the differential and integral calculus. The distinction between algebra and analysis is, however, not sharply defined. Sometimes the former term is confined to quantities growing out of the fundamental operations of addition, subtraction, multiplication, division, and the extraction of roots; while under analysis is included the relations of quantities which can not be expressed by any finite number of algebraic operations, and in which infinitesimals or limits have to be used.

From this application of the word analysis come the expressions "analytic geometry," "analytic mechanics," etc., which mean geometry, mechanics, etc., treated by algebraic symbols and methods.

S. NEWCOMB.

Analysis, Proximate Organic: an important branch of chemical analysis which seeks to separate and determine the *proximate* constituents of vegetable and animal matter and of products therefrom; that is, instead of separating *ultimately* the elementary constituents from each other, it is the function of proximate analysis to set apart by themselves the different important definite *compounds* which make up the immense variety of mixtures occurring in animal and vegetable structures, and the various tissues and juices thereof. This field of investigation, it will be seen, is of immense magnitude and importance, but of corresponding, indeed unlimited, complexity and difficulty. Nevertheless, certain general principles have been arrived at; and

a U. S. chemist, Albert B. Prescott, of the University of Michigan, has produced a systematic treatise upon the subject, to which the reader may be referred with confidence as well worthy of study. The subject, however, is one which has not received the attentive and systematic care from laboratory chemists that its importance demands; and it yet remains true that in proximate organic analysis success depends chiefly upon the original inventive talent and individual research of the chemist occupied therein, in too great a number of important cases that are constantly liable to turn up.

H. WURTZ.

Anal'ysis, Ul'timate Organic: a special branch of chemical analysis, which may also be appropriately designated the elementary analysis of hydrocarbon compounds, as a vast majority of the bodies to which it is applicable contain both carbon and hydrogen. It is founded on the general method of burning in a close apparatus a weighed quantity of the organic substance to be analyzed, which has been previously mixed with some mineral compound of oxygen capable of furnishing the latter element to the carbon and hydrogen of the organic substance. The mineral oxygen compounds mostly used are black oxide of copper and fused yellow chromate of lead. The carbonic acid gas and water (as steam) formed in this combustion are made to pass through another apparatus, or train of apparatus, containing chloride of calcium, to absorb all the water, and potash-lye, to absorb the carbonic acid gas. The tubes containing these latter two absorbents are weighed before and after the process, and the differences are the amounts of water and carbonic acid formed, from which the amounts of carbon and hydrogen in the original substance are readily computed. If oxygen is contained in the substance, it appears as the difference between the whole original weight and the sum of the carbon and hydrogen. If nitrogen be present, it has to be determined by a separate process, but it also necessitates certain precautions in the above process, to prevent the formation of oxides of nitrogen, which would be absorbed by the potash and vitiate the carbon determination. The products of combustion are therefore first passed over metallic copper heated to incandescence, which decomposes such oxides of nitrogen.

Determination of Organic Nitrogen.—The prevailing methods are two in number. By the Will-Varrentrapp method the nitrogen is converted into gaseous ammonia by ignition in admixture with a caustic alkali. A mixture of the hydrates of soda and lime, called "soda-lime," is used for the purpose. The ammonia is absorbed by an acid, and its amount determined by subsequent operations. By the Dumas-Melseus method the nitrogen is converted into its gaseous elementary form and measured in a eudiometer. Combustion with oxide of copper is generally employed in this method, with numerous essential precautions. Other modifications are employed when sulphur, phosphorus, chlorine, etc., are to be determined in organic compounds. To explain the apparatus required in these different methods, and the details, manipulations, and precautions necessary to practical success, would require a considerable treatise with numerous illustrations. For these it is necessary to refer, therefore, to the elementary textbooks of chemistry.

HENRY WURTZ.

Analysis, Volumetric: a branch of quantitative chemical analysis in which the substance to be estimated is subjected to characteristic reactions, solutions of known strength being employed for this purpose, from the quantity of which required the substance sought can be determined by aid of the fixed laws of equivalence. Volumetric processes usually require less time and less elaborate apparatus for their execution than the ordinary methods by weight; and as they afford equally, if not more, accurate results, they are particularly well adapted for technical purposes, such as the valuation of commercial products. Gay-Lussac, who first suggested this method of analysis, was impressed with the advantage of estimating silver by the use of a solution of common salt (sodium chloride); and this process will serve to illustrate one of the more simple applications of volumetric analysis. In the ordinary method of analysis a known weight of the substance containing silver is first dissolved in nitric acid; then hydrochloric acid is added, whereby insoluble argentic chloride is precipitated, which is separated from the fluid by filtration, washed, dried, fused, and weighed; and as the composition of argentic chloride is known, the amount of silver contained in the precipitate, and therefore in the original substance, can be easily calculated. It is

evident that the same result can be obtained by preparing a solution of sodium chloride of known strength, and ascertaining the quantity of this necessary to precipitate the silver completely as chloride from the nitric acid solution. This is done by slowly adding the salt solution to the silver solution, until a point is reached at which the precipitate ceases to form. The process is now stopped, and the exact number of divisions (grains or cubic centimeters) of the salt solution used ascertained by observing the graduated vessel from which it was taken; and as we know that 58.5 parts by weight of sodium chloride are exactly sufficient to convert 108 parts by weight of silver into silver chloride, and the strength of the salt solution is also known, the weight of the precipitated silver can be readily determined. The operation just described can be completed in less than half an hour, while a silver determination by the method first referred to would require at least half a day; while in regard to accuracy of result the volumetric process is also more advantageous. The liquids used in methods of this character are termed "standard solutions." The quantity of these solutions used in a determination can be ascertained either by weighing or by measuring, but the latter is usually resorted to. In order that a reaction may be applicable in volumetric determinations, it must take place quickly, and give rise to some change by which its termination can be readily detected by the eye, such as the appearance or disappearance of a color, a precipitate beginning or ceasing to form, etc. For this reason the number of processes available is limited, although many reactions that are useless in analysis by weight furnish valuable means for volumetric estimations. The apparatus used consists of a good chemical balance and several varieties of graduated glass vessels for the preparation and measuring of the solutions, in the use of which the French or metric system of weights and measures is most advantageously employed. The measuring apparatus embraces pipettes, flasks, and burettes. The pipette is simply a glass tube, having an enlarged body and a narrow stem, on which a mark is placed indicating its capacity. It is used by filling to the mark, and allowing the liquid to escape by a displacement of the finger from the upper end. The flasks used are graduated for the capacity of from $\frac{1}{10}$ liter to 5 liters. The burette, which is employed for the measurement of standard solutions, and usually has a capacity of 50 or 100 cubic cm., consists of a long glass tube of uniform caliber, having throughout its length equal divisions (cubic centimeters and fractional parts thereof). The burette of Mohr has at its lower end a caoutchouc tube, which can be opened or closed by means of a spring clamp; but as the rubber is not entirely without influence on some of the solutions used, it is in many instances advantageously replaced by a glass stopcock. The standard solution is generally prepared of such strength that it contains in each liter (1,000 cubic cm.) the whole or a fractional part of the molecular weight of the reagent employed, expressed in grammes. For instance, the molecular weight of oxalic acid, $C_2H_2O_4$, is 90. It is dibasic (see ACIDS), and one molecule is therefore equivalent to two molecules of a monobasic acid, such as hydrochloric acid. Its standard solution is prepared by dissolving in a liter of water a number of grammes equal to half its molecular weight, that is 45 grammes; each cubic cm. of this solution will contain $\frac{1}{20000}$ of the molecular weight of oxalic acid, and will exactly neutralize $\frac{1}{20000}$ of the molecular weight of an alkaline mono-carbonate, or $\frac{1}{10000}$ of the molecular weight of a caustic alkali. In the case of a substance like silver, it is more convenient to take $\frac{1}{10}$ of the atomic weight; that is, 10.8 grammes of silver are dissolved in nitric acid, and the solution is diluted to 1 liter; each cubic cm. of this liquid will then contain $\frac{1}{100000}$ of the atomic weight of silver (0.0108 gramme), and will precipitate $\frac{1}{100000}$ of the atomic weight of chlorine (0.00355 gramme) in the form of silver chloride. In the same way, normal solutions of the following acids and alkalis contain in a liter one-half or the whole of their atomic weight in grammes:

Sulphuric acid.....	gr. per liter, 49.
Hydrochloric acid.....	" " " 36.5.
Sodic carbonate.....	" " " 53.
Sodic hydrate.....	" " " 40.

A great advantage of the above system is that the solutions agree with each other, volume for volume; thus 100 cubic cm. of any of the above acid solutions will exactly neutralize 100 cubic cm. of any one of the alkaline solutions. Its convenience will be readily perceived from the following illustration: Suppose it is necessary to determine the purity of

a sample of soda-ash (impure sodic carbonate); if it were perfectly pure, 5.3 grammes would require 100 cubic cm. of one of the above normal acids for neutralization; and if this quantity is weighed out, dissolved in water, and the normal acid gradually added from a 100 cubic cm. burette until complete saturation takes place, the number of cubic cm. required will directly indicate the percentage of pure sodic carbonate present in the sample; thus if 85 cubic cm. of the acid solution were necessary, the sample contained 85 per cent. of sodic carbonate. It is, however, not always practicable to weigh out the substance composing the standard solution; in this case an approximately correct quantity is taken, and the exact strength of the solution determined by actual experiment. Processes in which the substance is brought into direct contact with the standardized solution of a reagent which combines with or decomposes it, as in the estimations of alkalies by acids, silver by sodium chloride, iron by potassic permanganate, etc., and also those determinations in which the standard solution reacts upon the substance, causing the liberation of an equivalent quantity of a representative body, which is estimated instead of the substance itself—such as the valuation of manganese ores, in which, upon boiling the substance in hydrochloric acid, an amount of chlorine equivalent to the oxygen present is evolved and its quantity determined—are called *direct* methods of volumetric analysis. Besides these, there are the *indirect* or *residual* processes, in which the amount of the substance to be analyzed is not directly estimated, but is calculated by using an excess of some agent of fixed strength, which decomposes or combines with it in a known proportion, and subsequently determining the excess used. Thus if a weighed amount of an impure sample of calcic carbonate be dissolved in a known excess of nitric acid, it is possible, by determining the amount of pure acid remaining by titrating backward with a standard alkaline solution, to ascertain the proportion of pure calcic carbonate contained in the sample examined.

Having referred to the apparatus employed in, and some of the features of, volumetric analysis, it remains to mention more particularly a few of the processes most commonly used. These may be conveniently classified into analyses by saturation, by precipitation, and by oxidation or reduction, although this division fails to embrace all of the volumetric methods resorted to. *Analysis by saturation* includes the processes of alkalimetry and acidimetry.

Alkalimetry, or the determination of the amount of alkali contained in alkaline mixtures, such as the commercial products *potash* and *soda*, etc., by volumetric methods, is based upon the fact that the alkalies and their carbonates readily form neutral salts with the strong acids which do not affect the color of litmus; whereas the smallest excess of either the alkali or the acid imparts to it a blue or red coloration. Sulphuric, oxalic, or hydrochloric acid is usually employed in the preparation of the standard acid solutions, which are best made of the strength previously prescribed. In addition to the remarks already made concerning the determination of an alkali by means of a normal acid solution a few details of the process should be added. A weighed quantity of the sample of alkali having been dissolved, the solution is distinctly colored blue by the addition of a few drops of solution of litmus. A burette is then filled to the zero point with the standard acid, and this is allowed to flow into the solution until a red coloration begins to appear. Owing to the carbonic acid liberated, this will occur before all of the alkali is saturated, and it is necessary to boil the solution in order to remove this source of error, when the blue color will reappear. The acid is then cautiously added by drops, heat again applied, and a little more acid added, until a distinct pink-red color, which does not disappear on boiling, is produced. We now know that complete neutralization has taken place, and, as the strength of the acid solution is also known, the amount of real alkali contained in the sample is readily calculated from the number of cubic centimeters used. The inconvenience occasioned by the presence of carbonic acid in the above process can be avoided by adding more acid than is really required to neutralize the alkali, and then ascertaining the excess taken by means of a normal solution of caustic alkali, and deducting it from the amount of acid used. Caustic lime, baryta, and strontia, and their carbonates, can be estimated in the same manner, the standard acid employed being the hydrochloric.

Acidimetry can be accomplished by a method precisely the reverse of that used in alkalimetry, a normal alkaline liquid being added to the solution under examination until

a blue color is imparted to the litmus. Caustic soda, either obtained directly in the pure state or prepared by the decomposition of sodic carbonate by means of lime, is usually employed as the normal alkaline solution; but a solution of 53 grammes of pure sodic carbonate in a liter of water is also often used. In special cases, as in the estimation of acetic acid (see VINEGAR), the salt formed does not possess a neutral reaction, and it is advisable first to prepare a solution of the acid of known strength, and then determine the quantity of the alkaline solution required to produce the change of color. The quantity of acid contained in numerous neutral salts, if the base is precipitated by an excess of caustic alkali or carbonate, can be estimated by first adding an excess of the standard alkaline solution, and then determining the excess used by titration with a normal acid; the amount of acid contained in many salts, the base of which is precipitated by sulphuretted hydrogen, can also be determined by titrating the filtrate from the precipitate with normal alkali.

Volumetric analysis by *precipitation* includes such determinations as that of silver, referred to in the beginning of this article. The end of reactions of this nature is frequently shown by the precipitate ceasing to form, but indications of greater precision and delicacy are often obtained by aid of a third body, with which a characteristic color is produced; thus, if, in the estimation of chlorine or chlorides by a normal silver solution, a little potassic chromate be added, the completion of the process is indicated by the formation of an orange-yellow color, proceeding from argentic chromate produced by the first drop in excess of the silver solution, and in the precipitation of phosphoric acid by uranic nitrate or acetate the end of the precipitation is indicated by a drop of the mixed solutions producing a brown color with yellow prussiate of potash. A method that has come into extensive use of late years is that devised by Volhard. This consists in dissolving in nitric acid, boiling to remove all the oxides of nitrogen, adding iron-alum, and then dropping in potassium (or ammonium) sulphocyanide, until the red color of ferric sulphocyanide remains. This method is capable of application to many different determinations.

Analysis by *oxidation or reduction* comprises numerous volumetric methods, which give very accurate results, and have to a great extent replaced the older process by weight. In these, substances which readily take up oxygen are titrated with oxidizing agents of known power; or substances which give up oxygen are deoxidized by an excess of a reducing agent, the excess of which is afterward determined by residual titration with a standard oxidizing solution. The oxidizing bodies most employed are potassic permanganate and dichromate, and iodine; the reducing agents being sulphurous acid, sodic hyposulphite, arsenious anhydride, and oxalic acid. One of the most important estimations coming under this head is the volumetric determination of iron, which is based upon the fact that when a solution of potassic permanganate is added to an acid solution of a ferrous (protoxide) salt, the latter is oxidized to a ferric salt, the purple-red color of the permanganate solution being destroyed so long as any of the ferrous salt is present; but as soon as the oxidation is completed the next additional drop of the solution imparts a distinct red coloration to the liquid. It is necessary first to reduce all iron contained in the substance examined to the ferrous state, which can be done by means of zinc and sulphuric acid. The strength or standard of the permanganate solution is also to be previously determined by reducing a known weight of pure iron to the ferrous state, and ascertaining the number of cubic cm. of the solution required to oxidize it, the value of 1 cubic cm. being noted on the bottle in which the solution is preserved. It is then only necessary to multiply the number of cubic cm. employed in an analysis by the value, or oxidizing powder, of 1 cubic cm., in order to ascertain the quantity of iron present in the substance taken. Potassic dichromate can also be employed as the oxidant, but in this case the termination of the process is not indicated in the liquid itself, but is shown by a drop of the mixture no longer producing a blue color when added to a solution of ferricyanide of potassium. Iodine often serves as an oxidizing agent by combining with the hydrogen of water to form hydriodic acid, while the oxygen liberated acts upon the oxidizable substances present, and, as the slightest excess of iodine imparts a blue color to starch, the reaction can be applied to the volumetric estimation of many bodies that readily take up oxygen, such as arsenious and sulphurous acids, etc. It is evident that these latter compounds can likewise be employed for the determination of free iodine. On the above reaction very accurate

and important volumetric processes are based, such as the estimation of oxygen in peroxides, in which, however, an indirect method is employed. Many substances containing oxygen, when boiled with hydrochloric acid, liberate a quantity of chlorine corresponding to a part or all of the oxygen present. Upon conducting the chlorine so evolved into a solution of potassic iodide, an equivalent amount of iodine is set free, which can then be estimated by adding a solution of starch-paste and titrating with a solution of sodic hyposulphite of known strength. The standard of the hyposulphite solution used is readily ascertained in the same manner by heating a *known quantity* of potassic dichromate with hydrochloric acid, conducting the evolved chlorine into a solution of potassic iodide, and estimating (in presence of starch) the number of cubic cm. of the hyposulphite solution required to reduce the iodine set free; the termination of the reaction being indicated by the disappearance of the blue color of the iodide of starch. Processes similar to that just described receive frequent practical application in the valuation of numerous articles of commerce, such as manganese, bleaching-powder, etc.

A method more curious than valuable, by which analytical determinations can be accomplished without the use of weights or standardized solutions, consists in taking a certain amount of the impure substance to be tested, balancing it with an equal weight of the pure substance, and submitting both to titration with a solution of unknown strength. It is easy to perceive that the impure substance will require for its decomposition a smaller quantity of the solution than the pure substance, and that the quantity required will be in proportion to its purity. The pure substance can, in some instances, be replaced by another of similar chemical activity (e. g. sodic carbonate by calcic carbonate, manganese dioxide by potassic dichromate, etc.). In addition to the examples cited above, volumetric processes, usually based upon the principles already mentioned, receive extensive application in the estimation of several metals (such as copper, zinc, tin, lead, and mercury) and numerous organic compounds (including sugar, tannic acid, alkaloids, the constituents of urine, water, wine, etc.).

Revised by IRA REMSEN.

Analytical Geometry: See GEOMETRY.

Anamó'sa: city and railroad junction: capital of Jones co., Ia. (for location of county, see map of Iowa, ref. 4-K); on the Wapsipinicon and Buffalo rivers; 50 miles S. W. of Dubuque. It has excellent quarries of building-stone and a State penitentiary. Pop. (1880) 2,083; (1890) 2,078; (1900) 2,891.

Ananas'sa Sati'va: See PINEAPPLE.

Anapa': a seaport and fortified town of Russian Circassia; on the north shore of the Black Sea; near the mouth of the Kuban (see map of Russia, ref. 11-D). The harbor is not safe in stormy weather. The town has been by turns the property of Turks and Russians, and now belongs to the latter. Pop. 5,357.

Anapæ'stic Meter (Gr. ἀνάπαιστος): originally a marching measure. The anapaest consists of two short syllables followed by a long syllable, and is largely used in systems of pairs for entrance and exit songs of the Greek drama, and in tetrameters in Aristophanic comedy. See METRES.

Anaph'ora [Gr. ἀναφορά, a carrying back, recourse; ἀνα-, back + φέρειν, carry]: in rhetoric, a repetition of a word or phrase at the beginning of two or more consecutive sentences or clauses, as, "It is sown in corruption, it is raised in incorruption. It is sown in dishonor; it is raised in glory. It is sown in weakness; it is raised in power."

An'archist: one who believes that political evil is to be remedied by the abolition of government. Proudhon (*q. v.*) is, on the whole, the writer who is to be regarded as the founder of modern anarchism; but it was taken up most actively by the Russian Nihilists (see NIHILISM), and made the basis of the most vigorous practical agitation. Next to Russia, Spain is the country where the anarchists have made most headway; Portugal, Italy, and France have also been somewhat involved in the movement. The International Workingmen's Association, founded in 1864, was a combination of anarchists and socialists, who worked together in agitation, though their theories were diametrically opposed; the socialists wishing to avoid inequality by increasing state interference, the anarchists by abolishing it. But in 1872 the combination was broken up; the socialists proper ("Centralist Democratic Socialists"), headed by Marx,

holding that you can not have equality or co-operative production without a state to enforce it; while the anarchists, or anarchic socialists, headed by the Russian Bakunin, believing that this would involve tyranny, wished to have property held by communistic associations of workmen, formed freely without political compulsion. As to the means by which this result is to be secured, different groups of anarchists are not agreed. Some disclaim violence, and believe in the power of moral principles, like those of the early Christian Church. Others, unfortunately more numerous and influential, seek revolution for its own sake, and hold that after this is accomplished it will be time enough to consider what to do next. On this account anarchism, in its more important practical aspects, is not to be regarded as a body of doctrines, but as a dangerous means of agitation, many of whose partisans do not hesitate to countenance the use of dynamite. The best known leader of the American anarchists is Johann Most; the paper in which he advocated his doctrines was the *Freiheit* (Freedom). The anarchists of the U. S. are almost entirely foreign born; their greatest strength seems to be in Chicago. The most serious conflict with the law was in the Chicago riot of May 4, 1886. Several of the leaders were sentenced to death Aug. 20, 1886, and executed Nov. 11, 1887; but the popular reaction against lawlessness did even more than the execution of the leaders to check the growth of anarchism in the U. S. In Spain and France the anarchists have shown considerable strength of late years, and the use of dynamite seems to be a most serious danger to the police authority in each of these countries. See COMMUNISM, NIHILISM, and SOCIALISM.

ARTHUR T. HADLEY.

Anar'rhichas [from Gr. ἀναρρῆχασθαι, to clamber up; ἀνά, up + ἄρρῆχασθαι, climb]: a genus of fishes allied to the Blennies, characterized by having their mandibular, palatine, and vomerine bones armed with large osseous tubercles bearing on their summits enameled teeth. It includes the wolf-fish, which is common to both sides of the Atlantic, and other related species. See WOLF-FISH.

A'nas [Lat. *A'nas*, a duck]: a genus of ducks including what may be called the true or typical species, such as the mallard (*Anas boschas*), the black duck (*Anas obscura*), and related forms. The bill is about as long as the head, rather longer than the tarsus, with the sides parallel and the nostrils high up. The species of the genus are *par excellence* fresh-water birds and well flavored. The various limitations of this genus afford a good epitome of the progress of ornithology. With Linnæus the name *Anas* was almost equal to the family *Anatidæ*, for it included swans, geese, and all ducks save the fish-eating mergansers. A little later the genus was so restricted as to comprise only the fresh-water or river ducks of the sub-family *Anatinae*, as contrasted with the sea-ducks, *Fuligulinae*. It was then limited to a very few species, closely allied to the mallard, and, finally, was so extended as to include the teal and others.

F. A. LUCAS.

Anasarca: See DROPSY.

Anasta'sia: the name of several female saints of the Greek and Roman churches. (1) *Anastasia the Elder*, who is said to have been a pupil of Peter and Paul, and to have suffered martyrdom in the time of Nero. Her day is Apr. 15. (2) *Anastasia the Younger*, whose martyrdom by burning at Aquileia in 303 brought to an end the persistent persecutions of her heathen husband Publius. Her day is Dec. 25 in the Latin Church, and Dec. 22 in the Greek. (3) *Anastasia*, a Greek Christian maiden of good family and great beauty, who had attracted the attention of the Emperor Justinian. The better to resist his dishonorable proposals she retired to Alexandria, where for twenty-eight years, until her death in the year 567, she lived as a monk, no one ever suspecting her sex. Her day is Mar. 10.

Anasta'sius I.: Emperor of Constantinople; b. at Durazzo about 430 A. D. He succeeded the Emperor Zeno in 491. The orthodox, who considered him a heretic, revolted and defeated his army in 514. D. in 518 A. D.

Anastasius II.: became Emperor of the East in 713 A. D. Theodosius was chosen emperor by his army, which took Constantinople and deposed Anastasius in 716. D. in 720 A. D.

Anastasius I., SAINT: a native of Rome; became pope about 398 A. D. He condemned the doctrines of Origen. D. in 402 A. D.—**ANASTASIUS II., SAINT** (pope), a native of Rome, succeeded Gelasius I. in 496 A. D. D. in 498.—**ANASTASIUS**

III. was chosen pope in place of Sergius III. in 911. D. in 913.—ANASTASIUS IV. succeeded Eugenius III. as pope in 1153. He died at an advanced age, Dec. 2, 1154.

Anasta'sius, surnamed THE LIBRARIAN: a Roman priest who was librarian of the Vatican. He compiled an *Ecclesiastical History* in Latin from Greek sources, and wrote other works. D. about 890.

Anastasius Grün: See AUERSPERG.

Anastat'ica [from Gr. ἀνά, up + στήναι, stand]: a genus of cruciferous plants containing the rose of Jericho (*Anastatica hierochuntina*), which grows in Palestine and North Africa, and has singular hygroscopic properties. Under the influence of drought it rolls up into a ball, becomes detached from the ground, and is carried away by the wind after the manner of the "tumble weeds" of our American plains. When it comes into contact with moisture it expands into its natural form, and is hence called "resurrection plant." It retains for many years this property of expanding when moistened.

Anastatic Printing: See ZINCOGRAPHY.

Anas'trophe [Gr. ἀναστροφή, a turning back; ἀνα-, back + στρέφειν, turn]: in rhetoric, a species of inversion or departure from the usual order of succession in words, as when Scott, in the *Lady of the Lake*, says, "Clattered a hundred steeds along," for "A hundred steeds clattered along"; so Vergil in the *Æneid*, lib. i. l. 32, has "*Maria omnia circum*" for "*circum omnia maria*" (around all the seas).

An'atase [from Gr. ἀνάτασις, extension; ἀνά, up + τείνειν, stretch]: a name of titanite acid or oxide of titanium, which occurs in octahedral crystals, having a splendid and adamantine luster. Some specimens found in Brazil resemble diamonds so much as to be mistaken for them. Called also *octahedrite*. See TITANIC DIOXIDE.

Anath'ema [Gr. ἀνάθεμα, a thing devoted (to evil) or accursed; ἀνά, up + θείναι, place]: a Greek word, the primary meaning of which was something "placed" or "hung up" in the temples of the gods, and hence "consecrated" or "devoted." Among the Jews and Christians it is a curse or denunciation uttered by ecclesiastical authority, and a form of excommunication of heretics and other offenders.

An'athoth, or **A'nata**: an ancient Jewish city of refuge, about 4 miles N. E. of Jerusalem; is supposed to have been the native place of the prophet Jeremiah.

Anat'idæ: a family of web-footed birds, of which the genus *Anas* is the type. It includes the duck, goose, swan, and others. Cuvier gave them the name of *Lamellirostres*.

Anato'lia, **Anado'li**, or **Nato'lia** [from Gr. Ἀνατολή, the rising or orient]: the modern name of Asia Minor, which is a large peninsula, bounded on the N. by the Black Sea and the Sea of Marmora, on the S. by the Mediterranean, and on the W. by the Grecian Archipelago. The Euphrates forms part of its ill-defined eastern boundary. It lies between lat. 36° and 42° N., and between lon. 26° and 41° E. The length from E. to W. is about 700 miles, and the area is estimated at 204,434 sq. miles. The western coast is indented with numerous gulfs, and presents many high and precipitous cliffs. The interior is an elevated plateau, inclosed by two mountain-ranges—namely, Mount Taurus, which extends through the southern part from the Euphrates to the archipelago, and Anti-Taurus, which traverses the northern part. The general direction of these ranges is nearly E. and W. Some peaks of Mt. Taurus attain a height of 10,000 feet or more. Between these two long ranges are several others which rise to a great height. The highest summit in Anatolia is the volcanic Arjish-Dagh, or Mt. Argæus, which is situated 13 miles S. of Kaisareeyeh, and is 13,000 feet above the level of the sea. Mt. Olympus, about 8 miles S. of Brusa, has an altitude of 8,800 feet.

The largest river of Anatolia is the Kizil-Irmak (anc. *Hatys*), which rises in the east part and enters the Black Sea. The western part of the peninsula is drained by the Meander and the Hermus (Sarabat), which flow westward into the Ægean Sea. In the central part are a number of salt lakes and barren steppes of large extent. The Katakekaumene, or "burnt country," a volcanic waste, is the best known of these regions.

