Anaximenes of Lampsacus: a Greek historian and preceptor of Alexander the Great, about 340 B. C. He wrote a history of the reign of Philip of Macedon, and another of the exploits of Alexander, neither of which is extant. To this Anaximenes is attributed, by Spengel, the *Ars rhetorica ad Alexandrum* found among the writings of Aristotle.

Ancachs': a department of Peru; bounded N. by the department of Libertad, E. by Huanuco and Junin, S. by the department of Lima, and W. by the Pacific. The department extends from the Andes to the Pacific, and contains all climates and their products. The chief occupations of the inhabitants are agriculture and the raising of cattle. A railroad extends from Chimbote to the capital, Huaraz. The rich silver mines in the mountains, as well as the rivers containing gold, are but very little worked at present. Area, 17,405 sq. miles. Pop. 284,091.

Ancelet, JACQUES ARSÈNE FRANÇOIS POLYCARPE: French dramatic poet; b. at Havre, Feb. 9, 1794; produced in 1819 a tragedy entitled *Louis IX.*, which was warmly applauded, and procured for him a pension of 2,000 francs. Among his other works are an epic poem called *Marie de Brabant* (1825); *Fiesque*, a tragedy (1824); and *Olga*, a drama (1828). He was admitted into the French Academy in 1841. D. at Paris, Sept. 7, 1854.

His wife, MARGUERITE VIRGINIE CHARDON, b. at Dijon, Mar. 15, 1792, was a novelist and an artist. She wrote several dramas and tales. D. at Paris, Mar. 21, 1875.

An'cestor [O. Fr. *ancestre* < Lat. *anteces'sor*, predecessor; *ante*, before + *ce'dere*, go]: one who has preceded another in the direct line of descent. In law it signifies one from whom an estate has been derived by inheritance; a deceased person from whom, on account of his decease, an estate has passed to another, called an heir, by operation of law. Ancestor and heir are correlative terms. A brother may be the ancestor of a brother, or a child of a father, wherever those persons can take land from such relatives by inheritance.

Ancestor-worship: See ANIMISM.

Ancestry of Plants: It is evident that the present vegetation of the earth is descended from previous vegetation. It is, moreover, certain that as we go back in time the vegetation is less and less like that of the present. A study of the preglacial plants shows that they were much like those of the present, but still with marked differences. Eocene plants were less like present plants, and cretaceous plants still less. As we come from the past toward the present, there is such a relation between the plants of successive periods as can best be explained by supposing that the later descended from the earlier.

On structural grounds we may suppose that the green algae (*Chlorophyceæ*) have descended from the water slimes (*Schizophyceæ*); that from the green algae have descended the brown algae (*Phaeophyceæ*) and red algae (*Florideæ*); while from the latter have come the stoneworts (*Charophyceæ*) and mossworts (*Bryaceæ*). The fernworts (*Pteridophytes*) are closely related to the lower mossworts, and may have originated from them, or with them. Gymnosperms appear to be slightly modified lycopods. Whether the angiosperms descended from the lycopods or the gymnosperms is questionable. The primitive monocotyledons and dicotyledons were probably much alike. Their flowers probably had many parts, all free, as in water-plantains (*Alisma*) and buttercups (*Ranunculus*). From these simple types arose, among monocotyledons, the lilies, irises, and orchids; and among the dicotyledons, the crucifers, pinkworts, mallows, geraniums, roses, beans, passion-flowers, heaths, gentians, figworts, mints, bell-flowers, and composites, by various kinds and degrees of union of parts. On the other hand, by a reduction and simplification—in short, by a catagenesis as to floral structure—there appeared among monocotyledons the aroids, palms, sedges, and grasses, and among the dicotyledons, chenopods, amaranths, spurgeworts, nettleworts, oaks, walnuts, and willows. CHARLES E. BESSEY.

Anchi'ses (Gr. Ἀγχίσης): Trojan prince related to Priam: was, according to tradition, a favored lover of Venus, and the father of Æneas, with whom he escaped from Troy. He is said to have died in Sicily.

Anchisaurus: a genus of small, carnivorous Dinosaurs from the Triassic. These extinct reptiles are of special interest, because they are now supposed to be the animals that made many of the so-called "bird-tracks" found in the Connecticut valley. They walked mainly on their hind legs, and the structure of the hind feet shows that the impressions thus made would be very similar to the three-toed footprints formerly regarded as made by birds. Several skeletons of this genus and of an allied form, *Ammosaurus*, are preserved in the Yale Museum. Remains somewhat similar have been found in various parts of the world. O. C. MARSH.

Anch'or: an iron implement used to hold a vessel in place in comparatively shallow water. It consists of a round, straight bar called the *shank*, at the upper end of which is a transverse piece called the *stock*, and of two curved arms at the lower end of the shank, each of which arms terminates in a triangular plate called a *fluke* or *palm*. The junction of the two arms is the *crown*. The stock is at right angles to the plane of the flukes. The cable is fastened to a ring in the upper end of the shank. When the anchor is let go, the crown first strikes the ground. The anchor then falls over, so that one end of the stock rests upon the ground, and the movement of the ship causes the anchor to cant and one of the flukes to enter the ground, and to penetrate deeper in proportion as the strain or traction on the cable increases. In one form of anchor the arms are pivoted to the shank, instead of being rigidly fixed. Men-of-war and large merchantmen carry two large anchors of equal size at the bows, thence called bower anchors, and two of smaller size, called the sheet anchor and spare anchor. For particular and special services they have also the "stream" and the "kedg" anchor. Smaller vessels have fewer anchors and of inferior size. When one anchor is down, the ship is said to be at single anchor. When the anchor is dragged out of the ground by the movement of the vessel, it is said to come home, and when the cable becomes twisted around the anchor it is said to be foul. *To weigh anchor* signifies to heave up or raise the anchor out of the ground to the bow. Revised by S. B. LUCE.

Anch'orage: a body of water where ships may anchor. The water should not be too deep, as in that case the cable, extending nearly vertically, will be apt to pull the anchor out of the ground. The bottom that holds best is sand or stiff clay. The term is also applied to the toll or harbor dues which the owner or captain of a ship pays for permission to east anchor.

Anchor-ice, also called *ground-ice* and *ground-gru*: ice which forms at the bottom of streams or lakes, but also often applied to ice in the water below the surface. In the first case it sometimes brings up anchors when it rises, in the latter it clogs up water-wheels, screens, and pipes. It is of various origin. Sometimes the bottom of a body of water is below the freezing-point, in which case there may be ice at both the bottom and top of the stream. Sometimes the whole mass of water is below freezing, but the wind or the current keeps crystals from forming, except at the bottom or, with a slow current, through the mass. At other times eddies break up the ice and carry it into the water, or large flakes (or small masses) of snow form nuclei for ice in very cold water. M. W. H.

Anch'orite, or **Anch'oret** [from Gr. ἀναχωρητής, deriv. of ἀναχωρεῖν, retire; ἀνα-, back + χωρεῖν, withdraw]: a hermit or person who has retired from the world and devoted himself to ascetic religion in solitude. The term was first applied to Christians of the third century who retired to caves and solitary places in the deserts of Palestine, Egypt, and Syria, to which, in some cases, they were driven by persecution. They often subjected themselves to painful privations and various forms of penance. The first of these anchorites was Paul of Thebes, who died in 340, aged 104 years. The so-called "father of monachism" was Antony of Coma, in Upper Egypt, who was born in 251 and died in 356, aged 105 years. One anchorite, Simeon Stylites, is said to have lived many years on the top of a pillar in Syria, about 420–450 A. D. The chief difference between an anchorite and a monk is that the former lived alone, and the latter associated with other monks. The first monastery was founded by Pachomius, on the island of Tabenna in the Nile, about the year 340; the first nunnery, some eight years later.

Ancho'vy (*Stolephorus encrasicolus*): a small fish, from 5 to 7 inches long, which abounds in the Mediterranean Sea and the Atlantic shores of Europe. It belongs to the

Stolephoridae, a family related to the herrings, and is distinguished by a sharp-pointed head, the upper jaw longer

Anchovy.

than the lower, and the deeply cleft mouth extending behind the eyes. It is salted and packed in small barrels for exportation, and used for sauces, pastes, etc. Many other species of anchovy are found in U. S. waters, some of them of value as food.

Revised by D. S. JORDAN.

Anchovy-pear (*Gri'as cauliflo'ra*): a tree of the family *Myrtaceae*, which grows in the West Indies in moist ground or shallow water. It bears a fruit (a drupe) which is pickled and used for food.

Anchylosis: See ANKYLOSIS.

Ancient Order of United Workmen: a secret order, having three degrees, composed of men of all useful professions and occupations. It is purely fraternal and benevolent in its teachings and practice, and has no connection or affiliation with any of the labor organizations of the day. The principal feature of the order is its beneficiary fund, by means of which, in case of death, a stipulated sum is paid to each member's family or such person or persons as he has designated. The order originated in Meadville, Pa., Oct. 27, 1868. It now has grand lodges in California, Iowa, Indiana, Illinois, Kentucky, Minnesota, Missouri, Michigan, New York, Tennessee, and Wisconsin, and subordinate lodges in other States.

Ancients, Council of: in French history, one of the two assemblies composing the legislative body in 1795-99. It consisted of 250 members, each of whom had to be at least forty years old. It was dissolved by the revolution of the 18th Brumaire.

Ancile (plu. *Ancilia*): the shield of Mars, which, according to tradition, fell from heaven in the reign of Numa, when an oracle declared that Rome could never be taken while this shield remained in that city. Numa committed it to the custody of the Salii or priests of Mars, and had eleven other shields made precisely like it in order to prevent the genuine shield from being stolen.

Ancillon, an-sē-yon', JOHANN PETER FRIEDRICH: German historian and statesman, of French extraction; b. in Berlin, Apr. 30, 1767. He was the pastor of a Protestant church in that city in the former part of his mature life. In 1801 he published *Mélanges of Literature and Philosophy*. His principal historical work is a *View of the Revolutions of the Political System of Europe since the Fifteenth Century* (in French, 4 vols., 1803-05), which was very successful. He was soon appointed royal historiographer and councilor of state. In 1831 he became Minister of Foreign Affairs. Although Ancillon had the reputation of a certain liberality, he managed affairs in a very reactionary spirit and in close sympathy with the policy of Austria. D. in Berlin, Apr. 19, 1837.

Anco'na: a province of Central Italy; bounded N. by Pesaro and Urbino, E. by the Adriatic, S. by Macerata, and W. by Perugia. Area, 736 sq. miles. The country is chiefly mountainous, and is traversed by the Esino and Musone. The chief articles of export are grain, oil, wine, and hazelnuts. The chief branch of industry is the silk manufacture. Chief town, Ancona. Pop. (1879) 273,351; (1890) 271,910.

Ancona [Gr. ἀγκών, angle, alluding to its position on the coast]: an important city and seaport of Central Italy; on the Adriatic; 132 miles by rail N. E. of Rome; capital of the province of Ancona (see map of Italy, ref. 4-E). It is built on the slope of a hill, and presents a picturesque appearance from the sea. It is supposed to have been founded about 400 B. C. Among the remarkable public buildings are a cathedral, the government palace, the town-house, and a triumphal Corinthian arch which was built by Trajan of white marble. It has a college, ten churches, and several convents. The harbor is one of the best on the Adriatic. In 1732 it was declared a free port. Ancona is connected by railways with Rome, Bologna, and Brindisi. It has considerable trade, carried on by steamships which ply between

this point and the Levant. The chief articles of export are wool, grain, silk, oil, alum, sulphur, fruit, and soap. Ancona was taken in 1832 by the French, who occupied it until 1838. Lat. 43° 38' N., lon. 13° 30' E. Pop. 48,572.

Ancona, ALESSANDRO, d': Italian critic and Romance philologist; b. in Pisa, 1835; studied in Florence and Turin. He took an active and patriotic part in the exciting political events which ended in Italian independence; but immediately after the peace of Villafranca he withdrew from public life and devoted himself to studies. In 1861 he became Professor of Italian Literature in the University of Pisa, taking the place left vacant by the resignation of De Sanctis. Here he soon became a power in furthering the new science of Italian, and Romance philology in general. His publications have been numerous, and his pupils (among them Rajna, Vitelli, D'Ovidio) have become in their turn leaders. Among the works of D'Ancona are especially noteworthy: *I precursori di Dante* (1874); *Origini del Teatro in Italia* (1877); *La Poesia popolare italiana* (1878); *Varietà storiche e letterarie* (two series, 1883-85); *Studi sulla letteratura italiana de' primi secoli* (1884). A. R. MARSH.

Ancre, LE MARÉCHAL, d' (originally *Concino Concini*); Italian courtier; b. at Florence. He formed part of the retinue of Maria de Medici (queen of Henry IV. of France) when she went to Paris in 1600, and he married Eleonora Galigai, who had much influence with that queen. His talents for intrigue and the favor of the queen (who in 1610 became regent) raised him suddenly to power. In 1613 he was appointed a marshal of France and Prime Minister. Having excited general odium by his rapacity, he was assassinated at Vitry, April 24, 1617, by De Luynes and other conspirators.

An'ens Mar'tius: fourth King of Rome; a grandson of Numa; succeeded Tullus Hostilius about 640 B. C. He promoted the religious institutions of Numa, and is considered the founder of the plebeian order. He waged war against the Latins, whom he subdued, founded Ostia, and built the Pons Sublicius (Bridge of Piles). D. about 616 B. C.

Ancy'ra (Gr. Ἄγκυρα): an ancient city of Galatia, in Asia Minor; said to have been built by Midas; about 30 miles W. of the river Halys. Under the Roman empire it was an important city and the capital of Galatia. It had a famous temple of Augustus in which was the *Monumentum Ancyranum*. Its site is occupied by the modern city of ANGORA (q. v.). Two councils of the Church were held there—one in 314 and the other in 358 A. D.

Andalu'sia (formerly called *Vandalusia*, from the Vandals; Sp. *Andaluc'ia*): the southern portion of Spain; bounded N. by Estremadura and La Mancha, E. by Murcia and the Mediterranean, S. by the Mediterranean, W. by Portugal and the Atlantic Ocean. It is supposed to correspond to the *Tarshish* (the western) of the Bible and the *Batica* of the Romans. The Sierra Morena extends along the northern border, and the southern part is traversed by the Sierra Nevada, the highest summits of which rise about 11,000 feet above the sea. The largest river is the Guadalquivir, which flows southwestward and enters the Atlantic. The soil of the valleys and plains is fertile. Silver, copper, iron, lead, and mercury are found here. The chief products are grain, cotton, wine, wool, sugar, olives, oranges, and figs. The climate is delightful. The Andalusian breed of horses has long been celebrated. Andalusia is divided into eight provinces—viz., Almería, Granada, Jaen, Cadiz, Córdoba, Málaga, Huelva, and Sevilla. It corresponds to the kingdoms of Seville, Jaen, Córdoba, and Granada, into which the Moors divided the southern part of Spain. Area, 33,802 sq. miles. Pop. (1887) 3,429,813.

Andalu'site: an anhydrous silicate of alumina, which is found in Andalusia and other places, and occurs in four-sided prisms. It may be distinguished from felspar by its greater hardness and infusibility. A peculiar variety called chiastolite or macle is very abundant at South Lancaster, Mass. It occurs in stout crystals, having the axis angles of a different color from the rest, exhibiting a tessellated appearance on the cross section. See Dana's *System of Mineralogy*, 5th ed.

Andaman' Islands: a group of small, densely wooded islands; in the Bay of Bengal; between lat. 10° and 13° N., and about 93° E. lon. (see map of S. India, ref. 6-K). Area, 1,760 sq. miles. They are 180 miles S. W. of Cape Negrais. The inhabitants are in the lowest stage of barbarism, and are said to resemble none of the races of the adjacent parts

of Asia. It has been used as a penal colony for Hindus by Great Britain. The Earl of Mayo, the Governor-General of India, was murdered here by a convict on Feb. 8, 1872. The population numbers (1901) 24,499, including about 6,000 natives. The chief settlement is Port Blair. The two groups, Andaman and Nicobar, have been united under a commissioner at Port Blair. Both groups are in communication with Calcutta by steamer.

Andante [Ital. pres. participle of *anda're*, go]: an Italian musical term indicating the time in which a piece is to be performed. It denotes a movement that is moderate, rather slow and sedate, but distinct and flowing.

Andaques Wax: See **WAX**.

Andenne, aân'den': town of Belgium; province of Namur; on or near the Meuse, and on R. R. from Namur to Liège; 12 miles by rail E. of the former (see map of Holland and Belgium, ref. 11-F). Porcelain and tobacco-pipes are made here. Pop. 7,114.

An'derlecht: a market-town of Belgium; province of Brabant; 10 miles S. W. of Brussels (see map of Holland and Belgium, ref. 10-D). It has breweries and large dyeing establishments. Pop. 17,729.

An'dersen, CARL: Danish lyric poet; b. in Copenhagen, Oct. 26, 1828. At the age of nine he went to Iceland, where he resided until 1848, when he returned to Copenhagen. He wrote the words for Gade's famous musical compositions, *The Crusaders* and *Kolanus*. *Over Skjær og Bræding* (Over Sherry and Beaker) contains a series of sketches of life in Iceland. D. in Copenhagen, Sept. 1, 1883.

R. B. ANDERSON.

Andersen, HANS CHRISTIAN: Danish poet and novelist; b. at Odense, in the island of Fünen, Apr. 2, 1805; son of a poor shoemaker, who died when Hans was nine years old. In 1819 he went to Copenhagen to seek employment in the theater, but was rejected because he was too lean. Before this period he had written several tragedies and poems, among which was the *Dying Child*. He made various unsuccessful efforts to obtain employment, and passed several years in adversity until he found generous friends, who in 1828 placed him in the university, where he was educated at the public expense. In 1830 he published a volume of his collected poems. His friends procured for him a royal stipend, and in 1833 he visited Italy. He recorded his impressions in *The Improvisatore* (1834), which is unrivaled as a picture of scenery and manners. He afterward traveled extensively in Europe and the East. He related some episodes of his early life in a book entitled *Only a Fiddler* (1837). Among his other works are *The Poet's Bazaar* (1842); *Ahasuerus*, a drama; *The Two Baronesses*, a tale in English, all of which display original genius and a rich imagination; but by far the most popular of his works is his *Tales* (first collection, 1835), of world-wide reputation, translated into many languages, and enjoyed by all classes on account of their humor, imagination, and simplicity. The *Tales* gave him his note as the Children's Friend. His works have been translated into many languages. See Hans Andersen, *True Story of My Life* (in German, 1847, continued to his death by Jonas, 1879). D. in Copenhagen, Aug. 4, 1875.

Revised by S. M. JACKSON.

An'derson: city; five railroads; capital of Madison co., Ind. (for location of county, see map of Indiana, ref. 6-F); on the West Fork of White river; is a manufacturing city, having a hydraulic canal with 44 feet fall. It has a number of natural-gas wells. Pop. (1880) 4,126; (1890) 10,741; (1900) 20,178.

EDITOR OF "INTELLIGENCER."

Anderson: on railroad; capital of Anderson co., S. C. (for location of county, see map of South Carolina, ref. 4-C); has five churches, and is the seat of Patrick Military Institute, Anderson Female College, and a high school for boys and girls. Principal industries include a cotton-mill and a shoe-factory. Pop. (1880) 1,850; (1890) 3,018; (1900) 5,498.

EDITOR OF "BULLETIN."

Anderson, ALEXANDER, M. D.: b. in New York city, Apr. 21, 1775; graduated in 1796 as M. D. at Columbia College, but practiced only two years, and became the earliest wood-engraver in the U. S. He made the cuts for Webster's *Spelling Book*, illustrations for an edition of Shakspeare, and published an illustrated *General History of Quadrupeds* (1804). D. at Jersey City, Jan. 17, 1870.

Anderson, GEORGE B.: b. at Wilmington, N. C., in 1831; graduated at West Point 1852; became first lieutenant of

the Second Dragoons in 1855; adjutant 1857; resigned Apr. 25, 1861; was made a brigadier-general in the Confederate army; commanded the defenses of the coast of North Carolina in Nov., 1861; led a brigade at the battle of Antietam, and received a wound which caused his death at Raleigh, N. C., Oct. 16, 1862.

Anderson, JAMES, M. D.: was physician-general of the army of the East India Company at Madras in the latter part of the eighteenth century. He was famous for the zeal and ability he manifested in his persistent efforts to introduce the cochineal, silkworm, mulberry-tree, etc., into Hindustan, and he published letters on these subjects to Sir Joseph Banks and others. D. Aug. 5, 1809.

Anderson, JAMES, LL. D.: Scottish writer on political and rural economy; b. at Hermiston, near Edinburgh, in 1739. He was a practical as well as a scientific farmer, and introduced the use of an improved form of plow. In 1777 he published *Essays Relating to Agriculture and Rural Affairs* (3 vols.). He removed to Isleworth in 1797, and there issued a monthly periodical called *Recreations in Agriculture, Natural History*, etc. (1799-1802), in which he anticipated the famous theory of rent afterward adopted by Malthus and Ricardo. D. there Oct. 15, 1808.

Anderson, JOHN, F. R. S.: Scottish naturalist; b. at Roseneath, Dumbartonshire, in 1726; educated in the University of Glasgow. He became in 1760 Professor of Natural Philosophy in that institution. In 1786 he published a valuable work entitled *Institutes of Physics*. He gave gratuitous scientific lectures to the working-classes for many years. By his last will he founded a useful institution (in Glasgow) called Andersonian University, or Anderson's College. Its curriculum corresponds to that of Glasgow University, except that there is no instruction in theology, but the object is to attract the masses. From small beginnings it has grown to its present proportions, with its staff of twenty professors and lecturers and its thousand students. The original endowment has been greatly increased by recent gifts from Scotch philanthropists. D. at Glasgow, Jan. 13, 1796.

S. M. JACKSON.

Anderson, JOHN, M. D., LL. D., F. R. S., etc.: physician; b. in Edinburgh, Oct. 4, 1833; M. D., University of Edinburgh, 1862; appointed superintendent of the Indian Museum in Calcutta in 1865; afterward called to the chair of comparative anatomy in the Medical College, Calcutta; scientific officer of two government expeditions to Western China in 1868 and 1874; retired from the Indian service in 1887; author of *Mandalay to Momien*; *Catalogue of the Mammalia in the Indian Museum*; *Handbook to the Archaeological Collections of the Indian Museum, Calcutta*, etc.

C. H. T.

Anderson, JOSEPH: b. near Philadelphia, Nov. 5, 1757; was an officer in the Revolutionary war; became a lawyer, was appointed a territorial judge by Washington (1791), was U. S. Senator from Tennessee (1797-1815), and first comptroller of the U. S. treasury (1815-36). D. in Washington, D. C., April 17, 1837.

Anderson, LARS: See **ANDRÆ (LAURENTIUS)**.

Anderson, MARTIN BREWER, LL. D., L. H. D.: of Scotch-Irish descent on his father's side; b. at Brunswick, Me., Feb. 12, 1815; graduated at Waterville College (now Colby University), Waterville, Me., in 1840; was tutor in the college two years, and then Professor of Rhetoric nearly seven years. In 1850 he removed to New York city and became editor-in-chief, and in part proprietor, of the *New York Recorder*, a weekly Baptist newspaper. In 1853 he was chosen president of Rochester (N. Y.) Baptist University, which position he resigned in 1888. He published many review articles, addresses, and educational papers. See his life by Asahel C. Kendrick. D. at Lake Helen, Fla., Feb. 26, 1890.

Anderson, MARY: actress; b. at Sacramento, Cal., July 28, 1859; educated at the Ursuline convent in Louisville, Ky., and determined, when only thirteen years of age, to devote herself to the art of acting. Having met with Charlotte Cushman, the celebrated tragedian, in Cincinnati in 1874, she went to New York to take lessons in elocution and other dramatic requirements, and about a year after her return to her native place she made her *début* there as Juliet, Nov. 27, 1875, with great success. After visiting all the principal cities of the U. S., she in 1883 went to England, where she also played with success. In 1890 she was married to Antonio F. de Navarro. She has since retired from the stage.

Revised by B. B. VALLENTINE.

Anderson, RASMUS BJÖRN: author; b. at Albion, Wis., of Norwegian parentage, Jan. 12, 1846; educated at Luther College and University of Wisconsin; Professor of Scandinavian Languages and Literature, University of Wisconsin, 1873-84; U. S. minister to Denmark, 1885-89; author of *Norse Mythology* (5th ed. 1890); *America Not Discovered by Columbus* (1874); *Norse Mythology* (1875); *The Younger Edda*; and has made numerous translations, notably one of the works of Björnson in 7 vols.

C. H. T.

Anderson, RICHARD HERRON: soldier; b. in South Carolina, Oct. 7, 1821; was graduated at West Point in 1842; served in the Mexican war; resigned as captain of dragoons, Mar. 3, 1861, to accept a commission in the Confederate army; major-general (C. S. A.), Aug., 1862; lieutenant-general (C. S. A.), May, 1864; he commanded a division at Gettysburg. D. in Beaufort, S. C., June 26, 1879.

Anderson, ROBERT, M. D.: Scottish biographer; b. in Lanarkshire, Jan. 7, 1750; became a resident of Edinburgh in 1784; wrote a *Life of Dr. Johnson*, and published a good edition of *The Works of the British Poets, with Prefaces Biographical and Critical* (14 vols., 1792-1807). D. at Beaufort, S. C., Feb. 20, 1830.

Anderson, ROBERT: soldier; b. near Louisville, Ky., June 14, 1805; graduated at West Point, 1825; and May 15, 1861, brigadier-general U. S. A. His father was colonel in the Revolutionary army, and his mother a cousin of Chief Justice Marshall. He was private secretary 1825-26 to a relative upon his mission as U. S. minister plenipotentiary to the republic of Colombia, served at artillery school for practice 1826-28, chiefly on ordnance duty 1828-35, assistant inspector-general of Illinois volunteers in the Black Hawk war 1832, engaged at the battle of Bad Axe, at Military Academy as instructor of artillery 1835-37, in Florida war 1837-38 (brevet captain), in several actions, as aide-de-camp to Maj.-Gen. Scott while removing Cherokees to the West 1838, as assistant adjutant-general eastern department 1838-41, chiefly in garrison 1845-53, in war with Mexico 1847, engaged at Vera Cruz, Cerro Gordo, Amozoque, and Molino del Rey (severely wounded and brevet major), member of artillery boards 1841-60, governor of Harrodsburg Military Asylum 1853-54, inspector of ironwork for public buildings 1855-59; in command of defenses of Charleston harbor, S. C., 1860-61. In the civil war, after evacuating Fort Moultrie, he moved to Fort Sumter, which he surrendered after a heavy bombardment, Apr. 12-13, 1861 (brevet major-general); in command of department of Kentucky and of the Cumberland 1861, which his shattered health compelled him to relinquish. Till he was retired from active service, Oct. 27, 1863, he performed but little duty. He translated *Instructions for Field-Artillery, Horse and Foot* (1840), and *Evolutions of Field-Batteries* (1860). In vain he sought restoration for health abroad, his strength gradually failing till he died Oct. 26, 1871, at Nice, France, aged sixty-six.

Anderson, RUFUS, D. D., LL. D.: b. at North Yarmouth, Me., Aug. 17, 1796; graduated at Bowdoin College in 1818; and studied theology at Andover 1819-22. In 1824 he became assistant secretary, and in 1832 corresponding secretary of the American Board of Foreign Missions, which position he filled with distinguished ability for thirty-four years. He visited officially a part of the Mediterranean missions 1828-29, and another part 1843-44, the Indian missions 1854-55, and the Sandwich islands in 1863. At the age of seventy he resigned his position in the Board of Missions (1866), at which time, without any previous knowledge on his part, he was presented, as a testimonial to his faithful and meritorious services, with \$20,000 (contributed chiefly by the merchants of New York and Boston), which sum he made over to the board, reserving to himself the right to draw from it whatever might be necessary for his support. Among Dr. Anderson's numerous publications may be named: *Observations on the Petopounnesus and Greek Islands* (Boston, 1830); *The Hawaiian Islands, their Progress and Condition under Missionary Labors* (Boston, 1864); *A Heathen Nation Evangelized: History of the Mission, etc., to the Sandwich Islands* (1870); *History of the Missions of the American Board of Commissioners for Foreign Missions to the Oriental Churches* (1872). He was one of the founders of Mt. Holyoke Female Seminary, at South Hadley, Mass., several years president of trustees of Bradford Academy, Mass., and also a member of the board of trust of Andover Seminary, Mass. D. in Boston, May 30, 1880.