The rocks which underlie the upper regions of Anatolia are mostly granite, serpentine, and schist. Along the southern and western coasts calcareous rocks predominate, and marble is abundant. Numerous extinct volcanoes and rocks of volcanic origin occur in different parts of the country.

The climate presents a great diversity in consequence of the inequality of the surface. The western shores have been celebrated in all ages for their mild and genial climate, and the coast of the Black Sea is favored in that respect. The central plateau is very hot in summer and cold in winter, partly because it is not well watered and is generally destitute of forest trees. The northern region and the other sea-coasts are covered with extensive forests of oak, ash, beech, plane, and other trees good for timber. The coasts of the Ægean and Black Seas have a very luxuriant vegetation and a fertile soil. Among the chief products are sugar, wine, opium, tobacco, olives, figs, wheat, barley, and silk. The flora of Southern and Western Anatolia is extremely beautiful. The mountains are infested by panthers, bears, and wolves.

Anatolia, which forms a part of the dominions of the Sultan of Turkey, comprises the pashalics of Anatolia, Itchelee, Karamania, Adana, Marash, Sivas (or Room), Trebizond. The population, estimated at 10,970,000, not including Armenia, consists of Ottoman Turks, Turkomans, Greeks, nomadic Koords, and Armenians. The cultivation of the soil is generally neglected here, and the principal branches of industry are the production of opium, wine, and oil, and weaving shawls and carpets. The chief cities are Smyrna, Brusa (or Bursa), Sinope, Angora, Konieh, Kutaieh, and Trebizond. In ancient times this peninsula was occupied by many powerful kingdoms and famous cities. See ASIA MINOR, IONIA, LYDIA, PONTUS, etc., and Hamilton's *Researches in Asia Minor* (1842); Tchihatcheff's *Asie Mineure* (1853-60); and Barth's *Reise von Trapezunt bis Skutari* (1860). Revised by M. W. HARRINGTON.

Anatolia: a pashalic of Asiatic Turkey, forming the peninsula of Asia Minor. It is the largest and richest province in the Turkish empire, and the most populous in Western Asia, comprising a large part of the Anatolia described above. Area, 208,327 sq. miles. Pop. 9,125,000.

Anat'omy [from Lat. *anatomia*, from Gr. ἀνατομή, a cutting; ἀνά, up + τέμνειν, cut]: literally the dissociation of parts by cutting up or dissection; now usually that division of *biology* having for its object the study of the structure of organized bodies. Since the latter, obviously, may belong either to the vegetal or to the animal kingdom, anatomy may relate to the structure of plants—*phytotomy*—or to that of animals—*zootomy*. Vegetal anatomy will be treated in connection with *botany* (*q. v.*), the anatomy of animals alone being here considered.

The vast field included within the comprehensive embrace of "anatomy" and the various points from which it may be approached render the recognition of certain subdivisions necessary. The study of form and construction by comparison of the structure of different animals, including man, constitutes *comparative anatomy*—the importance of which for a proper appreciation of the structure of man can not be overestimated. *Human anatomy*, or *anthropotomy*, on the contrary, confines investigation to the human body. Human anatomy, or the special anatomy of man, is further treated from different aspects: the description of the individual constituents of the entire body constitutes *descriptive* or *systematic anatomy*; the discussion of the position of parts and their mutual relations is *topographical* or *regional anatomy*; when considered especially as to the requirements of the surgeon and physician it is termed *surgical* or *applied anatomy*; the actual dissection and separation of parts, with a view to their study and exhibition, constitutes *practical anatomy*. The investigation of the changes of form and structure, from the earliest stages to the adult condition, belongs to *developmental anatomy*; while the recognition of the laws determining and underlying the formation and variation of organisms is the province of *morphological anatomy*. The description of organs and bodies changed by disease is *pathological anatomy*.

The consideration of the structural elements of organisms constitutes *general anatomy*, or *histology*; from the fact that such studies necessitate the use of the magnifying glass, the term *microscopic* or *minute anatomy* is frequently employed as synonymous. Conversely, *gross anatomy* denotes the examination of such details of arrangement as are displayed by the scalpel to the unaided eye. Descriptive anatomy is subdivided into various systems; thus *osteology* treats of the bones; *syndesmology* describes the joints; *myology* recounts the muscles; *angiology* refers to the blood-vessels and circulatory system; *neurology* relates to the nervous system; *splanchnology* pertains to the description of the viscera or

organs. For accounts of the various organs and tissues, see EYE, EAR, HEART, BONE, MUSCLE, etc.

In sketching the outlines of the history of anatomy three epochs are recognizable. The first era begins with the earliest attempts to gain anatomical knowledge, embraces the sum of all the observations and traditions of the ancient classical authors, and terminates in the general extinction of learning during the Dark Ages. The second period dates from the revival of anatomy in the Italian schools during the fourteenth century, and is especially marked by the notable advances and lasting impressions made by the genius of Vesalius and his followers in the sixteenth century, the impetus of whose labors was felt throughout the medical world. The third epoch commences with the establishment early in the nineteenth century of the fundamental principle announced by Caspar Friedrich Wolff, that all organized beings originate by the differentiation of simple cells, the descendants of the ovum, in opposition to the then prevailing and accepted theory of preformation, by which all parts of the new organism were considered to exist from the beginning perfectly formed, although of infinitesimal dimensions. The doctrine that both plants and animals are composed of elementary structural particles (the cells), also advanced by Wolff, shortly afterward received additional support from the researches of Schleiden and Schwann. The expansion and future application of the principles advanced by Wolff and his immediate successors, together with the fruitful labors of subsequent anatomists in the new fields of embryology and morphology, alone have rendered possible the development of the broad and comprehensive science which anatomy, in its widest sense, to-day represents.

The claims of human anatomy as a science of great antiquity are not supported by trustworthy evidence; on the contrary, there is sufficient reason to regard human anatomy, as a systematic study, as of comparatively recent origin. There is little to warrant the assumption that the practice of sacrificial rites and of embalming yielded more than the crudest notions regarding the anatomy of the lower animals among the ancients. It is first to Hippocrates (460–377 B. C.) that a knowledge of anatomy can be ascribed with propriety, and even then it is only regarding human osteology that Hippocrates possessed ideas approaching accuracy. On the authority of Galen, the first anatomical work is to be credited to Alcmaeon of Croton (500 B. C.). It is very doubtful whether Hippocrates practiced dissection upon the human body. Following the "Father of Medicine," stands the name of that great student of nature, Aristotle (384–323 B. C.), whose contributions to natural history were enriched by original observations of such detail and accuracy, regarding the structure of the lower animals, that he may justly be regarded as the founder of comparative anatomy. His dissections having been entirely confined to the lower animals, Aristotle knew little of human anatomy, as shown by the many erroneous ideas which he entertained. On the other hand, anatomy is indebted to him for the recognition that the blood-vessels are derived from the heart, and that the latter is filled with blood; to the main stem he applied the name aorta. Aristotle had likewise relatively clear notions regarding the digestive organs, recognizing various divisions of the intestinal tract, as jejunum, cæcum, colon, and rectum.

To Herophilus (310 B. C.) and Erasistratus (300 B. C.), members of the illustrious Alexandrian school, belong the honor of practicing the earliest well authenticated dissection upon human bodies, a privilege rendered possible by the support of an enlightened ruler. Herophilus devoted himself assiduously to human anatomy, as well as to zoöatomy in general, in which his fame soon became widespread. The choroid plexus, the fourth ventricle, and its calamus scriptorius, the torcular Herophili, and the duodenum are among the discoveries associated with his name. Erasistratus shares with his contemporary the distinction of human dissections, and discovered the valves of the heart, formed a correct idea of the nerves as issuing from the brain, and indeed seems to have distinguished between nerves of sensation and motion; he also firmly established the doctrine that the arteries were filled by vital air (pneuma), while the veins contained nutritive fluid (the blood).

The achievements of these noted men were followed by a period of decline, in which but few additions to anatomical knowledge were recorded. After the decadence of the brilliant Alexandrian school, the exceptional services of Marinus and his pupil Quintus, and later Ruffus, alone rescued anatomy for a time from the neglect into which it had fallen.

Early in the second century of the Christian era human anatomy was not only restored to its former condition, but materially advanced by the genius of Claudius Galenus (130–200 A. D.), who, for nearly half a century, enthusiastically pursued the studies and investigations which justly entitle him to be regarded as the most accomplished anatomist of the ancients. The correctness of his comprehension regarding the structure of man, no less than the acuteness of his observations and the sagacity and judgment of his conclusions, seems the more remarkable when it is learned that Galen's dissections were limited to lower animals—chiefly monkeys—and that his scalpel was never turned toward a human subject. Indirectly the pupil of Quintus, Galen devoted himself to the anatomical writings of Marinus, as representing the knowledge still preserved from the ashes of the Alexandrian school. Among other important facts, Galen recognized and proved that the arteries contained not air, but blood. His understanding of the nervous system—especially the brain—of the thoracic and abdominal viscera, together with that of the muscles and bones—his knowledge of osteology being especially accurate—mark him as foremost of the anatomists of his time; his writings remained the common source of anatomical lore for fourteen centuries, and the influence of his teaching gave way only before the new era of anatomy founded by Vesalius. With the death of Galen (200 A. D.), anatomy entered upon a period of decline and almost total extinction.

The dawn of the returning light of intelligence at the close of the Middle Ages found anatomy feebly cultivated in the Italian schools, the teachings of Galen still affording the principal source of inspiration. In 1316 Modino (1275–1325) appeared at Bologna, and by his lectures and demonstrations instituted the instruction which soon made his school the center of anatomical activity. Modino, regarded as the father of modern anatomy, forms the connecting link between the anatomy of the ancients, as represented by Galen and the new science appearing with the advent of Vesalius and his followers. The names of Marzio, Montagna, Zerbi, Achillini, Carpi, Massa, Benedetti, Guintherus, and Sylvius represent the more prominent of those who shared the "restoration period" of anatomy. Leonardo da Vinci, Michael Angelo, Tizian, and Rafael are credited with having deeply interested themselves in a science so closely related to their art.

The advent of Vesalius (1514–64) marks a new epoch, characterized by the breaking down of the traditions of more than fourteen centuries. The ancient theories and speculations, which still appealed with an authority begotten by age, were subjected by Vesalius to the searching scrutiny of investigation, and when found wanting were replaced by the facts revealed by his scalpel and observation. The fruits of his dissections and study appeared in a volume, the first comprehensive and systematic description of the human body. The veneration in which the teachings of Galen were still held is instanced by the explanations offered by Sylvius extenuating the inaccuracies of Galen pointed out by Vesalius; rather than admit the fallibility of his long-revered master, Sylvius declared that the human body had undergone changes during the time intervening between the studies of Galen and the dissections of Vesalius. After a brilliant but stormy career, by his success incurring the bitter hatred of his opponents, Vesalius's life drew to an ignominious end. During the hastened return from a pilgrimage to Jerusalem, undertaken after recovery from severe illness (and not, as often alleged, as a penance imposed by the Church for indiscreet dissection), he was shipwrecked on the island of Zante, and died in abject poverty.

Contemporaneous with Vesalius were Fallopius (1523–62), Eustachius (1517(?)–74), Columbus (1497(?)–1559), Varolius (1543–75), Vidius (1542–67), Fabricius (1537–1619), and Casserius (1561–1616).

The seventeenth century, rich in advances in anatomical knowledge, has a conspicuous figure in William Harvey (1578–1657), whose clear perception led him to the satisfactory demonstration of the circulation of the blood in 1619. This great physiological and anatomical truth had already been partially grasped by Servetus, Columbus, and Fabricius. Among the anatomists of this century were Aselius (1581–1626), Pecquet (1672–74), Rudbeck (1630–1702), Malpighi (1628–94), who first demonstrated the capillary blood-vessels and the blood-cells, and by the use of the microscope added many new facts; Glisson (1597–1677), Bellini (1643–1704), Wharton (1610–73), Willis (1622–75), by whose labors

the anatomy of the brain was greatly advanced; Lower (1631-91), Highmore (1613-84), Cowper (1666-1709), Nuck (1650-92), Ruysch (1638-1731), Leeuwenhoek (1632-1723), who cultivated microscopical anatomy with great success; Vieussens (1641-1717), Wirsung (1613-43), Peyer (1653-1712), Brunner (1653-1727), Bartholinus (1655-1738), and Stenson (1638-86).

During the eighteenth century anatomy was faithfully cultivated by men earnestly desirous to free their science from traditions unsupported by truth, and to supplement the important facts established by their predecessors by accurate details. Nor must it be forgotten that these men were hampered by the limitations of their age, feeble in the development of the collateral sciences, as physics and chemistry, as well as by the imperfection of the methods and instruments of research. Especially conspicuous stand the names of Hunter, Haller, and Bichat.

Prominent among the anatomists of this period were Valsalva (1666-1723), Santorini (1681-1737), Morgagni (1682-1771), Albinus (1697-1770), Winslow (1669-1760), Douglas (1675-1742), Monro (1732-1817), William Hunter (1718-83), John Hunter (1728-93), whose lasting achievements stand as monuments to his remarkable energy and genius; Lieberkühn (1711-65); Haller (1708-77), famous as a profound and philosophical thinker; Meckel (1724-74); Wrisberg (1739-1808); Sömmerring (1755-1830); C. F. Wolff (1735-94), the founder of modern embryology and the earliest promulgator of universal cell-formation; Bichat (1771-1802), the father of histology.

The development of anatomy during the nineteenth century contributes a remarkable page to its history. The early decades, marked by the continued activity of many of the anatomists already mentioned, were succeeded, toward the middle of the century, by the growth of a new school, following the establishment of the modern views concerning the structure and origin of organisms; upon the foundations laid by Wolff and Schwann arose the doctrines of modern histology and embryology. Shortly after, improvements in the microscope and in methods of investigation gave additional impulse to these studies, which, during the last decade, have been still further advanced by recent similar improvements.

The increased facilities of exact investigation into the life-history of animals have yielded brilliant results in the broadening and increased accuracy of our conceptions of the relations of anatomical data. In addition to the advances in these fields, improvements in anatomical technique, as in preservation, injecting, maceration, etc., have rendered the demonstration of the various parts of the body far more perfect and instructive; topographical anatomy, likewise, has gained by the introduction of frozen sections, as supplementing the usual dissections.

Without attempting even an incomplete enumeration of the many investigators who have contributed to the general advancement of anatomy during the present century, reference may be made to Mascagni (1752-1815), Searpa (1747-1832), Magendi (1783-1855), Cruveilhier (1791-1874), Bell (1774-1842), Sharpey (1802-80), I. F. Meckel (1781-1833), Tiedemann (1781-1856), Langenbeck (1776-1851), Rosenmüller (1771-1820), Stilling (1810-79), M. Schultze (1825-74), Bischoff (1807-82), Heule (1809-85), Reichert (1811-83), Arnold (1803-90), and Leidy (1823-91); and more recently Owen, Huxley, Turner, Flower, Kölliker, Hyrtl, Waldeyer, His, Sappey, Schwalbe, Leydig, Gegenbaur, Rüdinger, Wiedersheim, Flemming, and many others.

The investigation of the human body has been so diligently pursued in the past that our knowledge of it is to be extended only by a more intimate acquaintance with its structure, and by a broader basis of comparison. The recognition of this fact has led anatomists to devote themselves largely to histology, embryology, and morphology as the most fruitful fields for research. The rich harvest of new facts, recorded since about 1880 up to the present time (1892) concerning the structure of various organs (especially of the nervous system), the development of the body, and the significance and relation of obscure parts, proves such anticipations to be well founded. GEORGE A. PIERSOL.

Anatomy, Comparative: the science of the structural constitution of animals; so called because it is derived from the comparison of the anatomy of different animals.

Animal bodies consist either of homogeneous substance or of that substance disposed in tissues. Tissues, in the vast majority of cases, are made up into organs, the sim-

plest forms of which are the sac, the tube, and the segment. By multiplication and modification of these elements, organs become complex. The simplest expression of tissue is, on the other hand, the nucleated cell, and all tissues are made of multiplied and modified cells, with the addition of unorganized or homogeneous substance.

This substance, whether homogeneous or exhibiting structure, is chemically identical throughout the animal kingdom, and constitutes the living part of plants. It belongs to the class of protein compounds, and is called gelatin, albumen, fibrin, etc., or, regarded structurally, protoplasm or sarcode. Its composition is $C_{24}H_{17}N_3O_8$, with very small amounts of sulphur and phosphorus added under some circumstances. It is therefore a nitril of cellulose—i. e. $C_{24}H_{20}O_{20} + 3NH_3$.

According to the latest investigations, the cell is not a hollow body, but consists of protoplasm (the cytoplasm) which may or may not possess a superficial layer, which represents the wall (but which may be of considerable thickness), and a smaller body within it, which is called the nucleus. This nucleus may contain another visibly distinct body, or nucleolus. It is connected with the cell-wall by a system of radiating fibers, which, like the nucleus, can be stained with various reagents, the stainable substance being called chromatin. The essential difference between the chromatin and the cytoplasm consists in the

FIG. 1.—Amœba, Rhizopods.

fact that all growth originates in the nucleus; that is, all cell-division has its origin there. Hence it has been called the germinal matter, while the cytoplasm is termed formed matter. Formed matter exhibits the active functions of life other than growth. Thus it contracts, as in muscular tissue, or is irritable and conductive of force, as in nerves. It constitutes the primary substance of secretions, by its breaking down and mingling with special compounds brought by the blood. It may then be concluded that the formed protoplasm or cytoplasm converts energy into motion, chemism, etc., while the germinal or nuclear matter converts it into growth-force.

The science of the structure of tissues is termed **HISTOLOGY**, and is treated of under that head. The present article will include only the description of organs, or organography.

I. ORGANS AND SYSTEMS.

Tissues arranged and united in forms, so as to be usable for vital processes, form organs. All organs not constructed of cells alone are composed of elementary parts, which may be regarded as repetitions of the sac, the tube, or the segment, no matter how complex they may be. The organs are classified into systems by their structural connection with one another, which, of course, signifies functional association for some common vital process. The systems are as follows:

1. *Cellular Systems*.—The nervous, the muscular, the mucodermal.
2. *Sac and Tube Systems*.—The digestive, the circulatory, the respiratory, the urogenital.
3. *Segment System*.—The skeletal and epidermic.

The nervous system consists of central bodies or ganglia, and nerves which extend from them to the periphery of the body. The structure presents much variation among the several groups of animals. The muscular is composed of muscles and the tendons by which they are attached to the part of the skeleton to be moved by them. The muscles are composed of innumerable fibrillæ inclosed in a common sheath. The bundles in invertebrate animals are smaller, till in some of the lowest they are composed of but few fibrillæ. Unstriped fibers exhibit less energetic contractions than the striped. They prevail in invertebrate animals, excepting the *Arthropoda*, where the muscles are striped. The fibers in vertebrates are striped, excepting in involuntary muscles, where they are unstriped, save only in the heart.

In invertebrates they may have thick sheaths, and the contents are frequently granular. In most *Arthropoda* the central part of the striped fibrillæ retains the original cell-nuclei in one or more columns. The mucodermal system covers the body externally, and as mucous membrane enters and lines all the cavities that communicate with the open air; as serous membrane it lines the closed cavities. In animals no system presents greater varieties of exterior structure. In invertebrates it is sometimes hardened in segments produced by a deposit of lime, which resemble bone (sea-urchin), or form a more elastic substance—chitin (*Arthropoda*). In vertebrates it may support osseous pieces of various forms (scales), or hairs, or feathers, which are simply enlarged hairs finely branched. Finally, as horn, it appears as nails, claws, and horn-sheaths; these are simply thickened epidermis.

The digestive system is a tube usually open at both extremities. Portions of its course are enlarged into stomach, large intestine, etc., while glandular bodies are distributed along it from one end to the other, and pour their contents into it. These glands are formed of sacs, in a few cases

FIG. 2.—*Epistylis nutans*.

simple (Fig. 23) (gastric glands of stomach), in others simply forked, but usually many times divided and subdivided, forming masses of lobules. Some of these bodies are almost universal in the animal kingdom. Thus it is usual to find one or more situated near the cavity of the mouth (Fig. 24), which secretes a fluid to aid in deglutition; another, most frequently met with, discharges its secretion into the alimentary canal just beyond the stomach.

This is the liver and its representatives. The walls of the canal are supplied with several layers of muscular tissue in the vertebrates, and in a less complex form in lower animals. The circulatory system consists of tubes for the conduct of the results of digestion throughout the body; it consists of branches of the digestive canal in the lowest types (*Medusæ*), but becomes highly specialized, so that communication with that system is had by endosmosis only. It early acquires a special muscular enlargement, which pulsates. This organ becomes more specialized, isolated, and divided, and is known as the heart. The arteries (which take blood from it) are muscular throughout their length. The veins are not so, but are distinguished by the presence of valves in the higher animals.

The respiratory system consists of a series of tubes which carry air through the body; in some animals (snails, spiders) these are blind, forming pulmonary sacs, on which capillary arteries are distributed. In animals inhabiting the water this system is little or not at all developed, it being replaced by branchiæ or gills. In vertebrates it does not exist, but large sacs, connected by tubes with the digestive system, answer the same functional purpose, except among fishes, where it is used as a float. Gills attached to the head-skeleton aërate the blood in this class.

The urogenital system consists of tubes, sacs, and glandular and cellular bodies, which are connected with the outer air at the posterior end of most animals, and are usually blind at their termini. Their exit is usually common to the alimentary canal, the so-called cloaca. These organs exhibit usually bilateral symmetry, the opposite sides having distinct exits, except among females of some of the higher animals, where the discharge-tubes unite and form a chamber called the uterus. The tubes are termed oviducts (or tubæ Fallopii), and terminate near to a fibrous and cellular body, the ovary. In its circumference appear cells, which grow, and after discharge are modified into the embryo. Originally, the embryo-cells of low animals grow into adults by a simple process of division, but in higher forms a stimulus to such growth is

required from the other or male sex. In this sex the ovaries produce, by a form of secretion, independent cells, each of which bears a long cilium or lash (spermatozooids), and being modified in structure are properly termed testes. The efferent tube is called the vas deferens. These only unite near their point of exit. The urinary system is present in the vertebrates only. Tubes connect it with the reproductive canals near their termini. These are derived from paired glandular bodies, the kidneys, and usually unite into a common reservoir before exit—i.e. the urinary bladder. The object is the removal of uric acid, etc., from the blood.

The skeletal system exists only in vertebrates. It constitutes the solid framework of the body, and is axial or internal. It is composed of cartilaginous and osseous tissue. It is composed of segments, which possess a solid centerpiece and two opposite arches attached to it—one superior, the other inferior. It thus forms two tubes connected by a solid axis. The upper protects the nervous—the lower, the nutritive organs. Each segment is divisible into sub-segments, which are originally separate. These are much modified in form at the anterior extremity of the body—above, to contain the brain; below, to aid the sense of hearing, to accomplish mastication, respiration (in fishes), etc. Appendages to inferior segments are seen in limbs, which are the supports of the body and overcome resistance in motion. They are also composed of segments arranged in lines or radii.

II. CLASSIFICATION OF ANIMALS.

All known animals are referable to seven "branches" or primary types. Four plans of structure cover these, without expressing their intimate or essential structure. The four are the radiated (*Cœlenterata* and *Echinodermata*); the longitudinally jointed, with external and ring-shaped skeleton (*Vermes* and *Arthropoda*); the bag-shaped (*Mollusca* and some *Protozoa*); and the vertebrate, whose essential character is mentioned above under the skeleton of the *Vertebrata*. The characters may now be given in more detail.

Branch I., *Protozoa*.—Low animals, composed of single cells or protoplasmic masses, without blood or nerves. When symmetrical, bilateral or radiate.

FIG. 3.—*Vioa Freyeri*, Hanc.: a, entire animal on a shell of *Placuna placenta*; b, c, the sponge removed, the branches in different stages of growth; d, spicules.

Branch II., *Cœlenterata*.—Multicellular animals, without body-cavity (cœlom), and consisting of two layers only (ecto-

derm and entoderm) inclosing a sac-like stomach or common cavity. The circulatory system is wanting or represented by branches from the digestive cavity. A peripheral nervous system. The form is radial and bilateral, or radial only.

Branch III., *Echinodermata*.—Digestive system independent of the body-walls, not filling the cavity; the circulatory system present, largely isolated; a water-circulatory system; nervous system an œsophageal ring, with radii; skin with hard protective bodies. Form bilateral and radial.

Branch IV., *Vermes*.—Digestive system isolated, cœlom present or absent; circulatory system incomplete or wanting; nervous system an œsophageal ring, connected by a nervous axis with ganglia, or consisting of the chief ganglia only. No jointed limbs; body elongate.

FIG. 4.—*Pelagia*.

Branch V., *Mollusca*.—Alimentary canal complete, isolated; circulatory system incomplete at the distal extremities; nervous system with ring round œsophagus, which bears a ganglion above and one below; a third ganglion inferiorly placed, connected by a ring with the former. Form sac-like.

Branch VI., *Arthropoda*.—Digestive system complete; circulatory with complete central organ, but open extremities; nervous system with œsophageal ring and ganglia, and generally an axis on the inferior surface of body, with ganglia at intervals. Skin hardened into a chitinous, jointed skeleton, which is furnished with jointed legs. Form bilateral.

Branch VII., *Vertebrata*.—Alimentary system complete; respiratory, a branch from it; circulatory, with complete circuit; nervous, of a longitudinal ganglionic axis on the upper side (spinal cord), with usually ganglionic bodies at one end (brain). An internal bony or cartilaginous skeleton, consisting of solid axis, a superior tube for nervous and an inferior for other systems. Form bilateral.

A few decades ago the number of species of animals known was stated to be 500,000, of which 400,000 were Arthropoda; of the remainder, 25,000 were Vertebrata. There are now estimated to be at least 1,000,000 species of Insecta alone.

The classes of animals number thirty-six, distributed and defined as follows:

PROTOZOA.—*Rhizopoda*.—Bodies of unorganized protoplasm, which throws out threads or arms of the same substance, which are elastically retractile. No internal organs. Often a siliceous or calcareous covering, which is perforated. (Fig. 1.)

Infusoria.—Body with wall distinguished from contents, with mouth and often anus; often a contractile vesicle and ovarian nucleus. Surface frequently ciliated. (Fig. 2.)

CŒLENERATA.—*Spongia*.—(Fig. 3.) Body cavity surrounded by flagellate cells, which are generally supported by axes of a horny, calcareous, or siliceous nature, forming branched masses. Body-walls perforated by canals. No thread-cells.

Medusa (jellyfish).—Digestive system an open sac without œsophagus or septa, from which canals radiate as isolated grooves. Passing through a hydroid metamorphosis. Form discoidal. (Fig. 4.)

Ctenophora.—An œsophagus and gastric cavity without septa or radiating tubes. Form globular, cylindrical, or band shaped, with eight meridional rows of vibratile plates.

Anthozoa (corals, etc.).—Digestive system an œsophagus and an appended sac, the latter divided round the walls by vertical septa into grooves, which continue into tubular tentacles. Septa and skin often filled with deposit of carbonate of lime. (Fig. 5.) No hydroid metamorphosis.

ECHINODERMATA.—*Crinoidea*.—Body cup shaped, the surface covered with mineralized plates, which are solidly

united, but wanting on a part next the stomach; arms and stem present, formed of articulating segments. (Fig. 6.)

Asterida.—Body depressed, star shaped, covered with calcareous plates, which are wanting on a part of the dorsal surface, and which articulate with each other in clusters (starfishes). (Fig. 7.)

Echinida.—Body discoidal or globular, surface covered with calcareous plates, which are immovably united together; no arms (sea-urchins). (Fig. 8.)

Holothurida.—Body elongated, cylindrical, covered with soft skin; a calcareous ring round œsophagus; mouth surrounded by tentacles; anus terminal (trepangs). (Fig. 9.)

VERMES.—*Rotatoria*.—Alimentary canal developed in the hollow body; ciliated disks or wheel-organs for movement; a water-circulatory system.

Turbellaria.—Body unjointed, flat, solid, except in the developed digestive canals; nervous system of two supra-œsophageal ganglia; surface covered with cilia. No anus.

Cestoda.—Body jointed, nearly solid, without digestive system; head with suckers and hooks; a water-circulatory system (tapeworm).

Trematoda.—Body not jointed, solid except in the developed digestive tubes, and water-circulatory system; head with suckers and hooks (flukes). No anus.

Acanthocephala.—Body hollow, not jointed, cylindrical, without digestive canal; head with a hook-bearing proboscis.

Nematoda.—Body hollow, unjointed; digestive canal well developed.

Gephyrea.—Body cylindrical, not jointed, alimentary canal complete in the hollow body; a nervous system, an œsophageal ring and abdominal axis.

Annelida.—Body hollow, segmented, with well-developed digestive canal and nervous system; the latter an œsophageal ring and abdominal ganglion chain; a system of respiratory tubes (earthworm, etc.). (Fig. 9.)

MOLLUSCA.—*Bryozoa*.—Head, tongue, and foot wanting; a shell-producing mantle inclosing the hinder portion of the body; mouth surrounded by a crest of tentacles as respiratory organs. Nervous system rudimental. (Fig. 10.)

Brachiopoda.—Head, foot, and tongue absent; mantle large, bearing large shells, which are dorsal and ventral; branchiæ supported on two spiral arms, which are attached to the shell. (Fig. 11.)

Acephala.—Head and tongue wanting, foot anterior; mantle covering the body on each side, and inclosing lamini-form branchiæ; two shells, right and left (mussel, clam). (Fig. 12.)

Gasteropoda.—Head, tongue, and foot present, the latter extending posteriorly; mantle small, posterior; gills comb-like on the back. Shell, when present, single, spiral (conch, snail). (Fig. 13.)

Pteropoda.—Head, tongue, and foot, the latter developed into two lateral fins; mantle covering the hinder part of body; gills comb-like on the back. (Fig. 14.)

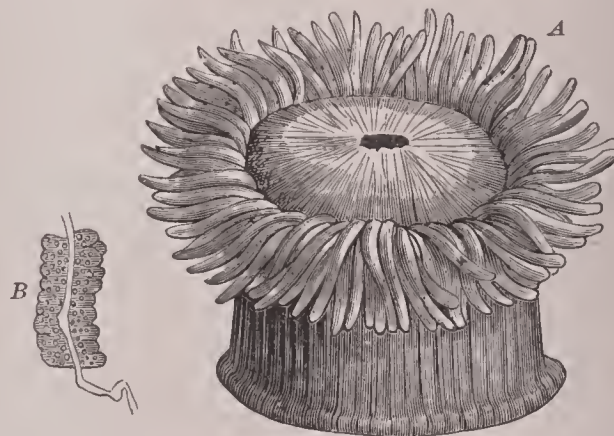

FIG. 5.—*Paractis alba*: A, expanded; B, the reproductive organ of *Cereus*.

Cephalopoda.—Head and tongue present; foot divided into arms, which radiate from the mouth as a center; posterior part of body inclosed in a mantle; gills on back; cartilages behind eyes, and ganglia in head (cuttlefish). (Fig. 15.)

ARTHROPODA.—*Crustacea*.—Two pairs of antennæ; post-abdomen developed; limbs on all segments of the body, those of the thorax converted into mouth-organs; respiratory organs, gills or wanting (shrimp, crab). (Fig. 16.)

Arachnida.—No antennæ nor anterior cephalic segments;

the last pair of cephalic limbs of the form of legs; three additional pairs on the thorax; head and thorax united into a cephalothorax, abdomen and developed post-abdomen without legs; respiration by tracheæ or sacs (spider, scorpion).

Myriopoda.—One pair of antennæ; a part of the thoracic limbs used as mouth-organs; abdomen not distinguished, many jointed, furnished with limbs throughout; post-abdomen rudimentary; respiration by means of tracheæ (centipedes).

Insecta.—One pair of antennæ; abdomen without limbs, post-abdomen rudimentary; three pairs of limbs on the thorax; respiration by means of tracheæ; usually two pairs of wings (insects). (Fig. 17.)

VERTEBRATA.—*Tunicata*.—Notochord in the tail of the larva or adult; head, tongue, and foot wanting; a large bag-like mantle, which incloses a fissured branchial sac. Nervous system with one central ganglion. (Fig. 18.)

Enteropneusta.—No mantle; branchial fissures external; a chorda dorsalis, but no other skeleton. Nervous system consisting of dorsal and ventral axes.

Leptocardii.—Notochord below the nervous axis. No cranium; no brain; heart with one chamber; five aorta-roots. Branchial sac and fissures internal (lancelet).

Agnatha.—Cranium and skeleton cartilaginous; no mandibular arch; heart with two chambers; five aorta-roots; (lamprey).

Pisces.—Cranium and skeleton osseous or cartilaginous, or both, with under jaw complex, and supported by hyomandibular bone, etc. Limbs with many segments in indefinite number, forming fins; pelvis mostly represented by pubis. Brain well developed; hemispheres with a velum; optic lobes generally larger; cerebellum distinct; two chambers of the heart; five aorta-roots on each side. Basicranial axis not ossified.

Batrachia.—Skeleton osseous; cranium with parasphenoid, no basisphenoid; under jaw complex, and supported by a single "quadrate" bone; two occipital condyles; limbs with humerus and two propodial bones and few radii forming feet; pelvis present; brain with cerebral hemispheres largest, and small cerebellum. Three chambers to the heart; four or three aorta-roots; a coracoid bone, e. g. the salamander, frog. (Fig. 19.)

Monocondylia.—Skeleton osseous, with coracoid bone and mandible, latter complex, and supported by quadrate; no

FIG. 6.—*Platycrinus triacontadactylus*, McCoy: A, side view; B, terminus of arm; C, articular surface of a stem-segment; D, structure of the basin or body.

parasphenoid, but sphenoids and a basi-occipital with one occipital condyle; brain with large cerebral hemispheres; two or one aorta-roots and aorta-bows; heart with three or four chambers; limbs as in *Batrachia*.

Mammalia.—Skeleton osseous, generally without coracoid bone; with the simple mandible sessile on the squamosal bone; basicranial axis ossified, and with two occipital condyles; limbs with distinct tarsal and usually metatarsal bones; optic lobes small; cerebral hemispheres very large; one aorta-root and bow, turning to the left; heart with four chambers.

The preceding descriptions express a few of the structural

peculiarities of the animals included in the respective divisions—i. e. such as are common to those of each, and by which they may be distinguished from each other. But the innumerable characters found in the subordinate or contained divisions and species of each remain to be considered.

III. THE NERVOUS SYSTEM.

1. IN INVERTEBRATES.—In *Protozoa*, where the nervous system has not been certainly discovered, spontaneous movements in the taking of food and moving from place to place are readily observed. It is therefore evident that the contractibility of their protoplasmic walls is under the direction of stimuli which do not require nerves for their conduction or direction. The nervous system of higher animals must therefore be looked upon as designed for the specialization or location of movements—a capacity entirely necessary to the activity of special mental powers. These demand particular movements for special objects; hence the necessity of concentrating the directors of movements in particular parts—i. e. nerves, muscles, etc.

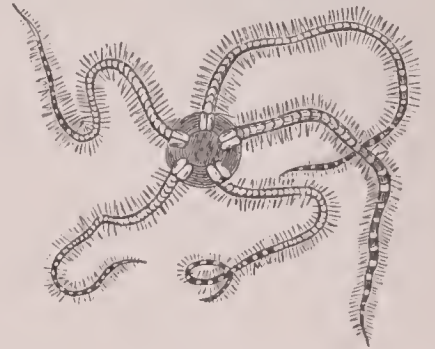

FIG. 7.—*Ophiura*.

In *Cœlenterata* one or two nervous threads follow the border of the disk, except in *Hydra*, etc., where nervous functions are performed by neuromuscular cells.

In the *Bryozoa*, the lowest mollusks, there is not certainly known to be an œsophageal ring, but there is a considerable ganglion above the gullet, which sends nervous threads around the horseshoe respiratory crest. One of these extends on each side at the base of the processes; but, though they approach, they are not known to unite on the inside of the arc. In *Tunicata* in like manner a single ganglion exists above the œsophagus, between it and the vent, and sends out nerves in a radiating manner. These are distributed to the orifices of the body and to the muscles. In *Brachiopoda* the system is more highly developed, there being a complete œsophageal ring, with a broad, band-shaped ganglion on the inferior side. The latter represents two united ganglia, and gives off on each side a strong nervous trunk. These trunks turn forward and outward, and soon divide, the weaker branch going to the spiral respiratory arms, representing that above described in the *Bryozoa*. The stronger branch goes to the muscles that close the shells, to the mantle, etc. Each one forms a ring in the former locality, which gives off small threads. In *Acephala* (called also lamellibranchs or bivalves) there are three well-separated pairs of ganglia, the ganglia of each pair connected by a commissure. The anterior pair is near the mouth; they are rarely united (*Mesodesma*, *Teredo*); they give off on each side a nervous thread which extends to the foot, and is connected with the foot-ganglion pair. These are wanting in the oyster and other genera which want the foot. This forms an open œsophageal ring. The nerves of the foot are derived from the ganglion, but none of the intestinal nerves. These are derived from the third pair of ganglia, which are the most posterior, and which are connected with the front pair by a nervous stem on each side, forming a second ring round the digestive axis. It sends nerves to the mantle, gills, etc., meeting those from the anterior ganglia. In *Ostrea*, *Pinna*, *Mytilus*, etc., its nerves contribute to form a circuit which extends round the edge of the mantle, connecting with the anterior pair.

In *Gasteropoda* the ganglia and commissures are homologous with those of the *Acephala*, but the former are concentrated near the mouth, forming much more contracted rings. The two supra-œsophageal ganglia (or "brain ganglia") are connected by short commissures. They send down commissures to the foot-ganglia, which are close to the œsophagus; the visceral ganglia or third pair are behind these, and connected with the superior ganglia by special commissures; sometimes they are on the upper side of the œsophagus, and connected by commissure below it. The superior sends nerves to the lips, mouth, tentacles, and eyes; the foot-ganglia to the under side of the œsophagus, to the ear, and the foot; the visceral ganglia to the mantle, gills, heart, intestines, and certain muscles. In the naked division (*Opisthobranchia*) the upper ganglia give a special ganglion

to the tentacles; the foot-ganglia in like manner are adjoined by a pair for the gills. In *Chiton* all three pairs of ganglia are found on the inferior side of the œsophagus. In *Turbo*, *Littorina*, *Janthina*, *Phasianella*, and *Patella* the superior pair occupies the opposite sides of the gullet. In *Natica* all three are closely massed together. As in other higher *Mollusca*, a sympathetic nervous system exists which supplies the involuntary organs of the body.

The *Pteropoda* exhibit the three pairs of ganglia connected by commissure. In the *Gymnosomata* they are all separate, but in the *Thecosomata* they are concentrated on the lower side of the œsophagus, so as not to be readily distinguished.

In *Cephalopoda* this system displays the most concentrated type known among mollusks. In *Nautilus* the ganglia are almost confluent, and form thick bands, one above and two below the œsophagus. The cerebral pair give off each an enormous optic nerve, appropriate to the size of the eyes in this class. The pedal pair supply the tentacles and organ of hearing, and the visceral pair the other organs. The inferior arches rest on the cephalic cartilage which characterizes the *Cephalopoda*.

The nervous system is in many of the *Vermes* very imperfectly developed, including the œsophageal ganglia with a few divergent nerves. In the *Annelida* the most highly developed condition is observed, where each body segment possesses a ganglion connected by a longitudinal double commissure, which originates from the ring. In the *Arthropoda* this type is also the basis of the various arrangements observed, and is constantly discoverable in the larvæ of the various forms. As a general rule, it may be understood that where a special organ exists the ganglion of the segment in or on which it is placed is enlarged for its supply, as in the thoracic ganglia of insects. Here several segments are confluent; correspondingly, nervous ganglia unite, forming larger masses, thus supplying the legs and wings. The transition from the simple type found in the larvæ to

FIG. 8.—Echinus.

the modified and concentrated types of the adults has often been observed in tracing the history of the growth and metamorphosis of insects. In the *Crustacea* and *Arachnida* the concentration is carried still further than in insects. Thus in some lower *Crustacea* there are numerous ganglia, and the lateral commissures of the abdominal axis are only united in front; in the highest division, the *Decapoda* (crabs, lobsters, etc.), the axis is largely undivided, is short, and the ganglia are massed together. In the scorpions (*Pedipalpi*) there are but few distinct ganglia, but in the spiders (*Aranea*) there are no ganglia in the abdomen, and the nervous axis is short, massed together, and undivided. On the other hand, in the lowest *Arachnida*, the *Acarida*, there is no abdominal axis by defect, and the œsophageal ring is incomplete above, reminding one of the condition of the lowest *Mollusca*.

2. IN VERTEBRATES.—In this branch the nervous system reaches its highest development, though in the lowest form, the *Leptocephali*, it can hardly be considered to be more perfect functionally than in many *Mollusca*. Here there is a spinal cord or medulla, but no brain, but in its place a slight enlargement of the diameter of the medulla.

The spinal cord of vertebrates, like the brain, is composed of gray and white nerve-tissue, the gray being the ganglionic or cellular tissue, and the white the fibrous or conducting. Unlike the brain, the spinal medulla possesses the white substance externally, and the gray internally. The cord is divided longitudinally by an anterior and a posterior fissure of some depth, and by two less profound lateral ones. The gray substance exhibits in section a crescentic outline, the horns of the crescent being turned externally and reaching the lateral grooves. Here each horn gives origin to a nervous stem, and the two soon unite and pass out through a foramen between the vertebrae. The posterior bears a ganglion, and is devoted to the function of sensibility or feeling; hence it is termed "sensory." The anterior is the smaller, and is termed "motor," as its office is to convey the stimulus

which gives origin to muscular movements or contractions. After leaving the spinal column the single stem divides again, each branch containing fibers from both roots. The extremity of the cord is divided into a number of radiating threads, together constituting the cauda equina. In all the *Vertebrata*, from the *Dermopteri* to (and including) the *Aves*, there is an axial tube of small diameter; in *Mammalia* this is wanting, except a short anterior trace of it. Birds add the peculiarity of a sinus rhomboidalis, which is a long rhomboidal expansion of the tube in the sacral region (rump); which is open superiorly. The spinal nerves in many of the branches form networks by unions and separations opposite the fore and hind legs, which are called the brachial and sacral plexus. The ganglia of the sensory root are in the *Batrachia* accompanied each by a deposit of white phosphate of lime, forming a rounded mass. In some fishes with a short spinal cord, the division of the cauda equina takes place far anteriorly, as in *Diodon* and most other *Plectognathi*, thus leaving a very short axis.

The anterior part of the column enlarges, and is called the medulla oblongata; as this is within the cranium, it is reckoned as part of the brain. The six columns are here better defined, and there are added two well-defined oval prominences termed the corpora olivæformia between the lateral columns of *Mammalia*. This contains a corpus dentatum of gray matter. The fibers of the posterior columns cross or decussate; they are, however, only those of the anterior or motor root of the spinal nerves that do so, having passed upward through the column; the fibers of the posterior roots decussate in the gray matter of the cord near their exit, and pass thence into the brain without further exchange. The divergence of the posterior columns leaves a rhomboidal cavity or basin in the superior face of the medulla, which is the fourth ventricle. The roots of the auditory (seventh) nerve originate below its fundus. This chamber is variously exposed in different vertebrates. The postero-lateral columns (corpora restiformia) diverge upward and backward, and support the first great brain ganglion, the cerebellum. In the *Elasmobranchi* (sharks, etc.) the fourth ventricle is greatly extended laterally, having a lobate outline, with sinuous walls; in other *Vertebrata* this peculiarity does not exist. In *Marsipobranchii* one division (*Hyperotreti*) exhibits prominent lateral lobes, which do not open externally; they are wanting in the remainder of the class (*Hyperoarti*). In many bony fishes there are ganglionic enlargements of the medulla, corresponding to the origin of the nervus vagus; hence vagal lobes. There are numerous lobes on the medulla of the pike. The medulla is straight in most vertebrates, but in *Reptilia* and birds it is bent rather abruptly downward and forward after entering the cranium.

The cerebellum is a simple oval or flat body in the fishes, *Batrachia*, and reptiles, excepting in the crocodiles. In these it develops two small lateral lobes, while the middle portion, now called the vermis, becomes transversely grooved. In the birds the lateral lobes are a little larger and the plicæ deeper, and on section it yields a digitate and serrate outline of gray matter with a white center, called the arbor vitæ. In *Mammalia* the size is increased, especially as regards the lateral lobes. In *Marsipobranchii* it is small—in the division *Hyperoarti* apparently composed of two lateral ganglia. In sharks it is much enlarged longitudinally, and on section displays a weak arbor vitæ; in *Pristis* (sawfish) it even reaches the cerebrum, covering the optic lobes. In other fishes it is smaller, in the usual osseous orders a flat transverse commissure bridging the fourth ventricle, in *Polypterus* it is similar, but in *Lepidosteus* and *Amia* it is larger and oval. In *Batrachia* and in *Dipnoi* it is more insignificant than in any other division, being a very small transverse commissure, not nearly covering the fourth ventricle. In *Batrachia* this cavity contains a triangular network of blood-vessels, which fits it, called the plexus chorioideus; this is only seen elsewhere in the tortoises (*Testudinata*). In reptiles the cerebellum is still small and transverse, but exceeds that of the *Batrachia*; it is convex and scutiform; the fourth ventricle is nearly closed. In the crocodiles it is first approximately closed.

Anterior to the cerebellum, the brain is best understood as a double body, bilaterally symmetrical, and composed of a series of ganglia on each half of the divided axis or prolongation of the medulla oblongata. These ganglia are, primarily, the optic lobe, the cerebral lobe or hemisphere, and the olfactory lobe. The middle columns of the medulla support the optic lobes, while the cerebral lobes are supported

by the middle and anterior columns. The optic lobes are the largest of the ganglia from the *Dermopteri* to the *Batrachia* (Fig. 19), with the following exceptions: the cerebral hemispheres are larger in elasmobranchs and *Polypterus*. The lobes are sub-globular, and exhibit no marked external peculiarity till we reach the *Batrachia*, where they are smaller than the hemispheres, as in all the succeeding classes. In the tailless *Batrachia* (*Salientia*) they are divided transversely, forming four sub-round bodies; it is possible that the anterior one should be considered the lobus ventriculi tertii, or optic thalamus, of the next ganglion or cerebrum; but as it is united with the posterior in the tailed *Batrachia* (salamanders) and *Proteida* (*Necturus*) (Fig. 20), they are more probably the anterior bodies of the corpora quadrigemina of mammals. The posterior, and half or all of the anterior, are covered by a fold or lamina, which rises from the posterior part of the posterior bodies in the *Salientia*. In the *Urodela* the posterior is reduced, like the cerebellum, to a narrow transverse commissure, while in *Necturus* both it and the cerebellum are wanting.

FIG. 9.—*Cladodactylus doliolum*.

In *Reptilia* the optic lobes are more simple, but they are partially divided into superior and inferior bodies. In lizards the superior is laminar, and separated by a vacuity from the inferior; but in serpents the latter is a mere fissure. In harmless snakes (Fig. 22) the lateral bodies are connected by a commissure, but in the venomous *Trigonocephalus* and *Bungarus* they are united behind; in *Vipera* the superior and inferior bodies appear to be quite separated from each other. In birds the optic lobes are simple, and situated infero-laterally, since the cerebellum and hemispheres are in contact. In *Mammalia* they are superior, and continuous with each other, and consist of four protuberances, the corpora quadrigemina. They are much reduced in size, and cover a narrow vacuity or tube, the aquæductus Sylvii. In front of the anterior pair is situated a sac-like body, the pineal gland, which is the rudiment of an important organ of the brain of lower orders, the epiphysis. This is a highly vascular membranous body, which rises to the inner surface of the cranium in *Marsipobranchii*, fishes, *Batrachia*, and *Reptilia*. It is very variable in structure in fishes; in reptiles (lizards) it often communicates with the outer surface by the foramen parietale of the table of the skull. It is supposed by some anatomists to be a sensory organ. Directly opposite to it another sac descends from the cavity below the optic lobes (the aquæductus Sylvii), which is termed the hypophysis. It exists in the classes which possess the epiphysis, and is represented among *Mammalia* by the pituitary body and infundibulum.

The cerebral hemispheres are small in the classes below the *Batrachia*, except in sharks and a few fishes, as the *Dipnoi*, *Polypterus*, and *Ginglymodi* (gar). In the *Actinopterygia* they are overarched by a membranous roof (velum) lined with epithelial cells. In *Dipnoi*, *Crossopterygia*, *Chondrostei* (sturgeons), *Ginglymodi*, and *Halecomorphi* (*Amia*) the hemispheres are at a distance from the optic lobes, being supported by the elongate crura of the medulla oblongata; in other classes and orders the hemispheres are sessile. In the mammals alone we find the pons varolii, a body of transverse fibers which cross and bind together these crura cerebri on the inferior side. The hemispheres in the mammals present many peculiarities; their size is increased, and in many the surface is thrown into vermiform ridges or "convolutions." In the fishes and higher types they are hollow, inclosing the "lateral ventricles." The floor of these is occupied by various bodies in the different types. Thus in *Batrachia* there is a body on the inner side of each. In reptiles this is represented by a narrow body, while another mass

occupies the outer part of the floor of the ventricle. In *Mammalia* two bodies, little separated, occupy this position—viz., the "lobus ventriculi tertii" (or thalamus opticus) and the corpus striatum. The cerebral hemispheres are not directly united till in certain birds we find a narrow bridge connecting them, the fornix. In the lowest *Mammalia* (*Marsupialia*, etc.) we observe another connecting body in a rudimental state above the fornix. This is the corpus callosum, which in higher mammals is a massive bridge, and much larger than the fornix. There is another bond of connection called the anterior commissure, which is short and sub-cylindric: its size in mammals is nearly in inverse ratio to the development of the corpus callosum. The ventricles are separated by the septum lucidum in this class only, but are much reduced in the monotremes (duck-bill). The characters of the brain in the orders of *Mammalia* may be best expressed in tabular form, thus:

I. No calcarine sulcus nor hippocampus minor; corpus callosum rudimental; hemispheres smooth, leaving cerebellum and olfactory lobe exposed; *Monotremata*, *Marsupialia*.

II. Corpus callosum well developed, short, without rostrum; no calcarine sulcus nor hippocampus minor; hemispheres smooth, short; olfactory lobes and cerebellum not covered; *Edentata*, *Glires*, *Insectivora*, *Chiroptera*.

III. Corpus callosum longer, with a recurved rostrum in front; no calcarine sulcus nor hippocampus minor; the hemispheres convoluted, and partially covering the olfactory lobes and cerebellum; *Proboscidea*, *Hyracoidea*, *Diplarthra*, *Carnivora*: (hoofed and carnivorous animals).

IV. Corpus callosum long, with rostrum; a calcarine sulcus and hippocampus minor; hemispheres mostly convoluted, partly or wholly covering the olfactory lobes and cerebellum; *Primates* (monkeys, man).

Exceptions to the definition of the Primates are seen in some of the *Lemuroidea*, in which the hemispheres are smooth. In man they have nearly twice the size seen in the allied forms of apes (chimpanzee, etc.). The calcarine sulcus is on the lower side of the posterior part of the hemisphere, and the hippocampus minor is the convex body within the ventricle, which its presence causes; it forms the inner wall of the posterior horn of that chamber.

The olfactory lobes are very large in elasmobranchs, and are connected with the hemispheres by a narrow commissure. In fishes they are less developed, and in batrachians are sub-cylindric and separated by a groove. In reptiles they are continuous with the hemispheres, obpyriform in shape, and often slender; they are frequently hollow. In birds and mammals they bear a smaller proportion to the whole brain, and are entirely concealed in Primates.

The optic nerve originates by fibers derived from the optic lobes. Its fibers decussate or cross from the right side to the left and *vice versa*, shortly after leaving the brain in all Vertebrata, excepting the lower Actinopteri (*Halecomorphi*, *Ginglymodi*), and Chondrostei, the Elasmobranchii, and the

FIG. 10.—*Plumatella*: a, natural size; b, magnified; c, the vent.

Marsipobranchii. In all of these the nerves are connected by a commissure, which is in part (*Amia*) composed of fibers which leave the brain and return again, forming a short circuit. In the *Marsipobranchii* this "chiasma" takes place near the roots of the nerves; in the others, at a greater distance from the brain.

The remaining cranial nerves are in fishes only four pairs, the vagus, glossopharyngeus, trigeminus, and facialis. The first two and the last two are each approximated. The vagus exhibits in the fishes above the *Marsipobranchii* two

FIG. 11.—*Spirigera concentrica*: *ab*, insertion of adductor muscles; *c*, of divaricator muscles; *e*, of adjustator ventralis; *g*, branchial arms; *h*, hinge sockets; *i*, gill-bridge; *k*, hinge teeth; *r*, tubular body.

distinct roots. The first is the nervus (ramus) lateralis, which extends posteriorly beneath the scapular arch, and runs along the middle of the side of the body to the tail; it is abortive in *Marsipobranchii*. The second or larger nerve supplies the gills and viscera. The nervi trigeminus et facialis have four distinct origins, which sometimes unite and form one or two plexuses outside the cranium. The branches are distributed to different parts of the head; but one, which especially characterizes many bony fishes, but is wanting in *Clupeidae*, *Plectospondyli*, *Amia* (gar), *Chondrostei*, and elasmobranchs, the ramus lateralis, runs upward within the cranium, issues above, and extends along the back to the caudal fin, supplying the dorsal fin. In *Marsipobranchii* and *Dipnoi* the glossopharyngeal is a branch of the vagus; in other vertebrates it is distinct.

In *Batrachia* the rami laterales of the vagus are present; and the glossopharyngeus unites with the vagus, forming a ganglion, from which nerves issue. The origins of the nervi trigeminus and facialis are wholly or in part common, and they support a ganglion Gasserii. The hyoid and scapular muscles are supplied from the first pair of spinal nerves, and the vagus supplies branches to the scapula. These characters are in part those of reptiles, but more prominently those of fishes. In the *Reptilia* there are nervi accessorii, as well as hypoglossi. The latter supply the hyoid and scapular regions, and the former certain muscles inserted in the scapula in front. The rami laterales of both vagus and trigeminus are not present, and the facialis has a distinct origin. In mammals all these nerves are present, except laterales, but the facialis frequently is identical with the trigeminus in origin.

IV. THE MUSCULAR SYSTEM.

Muscles are entirely wanting in the *Protozoa* and in the *Cœlenterata*, excepting the *Medusæ*. In the latter, delicate bundles of unstriated fibers exist, extending vertically from both the inner and outer surfaces of the umbrella, while between them concentrically curved bundles run between the eight circulatory canals. Among echinoderms the innumerable segments of which they are composed give origin and insertion to many muscles. In addition there are muscles devoted to the masticatory apparatus. This consists in *Echinoidea* of five tooth-like bodies, which form a pyramidal mass when closed. For the opening and shutting of these, twice ten paired and twice five single muscles are arranged, as well as several others. In *Holothurida* five longitudinal muscles extend from the hard œsophageal ring to the vent. A sphincter closes the mouth, and the superior part of the gullet is thickened with muscular walls. The tentacles possess muscles.