Anderson, WILLIAM, D. C. L.: civil engineer; director-general of ordnance-factories of the United Kingdom; b. in St. Petersburg, Jan. 5, 1835; educated at the High Commercial School in that city, and when he left in 1849 was head of the school, silver medallist, and, although a British subject, the freedom of the city was conferred on him. In 1849 he became a matriculated student in the department of applied sciences in King's College, London, leaving in 1851 with the degree of associate. He was then for three years a pupil of Sir William Fairbairn & Sons, being employed chiefly on important outwork. From 1855 to 1864 he was a partner of Courtney & Stephens, Dublin, building bridges, cranes, and railway appliances. In 1863 he became president of the Institution of Civil Engineers of Ireland. In 1864 he entered the firm of Easton & Amos, London, and later became the head of the house of Easton & Anderson. He is a member of the council of the Institution of Civil Engineers, vice-president of the Institute of Mechanical Engineers, visitor of the Royal Institute, and vice-president of the Society of Arts. He translated the remarkable work of Chernoff *On Steel*; the researches of Gen. Kalakonstki on *Internal Stresses in Cast Iron and Steel*; author of lectures on the *Generation of Steam*; on *Hydraulic Machinery*; on the *Monerieff Hydro-pneumatic Gun-carriage*; and *On the Conversion of Heat into Work*. In August, 1889, he was made director-general of the Royal Ordnance-factories. In 1889 he was president of Section G of the British Association. The University of Dublin has conferred on him the honorary degree of D. C. L.

WILLIAM R. HUTTON.

Andersonville: near Anderson R. R. sta., Sumter co., Ga.; (for location of county, see map of Georgia, ref. 5-G); 11 miles N. E. of Americus. During the civil war it was the site of a Confederate military prison for Federal soldiers. The mortality at this prison was very great; 12,926 prisoners of war died here. One Henry Wirtz, a Swiss adventurer, was the superintendent of the prison, and after the close of the war he was tried and convicted by a military commission on charges of excessive cruelty to the prisoners, and was executed Nov. 10, 1865. The Confederate authorities, in at least two official reports, attributed the excessive mortality to the bad management of the prison. Andersonville is now the site of a national cemetery, in which the deceased Union soldiers are buried. The cemetery is well laid out, trees have been planted, and the names of most of the dead have been ascertained and inscribed on headboards. Pop. (1880) 308; (1890) not given; (1900) 245.

Andersson, NILS JOHAN: Swedish botanist; b. at Gördseruan, Sweden, Feb. 20, 1821. He traveled extensively in Lapland and other parts of Scandinavia, and made a journey around the world 1851-53. His works are *En Verldsomsegting* (1853-54); *Satices Lapponice* (1845); *Cyperaceæ et Gramineæ Scand.* (1849-52); *Om Gatapagosöarnes Vegetation* (1854); and *Monographia Salicium* (1867). D. at Lund, Mar. 27, 1880.

R. B. ANDERSON.

Anderton, THOMAS: an English amateur musician who has gained an estimable reputation by his choral compositions. His first work of importance was *The Song of Deborah and Barak* (1871). His cantata *The Wreck of the Hesperus* (1882) is a fine setting of Longfellow's poem, and this same poet furnished the text for his next cantata, *The Norman Baron* (1884). For the Birmingham festival of 1885 he composed the cantata *Yule Tide*, which was performed with much success, and has been sung several times in the U. S. Mr. Anderton was born about the middle of the nineteenth century, and is much interested in the promotion of English choral music.

D. E. HERVEY.

An'des [Sp. *Cordille'ra de los An'des*; possibly from Peruvian *anti*, meaning metal or gold, or *Autis*, the name of a tribe resident in the mountains]: a South American range of mountains, one of the most prominent features of the globe. It extends along the western border of the entire continent, nearly parallel to the Pacific coast, from the Strait of Magellan to the Isthmus of Darien, a distance of about 4,500 miles. In length it far exceeds every other mountain-chain on the earth. The general direction of this chain is nearly north and south. The southern part of the Andes, for a distance of about 1,000 miles, consists of a single range or ridge, extending through Patagonia. North of that the system may be described as a basal mass with capping ridges called *cordilleras*. The Patagonian Andes rise to the height of 8,000 feet. The Chilean Andes, southward from 27° S., have an average width of about 130 miles, and in some places

are not more than 100 miles from the Pacific. The highest summit of the Chilean Andes, and probably of the whole chain, is the porphyritic Nevado of Aconcagua, which rises 22,900 feet above the level of the sea, and is about 100 miles N. E. of Valparaiso. In Chili also occur the volcanic peaks of Tupungato, 20,270, and Maypu, 17,764 feet high. The line of perpetual snow in the Andes of Northern Chili is about 14,000 feet above the sea.

About lat. 27° S. there are two *cordilleras*, which continue with some regularity northward into Colombia, where three are formed. In Bolivia and Peru these are called the Cordillera of the Coast and the Cordillera Real. The former extends northwestward along the coast of Peru, the summits of the range being about 100 miles from the ocean. The Cordillera Real, which traverses Bolivia, and is about 250 miles from the other range, is nearly equal in height to the Chilean Andes. The peak of Illampu, in Bolivia, has an altitude of 21,500 feet. These two parallel cordilleras are connected at several points by transverse ranges or groups called *knots*, and inclose the table-land of Desaguadero and Lake Titicaca, which is 12,800 feet above the level of the sea. The highest summit of the Peruvian Andes is the volcano of Arequipa, 20,300 feet high, and 55 miles from the Pacific coast.

Proceeding northward, we come next to the Andes of Ecuador, or Andes of Quito, which extend from lat. 5° S. to the table-land of Quito, inclosed between two ranges of enormous volcanoes. Among these the highest are Chimborazo, 20,545 feet, and Cotopaxi, 19,498 feet (Humboldt says 19,069). The form of the latter is that of an almost perfect cone. "Among all the volcanoes that I have seen," says Humboldt, "the conical form of Cotopaxi is the most beautifully regular." See COTOPAXI.

There are a number of passes which cross the Andes, but all at a great elevation, and mostly dangerous as well as arduous. Several passes among the Peruvian and Bolivian Andes are about 15,000 feet above the sea, and the lower passes are not less than 12,000 feet. A railway is nearly completed (1893) across the South American continent, crossing the Andes S. of Aconcagua.

Minerals.—The rocky foundations of these grand barriers are granite, gneiss, mica-slate, greenstone, porphyry, quartz, and other metamorphic rocks. Humboldt saw in Peru vast masses of quartz 7,000 or 8,000 feet in height. The Andes are celebrated for their mineral riches, consisting of large quantities of gold and silver. Platinum, mercury, copper, tin, and iron are also found among them. The most productive gold mines are in Peru and New Granada; the silver mines of Potosi are among the richest in the world. Few parts of the globe are subject to so frequent and destructive earthquakes as the countries adjacent to the Andes and inclosed between its different ranges. The cities of Quito, Lima, Callao, and Valparaiso have been nearly ruined by them in recent times. The number of volcanoes among the Andes is about fifty, thirty-six of which are classified as active, and the others are doubtful, not having been seen in a state of eruption by any European. "It is but rarely," says Humboldt, "that the elastic forces at work within the interior of our globe have succeeded in breaking through the spiral domes which, resplendent in the brightness of eternal snow, crown the summits of the Cordilleras; and even where these forces have opened a permanent communication with the atmosphere through circular craters or long fissures, they rarely send forth currents of lava, but merely eject ignited scoriæ, steam, sulphuretted hydrogen gas, and jets of carbonic acid." (*Cosmos*.) This illustrious traveler states that he found pelagic shells on a ridge of the Andes more than 15,000 feet above the sea.

The geological structure of the Andes is as yet but imperfectly known, and is probably not the same in all parts of the chain. Like all great mountain systems, the Andes have been produced by elevatory forces acting at different and in some instances widely separated periods. Carboniferous, Triassic, Jurassic, and Tertiary rocks have been recognized on their flanks; and the older Palæozoic will undoubtedly be found to make up a part of their mass.

Climate.—The limit of perpetual snow on the Andes that are near the equator is about 15,000 feet, and among the Bolivian Andes, about lat. 20° S., it is said to be 17,000 feet. Glaciers rarely if ever occur in the central or tropical portions of the Cordilleras. Between the equator and lat. 30° S. the prevailing wind blows from E. to W., and the eastern side of the Cordillera intercepts nearly all the moisture, so that little or no rain falls in Peru and Northern Chili on the

western slope, or on the narrow tract between the Andes and the ocean. The changes of weather among these mountains are sudden and violent, and the electric storms are very terrific. Here are exhibited greater variations and contrasts of climate than in any other region of the globe. The elevated plains within the tropics have a cool and salubrious climate, and the fruits of the temperate zone here flourish under the equator. Although the Andes are inferior to the Himalayas in altitude, they present a more remarkable variety of phenomena. "This portion of the surface of the globe," says Humboldt, "affords in the smallest space the greatest possible variety of impressions from the contemplation of nature. Among the colossal mountains of Cundinamarca, of Quito, and of Peru, furrowed by deep ravines, man is enabled to contemplate alike all the families of plants and all the stars of the firmament. There at a single glance the eye surveys majestic palms, humid forests of *Bambusa*, and the varied species of *Musaceæ*, while above these forms of tropical vegetation appear oaks, medlars, the sweetbrier, and umbelliferous plants, as in our European homes. . . . There the depths of the earth and the vaults of heaven display all the richness of their forms and the variety of their phenomena. There the different climates are ranged the one above the other, stage by stage, like the vegetable zones whose succession they limit; and there the observer may readily trace the laws that regulate the diminution of heat as they stand indelibly inscribed on the rocky walls and abrupt declivities of the Cordilleras."

Revised by MARK W. HARRINGTON.

Andesite: a volcanic rock of which there are many varieties. The name was first used by Von Buch for certain rocks brought by Von Humboldt from the Andes mountains. The silica percentage of the Andesites ranges between 53 and 63. Chemically and mineralogically they are the surface or lava equivalents of the *Diorites* (*q. v.*). The distinctive features of the type Andesite are mainly structural, indicating the conditions under which they solidified. (See Rocks.) All andesites contain some triclinic feldspar, usually oligoclase or andesine, as an essential constituent. The main basis of their specific subdivision is given by their other components. If they are acid enough to contain free silica, they are known as *Dacite*. According to the nature of their ferro-magnesian constituents they are classified as *mica-andesite*, *hornblende-andesite*, *mica-hornblende-andesite*, *augite-andesite*, *hypersthene-andesite*, etc. The term andesite should properly be applied to only such rocks as have a fine-grained or glassy base. Equivalent rocks with a more coarsely crystalline ground-mass are called *porphyrites*. Andesites are exceedingly wide-spread in volcanic regions. They were formerly often mistaken for trachytes, which they frequently resemble. Von Richthofen has shown that they are usually the oldest lavas of a given district, the subsequent eruptions becoming alternately more acid and more basic. Andesites are very extensively developed in the Western U. S., where they have been carefully studied. By partial alteration they may produce the so-called *propylites*.

G. H. WILLIAMS.

Andijan: a city of Ferghana, Turkestan, Asiatic Russia; the capital of the region in Baber's time (fifteenth century); lat. 38° 50' N., lon. 72° 20' E.; elevation, 1,170 feet (see map of Asia, ref. 4-D). It is in the valley of the upper Syr Darya, and is a station on one of the most important caravan routes of Central Asia. Pop. (1886) 30,620; (1897) 46,680.

Andi'ra: a genus of plants of the family *Leguminosæ*. The *Andira inermis*, called cabbage-tree or cabbage-bark tree, is a native of the West Indies. The bark of the *Andira*, called worm-bark, is a powerful anthelmintic.

An'dirons [O. Fr. *andier*, Mod. Fr. *landier*, for *l'andier*. The latter part of the Eng. is due to folk-etymol. connection with *iron*. Origin of *andier* obscure]: the metallic utensils used to support the wood which is burned in an open fireplace. They are called fire-dogs in some parts of Great Britain. They are often called "dogirons" in many parts of the U. S. The andiron consists of a horizontal bar, supported by three feet, and having an upright standard at one end. This was sometimes silver, and ornamented with arabesques or a human figure.

Andoc'ides (Ἀνδοκίδης): accounted the least of the ten Attic orators, is not the least in interest (440—after 391 B. C.). Involved with other young aristocrats in the mutilation of the Hermæ, 415 B. C. (see HISTORY OF GREECE), he went into exile, from which he returned only to be banished again. Four speeches are extant under his name, one of them spurious. A "gentleman orator," he has a certain native grace of narrative, and his speeches are of importance for Athenian history and social life. See Blass, *Attische Beredsamkeit*, 2d ed., i. 280; Jebb, *Attic Orators*, i. 71; text ed. Blass (1880), with English notes by Marchant (1889).

B. L. GILDERSLEEVE.

Andor'ra: a small republic under the joint suzerainty of France and the Spanish Bishop of Urgel, among the Eastern Pyrenees, between the French department of Ariège and the Spanish province of Lérida. Area, 175 sq. miles. It is surrounded by high mountains, and has rich mines of iron and a lead mine. It became autonomous in 790, and is governed by a council of twenty-four, elected for four years. The inhabitants are mostly farmers, cattle-raisers, and miners. Pop. about 6,000. Capital, Andorra.

An'dover: a market-town and parish of England; in Hampshire, 63 miles W. S. W. of London. The town is very ancient. It has a handsome church, which cost about \$150,000. Pop. about 6,000.

Andover: town (incorporated in 1646); on Boston and Maine R. R., Essex co., Mass. (for location of county, see map of Massachusetts, ref. 1-I); on the south bank of the Merrimack river. The village of Andover is pleasantly situated on the Shawsheen river, 22 miles N. of Boston. It has extensive water-power and manufactures of shoe-thread, woolen goods, rubber goods, printer's ink, lamp-black, lamps, and bronze goods, etc. It has a national bank and a savings-bank; a newspaper, a water-supply from a local lake, electric lights, a street-railway system, a free public library of over 12,000 volumes, and a good system of free public schools. Here are also Phillips Academy (a school for boys founded in 1778); Andover Theological Seminary (founded in 1807); and Abbot Academy for young ladies (founded in 1829). Pop. of township (1870) 4,873; (1880) 5,169; (1890) 6,142; (1900) 6,813.

EDITOR OF "TOWNSMAN."

Andover Theological Seminary: a Protestant charitable foundation for the training of Christian ministers. This seminary is one of the oldest in the U. S., and was an outgrowth from the provision originally made for theological instruction in Phillips Academy. It is under the control of the trustees of that academy, and is subject, as respects most of the foundations, to the visitation of an independent board of visitors. It was established upon endowments, given by Samuel Abbot, Mrs. Phœbe (Foxcroft) Phillips, John Phillips, William Bartlet, Moses Brown, and John Norris. It was opened in 1808, and in 1900 numbered 2,141 graduates who have entered the ministry chiefly of the Congregational and Presbyterian churches. It has taken a leading part in religious movements among Congregationalists, and has educated many writers as well as preachers. The *Bibliotheca Sacra* and later *The Andover Review* have been edited by its professors. Among its early professors were Leonard Woods, Moses Stuart, and Edward D. Griffin. The successor of Woods in the chair of doctrinal theology was Edwards A. Park, who was followed (1883) by George Harris. The faculty consists at present of nine professors. No charge is made for tuition. The seminary library contains 52,000 volumes, and with it is connected a valuable Palestinian museum.

W. L. ROPES.

Andra'da, DIOGO PAYVA DE ANDRADE: b. in 1528 at Coimbra, Portugal; became a Jesuit and one of the Portuguese delegates to the Council of Trent. D. in Lisbon, Portugal, in 1575.—His brother, THOMAS DE JESUS, was an Augustinian monk; taken prisoner in the battle of Alcacer in 1578, and kept in a dungeon till his death, Apr. 17, 1582. He wrote while there his famous book, *The Labors of Jesus*.

Andrada, ANTONIO, de: b. at Villa de Oleiros, Portugal, in 1580; entered order of the Jesuits in 1596 at Coimbra, Portugal; went to India as a missionary in 1601, and became superior of the missions of Mongolia. He made two journeys from there to Thibet, and published *New Discovery of the Grand Cathay, or Kingdom of Thibet* (1627). D. at Goa, Aug. 20, 1633.

Andrada, FERNÃO PEREZ, de: an officer in the Portuguese navy. He commanded a vessel in the fleet of Albuquerque, who made him admiral of a fleet of ten ships at

Malacca in 1511. He defeated the Sultan of Java in a naval engagement in 1513, was the commander of the first European fleet on the coast of China (1518), and opened commercial intercourse with that country.

Andrada e Silva, JOSÉ BONIFACIO, de: a distinguished Brazilian; b. at Santos, June 13, 1763. He acted a prominent part in the revolution by which Brazil became independent in 1822, and was prime minister in 1822-23. He wrote some scientific treatises and poems. D. near Rio, Apr. 3, 1838. See BONIFACIO, JOSÉ.

Andral, GABRIEL, M. D.: French physician; b. in Paris, Nov. 6, 1797; married a daughter of Royer-Collard. He published an able work called *Clinique Médicale* (4 vols., 1824-27). In 1839 he succeeded Broussais as Professor of Pathology and Therapeutics in Paris, and in 1842 became a member of the Institute. Among his works is a *Summary of Pathological Anatomy* (3 vols., 1829). D. at Chateaufieux, Feb. 13, 1876.—His father, GUILLAUME ANDRAL, was a celebrated physician.

Andrássy, JULIUS, Count: Hungarian statesman; b. at Zemplin, Mar. 8, 1823, of an ancient and noble family. He took a prominent part in the revolution of 1848 as an adherent of the popular cause, and was condemned to death in 1850, but he escaped and went into exile. When the right of self-government was restored to Hungary, in Feb., 1867, Andrássy was appointed premier of a new Hungarian ministry by the emperor. He succeeded Von Beust 1871-79, as minister of foreign affairs in the common ministry of the whole empire. D. at Volosca, Feb. 18, 1890.

An'dré, JOHN: British officer; b. in London, of Swiss parents, in 1751; entered the army in 1771. Having obtained the rank of lieutenant, he was sent to America in 1774. His superior talents and fine personal qualities procured for him a rapid promotion to the important position of adjutant-general, with the rank of major (1779). He was a good scholar, an artist, a versifier, and a man of varied accomplishments. Benedict Arnold having offered to betray West Point, Major André was selected by Sir Henry Clinton, the British commander, to make the necessary arrangements for carrying out the plot. André, assuming the name of Anderson, ascended the Hudson, and, having had a private interview with Arnold (Sept. 21, 1780), by whom he was furnished with maps and plans of West Point and a pass through the American lines, was, while returning to New York city by land, intercepted near Tarrytown by three armed Americans (John Paulding, David Williams, and Isaac Van Wart), who, discovering by incautious remarks on his part that he was a British officer, took him prisoner. On searching his person they found the plans in his boots. He made an unsuccessful effort to bribe his captors, who conducted him to Lieut.-Col. Jameson, who, with singular obtuseness, resolved to send him to Gen. Arnold, but was dissuaded by Major Tallmadge. Major André was tried as a spy by a board of six major-generals and eight brigadier-generals and condemned to be hung. Sir Henry Clinton made earnest efforts to save his life, but they were unavailing, and he was executed at Tappan, N. Y., Oct. 2, 1780. He behaved with dignity and fortitude on this occasion, and his fate excited deep and general sympathy. The day before his death he drew with a pen and ink a portrait of himself, which is now in the Trumbull Gallery of Yale College. A monument was erected to his memory in Westminster Abbey. Another monument on the scene of his execution at Tappan, erected by Cyrus W. Field, was destroyed by the neighbors. See his life by Winthrop Sargent (Boston, 1861), and *Arnold and André* by Wm. Abbatt (1899).

Andrea del Sarto: See SARTO.

Andrea Pisano, or **Andrea da Pisa**: sculptor; b. at Pontedera, near Pisa, in 1217; d. about 1348. He was a pupil of Giovanni Pisano, and continued the work of that master in its semi-Gothic character. His most important remaining works are the bronze doors in the south doorway of the baptistery at Florence; these are of extraordinary beauty, and of a delicacy of finish never surpassed in similar work. Shortly before his death he became architect of the cathedral at Orvieto, succeeding Lorenzo Maitani.

RUSSELL STURGIS.

Andre'æ, JACOB, D. D.: German Protestant theologian; b. at Waiblingen, in Württemberg, Mar. 25, 1528. He became chancellor of the University of Tübingen in 1562. He was incessantly active in efforts for the more complete organization of the Lutheran Church in Germany, participat-

ing in probably more theological conferences than any other Lutheran theologian, and traveling over all parts of Germany and into other European countries in pursuance of his mission. In April, 1561, he went to Paris to confer with King Antony of Navarre concerning the Lutheran faith. He is the principal author of the *Formula of Concord*. He left over 150 writings. D. at Tübingen, Jan. 7, 1590. See his life by J. A. Mosapp (Barmen, 1890).

HENRY E. JACOBS.

Andreæ, JOHANN VALENTIN: German writer; b. at Herrenberg, in Würtemberg, Aug. 17, 1586; became pastor at Calw in 1620, and chaplain or court-preacher at Stuttgart in 1639. He wrote numerous pamphlets attacking with satire the corruptions and formalism of the religious life of his times. He has been regarded as the founder of the order of Rosicrucians, but without sufficient evidence. D. at Stuttgart, June 27, 1654. "Andreæ," says Hallam, "was a man above his age."
H. E. J.

Andreæ, LAURENTIUS (in Swedish, *Lars Anderson*): a Swedish reformer; b. at Strengnäs, 1480. He was converted to Protestantism, and in 1524 was appointed Chancellor of Sweden by Gustavus Vasa. He produced in 1526 a Swedish translation of the New Testament. D. at Strengnäs, Apr. 29, 1552.

Andreani, ANDREA: engraver on wood; b. at Mantua about 1540; d. 1623. His most remarkable work is in chiaro-scuro, in which branch of the art he is one of the great masters.

An'dree, KARL THEODOR: German writer; b. in Brunswick, Oct. 20, 1808; was from 1838 to 1853 editor of several periodicals, as the *Bremer Zeitung* and *Deutsche Reichszeitung*, and was, 1858, appointed consul to Chili. Among his principal works are *Nordamerica* (2d ed. 1854); *Buenos Ayres und die Argentin Republik* (1856); *Geographische Wanderungen* (1859); and *Geographie des Welthandels* (1863-69). D. Aug. 10, 1875.

Andrée, S. A.: See the Appendix.

Andréossy, an'-dray'ô-se, ANTOINE FRANÇOIS, Count: French military engineer; b. at Castelnaudary, Mar. 6, 1761. He served in Egypt as general of brigade in 1798, and became a member of the Institute of Egypt. He was the chief of Bonaparte's staff on the 18th Brumaire, 1799, obtained the rank of general of division, and was sent as ambassador to England in 1802. Between 1804 and 1814 he represented France at the courts of Vienna and Constantinople. In 1826 he was chosen a member of the Academy of Sciences. He wrote, beside other works, *Constantinople and the Thracian Bosphorus during the Years 1812-14* (1828). D. at Montauban, Sept. 10, 1828.

An'drés, JUAN: Spanish Jesuit distinguished for learning; b. at Planes, Feb. 15, 1740. He was versed in Hebrew, Greek, Latin, Italian, and French. On the expulsion of the Jesuits from Spain in 1767 he removed to Italy. He produced in 1776 an able *Essay on the Philosophy of Galileo*, in Italian. His principal work is *On the Origin, Progress, and Present State of all Literature* (in Italian, 7 vols., 1782-99). He was appointed keeper of the royal library at Naples in 1806. D. Jan. 13, 1817.

An'drew, SAINT: one of the twelve apostles; was, like his brother Simon Peter, a fisherman of Galilee. He is supposed to have been the first disciple of Christ. The latter part of his life is involved in obscurity. According to tradition, he preached the gospel in Greece and Scythia, and suffered martyrdom in Patræ, in Achaia. He is the patron saint of Scotland. A cross formed by oblique beams, thus, X, is called St. Andrew's cross, because he is said to have been crucified upon one so shaped. St. Andrew's day is Nov. 30.

Andrew (or Andrés) I.: King of Hungary; was of the family of Arpad. He began to reign in 1046, and waged war against the Emperor Henry III. D. in 1058.

Andrew II. of Hungary: b. about 1176, and became king in 1205. He conducted an unsuccessful crusade against the Mohammedans in 1217. In 1222 he convoked a diet, to which he granted the Golden Bull, called the Magna Charta of Hungary. It confirmed the rights and privileges of the Hungarian bishops and nobility, whose revolts had disturbed his reign. D. Mar. 7, 1236.

Andrew III. of Hungary: grandson of the preceding; b. in Venice. He succeeded Ladislas III. in 1290, and was the last king of the dynasty of Arpad. His claim to the throne

was opposed by the pope, who supported Charles Martel (son of Charles II. of Naples) as the rival of Andrew. The latter defeated Charles Martel in battle in 1291. D. Jan. 14, 1301.

Andrew, JAMES OSGOOD, D. D.: bishop of the Methodist Episcopal Church South; b. in Wilkes co., Ga., May 3, 1794. He entered the itinerant ministry in the South Carolina Conference of the Methodist Episcopal Church Dec. 12, 1812, and was consecrated bishop at Philadelphia in May, 1832. By his second marriage, in 1844, he became the owner of a few slaves. The General Conference of the same year adopted resolutions requesting him to resign from his office of bishop. Thirteen of the southern conferences protested this action, and finally withdrew, forming the Methodist Episcopal Church South. He presided over this organization as senior bishop till his death, in Mobile, Ala., Mar. 2, 1871. In Apr., 1866, he was placed upon the retired list at his own request. He published *Family Government* and *Miscellanies*.

Andrew, JOHN ALBION, LL. D.: statesman; b. at Windham, Me., May 31, 1818; graduated at Bowdoin College in 1837, studied law, and was admitted to the bar of Boston in 1840. Having distinguished himself as an opponent of slavery, he was elected Governor of Massachusetts by the Republicans in 1860. In answer to the President's call for volunteers, Apr. 15, 1861, he dispatched five regiments in one week from that date. He was again elected Governor in 1861, and was afterward thrice annually re-elected. During the civil war he rendered important services to the cause of the Union by his eloquent speeches and messages, and gained great popularity by his assiduous attention to the welfare of the soldiers. D. in Boston, Mass., Oct. 30, 1867. A meeting of the members of the Legislature of Massachusetts adopted a resolution "that in his decease the Commonwealth and the nation alike have suffered an irreparable loss; that his reputation had become national, and we might well have hoped for him the highest national offices and honors."

Andrew, ORDER OF SAINT: a Scottish order of knighthood (called also *The Order of the Thistle*), named in honor of St. Andrew, the patron saint of Scotland. It was founded in the reign of James V., was revived by James II. of England in 1687, and re-established by Queen Anne in 1703. The star of the order of the Thistle consists of a St. Andrew's cross of silver embroidery, with rays emanating between the points of the cross, in the center of which is a thistle of gold and green. On a circle which surrounds this thistle is inscribed the motto "Nemo me impune lacessit" (literally, No one provokes me with impunity).

Andrew, ORDER OF SAINT: a Russian order founded by Peter the Great in 1698; the highest in the empire; bestowed only on the imperial family, princes, generals-in-chief, and persons of high rank. The badge of this order bears on one side a cross enameled in blue, and in the four corners of the cross the letters S. A. P. R. (*Sanctus Andreas Patronus Russiae*). On the reverse is a spread-eagle, with a legend signifying "For religion and loyalty."

Andrews, CHARLES, LL. D.: b. at Whitestown, Oneida co., N. Y., May 27, 1827; studied law in Syracuse, N. Y.; was admitted to the bar in 1849. He was in partnership with the Hon. Charles R. Sedgwick from 1851 until he was elected, May 17, 1870, associate judge of New York Court of Appeals. Prior to this he had held various official positions. He was district attorney of Onondaga co., N. Y., 1853-56; mayor of Syracuse in 1861, 1862, and 1868; was a delegate-at-large to the constitutional convention of 1867-68, and was appointed chief judge of New York Court of Appeals in 1881.

Andrews, CHRISTOPHER COLUMBUS: general of volunteers during the civil war (1861-66); b. at Hillsborough, N. H., Oct. 27, 1829; appointed brigadier-general of volunteers Jan. 5, 1864, mustered out Jan. 15, 1866. Was U. S. minister to Sweden 1869-76, and became U. S. consul-general for Brazil, 1882.

Andrews, EDWARD GAYER, D. D., LL. D.: preacher and bishop of Methodist Episcopal Church; b. in New Hartford, N. Y., Aug. 7, 1825; graduated at the Wesleyan University, Connecticut, in 1847; entered the ministry in 1848; became teacher in the Oneida Conference Seminary, Cazenovia, N. Y., in 1854; was elected its president in 1855; resumed the pastorate in New York East Conference in 1864; and was elected bishop in 1872. Since 1888 he has resided in New York city.

Andrews, ELISHA BENJAMIN, D. D., LL. D.: chancellor of Nebraska University; b. at Hinsdale, N. H., Jan. 10, 1844; prepared for college, but entered the army in 1861 and served till 1864, rising from private to second lieutenant; was wounded at Petersburg, Aug. 24, 1864, suffering the loss of an eye; graduated at Brown University, Providence, R. I., 1870; at Newton Theological Institute, Newton, Mass., 1874; principal of Connecticut Literary Institute, Suffield, Conn., 1870-72; pastor of First Baptist church, Beverly, Mass., 1874-75; president of Denison University, Granville, O., 1875-79; Professor of Homiletics in Newton Theological Institute 1879-82; Professor of History and Political Economy in Brown University 1882-88, spending one year in studying at Berlin and Munich; Professor of Political Economy and Finance in Cornell University 1888-89; president of Brown University 1889-98 (resigned on account of criticism by the faculty of his attitude on the silver question); superintendent of Chicago public schools 1898-1900; chancellor of the University of Nebraska, Lincoln, August, 1900; member for U. S. of International Monetary Conference, Brussels, 1892; author of *Institutes of Our Constitutional History, English and American* (1887); *Institutes of General History* (1889); *Institutes of Economics* (1889); *Institutes of Our Economical History and An Honest Dollar* (1894); *History of the United States* (1894); *Wealth and Moral Law* (1894); *History of the Last Quarter Century in the United States* (1896). C. H. THURBER.

Andrews, ETHAN ALLEN, LL. D.: scholar; b. at New Britain, Conn., Apr. 7, 1787; graduated at Yale College in 1810, and taught until 1839, when he retired to his native town and gave himself to the production of text-books in Latin. His most important work was his Latin-English lexicon (1850), based on Freund. With Stoddard he brought out a well-known Latin grammar. D. at New Britain, Conn., Mar. 25, 1858.

Andrews, GEORGE L.: general; b. at Bridgewater, Mass., Aug. 31, 1828; graduated first in his class at West Point in 1851. He was acting assistant Professor of Engineering at West Point (1854-55), and for distinguished services in the Army of the Potomac became brigadier-general and brevet major-general of volunteers. In 1871 he was appointed Professor of French, and in 1882 Professor of Modern Languages, at West Point. D. Apr. 4, 1899.

Andrews, GEORGE P.: See the Appendix.

Andrews, JAMES PETIT: historical writer; b. near Newbury, in Berkshire, England, in 1737. He published an amusing *Collection of Anecdotes, etc., Ancient and Modern* (1789). His most important work is a *History of Great Britain in Connection with the Chronology of Europe* (1 vol., 1794, unfinished). D. Aug. 5, 1797.

Andrews, or Andrewes, LANCELOT: a learned English theologian; one of the most illustrious of English prelates; b. in London, Sept. 25, 1555; educated at Cambridge and Oxford. He was one of the chaplains of Queen Elizabeth, who appointed him Dean of Westminster. He was one of the divines selected to translate the Bible under the auspices of James I., and became Bishop of Chichester in 1605. In 1609 he was translated to the see of Ely, and appointed a privy counselor; was considered the most learned English theologian of his time, except Ussher, and had a high reputation as a pulpit orator. His works, though uncritically edited and but fragmentary, place him in the front rank of English theologians. He became Bishop of Winchester in 1618; he was the author of religious works, among which was a *Manual of Private Devotions and Meditations for Every Day in the Week*. In polemics he assailed Bellarmine in his *Responsio ad Apologiam*, a treatise never answered. On Nov. 23, 1600, Andrews preached at Whitehall his memorable sermon on justification, maintaining the evangelical view as opposed to the sacerdotal. Andrews, in the Lambeth Articles, which mark an epoch in English Church history, adopted the doctrine of St. Augustine as modified by Aquinas. D. in London, Sept. 25, 1626.

W. S. PERRY.

Andrews, LORRIN: b. in East Windsor, Conn., Apr. 29, 1795; educated at Jefferson College, Pa., and at Princeton; sailed as a missionary to Hawaii in 1827; founded in 1831 the Lahainaluna Seminary, which became the Hawaii University, in which he was a professor. He was long a judge and privy counselor under the Government, and published parts of the Bible in the native tongue, wrote a Hawaiian dictionary, and various works on the history, etc., of the Sandwich islands. D. at Honolulu, Sept. 29, 1868.

Andrews, NEWTON LLOYD, Ph. D., LL. D.: Baptist educator; b. at Fabius, N. Y., Aug. 14, 1841; graduated at Colgate University, 1862, and Hamilton Theological Seminary, 1864; principal of Preparatory School, Colgate University, 1864-69; Professor of Greek Language and Literature, Colgate University, since 1868; Dean of Faculty, Colgate University, from 1880 to 1892. W. H. W.

Andrews, THOMAS, LL. D.: chemist; b. in 1813, and d. at Belfast, Ireland, Nov. 26, 1885. From 1835 to 1844 he practiced medicine, and from 1845 to 1879 was Professor of Chemistry in Queen's College, Belfast. His principal work was on ozone, and on the continuity of the liquid and gaseous conditions of matter. He was an honorary LL. D. of the Universities of Dublin, Glasgow, and Edinburgh, a F. R. L. and F. R. S. E., etc.

Andrews, THOMAS, F. R. S., F. C. S.: engineer; b. in Sheffield, 1847; educated at Broomhank School and by private tutors, and was carefully trained by his father in metallurgy, mining, and engineering. In 1871 he succeeded his father as proprietor of the Wortley iron-works and Silkstone colliery. He has devoted much research to questions involving the resistance of metals in railway construction, electro-magnetism, and heat dilatation of metals, and is the author of numerous scientific papers.

An'dria: a town of Southern Italy; in Bari, 14 miles by rail E. of Canosa (see map of Italy, ref. 6-G). It is the seat of a bishop, and has a fine cathedral, built in 1046; also a college. In the vicinity are numerous caverns (in Latin, *antra*), from which the name is said to be derived. Pop. 39,493.

An'dro, or An'dros: an island of Greece; in the archipelago, about 10 miles S. E. of Eubœa; is the most northern of the Cyclades. Length, 21 miles; width, 8 miles; area, 156 sq. miles. The surface is hilly, the soil is fertile. Andros is also the name of a town and port on the eastern coast. Lat. of Cape Guardia, its N. W. point, 37° 58' N., lon. 24° 43' E. Pop. of the island, 22,256.

An'drocles, or An'droclus: a Roman slave, whose adventures and friendship with a lion are mentioned by Aulus Gellius. He ran away from his master into Africa, and there entered a cave in which he met a lion that was lame. The lion presented to him a paw, from which Androcles extracted a thorn. To recompense him for this service the lion afterward supplied the man with food as long as he remained in that region. Androcles finally was captured and was condemned to fight with a lion in the amphitheater of Rome. This lion proved to be the same that he had met in the cave, and, though purposely kept from food to increase his ferocity, he instantly recognized his benefactor as a dog would his master. The man was then pardoned, and both the man and the lion were liberated.

Androm'ache (Gr. *Ἀνδρομάχη*): a celebrated and beautiful Trojan; wife of Hector, and one of the most admired characters of the *Iliad*. After the destruction of Troy she became the captive of Pyrrhus, and finally the wife of Helenus, a son of Priam. She is the subject of a tragedy of Euripides of that name.

Androm'eda (Gr. *Ἀνδρομέδη*): in classic mythology, a daughter of Cepheus, King of Ethiopia, and of Cassiopeia. She boasted that she was more beautiful than the Nereids. Neptune, to avenge this affront, sent a sea-monster to plague the Ethiopians. The oracle of Ammon having declared that the sacrifice of Andromeda would appease Neptune, she was chained to a rock, but was rescued by Perseus, and after death was transformed into a constellation. The constellation Andromeda may be seen during the autumn and early winter, and recognized by three stars of the second magnitude extending in a row from the N. E. corner of the square of Pegasus toward Perseus. S. N.

Andromeda: a genus of shrubs of the order *Ericaceæ*, found in America, Europe, and Asia. The *Andromeda polifolia*, common to both hemispheres, has fine rose-colored flowers. The *Andromeda floribunda* of the U. S. also has abundant and very fine flowers, appearing in April. The *Andromeda nitida* of the Southern States has fragrant blossoms. The U. S. has at least eight species, some of which are reputed poisonous to cattle.

Androni'cus I., COMNENUS (Gr. *Ἀνδρόνικος Κομνηνός*): a Byzantine emperor; grandson of Alexis I., Comnenus. He had superior talents, but was profligate and cruel. In his

youth he engaged in treasonable intrigues against the Emperor Manuel, who confined him in prison many years. Having been appointed regent during the minority of Alexis II., he murdered that prince and usurped the throne in 1183. He abused his power by the execution of many Greek nobles, victims of his revenge or jealousy, and carried his cruelty to such excess that his subjects revolted and tortured him to death Sept. 12, 1185.

Andronicus II., PALÆOLOGUS: a son of the Emperor Michael; b. about 1260. He began to reign at Constantinople in 1283. He waged war against the Turks without decisive result. His reign was inglorious, and he was dethroned in 1328 by his grandson, Andronicus III. D. Feb. 13, 1332.

Andronicus III., PALÆOLOGUS: a grandson of the preceding; became Emperor of Constantinople in 1328, and was defeated by the Turks in 1330. His reign was disastrous, and the Turks conquered several of his provinces. D. June 15, 1341.

Andronicus Rhodius (i. e. of Rhodes): a Greek Peripatetic philosopher who lived about 60 B. C. He collected and arranged the works of Aristotle.

Audropogon [from Gr. ἀνήρ, ἀνδρός, man + πῶγων, beard, i. e. having a beard like a man]: an extensive genus of grasses (according to Hackel, 193 species), mostly coarse and many of them tropical. The U. S. has about nineteen species, some of which are known as blue-stem grasses, and are valuable for hay upon the plains. As extended by Hackel, the genus includes sorghum cane, and broom corn, *A. sorghum*, of many varieties. *A. schoenanthus* is extensively cultivated in Ceylon and other Oriental regions for its oil. It is called oil of citronella, and is chiefly used in perfuming the so-called "honey-soap." Other foreign species are cultivated for their oils, which are sold as "oil of verbena," "lemon-grass," "geranium," etc.

Revised by CHARLES E. BESSEY.

Audros, Sir EDMUND: an English governor; b. in London, Dec. 6, 1637. He was Governor of New York from 1674 to 1682, and was appointed Governor of New England in 1686. His arbitrary and oppressive conduct, which rendered him very unpopular, may be accounted for by the fact that he was compelled to carry out the orders of his royal master, the Duke of York. His private character was excellent. On Apr. 18, 1689, the people of Boston revolted and deposed him. He was sent to England for trial the next year, but was never tried. He governed Virginia from 1692 to 1698. From 1704 to 1706 he was governor of the island of Jersey; afterward he lived in London; died there Feb. 24, 1714. S. M. J.

Audros, THOMAS: b. at Norwich, Conn., May 1, 1759; joined the American army at Cambridge, Mass., in 1775, and was engaged in the battles of Long Island, White Plains, and also in other engagements; enlisted in a New London privateer in 1781; was taken prisoner and confined at New York in the Jersey prison-ship, but soon after escaped; studied theology at Plainfield, and preached at Berkley, Mass., from 1788 to 1834, and there died Dec. 30, 1845.

Audroscoggin: a river which rises in Umbagog Lake, and flows southward through Coos co., N. H., to the western boundary of Maine, which it crosses. Running then in a general S. E. direction, it passes through Oxford and Androscoggin counties in Maine, and enters the Kennebec river 4 miles above Bath. Its length is 145 miles.

Audujar' (anc. *Illitur'gis*): a town of Spain; in the province of Jaen, on the Guadalquivir, at the foot of the Sierra Morena, 27 miles N. W. of Jaen (see map of Spain and Portugal, ref. 18-F). It has a trade in grain, fruit, and porous jars and pitchers, of which great numbers are made here, for the purpose of cooling water. Pop. 15,865.

Anel, DOMINIQUE: French surgeon and oculist; b. at Toulouse in 1678; practiced in Paris. He invented a probe and syringe, and was skillful in the treatment of aneurism and *fistula lachrymalis*. D. about 1728.

Anemometer [from Gr. ἄνεμος, wind + μέτρον, measure]: an instrument for measuring the velocity of the wind. It has taken very many forms, but the most usual, called Robinson's anemometer, from its inventor, consists of four hollow cups, on equal horizontal arms, turning on a vertical axis. The rotation of the cups is supposed to bear a fixed relation to the velocity of the wind, and a dial indicates

the miles of wind on this principle. Unfortunately this relation is not so simple, but varies with the instrument and with the velocity of the wind itself, and in practice a corresponding reduction is used. When a continuous record of the velocity is made automatically, the instrument is called an *anemograph*. A novel form of the instrument is one which measures only vertical currents and these have been found to be not infrequent. An instrument giving the direction of the wind only (that is a wind-vane) is sometimes called an anemoscope. MARK W. HARRINGTON.

Anemone [Gr. ἀνεμώνη, the wind-flower; from ἄνεμος, wind]: a genus of herbaceous plants of the family *Ranunculaceae*, natives of Europe, Asia, and North and South America. The species of anemone are numerous, and mostly have beautiful flowers, the size of which is increased by cultivation. The *Anemone hortensis*, or garden anemone, is highly prized and is extensively cultivated in Holland. It prefers a light soil. Among the other beautiful species are the *Anemone coronaria*, sometimes called poppy anemone; the *Anemone japonica*, a native of Japan; the *Anemone pratensis*, which has blue flowers; the *Anemone pulsatilla* (pasque flower), which grows wild in England, and has purple flowers; and the *Anemone nemorosa* (wood anemone), which has white flowers. In North America are found several species peculiar to this hemisphere, besides some which are common also in the Old World. Pulsatilla, a favorite remedy with homœopaths, is produced by a plant of this genus.

Anemone, properly **Sea-anemone**: a marine radiated animal belonging to the class *Actinozoa*. See ACTINIDÆ.

Anemoscope [from Gr. ἄνεμος, wind + σκοπός, observer, used as final element of compounds in sense "observing"]: an instrument which indicates the direction of the wind, as a vane or weathercock. Sometimes the vane turns a spindle which descends through the roof of the house into the chamber of the observer. An index fixed to the spindle indicates the direction of the wind on a compass-card fixed to the ceiling.

Aneroid Barometer: See BAROMETER.

Anet: a town of France; department of Eure-et-Loir, 9 miles N. E. of Dreux (see map of France, ref. 3-E). Near it is the plain of Ivry, where Henry IV. gained a decisive victory over the army of the League in 1590. Pop. about 1,500.

Aneurism [from Gr. ἀνευρυσμός, a widening; ἀνα-, back + εἶρύς, wide. The spelling with *-ism* for *-ysm* is due to false association with suffix *-ism*]: a pulsating tumor filled with blood, and communicating more or less directly with an artery, the tunics of which are wholly or partially destroyed. A "true" aneurism has one or more arterial coats in its wall. A "false" aneurism has a wall of condensed areolar tissue, the arterial coat having disappeared. A "traumatic" aneurism originates in a wound or other accidental injury. A "varicose" aneurism communicates with both an artery and a vein. When such dilatations occur in groups or knots, it is a "cirroid" aneurism. When the blood gets between the coats of an artery, and thus forms a tumor, it is a "dissecting" aneurism. The heart and its valves are liable to aneurismal dilatations.

Aneurisms, not due to injury, may usually be traced to degeneration of the coats of the artery. They are most frequent in the aorta near the heart, and give rise to a variety of distressing symptoms due to pressure, and may cause sudden death by rupture. Sometimes clots become deposited in the sac, and thus temporarily or permanently arrest the disease, but this is rare. The different methods of treatment all have this one common aim, to promote clotting in the sac. This may be accomplished by ligation of the vessels above or below the sac, or both; it may be similarly induced by digital pressure; or it may be brought about by introduction of foreign bodies, or in various other ways. The volume of the blood may be lessened, and the distension of the sac decreased, by prolonged fasting.

Revised by WILLIAM PEPPER.

Angara', or **Upper Tungus'ka**: a river of Siberia; divided into the Upper and Lower. The Upper falls into Lake Baikal; the Lower flows from the lake about 30 miles S. of Irkutsk. Passing by that town, it flows first northward, and afterward in a westerly direction, and enters the Yenisei, of which it is the principal tributary. Length, about 1,000 miles.

Angel [from Lat. *angelus* = Gr. ἄγγελος, messenger]: a ministering spirit; a spiritual, intelligent being employed

by God to carry commands, to announce glad tidings, and administer comfort to men. The Scriptures record many instances in which angels became visible to men (e. g. Gen. xviii.; xxxii. 1, 2). The ancient Hebrews believed in the existence of several orders of angels, among which were the seraphim and cherubim, and archangels. The only angels mentioned by name in the Bible are Michael and Gabriel. Raphael is mentioned in Tobit, a book of the Apocrypha. The popular notion that angels have wings is rather a poetical invention than a revealed truth. The belief in guardian angels has been cherished by Jews and Christians of all ages. Cf. Matt. xviii. 10.

ANGEL, an ancient English gold coin, so called from the figure of the archangel Michael piercing the dragon, which was on its obverse. The value of the angel (which continued to be coined until 1650) varied from 6s. 8d. to 10s.

An'gela Merici, or **Angela of Brescia**: b. at Desenzano, on Lake Garda, Lombardy, Italy, Mar. 21, 1470; founder of the order of the Ursulines (an order of celibate women in the Roman Catholic Church); entered a Franciscan convent, but returned to the world and began to teach young children; was called for that occupation to Brescia, where she spent the rest of her life. With eleven other maidens she organized, Nov. 25, 1537, at Brescia, an association under the patronage of St. Ursula for teaching small children, nursing the sick, and helping the poor, and she became its superior in 1537. It was at first not strictly a religious order, but soon became so. D. at Brescia, Jan. 27, 1540; canonized 1807. The order was confirmed by Paul III. in 1544.

Angel-fish (*Squatina angelus*), called also **Monk-fish**: a kind of shark with the flattened body of a ray, found on the coasts of Europe and on both shores of North America.

The angel-fish.

Its expanded pectorals suggest the conventional form of the wings of angels, hence the name. It is a sluggish and inoffensive fish. The name angel-fish is also applied to *Chaetodipterus faber* of the South Atlantic and Pacific coasts of North America, and to other chaetodont fishes of the tropics distinguished by bright coloration. D. S. J.

Angelica [Mediæv. Lat. *herba angelica*, angelic herb, on account of supposed beneficent properties]: a genus of plants of the family *Umbelliferae*, natives of the north temperate zone. They are mostly herbaceous and perennial, having bipinnate or tripinnate leaves. The *Angelica archangelica* (garden angelica) grows to the height of 6 feet, has greenish flowers, is aromatic, and contains resin and essential oil. Its root is used in medicine as an aromatic stimulant and tonic. This plant was formerly cultivated for the table, being blanched and used as celery. The U. S. has several species of *Angelica* and *Archangelica*, a kindred genus. It yields angelica balsam and angelic acid.

Angelica-tree, or **Hercules's-club**: a small tree or large shrub, found from Florida to Pennsylvania and westward. It is the *Aralia spinosa* of the family *Araliaceae*. It has a stout trunk, covered, like the branches, with prickles, and its leaves are very large and decomposed. Its flowers appear in July and August in great clusters, composed of very numerous umbels. This tree is common in cultivation.

Angelico, FRA: See FIESOLE. FRA GIOVANNI DA.

An'gell, JAMES BURRILL, LL. D.: author and scholar; b. at Scituate, R. I., Jan. 7, 1829; graduated at Brown University; studied two years in Europe; was Professor of Modern Languages and Literature at Brown University (1853-60); editor of the *Providence Daily Journal* (1860-66);

president of the University of Vermont (1866-71); and became president of the University of Michigan in 1871. He is the author of various articles in the *North American Review* and other quarterlies, as well as of a *Manual of French Literature* (1857), and *Progress in International Law* (1875). U. S. envoy extraordinary and minister plenipotentiary to China 1880-82. He was appointed a member of the U. S. Fishery Commission by President Cleveland, Sept., 1887. Minister to Turkey 1897-98, returning to University of Michigan.

Angell, JOSEPH KINNICUT: lawyer; b. at Providence, R. I. Apr. 30, 1794; graduated at Brown University in 1813. Among his works are a *Treatise on the Right of Property in Tide Waters* (1826), and *The Limitation of Actions at Law and in Equity and Admiralty*. D. in Boston, Mass., May 1, 1857.

Angelo: See MICHELANGELO.

An'gelus (or *Angelus Domini*, i. e. angel of the Lord): in the Roman Catholic Church a devotion in memory of the Annunciation, consisting of three descriptive scriptural texts alternating with the salutation "Hail Mary" (Ave Maria), followed by a versicle and response with prayer. Hence the bell tolled in the morning, noon, and evening to indicate the hour for the devotion. It was formerly rung at sunrise, noon, and sunset, but now more generally at the appointed time of six o'clock at morning and evening, and at noon. The sound of the angelus bell reaching the ears of a man and woman working in a field is the subject of the celebrated painting by Millet. C. H. T.

Angelus Silesius (properly *Johann Scheffler*): prominent German poet; physician to the Duke of Würtemberg; b. at Breslau, Silesia, 1624; was brought up a Protestant, but in 1653 joined the Roman Catholic Church, being led thereto by his studies in mediæval mysticism. He took priest's orders and changed his name as above. He presents the philosophic views of Meister Eckhart and Tauler in his mystical devotional works, among which may be mentioned the *Cherubic Traveler* (1674), and the *Sensuous Description of the Four Last Things* (1675). But it is as a poet that he lives, and some of his devotional songs still belong to the treasures of German hymnology. English translations of selections from his famous rhymed proverbs will be found in the *Massachusetts Quarterly* (Sept., 1849), and *Journal of Speculative Philosophy* (vols. iv., xii.). D. at Breslau, July 9, 1677. Special works on him have been written in German by Kahlert (1853), Schrader (1853), and Treblin (1877). Revised by JULIUS GOEBEL.

An'germann: a navigable river of Sweden; rises in the mountains between Sweden and Norway, collects the water of several lakes, and flowing southeastward enters the Gulf of Bothnia near Hernösand. Length, about 250 miles. Its banks abound with beautiful scenery.

Angers, formerly **Angiers** (anc. *Juliom'agus*): a city of France; capital of the department of Maine-et-Loire, and once the capital of the province of Anjou. It is on the Mayenne river, 4 miles N. of the Loire, and on the railway which connects Tours and Nantes, 60 miles by rail S. W. of Le Mans (see map of France, ref. 4-D). The old walls are converted into boulevards lined with handsome houses. It has a cathedral, a college, a library of about 35,000 volumes, a museum, and a school of arts and trades; also manufactures of linen and woolen stuffs, hosiery, silk twist, leather, etc. Here are the ruins of an ancient castle of the Dukes of Anjou, and the Hospice of St. Jean, founded by Henry II. of England. Lord Chatham and the Duke of Wellington attended a military school in Angers. Pop. of commune (1881) 68,049; (1886) 73,044; (1896) 77,164.

Angers, AUGUSTE REAL: Canadian statesman; b. in Quebec, Oct. 4, 1838; educated there and at Nicolet College; admitted to the bar 1860; appointed queen's counsel 1874; was a member of the Legislative Assembly 1874-79; and solicitor-general from Sept. 22, 1874, until March, 1876, when the ministry was dismissed by Lieut.-Gov. Letellier de St. Just. He was appointed judge of the Superior Court of the Province of Quebec, Nov. 13, 1880, and lieutenant-governor Oct. 20, 1887, an office which he held until Dec., 1892, when he entered the Dominion cabinet as Minister of Agriculture. NEIL MACDONALD.

Anghe'ra, PIETRO MARTIRE, de: Italian scholar and historian; b. of a noble family at Arona, on Lake Maggiore, in 1455. He emigrated to Spain in 1487, and became a priest. In 1501 he was sent by King Ferdinand on a mission to the

Sultan of Egypt, and in 1505 he was appointed prior of the church of Granada. He was also a member of the Council of the Indies. His most important work is a history of the New World and American discovery, entitled *De Rebus Oceanicis et Orbe Novo Decades* (1530), which is highly esteemed. D. in 1526.

An'gilbert, or En'gilbert, SAINT: statesman and Latin poet; b. in Northwestern Gaul. He married Bertha, a daughter of Charlemagne, and afterward became a confidential minister of that monarch. In the latter part of his life he entered a monastery. He wrote several short poems, and was called the Homer of his time. D. Feb. 18, 814 A. D.

Angi'na [Lat. *an'gina*, a choking, quinsy; from *an'gere*, strangle]: any disease attended by a sense of suffocation. See next article.

Angi'na Pec'toris (angina of the breast); called also **Breast Pang** and **Heart Stroke**: an intense pain occurring in paroxysms, and usually commencing in the region of the heart or at the lower end of the breast-bone, and extending along the left arm, more rarely going toward the right side. It is characterized by a sense of suffocation, faintness, and by the apprehension of approaching death. This symptom has been called the "spasm of a weakened heart," and is very seldom experienced by any but persons with an organic disease of that organ. The exciting cause is not unfrequently a strong and sudden emotional disturbance. Men over fifty years of age are most frequently attacked. Sometimes death occurs in a paroxysm. Morphia, nitrite of sodium, nitrite of amyl, and other sedatives are useful in the attack. Glass beads containing nitrite of amyl may be broken on a handkerchief and inhaled. Between the paroxysms a quiet, tranquil life is requisite.

Revised by WILLIAM PEPPER.

Angiosperms: those flowering plants whose seeds are inclosed in a pod of some kind—always, however, composed of one or more carpels. All ordinary flowering plants are angiosperms. Pines, spruces, cedars, etc., having naked seeds, are gymnosperms. See VEGETABLE KINGDOM.

CHARLES E. BESSEY.

Angle [from Lat. *an'gulus*, a corner]: the figure formed by two straight lines going out from the same point. The term, however, is extended to the case when the lines are curved, and to distinguish angles formed by straight from those formed by curve lines the former are sometimes called rectilinear, and the latter curvilinear. The lines which form an angle are called its sides, and the point where they meet is called its vertex. When a straight line, standing upon another straight line, forms two equal angles, each of them is called a right angle. The usual unit of measure of angles is the degree, which is defined as the ninetieth part of a right angle. The word angle is also extended to the case of planes meeting either in a line or a point; when two planes meet they are said to form a dihedral angle; when three or more meet, the angle is called solid or polyhedral.

S. NEWCOMB.

Angle, JAMES LANSING: jurist; b. at Henrietta, Monroe co., N. Y., Dec. 19, 1818; received an academic education, and was admitted to the bar in 1845. In 1877 he was appointed a justice of the Supreme Court of New York to fill a vacancy, and in 1883 he was elected for a full term, retiring on account of the constitutional limit of age, Jan. 1, 1889. D. at Greece, N. Y., May 4, 1891.

HENRY WADE ROGERS.

Angle-iron: a wrought-iron or steel bar rolled with a section shaped like an L. They are extensively used in the construction of buildings and bridges, being riveted to plates so as to form beams and columns. The largest angle-irons regularly in the market have legs about 6 inches long, and are nearly an inch in thickness, but special sizes and forms are made for use in ship-building. When in the shape of double angles, angle-irons are called channel-irons. See GIRDER.

MANSFIELD MERRIMAN.

Ang'ler (*Lophius piscatorius*): a fish found on the coasts of North America and Europe, and called the all-mouth, fishing-frog, or goose-fish. It belongs to a family of the spiny-rayed fishes called *Lophiidae*. It is from 3 to 5 feet long, has an enormous head and a very large mouth, furnished with a fringe of barbels. By means of these, and the first three spines of the dorsal fin, which are isolated, tentacle-like, and rise from the top of its head, it is sup-

posed to attract the fishes on which it preys. The *Lophiidae* are remarkable for the elongation of the carpal bones, the most striking character of the order *Pediculati*, to which they belong.

Revised by D. S. JORDAN.

Angles (Lat. *An'gli*): an ancient Low German tribe, from which England derives its name (*Angle-land*, England). They occupied a narrow district in the south of Schleswig, between the Schlei and Flensburg, whence some of them passed over in the fifth century in conjunction with other Saxon (or Low German) tribes into Britain, where they conquered the native Britons and established the Anglo-Saxon Heptarchy. That the Anglian settlers of Britain should have given their name to the island is due, possibly, to the fact that the tribal name "Angles" had come to be used as a generic term for the Saxon or (Low German) tribes; just as the word "Yankee" has come to signify to a European any citizen of the U. S.; but more probably to the fact that the Anglians were the first of the Low German settlers of Britain to accept Christianity, and hence to be recognized in the Latin literature of the period. See ANGLO-SAXONS.

Angler, or fishing-frog.