In *Mollusca* muscles are universally present, though fewer in number than in the groups just described. In *Bryozoa* (or *Polyzoa*) a system of muscles is arranged for the withdrawal of the crown into the sheath-like body; these are median, longitudinal, slender muscles. Those designed for

projecting it again are horizontal, curved, and situated on the inner wall of the body; the successive contractions of these from below upward will produce the result. Avicularia are peculiar bird-head-like bodies, situated near the mouth in the marine *Bryozoa*; they are furnished with a bird-like beak, with an under jaw which frequently closes with a snap, and slowly opens. These movements are conducted by muscles whose movements are automatic. The large mantle inclosing the body of the *Tunicata* is composed of two muscular layers—the one of transverse (hence annular) fibers, the other of longitudinal or oblique. Muscles for producing progressive movement or swimming are found in many genera. These are annular, and at intervals around the body. *Appendicularia* possesses a long and deep rudder-like tail, which contains muscular layers. The *Brachiopoda* are attached to a fixed body by a muscular arm or anchor, which enters the shell through a foramen. This is connected with the dorsal and ventral valves of the shell by corresponding opposite muscles, which determine the direction of its open borders. There are two pairs of adductor muscles arranged longitudinally, and two pairs of abductors (divaricatores), one of the pairs smaller, and sometimes wanting. There are muscles also in the mantle and branchial arms. In lamellibranchs or *Acephala* there are powerful musculi adductores. There is but one in the *Ostreidae*, *Aviculariidae*, and *Muelleriidae*. They are of very unequal size in the *Mytilidae*, but sub-equal in the remaining *Acephala*. In *Anomia* there are three.

There are also retractor muscles of the siphons, and a band around the edge of the mantle. The muscles of the foot are often large. The principal one divides next the body, and each half is inserted near the hinge of the shell between the adductor muscles. In *Gasteropoda* the muscular structures have a different arrangement. The foot is largely muscular, and its upper and posterior region gives insertion to the columellar muscle, which attaches the animal to the shell. It arises from the columella at the beginning of the last whorl. Its size depends on the size of the whorl and length of foot. Other muscles are devoted to the elongation or retraction of the proboscis and the penis. In *Cephalopoda* the columellar muscle is represented by a large symmetrically divided mass, which arises from the cephalic cartilages, and is inserted into opposite sides of the shell. An annular muscle surrounds the neck, and another the funnel. From the latter diverge the longitudinal muscles of the tentacles, which are perforated by radial muscular fibers. The mantle is occupied by a flat muscle. The usually muscular foot is here represented by a flat body, which projects forward from beneath the mantle. It is rolled up, forming a tube. By the energetic expulsion of water from the mantle-chamber through this tube the animal is driven through the water, the mantle end first.

The interior surface of the outer chitinous skeleton of the *Arthropoda* is lined with a muscular layer. Longitudinal and oblique muscles connect the annuli, which repeat each other in those forms (*Myriopoda* and larvæ) in which the segments are similar. Where (as in all the higher types) the segments are much specialized, the muscles are modified accordingly, either by increase of size or number. Muscles of the dorsal and ventral regions are usually more enlarged than those of the lateral, while in the types where the sides are soft, to allow of the movements of the back and belly plates, the latter are connected by straight muscles which pass through the viscera. All the limb muscles are within them, or are inserted into internal processes of the chitinous walls. Sometimes they are inserted into fibrous bodies which have been hardened by calcareous or chitinous deposit, which also subserve the purpose of levers.

Arthropoda possess muscles which perform the functions well known among vertebrates as rotators, elevators, depressors, retractors, protrusors, etc. But the flexors and extensors exceed the others greatly in importance and size. Their relative size is the reverse of what is seen in vertebrates; in the latter the extensors are the more important; in the *Arthropoda* the flexors exceed the extensors several fold.

2. In *Vertebrates*.—The muscles of the animals of this type are divided into two classes by their position and the

FIG. 12.—*Panopœa australis*.

relation they bear to the skeleton, and are termed episkeletal and hyposkeletal. The former are situated on the upper surface of the vertebræ—i. e. of the body and arches, including ribs—and are developed in the fœtus coincidentally with the vertebræ. Hence they are in segments which correspond to these, and are separated by intervals termed inter-muscular septa. The hyposkeletal are developed later, and below the vertebræ; they are in part attached to the latter, or to the abdominal walls, or the limbs.

In vertebrates below the *Batrachia* the hyposkeletal muscles are developed to a very slight degree. The segments of the episkeletal series (or myocommata) cover the sides of the body posterior to the head, and meet on the median line below. They present an angle forward, near their middles, having thus an open chevron shape. In *Batrachia* the tails and sides retain the largely developed myocommata, while the abdominal muscles have the character of those of the *Reptilia*. In these and higher Vertebrata the hyposkeletal muscles are well developed. In the latter numerous muscles (spinalis, semispinalis, longissimus dorsi, sacrolumbalis, intertransversales, levatores costarum, complexus, splenius, recti postici, and recti laterales) are derived, by subdivision, from the upper portion of the myocommata. In the same way the inferior half gives rise to the recti abdominis, which extend from the pelvis to the sternum; the sternohyoidei from the sternum to the hyoid apparatus; the geniohyoidei from the latter to the lower jaw. On the sides the derivative muscles are obliquely directed—viz., the external intercostales; the obliqui externi of the abdomen; the subclavius from the first rib to the clavicle, and the scaleni from the anterior dorsal ribs to the cervical ribs and processes; lastly, the sterno-cleido-mastoid extends from the sternum and clavicle to the skull. The fasciculi of these muscles are all directed, as is the lower part of the myocomma of the fish, from above, or dorsally, downward and posteriorly. The hyposkeletal muscles occupy the inner side of the body-walls, and include, besides many others, the diaphragm of *Mammalia* and birds. This septary muscle is wanting or rudimental in vertebrates below the *Aves*.

The muscles of the limbs are of two kinds: (1) those that originate from the body, and (2) those that take origin on some bone of the limb. The former move

the whole limb, the latter its parts. They are extensors, flexors, and rotators; among the most notable of the last is that which, in the *Mammalia*, rotates the radius of the fore arm on the ulna. Of flexors, the pectorales major and minor pertain to the fore limb; they are enormously developed in birds, subserving the function of flight. The extensor of the hind limb, the glutæus maximus, is greatly developed in man, as essential to the erect attitude. The longitudinal dorsal muscular tendons are generally ossified in birds.

A remarkable modification of the muscular system is seen in the electrical organs of certain fishes, the torpedo, electric eel (*Gymnotus*), and catfish (*Malapterurus*). Here a system of enormous cells, packed in parallel columns, discharges electricity instead of developing movement or contraction. The contents are gelatinous, and are divided by connective tissue into transverse disks, imitating striped muscular fiber.

The columns are vertical in the torpedo and longitudinal in the other genera. They are richly supplied with nerves which are distributed on one face only. The rays possess rudimental organs of the same kind at the base of the tail.

V. THE MUCO-DERMAL SYSTEM.

1. In *Cœlenterata*, *Echinodermata*, and *Mollusca*.—The superficial or cellular layer of the skin or epidermis is universally present in animals. The inferior layer in vertebrates is fibrous, and belongs strictly to the system of areolar or connective tissues; it is not found in the *Cœlenterata*, but is represented by a non-cellular, granular, and sometimes slightly striate “true skin.” In the *Cnidaria* and in polyps (*Anthozoa*) there are two or three layers of cellular skin, of which the lower contains the “nettle-cells.” These are minute bladders .02 to .07 mm. long, and one-third to two-thirds as thick, which contain a hair-like body coiled within them. These are suddenly projected upon external irritation, and act as irritants or offensive weapons upon the object they strike, producing sometimes severe smarting and paralysis. These cells occur also as an external lining of the mesenteric threads of polyps. The true skin is the layer in which is deposited the carbonate of lime, which, penetrating or not the folds of the internal cavity of the body, produces the radiating and tubular solid structures characteristic of corals. In the *Gorgoniidae* the deposit of the basis of the first simple, and therefore of the axis of the compound, animal, is horny; this is afterward covered with a thin calcareous layer.

In the *Echinodermata* the dermal system fulfills an important function, as the basis of deposit of mineral matter in the form of innumerable symmetrical segments. In the *Holothurida* these deposits are frequently isolated and internal, and sometimes entirely wanting; the tentacles always contain them. Among *Mollusca* the superficial layer consists of ciliated epithelium (except on the eye-peduncles). The true skin is fibrous, and contains many cells; it is in the form of a sac, and often reaches considerable thickness. An extensive fold derived from the posterior part of the body in *Cephalopoda* and *Gasteropoda*, or the superior in *Acephala*, envelops the body more or less completely. In mollusks which possess a shell the latter is produced by the margin of the mantle. This margin is supplied with glands which secrete or separate carbonate of lime, which they deposit on the general border. Thus the shell takes the form of the body, which the mantle closely enfolds. In *Gasteropoda* it is subcylindric; the shell has the same character, being sometimes partially or wholly straight (*Vermetus*, *Teredo*), or generally spirally twisted. In the bivalves the mantle has the form of two lateral oval laminae, thus producing the well-known form of the shells. The periodical deposits of lime by the mantle are seen in the lines of growth of all shells. The form of the mantle border is faithfully repeated in the shell; thus the projections caused by the protrusion of the proboscis in *Murex*, *Strombus*, etc., is seen in the convexities and canals of their margin. In *Acephala* the mantle extends beyond the body, inclosing a space known as the mantle-chamber. The margins of the mantle in a large number of families are extensively united, thus forming a nearly closed chamber. They are entirely separated in the oyster, the *Arca*, *Myophoria*, etc. They are sometimes only united by a bridge; when more extensively, there usually remains an opening through which the foot is protruded. Of these some leave a single opening at the posterior end of the body (*Mytilida*, *Unionida*), or the latter is divided into two (*Tridacna*, *Isocardia*, *Cyprina*). Of these the upper is the point of exit for excrement and water, while the lower admits water to the gills and food to the mouth. The lips of these openings are in many families prolonged into tubes, sometimes very extensively. These may be united or separate. They are either fixed or retractile; when the latter, the space they occupy in the shell requires that the line of attachment of the mantle to the shell should be indented, sometimes to a great degree. The opening for the foot also admits water. It is much reduced in size in genera with a rudimental foot (as *Gastrochæna*, *Aspergillum*, etc.), and is finally closed in *Pholadidea*. In this series of *Acephala* the siphonal tube is not retractile, and is strengthened by a calcareous deposit, to which the true valves become mere appendages, and with which they are finally completely fused (*Aspergillum*).

Besides the mineral substance, the colors of the shell are secreted by special pigment-glands on the margins of the mantle.

The shell is not always composed of carbonate of lime; in *Lingula*, *Pinna*, etc., the material is phosphate of lime, and resembles bone. The pearl layers of many shells are aragonite. The shell may be composed of laminae or prisms,

FIG. 13.—*Voluta undulata*.

or both. *Anomia* exhibits the first, *Inoceramus* the second, and *Strombus* the third type. In *Brachiopoda* the shell-valves are dorsal and ventral; in *Acephala*, right and left; in *Gasteropoda* and *Cephalopoda* the shell is central and single. In *Acephala* tightly closed valves indicate retractile siphons; posteriorly gaping shells, projected ones.

The valves are united by a marginal hinge, composed of teeth, pits, and cartilage ligament, in most families.

In *Gasteropoda* the coil may be flat (*Planorbis*) or much prolonged (*Mitra*). The "body-whorl" is that last made; it may be either contracted (certain snails), or greatly enlarged, as in *Cypræa*, where it almost or quite conceals all the other turns in its fold.

In the fossil *Endocardines* (or *Rudistes*) the valves are fastened by hinge processes on the inner face of the free and smaller valve.

The shell of *Cephalopoda* is distinguished by its septa. These inclose chambers, the animal only occupying the last one constructed. This structure is not without parallel among *Gasteropoda* (where the unused portion is generally broken off), but the *Cephalopoda* are peculiar in that the body is not entirely withdrawn from the first chamber, but leaves a long tube, which passes through all the chambers, and secretes a pearly sheath, which is known as the siphon of the shell. In life this contains nothing but air, which is wanting in carbonic acid. The margins of the septa are simple in *Nautilus*, *Orthoceras*, etc., but fold in a most complicated and symmetrical manner in *Ammonites*, *Baculites*, etc. In *Goniatites*, *Aturia*, etc., the folds are fewer and more simple.

The *Argonauta* (paper-nautilus) is peculiar in the character of its shell, which only belongs to the female. It possesses indeed no true shell secreted by the mantle, in common with other octopod genera, but that which bears the name is secreted by the margin of the large expansions of the two posterior arms. These inclose the shell, which is thus evidently a product of their inner face.

The byssus is a fibrous rope or thread-like body which is secreted by a gland in the foot of certain *Acephala*. By means of it the animal is attached to fixed bodies. It is well developed in *Mytilus*, rudimental in some *Uniones*.

2. In *Arthropoda*.—The external covering of the body and limbs of animals of this class has been already stated to be chitin. This substance is composed chemically of $C_{17}H_{14}NO_{11}$ —that is, a protein body, $C_8H_6NO_3$, plus a hydrated carbon, $C_9H_8O_8$. In higher *Crustacea* and in various *Myriopoda* (*Iulus*, *Polydesmus*, etc.) it is accompanied by an equal or even greater amount of carbonate and phosphate of lime; of these the former exceeds the latter in quantity. The chitin layer proper is a secretion from a layer of cells, which in turn lies above a stratum of connective tissue. The cells resemble the epithelial, and have distinct nuclei. The chitin originates from these as a transparent layer, but frequently becomes streaked or fibrous.

The pattern on which each segment of the arthropod body is constructed is that of an annulus composed of several pieces. These are a median dorsal and ventral, and a pair of lateral shields on each side. The number of these rings in the different orders averages twenty and less, but in some *Myriopoda* it rises as high as 140 (*Geophilus*). They are greatly modified in forming the head, to which five segments are reckoned by some (seven by others). In *Myriopoda* those remaining are very similar to each other, while in the other orders they are much modified, and generally arranged in groups. These are distinguished in insects as head, thorax, and abdomen; in *Crustacea* the first two and part of the third series are united into a cephalothorax, while the numerous remaining segments are the post-abdomen. In *Arachnida* only, however, we have the true cephalothorax, including head and thorax only, the abdomen remaining entirely distinct. The number of segments in the *Crustacea*, *Decapoda*, *Amphipoda*, and *Isopoda* is 20; in the *Copepoda* and insects, 12; in *Arachnida* it varies from 12 to 19.

The limbs of *Arthropoda* are composed of hollow, variously altered cylinders, articulated together where composed of more than one segment. In *Crustacea* and *Myriopoda* they are present on all the segments of the body; in *Arachnida* and *Insecta* on head and thorax only. In the last-named class only those of the head are modified to aid in seizing and devouring food; in the *Crustacea*, those of the thorax are partly (*Gammarus*) or wholly (*Astacus*) devoted to this service. As organs of progression only those of the thorax are employed in *Insecta*; in *Arachnida* the last head-limb is included; they thus possess four pairs of limbs, while the

Insecta have but three. The larvæ of lepidopterous and some (tenthredenid) hymenopterous insects possess false feet or pro-legs on the abdominal segments. In the former they are beset by an arched series of minute claws, which are absent in the latter. The abdominal legs of *Myriopoda* are, like the thoracic, simple. In *Crustacea* they are in part swimming organs, and many of them bear plates and fringes in which the blood is exposed and oxygenated.

The organs of the head, or altered feet, are in jawed insects as follows: 1, wanting; 2, antenna; 3, mandible; 4, maxilla; 5, labium. In insects with a tubular mouth it is similar, except that the third pair are bristles for puncturing, the fourth similar, and the fifth a tubular body or rostrum, inclosing them. The hemipterous rostrum is of this type. In *Lepidoptera*, where there is a tubular or suctorial tongue-like rostrum, the third segment is rudimentary, the fourth is the rostrum, and the fifth is the labium. Of the jawed type of the *Coleoptera* are the orders *Orthoptera* and *Neuroptera*. In the *Hymenoptera* (bees, etc.) the mandibles are developed as jaws, but the maxillæ are elongate, and form the opposed halves of a tube which incloses a projectile tongue. The suctorial orders, *Hemiptera* and *Lepidoptera*, have been mentioned; the structure in the *Diptera* (flies) is similar to that of *Hemiptera*.

The antennæ of insects are organs of special sense, but whether of hearing, smell, or taste is not well known. In the basal segment of certain *Crustacea* (*Sergestes*, etc.) a chamber containing grains of sand has been suspected to be an organ of hearing; while a microscopical nervous structure in the posterior wings of *Coleoptera* has been regarded as of similar significance. The antennæ are set with bristles, which evidently subserve the ordinary but here highly delicate sense of touch. The *Crustacea* are distinguished by the presence of two pairs of antennæ; the second pair only of these is present in other *Arthropoda*, excepting the larvæ of insects, where the first pair exists in a rudimental state, the second being absent. In *Myriopoda* they are as in *Insecta*, but in *Arachnida* both appear to be wanting; the second pair is, however, present as jaw-antennæ, taking the place of the absent mandibles.

In *Insecta* the forms of the antennæ are very numerous. The typical structure is that of a succession of (nine to twelve) sub-similar cylindric segments. Thus they appear in carnivorous and other *Coleoptera*, in phryganeid *Neuroptera*, acridiid *Orthoptera*, nematoceros *Diptera*, etc. In most *Diptera* they are excessively shortened and of few joints; the last is enlarged, and supports at its base a large bristle, which is frequently plumed. In *Lepidoptera Diurna* they are club-shaped; in *Sphingidæ*, triangular in section; and in *Lepidoptera Nocturna*, fusiform and often plumed. In many *Orthoptera* they are very short; in *Hymenoptera* short (bees), elbowed (ants), or much prolonged (*Ichneumonidæ*). The *Coleoptera* exhibit the greatest varieties. In some (*Elater*, *Dictyopterus*) they are serrated; in *Silphidæ*, short and clubbed; in *Longicornia* their length is often excessive; in *Curculionidæ* some of the basal segments are elongate, forming an elbow with the remainder. In *Lamellicornia* the terminal segments are expanded, leaf-like, on one side of the axis, and open and shut like the leaves of a book.

In *Myriopoda* the maxilla and labium of insects are represented by a large labium. In the *Strongylia* there are a second and third labia; but in *Chilopoda* the last is represented by a pair of powerful foot-jaws, which are perforated for the conduct of poison. The first leg corresponds to the third of the insect. In *Arachnida* the insect maxilla is represented by jaws, which are simple in spiders, acute, and perforated by a poison duct, but in *Phalangia*, scorpions, etc. (*Pedipalpi*), are furnished with an opposable joint, or are chelæ.

In *Crustacea* the second pair of maxillæ are not united into a labium, as in *Insecta*. The cephalothorax in some of the higher order of *Decapoda* (crabs, lobsters, etc.) is distinguished from the abdomen by a groove, as in the crayfish (*Astacus*); in all of them the ambulatory limbs arise from the abdomen. One or more of these are chelate (furnished with nippers) in the *Decapoda* and other orders, but in the *Stomapoda* the first pair has instead the last joint opposed to the whole length of the penultimate, forming a reversed scissor-like organ. The limbs of the post-abdomen usually bear branchial organs, while those of the last segment are in the form of plates, which, when extended, form a swimming shield (lobster), or are hook-like bodies for maintaining the hold in the shell (*Pagurus*).

The limbs in *Insecta* are always similar in construction, though the hinder may be much elongated (grasshopper), and never chelate. They consist of four regions—the coxa, femur, tibia, and tarsus. The coxa attaches the limb to the body by a ball-and-socket or hinge-like joint, and may be from globular to laminar in form. The femur is the stoutest joint, containing the muscles which flex and extend the rest of the leg. The tibia is slender and often long; the tarsus usually consists of several joints. In some *Hemiptera* it consists of but one or two; in most *Coleoptera* it embraces at least five. In the latter order the number is an important index of relationship. The lower groups (*Coccinellidae*, etc.) possess but three; the curculios, longicorns, etc., possess four, and the *Tenebrionidae* and others five in front and four on the hind limbs only; lastly, the sericorn, clavicorn, monilicorn, and other types, with five joints all round. The last joint usually consists of a pair of chitinous hooks; others may be modified by expansion, etc., for adhesion to vertical surfaces, etc.

3. In *Vertebrata*.—The skin in the *Vertebrata* is primarily smooth and soft. Its epithelial glands may secrete mucus, as in many fishes, or glands seated in the true skin may separate sweat. The latter are simple, convoluted, and with a long efferent duct. The epithelial layer produces the horny sheaths of claws and horns, feathers and hairs. *Mammalia* are generally covered with hairs, but in the manis it is thrown into extensive folds, which are cornified, and become the scales of those remarkable animals. In the shell of the armadillos it is ossified; and on the head of various vertebrates and on the body of tortoises it is penetrated by ossification, and fused with the skeleton below them. Hairs are an epithelial growth in the form of a hollow

FIG. 14.—Cleodora.

cylinder. The epidermis is sunk into a pit of the true skin, and then returns outward as the hair. It increases in length by addition of cells and pigment from below. A modification of the same structure is seen in feathers, where the axis is split laterally, and thus develops the barbs and fibrillæ on each side. Birds are covered with feathers. The first growth appears as down, in which the fibrillæ are softer and in much smaller number, so as not to be coherent; the bases of the true or mature feathers are furnished with the same. Those of the body are generally soft; in aquatic birds excessively dense on the lower surfaces. They arise from certain patches only. There is one on each scapular region, and one along the middle line of the neck above. Another is on the rump, and one on each side of the breast. The abdomen presents a large median patch. In ostriches, penguins, and a few others the feathers are evenly distributed over the whole body. Besides the main shaft of the feather, a second one is developed behind it in many birds. It is generally much smaller than the first, but it is equal to it in the *Casuariidae*. The largest feathers are developed on the caudal vertebrae and on the fore limb. In the latter they subserve the function of flight. Those attached to the carpus and manus are the longest and most important, their length bearing a direct relation to the powers of flight of the bird. These are the primary quills; they are enormously developed in the swallows and swifts, in the humming-birds and frigate-pelicans (*Tachypeles*), etc. They consist of naked shafts only in many of the ostriches. The quills attached to the fore arm are the secondaries; they are proportionately large in gallinaceous birds. Those inserted into the skin of the humerus are the tertiaries, and are most highly developed in the wading families (*Grallæ*) and certain song-birds—e. g. the *Molacillidae*. The caudal quills or rectrices are from twelve to eighteen in average number; they are greatly elongated in the tropic-bird (*Phaeton*), *Milvulus*, etc., and are almost wanting in some gallinaceous birds, in some tinamous, etc. The rump-feathers or tail-coverts are sometimes so developed as to conceal them, as in the peacock, *Pharomacrus*, *Egretta*, etc.

The scales of reptiles are areas of true derm, bounded by simple folds, which are covered exactly by epidermis. These areas may be filled with an osseous deposit, as in *Heloderma*; in snakes they are soft. In tortoises the intervening folds are very shallow, and remotely correspond to the skeleton below. The epithelial layer is horny (tortoise-shell), while

the derm is ossified and united with the osseous skeleton below. In *Crocodylia* the distinct ossifications occupy the dermal areas of the back, or on both surfaces of the body in the caimans, etc. The areas are symmetrically distributed on the head in serpents, most *Lacerilia* and some tortoises. In the first they are fewest and most regular, numbering usually nine on the upper surface. They correspond remotely with the cranial bones, and hence are called parietal, frontal, superciliary, prefrontal, internasal, rostral, etc. In venomous snakes and boas the vertex is frequently covered with scales.

Fishes frequently display ossifications of the epidermis as well as of the true skin, as on the cranium of sturgeons, their dorsal and lateral shields, etc. The scales which cover the bodies of most fishes are developed in pouches of the true skin by deposit of mineral matter. Their exposed surfaces are covered by epidermis, which enters between them, and reaches there the true skin. In eels they are small and separated. In fishes with closed swim-bladder (*Physoclysti*) the scales develop spinous projections which produce the effect of a comb on the margin, and are hence called etenoid. Most of those in fishes with the duct of the swim-bladder (*Physostomi*) have smooth surfaces and edges, and are termed eveloid. In many fishes of early periods, and some now living (*Lepidosleus*, *Polypterus*), the scales are pavement-like and glossy, with a layer of ganoin. These occur in all super orders of *Teleostomi*, but are rare in the *Actinopterygii*. Sharks have separated mineralized bodies, with flat bases and produced points, granules, etc., whence they have been termed placoids. In *Marsipobranchii* and *Leptocardii* the skin is smooth.

The internal parts of the mucodermal system are the mucous membranes. The former are continuous with the epidermis, and line the cavities of the digestive, respiratory, and reproductive systems. The serous membranes line the closed chambers, being continuous with the mucous membrane only at the fontanelles of the oviducts (tubæ Fallopii). In the thoracic cavity they form a sac, with one side thrust in upon the other, the thoracic viscera being on the outside of the entering portion. The abdominal viscera occupy in the same way the outside of the membrane lining the cavity, which is termed the peritonæum. In the thorax it is the pleura.

4. *The Teeth*.—These bodies are generally developed in an internal or external epithelial layer, like some of the dermal bony, or dentinal plates or pieces. In *Protozoa* and *Cœlenterata* they are wanting. In *Echinodermata* they are present as five hard sub-triangular plates, which close the mouth by their close contact, like radii from its center. In *Mollusca* they are described under the digestive system, so that it only remains to consider them in *Vermes* and *Vertebrata*. In the former they consist exclusively of hooks, mostly arranged round the mouth. In the Trematodes they occur, weakly developed in a few genera, in one of which they are attached to an organ at the posterior extremity of the body. In *Nematoda*, *Chiracanthus* has hooks on the head and body, and *Strongylus* horny teeth round the pharynx. In *Acanthocephala* all the genera possess a retractile proboscis, which is studded with recurved hooks in various circles. In *Cestoda*, the tapeworms have hooks as well as suckers on the head, which are especially well developed in the eystiereus larval stage. The *Tetrarhynchidae* possess four projectile proboscides, each of which is set with several rows of recurved hooks.

The teeth of vertebrates are developed on papillæ of the mucous membrane, which is usually sunk into a groove or successive cavities or alveolæ of the jaw and palate bones. True teeth are usually composed of a very dense substance allied to bone, called dentine. Exterior to this they have a deposit of a still denser and harder substance, the enamel, which covers the crown. The root is sheathed in a layer of true bone, the cement. Dentine is distinguished from bone (*osteine*) by the presence of great numbers of parallel tubuli, which radiate from the central cavity to the circumference of the tooth. Enamel is, on the other hand, of the nature of a secretion, filling vertical hexagonal cells which stand upon the dentine. Hence it is composed of prisms. It contains, like dentine, a trace of fluoride of calcium, besides the phosphate of lime of which both are composed. It is deposited in a layer of the ectoderm, while the dentinal membrane is endodermal.

In *Leptocardii* there are no teeth, and in *Marsipobranchii* they are horny processes in concentric series round the inside of the funnel-shaped mouth. The two largest are situ-

ated at the mouth of the œsophagus. In fishes generally, bony teeth are present, but are not usually developed in alveolar cavities, but on the surface of the bones.

In fishes the teeth are usually covered with dentine instead of enamel, and may be composed internally of true dentine, or of its variety, vasodentine. This substance retains the numerous blood-vessels which characterize the early stage of deposit of dentine, which are easily seen in a section of the teeth. Of such character are the teeth of

FIG. 15.—*Octopus vulgaris*.