Ang'leseay, or Ang'lesea (anc. *Mo'na*): an island and county of North Wales; in the Irish Sea; about a mile from Caernarvon, from which it is separated by the Menai Strait (see map of England, ref. 8-D). It is about 20 miles long and 17 miles wide. The surface is nearly level and the scenery rather tame; the soil is generally fertile, producing wheat, barley, oats, and potatoes. The principal rocks are mica-schists and limestone. Here are rich mines of copper and lead. The island is connected with the mainland by the Menai suspension bridge and the great Britannia tubular bridge, over which the Chester and Holyhead R. R. passes. The ancient *Mona* was an important seat of Druidical power. Area, 302 sq. miles. Pop. (1891) 51,098; (1901) 50,475.

Anglesey, EARLS OF, and Barons Newport-Pagnell, in the English peerage (1661), Viscounts Valentia and Barons Mountnorris in the Irish peerage. The earldom was established in the Annesley family by Charles II., but became extinct in 1761 in Richard Annesley, the sixth earl of this family. The title had been borne by Christopher Villiers, brother of the Duke of Buckingham, and his son Charles.

Anglesey, HENRY WILLIAM PAGET, Marquis of: British general and statesman; b. May 17, 1768; eldest son of the Earl of Uxbridge. He entered the army, gained distinction as a cavalry officer, and became a major-general in 1808. He inherited the title of Earl of Uxbridge on the death of his father in 1812, and entered the House of Lords. At the battle of Waterloo, 1815, he commanded the British cavalry, and lost a leg. Soon after this event he received the title of Marquis of Anglesey. In 1828 he was appointed Lord-Lieutenant of Ireland, but, having become an advocate of Catholic emancipation, was removed by Wellington in 1829. He held the same office from 1831-33, and was raised to the rank of field-marshal in 1846. D. April 29, 1854.

Anglesey, Marquesses of (1815, in the United Kingdom), Earls of Uxbridge (1784, in Great Britain), Barons Paget (1550, in England), and baronets (1730, in Ireland).—HENRY WILLIAM GEORGE PAGET, the third earl, was born Dec. 9, 1821, and succeeded his father in 1869. He was M. P. for South Staffordshire from 1854 to 1857. D. Jan. 30, 1880.

Ang'lesite: a sulphate of lead produced by the decomposition of galena; was so named because first observed in Anglesey. It occurs in rhombic prisms with dihedral terminations, and of a white, gray, or yellowish color.

Anglia, East: kingdom in the eastern part of Central England, comprising the present counties of Norfolk and Suffolk. Founded by the Angles in the sixth century; was successively dependent upon Kent, Mercia, and Wessex until formed into a Danish kingdom under Guthrum (878); was forced by Edward, the son and successor of Alfred, to acknowledge his authority (921), and henceforth formed a part of the kingdom of England.

Ang'lican Church: the Established Church of England; sometimes called the Anglo-Catholic Church; and, with its

colonial and missionary churches, and the Scottish, Irish, and American (Episcopal) Churches, often spoken of as the Anglican Communion. The creeds of this great division of Christendom are *The Apostles'*, *The Nicene*, and *The Athanasian*. The last mentioned creed is not included in the liturgy of the American Episcopal Church, although its doctrinal teaching must be considered as comprised in the avowal found in the preface to the American Book of Common Prayer: "This church is far from intending to depart from the Church of England in any essential point of doctrine, discipline, or worship, or further than local circumstances require." The creed of the Anglican Church was legally defined in the Thirty-nine Articles, first adopted in 1562. These articles, although retained in the English and American Prayer-Books, are not regarded as of equal authority with the Catholic creeds. See ENGLAND, CHURCH OF.

W. S. PERRY.

An'gling [deriv. of *angle*, a fishing-hook < O. Eng. *angul*; O. H. Ger. *angul* (> Mod. Ger. *angel*); related with Lat. *uncus*, hook, Gr. *δγκος*, barb, Sanskr. *anká-s*, hook; to be distinguished from Engl. *angle*, corner, which is a loan-word from Fr. *angle* < Lat. *angulus*]: the taking of fish with an "angle," as a hook was called in old English (see Habakkuk i. 15), was practiced by prehistoric man, as can be seen by the hooks of bronze found among the remains of lake-dwellers of Switzerland, which, in many respects, closely resemble some of the hooks made to-day, e. g. in having the point of the barb in the line of draft. A simpler, if not older, form of taking fish with a line, if not with an angle, was practiced by this prehistoric people, and also by the tribes of Greenland and Alaska; a double-pointed piece of wood, horn, or bone was used, with the line tied in the middle, so that when baited and swallowed by the fish it would set crosswise in the throat (see collection in U. S. National Museum, Washington, D. C.).

Angling as a sport originated in Great Britain, and naturally came to the colonies in America, and it is in the English-speaking countries that it has received its highest development, and where it has taken rank with such field-sports as shooting and fox-hunting. In many parts of the Continent of Europe angling has a few devotees, and in Japan there are also a few fly-fishers, but it is not recognized as a sport by the masses, who regard it merely as a means of catching fish for food. In Great Britain and the U. S. enthusiastic anglers travel long distances to kill a few salmon which they could buy at home for one-hundredth of the cost of their capture, an act which would cause them to be thought lunatics by many people in continental Europe, where they shoot for sport but fish only for food. Angling is practiced by our market-fishermen for cod, halibut, mackerel, and other fishes of salt water, and for lake trout, pike, etc., in fresh water, but by them it is called line or "trawl" fishing, to distinguish it from net-fishing.

The principal fresh-water fishes which are angled for are, in the sportsman's order of value, the salmon, brook and brown trout, black bass of two species, mascalonge and the pikes, lake trout, white and yellow perch, and then the smaller and less gamy species. In Great Britain they rank much the same, only there they have no mascalonge and no white perch. The fish are taken in two ways, with hand-lines or with a rod; and there are several variations of these modes. Natural baits, such as angleworms, minnows (alive and dead), frogs, grasshoppers, maggots, crickets, crayfish, and pieces of meat or fish are used. The artificial lures used are imitation flies and insects, rubber frogs and crickets, spinning metal plates (called "spoons"), artificial mice, etc. Angling for sport may be divided into classes, as fly-fishing, bait-fishing, trolling, skittering, and still-fishing. In fly-fishing a pliant rod is used, its length for salmon being from 15 to 20 feet and for trout and black bass from 8 to 11 feet; a reel and line of water-proofed silk, terminating in a leader or casting-line, of silkworm gut, which is from 6 to 15 feet long, proportionate to the length of rod, and from one to three hooks, which are variously dressed with feathers, tinsel, and other substances to imitate different insects on which trout and salmon feed, or are fanciful creations which resemble nothing. These are cast upon the surface in a manner which requires skill, and the fish rise to take them. In bait-fishing a rod may be used or the line cast and hauled by hand. Trolling implies towing either a live or dead minnow or a spinning metal bait behind a boat, which is propelled by sail, steam, or oars, and may be done with either rod or hand-line. In skittering, which requires a long, stiff rod, a

minnow, frog, or metal spoon is cast from boat or shore, and made to ricochet upon the surface of the water as the rod is smartly moved from one side to the other, and is mainly used to decoy the pike or pickerel. Still-fishing, as the name implies, is done from boat or bank with bait, and the fisher waits for a fish to find his bait and take it. This is also called "drop-line" fishing when done from a boat in salt water.

Reels are first mentioned in Baker's *Art of Angling* (London, 1651). He says: "Within two foot of the bottom of the rod there was a hole made for to put in a wind, to turn with a barrell, to gather up his line and loose it at his pleasure." Walton, in the second edition of his *Compleat Angler* (1655), says: "Note also that many use to fish for salmon with a ring of wire on the top of their rod, through which the line may run to as great a length as needful, when he is hooked. And to that end, some use a wheel about the middle of their rod, or near their hand, which is better observed by seeing one of them than by a large demonstration of words." These quotations show that the use of the reel is less than three centuries old, and it is believed that Walton never saw one.

In salt water flies are not used, the lures being natural baits or some bright, moving object equally attractive. Angling for striped bass, or "rockfish" as it is called south of Philadelphia, is considered the highest form of angling in salt water, and its devotees sometimes rank it with fly-fishing for salmon. Along the islands which form Buzzard's Bay, off the coast of Massachusetts, at Newport, and on the eastern end of Long Island, there are clubs composed of anglers who fish for the striped bass in the surf. Some of the clubs have elegant houses, such as the Squibnocket, Cuttyhunk, and Pasque island clubs, and have seats on the rocks bolted in and secured by an iron rail to keep the angler from being swept off while he, clad in an oilskin suit, casts his bait of menhaden or lobster tail out into the surf, hoping at some time to beat the record by taking a bass of 80 lb. on a rod and reel. Of late years angling for the tarpon, or tarpum, in Florida waters has attracted much attention, and fish of 160 lb. weight are reported to have been caught; but, in the opinion of scientific anglers this fish, while fighting gamely, has not the surroundings which give zest to the capture of a striped bass of less weight. The bluefish, or "taylor" of the Southern coast, is another gamy fish much sought for by anglers. It is taken by an ivory or leaden "squid," with a large hook at the end, by trolling it behind a sailboat going about 6 miles an hour; but the most sportsmanlike way to take it is by "chumming," which is done by cutting the oily menhaden into fine pieces, or "chum," and casting it on the water in a tide-way where the boat is anchored, to attract a school of fish which are taken on a rod and line baited with menhaden.

The literature of angling is voluminous, volumes sometimes being devoted to the capture of a single species of fish. The oldest English book on the subject is by Dame Julyano or Juliana Barnes, Bernes, or Berners, for in the twenty editions from 1486 to 1875 the name is variously spelled. It originally appeared as a portion of the *Boke of St. Albans*, which treated of "hawkyng and huntynge, etc." About 1500 an edition was issued with the title, *Here begynneth a treatyse of fysshynge wyth an angle*; the colophon reading, "Here endeth the boke of Fysshynge with other dyuers matters. Imprinted at London, by Wynkyn de Worde, dwellynge in Flete-street, at the sygne of the Sonne." Since then hundreds of books on angling have appeared. See *Bibliotheca Piscatoria*, T. Westwood and T. Satchell (London, 1883). *The Compleat Angler, or the Contemplative Man's Recreation*, by Izaak Walton, is a classic, and has gone through over 100 editions between 1653 and 1880.

The modern literature of angling is voluminous. Among the best works published in the U. S. are: *The American Angler's Book* (Phila., 1865); *Fishing in American Waters*, 1875; *Fishing with the Fly* (Troy, 1885); *American Fishes*, G. Brown Goode (New York, 1888); and *American Game Fishes*, by twenty writers (Chicago, 1892). Besides these there are works on special subjects, as *The Black Bass*, by Dr. Henshall; trout, salmon, and other fishes by many well-known writers.

FRED MATHER.

Anglo-Cath'olics: those members of the Anglican communion who are Catholic, but neither Roman nor Oriental. They are sometimes called "Puseyites," from one of their leaders, Dr. Pusey, and are otherwise known as **Tractarians**, from the series of ninety tracts issued by them be-

tween 1833 and 1841. They emphasize these four "Catholic principles": apostolic succession, baptismal regeneration, the real presence in the Eucharist, and the authority of tradition.

An'glo-Sax'on Language, now commonly called **Old English**: See ENGLISH LANGUAGE.

Anglo-Saxon Literature: The pagan Anglo-Saxons had their poets and orators, and after their conversion to Christianity there were good scholars in England. Most of their writings are, however, in Latin. The story of their learning and literature is not one of development. There were schools with bright beginnings, but decay followed soon, or quick destruction from pagan or other foes. Most of the books remaining in Anglo-Saxon are translations from Christian Latin. *The Oldest English Texts* (H. Sweet, 1885) contains all the Anglo-Saxon prior to 900, except the *Chronicle* and Alfred's works. It is mostly glossaries, inscriptions, and lists of names, but has some charters, a psalter, and two or three pages of poetry.

The prose writings in the Anglo-Saxon language may be classified as follows:

1. *Theological*.—The Gospels were read in the native tongue as part of the church service, and several manuscripts are preserved. Editions have been printed by Parker (1571), Marshall (1665), Thorpe (1842), reprinted in the U. S. by Klipstein, Bouterwek (1857), Surtees Society (1854-63). Bosworth (1865) has the Gothic, Anglo-Saxon, Wycliffe, and Tyndale in parallel columns. The standard edition is *The Holy Gospels in Anglo-Saxon, Northumbrian, and Old Mercian versions*, with collations of all the MSS. and the Latin versions, W. W. Skeat (1891). Ælfric's translation of the Heptateuch was published by Thwaites (1698), and Grein, *Bibliothek der A.-S. Prosa* (1872.) We have also versions of the Psalms: Thorpe (1835); Grein, *Bibliothek der A.-S. Poesie* (1858); Buelbring, Early English Text Society (1891). There are many *Homilies*. Ælfric, an eminent scholar, compiled or translated a series of eighty of them about A. D. 990, which were edited by Thorpe for the Ælfric Society (1844-46). The Early English Text Society has published *The Blicking Homilies* (R. Morris, 1874-80), and the *Rule of St. Benedict* (Logeman, 1888).

2. *Philosophical*.—King Alfred translated Boethius, *De Consolatione Philosophiæ*. It is freely rendered, with large additions and omissions by the royal author. Editions are by Rawlinson (1698), Cardale (1829), and Fox, in Bohn's Library (1864.)

3. *Historical*.—The most illustrious of the Anglo-Saxon scholars, Beda, known to many generations as "the Venerable Bede," wrote in Latin an *Ecclesiastical History of the Angles and Saxons*, which was translated by King Alfred into Anglo-Saxon. It abounds in picturesque details of the heroic adventures and characters of his time, and has been often reprinted and its best scenes repeatedly rendered into verse. (See, for some of them, Wordsworth's *Ecclesiastical Sonnets*.) The Anglo-Saxon translation was edited, with a Latin translation, by Abraham Wheloc (folio, 1644), by Dr. John Smith (1722), and for the Early English Text Society by Dr. Thomas Miller (1890-91).

The Anglo-Saxon Chronicle gives an outline of the history of Britain from the earliest times to Henry II., A. D. 1154. Copies were kept at the monasteries as early as the time of Alfred. As far as Beda's history extends, the *Chronicle* has been drawn from it or a common source. It is in general a meager affair. There are many editions: Thorpe's (1861) has seven parallel texts, a translation, and indexes. Earle's *Two of the Saxon Chronicles Parallel* (1865) has been revised by C. Plummer (1892).

The general *History of the World*, by Orosius, was translated by Alfred, with additions of some value. It has often been printed. Thorpe's edition in Bohn's Library has a translation and glossary (1857). H. Sweet's for the Early English Text Society (1883), Anglo-Saxon and Latin, reprints the Alfredian MS.

Many brief biographies are found in Beda and the *Homilies*, and some separate lives. That of St. Guthlac (see Wright's *Biographia Literaria*) has been several times printed; Goodwin, London (1848). That of St. Neot contains the story of Alfred's letting the cakes burn; Gorham (1820-24). Ælfric's *Lives of Saints* has been edited by W. W. Skeat for the Early English Text Society (1881-91).

4. *Law*.—A considerable body of laws has been got together. They begin with those of Æthelbirht, who was King of Kent at its conversion. Those of Alfred have an intro-

duction on the history of law, the laws of Moses, and their relations to Christ and Christian nations. The laws are full of valuable knowledge. The ecclesiastical rules relating to confession, penance, and the like are particularly suggestive. The best editions are Thorpe's and that of Schmid (Leipzig, 1858). The latter has translations into Latin and German, and valuable notes and a glossary.

5. *Natural Science and Medicine*.—Such are in *Popular Treatises of Science*, Wright (1841); *Leechdoms, Wortcunning and Starcraft of Early England*, Cockayne (1864-66). *Byrhtferth's Handbook*, Kluge (1855), contains weights and measures, numbers, etc. Translations of Beda's Latin treatises on science are in Cockayne.

6. *Grammar*.—There is a grammar by Ælfric in Somner's Dictionary (1659), J. Zupitza (1880). A Colloquy and glossaries, Wright (1857), R. P. Wülcker (1884).

ANGLO-SAXON POETRY is very different in metrical structure from the English. It is like the Old Icelandic, the Old Saxon, and the Earliest German. It is marked off into verses by alliteration, the recurrence of the same initial sound in the first accented syllables of words. A perfect verse of the common narrative kind has three alliterating syllables—two in the first section and one in the second; but the first section has but one in many verses. Each section has two principal beats or metrical accents, marking time for its two nearly equal divisions or feet. The beat prevailing falls on the first syllable of its foot, making a falling (trochaic, dactylic) rhythm, but it varies freely to rising (iambic, anapaestic), the number and position of the unaccented syllables changing more freely than in Modern English verse.

Þærpæs hæl' eôð hleah'tor;	hlyn' spyn'sôde,
word' pæron wyn'sume,	Eôde Wealh'ðeôp forð',
cpên' Hrôð'gâres,	cyn'nâ gemyn'dig,
grêt'te gold'-hroden	gum'an on heal'le,
and þâ freô'lic pif'	ful' geseal'de,
ær'est Eâst'-Denâ	êðel-pear'de,
bæd' hine blið'ne	æt þære beôr'-þeg'e.

There was lordly laughter;	there the lute resounded,
words were winsome.	Forth yode Wealhtheow.
queen of Hrothgar,	of courtesies mindful,
greeted gold-arrayed	the guests in the hall,
and then the cup of grace	gave the gentle wife
first to the sovereign liege,	lord of the East-Danes,
blithe she bade him be	at the beer-drinking.

Knowledge of the popular poetry was universal. It was disgraceful not to be able to chant in turn at the feasts. Beda, Aldhelm, Alfred learned and loved the old ballads, and made verses. Most of the poetry has perished. The early Christians condemned whatever was mixed with the old superstitions, and the Normans despised or neglected all Anglo-Saxon literature. But we have specimens of various kinds:

1. *The Ballad Epic*.—The old ballads are brought together, beautified, exalted, and fused into a long poem. *Beowulf* is the *Iliad* of the Anglo-Saxons. The exploits celebrated in it are for the most part combats with monsters after the manner of Hercules, but it has the usual epic variety—the wrath of the monster, the rousing of the hero, the fitting out of the ship, the voyage, the banquet, the wordy war of rivals, woman's graceful presence, the arming for fight, and desperate and long-drawn struggles. Only one manuscript of it remains. Little notice of it was taken till the late revival of Anglo-Saxon scholarship; but the interest in it has risen to a great height, and many editions, translations, and essays of elucidation and interpretation have appeared in Germany, England, and Denmark. We may mention Kemble (1833-37); Ettmüller (1840); Thorpe (1855); Grein, two editions (1857-67); Gruntvig (1861); Heyne, four editions (1863-79); and Socin-Heyne. Text by the MS., Wülcker (1881); Holder (1882). An autotype and transliteration by J. Zupitza, Early English Text Society (1882); an American edition by James A. Harrison and Robert Sharp (1883). Translations into imitative prose, by J. M. Garnett, Boston (1882); into imitative meter, John Leslie Hall, Boston (1892). Translations into Latin, Thorckelin (1815); portions, Conybeare (1826); G. S. Sandras (1859).

There are a few fragments to be classed with *Beowulf*. Such are the *Traveler's Song* and the *Fight at Finnsburg*,

both of which are given with *Beowulf* in many editions; *King Waldere*, G. Stephens (1860); R. P. Wülcker's *Kleinere Angels. Dichtungen* (1882).

2. *The Bible Epic* is a treatment of the Bible narrative similar to that of the ballad epic. The great master in this sphere is Cædmon, who is often called the Anglo-Saxon Milton. Beda, who lived in the same region, and may have seen him, tells us that he was an unlearned man, who could not sing the common secular ballads, and that a vision appeared to him and directed him to sing the Creation, and that his success was esteemed inspiration. He had many imitators, and whether the poems which remain are his is not known. These are four poems, called, by Grein, *Genesis*, *Exodus*, *Daniel*, *Christ* and *Satan*. Similar are a fragment of *Judith*, Cynewulf's *Christ*, *The Harrowing of Hell*, and some fragments. Of all these we have a critical edition and translation by Grein, and of Cædmon editions by Thorpe (1832); Bouterwek (1849-54). The manuscript is illuminated, and the illuminations were copied and published in 1833. There are American editions of Cædmon's *Exodus* and *Daniel*, T. W. Hunt (1883); *Judith*, A. S. Cook (1888); translation by Garnett (1889).

3. *Ecclesiastical Narratives*.—These are versified lives of saints and chronicles. We have *Andreas* (1,724 lines), *Juliana* (731 lines), *Guthlac* (1,353 lines), *Elene* (1,321 lines). American editions are *Andreas*, W. M. Baskerville (1892); *Elene*, C. W. Kent (1889); and a translation of *Elene* by Garnett (1889).

4. *Psalms and Hymns*.—Translations of a large part of the Hebrew Psalms, and a few Christian hymns and prayers.

5. *Secular Lyrics*.—A few from the *Chronicle*, celebrating the kings or others.

6. *Allegories, Gnomic Verses, and Riddles*.—*The Phoenix* (677 lines), *The Panther* (74 lines), *The Whale* (89 lines), Gnomic Verses and Riddles; *Dialogue between Solomon and Saturn*, in Grein, vol. ii., pp. 339-407—a favorite style with the Anglo-Saxons.

7. *Didactic, Ethical*.—Alfred's *Metres of Boethius* are versifications of parts of Boethius referred to under Prose Writings above. The best edition is Grein, vol. ii., pp. 295-339. Grein's *Bibliothek der Angelsächsischen Poesie* (Göttingen, 1857), with his translations and complete glossary, gives apparatus for the study of all these poems. New edition by R. P. Wülcker (1880-83).

Outlines of this literature are to be found in Morley's *English Writers* (London, 1867); Wright's *Biographia Brit. Literaria* (London, 1842); Eittmüller's *Scopas and Boceras* (Qued. and Lips., 1850); *Early English Literature* (to Wielif), translation from Bernhard ten Brink (1877), by H. M. Kennedy (1883); *Syllabus of Anglo-Saxon Literature*, J. M. Hart (1881), adapted from ten Brink: *Grundriss zur Geschichte der A.-S. Literatur*, R. P. Wülcker (1885); B. ten Brink, in *Grundriss der germanischen Philologie*, ii., i. 5 (1892).
F. A. MARCH.

Anglo-Saxons: a name given to the people which resulted from the consolidation of the different Low German tribes which in the fifth century overran Southern Britain. The name would seem to point to a blending of two distinct races, the ANGLES (*q. v.*) and the Saxons; but according to Latham (*Ethnology of the British Islands*) there is no distinction to be made between the Angles and the Saxons on the ground of the difference in name. "If," says he, "the Saxons of Anglo-Saxon England were other than Angles under a different name, they were North Frisians." According to the *Saxon Chronicle*, which is, with reference to these events, a mere paraphrase of Bede's *Ecclesiastical History of Britain*—the latter work being written about one hundred and fifty years after the last of the Saxon invasions, which the *Chronicle* records as if it were contemporaneous with them—there were seven distinct Teutonic "invasions" of Britain, beginning A. D. 449, and including parties of Jutes, Frisians, Saxons, and Angles. That Jutes, in the sense of people from Northern Denmark or people of Scandinavian stock, were the first of the Germanic invaders to land in Southern Britain is highly improbable; and the topographical nomenclature of Kent, where Hengist and Horsa, with their party of Jutes, are said to have settled, bears no traces of Danish influence. By "Jutes" we are probably to understand, generically, "Goths." Indeed, in Alfred's Anglo-Saxon translation of the passage in Bede which the *Chronicle* manifestly follows, the Latin *Jutis* is rendered by *Geatum* (Goths), a term which is elsewhere applied to Alfred himself. The *Chronicle* itself, by

the way, explicitly asserts (Bohn's ed., p. 341) that 787 was the first year when ships of Danish men sought the land of the English nation; one manuscript of the *Chronicle* says that Hengist landed with a party of *Angles*, while tradition calls him a Frisian, which he probably was.

The Saxon settlement of Britain was probably participated in by all the Low German tribes between the Elbe and the Schlei, although, on the ground of linguistic affinity, the Frisians would seem to have been most prominent. (See Latham's *Ethnology of the British Islands*; Marsh's *Origin and History of the English Language*; Nicholas's *Pedigree of the British People*; *Proceedings of the London Philological Society*, vol. v.) As soon as the Saxons had subjugated the Keltic inhabitants of Britain (who resolutely opposed the invaders, and many of whom were driven before them into the fastnesses of Wales, and across the sea into Armorica, though most of them were, doubtless, amalgamated with the invading race), they began to contend with each other. The various kingdoms forming the famous "Heptarchy" (or, to speak more correctly, the "Octarchy") were at length, in 827, reduced by Egbert, King of Wessex, into a single monarchy, which attained its highest point of power and glory under Egbert's grandson, Alfred the Great (871-901). The Saxon power was completely overthrown by William the Conqueror at the battle of Hastings, in 1066. For a full account of the Anglo-Saxons, their history, their laws, customs, etc., see Sharon Turner, *History of the Anglo-Saxons*; J. M. Kemble, *The Saxons in England*; also Lappenberg's *History of the Anglo-Saxon Kings*; and Freeman's *Old English History*.
J. H. GILMORE.

Ango'la: the name now given to the Portuguese territory on the west coast of South Africa, a part of which used to be called Lower Guinea. It extends on the coast from the mouth of the Congo southward to about lat. 17° S. and inland to a distance which is not well defined, though the territory claimed usually extends east of long. 20° E. It has the Congo Free State on the N. and N. E., and German Damaraland on the S. The eastern boundary is nominally the southward course of the Zambezi and the northward course of the Lubilash or the Kassai, both streams of the Congo system. It is subdivided into four districts, at least along the coast: the Congo district in the N., with the port Ambriz as capital, then in order Loanda, Benguela, and Mossamedes, each with a seaport-town of the same name as capital. Loanda is the capital of the colony, and is on the cable from Europe to the Cape. The area is about 600,000 sq. miles, and the population is variously estimated from 2,000,000 to 10,000,000.
M. W. H.

Angola: capital of Steuben co., Ind. (for location of county, see map of Indiana, ref. 1-G); on Fort Wayne and Jackson branch of the Lake Shore R. R., 45 miles N. of Fort Wayne; seat of State Normal College with 800 students during 1892; has three churches—Christian or Disciple, Congregational, and Methodist—and a high school; woolen, model, and barrel factories; founded in 1840. Pop. (1870) 1,072; (1880) 1,280; (1890) 1,840; (1900) 2,141. Steuben County has about seventy-five fresh-water lakes, some of them very beautiful and well stocked with fish.

EDITOR OF "REPUBLICAN."

Ango'ra, or **Angho'ra** (anc. *Ancy'ra*; Turk. *Engoor'*): a town of Asiatic Turkey, about 217 miles E. S. E. of Constantinople (see map of Turkey, ref. 5-F). It is situated on an elevated plain adapted to pasturage, and is celebrated for its breed of goats having long silky hair which is manufactured into shawls and a stuff called mohair. Large quantities of this hair are exported, and goats of this breed have been successfully introduced into the U. S. Here are remains of Greek and Byzantine architecture. The most remarkable is a white marble temple which was built by the ancient inhabitants in honor of Augustus; it has on its wall a famous inscription, much of it still legible, stating the most important events in the emperor's life. On July 20, 1402, a decisive victory was gained near Angora by Tamerlane, the Tartar conqueror, over Bayazeed (Bajazet), the Turkish sultan, who was taken prisoner. It was recovered by the Turks under Mohammed I. in 1415, and from that time has continued to be a part of the Ottoman empire. Pop. (1885) 30,000, one-third of whom are Armenians. See ANCYRA.

Angor'nu: See NGORNU.

Angostu'ra (i. e. narrows), or **Bol'ivar City**: an important city of Venezuela; capital of the state of Bolivar; on

the right bank of the Orinoco river, 263 miles S. E. of Caracas (see map of South America, ref. I-D). It is advantageously situated for trade, and exports cotton, indigo, coffee, tobacco, cattle, etc. It contains a college, a hospital, and a fine hall in which the congress of Angostura met in 1819. Pop. 8,484.

Angostura Bark: a bitter bark derived from *Galipea cusparia*, a moderately high tree growing near the Orinoco river. It occurs in flat or curved pieces of from 1 to 3 inches in length, half as wide, and about $\frac{1}{10}$ th inch thick. The color is reddish brown, and the inner surface smoother and lighter than the outer surface, which has a cork-like appearance. Angostura bark is used as an astringent tonic.

Angoulême, an'-goo-lām' (anc. *Inculis'ma* or *Iculis'ma*): a city of France, capital of the department of Charente, on the river Charente, and on the Paris and Bordeaux R. R., 83 miles by rail N. E. of Bordeaux (see map of France, ref. 6-D). It is situated on a hill, and has a cathedral, college, theater, public library, and several paper-mills. Linen and woolen stuffs are manufactured here. This town was the birthplace of Marguerite de Valois and of Balzac. Pop. (1896) 38,068.