Elasmobranchii, which are moreover of very various form. Thus they are pavement-like, with vertical lamellar roots, in skates and rays, or they are rootless and with swollen crowns of differing sizes, etc., arranged in symmetrical band-like pavements, as in cestracions. The crowns may be more elevated as in hybodonts, or finally isolated and with sharp apices and cutting edges in the existing squalodonts. In *Holocephali* the teeth are few and large, and are traversed by columns or bands of vessels with calcified walls. In *Dipnoi* the teeth form a single serrate cap for each jaw. In *Actinopterygia* the teeth are generally composed of a larger proportion of dentine. In sturgeons they are only present during immature age. In the *Lepidosteidae* the external or dentinal surface is inflected in deep folds, which are closed so as to resemble grooves externally. *Physostomi* generally have large teeth on the jaws, but in some *Characinidae* and all other *Plectospondyli*, *Coregonus* (grayling), some *Mormyri*, etc., there are none. In some of these fishes there are numerous teeth on the lower segment of the fifth pair of hyoid arches, or the "inferior pharyngeal bones." In *Characinidae* these are of very varied type; in *Catostomidae* the bones are much prolonged, and the teeth are comb-like in one row, and work against a projecting inferior table of the basioccipital bone. In *Cyprinidae* they are stout, in one or more short rows, and may be hooked, sharp edged, conic, or grinding in type, according to the food of the fish. This structure does not exist in other fishes. In *Esox* the teeth are raptorial and very numerous; in *Clupeidae*, rudimental and wanting. Only in the order to which the latter pertains, the *Isospondyli*, do we find fishes with fangs sunk in deep alveoli, the extinct *Saurodontidae* from the cretaceous formations. In *Nematognathi* they are more or less bristle-like, and packed together like a brush. In eels they are often dagger-like. In physoclystous (or the higher) fishes they are generally brush-like, frequently with canines intermixed; but in *Pediculati* they are large, incurved, on flexible ligamentous bases. In some *Plectognathi* they are incisor-like, and in *Pharyngognathi* those on the hyoid apparatus are greatly developed. The latter are sub-quadrate, oval, or narrow (*Scarus*), and arranged pavement-fashion for the crushing of hard substances, as shells, etc. In *Scarus* the teeth of the jaws are confluent into a shining, parrot-like beak, useful in seraping out shells and cutting off seaweed.

In *Batrachia* the teeth are usually small, often wanting (bufoniform Anura), or in the extinct *Labyrinthodontia* with deep complicated inflections of the dentine and superficial cementum. In reptiles we find teeth with fangs and with crowns, generally covered with enamel. These may be sunk in deep alveoli (*Rhynchocephalia*, *Aerodonta*, *Crocodylia*, *Ichthyopterygia*, *Sauropterygia*, *Ornithosauria*, *Dinosauria-Goniopoda*), or may be attached to the inner side of the outer alveolar wall (*Lacertilia* in general, and *Dinosauria-Orthopoda*: may stand immediately on the jaw-bones, without fangs (*Ophidia*), or on a thick column of ossified pulp (osteodentine) in an alveolus (*Pythonomorpha*). The crowns are generally compressed conic; in some (*Laelaps*) knife-shaped. In herbivorous lizards they present an oblique face inward. In *Crocodylia* the young teeth rise within the pulp cavity of the old, and throw them off; in most other orders the successional teeth appear at the side of the fang, and provoke absorption, which cuts off the crown of the old. Tortoises and birds are toothless; Anomodontia are so likewise, except a strong maxillary tusk.

In *Mammalia* the dental armature is distinguished into series—viz., the incisors, canines, premolars, and molars. Their normal number on each side of each jaw is I. 3; C.

1; Pm. 4; M. 3; total, 44. The incisors are normally flat and transverse edged; the canines longer and conic; the premolars compressed, with one to three cusps; and the molars oval in section, with a double series of cusps. In *Ornithorhynchus* there is but one, a horny tooth. In marsupials the number of incisors is excessive (as 8 or 10), or, as in kangaroos, less numerous and the median much enlarged. In these and their gigantic extinct allies two in the lower jaw are much enlarged as tusks. In *Glires* there are but two incisors above and below, which have enamel externally only; hence the inner face wears more rapidly, and the opposed pairs act as efficient cutters in gnawing. The other teeth are molars only, and these of the complicated type to be mentioned later. In *Insectivora* the incisors are enlarged, but in *Edentata* they are always wanting. In *Chiroptera* and *Carnivora* they are similar to each other, and much reduced. In *Quadrumana* they are well developed, broad, opposed cutters, and are generally 4-4 in number. The proboscidiens, on the other hand, have but one (the outer) pair of incisors in each jaw, which are developed into huge tusks above (*Elephantidae*) or below (*Dinotheridae*). In these cases the opposing pair is reduced or wanting. The *Artiodactyla-Ruminantia* are remarkable for the entire absence of superior incisors, and the close resemblance of the inferior canine to the lower incisors, producing the appearance of eight of the latter.

The canine is largely developed in the *Carnivora*, hogs, *Hippopotamus*, and the extinct *Amblypoda*. The premolars are wanting in rodents and many proboscidiens, but numerous in marsupials, insectivores, etc. In *Carnivora* they are numerous, and the last is peculiarly formed, being the sectorial or flesh-tooth characteristic of the order. The two outer tubercles and connecting ridge are developed into a longitudinal notched blade, while the inner remains a small tubercle at the front of the inner side. In dogs there are two tubercular molars behind it; in weasels and cats, one; in the extinct *Hyenodontidae* all of the molars are of the sectorial form.

Molar teeth are simply conic (haplodont), with tubercular crowns (bunodont), or the tubercles may be fused into crests (lophodont). The tubercles may be three in number (tritubercular); or four (quadritubercular); or numerous (multitubercular); or the tubercles may have crescentic sections (selenodont). In the first case they may be one or two rooted. Thus in cetaceans generally they are simple cones, covered with cement instead of enamel. In some extinct groups (*Zeuglodon*, etc.) the crowns are compressed and the roots two. In *Edentata* they are simple throughout, and covered with cement. This forms a thick layer and incloses a thin one of dentine, which by its superior hardness forms the ring-like grinding surface of the crown; it is filled within by osteodentine. In carnivorous and insectivorous animals the tubercles are usually three, and acute and ele-

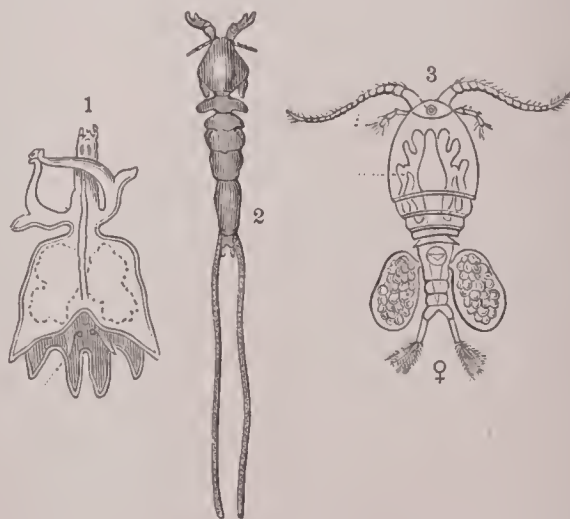

FIG. 16.—1. Brachiella. 2. Dichelesthium. 3. Cyclops.

vated; thus they appear in *Chiroptera*, many marsupials, *Insectivora*, etc. In carnivorous forms the two external tubercles above, and an external and internal below, are modified into a cutting blade, the two acting together like shears. In kangaroos, sirenians, tapirs, and *Dinotherium* they appear as two transverse crests or keels. These crests are multiplied in *Mastodon*, reaching six or seven. In *Stegodon* they are more numerous; the intervals are a little deeper, and with some cementum in their bottoms. In *Elephas* they are deepened to the roots of the tooth, and filled to the top with

cement; are narrowed by the approach of the much elevated transverse crests, which have now reached a great number. Their summits readily wear in use, and thus present bands of alternating dentine, enamel, and cementum.

The external tubercles may be connected by an external longitudinal crest, as in *Rhinoceros* and *Hyrax*. They may be modified so as to form two Vs, as in many *Perissodactyla*. The internal tubercles may remain conic (many *Perissodactyla*), be connected with the external by cross-crests (other

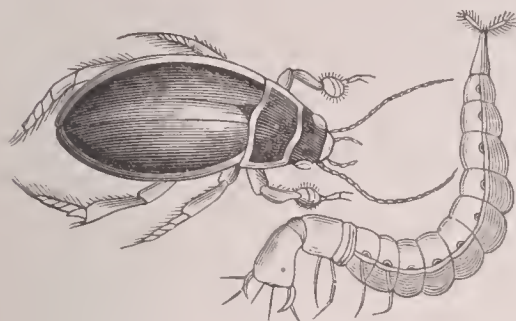

FIG. 17.—*Dytiscus* and larva.

Perissodactyla), or become like the external Vs, or crescentic in section (selenodont *Artiodactyla*). From this point the succession of forms seen in approaching the elephants is repeated in two series, ending in the ox and horse. The intervals deepen, the crescents become elevated, and the tops, being soon worn off in use, present a figure formed by the edges of enamel plates, which inclose islands of dentine. The spaces between them are filled with cementum. In the horse there are five crescent-shaped columns in the upper molars and three in the lower. In artiodactyls there are four above and mostly four below. In deer the crown and roots are sub-equal in length, but in the *Cavicornia* the crown is much the longer.

The same transition is seen in the rodents. In *Mus* the molars are only tubercular; in squirrels there are crests. In *Arvicola* and beavers there are deep inflections of the enamel of the sides of the tooth, producing a zigzag section when the crown is worn, while in *Caviidae* the tooth is entirely divided into several columns by the deep descent of the enamel coating from above. In porcupines figures are produced by both lateral and coronal folds.

Simpler teeth are seen in men and apes, where the molars present four obtuse tubercles (in the last sometimes five); and in the hogs, where the tubercles are more numerous, and sometimes irregular. In *Hippopotamus* each of the four tubercles is trifoliate in section.

VI. THE DIGESTIVE SYSTEM.

1. *In Invertebrates*.—The prominent features of the digestive system in *Cœlenterata* have been pointed out. There is none in the *Hydræ*, the inner surface of the urn-shaped body-cavity performing that function; an excretory pore exists in the foot-like support. In *Actinozoa* a small sac is sometimes formed at the fundus of this cavity by the reflection of the inner skin; it opens into the cavity, and is entered above by the mouth. The body-cavity is ridged on the sides by prominent folds, whose margins bear reproductive organs and nettle-cells. In the *Medusæ* the body is turned the other side up at maturity, though its position is that of the polyps in the larval state. The free stomach hangs below the basal cavity. The latter is sometimes wanting, and is ridged occasionally, as in polyps. It is produced downward in some genera by its walls becoming a peduncle for the stomach. The latter is bell-like, and often widely open; it is generally closable by the contraction of its margin. The latter bears bunches of tentacles, etc., which in the *Rhizostomæ* are greatly enlarged and prolonged into four leaf-like bodies, which bear the four mouths at their extremities, and tubular œsophagi throughout their length. From the basal chamber rise the four radiating tubular canals, which extend through the umbrella to a tube which passes round its margin.

In *Crinoidea* there is a central column to the basal cavity; round this the alimentary canal winds, and, returning, issues near the mouth. In *Asterioidea* the stomach is a sac, connected with the mouth by a short gullet, which is closable at the mouth. The stomach is divaricated into five pairs of bunches of cæca, which send out radial tubes, two into each arm of the animal. The vent is wanting in the *Ophiuridæ*, but present in most *Asteriidæ*; in the latter case there is an enlarged rectum, which gives rise to five horny radial cæca (often bifurcate), which alternate with those of the stomach. In the *Holothuridæ* the vent is present, and the alimentary canal elongate, and divisible into œsophagus (closed behind by a sphincter), intestine, and

rectum. The last receives the mouths of the respiratory organs.

In the *Vermes* this system does not branch radially; otherwise its character is very various. That it is a blind sac in many orders has been already shown. In those without arms it is either a simple blind tube (*Turbellaria-Rhabdocœla*, *Nepheleis*, *Aspidogaster*, *Branchiobdella*, etc.), or is early divided into two parallel tubes, as in Trematodes. In tapeworm and *Monostomum* these tubes unite at the posterior end of the body. In the *Nemertina*, in which the canal is simple, there are two constrictions at the end of the œsophagus, to the anterior of which is attached a projectile stylet furnished with venom-glands. In *Potia* the alimentary canal becomes a solid ligament, which is turned forward and attached to the wall of the cavity. In *Pontobdella* the blind canal is furnished with a few branches or cæca. In the *Turbellaria-Dendrocœla* it forms a large number of branching cæca.

In the families with vent, it is wound or knotted (*Capitibranchiata* and some *Dorsibranchiata*), simple (*Abranchiata*, *Gordiacea*, *Nematoda*), or furnished with cæca on the sides. There is but one on each side in *Hæmopsis*, but many in the leeches.

In *Vermes* in general there are no Cuvierian glands, and there are often liver-cells on the canal walls.

In *Mollusca* an anus and liver are always present, excepting that the former is wanting in most *Brachiopoda*. An almost universal peculiarity of mollusks is that the alimentary canal, after fewer or more numerous convolutions in the body-cavity, returns and issues not far from the mouth on the dorsal or lateral border of the body; this prevails from the *Bryozoa* to the *Cephalopoda*. The general characters of the canal can be expressed schematically as follows:

A. A more or less projectile œsophageal body or tongue, with a movable membrane armed with reverted horny teeth, and more or less retractile into a sheath; no crystal style in the stomach (except two or three genera). Stomach large, unsymmetrical; canal short, with a large pyloric cæcum; liver very large, lobular, discharging anterior to stomach; mouth with horny beaks: *Cephalopoda*.

Course of canal with two abrupt turns: 1, at transverse stomach; 2, of intestine double, under œsophagus; rectum transverse, opening in mantle hole; liver double, of many cæca, entering each end of stomach: *Gasteropoda-Scaphopoda*.

Course of canal little enlarged at stomach, and with an intestinal one; altogether a loop opening forward near heart; liver single, lobulate: *Gasteropoda-Heteropoda*.

Intestine short (straight), emptying on right side, never in breathing cavity (rarely on back), rarely issuing from anterior part of stomach; latter elongate (longitudinal), receiving straight œsophagus at either end or side, often divided in two or three, when one or more is furnished with

FIG. 18.—*Doliolum Ehrenbergii*, Kr.: 1, from above; 2, from side; 3, from below; a, mouth; b, vent; d, annular muscle-bands; e, endostyle; h, œsophagus; k, intestine; l, branchial membrane; n, nervous system.

horn-armed ridges or teeth; horny jaws: *Gasteropoda-Opisthobranchia*.

1. Liver lobulate, compact.
2. " " subdiffuse, with connecting canals.
3. " " of blind canals.
- a. Branching from large stomach-opening in body.
- β. " " in lateral body-wings.
- γ. " " in gills.
- x. Two posterior body-trunks of liver.
- y. One " " (including four families).
- z. Three " "

Stomach (with very few exceptions) elongate into a cæcum; intestine rising from middle and turning forward to the vent; ridges armed with horny plates in stomach: *Pteropoda*.

Stomach a widening of canal, rarely with one or two constrictions: intestine not convoluted (except *Chiton*), emptying into breathing cavity on right side; small flat jaws, sometimes horny; a pharyngeal lump, with internal cartilage supporting tongue, on lower side of end of œsophagus: *Gasteropoda-Prosobranchia*.

AA. Movable armed tongue wanting.

a. A crystalline style in cœcal appendage to stomach; lips at entrance of œsophagus; canal mostly uniform, much turned; end of rectum free in cloaca; stomach oval or round: *Acephala*.

aa. No crystal style; mouth opening between more or less cartilaginous spiral appendages: canal bound by an extra mesenteric sheath; stomach little distinct; liver double with large (sometimes several) discharge canals: *Brachiopoda*.

1. Canal shorter, ending in blind enlargement.

2. Canal longer, ending in lateral anus.

Mouth opening at base (or side) of a gill-sac: œsophagus short; stomach not large, simple, both with intestine, forming a V; latter directed forward, opening on same side as mouth: *Tunicata*.

Mouth surrounded with ciliated tentaculæ (in one genus with a conic lid): œsophagus well defined; stomach distinct, oftener double than single; intestine rising from end of first or single stomach, swollen in part of a straight course to anus near mouth: *Bryozoa*.

In *Gasteropoda* there is a pair of salivary glands; in most *Cephalopoda*, two pairs (in *Sepia* and *Loligo* but one pair, and in *Nautilus* none).

The radulæ, or tooth series, and their supporting band, present an enormous number of separate teeth in some of the

Cerithiida, *Turritellida*, *Cassidida*, *Tritoniida*, etc. (3—1—3).

e. *Ptenoglossa*; no middle plates; lateral plates similar, numerous ($\infty-0-\infty$): *Scalaria*, *Janthina*.

f. *Rhipidoglossa*; middle plates; laterals 4—6 or more, of various forms; outside of these numerous small hook-like teeth ($\infty-4-6-1-4-6-\infty$): *Neritida*, *Trochida*, *Haliotida*, *Fissurellida*. The *Pulmonata* (except *Testuella*) exhibit a close similarity to this division in their dentition.

The digestive canal in *Arthropoda* does not turn on itself as in mollusks, but issues at the extremity of the body opposite to that which it enters. The œsophagus is usually straight, and is expanded in the thoracic region into the usually longitudinal stomach. Anterior to this point it has sacciform dilatations (*Orthoptera*) or diverticula in some types, as the bees, *Lepidoptera*, flies, etc. After leaving the stomach, the canal, after few or no windings, reaches the anus.

In *Crustacea* and *Insecta* there is an extensive fatty mass on each side of the posterior part of the canal, known as the corpus adiposum; in *Arachnida* it is frequently wanting. The form of the stomach in this class varies; thus in *Pedipalpi* (scorpions, etc.), it is simple or nearly so, but in *Aranea* (spiders) and *Pyenogonum* (whale-louse) it branches into radiating diverticula; in the latter these penetrate even into the femora and tibiæ. The digestive system is supplied with various glandular organs. Those nearest the mouth are the "salivary glands," which are present in all the classes except the *Crustacea*. They are complex glands, and their secretion in some forms (larvæ of some *Lepidoptera*) hardens on exposure to the air into silk-like threads. The so-called liver-glands or tubes are situated either before or behind the stomach. As their function is unknown, and their position is inconstant, the above name is but provisional. In *Insecta* they are slender and tubular, sometimes very elongate and undivided. There are usually but four in *Coleoptera*, but more in *Orthoptera* and *Hymenoptera*, forming a whorl. In *Arachnida* (*Scorpio*, *Mygale*, etc.) and *Limulus* they are more complex, and present a series of more numerous openings into the intestine. In the decapod *Crustacea* the organ exhibits its highest development. It is there a complex follicular gland of large size on each side of the alimentary canal, and opening posterior to the stomach. Other simple glands are in the *Insecta* distributed over the surface of the stomach, and are inclosed by its muscular layer.

The stomach walls are thin or muscular, in some types ridged within and furnished with horny teeth: *Orthoptera*, some *Coleoptera*.

2. In *Vertebrata*.—In most of this branch of animals the stomach is present as a distinct enlargement of the alimentary canal, and the intestine is short or long as the food is flesh or vegetable and mixed in character. The liver is present in all, and is of a highly complex glandular character, except in the *Leptoecardi*, where it is a simple diverticulum of the alimentary canal.

In the *Leptoecardi* the pharynx is very capacious, and is abundantly fringed with long processes. It opens into a sac-like stomach, which is continued as the slender straight intestine to the vent. There are no teeth. In the *Dermopteri* the intestine is also simple and straight. In fishes it presents a good many variations. In some, as the sharks and silurids, the stomach is large, and the pylorus is remote from the cardiac entrance. In most *Clupeida*, *Hyo-dontida*, *Characinida*, *Amia*, and *Polypterus*, it is sac-like, with the pylorus near to the cardiac entrance. In most fishes the stomach is bent on itself, but in *Chimara*, *Symbanchus*, *Amphipnous*, *Fistularia*, and *Belone*, it is straight. The stomach in some sturgeons and in *Heterotis* and *Chatoëssus* (elnpeoids) is gizzard-like (i. e. sub-round), with muscular walls and tendinous lamina on the sides. It is closed at the pylorus in most fishes by an annular muscle. In the higher fishes (*Physoelysti*) there are generally found diverticula from the beginning of the intestine at the pylorus, which are termed pyloric caeca. They are also abundantly found in the lower groups, or *Physostomi*, but their entire absence is more common. They are wanting in *Nematognathi*, eels, *Fistularia*, *Chirocentrus*, *Hyo-don*, the *Gobiida*, and *Blenniida*, and in *Amia*, *Polypterus*, and the *Elasmobranchii*. They exist in vast numbers in some *Salmonida* and *Lepidosteida*, and are numerous in electric eels and sturgeons. In *Platax* there are but four, in *Choloyaster* two, and in *Amblyopsis* one.

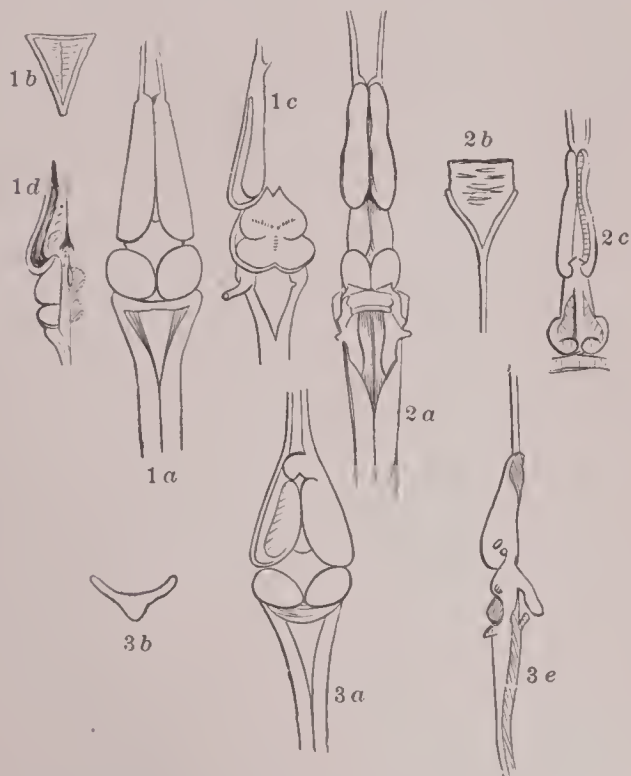

FIG. 19.—1. *Rana esculenta*. 2. *Dactylethra capensis*. 3. *Bufo viridis*. a, brain from above; b, choroid plexus; c, horizontal section of the lobes and hemispheres; d, of hemisphere; e, longitudinal vertical section.

Gasteropoda. In the *Cephalopoda* and *Pteropoda* they are less numerous. In some of the *Pulmonata* they number as many as 26,800. They are arranged in rows, longitudinal as well as transverse. The latter are more or less irregular in their course, but are strictly bilateral. There is a series of median plates or teeth, with one or more rows of lateral ones. The following divisions are indicated by the different tooth-structures in *Gasteropoda*:

a. *Rhachiglossa*; only median plates, which are often toothed (0—1—0): *Volutida*.

b. *Toxoglossa*; no median plates: on each side a single lateral tooth of an awl-like form; no basal membrane of radula; lateral teeth moved by special muscles (1—0—1): *Conida*, *Pleurotomida*.

c. *Hamiglossa*; a middle plate and single lateral plate (1—1—1): *Muriei*, *Bucciniida*, *Olivida*, *Lamellarida*, *Fasciolarida*, *Turbinellida*.

d. *Tenioglossa*; median plates, and on each side three lateral plates; fourteen families; among them *Littorinida*,

The succeeding part of the canal is generally to be distinguished into small intestine and rectum. These are separated by a strong valve in *Etasmobranchii* (except *Chimæra*), in *Lepidosiren*, *Potypterus*, *Zoarces*, *Acipenser*, *Mastacembelus*, and it is not strong in *Orestias* and *Clarotes*. The rectum is distinguished in the lower forms by the possession of a spiral internal valve or partition. In *Etasmobranchii*, *Potypterus*, and *Lepidosiren*, the spiral partition is

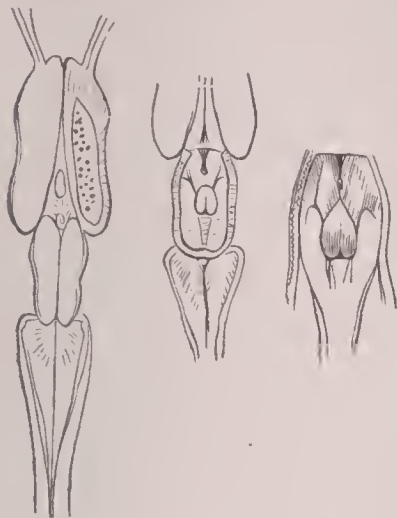

FIG. 20.—Brain of *Necturus maculatus*.

continuous by its inner margin with a median membranous axis, which is suspended from the ileo-cæcal valve; in *Raja miraletus* there is no axis, and the partitions are transverse and perforated; in *Squatina*, *Potyodon*, and *Acipenser ruthenus*, it has no axis, and revolves spirally on the wall of the rectum. It is also present in *Amia* and *Trachypterus*. In *Acipenser rubicundus* there is no spiral valve, but the walls of the rectum are areolate, somewhat as in tripe. The gall-bladder is always present, and discharges beyond the pylorus.

In *Reptitia* the divisions of stomach, intestine, and rectum are well marked; in *Batrachia* rather less so. In both the canal is elongate, and held in a folded position by a mesentery, but in batrachian larvæ it is much more extended, and is horizontally coiled. The liver is large in *Batrachia*, and usually in three lobes, but in the *Brevicipitidæ* and *Engystomidæ* there are but two. There is a sphincter valve at the pylorus, and sometimes one at the end of the small intestine. The gall-duct discharges below the pylorus. In tortoises, whether carnivorous or not, the alimentary canal is elongate.

In some *Emydidæ* and *Trionychidæ* there is a cæcum or sac on each side of the rectum, the bursa analis. In many *Lacertilia* the rectum is double or divided by a muscular valve; in *Iguana* and *Basiliscus* there is a septary valve with small orifices. In serpents the œsophagus is greatly elongate, and the gall-bladder peculiar in being separated from, and sometimes far behind, the liver. The rectum presents many peculiarities. In *Cælopettis* and *Homalopsis* the internal surface is longitudinally folded; in *Hydrophis* with short interrupted folds; in *Dryiophis*, *Dipsas*, *Vipera*, and *Crotalus*, transversely folded; in *Boodon geometricus*, *Bungarus*, *Elaps*, and *Ancistrodon*, the folds are developed into partitions, which are pierced by a single hole each. A pancreas is present in lizards and serpents.

The alimentary canal of birds is distinguished by the peculiarity of the stomach, which is a gizzard—that is, with walls composed on the convex face or borders of contractor muscles, which have a median and common tendon extended sheet-like on the plane side of the stomach. This is, however, not found in certain marine birds, as penguins, where the stomach is a simple sac; and it is little developed in *Sarcorhamphus* and *Vultur*. It is a double sac in *Apteryx*. The crop is a bag-like expansion of the œsophagus, for the temporary stowage of food; it is found in gallinaceous birds, vultures, etc.

Adjoining the stomach is frequently found another more symmetrical expansion, the proventriculus, whose walls are studded with simple glands, whose secretion softens hard food. It occurs in *Gallinæ* (*Crypturus*), *Insessores* (*Ibis*, ducks, condor, etc.). The rectum is not strikingly distinguished from the ileum, but it sends off at its origin two huge cæca, which extend forward toward the stomach on each side of the intestine. They are excessively elongate in *Phasianus*, *Crypturus*, *Dicholophus*, *Apteryx*, etc., and very short in *Apenodytes*, *Ibis*, etc. They are apparently absent in *Sarcorhamphus*.

In *Mammalia* the stomach, intestine, and rectum are well distinguished. There is neither crop, proventriculus, pyloric nor rectal cæca, nor rectal valves. The gall-bladder is not separated from the liver, and discharges below the pylorus, as does also the excretory duct of the pancreas. There are glands in the intestines of many forms, known as Peyer's, and the salivary glands of the œsophagus or pharynx are always present. The intestine (colon) is frequently prolonged

beyond the origin of the rectum, forming a cæcum; the mouth of the rectum is closed by a strong valve. The stomach is transverse, with a portion projecting beyond the esophagus—the fundus. This is excessively elongate in the bat, *Desmodus*. The stomach is simple or undivided in Primates, *Carnivora*, *Proboscidea*, *Perissodactyla*, *Chiroptera*, and squirrels. It is lobulate and subdivided in Monotremes, marsupials (generally), many rodents, some cetaceans, and most of all in artiodactyles (ruminants, etc.). In *Ornithorhynchus* the cardium and pylorus issue from a division one-third the size of the remainder of the stomach; in kangaroos the stomach is slender, saeculated, and wound in one and two-thirds turns on itself; the fundus is large. In the hog the fundus is profoundly sacculate. In *Artiodactyla-Ruminantia* there are four chambers, of which the first is generally the largest, being an enormous expansion of the fundus. In the musk it is not in direct communication with the œsophagus, but is so in the ox. In the former there are five sacs, the last the best defined, with reticulating ridges on the inner wall (tripe), and entered by both cardium and pylorus. The first stomach of the ox represents the first four of *Moschus*; it is followed by the reticulate, which receives the œsophagus; between it and the pylorus are two chambers, whose walls are thrown into elevated folds. The first division has strong papillæ on the inner walls, which are very large in the deer.