Angoulême, CHARLES DE VALOIS, Duke d': a natural son of Charles IX. of France; b. Apr. 28, 1573. Having formed a plot against King Henry IV., he was imprisoned from 1604 to 1616. He had the chief command of the royal army when it began the famous siege of Rochelle in 1628. D. Sept. 14, 1650.

Angoulême, LOUIS ANTOINE DE BOURBON, Duke d': b. at Versailles, Aug. 6, 1775; eldest son of the Comte d'Artois; afterward Charles X. of France. He emigrated with his father in 1789, and in 1799 married his cousin, Marie Thérèse Charlotte, a daughter of Louis XVI., with whom he lived in exile until 1814. He commanded the French army which intervened against the Spanish liberals in 1823, and restored Ferdinand VII. to absolute power. His abilities were mediocre. D. at Göritz, June 3, 1844.

Angoulême, MARIE THÉRÈSE CHARLOTTE, Duchess d': wife of the preceding; b. at Versailles, Dec. 19, 1778; a daughter of Louis XVI. In Aug., 1792, she was confined in the Temple with the king and her mother, Marie Antoinette. She was released in 1795, and exchanged for Camus and others who had been captured by the Austrians, after which she passed many years in exile. She appears to have had more energy than the other Bourbons. She became again an exile in 1830. D. in Vienna, Oct. 19, 1851.

An'gra (i. e. creek or bay): a seaport-town, and the capital of Terceira, one of the Azores; lat. 38° 39' N., long. 27° 12' W. It has a beautiful situation and a good harbor. It contains a cathedral, a military college, and an arsenal. Wine, grain, honey, etc., are exported from this town. Pop. about 11,000.

Angra Pequena, an-gra-pā-kān'ya: a bay and harbor in Great Namaqualand on the west coast of South Africa, between Walvisch Bay and the mouth of the Orange river.

Anguil'la: See EEL.

Anguilla, or **Snake Island**: an island in the Leeward group, in the West Indies, 4 miles N. of St. Martin (see map of West Indies, ref. 5-L). Area, 34 sq. miles. The island is low and covered with forests; it belongs to Great Britain. The staple products are sugar, tobacco, and cotton. Pop. (1891) 3,699.

Anguillula, an-gwil'yu-la [i. e. little eel; from Lat. *anguilla*, an eel]: a genus of minute animals belonging to the nematoid worms. Best known are those called "vinegar eels," *Anguillula aceti*, found abundantly in cider vinegar. They are remarkable for tenacity of life. *Anguillula fluviatilis*, after being dried until it becomes brittle, will recover its activity when placed in water. *Anguillula tritici* is found on blighted wheat. The dried embryos fall with the wheat, and grow in the damp earth, from which they make their way to the growing plant, remaining in it till the ears grow, when they take their place in the grains in which they complete and deposit their eggs. D. S. JORDAN.

An'guis [Lat., a serpent]: a genus of serpent-like lizards having the maxillary teeth compressed and hooked, and the palate not armed with teeth; body covered with smooth, bony scales, head with larger plates. See BLINDWORM.

Angular Motion of a point or a body is the same as that of the line or radius vector joining the moving point to some fixed point. The *angular velocity* of the body in

reference to the fixed point is the ratio of the angle described by the radius vector to the time occupied by its description.

Angus, EARL OF: See DOUGLAS.

Angus, Rev. JOSEPH, D. D.: Baptist minister and educator; b. at Bolam, Northumberland, England, Jan. 16, 1816; educated at the University of Edinburgh; became president of Regent's Park College (Baptist), London (1849). Author of *The Bible Handbook*, *Handbook of English Literature*, *Handbook of the English Tongue*, and other works; and editor of the best edition of Butler's *Analogy* (1855, 12mo, pp. 551). He was one of the revisers of the English New Testament for the American Bible Union; was a member of the committee of the convocation of Canterbury for revising the New Testament, and is a prominent member of the Evangelical Alliance, as a delegate of which he visited the U. S. in 1873.

Angus, SAMUEL: naval officer; b. in Philadelphia in 1784. He commanded the vessel which in 1814 conveyed Adams and Clay to Ghent on a diplomatic mission, and became a captain in the U. S. navy (1816). He served with distinction in the French troubles of 1800, in the war of 1812, and was four times wounded. D. at Geneva, N. Y., May 29, 1840.

An'halt: a duchy of Germany, almost completely surrounded by the Prussian province of Saxony; consists of two larger parts and four enclaves, having together an area of 906 sq. miles. The duchy is traversed by the Saale, the Elbe, and the Selke. While the eastern part is level, the western is mountainous and wooded. The soil is generally fertile. Cattle-raising is extensively and successfully carried on. Here are also mines of silver, copper, iron, and lead. The duchy has five gymnasia and three seminaries. Pop. (1895) 293,298. Capital, Dessau. According to the budget of 1891-92 the receipts and the expenses were both estimated at 11,082,000 marks. The Dukes of Anhalt claim to have descended from ALBERT I. (surnamed THE BEAR) (*q. v.*), the first Margrave of Brandenburg. In 1212 Anhalt was divided into three parts; it was united in 1570 by Joachim Ernst, and again divided into four branches—Dessau, Bernburg, Köthen, and Zerbst—upon his death in 1586. In 1793, after the extinction of the house of Anhalt-Zerbst, its dominions were divided by the remaining three. In 1807 the three houses joined the Confederation of the Rhine, and in 1814 the German Confederation. In 1847 the house of Anhalt-Köthen became extinct, and the Duke of Anhalt-Dessau took the administration of its dominions upon himself; and when, in 1863, the house of Anhalt-Bernburg also became extinct, Anhalt was again united under one ruler. See the works of Heine (1865); Kause (5 vols., 1861-66); and Siebigk (1867).

An'halt-Bern'burg, CHRISTIAN, Prince of: German general; b. in 1568; a man of superior abilities. He was the chief promoter of a league of Protestant princes formed against the emperor in 1608. He commanded the army of Frederick Elector Palatine which was defeated at Prague in 1620. D. in 1630.

An'halt-Des'sau, LEOPOLD, Prince of: an able German general; b. in 1676; commanded the Prussian troops under Prince Eugène in Italy and Flanders in 1706-12, and was second in command of the Prussian army which opposed Charles XII. of Sweden in 1715. D. in 1747.

Anhinga, an-hing'ga: the snake-bird, darter, or water-turkey (*Anhinga anhinga*); a swift, wary water-bird, allied to the cormorants; found in tropical rivers and ranging northward to the mouth of the Ohio.

An'holt: an island of Denmark; in the Cattegat; 7 miles long and about 4 miles wide; lat. of the lighthouse, 56° 44' N., lon. 11° 39' E. It is surrounded by dangerous shoals. Pop. 200.

Anhy'drite [from Gr. ἀν-, without + ὕδωρ, water (cf. ἀνυδρῶς, waterless) + suffix -ite]: a mineral composed of anhydrous sulphate of lime. It is harder and heavier than common sulphate of lime (gypsum), into which it is slowly converted by the absorption of water. It occurs in several varieties—viz., granular, fibrous, radiated, and translucent, sparry anhydrite or cube-spar, and compact anhydrite.

An'il: one of the plants from which indigo is obtained; a kind of indigo said to be a native of America, but now cultivated in the East Indies. It is very similar to *Indigofera tinctoria*.

Aniline [from Portug. *anil*, indigo = Arab. *annil*; *al*, the + *nīl* = Sanskr. *nīlī*, indigo, deriv. of *nīla-s*, dark blue]: *Phenylamine*, or *Amido-benzene*: discovered in 1826 by Unverdorben as a product of the distillation of indigo, and called by him *krystallin*, on account of the ready crystallization of its salts. It attracted much attention from chemists, and was made the subject of many researches, which contributed greatly to enlarge the facts and theories of modern chemistry. It did not acquire any commercial importance till 1856, when Perkin prepared from it the beautiful purple dye *mauve*. The brilliancy and intensity of this color attracted the attention of chemists and dyers, and in a short time an entirely new series of colors was discovered, by which the art of dyeing has been almost revolutionized.

Aniline is found among the products of the distillation of bituminous coal (in "coal-tar"), of peat, bones, etc. It is prepared, however, from benzene derived from the more volatile portions of coal-tar. The benzene, C_6H_6 , is converted by the action of nitric acid into nitrobenzene, $C_6H_5NO_2$, and this compound is changed to aniline by the action of iron and water together with some hydrochloric acid. The relation between nitrobenzene and aniline is indicated in the equation below:

Aniline is a colorless, mobile, oily liquid, having a faint vinous odor and aromatic burning taste. Its specific gravity is 1.002; boiling-point, $182^\circ C$. It is very poisonous. It dissolves very slightly in water; in all proportions in ether, alcohol, wood-naphtha, bisulphide of carbon, and in oils, fixed and volatile. The aqueous solution is faintly alkaline, and precipitates many metallic bases from solutions of their salts. With bleaching-powder it produces a violet-blue color, with sulphuric acid and potassic bichromate a bluish-black precipitate, and when treated with arsenic acid, stannic chloride, etc., it is converted into rosaniline. When exposed to the air, aniline acquires a yellow or red color, which is always noticed in commercial "aniline oil." It forms a numerous class of salts, most of which crystallize readily.

Aniline belongs to the class of compounds known as substituted ammonias, its chemical behavior showing that it is closely related to ammonia, the relation being shown by the formulæ:

Aniline is ammonia, one hydrogen atom of which has been replaced by phenyl, C_6H_5 .

Aniline is now manufactured in enormous quantities for the preparation of the different colors. *Aniline for red* is a mixture of aniline with two other compounds which resemble it closely. These bear to toluene, C_7H_8 , the same relation that aniline bears to benzene. They are called **TOLUIDINES** (*q. v.*). For *Aniline Pink*, see **SAFFRANINE**.

Revised by IRA REMSEN.

Aniline Colors: In 1835 Runge noticed the violet-blue color produced by chloride of lime with aniline, and Fritzsche subsequently showed that chromic acid formed with aniline a blackish-blue precipitate. In 1853 Beisenhirtz obtained a blue by acting upon aniline with potassic dichromate and sulphuric acid. It remained for W. H. Perkin to develop this reaction, and to lay the foundations of the great aniline industry which is now so extensive. In 1856 he isolated the color found in the last-mentioned reaction, called it *mauve*, and showed that it could be used as a dye. Many chemists at once turned their attention to the subject, and a great number of new colors of almost every tint and shade were discovered, which have taken the place in dyeing, and to a considerable extent in calico-printing, of the animal and vegetable colors in previous use. The chemical composition of many of these colors has been established, and many chemical facts of great importance have been developed by their study. See **COAL-TAR COLORS**.

ANILINE REDS.—*Rosaniline* salts are the most important of all the aniline colors. They are not only used for the production of brilliant tints on cotton, wool, and silk, but they constitute the material from which many of the other colors are prepared. Rosaniline is a colorless base of the

formula $C_{20}H_{21}N_3O$. It is produced by the action of oxidizing agents on a mixture of aniline and toluidine.

Medlock's process for the preparation of aniline red is as follows: The aniline oil, 1 part, is heated with $1\frac{1}{2}$ parts of a 75 per cent. solution of arsenic acid in a closed iron still provided with a stirrer. The product is boiled with water and filtered, and on adding to the solution common salt in excess, the crude hydrochlorate of rosaniline is precipitated. This is dissolved in boiling water, filtered, and allowed to crystallize. This salt of rosaniline, $C_{20}H_{19}N_3.HCl$, is known as *aniline red*, *magenta*, *fuchsin*, *solferino*, *roseine*, *azaleine*, etc. It appears in magnificent green crystals, with a metallic luster like that of the wing-covers of Brazilian beetles or cantharides. It is soluble in water and in alcohol, with a color varying from a beautiful cherry red to a crimson.

Coupiér's process for the preparation of fuchsin consists in treating with iron and hydrochloric acid a mixture of nitrobenzene with aniline and toluidine. This method has the advantage of avoiding the use of compounds of arsenic. It is now extensively employed.

ACID FUCHSIN, OR ACID MAGENTA.—When fuchsin is treated with fuming sulphuric acid an acid product is formed. The sodium or ammonium salt of this is known as *acid fuchsin* or *acid magenta*. It has the advantage that it dyes wool and silk in acid baths.

ANILINE VIOLETS AND BLUES.—By introducing alcoholic radicals into rosaniline in place of a part of the hydrogen, new dyes are formed. In 1863 Hofmann patented processes for the manufacture of dyes which have come into the market under the names *Hofmann's violet*, *dahlia*, *iodine violet*, etc. Since that time many other similar dyes have been added to the list. *Aniline blue* is prepared by treating aniline in the presence of certain organic acids at a temperature of about $180^\circ C$. with an excess of aniline. The final product of this treatment is triphenylrosaniline, which is pure aniline blue, *bleu de Lyon*, the only blue that has come into extensive use. This blue is insoluble in water, which rendered its application somewhat troublesome, as an alcoholic solution was necessary. Nicholson found that sulphuric acid produced a compound analogous to sulph-indigotic acid, soluble in water; this is now extensively manufactured under the name of "Nicholson's blue" or "soluble blue."

ANILINE GREENS.—*Aldehyde green*, called also *aniline green*, *viridine*, and *emeraldine*.—In 1861 Lauth obtained a beautiful but fugitive blue by the action of aldehyde on a solution of a rosaniline salt in sulphuric acid. A young chemist, Cherpin, endeavored to fix the color, and was advised by a photographer's apprentice to use sodic hypo-sulphite, a salt used for fixing photographs, on account of its property of dissolving argentic chloride, bromide, and iodide. Cherpin followed the unscientific advice, and obtained the most beautiful green. The original process of Lauth and Cherpin is still pursued, and is so simple that many dyers prepare the color for themselves. Aldehyde green is principally employed in silk-dyeing.

Malachite green is produced by the action of benzo-trichloride on dimethylaniline. It appears in commerce as a double salt with zinc chloride. Salts of its sulpho-acids are known as *Helvelia green*.

ANILINE BROWNS AND MAROONS.—Several browns have been produced directly or indirectly from aniline. De Laire obtained a maroon by adding rosaniline hydrochlorate to fused aniline hydrochlorate. Schultz prepared a fine garnet color by passing nitrous vapors through a solution of soda holding rosaniline in suspension. Jacobsen prepares a rich brown by heating picric acid and aniline together, dissolving the product in hydrochloric acid, and precipitating with caustic soda. He obtains another by heating ammonium chromate with aniline formate. Koechlin produces a brown on wool by printing on a mixture of rosaniline hydrochlorate (fuchsin), oxalic acid, and potassium chlorate, and on cotton by adding to this mixture some cupric sulphide. Browns are generally made from the residue of rosaniline.

ANILINE GRAY.—Castelhas has patented a process by which a beautiful gray is produced, which has, however, found little favor among dyers on account of its high cost. He subjects mauveine (Perkin's violet) to the action of sulphuric acid and aldehyde. Carves and Thierault prepare a rich gray, called by them *murein*, by mixing aniline, hydrochloric acid, potassic dichromate, copperas, and sulphuric acid.

ANILINE BLACK.—No one has yet succeeded in producing a good black dye from aniline, though the color produced on cotton, silk, or wool by immersing first in a solution of an

aniline salt, and then in potassic dichromate, is very near a black. In calico-printing, however, blacks of great intensity and durability have been discovered, which are now extensively used; in fact, except for mourning goods, in which the black predominates over the white, the aniline black is now used almost exclusively. Lightfoot discovered the first aniline black in 1863. He printed on the cotton a mixture of aniline hydrochlorate, potassic chlorate, cupric chloride, sal-ammoniac, acetic acid, and starch paste; exposed the cloth to the air for two days, and fixed the color with an alkali. Lauth improved the process by substituting cupric sulphide for the cupric chloride. Cordillot substituted potassium ferricyanide for the copper salt. Alfred Paraf in 1865 introduced a mixture of aniline hydrochlorate, potassic chlorate, and hydrofluosilicic acid, properly thickened. On exposing the goods in the "ageing-room" to a temperature of 32° to 35° C., the chloric acid is liberated, and oxidizes the aniline to a black.

APPLICATION OF ANILINE COLORS IN DYEING AND CALICO-PRINTING.—In silk-dyeing no mordant is required; to produce an even color, however, it is found best to use a weak soap solution with the dye; and sometimes a little acid is added, sulphuric or tartaric. For printing on silk the colors are thickened with gum-senegal, printed from blocks, and when dry the goods are steamed and washed. A discharge style may be produced by dyeing silk with a rosaniline salt, then printing on zinc dust thickened with gum. The rosaniline is reduced to colorless leucaniline, producing white figures on a colored ground. By mixing with the zinc colors which are not affected by it, colored figures are produced. For dyeing wool no mordant is required; the goods are simply handled in hot solutions; except in the case of Nicholson's blue, which is dissolved in an alkali, the goods after passing through the solution being subjected to an acid bath. For dyeing cotton, mordants are necessary. By subjecting the goods to (1) a decoction of sumach, (2) to sodic stannate, and finally (3) to dilute sulphuric acid, a stannic tannate is produced on the fiber which has a great affinity for aniline colors. For printing, the colors are thickened with albumen, or a solution of aluminum arsenate in aluminum acetate, and fixed by steaming.

Aniline colors are also used for inks, for coloring leather, soaps, vinegar, candies, ivory, horn, etc.; and lakes are prepared from them for paper-staining, printer's ink, etc.

The high cost of aniline colors is counterbalanced by the brilliancy of their tints and the simplicity of dyeing. The aniline color industry has acquired greater proportions in Germany than in any other country.

For further details, see Watt's *Dictionary of Chemistry*; Wurtz, *Dictionnaire de Chimie*, and specially *Die Farbstoffe*, von M. P. Schützenberger; *Deutsche Uebertragung*, von Dr. H. Schröder (Berlin, 1868-73). Special works on the subject are Becker's *Anilin-Färberei* (Berlin, 1871); Reimann's *Aniline and its Derivatives* (New York, 1868); Krieg's *Theorie und praktische Anwendung von Anilin in der Färberei und Druckerei* (Berlin, 1866); Schultz's *Chemie des Steinkohlenthurs* (Brunswick, 1887-90). Wagner's *Jahresbericht der chemischen Technologie*, from 1858 to date, contains the record of the progress of this important branch of chemical industry.

C. F. CHANDLER.

Revised by IRA REMSEN.

Au'imal [Lat., living creature; from *a'nima*, breath, life]: a member of that division of organisms which, among the higher forms, are clearly distinguished from plants. The growth of our knowledge of both divisions, however, renders it impossible to form a scientific definition which shall include all forms agreed upon to be animals, and exclude all known to be plants. Any line of division drawn between the two kingdoms is an artificial one. Any one character possessed by all animals belongs also to some plants, and *vice versa*. Among the lower forms of organisms, some exhibiting animal characters in the main possess also those belonging usually to plants. Among such forms some possess such different degrees of combination of those characters which are generally taken as diagnostic of animals on the one hand, and of plants on the other hand, as to make it impossible to say in which division the organism should be placed. To meet this difficulty a third division of organisms has been proposed, to which the name *Protista* has been given. While there are grounds for establishing such a division, naturalists have regarded it as an undesirable one, in that it practically increases the difficulty, in having three indistinct groups to decide among instead of two. In gen-

eral, it may be said that animals have a definite form; do not have chlorophyll in their cells, or cellulose in their cell-walls; have the power of voluntary motion; ingest their food (which must include some proteid substances in a solid form); possess a digestive cavity or canal, and organs of excretion.

DAVID S. JORDAN.

Animal Charcoal: See BONE-BLACK.

Animal'cule [Lat. *a'nimal'culum*, diminutive of *a'nimal*]: literally a "minute animal," commonly one whose figure can be discerned only by the aid of a microscope. In popular language it is mostly applied to the microscopic animals which zoölogists include in the classes of the *Protozoa*. Many of the so-called animalcules are now known to belong to the lower ranks of the vegetable kingdom.

Animal Electricity: See ELECTRICITY, ANIMAL.

Animal Heat: the temperature which each animal possesses during life. In reptiles, batrachians, and fishes among the vertebrates, and in all the invertebrates as far as has been observed, the temperature of the body may vary through a wide range, being at least slightly above the temperature of the medium in which they are found. These have been called *cold-blooded*, for which inaccurate term *eurhythmal* or *poikilothermal* has been proposed. In mammals and birds the temperature is very nearly constant for each species. Such animals are known as *warm-blooded*, *stenothermal*, or *homoiothermal*.

For each species of animals there is a degree at which the tissues of the animal best perform their activities, its *optimum* temperature. Cold-blooded animals must depend mainly upon their surrounding medium for this temperature, being able to produce but little heat for themselves. They possess the power, however, of withstanding great departures from the *optimum*, becoming in the mean time more or less inactive, especially in the lower temperatures. Warm-blooded animals, on the contrary, by having developed means for the production of heat in considerable quantities, are able to constantly maintain within their bodies the *optimum* temperature. This gives them the advantage of being capable of activity through all changes of temperature of their media. Their tissues have lost the power, however, of being able to endure, except in particular cases, any but slight departures from the *optimum* temperature. The exceptional cases are those of animals which have the power to pass into a state, that of *hibernation*, in which their temperature may become greatly reduced, being not far above the surrounding medium in the few cases studied. These animals become in this state like cold-blooded animals, in that their temperature may vary through wide intervals. The temperature of warm-blooded animals, while it is nearly constant in the species, varies with the species; for example: it is in man, 98.6° F.; the horse, 98.6°; the rat, 101.8°; the dog, 102°; the mouse, 106°; the goose, 107°; the turkey, 108°; the swallow, 111°. In man, in whom the temperature has been most carefully studied, it is found that even in health there is a slight variation from the mean of 98.6° for different times of the day, for different conditions of the body, and in different periods of life. The different tissues also range a little above and below the mean.

The heat which is produced in any one organ during its activity is distributed to other parts of the body by means of the circulation of the blood. The circulation of the blood also will distribute the effect of the cooling of any part of the body. The problem of keeping the animal body at a constant temperature is a very complicated one, and includes a means of nervous control of the production of heat on the one hand and of its loss on the other. The exact mechanism for the nervous control of the production of heat has not yet been made out. Loss of heat takes place mainly at the skin by radiation and by evaporation of the perspiration. The greater the amount of blood passing through the skin, the greater the loss of heat by radiation; the loss by this source being greatly increased by the evaporation of perspiration. Nervous reflex mechanisms control both the amount of blood flowing through the skin and the amount of perspiration secreted.

DAVID S. JORDAN.

Animal Magnetism: See HYPNOTISM.

Animal Mechanics: See LOCOMOTION of ANIMALS.

An'ima Mun'di: a Latin phrase signifying "soul of the world." It was used by ancient philosophers, who supposed that nature or all matter was pervaded by an ethereal essence and vital force, which organized and actuated created beings, but was inferior to the Divine Spirit. The Atmān

(Atmā) or Pārāmātmā of the Hindus was also regarded as the soul of the world in a somewhat different sense. The Atmān was supposed to be the original life-principle from which the universe was evolved.

An'imé: a resin which exudes from *Hymenæa Courbaril*, a tree of the natural order *Leguminosæ*, and a native of Brazil. It has been used as a medicine and as incense. In England the name animé is applied to a resin known in India as copal, and obtained from the *Vateria Indica*.

An'imism: practical belief in spirits, good or bad, having power over natural occurrences and the lives of men. It seems to be the predominating philosophy and religion of all savage races (e. g. those of America, the Pacific islands, Africa, and Asia), and of many nations well advanced in civilization, e. g. Greeks, Romans, Aztecs, Hindus, Chinese, Japanese. The subject can best be considered under several heads.

I. **SPIRITISM.**—Such phenomena as dreams, sickness, and death lead the savage to distinguish the body from the ghost-soul or spirit, which is material but impalpable, and in form like the body. Objects and animals as well as men have spectral forms. The souls of men exist after the body perishes—according to some tribes suffering transmigration, according to others going on their long and perilous journey to the land of shades, or becoming malignant demons, dreadful in their power for evil—though some spirits, especially those of ancestors and little children, are as powerful for good. Thus endowed, the spirits of the dead do not differ essentially from the demons with which also savage man peoples the world around him. The spirits can be propitiated by sacrifices, gifts, food, prayers, etc., or controlled by magic. But as fear is the most powerful emotion, the demons of darkness and destruction receive almost exclusive worship. Animistic religion seldom has any moral value. In fact, most of the sin and misery of heathenism—cannibalism, human sacrifice, the revolting licentiousness of the ancient Aztec feasts and of the present Central African secret societies, the terror of demons and monsters, and the oppression and cruelty of sorcerers and priests—are either closely dependent upon or directly traceable to animism. The theory of moral retribution, with its restraining effect, scarcely has a place. The spirits may enter into human bodies, producing inspiration, demoniacal possession, disease, or death; or into animals and objects.

II. **FETISHISM.**—A spirit taking up its abode in an animal or object, whether of its own accord or compelled by some spell or by some magic property of the object, makes the object entered a fetish. Or the object itself may be viewed as possessed of occult powers, and only later distinguished from the spirit residing in it. In both these ways has arisen the worship of fire, water, trees, animals, as fetishes.

III. **MAGIC.**—As fetishism can not be clearly marked off from spiritism on one side, neither can it from magic on the other, which is occult power not only over men and things, but especially over the spirits themselves, exercised by means of sacrifices, mystic rites, charms, fetishes, incantations, etc. Those who know the way of spirits thus become medicine-men or fetish priests, and are held in awe both for their power over the spirits and for their consequent power for good and evil over men.

IV. **ANCESTOR-WORSHIP.**—Ancestor-worship has been especially developed among the Japanese (Shintoism), Chinese, Hindus, Romans (manes-worship), Greeks, and Bantu tribes of Africa. While most spirits are malignant, those of ancestors are kindly disposed; but even on this basis there is no sharp distinction from spiritism, for as the father continues to care for his family, so does the chief for his tribe, or the Chinese god of gambling (himself a deified gambler) for the art he practiced on earth. The ancestral spirits are not more powerful than others, but they will listen to us and help us, or punish us for neglecting them and doing wrong. Among the Chinese ancestor-worship pervades and shapes all social, political, and religious life. Even political honors are sought largely for the sake of one's ancestors, and all change from their customs and institutions is resisted. Among many peoples the spirit of the first ancestor is pre-eminently endowed with supernatural powers, either as lord of the dead or as supreme deity and creator. Often, however, he is thought of as too far away and little homage is paid to him.

V. **POLYDÆMONISM, NATURE RELIGION, AND POLYTHEISM.**—Polydæmonism, advancing one step from primitive animism, assigns to each river, mountain, waterfall, and fountain its

spirit or god. Nature religion personifies the vaster powers, such as Heaven, Rain, Sun, Thunder, Sea, and Fire. Whether it develops out of animism and polydæmonism, or, as is certainly sometimes the case, arises independently, it is but animism on a larger scale. Polytheism differs from nature religion only in regarding its deities more as separate personalities. It may also arise in part out of ancestor worship. Among the Hindus, Greeks, old Norse, and modern Africans we find animism, fetishism, ancestor-worship, polydæmonism, polytheism, and monotheism undeniably existing together.

VI. **MODERN SURVIVALS OF ANIMISM ARE**—(a) of spiritism: belief in ghosts and haunted houses, feelings aroused in the dark after a ghost story, fear of darkness, spiritualism entire; (b) of fetishism: charms, veneration of sacred relics, holy water, lucky coins; (c) of magic: signs (such as dropping shears and spilling salt), incantations and charms against warts, omens on All-Halloween, the notion that a priest or ordained minister has peculiar religious authority and power, throwing rice at weddings, lucky and unlucky days and numbers, spiritualistic seances; (d) of ancestor worship: regard for the curse or blessing of parents or of the aged as possessed of supernatural potency, the thought that perhaps a sainted mother's presence is still with one; (e) of polydæmonism and polytheism: the worship of saints, haunted woods, streams, and wells, and personification in poetry and under the influence of strong emotion. In view of such survivals, it must be strenuously insisted that our own civilized human nature does not altogether differ from that of the savage, that his so-called superstitions are neither wholly foreign to us nor altogether to be despised, and that there is in him the same raw material of manhood and the same possibility of spiritual life and growth as in us.

ROBERT J. KELLOGG.

An'io (the modern *Tevero'ne*): a river of Latium (Italy); flowed nearly westward, passed by Tibur, and entered the Tiber 4 miles N. of Rome. Length, about 55 miles. Ancient Rome was in part supplied with water from the Anio by two aqueducts, respectively 43 and 62 miles long.

An'ion: See ANODE and ELECTROLYSIS.

An'ise, Oil of: an essential oil obtained by distilling anise-seeds or star-anise with water. Oil of fennel, from *Anethum feniculum* and *Artemisia dracunculus*, is of a similar chemical composition. Oil of anise and of fennel contain a hydrocarbon oil, said to be isomeric with oil of turpentine, and an oxidized oil, $C_{10}H_{12}O$, called anethol or anise camphor, which solidifies at temperatures below $10^{\circ}C$.