In many of the *Gtires* (e. g. *Fiber*) the cæcum is exceedingly large and long. In the Primates, etc., it terminates in a narrow, curved extremity, the processus vermiformis.

VII. THE CIRCULATORY SYSTEM.

1. In *Invertebrata*.—This system, as is well known, consists of organs for the propulsion and conveyance of the fluid results of digestion throughout the body for the maintenance of all its functions. It consists essentially of a system of tubes radiating from the central muscular organ, in which resides principally the contractile or propulsive activity. This center is in the lowest forms simply a tube, but is greatly specialized in the highest forms. We may divide the system into the systemic, the water-vascular, and the lymphatic systems. The second is found in the aquatic invertebrates, and the last in vertebrates only.

The systemic circulatory tubes first appear in *Cœlenterata*. In *Protozoa* the contents of the body are in motion, and in *Amœba* the movement is that of an elongate vortex (Ryder). In no cœlenterate class excepting the *Medusæ* do the tubes appear as isolated; they have been already described as radiating from the stomach or the adjoining body-cavity, and continuing round the margin of the disk as a single tube. The *Echinodermata* possess a true circulatory system, with a well-developed water-vascular system. The vessels of the former are not derived from the stomach, but form an isolated series. The peculiarities of the classes are as follows:

a. Vessels arising from a basal sac, which connects by a short tube with stomach; vessels radiating, penetrating the pieces and arms: *Crinoidea*.

aa. From an oral ring.

b. Superior and inferior oral and anal rings: an asymmetrical heart, emptying into the former; no respiratory artery; stomach arteries (five) collected into two, which enter superior ring at point of entrance of heart: *Asteroidea*.

Rings and heart connected by marginal intestinal artery: *Echinoidea*.

bb. Only oral circulatory ring; no heart; distinct respiratory artery (where lungs exist); intestinal arteries gradually disappearing posteriorly: *Hotothurida*.

In echinoids and asterioids there is a septary column extending from the upper to the lower surface, unsymmetrically near the middle line. In a fold of it are placed the shell-canal of the water-circulatory system, and the heart. The latter has a narrow opening into the oral ring, which from this fact is termed arterial. The opposite end of the heart communicates by a duct with the superior anal or venous ring. The arterial ring is the smaller and more muscular, and lies between the more superficial nervous ring and the deeper water-canal ring. In the asterioids it sends an artery along the median line of each arm below. The venous ring is larger, and sends two vessels, one on each side of each arm. In *Hotothurida* the vessels are delicate and not largely developed. In all classes the tubes are without cilia internally, and have a wave-like pulsation in life.

The water-circulatory system is greatly developed in the *Echinodermata*, and forms the basis of their means of move-

ment from place to place. Its central organ consists, first, of a ring canal, which surrounds the œsophagus within the arterial ring; secondly, of a calcareous (or shell) canal which rises from a point on the ring canal to the dorsal (or anal) side of the body, and terminates in a peculiar shield, the madreporic plate, which is perforated by numerous pores. In the *Holothurida*, where the body is elongate, the shell canal does not reach the posterior end of the body, but terminates freely in its cavity, sometimes in one, often in many tubes, each of which terminates in a madreporic plate. The peripheral system consists of five vessels, which arise from the ring canal, and run at equal distances along the interior face of the body-walls (on the medial line of the arms in *Asterioidea*), and send branches right and left. These terminate in a large hour-glass-shaped sac on each side in *Asterioidea*, the "ampullæ," or in numerous smaller ones in *Holothurida*. These project through pores (ambulaera) between the plates, hollow processes which frequently are enlarged as a wart at base or end, and which are used as feet. They are regularly arranged in bands in *Asteriida* and *Echinida*, but in some holothurians are distributed in patches (*Psolus*) or all over the body, or in two kinds—one dorsal, the other ventral (*Holothuria*). They are retractile and protrusible by erection. The interior of the water-vessel system is covered with cilia. In all the classes the œsophageal ring communicates with "Poli's vesicles," small bladders situated round its circumference.

In *Mollusca* and *Articulata* the arterial and venous vessels are not universally continuous at their extremities by capillaries, as in *Vertebrata*, but the circulating fluid is emptied into cavities of the connective tissues or lacunæ, whence it is taken up by the extremities of the veins by suction. In some of the highest forms of both (*Cephalopoda*, *Pedipalpi*) the capillary vessels are numerous. The prominent peculiarities of the classes in respect to circulation may be indicated as follows:

A. No distinct central organ or vascular system.

a. No lacunary canals; liquid moves in continuous inner continuity of body, without definite direction and with doubtful external orifice: *Bryozoa*.

aa. Vessel-like lacunary system; five large sinuses; post-abdominal and foot largest; anal (annular) throat and buccal smaller; two mantle-edging vessels: *Scaphopoda*.

AA. A distinct heart.

a. Neither arteries nor veins; no chambers to heart; a system of canal-like lacunæ decussating from a dorsal and ventral principal; one through the gill-sac, and with fine body ramifications, continuous with each other; two (sometimes more) from heart: *Tunicata*.

aa. A venous system.

No branchial auricle or gill-hearts; one ventricle, and a false heart on each mantle artery; a venous system: *Brachiopoda*.

One branchial auricle; no gill-hearts; one branchial artery; ventricle embracing the intestine: *Gasteropoda*.

Two branchial auricles; no gill-hearts; two branchial arteries; ventricle embracing intestine: *Acephala*.

Two branchial auricles, and two hearts or expansions on the two branchial arteries; a circulus cephalicus; ventricle not embracing intestine: *Cephalopoda*.

aaa. No venous system, or a rudiment rarely; branchial veins and arteries: *Crustacea*.

AAA. No distinct heart; a longitudinal dorsal sinus, more or less subdivided.

a. No pulmonary arteries or veins; no venous system: *Insecta*.

aa. No venous system; a pulmonary artery and vein: *Arachnida-Araneæ*.

A venous system: *Arachnida-Pedipalpi*.

In *Acephala* and *Gasteropoda* the ventricle receives the contents of certain veins direct, without aëration in the gills; hence the blood forced into the aorta is, as in most reptiles, of a mixed character. In *Cephalopoda* all the venous blood passes through the gill-hearts and gills, and is oxygenated before returning through the auricles to the ventricle. In a few *Gasteropoda* there are two auricles, as *Haliotis*, *Fissurella*, *Chiton*. In a few *Acephala* (as *Ostrea*) the ventricle does not embrace the intestine.

In *Gasteropoda* the vessels of this system form extensive ramifications in the foot. They have, moreover, communication externally by pores, which enables them to absorb large quantities of water. By means of this water-vascular system the foot is inflated, as in erectile tissue, to a size which would forbid its withdrawal into the shell were it not for the power of expulsion of the water.

Among *Arthropoda*, the decapod *Crustacea* and the pedipalp *Arachnida* only possess a complete circuit with veins and capillaries. In the former the heart sends two aortas forward and two backward; the larger (inferior) of the former is the aorta cephalica, and supplies the head; the two posterior are the aortæ abdominales superior and inferior. A large sinus in the bottom of the anterior abdomen gives origin to the branchial arteries. In *Myriopoda* the dorsal trunk gives off a pair of lateral trunks to each segment of the body. From the anterior section of the dorsal trunk in *Chilopoda* the lateral arteries unite beneath the œsophagus, and give rise to a longitudinal vessel which accompanies the abdominal nervous axis. In insects the lacunar currents of the body are four principal ones—i. e. one beneath the dorsal trunk, one along the nervous chain, and one along each side. The blood also circulates outward in the tubular ribs or nervures of the anterior part of the wings, and returns along the posterior.

2. In *Vertebrata*.—In the fishes generally the heart is the right or venous heart (except in *Dipnoi*), but always there are vessels passing directly from the gill-veins into the aorta, whether the gill-veins return arterial blood to the ventricle (making mixed blood) or not (leaving venous blood). The first case occurs among *Dipnoi*; the second in *Monopterus* (apodal). In *Amphioxus* the usual trunk-like divisions of the heart are blended into one chamber. The gill-artery is rhythmical, pulsating, as also the origin of the special gill-arteries; so also is the portal vein, which has the same peculiarity in *Myxine*.

The aorta often forms no distinct isolated circulatory trunk. Sometimes arterial blood passes through a cartilaginous canal, which inwardly is only isolated by perichondrium, as in *Acipenser* and *Spalularia*. In other fishes it is also not isolated, but with its dorsal face (on which an elastic longitudinal band runs) let into the vertebral column (*Esox*, *Salmo*, *Silurus*, *Alosa*, etc.). Many arteries subdivide minutely into retia mirabilia, then continue from the reunited vessels. The arterial blood of the *Chorioidea* of most fishes must pass through such structure twice before passing into its branches.

In the venous system, not only in the veins that pass to the liver, do the stems lose themselves in capillaries, in order to be again collected into one or more trunks to go to the heart, but in many fishes this structure prevails in most of the veins of the body. The vena caudalis and the intercostales very often subdivide minutely and mix with (or surround) the renal, suprarenal, and other arterial glandulariform bodies, before they return to the veins for the heart. Many veins of walls of the trunk, of the swim-bladder, and of the generative organs appear as roots of the portal system. These structures delay and prolong the venous circulation.

Stagnation of venous blood-currents is common, also blind closings of veins and obliteration of connecting trunks; and at certain periods the so-called "blood-corpusele-holding" cells and membranes are met with—e. g. in the kidneys.

In *Leplocardi* the portal heart is behind (above) the colon; it pulsates from behind forward. It bends sharply forward, and enters into the gill-artery heart, taking up the venæ cavae during the curve. The gill-artery heart is straight, equally thick, its cavity without the pericardium longitudinal in the median line, beneath the whole length of the gill membrane. From it emerge regularly (alternating as beginnings of the gill-arteries) small contractile bulblets in the intervals between the pointed arches of the gills. From the latter the blood is transferred into a dorsal contractile aorta through the gill-veins. Independently of what passes through the gills, a part of the blood is led directly into the aorta by two contractile arterial bows (one on each side of the posterior end of the oral cavity), which issue from the gill-artery heart. These aorta-bows exist also in *Amphipnous*, where each gill-arch that does not bear a gill contains an arterial bow. In *Monopterus* one-fourth the blood passes the gills and traverses an arterial bow in the fourth gill-less gill-arch. The portal-vein heart extends the whole length of the intestine. It pulsates from behind forward, with pauses (as in the gill-heart) of about a minute. The venæ-cavae heart is on the dorsal side of the intestine, from the anterior point of the colon, increasing posteriorly to the end of the colon, where it suddenly turns over into the gill-artery heart. Its contraction alternates with that of the inferior or portal-vein heart. This colon (which is green) is equivalent to the liver, and gives blood to the venæ-cavae or portal heart. On each side of the aorta, on the upper arches of the gills, is a

vena cava descendens, which meets a posterior vein (vena cava ascendens), and together they empty themselves into the curve of the venæ-cavæ heart just before entering the gill-artery heart. The blood is colorless.

In *Marsipobranchii*, *Etasmobranchii*, and *Actinopteri* the muscles of the heart are always of striped tissue. The right or venous heart has the following divisions: an auricle receiving the united veins through a sinus venosus, a ventricle, and a bulbus arteriosus.

There are valves between all these. In *Marsipobranchii* the auricle is more roomy than the ventricle, and is separated from the sinus by a membranous double valve; it has two membranous valves in the ostia venosa and ostia arteri-
alia, each. From the latter proceeds the truncus communis branchialis, which is somewhat "bellied" at its origin, but has no evidence of muscular structure.

In *Elasmobranchii*, *Crossopterygia*, and lower *Actinopterygia*, there is a bulbus arteriosus, similar in possessing a ring-like layer of striped muscle-tissue, which ceases abruptly at the boundaries of the gill-arteries, and in numerous valves which are affixed by threads. There are two cross-rows of these in *Chimæra*, *Carcharias*, *Scyllium*, and *Gateus*; three in *Sphyrna*, *Mustelus*, *Acanthias*, *Atopias*, *Lamna*, *Rhinobatus*, and *Torpedo*; four in *Hexanchus*, *Heptanchus*, *Centrophorus*, and *Trygon*; four to five in *Raja*; five in *Scymnus*, *Myliobatis*, *Pteroptatea*, and *Squatina*. There are nine in *Polypterus*, each of which contains three complete and some abortive valves; there are fifty-four to sixty in *Lepidosteus osseus*. In *Amia* there are but three rows; the two inferior, in the bulbus, with two large and two small valves; the superior with only two.

In most *Actinopterygia* there is no striped muscle-tissue on the outer layer of the bulbus, but an elastic material of thread-bundles, which is produced into pillars on the inner side. There is one pair of valves at the ostium bulbo-ventriculare; between these are sometimes one or two smaller adjoining valves. The only exceptions are species of *Butyrinus*, where there are four valves in two rows, with no muscular bundles round the bulbus. In sharks, *Crossopterygia* and lower *Actinopterygia*, there is a pair of valves at the ostium sino-auriculare, often attached by strong threads. In *Acipenser* there is a ring-like valve in two parts—one with four, the other with five pockets, each one attached by a strong thread. The large, expansible, thin-walled auricle has usually on one or two sides an auricula. Within it are numerous trabeculæ carneæ. The ventricle is on the abdominal side of the auricle. The latter in passing over it is narrowed sometimes (e. g. in *Petromyzon*) for some length. There are usually two valves in the ostium arterio-ventriculare, sometimes four in *Orthogoriscus* and *Acipenser*.

The heart's position is usually between the claviculæ, but in *Apodes*, and particularly in *Symbranchii*, the heart is more posterior. In sharks it lies in its sac immediately under the elongation of the copulæ of the gill-arches, which pass through the cartilago subpharyngea impar. In *Petromyzon*, with the pericardium, it lies in a sort of incomplete capsule, which is separated from the gill-cavity by muscles forming a kind of diaphragm.

The heart-capsule (in all fishes except *Leptocardii*) is fibrous, is attached to the bulbus arteriosus, and often sends thread-like processes to the heart proper, which are often tendinous, sometimes accompanied by blood-vessels, as in *Anguilla*, or are blood-vessels only, as in *Acipenser*.

In *Dipnoi* the auricle is externally one, internally divided by an incomplete septum. Into the left auricle enters the vena pulmonalis, at whose entrance is placed a semilunar valve. There is no valve at the ostium atrio-sinuum. From both auricles the ventricle is entered by a common ostium, which has a valve. The ostium possesses a papillar muscle, which is bound with a thread-cartilage which closes the ostium during systole. The bulbus arteriosus (without valves at its origin) forms a curve. It contains two lateral, longitudinal spiral foldings of different lengths, which fade away at their extremities.

In *Podopterygia*, on the upper surface of the heart, are numerous bottle or vesicle shaped elevations, which are of different sizes in different or in the same animal, sometimes large, sometimes almost wanting. A varied number of arterial vessels from the subelavia and mammaria penetrate the heart-sac and distribute themselves to these elevations, which have various arrangements. These surround bladders which involve their entering arteries in rosy, spongy tissue composed of granules and meshes of fiber and cells containing granules. Vessels enter the heart from the bases of these.

In general, on the trunks, except in the *Leptocardii*, from the anterior extremity of the bulbus arteriosus (which is external to the heart-sac), there issues an incontractile "gill-artery trunk," from which on each side issue directly or indirectly, through other communicating trunks, the branchial arteries.

In myxinoids the truncus communis branchialis is variable, running in a membranous cavity which surrounds the anterior end of the ventricle, and projects into the membranous pouch that envelops the gill-sac. Each gill-sac contains an artery which forms a circle at the entrance of the gill-branches, and sends off radiating arteries. In *Petromyzon* four arterial branches on each side leave the truncus communis branchialis, which divides anteriorly into two trunks, each of which divides into three arteries, and an anterior twig is sent to the anterior row of gill-lamellæ. The special branchial arteries pass (except the first and last) between the two gill-pouches, and give their branches through diaphragms to the gill-arches.

In *Etasmobranchii*, from the truncus branchialis communis there issue on each side one or two trunks, each of which afterward divides into two. In *Raja* and *Pristis*, where one goes off, it divides into three, and the terminal portion into two. In *Pristis* the first of the three runs forward to the trunk in the cartilage, and is taken up by it. The special branchial arteries issuing from the primordial trunks pass between the two rows of gill-lamina, which are in separate gill-sacs, a special artery supplying the anterior hyoid gill. In many fishes (*Lepidosteus*, *Acipenser*) the first gill receives the first branch from the arteria branchialis, and the last gill the last branch. In these the branchial arteries run toward the first gill, then bend posteriorly and give off branches successively. In *Spatularia* the first gill receives the second branch, the second gill the first branch, the others regularly. The arrangement in *Amia* is as in the other *Actinopterygia*.

In *Actinopterygia* the gill-artery stem runs forward in a canal beneath the copulæ of the gill-arches, which bound it above; laterally it is bounded by processes of the same; beneath by the culiform membrane (which latter is wanting in *Apodes*).

Often (e. g. in *Satmo*) it gives off first a common stem, which divides to the fourth and third gill-arches; then gives one to the second arch, and one to the first, by the forking of the trunk. But (e. g. in *Murenophis punctata*) two distinct branches of the common trunk can be given to the two posterior gill-arches. In *Dipnoi* two trunks leave the branchial artery on each side: (1) a common vessel for the half gill and the two gill-less "visceral" arches, and (2) a

stem for the posterior gill. The first divides in two, which as aorta-bows unite under the skull to form an aorta-root. The first aorta-bow gives off a branch for the half gill, which sends off the carotid before entering the half gill. The aorta-bow gives off also a posterior carotid before union with the posterior aorta-bow. From the second goes an artery for the fibers of the external gill. The second trunk divides into two gill-arteries for the fourth aorta-bow. The extremities of both become arteries for the outer gill-threads.

FIG. 21.—Brain of *Varanus niloticus*: 1, horizontal section of optic lobes; 2, vertical section.

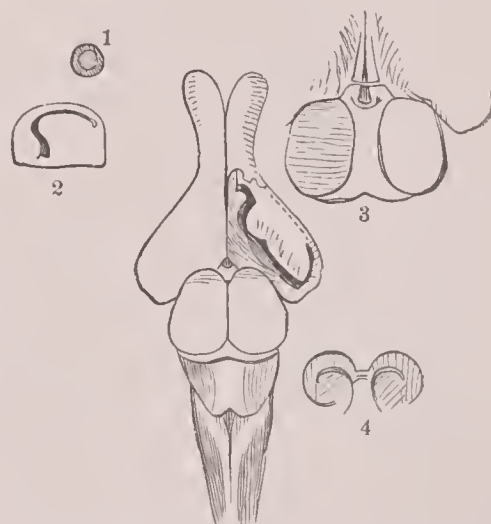

FIG. 22.—Brain of *Dipsas dendrophila*: 1, vertical section of olfactory lobe; 2, vertical section of right hemisphere; 3, vertical section of optic lobes; 4, transverse section of lobes.

The last gill-artery from its upper extremity gives off a branch for the posterior half gill.

The gill-veins unite (in the absence of an arterial heart) for the construction of the great arterial trunk. But often arterial trunks for the body go immediately from the gill-veins. The carotid arteries leave the gill-veins. In myxinooids the gill-veins, after leaving the gill-sacs, form a median trunk, which is prolonged posteriorly as an aorta and anteriorly as an arteria vertebralis impar. All or most of the gill-veins are connected by a trunk running parallel to the aorta, which is continued anteriorly as the arteria carotis communis. Both carotids accompany the oesophagus forward, giving branches to it and to the hyoid region. Each divides behind the head into the arteria carotis externalis (for the tongue and the muscles of the head), and the arteria communis internales, which unite, forming a bow, at the origin of the vertebral column, which receives the vertebralis impar; from the latter originates a median head-artery, which, extending anteriorly, gives off branches for the nose, etc. In *Petromyzon*, with the exception of the first and last, each gill-vein issues from the interstitium between two adjacent gill-sacs. There is no arteria vertebralis impar. The carotis communis rises from the first gill-vein, which sends another branch to the formation of the aorta. Each carotid divides into an external and internal; the two internal carotids do not unite to form a median head-artery.

FIG. 23. — Tubular follicle of the pig's stomach.

In other fishes each gill-vein originates from the two connected "gill-leaf rows," except those from the two half gills. In *Elasmobranchii* all or most of the gill-veins come together to form the aorta, either immediately or after the union of some (thus forming homologues of the aorta roots).

The arrangement of the carotids is various. In *Chimæra* the first gill-vein from the half gill forms the posterior carotid; the second, which like the rest contributes to the aorta, sends off the carotis anterior. In *Raja* the posterior carotid originates from the aorta-root which is formed by the union of the two first gill-veins. It runs in the canalis spinalis. The carotis anterior originates from the vessels of the pseudobranchiæ of the spiracle. In *Chimæra* and *Rajidae* the posterior carotids remain ununited; wherefore no anteriorly united circulus cephalicus exists. In the sharks they run under the base of the skull, and unite and give origin to the cerebral artery.

In the *Teleostomi* there are various arrangements of the gill-veins in the formation of the aorta. The carotids are as in *Elasmobranchii*. (See *Raja* above.) In *Lepidosteus* there is a third cerebralis from near the origin of the aorta. In it the union of the anterior gill-veins is the origin of the aorta. The second pair unite below this, and forming a thicker trunk receive the first aorta. The third pair unite below the union of the second pair and the aorta origin, and forming a still thicker trunk, receive the second stem, all forming three steps in profile. The sections would be—first \circ , second z , third z . The posterior carotid comes off anteriorly to the mouth of the third pair of gill-veins. The subelavians are vessels disproportionately large; they come off on each side a little behind the embouchure of the posterior gill-vein tube, take the place of the cœliac and superior mesenteric arteries, and send a branch to the stomach, which does not give a strong branch to the spleen, but approaches the pylorus as a bundle of little vessels. In *Actinopterygia* a complete arterial circle (circulus cephalicus) is formed by the gill-veins without the cavity of the cranium. The gill-veins of each side unite to form the commencement of the aorta, and run together anteriorly as the sphenoidium, through a cross anastomosis. This circulus can be wider or narrower. It is the former when all the gill-veins of each side unite into the aorta-bow, and where both bows are connected anteriorly by a cross trunk, and unite posteriorly to form the aorta, as in *Gadus* and *Lota*. It is narrower when each of the bows forming the aorta is formed from the anterior gill-veins only, and where the hinder gill-veins enter the aorta; e. g. *Scomber*, *Salmo*, etc. The aorta is sometimes independent, free, entirely surrounded by strong tissue, as in most *Actinopterygia*, sometimes in a canal of the processes of the vertebræ, without the usual distinct trunk-envelope; sometimes it is in a canal inferior to the vertebral

column, with the superior surface thin walled. The commencement of the aorta, in which the gill-veins empty, is under the cranium, first inclosed superiorly by the basilar cartilage. A short section is enveloped below by a fibrous membrane, but soon it is inclosed beneath by the vertebral arch elements, which are arched upward and supplied with intervertebral cartilage. Along the whole length of the aorta-canal there runs in its cavity, from the base of the skull, an elastic band which adheres above to a skin-fold whose continuation as a very thin perichondrium lines the inner side of the canal, to which it closely adheres.

In the *Elasmobranchii* and many *Actinopterygia* the aorta is embedded in a gutter of the vertebral bodies. On the side of this there are (in *Esox*) fibrous longitudinal ridges. In these the aorta possesses an external skin on the inferior surface only. It appears from point to point swollen with sinuses. Each such swelling is separated from that succeeding by a contraction. There is a small cross bridge of thread tissue within from one lateral ridge to another. Within the canal is found (in *Esox*, *Clupeidæ*, *Salmonidæ*, *Silurus*, etc.) a fibrous longitudinal elastic band, as in *Acipenser*. It commences at the skull beneath, and extends along the whole vertebral column. As an immediate continuation of the basis of this is the elastic artery-envelope. Although in *Plectospondyli* the aorta is more isolated from the vertebral column, and the fibrous longitudinal band is absent, it yet exhibits sinuses in regular position. When the aorta is free it does not always run under the median line; in *Belone* it is on the left side.

In *Reptilia* and *Batrachia* the aorta is formed of two roots (which do or do not result from more than one pair of aorta-bows) from the bulbus arteriosus, and which embrace the oesophagus. A ramus communicans anterior exists between the carotids. Branches of the aorta either become intercostal arteries, or enter the intervertebral foramen for the spinal canal.

The *Batrachia* have a carotid from each anterior aorta-bow, and a pulmonalis from each posterior aorta-bow. In all *Urodela*, aorta-bows, either united or directly or indirectly issuing from the bulbus arteriosus, contribute to the formation of an aorta-root by the perennial rami communicantes on each side. The *Trachystomata* agree with fishes in the arrangement of the greater vessels. The bulbus arteriosus upon issuing from the ventricle makes a bend to the right side, and is thereafter in its longer portion straight. At its fore end three arches on each side issue, which are functionally gill-arteries. Through the union of three corresponding gill-veins into one stem an aorta-root arises, two of which form the aorta. The anterior gill-vein sends out a carotid, the hinder a pulmonic artery. The *Proteida* have the system differently arranged. The bulbus is divided into two diverging branches, each of which results in two aorta-bows. The anterior follows the first gill-vein; the second divides in two, of which the anterior follows the second gill-vein; the posterior the third. Each of the two aorta-bows proper consists of an uninterrupted continuation and a respiratory portion. The third bow wants the direct continuation. Each of the three respiratory portions consists of a gill-artery, intermediate respiratory vessels, and a gill-vein. The two anterior gill-veins of each side empty into the continuation of the original aorta-bows. The third gill-vein passes over into the continuation of the second aorta-bow. The continuation of the two primitive aorta-bows and the second and third gill-veins forms an aorta-root. The point of confluence of the aorta-roots lies over the heart. The anterior vessel which results from the union of the continuation of the anterior aorta-bow and anterior gill-vein has two branches—an arteria hyoidea mandibularis and a carotis interna anterior. Each aorta-root formed from the second aorta-bow possesses a posterocephalic elongation forward, which gives off a carotis posterior, and forms the commencement of an arteria vertebralis. The aorta-root gives off posteriorly a visceral artery, which, after branching for the oesophagus, is destined to become a spermatica interna. From the single aorta proceed subelavian arteries, which are continued as the epigastric, gastric, cœliac, many small mesenteric, renal, and symmetrical iliac vessels. Besides, there are pairs of dorsal arteries, which pierce the transverse processes on each side, and emerge in the longitudinal vertebral artery. In *Cryptobranchus* four vessels on each side go directly from the bulbus arteriosus. They follow the gill-arches. The anterior finally becomes the carotid. The two middle vessels form the aorta-root, and, after giving off branchlets for the head, unite close behind the cranium.

The fourth vessel bends over the œsophagus, gives it branches, gives a branch to the third aorta-bow, and becomes the pulmonary artery. In *Salamandra* the bulbus arteriosus gives origin on each side to four aorta-bows with three mouths. The three posterior bows on each side form aorta-roots which are prolonged anteriorly. The union of both bows into an aorta occurs behind the skull, beneath the first vertebra and above and before the heart. The carotis divides into the cerebral and occipital. An obliterated continuation of the anterior aorta-bow, binding it to an aorta-root, is called ductus Botalli. The fourth aorta-bow, whose mouth is that of the third, sends off a visceral artery which gives branches to the pericardium and œsophagus, and becomes the pulmonalis. The aorta is under the vertebræ, and descending gives off the subclavian and intercostal (in pairs), the gastric, cœliac, mesenteric, and numerous renals. Between the kidneys go off the iliaes (which give off the femoralis and epigastrica), and a cloacal branch which is continued as a caudal artery.