Anise-seed: the fruit of the *Pimpinella anisum*, an annual herbaceous plant of the family *Umbelliferae*; a native of Egypt. It is cultivated in Syria, Malta, Spain, and Germany. Anise-seed is used in medicine as a stimulant and a carminative, and is also used to flavor liqueurs and as a condiment. Anise-seed contains a volatile oil which is employed for similar purposes. A large part of the anise oil of commerce is from star-anise, the fruit of *Illicium anisatum*, a small tree of the order *Magnoliaceae*. The whole plant is carminative and is used by the Chinese as a spice. Its properties are those of the *Pimpinella*. It is imported from Annam and China. This latter is largely used for flavoring the Dutch aniseed and the anisette de Bordeaux.

L. H. BAILEY.

Anise-tree [so named from the smell, which resembles that of anise]: either of two small trees or large shrubs of the order *Magnoliaceae*, growing in the Gulf States—the *Illicium floridanum* and the *Illicium parviflorum*. Both are evergreen, the former with dark purple and the latter with small yellow flowers, appearing in May and June. The star-anise oil of commerce is the product of the *Illicium anisatum* of Eastern Asia, and it is believed that the same oil might be obtained from the *Illicium floridanum*. The *Illicium parviflorum* has a taste and smell resembling those of sassafras. The *Illicium religiosum* of China yields a fragrant incense for temple-worship.

Anisol Red: See AZO-COLORS.

Aniu'y, GREATER: a river of Northeast Siberia; rises about lat. $67^{\circ}N$., and, after a course of 270 miles, enters the Kolyma near lat. $68^{\circ}N$. The LESSER ANIUY rises in lat. $66^{\circ}30'N$., and falls into the Kolyma near the mouth of the Greater Aniu'y. Length, about 250 miles.

Anjer: seaport of Java; on the Sunda Straits; 69 miles W. of Batavia (see map of East Indies, ref. 8-C); formerly often touched at by vessels bound to China and Japan, or for Batavia, to take in provisions, and to land the mails and

passengers which go to Batavia overland; was destroyed by the Krakatoa eruption in 1883. Its site is now occupied by a high-peaked hill, and the port has been removed to New Anjer, 10 miles N. E.

Anjou: a former province and duchy of France, intersected by the river Loire; was inhabited in ancient times by the Andegavi, who were conquered by Cæsar. It now forms the department of Maine-et-Loire and part of Sarthe, Mayenne, and Indre-et-Loire. Its capital was Angers. Geoffroy, Count of Anjou, married Matilda, a daughter of Henry I. of England, and was the founder of the royal house of Plantagenet. His son Henry was Count of Anjou and King of England. Anjou was annexed to the crown of France about 1204, and was bestowed as a fief on Charles (a brother of St. Louis), who became King of Naples. Louis, a son of King John, was the first Duke of Anjou, which was erected into a duchy about 1360. Anjou was finally annexed to the French crown in 1480, after which the younger sons of several kings bore the honorary title of Duke of Anjou. Pop. about 550,000.

An'karström, JOHAN JAKOB: Swedish regicide; b. May 11, 1762; was a partisan of the aristocracy. Having formed a conspiracy with Count Horn and others, he assassinated Gustavus III. at a masked ball in Stockholm, Mar. 16, 1792. He was condemned to death, and, after he had been publicly whipped for three successive days, was beheaded on Apr. 29 of that year.

Anker, ang'kér: an old European liquid measure (now disused, except in Denmark and Norway), having different values in different countries. The anker of Copenhagen is a little more than $9\frac{1}{4}$ U. S. gal., or a little less than $8\frac{1}{4}$ imperial gal. The anker of Hamburg was 9.54 gal.; of Bremen, 9.57; of Lübeck, 9.89; of Amsterdam, $10\frac{1}{4}$; and of Berlin (old measure), 12.45; later measure, 9.07.

An'klam: a town of Prussia; in Pomerania; on the Peene; 109 miles by rail N. of Berlin (see map of German Empire, ref. 2-G). It has manufactures of linen and woolen goods. It belonged formerly to the Hanseatic League. Pop. (1890) 12,917.

Anko'bar: a town of Abyssinia; capital of Shoa; 8,200 feet above sea-level, and about 265 miles S. E. of Gondar (see map of Africa, ref. 4-G). It contains a royal palace, and is a favorite residence of the monarch. Pop. 7,000.

Ankylo'sis, or **Anchylosis** [from Gr. ἀγκύλωσις, stiffening of joints, deriv. of ἀγκύλος, crooked]: in surgery, a stiffened and more or less fixed and immovable joint, so called from the crookedness often seen in limbs with such joints. Ankylosis may result from suppurative inflammation, as in "white swelling" of the knee, and is to be regarded as a favorable termination of such disease. These cases result often in neo-plastic exudations—new tissues—adhering to the cartilages of both articulating bones; and not unfrequently these new growths are partly or completely ossified, converting the two bones into one. The cartilages or ligaments of a joint may become shrunken from disease, the opposing synovial membranes may adhere to each other, or other important structural changes may prevent motion. "Spurious ankylosis" is a case in which a spasm or cicatricial contraction of the muscles, or even of the skin, prevents motion, while the joint itself is not the seat of disease. Cases of so-called hysteria sometimes are accompanied by a stiffness of one or more joints; but such cases are readily detected after the administration of an anæsthetic, when the joint at once becomes movable.

The prospect of recovery of motion in an ankylosed joint is small indeed. Joints stiffened at an inconvenient angle may be put into better shape during anæsthesia, and then be allowed to become ankylosed again in the desired position. Excision of joints has been considerably practiced, and with some success as a means of cure.

An'na: on Illinois Central R. R., Union co., Ill. (for location of county, see map of Illinois, ref. 11-E); situated in the midst of a fruit-growing region, 37 miles N. of Cairo. Pop. (1880) 1,494; (1890) 2,295; (1900) 2,618.

Anna, SAINT: supposed to have been the mother of the Virgin Mary, but not mentioned in the Bible. The Roman Catholic Church celebrates an annual festival in her honor July 26; the Greek Church Dec. 9.

An'naberg: a mining-town of Saxony; in the Erzgebirge, 18 miles S. of Chemnitz (see map of German Empire, ref. 5-G). It has mines of silver, cobalt, and tin, and manufactures of lace and silk ribbons. Pop. (1890) 14,960.

Anna Carlov'na: Regent of Russia; b. at Rostock, Dec. 18, 1718; daughter of the Duke of Mecklenburg, and a niece of Anna Ivanovna, Empress of Russia (*q. v.*). She was married in 1739 to Anton Ulrich, Duke of Brunswick-Wolfenbüttel, and had a son, Ivan, whom Anna Ivanovna designated as her successor. Soon after the death of that empress, in 1740, Anna Carlovna assumed the office of regent. She was deprived of power by a conspiracy which raised Elizabeth to the throne in Dec., 1741. D. in exile at Cholmogory on the Dwina, Mar. 18, 1746. See Brückner's *Die Familie Braunschweig in Russland* (St. Petersburg, 1876).

Anna Comne'na: learned Byzantine princess and writer; b. Dec. 1, 1083; daughter of Alexis I., Emperor of Constantinople. She was carefully educated in poetry, science, and Greek philosophy, was famous for her beauty and talents, and became the wife of Nicephorus Bryennius. On the death of her father, in 1118, she conspired against her brother John, and attempted to usurp the crown or to place it on the head of her husband, but failed. She afterward became engaged in literary pursuits, and wrote in Greek a life of her father, entitled the *Alexiad*, which is an important historical document. It covers the period 1069-1118, including that of the first crusade. The style is rather affected; best edition by Reifferscheid (2 vols., Leipzig, 1884). D. in a convent after 1148.

Anna Ivanov'na: Empress of Russia; b. at Moscow, Jan. 25, 1693; daughter of Ivan, a brother of Peter the Great. She was married in 1710 to the Duke of Courland, who died in 1711. She succeeded Peter II. on the throne in 1730, and permitted her favorite Biren to control the empire. He abused his power with great cruelty, and executed and banished many thousand persons. She died Oct. 28, 1740, and was succeeded by Ivan.

An'nals: in Roman history, official chronicles of events kept by the Roman *pontifex maximus* down to 131 B. C. When Rome was sacked by the Gauls, 390 B. C., all the existing annals were destroyed except a few fragments, which is one cause of the obscurity of early Roman history. History in the form of annals was afterward written by private citizens. The Chinese claim similar annals of the history of their nation back as far as 3000 B. C. See Nitzsch, *Die römische Annalistik* (Berlin, 1873).

Annam' (literally, peaceful south): an empire in South-eastern Asia, on the east coast of the Indo-Chinese peninsula, now under French protectorate. It is a part of what used to be called Cochin-China, and is a strip of coast about 1,400 miles long by sometimes only 50 broad, though the western boundary is not well defined, the tribes between Annam and Siam being fairly independent. Tonking lies to the N. of this country, and Lower Cochin-China to the S. The area of Annam proper is about 27,000 sq. miles, and of the independent tribes nominally under it about 20,000 sq. miles. The population is estimated at about 5,000,000. The capital is HUÉ (*q. v.*).

INHABITANTS.—The Annamese are confined, for the most part, to the coast region. They form an ancient and rather ill-favored race of Mongolian relationship. They are short, tawny, with low forehead, flat face, and very projecting high cheek-bones. The nose is flat and small, mouth large, teeth blackened by the use of the betel-nut, the areca-nut, and lime; the neck is short, shoulders sloping, body thick-set and clumsy. But they are especially characterized by two features well known to their neighbors. The first is a curious swagger in the gait, described as theatrical, and due to the structure of the pelvis and the femur; the second, a greater separation of the great toe from the rest than is found in any other people walking habitually barefoot. The Chinese annals refer to this over 4,000 years ago. They are generally Buddhists, but there is a sprinkling of Roman Catholics. The language is allied to Chinese. See Frey, *L'annamite, mère des langues* (1892).

Among the Annamese live many Chinese and Cambodians, and in their hands is nearly all the commerce of the country. In the hills of the W. and forests of the S. W. live several wild tribes; the Mois in the S., a wretched race in the scale of civilization; the Chams, a people of Mohammedan religion and Arab characteristics, apparently degraded from a higher status; the Laos in the N. W., and many others. The inland regions are but little known.

PRODUCTIONS.—The principal productions are rice, cotton, tobacco, sugar, silk, pepper, cardamoms, ivory, lac, ornamental woods, bamboos, cinnamon bark, tea, and coffee. The chief imports are rice, cottons, yarn, paper, and opium.

Gold is washed out of the hills, and a French company was formed in 1891 for working the coal mines at Turane. Fishing is an important industry. The trade is chiefly with China and France, a little with Japan, Siam, and Burma.

WEIGHTS AND MEASURES: (1) *Weight*.—The cân or catti = 1·3775 lb. av., or 624·913 grammes. Multiples, 10 cân = 1 yen; 5 yen = 1 binh; 2 binh = 1 ta; 5 ta = 1 quăn. Sub-multiples, $\frac{1}{2}$ cân = 1 nen; $\frac{1}{10}$ nen = 1 luong; $\frac{1}{10}$ luong or liang = 1 dong; $\frac{1}{10}$ dong = 1 phan; $\frac{1}{10}$ phan = 1 li. The li = 0·602 grain = 0·03905 gramme, and is fancifully subdivided decimally to the millionth part.

(2) *Length*.—For merchants' measure the thuoc = 25·58 inches = 649·7 mm., is the unit base. Multiples, 10 thuoc = 1 truong; 3 truong = 1 that; 10 that = 1 gon = 213·17 yards = 194·92 meters. Sub-multiples, $\frac{1}{10}$ thuoc = 1 tac; $\frac{1}{10}$ tac = 1 phan; $\frac{1}{10}$ phan = 1 li = 0·258 inch. For builders' measure, the thuoc = 19·18 inches = 487·16 mm. Multiples, 5 thuoc = 1 ngu; 3 ngu = 1 sao; 10 sao = 1 mau = 79·92 yards = 72·8775 meters. Sub-multiples, as before, the li being $\frac{1}{1000}$ thuoc, or 0·01918 inch = 0·487 mm. For road-measure, the dam = about 0·55 mile = 0·885 km., is the unit; sub-multiple, $\frac{1}{2}$ dam = 1 li = 0·275 mile = 0·4476 km.

HISTORY.—The people claim to have come from the south of China. About 2357 B. C. Chinese annals mention them under a name meaning "the people with the big toe." They were vassals to other nations, chiefly the Chinese, until about the tenth century of our era, when they threw off this yoke and remained practically independent until they came under the French. In 1787 the King of Cochinchina made a treaty of alliance with France, with a small cession of territory. This gave France predominant influence, and Christianity made rapid progress until 1820, when a party hostile to foreigners prevailed. In 1858 the execution of a French subject gave occasion for a war with Annam, which resulted in the seizure of Saigon, in the present French Cochinchina. In 1862 the Annamese Government abandoned three provinces to France; in 1867 three more; in 1872 two ports were opened to foreign commerce; and in 1886 a French protectorate was established over what remained. The present king is Bun Can, proclaimed in 1889. French troops occupy the citadel of the capital; Annamite officials administer internal affairs. There are 23,230 soldiers, of whom 11,830 are natives. The capital is Hué, near the coast, in about lat. 16° 30' N. See **INDO-CHINA**.

MARK W. HARRINGTON.

An'ndale: See **DUMFRIES**.

Annandale, THOMAS, M. D., F. R. C. S.: English surgeon; b. at Newcastle-on-Tyne, Feb. 2, 1838; M. D., University of Edinburgh, 1863; acted as assistant and lecturer in University of Edinburgh until 1877, when he was appointed Regius Professor of Clinical Surgery in the same; author of *Abstracts of Surgical Principles* (1868-70); *On the Pathology and Operative Treatment of Hip Disease* (1876), etc.

An'na Peren'na: a goddess of the Roman mythology. According to Vergil and Ovid she was a daughter of Belus and sister of Dido. She went to Italy, and was received kindly by Æneas. Her favor was invoked by the Romans to obtain health and long life.

Anna Petrov'na: eldest daughter of Peter the Great of Russia and the Empress Catharine; b. in 1708; was married to Frederick Charles, Duke of Holstein, in 1725. She was mother of Peter III. of Russia. D. in 1728.

Annap'olis, or Annapolis Royal: a seaport of Nova Scotia; at the mouth of the river Annapolis (see map of Quebec, ref. 2-A). It is one of the oldest settlements in North America, and was founded in 1604 by the French, who called it Port Royal. The harbor is good, but difficult of access. This town was the capital of the province until 1750. Pop. 2,800.

Annapolis: city; capital of Maryland, and county seat of Anne Arundel County (for location of county, see map of Maryland, ref. 3-F); is a port of entry on the south bank of the Severn river, 2 miles from its entrance into Chesapeake Bay, 20 miles S. by E. of Baltimore, and 22 miles E. by N. of Washington, and 40 miles by rail to the latter city by the A., W. and B. R. R., and 26 miles from Baltimore by the A. and B. Short Line. The Eastern Shore R. R. also passes through this city to Ocean City via Bay Ridge, across the Chesapeake Bay. It has also water communication with Baltimore daily by steamboat. Annapolis contains a State-house, Governor's mansion, court-house, land-office, comptroller and treasurer's buildings, and jail. It is also the

seat of St. John's College and the U. S. Naval Academy. (See **NAVAL ACADEMY**.) A bronze statue of Maj.-Gen. John de Kalb was unveiled here Aug. 16, 1886. There is also a

State Capitol, Annapolis, Md.

bronze statue in front of the State-house of the late Chief Justice Roger B. Taney. It is also the seat of the Court of Appeals. The harbor, or Annapolis Roads, is one of the finest in the country, there being a depth of 60 feet in the channel up to Round Bay in the Severn river, 7 miles from the city. The city has both gas-works and water-works. Pop. (1880) 6,642; (1890) 7,604; (1900) 8,402. **EDITOR OF "CAPITOL."**

Ann Ar'bor: city and important railroad center; capital of Washtenaw co., Mich. (for location of county, see map of Michigan, ref. 8-J); on the Huron river; 38 miles W. of Detroit. The situation is elevated and pleasant. Here is the State University, one of the most flourishing institutions in the country, founded in 1837. (See **MICHIGAN UNIVERSITY**.) Ann Arbor has manufactures of furniture, organs, agricultural machines, wagons and carts, etc., and several flouring-mills. Pop. (1870) 7,363; (1880) 8,061; (1890) 9,431; (1900) 14,509.

An-Nā'sir (or Al-Nassir) Ledinil'lah (i. e. the defender of the religion of God): one of the Abassid caliphs; began to reign at Bagdad in 1180. He was a liberal patron of learning, and successfully defended his dominions against several aggressive enemies. D. in 1225.

An'nates [from mediev. Lat. *anna'ta*, a year's (*annus*) work]: the tax of "first-fruits" imposed by the popes on all bishops on their accession, and equal to one year's revenue of the benefice. The Council of Pisa (1409) complained of the custom; that of Bâle (1435) called it simony; that of Trent (Nov. 11, 1563) prohibited it, but it was recognized by concordat with Naples in 1818. In England, annates were first levied in 1213. In 1534 they were made payable to the king (Henry VIII.) instead of the pope. Queen Mary gave them up on her accession to the throne, but in the first year of Elizabeth's reign they were resumed by the crown, and continued to form part of the royal revenue until Queen Anne restored them to the Church under a scheme for their appropriation to the increase of poor livings. See **QUEEN ANNE'S BOUNTY**, under **BOUNTY**. W. S. PERRY.

Annatto: See **ANNOTTO**.

Anne: Queen of Great Britain and Ireland; the last sovereign of the house of Stuart; b. at St. James's Palace, London, on Feb. 6, 1665. She was the second daughter of James II. and Anne Hyde, who was a daughter of the famous Lord Clarendon. She was educated in the Protestant religion, to which she afterward manifested a constant devotion, although her father, after his accession to the throne, attempted to convert her to the Roman Catholic faith. On July 28, 1683, she was married to Prince George

of Denmark, a brother of Christian V. At an early age she formed an intimacy with Sarah Jennings (afterward the Duchess of Marlborough), who exercised an almost unbounded influence over her, both before and after her accession to the throne. Anne was the mother of seventeen children, all of whom died young and before she became queen. In the revolution of 1688 she supported the cause of the Prince of Orange, but was afterward implicated in intrigues for the restoration of her father. Anne succeeded William III., who died Mar. 8, 1702, at a time when the strife of parties was extremely violent. She pursued the foreign policy of the late king, which involved England in the long war of the Spanish succession as the ally of Austria and the enemy of France. Among the important events of her reign were a number of signal victories gained by the Duke of Marlborough over the armies of Louis XIV., and the union of England and Scotland in 1707. Her political principles, if she had any, were favorable to royal prerogative rather than constitutional liberty, and rendered her partial to the Tories. Anne became gradually alienated from the Duchess of Marlborough, who was a Whig, and transferred her favoritism to Mrs. Masham, whose intrigues undermined the Whig party so effectually that the Tory statesmen, the Earl of Oxford and Lord Bolingbroke, came into power in 1710. The queen and these Tory ministers concurred in designs and intrigues to secure the succession to her brother, the Pretender. The European war was ended by the treaty of Utrecht, April 11, 1713. Lord Bolingbroke became prime minister in place of the Earl of Oxford in July, 1714. Anne died of apoplexy on Aug. 1, 1714, and was succeeded by George I. The period of her reign, illustrated by the genius of Newton, Addison, Pope, Bolingbroke, Swift, De Foe, and Arbuthnot, was almost as celebrated in literature as the Augustan age of Rome, although she did little to make it so. See Oldmixon, *Life of Queen Anne* (1716); Strickland, *Lives of the Queens of England*; Ashton, *Social Life in the Reign of Queen Anne* (1883).

Anne of Austria: daughter of King Philip III. of Spain; b. Sept. 22, 1601; married Louis XIII. of France, Nov. 9, 1615; mother of Louis XIV. and Philip, founder of the House of Orleans; made regent after the death of her husband 1643; put the government in the hands of Mazarin; after his death (1661) retired to Convent of Val de Grâce. D. Jan. 20, 1666. Weak as a ruler, her regency was disturbed by the civil war of the Fronde. See Freere's *Regency of Anne of Austria* (2 vols., London, 1866).

Anne of Brittany: Queen of France; b. at Nantes, Jan. 26, 1476; daughter and heiress of Francis II., Duke of Brittany; married Charles VIII. of France, Dec. 6, 1491, Brittany, her dowry, then becoming united to France. After her husband's death (1499) she married his successor, Louis XII., whom she ably assisted. She was left a widow a second time in 1512, and died Jan. 9, 1514.

Anne of Cleves: b. Sept. 22, 1515; daughter of John, Duke of Cleves; became the fourth queen of Henry VIII. of England, who, on Thomas Cromwell's advice, married her to please the German Protestants Jan. 6, 1540. She was divorced July 9 of the same year, and retired to private life on a pension of £3,000 per annum. D. at Chelsea, July 16, 1557, and was buried in Westminster Abbey.

Anne of Denmark: wife of James I. of England; b. at Skanderborg, Jutland, Dec. 12, 1574; married at Upslo, Norway, Nov. 23, 1589; died at Hampton Court, Mar. 2, 1612. She was rather frivolous, very fond of pageants and masquerades, given to expensive building, and leaned toward Romanism, but was prevented from public avowal.

Anneal'ing [from Old Eng. *on-alan*, set on fire, make hot, burn]: a process of tempering glass and certain metals by heating them and then cooling them slowly, in order to render them less brittle and more tenacious. The extreme brittleness of glass that has not been annealed is seen in the glass toys called "Prince Rupert's drops," which, if scratched with a file, will collapse into powder or small fragments. Glass vessels are annealed in a long oven, one end of which is hotter than the other, and the trays in which the vessels are placed are slowly drawn into cooler and cooler parts. The operation of annealing large vessels requires several days. Iron, steel, brass, and other metals which are hammered into plates or drawn into wire become brittle during the process, and require to be annealed by cooling them slowly in water or air. Steel is tempered and hardened by a process of annealing, being placed in an oil-

bath or surrounded by a metallic compound which has a low fusing-point. The soft metals are annealed by immersion in water, which is boiled and then cooled slowly.

Annecey: a town of Eastern France; in Upper Savoy; pleasantly situated at the N. W. extremity of Annecey lake, 22 miles by rail S. of Geneva (see map of France, ref. 6-I). It has a cathedral, a bishop's palace, a church in which are preserved the relics of St. Francis de Sales, an old castle (formerly the residence of the Counts of Geneva), glass-works, cotton-mills, etc. It was once the capital of the Counts of Geneva. It passed from them to the Counts of Savoy, afterward Kings of Sardinia, who ceded it to the French in 1860. It shows traces of Roman origin. Pop. (1881) 11,334; (1891) 11,947; (1896) 12,894.

Annecey, Lake of: in Upper Savoy, 22 miles S. of Geneva, about 24 miles W. of Mont Blanc, and 1,426 feet above the sea. It is about 9 miles long and from 1 to 2 wide. Its waters are discharged through the Fieran into the Rhône.

Anneke, aan'ne-ke, JANS: See BOGARDUS, EVERARD.

Anneke, MATHILDE FRANCESKA GIESLER: b. on the estate of her grandfather, near Blankenstein, Prussia, Apr. 3, 1817. Early in life she engaged in literary pursuits, and took a deep interest in the political and social freedom of her country. When her husband, a Prussian officer and powerful leader in the revolution of 1848, was imprisoned under sentence of death at Cologne, Madame Anneke put a printing-press into her parlors, and herself edited a paper in the interests of the revolution. She served on the battle-field as one of her husband's staff. When the revolutionists were overpowered she, with her family, sought refuge in America, where she has been one of the most earnest champions of woman's enfranchisement. She edited the *Frauen Zeitung* at Milwaukee, Wis., in 1850, where she became principal of an academy for young ladies. SUSAN B. ANTHONY.

Annel'ida (from Lat. *annellus*, a little ring): a class of animals in which the long cylindrical body is divided into a series of rings or segments, each like its fellows. These segments each contain a portion of the internal organs, but they lack jointed appendages. (See ARTHROPODA.) There is usually a well-developed circulatory system consisting of dorsal and ventral vessels and communicating transverse branches. The nervous system consists of an anterior brain connected with a series of ventral ganglia (a pair in each segment) by two nerve-cords, one passing on either side of the throat. The mouth is ventral, the alimentary canal usually straight. Respiration takes place either by the general body-surface or by gills which may be developed upon the head or upon the segments of the body. In some there are also paired outgrowths from the body, strengthened by bristles, which serve as locomotor organs. The reproduction is usually by eggs, a few forms dividing spontaneously into two new individuals. Most of the Annelids are marine, but some occur in fresh water and a few (see EARTHWORMS) in moist earth. The Annelids include (1) the *Hirudines* (see LEECH); (2) the *Chatopods* (*q. v.*), and (3) the *Myzostomata*, a group of peculiar forms parasitic on the crinoids. J. S. KINGSLEY.

Annenkoff, MICHEL: See the Appendix.

An'ni, or Ani (anc. *Ab'nicum*): a ruined city of Asiatic Turkey; on the Arpa-Chai river; 28 miles E. by S. of Kars; capital of the Bagratian Kings of Armenia until taken by Alp-Arslân (1064); destroyed by an earthquake in 1319. Here are ruins of an ancient palace and citadel; also some Armenian churches nearly entire. These ruins plainly show the former importance of the city.

Annihila'tionist: one who denies the existence of the soul after death. Annihilationists are of two classes: those who believe that annihilation is the final doom of the incorrigibly wicked, and those who believe that immortality is not a natural attribute of man, but is specially conferred by God on those who through faith and obedience become part-takers of the divine nature. See FUTURE STATE.

C. K. ADAMS.

Anniston: city and railroad junction, Calhoun co., Ala. (for location of county, see map of Alabama, ref. 3-E); has cotton-factory, iron-works, car-factory, rolling-mills, pipe-works, six furnaces, etc. Pop. (1880) 942; (1890) 9,998; (1900) 9,695. EDITOR OF "WATCHMAN."

An'nius of Viter'bo (It. *An'nio da Viter'bo*): a learned Italian Dominican monk, whose proper name was GIOVANNI NANNI; b. at Viterbo about 1432. He wrote a Latin *Trea-*

tise on the Empire of the Turks (1471). He published at Rome, in 1498, *Seventeen Volumes of Various Antiquities with Commentaries*, containing extracts from the lost works of Berosus, Manetho, and other ancient historians, which proved to be forgeries. D. in 1502.

Anniver'sary [from Lat. *anniversaria*, adj., sc. *dies*; *annus*, year + *ver'tere*, *versus*, turn]: the annual return of a memorable day; the day on which some remarkable event is annually celebrated. Among the Jews the Passover was an anniversary in commemoration of the exodus from Egypt. The principal religious anniversaries of Christians are Christmas, Epiphany, and Easter. Anniversary days in the Roman Catholic Church are days on which an office is annually performed for the souls of the deceased.

Annobom', or **Annabon'**: island; 4 miles long and 2 wide; in the Gulf of Guinea (see map of Africa, ref. 6-C); was discovered Jan. 1, 1473, by the Portuguese, and has a population of about 3,000. Area, 6.6 sq. miles.

Annolied: a German poem in praise of Anno, a local saint of the city of Cologne. The poem, which is of great literary and linguistic value, was probably written in 1073, soon after the death of Anno, Archbishop of Cologne. It was edited for the first time by Martin Opitz (1639). See Wilmann's *Ueber das Annolied* (Bonn, 1886). JULIUS GOEBEL.

Annonay (Lat. *Annonæum*, or *Annoniacum*): a town of France; department of Ardèche; 37 miles S. S. W. of Lyons, at the junction of the rivers Cance and Déaume (see map of France, ref. 7-G). It has a suspension bridge and large manufactories of glove-leather. Paper of fine quality is made here. The Montgolfiers, who invented balloons, were natives of the town. Pop. (1896) 17,028.

Annot'to, or **Annat'to**: a red coloring-matter; is the pulp of the seeds of the *Bixa orellana*, an exogenous shrub which grows in South America and the West Indies, and belongs to the natural order *Flacourtiaceæ*. It is soluble in alcohol, ether, and in potash and soda, either caustic or carbonated. It contains a yellow principle called bixin. It is used as a dye, but its colors are fugitive. The pulp is used to color cheese, is an ingredient in some varnishes, and is employed in medicine to color ointments and plasters. In South America annotto is mixed with chocolate to improve the flavor.

An'mal (*annua'lis*, deriv. of *an'nus*, year): a plant which lives only one year; a plant which within the space of a year passes from a seed into a perfect plant, bears its fruit, and perishes. The duration of the life of annuals is generally much less than a year. Some plants which are annuals in one climate are perennials in another, as the castor-oil plant.

Annual Layers of Wood: In ordinary trees there is one period of growth each year, and this produces one layer of wood on the stem for each year's growth. When there are two periods of growth in a year, there are two wood layers. In cool climates, as there is rarely more than one growth period, the rings of wood are as many or about as many as the years during which the stem has lived, but as we go to warmer climates there is greater irregularity.

CHARLES E. BESSEY.

Annu'ity [from Fr. *annuité* < Mediev. Lat. *annuitas*, deriv. of *an'nus*, year]: a rent or sum of money which a person is entitled to receive every year. If the payment is to be continued through a period of uncertain length, it is called a *contingent annuity*; if it is payable for a definite number of years, it is an *annuity certain*. A person who has unemployed capital may find it advantageous to convert it into an annual income, which he is entitled to receive as long as he lives, and which is called a life annuity. The person who receives an annuity is called an annuitant. An annual income which is not to be paid until a number of years have elapsed is a deferred annuity. Those who invest money in the public funds of Great Britain are entitled to an income which is virtually a perpetual annuity, so that when each annuitant dies he may leave it to his heir. The accurate determination of the value of annuities in present money is a complex question of great importance and considerable difficulty, for the solution of which correct tables of vital statistics are requisite. The rate of interest is also an important element in the calculation of annuities. Great labor has been expended by several learned men in the formation of tables of the value of life annuities at all the different ages of human life.

ANNUITY, in the law of England, is a sum of money pay-

able every year, and charged on the person or personal estate of the individual who is bound to pay it; thus differing from a rent-charge, which is charged on real estate. Annuities are often paid by a person who borrows money (who is called the grantor) to the person who lends the money (who is the grantee). An annuity is either for a term of years, for a life or lives, or in perpetuity; and the last, although charged on personal property, may descend as real estate.

Revised by HENRY WADE ROGERS.

An'nulus [Lat., a ring]: a botanical term used in several senses. In mosses it denotes a rim external with respect to the peristome; in ferns it is an elastic rib which girds the theca or spore-case, and by its contraction disperses the spores: the collar which surrounds the stipes of some fungi just below the hymenium is also called an annulus.

Annuncia'da (the Order of Knights of the Annunciation): founded by Amadeus VI. of Savoy in 1362; an order originally called the Order of the Collar. The reigning King of Italy is grand master of the order.

Annuncia'tion, Feast of: a festival of the Church, observed at least as early as the tenth Council of Toledo (A. D. 656), and noticed in the acts of the Council in Trullo held A. D. 692, in commemoration of the announcement of the conception of the Saviour to the Virgin Mary by the angel Gabriel. It is celebrated on March 25, which is called Lady Day. A synod held at Worcester, England, A. D. 1240, forbade all servile work on this festival.

Ann'ville: village on Philadelphia and Reading R. R., Lebanon co., Pa. (for location of county, see map of Pennsylvania, ref. 5-H); is a manufacturing town in a farming district, and is the seat of Lebanon Valley College. Pop. (1880) 1,431; (1890) 1,283; not returned separately in 1900.

Ano'a: a small species of wild buffalo (*anoa depressicornis*), having the horns erect; it was originally classed with the antelopes, to which it has no close affinity. It lives in Celebes.

An'ode [from Gr. *ἀνοδος*, way up; *ἀνά*, up + *ὁδός*, way]: in electrolysis, the positive pole, or that surface by which the galvanic current enters the body (electrolyte) undergoing decomposition. The negative pole, or the surface by which the current goes out, is called *cathode*. The elements of electrolytes are called *ions*, and those which go to the anode are named *anions*. Thus in the decomposition of water by a galvanic battery, water is the electrolyte, the platinum plate connected with the positive pole is the anode, and the oxygen is the anion.

An'odyne [from Gr. *ἀνώδυνος*, painless; *ἀν-*, not + *ὀδύνη*, pain]: a medicine which diminishes pain. Opium, morphine, the anæsthetics, cannabis Indica, etc., are the chief anodynes—most of which tend actively to cause sleep. Some hypnotics, or sleep producers, however, like chloral, are not anodynes.

Anoint'ing [from O. Fr. *enoint* < Lat. *in-unctus*, partic. of *in-ungere*, anoint]: an Oriental custom of pouring aromatic oil on the head as a mark of honor. It was practiced at the coronation of kings and the consecration of high priests and prophets, as in the case of Saul, David, Aaron, and his sons. Spikenard, myrrh, and olive oil were sometimes used for this purpose. Anointing forms a part of the ceremonial of various sacraments in the Roman Catholic and the different Oriental churches. In the form used for the coronation of English kings and queens, the anointing is done by the Archbishop of Canterbury.

Revised by W. S. PERRY.

Anoka: city on railroad, capital of Anoka co., Minn. (for location of county, see map of Minnesota, ref. 9-F); on both sides of Rum river at its junction with the Mississippi, 15 miles N. N. W. of Minneapolis; has good water-power on Rum river. Flour, lumber, sash, doors, blinds, starch, shoes, carriages, machinery, etc., are manufactured. The city is connected with Champlin, on the other side of the Mississippi, by an iron bridge 900 feet long, and has a business college, high school, etc. Pop. (1880) 2,706; (1885) 4,629; (1890) 4,252; (1900) 3,769.

EDITOR OF "HERALD."

Ano'lis (Lat. form of *anoli*, name native in Antilles): a genus of lizards of the family *Iguanidæ*, natives of the warm parts of America, remarkable for their power of inflating the skin of the throat. They move with great agility, and exhibit great brilliancy of color, which is susceptible of change, and has consequently caused them to be popularly called chameleons, from which, however, they are very dis-

tinct. About 100 species are known; one of them (*Anolis carolinensis*) is common in the forests of the Southern States.

Anomalis'tic Year: the interval of time in which the earth completes a revolution with respect to any point in its orbit, or the interval which elapses between two successive passages of the earth through its perihelion. It is 4 minutes and 39 seconds longer than a sidereal year, and its length is 365 days, 6 hours, 13 minutes, and 45 seconds.

Anomaly [Gr. ἀνωμαλία; ἀν-, not + ὁμαλός, even]: in astronomy, the angular distance of a planet from its perihelion. The anomaly as above defined is the *true anomaly*. If we suppose a fictitious planet to set out from perihelion with the true planet, and to revolve uniformly about the sun at such a rate as to return to perihelion at the same time as the true planet, the anomaly of the fictitious planet is called the *mean anomaly*.

Anomia [from Gr. ἀνομος, irregular; ἀ-, not + νόμος, law]: a genus of lamellibranchiate mollusks related to the oyster. The shell consists of two unequal, irregular thin valves, of which the flatter one is deeply notched at the cardinal margin. Numerous species, living and fossil, are found in various parts of the world.

Anona [Sp., the custard-apple]: a genus of exogenous trees of the family *Anonaceae*, natives of hot climates. *Anona reticulata* bears an edible fruit called the custard-apple, because its seeds are surrounded by a whitish, sweet, cream-like pulp. The cherimova, an excellent fruit of Peru, is produced by the *Anona cherimolia*.

Anonymous [from Gr. ἀνόνομος, nameless; ἀν-, not + ὄνομα name]: literally, nameless; a term applied to books published without the name of the author. Those which appear under an assumed name are called *pseudonymous*. The political articles of the English journals are generally anonymous, and so are the critical articles in the great quarterly reviews. Anonymous books cause much difficulty and perplexity to bibliographers and the compilers of catalogues. The best account or catalogue of such works is Barbier's *Dictionnaire des Ouvrages Anonymes et Pseudonymes* (3 vols., Paris, 1822-24); Halkett and Lang, *Dictionary of Anonymous and Pseudonymous Literature* (4 vols., Edinburgh, 1881-87).

Anoplothe'rium [Lat. form, from Gr. ἀνοπλος, unarmed; ἀν-, not + ὄπλον, weapon; + θηρίον, wild beast]: a genus of extinct artiodactyle quadrupeds, found in the strata of the Upper Eocene formation near Paris, and in Lapland, India, etc. They are characterized by their shortness and small size of the canine teeth, have the teeth arranged in a continuous series without vacant interspaces, and of uniform height—a structure which occurs in no existing animal except man. The *Anoplotherium commune* was about the size of a wild boar.

Anor'thite: a felspathic mineral found at Vesuvius and elsewhere; essentially an anhydrous silicate of lime and alumina.

Anotto: See ANNOTTO.

Anquetil du Perron, ănk'teel'dü-păr'rôn', ABRAHAM HYACINTHE: Oriental scholar; b. at Paris, Dec. 7, 1731. He began early to study Hebrew, Arabic, and Persian, and in 1754 he conceived the idea of visiting India, chiefly in order to gain from the priests a knowledge of the Zoroastrian books. Being without means, he enlisted as a common soldier in a regiment bound for India. He spent seven years in India, collected MSS., learned the language of the religious books of the Parsees, and returned to France in 1762. In 1763 he became a member of the Academy of Inscriptions. In 1771 he published his *Zend-Avesta, ouvrage de Zoroastre* (Paris, 3 vols.), the first translation of the sacred books of the Parsees that ever appeared in any European language. (See AVESTA.) Anquetil also wrote two volumes on *l'Inde en Rapport avec l'Europe* (Paris, 1798). He published a Latin rendering of a Persian version of the Sanskrit *Upanishads* under the title *Oupnek'hat* (2 vols., 1804). This work is interesting on account of its influence on Schopenhauer and his philosophic system. D. at Paris, Jan. 17, 1805.

Revised by A. V. WILLIAMS JACKSON.

Ansaries: See NUSAIRIEH.

Ans'bach (Fr. *Anspach*, anc. *Onolzbach*): a fortified city of Bavaria; on the Rezat, 27 miles S. W. of Nuremberg (see map of German Empire, ref. 6-E). It has a castle, the former residence of the margraves of Ansbach-Baireuth, a

public library, and manufactures of cotton and half-silken stuffs, tobacco, earthenware, cutlery, etc. Pop. 14,234.

Anscha'rins, or **Ans'gar**, SAINT: called the "Apostle of the North"; b. in Picardy, Sept. 8, 801. He propagated Christianity with success in North Germany, Denmark, and Sweden, and became the first Archbishop of Hamburg in 832. D. at Bremen, Feb. 3, 865.

Anschütz, CARL: musician; b. at Coblenz, Germany, in Feb., 1813; studied first under his father and then under Friederich Schneider, of Dessau, whose daughter he married; was appointed successively conductor of the Royal Musical Institution at Coblenz and the orchestra of the theater, receiving the title of Royal Musical Director. In 1848 he resigned and went to Nuremberg; in 1849 to Amsterdam, and in the same year to London, where he conducted operas and concerts. In 1857 he removed to New York and conducted Italian opera for three years. In 1862 he introduced German opera in that city. All of his life was spent in conducting orchestras and singing societies, in which he was very successful. D. in New York, Dec. 29, 1879.

D. E. HERVEY.

Ans'dell, RICHARD: English painter of animals; b. in Liverpool in 1815; obtained gold medal in Paris (1855). D. at Farnborough, Apr. 20, 1885.

Anse de Panier [Fr., handle of a basket]: an epithet applied to an elliptical or three-centered or five-centered curve when used for an arch.

An'selm: Archbishop of Canterbury and the father of Scholastic theology; b. at, or near, Aosta in Piedmont in 1033; d. at Canterbury, Apr. 21, 1109. He studied in the monastery of Bec, Normandy, which had obtained a great reputation under the priorship of his countryman Lanfranc. In 1078 he was himself elected Abbot of Bec, and added new luster to the institution both as a teacher and as a writer. In 1093 he was made Archbishop of Canterbury; but, though he was a man of great humility, having adopted the Gregorian views of the relation between Church and state, he was willing to brave exile (1097) rather than submit to the demands of the king. His principal works are the tract *De Veritate* which contains the ground-work of his theory of knowledge, and the *Monologion* and *Proslogion*, all written while he was at Bec. The *Monologion* demonstrates the real existence of God on the ordinary grounds of realism; while the *Proslogion* sets forth the ontological evidence of the existence of God. The *Monologion* and *Proslogion* have been translated and annotated by Bouchitté, *Le Rationalisme Crézien* (Paris, 1842). It is the celebrated *Cur Deus Homo*—the greatest of Anselm's writings (Eng. translation by Prout, 1887)—which has laid the foundation of the orthodox doctrine of the atonement. The second volume of Hasse's *Anselm von Canterbury, Philosophie* (1852), is devoted to Anselm's Scholastic writings. Anselm had originally studied law, and the fundamental conceptions on which he based his doctrine of atonement were derived from, or at least influenced by, the *jus Romanum*. He also wrote a number of devotional books distinguished by the ease and naturalness of his Latin style. The best collected edition of his works is that by Gerbcron (Paris, 1675; 2d ed. 1721); and in Migne, *Patrologiæ Cursus Completus*, vol. clv. See also the translations in the *Bibliotheca Sacra* (viii., ix. and xii.). His *Life*, by Hasse (1843), was translated from the German by W. Turner (Lond. 1850). *St. Anselm*, by R. W. Church (Lond. 1870, and frequently reissued), is a monograph of great value. Möhler's *Anselm* was translated into English in 1842. Remusat's *Anselm de Cantorbéry* appeared in 1855, and a second edition in 1868. See *Life and Times of St. Anselm*, by Martin Rule (2 vols., 1883).

Revised by W. S. PERRY.

Anseres [Lat. pl. of *anser*, a goose]: an order of birds comprising the geese and ducks; the equivalent of *Lamellicornes* (q. v.) or *Chenomorphæ*.

Anson, GEORGE, Lord: b. at Colwich, in Staffordshire, Apr. 23, 1697; became a post-captain in the royal navy in 1724, after which he passed several years on the Carolina station. In 1740 he was appointed commander of an expedition to the South Sea, in which he exhibited great prudence and courage amid disasters and dangers caused partly by the unseaworthiness of his vessels. Having circumnavigated the globe and made some important discoveries, he returned in 1744 with several Spanish prizes to the value of £500,000. He defeated a French fleet in May, 1747, and for this service was rewarded with the title of Baron

Anson of Soberton. He was First Lord of the Admiralty from 1751 to 1756, and admiral of the fleet in 1761. D. at Moor Park, Hertfordshire, June 6, 1762. A narrative of his voyage round the world was published (1748).

Anso'nia: railroad center, formerly in the town of Derby, New Haven co., Conn., on the Naugatuck river, 12 miles W. N. W. of New Haven (for location of county, see map of Connecticut, ref. 11-F). It has a variety of manufactures of brass and iron, etc. Pop. (1890) 10,342; (1900) 12,681.

EDITOR "SENTINEL."

Ansonians, or Ansyreeh: See NUSAIRIEH.

Ansoerge, CHARLES: b. at Spiller, Silesia, in 1817; graduated at the collegiate institute of Breslau; became a teacher and editor, and was banished by the Prussian Government on account of his liberal opinions; removed to Boston, Mass., in 1849; was organist and chorister of the First church, Dorchester, Mass., thirteen years; also taught music for several years in the asylum for the blind in South Boston, Mass.; removed to Chicago, Ill., in 1863, where he died Oct. 28, 1866.

Ansoerge, CONRAD: pianist; b. in Bachwald, Siberia, Russia, Oct. 15, 1862; studied there and at the Leipzig Conservatory. In the season of 1886-87 made a success in recitals at Berlin; made his first appearance in New York in January, 1888, and has since played in all the large cities of the U. S. He has composed considerably for the piano.

D. E. HERVEY.

Anspach, ELIZABETH BERKELEY, Margravine of: daughter of Augustus, Earl of Berkeley; b. in 1750. She was accomplished, and remarkable for versatility of genius. In 1767 she was married to Mr. Craven, who became Earl of Craven, and died September, 1791. She was married in the following month to the Margrave of Anspach, but then she had been separated from Lord Craven since 1780. She wrote and performed dramas, and published entertaining autobiographic memoirs. D. at Naples, Jan. 13, 1828.

An'sted, DAVID THOMAS, F. R. S.: English geologist; b. in London in 1814; educated at Cambridge. He became in 1840 Professor of Geology in King's College, London, traveled in America and elsewhere, and published a great number of works, among which are *Geology, Introductory, Descriptive, and Practical* (2 vols., 1844); *The Ancient World, or Picturesque Sketches of Great Britain*; *The Great Stone Book of Nature* (1863); and *The World We Live In* (1869). D. near Woodbridge, Suffolk, May 20, 1880.

An'ster, JOHN, LL. D.: b. in Cork co., Ireland, 1798; was a friend of Coleridge, and regius Professor of Civil Law in the University of Dublin. He produced *Poems and Translations from the German* (1819), and a translation of *Faust* (1835), and contributed many articles to *Blackwood's Magazine*. D. at Dublin, June 9, 1867.

An'stey, CHRISTOPHER: English humorist; b. Oct. 31, 1724. He was educated at King's College, Cambridge, where he held a fellowship from 1745 to 1754. He translated Gray's *Elegy* into Latin; but his principal work was the *New Bath Guide* (1766), a series of letters in verse satirizing society at that fashionable watering-place. D. at Bath in 1805.

HENRY A. BEERS.

Anstey, F.: See GUTHRIE, THOMAS ANSTHEY.

An'swer [O. Eng. *and-*, against + *swarjan*, swear, affirm]: the reply given to a question or request; specifically in the law of evidence the reply of a witness to a question put to him. It also means a pleading interposed in a court of equity by the defendant to the bill or information of the plaintiff. In New York, since the adoption of the code of procedure, and in a number of the other States, it is the name given to the defendant's pleading in all cases, except where he resorts to a demurrer. See DEMURRER.

Ant, or Emmet: a hymenopterous insect, closely allied to the bees and wasps; remarkable for industry, ingenuity, and muscular strength. There are numerous species, widely distributed in temperate and tropical countries. They live in societies composed of males, females, and neuters, the last of which are sterile females and are destitute of wings. The neuters do the work of the community, building and repairing the nests, nursing the young, etc. In some cases they have their jaws greatly enlarged, and serve the community as soldiers. The males and females have wings, and are larger than the neuters, but less numerous. After the

pairing season is past the females lose their wings, and are carefully waited on by the workers until the eggs are laid. In winter most species remain dormant, and neither work nor eat. The popular notion that they collect in summer a hoard of grain for their subsistence during the winter seems to have been largely based upon erroneous observation. They are mostly carnivorous, and will attack a living animal many times larger than themselves. Another favorite food of some species is the honey-dew, the sweet excretion of aphides, or plant-lice. They often confine these aphides as man does his milch cows, and obtain from them, by a process like milking, a regular supply of honey-dew. Perhaps the most remarkable of all this interesting group of insects are the "honey-ants" of Mexico, New Mexico, and Arizona. They live in colonies resembling those of the common brown ant of the U. S. Certain members of the community, however, during the summer season store up honey in their abdomen, and soon become incapable of locomotion. They are then placed in subterranean galleries set apart for that purpose, and are systematically fed by the others. In time the distension of the abdomen becomes so great that the victim ants resemble small, spherical, pellucid grapes. Later in the season, when food is scarce, these fattened ants are in turn devoured by the other members of the colony. Ants appear to be endowed with greater muscular strength than almost any other insect of equal size. They display great ingenuity in the construction of their habitations, called ant-hills or ant-nests. The large ants of South America raise their ant-hills to the height of 15 feet or more. Some species, called mason ants, perforate galleries in the clay, and support by pillars and arches the roof of their house. Others, called carpenter ants, excavate cells and labyrinthine galleries in the trunks of living trees. Ants are supposed to have a faculty of conversing or communicating with each other by rubbing their antennæ together. These insects are generally very pugnacious, and often fight pitched battles with other ants. The Swiss naturalist Huber has given a detailed account of their battles, martial exploits, and predatory expeditions. Still more marvelous and paradoxical is the well-attested fact that some species, as the *Formica rufa* and the *Formica rufescens* (or amazon ant), reduce other ants to slavery, and that the principal motive of their wars and piratical excursions is to capture larvæ and pupæ or nymphs, which they carry home for slaves. "At the head of these daring slave-makers," says Pouchet, "we must put the red ant or amazon, the military expeditions of which have been most carefully observed by the naturalists of our epoch. They are so frequent that one may enjoy the sight of them any fine day during the summer season." After describing the siege and capture of a nest by these amazons, he adds: "Then the whole army laden with booty, and sometimes stretching out in a line 40 meters in length (130 feet), triumphantly returns to its city in the same order as at its departure." (*The Universe*.) These slave-holding ants have often a great aversion to labor, and when they perform a journey are carried by their slaves. In some cases they depend upon the slaves to feed them, and perish surrounded by food if left alone. The fact that ants work all through the night, and seem never to sleep, was noticed more than 150 years ago in the *Guardian* (vol. ii., No. 156). A battle of ants has been described by Huber in these terms: "I shall not say what lighted up discord between these two republics, the one as populous as the other. The two armies met midway between their respective residences. Their serried columns reached from the field of battle to the nest, and were 2 feet in width. . . . The field of battle, which extended over a space of 2 or 3 sq. feet, was strewn with dead bodies and wounded; it was also covered with venom, and exhaled a penetrating odor. The struggle began between two ants, which locked themselves together with their mandibles, while they raised themselves upon their legs. They quickly grasped each other so tightly that they rolled one over the other in the dust." At the approach of night the two armies effected a retreat, but the next day the carnage was renewed with equal or greater fury. The workers and females are provided with stings which owe their virulence to the presence of *formic acid*, secreted by a gland in connection with the sting. The carnivorous species of ants perform a useful service by devouring the carcasses of dead animals. Their voracity is such that a clean skeleton of a small animal may be obtained by burying it for a short time in an ant-hill. The termites of tropical countries, sometimes called white ants, are not prop-

erly ants, but belong to a different order of insects, the *Neuroptera*. (See TERMITES.) See P. Huber's *Traité des Mœurs des Fourmis Indigènes*.

Revised by DAVID S. JORDAN.

Antacid, ăn-tă'sid (*anti-* + *acid*): a remedy for acid in the stomach or in the blood. The alkalies, lime-water, magnesia, etc., are mostly used for this purpose, vegetable acids, like the citric (lemon juice, etc.), being often administered with them. These acids become carbonic acid in the blood, forming bicarbonates with the alkalies. This antacid treatment is much resorted to in acute rheumatism.

Antæ'us (in Gr. Ἀνταῖος): a fabulous Libyan giant; son of Neptune and Terra; famous as a wrestler. He was invincible as long as he continued in contact with the earth (Terra), but he was conquered by Hercules, who raised him into the air and strangled him to death.

Antagonism of Drugs: The expression "antagonism" is used to signify that relation of the actions of different drugs on the animal economy which is shown when the usual effects of the action of one are prevented or suppressed by the action of another. This, it will be noted, is brought about by the *opposed actions* of the different drugs, and not by any change in the chemical composition of either. The latter process is, by English-speaking writers, called "antidotal," while French authors define antagonism as a form of antidotal action. When a solution of chloride of sodium is given after nitrate of silver has been swallowed, there is a chemical reaction, by which the soluble and caustic silver nitrate is converted into an insoluble and harmless silver chloride. This is an example of antidotal action—a chemical process. Antagonism, on the other hand, becomes effective by a physiological process. An example of this may be seen when strychnia and chloral are administered together. Strychnia increases the excitability of the respiratory center in the brain and of the spinal cord, while chloral lessens their excitability; and the effect of an otherwise fatal dose of strychnia may be counteracted by means of a suitable dose of chloral. Conversely the administration of strychnia may prevent death from chloral poisoning. Another illustration of antagonism may be seen in opium and belladonna, or their active principles, morphia and atropia. One of the most manifest effects of opium is to strongly and persistently contract the pupil of the eye, while belladonna as strongly and more persistently dilates the pupil. These effects of opium and belladonna are of less importance, however, than is their action upon the respiration, which is depressed by opium and stimulated by belladonna. To present another illustration of antagonism, pilocarpine and atropine produce diametrically opposite effects upon the function of perspiration, which is markedly increased by pilocarpine and diminished by atropine.

The process by which antagonism is made effective is not clearly understood. Certain writers have held that it is, after all, like that of chemical antidotes. Dr. Lauder Brunton, a distinguished English writer on drugs, answers the natural objection, that the minuteness of the dose which is effective is an argument against the notion of a chemical change, by stating that he has, by the addition of a single drop of liquor potasse, converted a milky-looking fluid, composed of the nuclei of blood-corpuscles of fowls suspended in water and measuring 90 cubic cm. (about 3 fluid ounces) into a solid jelly-like mass. This experiment may not appear to others to furnish a true parallel to the case when but a hundredth of a grain of one of the vegetable alkaloids is taken into a human body, but it indicates what important physical changes may take place in living organisms when but a slight change is effected in their chemical surroundings.

The great majority of observers and experimenters regard the antagonism of drugs as dependent upon antagonistic physiological processes, as stated above, holding that it is an antagonism of their effects: so that the same part—nerve, gland, muscle—being by one drug stimulated and by another restrained, exhibits the usual effect of neither, or that of one or the other only because, and in proportion as, the dose of one or the other is relatively larger. The simplest form of antagonism would be presented by two drugs, one of which had the power to excite contraction of a muscle, while the effect of the second was limited to preventing contraction of muscular tissue by direct action upon its fibrils. Such an example of antagonism is unknown, however. This is due to two facts: One, that there are no two drugs the modes of action of which are precisely parallel; and the other, that the activity of physiological processes may be

increased or diminished in a variety of ways, both direct and indirect. For example, opium and belladonna, which antagonize each other, are both antagonistic to gelsemium; while the action of the heart or stomach may be influenced by immediate stimulation or repression, or by impulses conveyed from a nerve center as the result of a complicated process of nerve activity. As a result of these conditions, not a single instance of complete and exact antagonism of drugs has yet been discovered. With this statement disappears a certain part of the hope that rises at the first contemplation of the subject, that for every poison there may be a physiological antidote; nevertheless, such knowledge of the antagonism of drugs as is at hand is put to useful service to prevent the usual result of poisoning or to check the excessive action of drugs where too large a dose has been administered, or the recipient has proved to be exceptionally susceptible to their action. The well-known administration of strong coffee to persons poisoned with opium is an example of the former utilization of antagonism, and giving atropine to check excessive salivation produced by physostigma or bromal is an example of the latter.

The most important examples of antagonism of drugs, in a practical sense, are those of aconite and digitalis, of belladonna and opium, of chloral and strychnia, of chloroform and amyl nitrite, and of physostigma and atropine. Experiments now going on in many laboratories—especially in Germany—have led to the belief that certain products of disease germs may act as physiological antidotes or antagonists in a sense to other products of the same disease germs or to the products of other germs, and German investigators have produced in animals, by injecting into them various substances obtained from disease germs, two states (like those called by Pasteur refractory), which they call—one germ-proof, and the other virus-proof. This study is yet in its infancy, but the results obtained encourage the hope that something of more than speculative interest may be discovered.

CHARLES W. DULLES.

Antagonist Muscles: Every muscle or set of muscles in the animal body is opposed in its action either by some other muscle or muscles, or by elastic ligaments. Generally it is the former; thus in the human arm we have the *triceps extensor* muscle antagonized by the *biceps flexor* and the *brachialis anticus*, etc. In no case is there well-defined dilatation of a muscle. Flexor muscles predominate in power over extensors.

Antal'cidas [from Gr. Ἀνταλκίδας]: a Spartan diplomatist who was sent on a mission to Persia when Sparta was in a critical position, and negotiated a treaty called the Peace of Antalcidas, in 387 B. C. This treaty excited general indignation among the Greeks, whose interests the Spartans sacrificed to gratify their enmity to Athens and Thebes. One of the articles of this treaty stipulated that all the Greek cities of Asia Minor should be subject to the King of Persia.

Antanac'lasis [Gr. ἀνανάκλασις; ἀντί, against (and hence implying contrast) + ἀνακλάειν, bend back]: in rhetoric, a figure in which a word is repeated, but in a different sense or different inflection from the first, which gives a kind of antithetical force to the expression; as "Learn some *craft* when young, that when old you may live without *craft*."

Antanana'rivo', or **Tananarivo'** [literally, at the city of a thousand (homesteads or compounds); from Malagasy *an*, at + *tāna*, city + *rivo*, thousand]: the capital and chief city of MADAGASCAR (*q. v.*); situated in a mountainous region in the middle of the island; in 18° 56' S. lat.; 166 miles S. W. of Tamatave (see map of Africa, ref. 8-1). It is built on a series of eminences about 600 feet above the neighboring valley, and about 5,000 feet above the level of the sea. It is reported to be a large city, and to have manufactures of gold chains and silk stuffs. The private houses are mostly of wood. Pop. estimated at 100,000.