In the *Salientia*, on each side are three bows, of which the foremost and hindmost do not contribute to form the aorta-root, which is a continuation of the middle bow. It unites with that of the other side far posteriorly. Two pipes issue from the bulbus. There is one semilunar valve at the base of each. Each of these vessels is internally divided by two partitions into three canals, and each partition is prolonged to the wall of each issuing vessel. At the farther end of the anterior of these canals is an enlargement (carotid tumor), from which issue the arteria hyoidea (lingualis) and the carotid. The middle canals form the aorta-roots. The right is large, but the left small, after giving off the cœliaco-mesenteric artery, which is so large as to appear like its proper continuation. The third canal gives off two branches. The first, after giving branches, becomes a strong cutaneous vessel, which, with its accompanying vein, running between the levator and anterior adductor muscles of the humerus, gives off branches to the integument of the whole back. The second branch is the pulmonary. Each aorta-root before their union gives off other branches to the larynx, œsophagus, and shoulder; also a subclavian and a supraver-tebral artery, which runs longitudinally, crossing the diapophyses, and giving a branch to each intervertebral foramen. The left root also gives off a cœliaco-mesenteric artery. The descending aorta gives branches for the kidneys and generative organs. To the two latter go five and six vessels. Each gives a branch to the kidney on one side and to the genitals on the other. Division into common iliac arteries then takes place. *Cæcilia* has a long muscular bulbus, at whose narrow origin are valves. The cavity is divided by a septum at its anterior extremity into dorsal and ventral chambers. The dorsal terminates in the arteria pulmonalis for the lung; from the ventral proceed two aorta-roots, each of which near the trachea reaches to the hyoid apparatus, and forms a bow behind the skull, from which the carotids proceed. The union of the aorta-roots is hypaxonic, above and a little before the heart. Each root gives off intervertebral (mostly obliquely directed forward) and vertebral arteries.

In *Reptilia* there is a completed form of heart. The division of the auricles is externally visible. The division of the ventricles is partial or complete. In embryonic forms the position of the heart is near the gill-slits. This state is characterized by the presence of several aorta-bows which embrace the œsophagus, and form the aorta-roots by successive obliterations of most of the aorta-bows and their connecting anastomoses. There is a ductus Botalli, so that each aorta-root is permanently formed, either through confluence of two aorta-bows, or it is a continuation of a single trunk.

In *Lacertilia*, *Ophidia*, and *Testudinata*, in the ventricle are found fleshy columns of various sizes, which inclose spaces opening into a common cavity. The septum ventriculorum (more or less incomplete) is connected to the sides of the ventricle by tendinous or fleshy cords. The left ventricle is narrower, more dorsal, thick walled, communicating with the left auricle; the right is broader, straight, ventral. That into which arterial blood enters, and which, as regards its position, is homologous with the left ventricle, is called the cavum arteriosum; the right is the cavum venosum. No trunks arise from the first. From the cavum venosum there issue by three ostia the arteria pulmonalis and two trunci arteriosi, each ostium having three semilunar valves. The space between the orifice of the arteria pulmonalis and those of the trunci arteriosi is the originating point of a flap or muscular valve which ex-

tends toward the right border of the ventricle. This divides the cavum venosum into two incomplete cavities, an anterior and posterior, which are completely separated by the systole, during the latter part of which it shuts the entrance to the arteria pulmonalis. A simple bulbus arteriosus is wanting, but its place is supplied by the confluence of the bases of the three great vessels, which are then separated by simple walls. This arterial trunk, containing a cone, is covered by the pericardium, and wants (except in some *Testudinata*) the striped muscular walls.

In *Lacertilia* the heart is not far removed from the hyoid region. It is farthest in *Amphisbæna*; next farthest in the *Varanidæ*. Among *Varanidæ* the septum atriorum is nearly complete, except near the ostium venosum dextrum. Among *Pachyglossa*, *Geconidæ*, *Chalcididæ*, and *Scincidæ*, the septum is very incomplete. The walls of the great vessels are united near their origin. A peculiarity of most *Lacertilia* is that each aorta-root takes up the common carotid from an arterial trunk which originates afterward, so that each aorta-root is formed by the union of two aorta-bows as follows: The trunci arteriosi continue, the right as an aorta-root, the left the same after giving off the truncus impar, which divides into the carotids. Each of the latter gives off near its basis an outward directed arterial bow, which empties into the aorta-root of its side. It constitutes thereafter a primitive aorta-bow, whose original branches are the carotids. This occurs in (1) *Scincus*, *Anguis*, *Pseudopus*, *Lacerta*, *Ameiva*, *Platydactylus*, *Uromastix*, *Iguana*, etc., and the aorta-bows from the truncus impar are obliterated, while they are utterly wanting in (2) *Varanidæ*, *Chamæleonidæ*, *Amphisbæna*.

The heart of serpents is far removed from the hyoid region, and the form is elongate. The end of the pericardial sac appears confluent with the serous lining of the thorax. The cavum venosum arteriosum is always incomplete. The walls of the three arterial trunks are separate, as far as is known. The left trunk continues as the aorta-root without branches; the right gives off the coronaries, etc.; then, where it turns itself posteriorly, a subvertebral anterior branch; then numerous intercostals.

The truncus caroticus impar divides into two arteriæ carotides communes, of which the right is scarcely visible in some species; but when visible it may be smaller than, equal to, or larger than, the left.

The *Testudinata* have the heart broad, abbreviated posteriorly, and widely removed from the hyoid apparatus. The outer sac of the pericardium is attached to the end of the ventricle by a band which incloses the portal vein. The valve, stretching to the right wall of the ventricle, is in some furnished with an ossified cartilage. The walls of the three trunks are slightly united near their origin, forming a bulbus, which in *Emys europæa* is surrounded by a ring of striped muscle-tissue. The truncus dexter soon after its origin gives off a short anterior arteria innominata, which gives off the carotids and subclavians. The truncus sinister gives off (before union with the dexter) the cardiac branch for the heart and œsophagus; also the gastro-epiploica and mesenterica. After these branchings the aorta-root is narrow. From each side the neck there runs to the rump, over the diapophyses in the canal covered by the carapace, a trunk, which, besides the intervertebralis, gives off arteries analogous to the intercostals. The continuation of this is a caudalis, superior to the diapophyses. The intercostals of each side open into a lateral longitudinal trunk, which communicates anteriorly with the subclavian, posteriorly with the iliac vessels. From the aorta proceed symmetrical spermatic, suprarenal, iliac, renal, and hypogastric vessels. It is continued as the caudalis inferior.

The *Crocodylia* have a complete septum ventriculorum; the right ventricle anterior; each ventricle emitting its respective truncus arteriosus. There is an opening connecting the trunci arteriosi (which corresponds to the bulbus arteriosus), by which arterial and venous blood are mixed. The heart is over the sternum; the left ventricle is thick walled; the right more capacious, reaching to the apex. The right contains a muscular fold which is stretched

FIG. 24.—Lobule of parotid gland magnified.

from a septum behind the origin of the pulmonary artery to the outer wall. It has two valves at each ostium venosum. From the left ventricle issues the truncus arteriosus dexter; from the right ventricle the truncus sinister and pulmonalis. These two trunks are separated at their origin by a common septum; at the origin of each are two semilunar valves. The walls of all three are united between the trunci arteriosi near the semilunar valves. Before uniting, the trunci arteriosi give off the dexter truncus innominatus and subclavia dextra. From the truncus arteriosus sinister, near its union with the dexter, issues the cœliac artery; it then becomes much narrower. The common carotid divides near the head into two branches. Besides these there are other branches to the larynx, neck, tongue, and other parts.

In *Aves* (birds) the septum ventriculorum is complete. The heart's position is in the middle line of the thorax, its axis parallel with that of the body, its apex between the lobes of the liver, the heart-sac attached to the membrane of the lungs. The auricular appendages do not project, but are tightly drawn down. The right auricle is stronger and with larger appendages than the left. They have comb-shaped muscular columns or ridges. Into the right auricle empty the venæ cavæ. At the mouths of the veins are weak muscular flaps which are attached to the pectinate muscles, whose contraction assists the passage of venous blood into the right ventricle; the fœtal foramen ovale is closed. The chambers of the ventricles are not very different in size; they do not reach the apex. The septum is very convex into the right chamber. The orifice of the right ventricle is closed by a very strong muscular valve as thick as the outer wall. It is strongest in *Natatores*, weakest in *Cursores*, especially in *Apteryx*, where it is almost membranous, and is attached by its free borders by short chordæ tendineæ to the wall of the ventricle. Its free border in most is turned toward the convex septum, to which it is closely pressed in systole, thus preventing regurgitation. It is opposed by a second very weak muscular valve. At the origin of the pulmonalis are three semilunar valves.

From two low ridges at the orificium atrio-ventriculare sinistrum proceed usually numerous tendinous threads, which attach themselves to two or three valves which correspond to the mitrals. Three semilunars are found at the origin of the aorta. The boundaries of the left ventricle are nearly three times the thickness of those of the right. The left auricle has numerous and complicated muscle-bundles: it receives two pulmonic veins through one ostium. There is a valve-like muscular process whose free border is turned to the cavity, and apparently directs the blood to the ventricle. The single aorta, giving off immediately the coronaries, very soon divides; the truncus arteriosus has a branch which is either the innominata or subclavia. In the latter case there is a common carotid. It continues as aorta descendens on the right side of the vertebral column. The left arterial trunk is an innominate or a subclavian. Either each innominate furnishes its common carotid, which is most usual, or the left or the right furnishes a truncus carotieus impar. Examples of the first kind are furnished by all *Natatores* (except *Podiceps*); of the second by many *Insessores*, and some of the *Cursores*; of the third the *Phœnicopterus* furnishes the only example. In *Botaurus stellaris* both aortas unite on the neck. Sometimes one of the two carotids runs laterally and superiorly on the neck (e. g. *Psittacus chrysotis*). They run in the whole length of the canal, beneath or in front of the vertebral processes. From each originates a vertebral artery, which does not form the basilar, which results from the union of branches of the cerebral carotids; and after giving off branches finally results in the arteria spinalis anterior. When one truncus carotieus only exists, the vertebralis of the imperfect side originates from the subclavian. Sometimes (in *Anas boschas* and *Ciconia nigra*) the vertebralis continues itself downward in the canal of the rib attachments as the common stem of the intercostales. From the aorta descendens arise more or less numerous intercostales and lumbales, a strong cœliaca, then a mesenterica superior (both penetrating the diaphragm in *Apteryx*), afterward renals; from which branches for the generative parts proceed. Next are two crurales, each giving off an epigastrica. Each results in the ischiadica, which descends to the knee. The sacra media usually gives off the renales posteriores, the mesenterica inferior, two lateral pudendæ internæ, and the hypogastricæ. Finally, it produces the vascular network on the breast and abdomen

which is devoted to the panniculus adiposus laid bare by the shedding of feathers during incubation.

In *Mammalia* the heart is unattached by cellular tissue to the diaphragm, except in man, the higher apes, and *Cetacea*. It is straight (except in man, the higher apes, and *Talpa*), has two ventricles, and the foramen ovale is always closed. The ventricles are externally separated (in part) in *Sirenia*. It has a valvula tricuspidalis; in *Ornithorhynchus*, a transverse muscular valve of the right ventricle, as in birds; the valve in *Echidna* is membranous, has a large tuberculum Loweri,* and no Eustachian valve (in *Felis*, *Canis*, *Ursus*, *Phoca*, *Gulo*, *Mustela*, *Procyon*, *Talpa*, *Halmaturus*, *Equus*, *Sus*, and *Ruminantia*). There is no tuberculum, but there are two semilunar valves to the vena cava ascendens in *Didelphis*, *Dasyppus*, *Hystrix*, *Cavia*, *Lepus*, *Sciurus* (in *Sciurus maximus* a trace of the tubercle). No Eustachian valve, but a cross-band below the fossa ovalis, with filamentous muscle-processes in *Myrmecophaga* and *Bradypus*. It has a Eustachian valve and weak tuberculum Loweri in man, many apes, lemurs, *Lutra*, etc. Both valve and tuberculum are wanting in *Ornithorhynchus* and *Delphinus*.

In many ruminants and perissodactyls in advanced age there is a single or double bone in the septum atrio-ventriculare, and occasionally in *Equidæ* in the septum opposite the ostium venæ cavæ ascendens. The aorta-stem at its root is single and curved to the left; it soon gives off coronales (one only in *Elephas*). Its branches vary; e. g. (1) A short aorta divides into an anterior (superior) and posterior. (2) The aorta superior gives off a subclavia sinistra, and continues as the truncus carotieus, or divides into a truncus carotieus and both subclaviæ; in *Equidæ* it also gives off the vertebralis dextra. From the aorta-arch originate the innominate giving off carotides subclavia dextra and subclavia sinistra in most *Marsupialia*, in *Rodentia*, *Edentata*, *Carnivora*, *Sorex*, *Halicore*, *Auchenia*, *Sus*; in which last the two carotids spring from a truncus impar vel primus. (3) In other cases two trunci innominati alone are given off, as in *Chiroptera*, *Talpa*, *Phocæna*. (4) The aorta gives off a truncus anonymus dexter, carotis sinistra, subclavia sinistra (as in *Monotremata*, *Phascolumys*, and *Bradypus*, *Dasyppus*, *Cyclotura didactyla*, all *Muridæ*, *Erinaceus*, *Phocidæ*, many *Quadrumana*, man, etc.). (5) Two subclaviæ arise, with a truncus carotieus impar between (*Elephas*). (6) Besides the above subordinate arteries from the aorta are thoracica interna sinistra and dextra from innominate dextra in *Phocæna* and *Halicore*. In some plunging animals occur widenings of the aorta (*Lutra*, *Phoca*, the young of *Delphinus*, *Monodon*, etc.). The common carotids have their length proportioned to that of the neck. In the short-necked *Delphinidæ* there is none, both carotids springing from the innominate. It is often divided into two (facialis and cerebralis). The cerebrales enter as single trunks into the cranium in *Quadrumana*, *Chiroptera*, *Insectivora*, *Rodentia*, *Marsupialia*, *Equidæ*, and some *Carnivora*, as *Ursus*, *Lutra*, *Canis*, *Mustela*, or pass through a rete mirabile (*Phocæna*) formed of branching trunklets, or springs from a rete mirabile formed from its origins (*Ruminantia*, *Suidæ*, *Felidæ*). When without retes the cerebrales have various points of origin. The retia mirabilia of the *Delphinidæ* (with artery traversing) are principally formed from the branches of the carotis interna, yet are closely connected with retia lying outside the cranium, formed of branches of the carotis externa and cervico-occipitalis. The rete of each side always communicates with that of the other. The always present circulus Willisii is formed either partly in the cerebrales and partly by division of the basilaris, or through the cerebrales and divided basilari-occipitales or only by the cerebrales. There are still other modifications of the circle of Willis. In many *Edentata*, and in *Stenops* and *Tarsius*, the arm-arteries possess many retia mirabilia (*Dasyppus sexcinctus*, etc.). In *Bradypus* and *Stenops* the trunk of the brachialis passes through many embracing extended arterial vessels. In *Cyclotura didactyla* and *Tarsius*, the artery empties itself into these; in other cases they are confined to the forearm.

The aorta thoracica of most *Mammalia* is peculiar in not giving off immediately the intercostales. In *Mustela* there springs from it at the extremity of the chest a trunk (which divides into two vertebrales), from which the arteriæ intercostales issue. In the *Delphinidæ* there are two descending arteriæ thoracicæ internæ (or mammariæ internæ), which arise, the left from the arcus aortæ, the right from the innominate dextra, which give off the five anterior inter-

* A process separating the mouth of the vena cava descendens from the vena cava ascendens in the right auricle.

costales. The branches of the aorta abdominalis are usually the phrenicæ inferiores, suprarenales, renales, spermaticæ internæ, lumbales, the cœliacæ, the mesenterica superior, and the mesenterica inferior. The cœliacæ and mesenterica superior are one stem in *Cavia cobaya*, or originate as one and soon divide (*Talpa* and *Vespertilio murinus*), or originate separately, but connect by strong anastomoses (*Phocæna*). The mesenterica inferior often is trifling, in *Marsupialia* and *Monotremata* wanting. The arteriæ iliacæ communes (so called) seldom are homologous with those of man. In *Cetacea* they correspond generally with the hypogastricæ. They give off the epigastricæ, which otherwise come from the crurales. In most *Mammalia* they are homologous with the crurales, since not from them, but from a continuation of the aorta, are given off the hypogastricæ, or at least vessels which rise in *Homo* from the hypogastricæ. So in *Monotremata* and *Marsupialia* the ischiadicæ, and in many others the sacra laterales, spring in pairs from the aorta beyond the iliacæ communes. In some, with strong skin-muscle or skin-system, from the crurales arise large musculo-cutaneæ, which anastomose with similar descending branches of the axillares (*Erinaceus*). The division of the eruralis is higher or deeper than in *Homo*. In the posterior extremity of the *Phocidæ*, in many *Edentata*, and *Stenops* are retia mirabilia, which are weaker than those of the upper extremity, and the sacra media is a continuation of the aorta; larger in large-tailed animals, running in an inferior vertebral canal, often forming retia (*Stenops*, *Bradypus*, *Myrmecophaga*). In *Phocæna* it passes through retia; sometimes weak (in *Erinaceus*, *Lepus*, ruminants, often in *Equidæ*). There is none in *Manatus australis*, where the aorta forms two hypogastricæ, which lose themselves in two huge retia subvertebralia.

VIII. THE RESPIRATORY SYSTEM.

Apparatus for oxygenating a circulating fluid is wanting in *Protozoa* and *Cœlenterata*. In the other branches its type varies so that a number of distinct systems must be recognized, which are adaptations of as many distinct regions of the body for the purpose of respiration. These may be reckoned as follows:

1. The external pore-system of the *Echinodermata*.
2. The system of diverticula from the alimentary canal of the *Holothurida-Dendropneumones* and of most *Vertebrata*.
3. The gill-system of *Mollusca* and *Crustacea*.
4. The tracheary system of terrestrial *Arthropoda*.
5. The pharyngeal gill-system of *Ascidia*, fishes, and *Batrachia*.

It will, however, be convenient to divide the subject first between the *Invertebrata* and *Vertebrata*.

1. In *Invertebrata*.—The wall of the body of the *Echinida* and *Asteroida* is pierced with a great number of pores, which terminate in blind sacs and are filled with water. In all *Echinoderms* the cavity of the body is filled with water, by which blood is oxygenized. It enters through perforated plates (laminae cribrosæ) situated in the angles of the arms in the *Asteriida*, but the orifices which admit it into the body of the *Holothurida* are not certainly known. In the latter class singular organs called the "slipper-shaped bodies" depend freely from the viscera; their hollow stems are said to contain a blood-vessel; the extremity is like the open end of a short slipper.

The *Holothurida-Dendropneumones* possess an extensive system of branching blind tubes, which form a mass extending throughout the body. They form two bodies, one on each side of the rectum, and open into the latter near the anus: from it they are filled with water. In some *Asteriida* (*Petraster militaris*) five radiating tubes, the one for each arm, issue from the rectum, and are filled and emptied of water from it.

In *Polyzoa* (*Bryozoa*) and *Brachiopoda* we have a somewhat similar arrangement of branchiæ. In the former they form a double crest of tentacular fringes round the mouth; they are hollow, and the circulatory fluid moves through them, as elsewhere in the body-cavity, by ciliary movements on its walls. In *Brachiopoda*, as already stated, there are well-developed arteries. The gills are situated as fringes on straighter and shorter or longer and spirally coiled arms within the shell, one on each side of the mouth. Their position is somewhat like that in the *Polyzoa* when retracted. In hingeless *Brachiopoda* the calcareous arms are wanting, but here the gill supports are cartilaginous. In *Lingula* the inner surface of the mantle is furnished with folds and

erests, which are supposed to aid respiration. In the *Acephala* the arrangement is totally different. The gills are curtain or sheet like (whence the name of this class, *Lamellibranchiata*) and hang two from each side of the body within the mantle. Sometimes their margins are free (many *Monomyaria*, *Mytilidæ*, *Arcidæ*, *Lithodomus*, *Cyclas*, etc.); in others immediately united (*Veneridæ*, *Mastra*, *Donax*, *Unionidæ*, *Pholadidæ*, etc.), or are connected by an intervening membrane (*Solenidæ*, *Cardium*, etc.). The union of the pairs of margins incloses two chambers, one within the other. Each gill-lamella consists of two layers, which inclose tubes and other cavities between them. Sometimes the outer gill lacks one layer, or sometimes the whole gill is wanting (*Lucina*, *Corbis*, etc.). In others its outer lamina is truncated above, so as to expose the ends of the cavities it embraces. The lamellæ of the opposite sides are symmetrical or not, in accordance with the relations of the shell-valves.

The branchial structure in *Gasteropoda* presents many varieties. In the division *Opisthobranchia* the branchiæ and auricles lie behind the ventricle of the heart; in *Prosobranchia* the relative positions are reversed. In the former the branchiæ are variously extended processes of the dorsal integument of the body, each of which is supplied with an artery. In the lowest group, the *Dermatobranchia*, these branchiæ are wanting, and the arteries are distributed for blood aëration beneath the dorsal integument. In the *Placobranchia* they are represented by lateral wing-like expansions of the integument, which may fold over the body. In numerous types the processes are distributed over the body in thread, prism, leaf, and other forms. These are the *Ceratobranchia*; many of the processes contain liver-cells. In the *Polybranchia* the processes are arranged along the back, and are branched or forked, and sometimes of diverse forms on the same animal. Other families, as *Dorididæ*, have a rosette of branchiæ round the arms only. All the preceding groups form the "naked-gilled" primary division, *Nudibranchia*. In the remainder of the sub-class the gills are concealed by the edge of the mantle, forming the *Tectibranchia*. The least specialized of these (*Hypobranchia*) have symmetrically arranged fringes round the edge of the body, with but few interruptions; while in the higher division, *Pleurobranchia*, the fringe exists on one side only. The fringe becomes more localized and drawn under the mantle as the size of the shell increases in the succession of genera. Especially in *Bulla*, where the shell is large, the gill is drawn beneath the mantle, and concealed by the up-turned margin of the foot.

In *Prosobranchia* the gill or mantle-sac is generally well defined. It consists of a chamber bounded within by the body-wall and above by the mantle, which also closes it laterally by adhesion to the body-wall. The gills and excretory orifices of the digestive, urinary, and genital systems are seen on its walls. There is generally a single gill, shaped like a half feather, and with two dependent (in *Paludina* three) laminae of transparent membrane. In many genera there is a rudiment of a second, while in a few the latter is well developed. The orifice of the mantle-sac is on the left side, and can be closed by a sphincter muscle. The mantle is originally composed of lateral halves, which are not always completely united; their separation at the margin produces the deep fissure in the shell of *Pleurotoma*, and divisions higher up correspond to the holes in the shell of *Hyaliotis*. In the latter genus there are two gill-sacs and two gills, and in others two gills. In some a thickened rib marks the halves of the mantle, and the two gills are placed closed together on it, so as to appear as one. In *Patellidæ* and *Chitonidæ* there is no distinct gill-sac, the branchiæ being marginal fringes, as in many *Opisthobranchia*. In the *Pulmonata* the mantle-sac does not contain any gills; it has an opening on the right side of the body, produced by a fissure in the mantle margin, which is closed by a sphincter muscle. This orifice opens and shuts regularly for the admission of air. The mantle-sac becomes a lung by the distribution of the venous trunks and branches over its surface. An extensive ring-like trunk (circulus pulmonalis) surrounds its margin, from which vessels converge toward the center, forming a network which gathers itself again into a few, then a single trunk, the vena pulmonalis, which empties into the auricle of the heart.

In *Cephalopoda* the mantle is free, and incloses a cavity on the abdominal, instead of, as heretofore, the dorsal face of the body, agreeing in this respect with the *Pteropoda*. The cavity contains two branchiæ in the greater number of

genera (Dibranchiata), or four in *Nautilus* and probably its extinct allies, the *Ammonitidæ*, etc. These constitute the sub-class *Tetrabranchiata*. The gills are elongate, triangular, feather-shaped bodies, whose axis bears on one side the artery, on the other the vein. In *Dibranchiata* it bears a row of bows on each side, in which a blood-vessel passes from artery to vein. On each of these stand bipinnate processes, so that the whole becomes tripinnate. The arch bounds a membrane in the decapod division, but in the *Octopoda* the loop is not closed. In *Tetrabranchiata* the first branches of the gill are leaf-like, with pinnate, leaf-like subdivisions. They are free in the mantle-sac; those of the dibranchiates are attached to the mantle.

In all *Crustacea* except the *Decapoda* the gills consist of fringes and expansions of the limbs. In the latter they are regular feather-shaped bodies, arranged within an abdominal cavity above the limbs; the bases form a curved line and the apices are directed inward. The tracheary system prevails in all other *Arthropoda*. It consists of a great number of tubes, which communicate with the air by means of small orifices or stigmata. These pierce the walls of the segments, usually one on each side, where they are present. They subdivide to a great extent internally, and penetrate all the organs of the body. There are marked varieties of this structure. Instead of issuing by stigmata, the trachea may be produced into a leaf-shaped process which arises from the usual position of the stigma, and may there ramify extensively within the lamella, constituting a trachean gill. This occurs in the larvæ of many *Neuroptera*. The walls of the tracheæ are elastic, yet firmly bound by a spiral thread, whose close volutions form an interior layer of the tube-wall. In other localities it is wanting, and the tube expands sac-like. In some insects these exist near the stigmata. In the *Arachnida* (except the group of low forms, the *Trachearia*) this sac-like structure only exists as a large pulmonary chamber, with single stigma, situated on the anterior part of the abdomen on each side.

In insects the stigmata rarely exceed nine or ten pairs; in *Myriopoda* they are far more numerous. In the *Acarina* there are but two. In insects they usually have a valve, which opens externally to prevent the entrance of foreign bodies; in some forms they project in laminae, branched, pinnate, or botryoidal. In the larvæ of many *Phryganeidæ* and some *Lepidoptera* the trachea-gills are arranged in six rows along the back. In the larvæ of *Libellula* and *Æschna* they are attached to the inner wall of the rectum.

2. In *Vertebrata*.—In *Ascidia* there are no free or pinniform gills. There is, on the contrary, a large pharyngeal cavity, which lies between the mouth and the digestive system proper, the alimentary canal both issuing from and discharging into its cavity in many cases. In others it discharges at the side. The pharynx may occupy a small part of the whole length of the cavity of the body: in the latter case the other organs are pushed to one side of it (*Boltenia*, e. g.). The mouth and other parts are frequently furnished with cilia. The gills consist of a sac whose walls are abundantly pierced by holes of different forms in the different groups, or it is reduced to a band of such structure only.

In the *Leptocardi* there is a large pharyngeal cavity, with a large open mouth whose border is supported by a cartilage. This gives out branches which are the axes of abundantly ciliated tentacles which surround the mouth. On the sides of the pharynx are numerous fissures, which communicate with the outer medium. In the *Marsipobranchii* the respiratory organs consist of a series of sacs on each side (which number seven to ten), on whose septary walls the arteries and veins are distributed. In some genera these communicate internally with the pharynx or œsophagus; in the lamprey, on the other hand, with a blind tube which lies beneath the œsophagus and empties into the pharynx. Each sac opens externally by a slit. In *Etasmobranchii-Ptagiostomi* (sharks, rays) the arrangement is similar, the slits numbering five, rarely six and seven and communicating with the œsophagus. The septary walls are double, and contain a cartilaginous arch with radii, which elevate the walls into transverse ridges. A trace of the first embryonic external fissure remains in this order as a spiracle or tube from the pharynx to the sides of the top of the head behind the eyes. In *Hotocephali* (*Chimæra*) the external slits are concealed by an opercular flap, which produces the appearance of a single slit. In *Teleostomi* the hyoid respiratory system is fully developed. The arches support, instead of sac-septa, radiating fringe-like laminae, which receive the branches of the branchial artery and vein. The fissures are

only those between the arches, which are covered externally by an osseous "operculum" or lid. The number of branchiæ is usually four and a half, but in some *Pediculati* there are but three, in some eels but two. In *Lepidosiren* there is but one. While the processes are usually narrow, lamellar, in *Lophobranchii* they are subcylindric and branched, each one forming thus a tuft; their number is also reduced.

Besides these fringes there are in some *Dipnoi* and some *Batrachia* (*Trachystomata*, *Proteida*), and in the larvæ of many salamanders, cartilaginous processes of the arches which bear a double row of fringes, forming the external gills.

The true pulmonary system consists of ducts and chambers, which originate from the alimentary canal, and are connected with it or the pharynx. It is not found in any *Vertebrata* below the *Teleostomi* and *Dipnoi*. On the other hand, the hyoid respiratory organs do not exist above the *Batrachia*. In *Teleostomi* the pulmonary system consists of a sac with walls either thin and semi-transparent, or rarely thicker and lined with muscular meshes or a few cells (*Lepidosteus*, etc.). In *Physostomi* it is connected with the stomach or œsophagus by a tube, the ductus pneumaticus; in *Lepidosteus* the latter enters the œsophagus on the upper side; in *Polypterus* on the under side of the same. In *Physoclysti* this sac is entirely isolated. Its function is that of a float, and it is hence called the swim-bladder. It usually forms a single chamber, but in *Cyprinidæ*, *Characinidæ*, and *Sternopygidæ*, it is divided by narrow constrictions into two, sometimes into three, chambers. In *Cobitidæ* and some *Siluridæ* (*Ctarias*, *Gasterobranchus*, *Ageniosus*, and *Saccobranchus*) the anterior part, or the whole of it, is inclosed in an osseous case. In *Gadidæ* the diapophyses are expanded and adherent to it; in *Campostoma* it is suspended in the abdominal cavity, and surrounded by the spirally coiled intestine. It is furcate, and sometimes branched posteriorly, in *Scianidæ*. In *Nematognathi* and *Plectospondyli* it is immediately connected with the auditory organs by a chain of small bones, which are supported on the sides of the anterior vertebrae. Besides *Lepidosteus* and *Amia*, the genera *Platystoma* (*Nematognathi*) and *Chirocentrus* (*Isospondyli*) possess cellular layers on the inner side of the swim-bladder. In *Saccobranchus* a sac extends on each side above the ribs from the pharyngeal cavity, which is designed to contain water to supply the gills during drought. In *Dipnoi*, *Lepidosiren* has the swim-bladder deeply divided longitudinally, its halves being homologous with lungs. They are cellular within, and lie above the alimentary canal next the vertebral column. They unite, and passing round the œsophagus enter it below by a glottis with small cartilage. In the *Dipnoan Ceratodus* there is but one lung.

In *Batrachia* we have a further development of the structure seen in *Lepidosiren*. Here the sacs are separate, being connected by the branches of the tube or trachea which leads to the œsophagus. The sacs, now lungs, are occupied by a central longitudinal cavity and a thick layer of cells round the walls. The trachea from this order upward consists of cartilaginous rings, partly or completely closed, which are modified at the glottis into a vocal organ. This consists of a number of segments, the uppermost of which support two parallel tendinous plates (chordæ vocales), whose edges are separated by a slit-like opening, which is opened or contracted by their relaxation or tension. The trachea is longer in reptiles and other vertebrates than in *Batrachia*, and its inferior branches are called bronchiæ. In all, the œsophagus passes above the lungs, and the stomach is behind them. The interior of the lung continues as a sac in reptiles, being especially elongate and thin walled posteriorly in serpents. In these animals one of the lung-sacs is nearly always wanting or rudimental. In birds and *Mammalia* the central cavity is only represented by the bronchi and their branches, the cells occupying the remaining space. In *Aves* the bronchi are each dilated into a chamber, which is furnished with muscles for altering its form. These are most fully developed in singing birds, of whose musical faculties they are the organ.

IX. THE UROGENITAL SYSTEM.

1. In *Invertebrates*.—*The Reproductive System*.—In the lowest forms of life reproductive organs are only periodical appearances, and their sexuality can be determined only by microscopic examination of their products. In most *Echinodermata* the organs are permanent, but it is not till we reach *Mollusca* with a head that the organs of the sexes essentially differ. A usual mode of reproduction in *Pro-*

tozoa and *Cœlenterata* is by budding and by fission. The production of ova is a higher form of the budding process, the result being a germ of a new generation, which may or may not require the offices of opposite sexual cells for their further development. Examples of full development of the female element alone (agamogenesis) are known in animals as high in the series as insects. In the *Mollusca* the two sexual elements, ova and spermatozooids, are constantly produced, even in hermaphrodites, although they may be the products of the same glandular follicles, as in *Gasteropoda-Opisthobranchia* and *Pulmonata*, and in *Pteropoda*.

The following table exhibits the relation of the classes as far as the *Vermes*:

I. No Urinary Apparatus.

♂ ♀ organs identical.

Radiata.

* No permanent generative organs.

Anthozoa. Either androgynous on each mesenterial fold, or the fold monœcious, or rarely the animals diœcious; spermatozoa or eggs in sacs, which are in band-like mass on sides of mesenterial folds.

Hydræ. Androgynous; the eggs single in a lower sprout, spermatozoa in a higher sprout; no permanent organs.

Medusæ. Diœcious; eggs and spermatozoa developed in large cells or bladders, which are attached to stomach, water-canals, mouth, feet, border, etc.

Ctenophora. Androgynous and monœcious; capsules of both kinds in combined or separate bands on radial water-canals; sometimes on central canal or stomach, emerging by same canals.

Crinoidea. Comatula; sacs on swollen bases of pinnules monœciously containing eggs or spermatozoa without tails. (By one observation sometimes androgynous.)

** Permanent organs.

Asteriida. One or many blind sacs each side of septum (which terminates between arms near or far off); sometimes found to reach the end of the arm; much subdivided; orifice of emission through lamina cribrosa in some *Asteriadae*; into the body-cavity in others and in *Ophiuridae*; all androgynous, with very few diœcious exceptions; in some not known.

Echinida. Diœcious; five (ever less?) sacs or masses of saclets, each opening by narrow ducts through separate openings (sometimes four or three) near vent, and lying near together, reaching to middle of shell; males white colored, yellow, red, etc.

Holothuriida. Bunch of few or many tubes embracing œsophagus, and opening on median dorsal line; diœcious, or in *Synapta* and *Apneumona* androgynous; the spermatozoa in projecting masses of walls of ovary-tube.

Mollusca.

* Generative organs not always permanent.

Bryozoa. Androgynous; ♂ organs round body below stomach on a string, with many cells, containing spermatozoa; ♀ with very few ripe ova behind stomach, also on a string; spermatozoa bursting into body-cavity, and reaching ovary; ova break through outer wall or a posterior orifice.

** Always permanent.

Brachiopoda. Androgynous; a thick branching glandular body following pallial or generative artery filled with ovary-cells, and surrounded and penetrated by a reddish cell containing male element; discharging near mouth from a large, much-plicate, trumpet-mouthed oviduct, which is not continuous with genital mass.

II. Urinary Organs Present (Bojanus's Glands).

A. ♀ ♂ organs identical, permanent.

Acephala. ♀ and ♂ organs not different, of minute cells gathered in more or less compressed masses, which form main mass, or more simple along central tube or duct, which passes through Bojanus's body or unites with duct of latter, or has opening near latter; spermatozoa in *Dimyria* long headed and round headed; in *Monomya* round only; diœcious, except a *Pecten* or *Cardium*, etc., and hermaphrodite individuals of *Anodonta*. In *Unionida* sexes externally different; gills serve as brood-sac. Androgynous; genera *Ostrea*, *Cyclas*, *Pandora*, *Pecten*, etc.

AA. ♂ organs distinguished by penis or stylet.

a. Animals hermaphrodite.

Gasteropoda-Opisthobranchia. Spermatozooids and ova produced by the same glandular body (with few exceptions).

Gasteropoda-Pulmonata. An oviduct with abdomen gland and seminal receptacle; a vas deferens terminating in penis; a stylet-sac with stylet, all emptying into a common cloaca.

Pteropoda. Similar to the last, but no distinct vas deferens, and no stylet; penis usually separate from and in front of vagina.

aa. Sexes distinct.

Gasteropoda in general. Penis behind the right eye; ovary and testis embedded in the liver; oviduct frequently enlarged into a uterus, issuing on the right side; rarely an albumen gland or receptaculum seminis; no stylet.

Cephalopoda. ♀ with ovary inclosed in a peritoneal sac, and with two (sometimes one) oviducts continuous; ♂ without stylet; with a vas deferens and so-called seminal vesicle and prostata near the penis.

The preceding structures present in their details the greatest variety. The generative organs are situated on the right side of the body, but the exits are in some groups on the opposite side, and usually (the female at least) in the mantle-sac. Their inner walls are lined with ciliated epithelium. The stylet is a slender, acute calcareous body of various form, which is inserted into the vagina or body of the other individual in coitus. Its function is supposed to be that of an irritant only.

The males of *Cephalopoda* are more readily distinguished from the females than in *Gasteropoda*, being generally smaller. In *Argonauta* only the female bears the shell. But the chief peculiarity of the male is seen in the modified structure of one of the arms, by which it is said to be "hectocotylized." It differs from other arms in being stouter and entirely hollow, terminating in a hollow thread, which is open at the extremity, giving exit to the contents. It is developed in the outer wall of a bladder, and is first closely rolled together; the thread bears a bladder which is later lost. The primary bladder finally bursts, its remains forming a fringing membrane on the sides. At the period of impregnation its cavity becomes, in some way unknown, filled with spermatozooids. During an embrace it is torn off, and enters the mantle-sac of the female. It swims independently as a worm, and several are sometimes found in one female. The spermatozooids are supposed to be discharged into the vagina by the hollow thread.

Many opisthobranchs are self-impregnating. *Pulmonata* impregnate one another, while in *Lymnaea* an individual impregnates a second, and is impregnated by a third, forming thus a chain of individuals.

In *Arthropoda* the sexes are always in separate individuals (diœcious), excepting in the lowest *Crustacea* (*Cirri-pedia*) and the lowest *Arachnida* (*Tardigrada*). These orders are either sessile or with but little power of movement; hence the appropriateness of their monœcious condition. The sexes of *Arthropoda* are generally distinguishable by external characters, but it is in the *Insecta* and *Entomostraca* (*Lernæoidea*) that this difference becomes most remarkable. Thus in *Hymenoptera* (bees and ants) and *Neuroptera* (termites) not only are the sexes very distinct, but there are other forms (neuters, workers, soldiers, etc.) produced in connection with imperfect development of the reproductive organs. In the bees and wasps the additional forms are repressed males; in ants, repressed females. In termites it is asserted that both sexes contribute to produce them.

The external orifices of the reproductive system are confined to the abdomen, and are below and before the vent of the alimentary canal. In most orders they are posterior, but in *Myriopoda*, scorpions, and some higher *Crustacea* they are in front of the abdomen. The female internal organs consist of ovary and oviduct on each side, or the two oviducts may unite into one on the middle line, or there may be a single median ovary. On the oviduct are usually found diverticula, the receptaculum seminis (which is wanting in *Crustacea*, except *Ostracoda*), and another sac of uncertain use. The lower part of the oviduct is enlarged and the muscular walls are thick, forming a vagina, which often continues past the proximal part of the oviduct as bursa copulatrix. The ovaries consist of cœca of varying forms. In *Crustacea*, *Arachnida*, and *Myriopoda* they are few in number, but in *Insecta* they are very numerous, forming a

gland-like body whose component cæca are bound together by connective tissue. In *Termes* their number reaches 2,000 to 3,000. Other glands (glandulæ sebaceæ) pour their contents into the oviducts, which serve many important purposes—i. e. to attach the eggs to a solid base (*arilus*) or to the parent's body; to construct a shell (*Blatta*) or cocoon. In certain low *Crustacea* (*Lernæoida*, *Isopoda*, etc.) these glands open outwardly independently of the oviducts, and the secretion forms a sac round the eggs, by which they are suspended externally. The last abdominal segments in many insects are modified into organs designed for the conduct of eggs to a proper nidus; thus in *Orthoptera* it is composed of saber-shaped plates with saws within; in *Hymenoptera* it is partly represented by an offensive weapon, the sting. In *Chrysididæ*, *Diptera*, and *Phalangia*, and *Acari* they are modified into a tube which is projected telescope-fashion.

The male organs of *Arthropoda* consist of testes, vasa deferentia, glands, vesiculi seminales, and penis. The testes resemble the ovaries of the female in structure and position, but are frequently less complex. They are more commonly also united on the median line, as in low *Crustacea* (*Cyclopidæ*, *Cyprididæ*), *Myriopoda*, and among *Insecta* in *Lepidoptera*, many *Hymenoptera*, *Orthoptera*, etc. The vasa deferentia, on the other hand, remain distinct in these cases, except in *Scolopendra* and various *Entomostraca*. In many *Crustacea* and chilognath *Myriopoda* the vasa deferentia issue externally separately, but in many others unite to form a ductus ejaculatorius, which is enlarged in diameter. The muscles of this region are especially developed where a penis is well developed. Glandulæ mucosæ discharge into these ducts in insects and myriopods, but are wanting or rare in *Crustacea* and *Arachnida*. They are sometimes sac-like, sometimes filiform. They secrete a substance which hardens round a body of seminal secretions, forming a capsule which is usually taken into the female vagina, but may be attached to the body externally, or even (*Chilopoda*) to external objects.

The penis is present in most *Arthropoda*, but is wanting in *Entomostraca*, *Chilopoda*, and scorpions. In *Crustacea*, *Brachyura*, and *Isopoda*, etc., it is double. In all cases it is composed of a modified pair of limbs which are especially clear in crabs. The intromittent organ is occasionally far removed from the orifice of the vasa deferentia. In spiders (*Aranea*) the extremity of the palpus bears a receptaculum seminis and penis, which the animal fills voluntarily by application to the external orifice, and discharges in the oviduct of the female. In *Argulus* a similar mode of connection depends on the structure of one of the legs, and in chilognath *Myriopoda* a pair of legs is altered for a similar purpose. In certain tailed *Decapoda* there are two pairs of such organs, those on the last segment of the post-abdomen serving as conductors from receptacles in the fifth pair of legs. In dragon-flies the exceptional case occurs where the accessory organ is a fissure in the second abdominal segment.

In *Vermes* the type of the reproductive system presents the varieties seen in *Mollusca*. Thus they are androgynous, monœcious, and diœcious. Many of them develop by an alternation of generations, the one produced by true reproduction, the other stages by gemmation. In *Turbellaria* (or planarians) the *Dendrocela* are bisexual, but the *Rhabdocela* possess a common outlet for the two organs, testis and ovarium. *Trematodes* (flukes) are monœcious, each animal possessing distinct sexual organs of both kinds. The developmental stages of the young vary from three to six, and all but the first of these are due to gemmation in the cavity of preceding stages, or metamorphosis while encysted, etc. In tapeworms (*Cestodes*) the animal is made up of a head with organs of attachment, which, posterior to a long neck, is followed by a great number of identical segments. These contain each male and female organs, and a water-vascular system. The ovary and testis are at opposite ends of the segment, and between them is the branched uterus. This terminates in a vagina, which is approximated by a sheath containing a penis, which is perforated by the vas deferens. There are glands attached to the female organs. Each segment of a cestode is then self-impregnating. In *Acanthocephala* and *Nematoda* we have the higher condition of an entire separation of the sexes. In the former there is a penis which is retracted in a bursa which is prehensile in function. In this order there are alternate generations produced by gemmation in the body of the nurse stage. In *Nematodes* many genera

(*Strongyliidæ*, *Ascaridæ*, and *Filaridæ*) are furnished with a penis and bursa at its base. In the last family *Trichocephalus* has a bristle-like penis, one-third the length of the body, which, when projected, is accompanied by an extended sheath. In *Ascaridæ* the penes or "spicula" are two in number. In *Sclerostomum* (gapeworm) the male is much smaller than the female, and becomes attached to her permanently. In *Heterura* he remains attached for considerable periods. *Cucullariidæ* are without bursa. In *Anguillula* and other genera there are two oviducts, which unite to form a single vagina.

aa. The Urinary Organs.—These are present in *Mollusca* from the *Acephala* upward. In the latter they are represented by a pair of kidneys and their discharge ducts only. These are called "Bojanus's organs"; they are relatively of large size, and lie one on each side above the heart, etc., extending from muscle to muscle. They are frequently united together along the middle line. They are hollow and spongy, and their fibers are lined with secreting cells. They terminate either by a single duct near that of the reproductive system, or unite with the latter, or the genital duct enters that of Bojanus's bodies. These bodies have communication with the external water, and by a cribriform surface with the heart-sac; likewise with the capillary veins. The function of the organs is not only that of a kidney, but as a mingler of water with the blood.

In *Gasteropoda* the kidney is single and contains calcareous nodules; its secretion is purple in *Murex*; it is large and hollow, and contains water. It is surrounded by a network of veins, which frequently open into it, so that blood-corpuscles are found in it, as well as its products in the blood. It usually opens directly into the mantle-sac, but otherwise by a ureter, and always independently of the rectum, vagina, or vas deferens.

The kidneys of *Cephalopoda* differ much from those of other classes, and for a long time their nature was considered doubtful. They form a large, rather loose mass on that part of the vena cava which approaches the gills, and on the gill-veins as well, consisting of a great number of minute sacs with bifurcations and internal processes. Each principal one opens by a fissure in the walls of the vein. They are constantly in motion.

In *Arthropoda* the existence of kidneys is a matter of question. The vasa Malpighii (described under the DIGESTIVE SYSTEM) are diverticula of the alimentary canal, and their function was formerly believed to be that of the liver. Gall has, however, never been found in them, but on the contrary uric acid. This has also been found in the intestine and in the corpus adiposum.

2. In *Vertebrata*.—*a. The Reproductive System.*—Vertebrates are usually diœcious, but a few fishes—viz., the eels and certain Serrani—are hermaphrodites. The organs of the female are primarily an ovary; an oviduct may or may not be present. Thus in the *Leptocardii* the ovaries are collections of cells along the sides of the abdominal cavity, which drop their ova into it, which are discharged by an orifice anterior to the anus. In *Marsipobranchii* the structure is similar, except that the ovarian cells are collected into plate-like masses. In *Elasmobranchii* the ovaria are included in a peritoneal sac; occasionally, as in *Squalida* and *Scylliidæ*, there is but one, medial and symmetrical. The oviducts are here present, and are homologous with the tubæ Fallopii of mammals; each dilates into a uterus, and empties into a common pro-rectal cloaca. Their proximal ends are open and expanded, presenting the so-called fontanelles. In true fishes we have various structures: in the *Salmonidæ* and some *Clupeidæ* there are no oviducts, but the eggs fall into the abdominal cavity and are expelled through a pore. In most other fishes and in *Lepidosteus* the ovarian membrane is prolonged as an oviduct, and usually discharges externally without union with other canals; in *Lepidosteus* they enter the ureters. They are united in various Physoclysti. They are, as in *Elasmobranchii*, open as internal fontanelles in *Amia*, *Chondrostei*, and *Polyp-terus*; in all they have a common external opening with the ureters.

In *Batrachia* the tubæ Fallopii are proximally open, and extend in many coils far in front of the ovaries. They are distally united with the ureters. In *Reptilia*, *Aves*, and *Mammalia*, the oviducts (or tubæ Fallopii) are not ordinarily connected with the ovaries, but only at certain seasons by their trumpet-shaped fontanelles. In birds these organs are not developed on one side of the body. In reptiles, birds, and monotrematous mammals, the genital, urinary, and di-

gestive canals have a common exit or cloaca. In marsupials and placentals the genito-urinal excretory ducts are separated from the digestive, being in the female distinct or opening into a common vulva, but in the male are united for some length. In *Mammalia* the females are viviparous, and the ovum is hatched in expansions of the oviducts, or uteri. In marsupials these are separate, and the distal parts of the oviducts are not united into a vagina. In placental mammals, on the contrary, the oviducts unite, forming a single undivided vagina. In *Edentata* and *Glires* this union does not produce an expanded uterus, as the young are developed in the separate oviducts; but in higher mammals the enlarged oviducts unite into a muscular chamber, the uterus. A false uterus occurs in the kangaroos by the union of the cavities of the oviducts near the middle of their length; two opposite symmetrical curvatures are in contact, and their adjacent walls disappear: they then turn shortly back (forward in the animal) and make another short bend before they take a direction to the external orifice.

In placental mammals the embryo is attached to the wall of the uterus by a body called the placenta. It is on the chorion, and presents to the wall great numbers of villi, which interdigitate with corresponding processes from the mother. Both are furnished with abundant blood-vessels, which maintain intercommunication with each other, thus nourishing the embryo. As we descend the scale we only find a trace of this structure in some of the sharks. The allantois is an embryonic structure which characterizes exclusively vertebrates above and including *Reptilia*. The amnion is another sac, formed by the folding of the germinal layer of the embryo over its back; the edges of the folds then uniting, the two inner inclose the amniotic sac; the outer becomes the chorion. The amnion is absent, like the allantois, in all classes below *Reptilia*.

The placenta exhibits several distinct typical forms in *Mammalia*; it may be disciform or ring-like (zonary), or may be scattered in tufted bodies over the chorion (cotyledonary), or the villi may be scattered all over the same (diffuse). The orders of mammals may be thus arranged in this respect:

1. With decidua, placenta discoidal: *Primates*, *Chiroptera*, *Insectivora*, *Glires*, *Edentata* (*Orycteropidae*, *Dasyptidae*).

2. With decidua, zonary: *Carnivora*, *Proboscidea*, *Hyracoidea*.

3. Without decidua, cotyledonary: *Perissodactyla*, *Artiodactyla-Ruminantia*, *Edentata* (*Bradypidae*).

4. Diffuse: *Artiodactyla-Omnivora*, *Cetacea*, *Edentata* (*Manidae*).

The male organs are, in the early stages of growth, as in the lower animals, undistinguishable in structure from the female. They are homologous with the latter in details, even when most distinct. The relation may be thus expressed:

♂		♀
Testis.		Ovary.
Vas deferens,	}	Oviduct,
Uterus masculinus.		Uterus.
Cowper's glands.		Cowper's glands.
Penis.		Clitoris.
Serotum.		Labia majora.
Preputium.		Labia minora.

The vas deferens is, however, generally a persistent Wolffian duct, which in the embryo is the excretor of the embryonic bodies (Wolf's) which precede the kidneys. The Fallopian tube of higher mammals, on the other hand, is the persistent Müllerian duct, which passes outside of the former. In the batrachian *Urodela* the efferent ducts of the testis pass through the kidney and empty into a genito-urinary duct, while in *Salientia* (except *Discoglossidae*) they only pass through the edge of the kidney and discharge into the ureter.

Among reptiles the penis is present in the tortoises and crocodiles only, and in no lower forms; it is merely grooved beneath. In the ostrich it is quite similar. In the lower groups of birds it is present, but wanting in the more specialized; in *Mammalia* it is universal. It is composed of two superior bodies, the corpora cavernosa, originating from the pubis, and the corpus spongiosum, whose lower face embraces the urethral tube, and whose extremity forms the glans or head. The testes are almost universally situated near the kidneys, in the abdominal cavity, but in the higher mammals they descend from that position, and carrying a fold of the serous membrane (tunica vaginalis) and muscle

(cremaster), they are suspended externally, generally behind the penis; in *Marsupialia* in front of it. In some rodents and others this descent of the testes is periodical.

aa. Urinary organs.

Kidneys are present in the higher *Vertebrata*, inclusive of the *Reptilia*, but are supposed to be represented in *Batrachia* and fishes by structures which are embryonic in the former—i. e. the Wolffian bodies. The latter consists of two bodies, one on each side of the vertebral column, and are composed of transverse tubuli terminating in expansions which embrace convoluted capillaries, the "Malpighian tufts." The Wolffian tubules empty into the Wolffian duct, which extends along their outer side, and empties in the embryo into the allantois. The kidneys appear later in embryonic life, behind the Wolffian bodies, and have a similar structure. They also discharge by a duct on each side, which is distinct from the Wolffian, and constitutes the ureter. This discharges at first into the allantois, but with the approach of the lateral walls in the embryo, and the closing of the ventral fissure, a portion of the allantois is included, and becomes the urinary bladder.

The *Leptocardii* are not known to possess either Wolffian bodies or kidneys. In the Pisces the connection of the ureters with the oviducts is various. Thus in *Polypterus* they unite and enter a single tube, the united ureters. In *Lepidosteus* each ureter receives its corresponding oviduct; in *Amia* the oviducts are open proximally. In *Batrachia* the ureters are always connected with the oviducts. In the tailed order the ureter becomes a genito-urinary duct, because it receives the vasa efferentia of the testis, which pass through the kidney to reach it; it empties into the cloaca. In the *Salientia* the vasa efferentia enter the kidney, but do not reach the ureter, but are collected into a special duct analogous to the deferens, which enters the ureter at its lower part. This tube also receives the secretion of the kidneys, so that the original ureter becomes useless, and is atrophied in the frogs, or persists as a caecum in the toads. In the discoglossid frogs the arrangement is as in the salamanders. In the allantoid vertebrates the ureters discharge into the urinary bladder, which in turn empties by a single urethra, of greater or less length, into a genito-urinary chamber in the higher *Mammalia*, or the cloaca in the other classes. It is continued throughout the penis in those males that possess that organ. The kidneys in most *Carnivora*, in the *Cetacea*, and some *Artiodactyla*, are lobulate, or like a bunch of grapes in form, as is seen in the embryos of man and other mammals. In the cats (*Felidae*) the divisions are not visible externally.

The osseous system will be discussed in an article especially devoted to that subject.

EDWARD D. COPE.

Anaxagoras (Ἀναξαγόρας): Greek philosopher of the Ionian School; b. at Clazomenæ, near Smyrna, about 500 B. C. He passed nearly thirty years at Athens, to which he removed about 480, and enjoyed the friendship of Pericles. He wrote a *Treatise on Nature*, of which small fragments are extant. In 450 B. C. he was accused of impiety, and, though defended by Pericles, was condemned to death or banishment, and retired to Lampsacus, where he died in 428 B. C. He appears to have maintained the eternity of matter. Combining great sagacity and close reasoning with diligent observation, he rendered important services to physical science. He ascribed the origin of the world and the order of nature to the operation of an eternal self-existent and infinitely powerful principle which he termed Nous (Mind). He taught that generation and destruction are only the union and separation of elements which can neither be created nor annihilated, demonstrated that air is a substance, explained the theory of eclipses, and refuted the doctrine that things may be produced by chance. See Erdmann's *History of Philosophy*.

Anaxarchus (Ἀναξαρχος): a Greek philosopher; b. at Abdera, in Thrace; accompanied Alexander the Great in his expedition against Persia in 334 B. C. He gained the favor of that prince, whom he survived a short time.

Anaximander (Ἀναξίμανδρος): Greek philosopher; b. at Miletus about 610 B. C.; was a disciple of Thales. He is said to have discovered the obliquity of the ecliptic, and to have invented the sun-dial. According to tradition, he taught that the earth is a cylinder, that the sun is a globe of fire as large as, or larger than, the earth, and that infinity is the beginning and end of all things. He appears to have been the first Greek who wrote any work in prose on geometry or philosophy. D. about 546 B. C.

Anaxim'enes (Ἀναξίμενης): a Greek philosopher of whom little is known; b. at Miletus, in Asia Minor; date uncertain. He taught that the original principle or primary form of things was air, or a subtle ether which is in perpetual motion.