An'tar, **An'tara**, or **An'tarah-Ibn-Sheddâd'**: a celebrated Arabian prince, poet, and warrior who lived about 550 A. D. He was the author of one of the seven poems which are called Mo'allakat (suspended), because they were suspended in the Kaaba or temple at Mecca. His martial exploits were a favorite theme of Arabian poetry and romance. He is the hero of a celebrated romance, translated into English by T. Hamilton, entitled *Antar, a Bedouin Romance* (1819).

Antarc'tic [from Gr. ἀνταρκτικός, opposite the north; ἀντί, against + ἄρκτος, bear, the constellation of the Bear, and

hence the north]: opposite to Arctic. The Antarctic Circle is one of the small circles of the sphere parallel to the equator, and distant $23^{\circ} 27\frac{1}{2}'$ from the South Pole.

Antarctic Current: a drift-current which commences on the shores of Victoria Land, in the region of perpetual frost. It carries vast quantities of ice and cold water toward the N. E. and E., and becomes converted into a coast-current, washing and cooling the western shores of South America, thus performing a work nearly the converse of that performed by the Gulf Stream on the shores of Europe. It conveys drift-ice to the latitude of about 55° .

Antarctic Ocean, or Southern Ocean: the large body of water around the South Pole included within the Antarctic Circle; and also a general term designating that vast sea S. of the Atlantic, Pacific, and Indian oceans. It has not been explored so thoroughly as the Arctic Ocean, and was long considered impenetrable for ships, on account of the ice, which extends much farther from the Pole (about 10°) than in the Arctic Ocean. Area, about 7,900,000 sq. miles. Sir James Ross explored the Antarctic Ocean as far as 79° S. In Jan., 1841, he discovered in lat. $77^{\circ} 32'$ S. and lon. 167° E. a volcano 12,400 feet high, which he called Mt. Erebus. The portions of land which have been discovered in this ocean are as follows: South Georgia (1,600 sq. miles); South Orkney islands (650 sq. miles); South Shetland islands (850 sq. miles); Graham Land (39,000 sq. miles); Alexander Land (1,100 sq. miles); Victoria Land (127,000 sq. miles); Wilkes Land (64,000 sq. miles); Kemp island and Enderby Land (10,800 sq. miles). Total land area, 245,000 sq. miles.

M. W. H.

Antarctic Researches: The first navigator who explored Antarctic regions was Capt. Cook, who in Jan., 1774, reached lat. $71^{\circ} 10'$ S. in lon. $106^{\circ} 54'$ W. In 1823 Capt. Weddell penetrated to lat. $74^{\circ} 15'$ S. in lon. $34^{\circ} 16' 15''$ W., and found there an open sea. In 1839 Capt. Wilkes, of the U. S. navy, conducted an exploring expedition toward the South Pole. He discovered in Jan., 1840, a portion of a large continent in lat. $61^{\circ} 30'$ S. and lon. 161° E. He traced the coast westward to lon. 101° E., but was prevented from landing by an impassable barrier of ice. Capt. Sir James Ross, who commanded a British expedition in 1839-43, penetrated as far as 78° or 79° S. He computed the position of the southern magnetic pole to be in Victoria Land, lat. $75^{\circ} 5'$ S., lon. $154^{\circ} 8'$ E. See POLAR RESEARCH.

Antares [from Gr. *ἀντί*, against, similar to + *Ἄρης*, Mars, because this star was thought to resemble Mars]: a ruddy double star, the most conspicuous in the constellation Scorpio.

Ant-birds (*Formicariidae*): a large family of South American passerine birds; of very retiring habits, living in thorny thickets, and feeding chiefly upon ants. They are remotely related to the fly-catchers.

Ant-catcher and **Ant-thrush:** a bird of tropical and sub-tropical countries, belonging to the family *Pittidae*. The ant-catchers feed upon ants, and are nearly allied to the fly-catchers. They have very powerful voices, a straight, sub-cylindrical bill, hooked at the tip, slender legs, and short tail. The typical genus is *Pitta*, the numerous species inhabiting the Oriental and Australian regions, many of them being peculiar to individual islands of the Malay Archipelago. The giant ant-catcher of Sumatra (*Pitta gigas*) is of a fine green color.

Revised by D. S. JORDAN.

Ante: a Latin preposition, meaning before, in either space or time; now used in English as a prefix (ante-), with the same signification. It is used to form nouns (accented on the prefix) and adjectives (accented on the radical); as, antechamber, anteroom, antenup'tial, antedilu'vian.

Ant-eater: a South American mammal of the order *Edentata*. Ant-eaters have no teeth, and feed on ants and other insects, which they catch by thrusting among them the long tongue covered with a viscid saliva. The head is much elongated, and the tail, which is covered with long hair, is about as long as the body. The toes are united as far as the base of the claws, which are very large and strong, adapted for the purpose of tearing open ant-hills. The great ant-eater (*Myrmecophaga jubata*), sometimes called the ant-bear, is about $4\frac{1}{2}$ feet long, exclusive of the tail, which is about $2\frac{1}{2}$ feet. It has four claws on the fore feet, and five on the hind feet. It is a sluggish animal, and frequents swampy ground along rivers, feeding mainly on the termites or white ants. The little ant-eater (*Cycloturus didactylus*) is not more

than 20 or 21 inches in entire length. It is remarkable for a peculiar structure of the skeleton. On a side view the cavity of the chest is completely hidden by the ribs, which are greatly flattened and overlap each other. The species is arboreal in habits, and has its feet specially modified for climbing. It has two claws on the fore feet and four on the hind feet; these claws are compressed, curved, and very sharp. The name ant-eater is sometimes given to the aardvark (*Orycteropus capensis*) of South Africa,

Great ant-eater.

to the pangolins, the *Echidna*, and to other mammals which subsist on ants and other insects.

Revised by D. S. JORDAN.

Antecedent [Lat. *antecedens*; *an'te*, before + *ce'dere*, go]: that which goes before or precedes in time or in place. In grammar, the noun to which a relative pronoun refers; in logic, the first of two propositions in an enthymeme, and the first member of a hypothetical proposition; opposed to the consequent; in mathematics, the first of two terms composing a ratio. Thus in the ratio $A : B$, A is the antecedent, and B is the consequent.

The word in the plural is used in a different sense, as in speaking of a person's *antecedents*—i. e. his previous conduct and character, his early history or primordial relations.

Antedilu'vian [from Lat. *ante*, before + *dilu'vium*, deluge]: a term applied to any person or thing that existed before the Flood—i. e. the Noachian Deluge. According to the chronology of the Hebrew text of the Bible, this flood occurred 1,656 years after the creation of man. The date of this event, according to the Septuagint version, is several centuries later. Chevalier Bunsen adopted the theory that the Flood occurred about 10,000 years ago. Geologists do not recognize that the earth was ever inundated by a simultaneous universal deluge since it was inhabited by man.

Antelope [O. Fr. *antelop*, viâ Lat. from Gr. *ἀνθόλοψ*, etymol. unknown]: any member of an extensive group of hollow-horned ruminants distributed among several sections or sub-families of the family *Bovidae*. The group comprises numerous genera and species, the genus *Antelope* being the typical one, natives of Europe, Asia, Africa, and America, remarkable for their elegant figure and extreme agility. They are mostly gregarious, inoffensive, and timid animals, and vary greatly in size and form. The greater numbers of them are found in Southern and Central Africa. Asia produces numerous species. Among the various species are the gazelle (*Gazella dorcas*), the beauty of whose eye is proverbial; the addax or Nubian antelope; the stein-bok, eland, and spring-bok of South Africa; and the chamois of Europe. The antelopes are probably the fleetest of all quadrupeds. Their flesh is a favorite article of food. The Rocky Mountain goat is another antelope (*Mazama montana*). "Born in the scorching sun," says Sir S. W. Baker, "nursed on the burning sand of the treeless and shadowless wilderness, the gazelle is among the antelope tribe as the Arab horse is among its brethren—the high-bred and superlative beauty of the race. Entirely free from fat, and nevertheless a mass of muscle and sinew, the gazelle is the fastest of the antelope tribe."

The common antelope or black buck (*Antelope cervicapra*) is found in India and throughout Southern Asia. It is a very beautiful animal, and is distinguished for its timidity and swiftness. Its flesh, like that of most antelopes, is dry and rather unpalatable. The Oriental bezoar, a phosphatic concretion prized in the East for its supposed medicinal

virtues, is derived from the intestines of this animal. The horns of the antelope differ in structure from those of the deer; in the latter the horns (which are more properly called antlers) are deciduous but in the antelopes they consist of a

Antilope cervicapra, the common antelope.

horny sheath surrounding a conical support of bone. Their growth is gradual, and they are not yearly shed and renewed, but are retained during the life of the animal. In some groups of antelopes both sexes have horns; in others, only the male. The prong-buck or prong-horned antelope of America (*Antilocapra americana*) is not a true antelope, having deciduous branched horns. See ANTILOCAPRA.

Revised by D. S. JORDAN.

An'te Na'ti (Lat., born before): a term applied to such of the Scotch as were born before the accession of James I. to the throne of England, and who were considered as aliens by the English.

Anten'nae, singular **Anten'na** [from Lat., sail-yards]: jointed filaments or tubular sensiferous organs attached to the heads of insects and crustaceans. They are sometimes called feelers, and are supposed to be organs of touch (or, according to some naturalists, organs of hearing). An insect has two antennae, which are very flexible, and are composed in some species of a great number of joints. A crustacean has four antennae.

Antenna'rius [from Lat. *antenna*, feeler]: a genus of pediculate fishes of very odd fantastic shapes and colorings. The first dorsal spine is tentacle-like, the second and third dorsal spines are covered with skins, and appear as humps on the back; the body often bears numerous waving filaments. This, with the strange coloring, causes them to resemble seaweeds, mud, sand, or rocks. The pectoral fins are extended into a limb somewhat free from the body. It is used as a leg in crawling over seaweeds and rocks. The species are numerous, and found in warm seas, especially among corals, one species, *A. histrio*, frequenting floating masses of *Sargassum*.

DAVID S. JORDAN.

Antequ'ra (anc. *Antiquaria*): a city of Spain; province of Malaga; 22 miles N. N. W. of Malaga; on the left bank of the Guadalhorce (see map of Spain and Portugal, ref. 19-E). It has many monasteries and convents, and large factories of flannel, paper, silk, and soap. The population of Antequera consists largely of hidalgos, with whom the vendetta was a common practice as late as 1845. Pop. 27,201.

Ant'eros (*Ἀντέρος*): in the Greek mythology, a being opposed to Eros or Cupid, the god of Love, and fighting against him; also the deity who punishes those who do not return the love of others.

Anth'e'lia [from Gr. *ἀνθῆλιος*, opposite the sun: *ἀντί*, against + *ἥλιος*, sun]: luminous colored rings observed under certain conditions around the shadow of the spectator's own head. The conditions of the phenomenon are two: first, that the sun be near the horizon, and secondly, that the shadow be projected on a surface covered with dew-drops, as a field of grass, or on a dense fog-bank distant about 50 yards. They occur chiefly in the polar regions.

Anthelmin'tics [from Gr. *ἀντί*, against + *ἐλμινς*, -ινθος, worm]: medicines which either destroy or drive out intestinal parasites; the former are called vermicides, the latter vermifuges. The last-named are most commonly employed. Against the ordinary lumbricoid worm (*Ascaris lumbricoides*) an infusion or fluid extract of senna and spigelia (pinkroot) is safe and efficacious. To drive out the worrying seatworms or threadworms (*Oxyurus vermicularis*) nothing is better than quassia, introduced into the bowels in enema. For the more formidable tapeworm (*Tænia*) oil of turpentine, oil of fern, kousoo, pumpkin seeds, and pomegranate seeds are used. It is important that the head of the tapeworm shall pass away, as, till that happens, the joints continue to be reproduced. In all cases of worms attention is needed to the general condition of the digestive organs.

An'them [O. Eng. *antefn*, viâ Lat. from Gr. *ἀντίφωνα*, sounding in response; *ἀντί*, against + *φωνή*, voice]: a musical composition in free form; a mixture of motett and cantata, with instrumental accompaniment, adapted to scriptural words. It may contain solos, duets, etc., but the main composition is generally understood to be for chorus.

Anth'e'mius (in Gr. *Ἀνθέμιος*): Greek architect and mathematician; surnamed TRALLIANUS, from his native place, Tralles, in Lydia; was a brother of Alexander Trallianus. He was patronized by Justinian at Constantinople, and designed the celebrated Church of St. Sophia, the first stone of which was laid in 532, and which was dedicated Dec. 25, 537. He died about 534. See CONSTANTINOPLE.

Anthemius, or **Anthemius Proco'pius**: a Roman emperor, who began to reign at Rome in 467 A. D., before which he was a favorite general of Leo, the Emperor of the East. He was the father-in-law of Ricimer, who became his enemy. Anthemius was defeated in battle by Ricimer, and put to death in 472 A. D.

An'ther [from Gr. *ἀνθηρός*, belonging to the flower (*ἄθος*)]: the essential part of the stamen, is the case which contains the pollen. Morphologically considered, the anther is the lamina of a transformed leaf divided into two lobes or cells by the connective, which corresponds to the midrib of the leaf. When the anther is a direct continuation of the filament, it is said to be *innate*, as in the barberry; when it grows to the face or side of the filament, it is *adnate*, as in the magnolia; and when the apex of the filament is attached to the middle of the anther, the latter is *versatile*, as in the grasses. The anther generally opens, for discharging pollen, a longitudinal slit from top to bottom of each cell, but sometimes only at the apex or some other definite point. See FLOWER.

CHARLES E. BESSEY.

An'therid (plu. **Antherids**), or **Antherid'ium** (plu. **Antheridia**) [*anther* + diminutive suffix *-idium* (Gr. *-ιδιον*)]: the organ of cryptogamous plants, analogous in function to the anther of the phanerogamous flowers. Antheridia are variously situated on the surface of plants or within their tissue, and usually contain small bodies called antherozoids, which exhibit rapid movements.

CHARLES E. BESSEY.

Antho'dium [from the Gr. *ἄθος*, flower + *εἶδος*, likeness]: a head of flowers, the same as a capitule, applied to the flower of the thistle and other *Compositæ*, in which a number of flowers are combined in a head and surrounded by a common involuere.

CHARLES E. BESSEY.

Anthol'ogy [Gr. *ἀνθολογία*, collection of flowers; *ἄθος*, flower + *λέγειν*, collect]: in ancient literature, a collection of short pieces of poetry on amatory, convivial, or moral subjects, or a selection of beautiful thoughts and sentences in prose or verse, mostly epigrams. The first collection in Greek entitled an anthology was made by Meleager, a Syrian poet who lived about 80-60 B. C. Another collection, compiled by Constantine Cephalas in the tenth century, was discovered by Salmasius, and is now extant. This anthology, augmented by epigrams found on ancient monuments, was edited by Brunck, under the title of *Analecta Veterum Poëtarum Græcorum* (1776). A revised edition of the same was published by Jacobs, entitled *Anthologia Græca sive Poëtarum Græcorum Lusius ex Recensione Brunckii* (Leipzig, 1794-1814). Scaliger published a Latin anthology in 1573, *Catalecta Veterum Poëtarum*, greatly enlarged in Burmann's *Anthologia Latina* (2 vols. 4to, 1759). Collections of poetry which may not inappropriately be termed anthologies are also found in the literatures of Arabia, Turkey, Persia, and China.

Revised by B. L. GILDERSLEEVE.

An'thon, CHARLES, LL.D.: classical scholar; b. in the city of New York, Nov. 19, 1797; graduated at Columbia College in 1815. He studied law, and was admitted to the bar in 1819, but never practiced. In 1820 he became adjunct Professor of Ancient Languages in Columbia College, and in 1835 principal professor of the classics. He published an edition of Horace with notes (1830), and of the classical works usually read in schools; also a *Classical Dictionary* (1841). D. in New York city, July 29, 1867.

Anthony: city; capital of Harper co., Kan.; in a farming and stock-raising district; on M. Pac., St. L. and San F. and Om., H. and Gulf R. Rs.; 69 miles S. W. of Wichita. Has salt-works, 2 flouring-mills, opera-house, water-works, electric lights, etc. Pop. (1890) 1,806; (1900) 1,179.

Anthony, HENRY BOWEN: statesman; b. at Coventry, R. I., Apr. 1, 1815; graduated at Brown University in 1833; was editor of the *Providence Journal* (1838-59); Governor of Rhode Island (1849-51); and U. S. Senator from 1859 until his death; was a delegate to the Philadelphia "Loyalists'" Convention in 1866. Elected president *pro tem.* of U. S. Senate, 1883, but declined the office on account of ill health. D. at Providence, R. I., Sept. 2, 1884.

Anthony, SUSAN BROWNELL: b. at South Adams, Mass., Feb. 15, 1820; was the daughter of a Quaker. She was fifteen years a teacher in New York. Since 1852 she has been an active leader of the woman's right movement; she has also been long distinguished for zeal in the temperance and anti-slavery causes. Since the civil war she has labored mainly in the cause of woman suffrage. She is part author of *The History of Woman Suffrage* (1881-86). See biography (2 vols., 1898).

Anthony, SAINT: See ANTONY, SAINT.

Anthony's Nose: a mountain in the Highlands, E. of the Hudson river; partly in Philipstown township, Putnam co., and partly in Cortlandt township, Westchester co., N. Y. It rises 1,228 feet above the river. In making the railroad-cutting through its base many beautiful minerals were found.

An'thophytes (*Anthophyta*): the highest of the several branches of the vegetable kingdom, characterized by the production of flowers and seed. They are known otherwise under the names *flowering plants*, *spermaphytes*, and *phanerogams*. They are very naturally separated into (1) those with naked seed (*gymnosperms*), including pines, spruces, cedars, etc., and (2) those with the seed inclosed in an ovary (*angiosperms*), including ordinary flowering plants, as lilies, grasses, orchids, buttercups, oaks, roses, bellflowers, sunflowers, etc. See VEGETABLE KINGDOM. CHARLES E. BESSEY.

Anthosid'erite [from Gr. *ἄνθος*, flower + *σιδηρίτης*, iron-stone; from *σίδηρον*, iron]: a hydrated silicate of iron occurring in fine fibrous tufts, with a radiated structure. It is found at Antonia Pereira, in Minas Geraes, in Brazil.

Anthoxan'thum [from Gr. *ἄνθος*, flower + *ξανθός*, yellow]: a genus of grasses, natives of Europe. The flowers are a dull yellow when ripe. It includes the sweet vernal grass (*Anthoxanthum odoratum*) which grows in meadows and perfumes the air with an exquisite fragrance. It is naturalized in the U. S.

Anthozo'a: the class of cœlenterates which contains the coral polyps. See ACTINIDÆ.

An'thracene, or **Paranaph'thalene** (C₁₄H₁₀): a hydrocarbon existing in coal-tar, and extracted from the last portions of the distillate from this substance. The products of the distillation of coal-tar as ordinarily conducted are: (1) Crude coal-tar naphtha, containing benzene, toluene, etc., lighter than water; (2) heavy oil of coal-tar, or "dead oil," heavier than water, and containing about 10 per cent. of PHENOL (*q. v.*) and cresol, and much naphthalene; (3) green oil, which becomes semi-solid on cooling, owing to the crystallization of anthracene; (4) pitch, which remains in the still. Versemann and Fenner have patented the further distillation of pitch till only coke remains in the still. They thus obtain a much larger yield of green oil, and increase the product of anthracene from one-half of 1 per cent. to 2 per cent. of the original tar. The semi-solid green oil has been used in England to some extent as a cheap lubricator or wheel-grease, under the name of "green grease." The anthracene is separated from the green oil by chilling and pressing. In its crude state it contains considerable oil, naphthalene, pyrene, chrysene, chrysogen, retene, anthraflavic acid, etc. To purify the crude anthracene cake, it may be subjected to distillation, the first and last portions being rejected, the intermediate portion being recrystallized from benzene or

coal-tar naphtha; or the crude cake may be washed with petroleum naphtha to remove oils, etc., and then recrystallized from benzene. Thus obtained, anthracene is always colored yellow by chrysogen, which may be destroyed by exposing its solution to the direct rays of the sun. Graebe and Liebermann prepared anthracene by the action of zinc-dust on alizarin, the coloring-matter of madder, and were from this led to devise a method for preparing alizarin from anthracene—an operation which is now the basis of a very important industry. See ALIZARIN.

Anthracene is obtained in beautiful white, crystalline laminae, melting at 213° C., and distilling at 360° C. Anthracene is insoluble in water, soluble in alcohol, benzene, and bisulphide of carbon to the extent of 0.6, 0.9, and 1.7 per cent. respectively. Heat greatly increases its solubility in these liquids. It is also soluble in ether and the essential oils, especially oil of turpentine. Light petroleum naphtha, which dissolves naphthalene readily, has little effect on anthracene. Oxidizing agents, such as potassic dichromate and sulphuric or acetic acid, change anthracene into anthraquinone (C₁₄H₈O₂), which is easily converted into alizarin (C₁₄H₈O₄) by a process described in the article ALIZARIN (*q. v.*). Oil of vitriol dissolves anthracene. With bromine and chlorine, anthracene forms several substitution products. On mixing alcoholic solutions of picric acid and anthracene, beautiful ruby-red needles of picrate are obtained.

Revised by IRA REMSEN.

An'thracite [Lat. *anthracites*, from the Gr. *ἄνθραξ*, a coal]: an important fossil fuel, the hardest variety of stone-coal, consisting, when pure, almost exclusively of carbon. It has a conchoidal fracture, a black color, and an imperfectly metallic luster, from which it is sometimes called *glaucous coal*. It burns slowly, with intense heat, without smoke, and with little flame. Anthracite may be of any geological age. In China the coals are mostly, if not altogether, of Mesozoic age, and over large areas they are anthracitic. Near Richmond, Va., trap dikes bursting through the Triassic coal-beds have changed some of them locally into a spongy anthracite, a "natural coke." Near Santa Fé, N. M., and Crested Buttes, Col., outbursts of volcanic rock have, over many square miles, converted cretaceous lignite into anthracite. The Triassic coal of Los Bronces, Sonora, has been extensively metamorphosed by the action of igneous rocks, and on Queen Charlotte island, N. of Vancouver's island, a local eruption of trap has converted a cretaceous lignite into one of the most compact and brilliant anthracites known.

Although anthracite occurs, and is mined in small quantities, in Wales, it is of great industrial importance only in the U. S., the most productive beds being those of Pennsylvania, while a relatively moderate tonnage is mined in Colorado. The anthracite region of Pennsylvania is situated in the northeastern part of the State, between the Washington meridian and that of 1° 10' E., and the N. parallels of 40° 25' and 41° 40'. The area of the whole region is about 1,700 sq. miles, of which about 470, exclusive of the Loyalsock, are underlaid by workable coal-beds. It is divided into the following prominent divisions:

1. Southern or Pottsville field, with an area of about 140 sq. miles, extends from the Lehigh river at Mauch Chunk S. W. to within a few miles of the Susquehanna river, directly N. of Harrisburg. The eastern end of this field, known as the Lower Lehigh or Panther creek basin, between Tamaqua and Mauch Chunk, has generally been included by the coal-trade in the Lehigh field, because its coals resemble more closely those of the Upper Lehigh field, and because the shipments from it to market have been largely made through the Lehigh valley.

2. The Western Middle or Mahanoy and Shamokin field has an area of 90 sq. miles, and lies between the easternmost head-waters of the Little Schuylkill river and the Susquehanna. The two coal-fields, the Southern and the Western Middle, are frequently designated in a general way as the Schuylkill region.

3. The Eastern Middle or Upper Lehigh field has an area of 40 sq. miles, and lies between the Lehigh river and Catawissa creek.

4. The Northern or Wyoming and Lackawanna field, which has an area of 200 sq. miles, lies in the two valleys from which it derives its geographical names.

5. The Loyalsock is at the head-waters of Loyalsock creek. The greatest length of the anthracite regions, from its northeastern to its southwestern end, is about 115 miles,

while the greatest width, containing the first four fields, is about 40 miles between Mauch Chunk and Shickshinny.

The first organized effort to mine anthracite coal was in 1793 on the Mammoth bed at Summit Hill, but regular shipments did not begin until 1820. It was not until 1825 that it was used for the generation of steam, and not until 1839 that it was employed as an exclusive fuel in the manufacture of pig iron.

The thickness of the productive coal measures overlying the Pottsville conglomerate, and of their included coal-beds, varies so much that it is impossible to select any one section to illustrate the thickness, character, and succession of the coal-beds and their included rocks throughout the region. At Tamaqua, in the southern coal-field, the coal measures are 2,300 feet thick, and contain twenty-one coal-beds with an aggregate thickness of 126 feet, one bed, the Mammoth, being 114 feet thick a short distance E. of Tamaqua. At Pottsville there are about 3,300 feet of measures, which contain twenty-eight individual beds with an aggregate thickness of coal of 154 feet. In the Western Middle field there are in the eastern half thirteen individual beds of 110 feet thickness of coal, the Mammoth reaching over 100 feet in thickness at Shenandoah. At one point in the Black creek basin of the Upper Lehigh field the Mammoth bed is between 60 and 90 feet thick over a large area where the coal is quarried. At Scranton, in the Southern field, there are eleven beds with an aggregate thickness of 72 feet of coal, while in the vicinity of Wilkesbarre thirteen coal-beds have a total thickness of 94 feet. These coal-bed thicknesses include slate and bony coal, so that the thickness assigned to the beds does not represent the actual thickness of coal which can be mined and sent to market.

The following analyses are given as representing the average composition of Pennsylvania anthracite:

AVERAGE ANALYSES OF PENNSYLVANIA ANTHRACITES.

NAME OF COAL-BED.	Name of coal-field.	Water.	Volatile matter.	Fixed carbon.	Sulphur.	Ash.	Specific gravity.
Wharton	Eastern Middle..	3.713	3.080	86.404	0.585	6.218	1.620
Mammoth	"	4.119	3.084	86.379	0.496	5.922	1.617
Primrose	Western Middle..	3.541	3.716	81.590	0.499	10.564	1.654
Mammoth	"	3.163	3.717	81.143	0.899	11.078	1.657
Primrose	Southern.....	3.008	4.125	87.982	0.506	4.379	1.584
Buck Mountain.	Western Middle..	3.042	3.949	82.662	0.462	9.885	1.667
Seven Foot.....	"	3.410	3.978	80.868	0.512	11.232	1.651
Mammoth	Southern.....	3.087	4.275	83.813	0.641	8.184	1.631
Mammoth	Northern.....	3.421	4.381	83.268	0.727	8.203	1.575
B. Bed.....	Loyalsock.....	1.295	8.100	83.344	1.031	6.230

In order to provide for its combustion, with suitable draft, anthracite coal must be broken and screened, the following being the sizes of the sieve meshes:

NAME OF SIZE.	Through.	Over.
Broken or grate.....	4 inches.	2.5 inches.
Egg.....	2.5 "	1.75 "
Stove.....	1.75 "	1.25 "
Chestnut.....	1.25 "	0.75 "
Pea.....	0.75 "	0.50 "
Buckwheat.....	0.50 "	0.25 "

Even smaller sizes are now made, locally known as "rice," "mustard-seed," etc. The waste in mining is now much smaller than formerly, being 15 to 30 per cent., and the waste in the breakers has been reduced to 6 to 20 per cent. A good many of the culm piles accumulated in former years are being worked over again, the modern improvements in dressing machinery and better methods of burning fine coal having made it profitable.

Its cleanliness and freedom from smoke have made anthracite the standard household fuel, but it is steadily losing ground for the generation of steam in competition with the better bituminous coals, and for blast-furnace use in competition with coke.

The annual report of the U. S. Geological Survey for 1899 places the total production for that year from 359 mines at 60,418,005 short tons (an increase of 7,035,361 short tons over the product in 1898), of which 53,562,030 tons were loaded at the mines for shipment, 1,281,962 tons were used by employees and were sold to the local trade at the mines, and 5,574,013 tons were used for heat and steam at the mines. The average number of days worked at the collieries was 173, the total number of persons employed being 139,608. The value of the coal at the mines was \$88,142,130, or \$1.46 per ton, including all sizes sent to market. The total ship-

ments of anthracite coal from 1820 to 1899 inclusive were 1,126,905,164 long tons—379,950,635 tons coming from the Schuylkill region, 194,438,217 tons from the Lehigh region, and 552,516,312 from the Wyoming region.

The following table shows the distribution of anthracite coal for 1899:

DISTRIBUTION OF ANTHRACITE COAL FOR 1899.

Sections.	Long tons.
Pennsylvania, New York, and New Jersey	31,000,649
New England States.....	7,143,631
Western States.....	6,207,879
Southern States.....	1,589,380
Pacific coast.....	15,868
Export.....	1,707,796
Total.....	47,665,203

The total output of the small mines of true anthracite in Colorado and New Mexico was in 1899 96,196 short tons.

See *Reports of the Second Geological Survey of Pennsylvania; Mineral Resources of the United States* (U. S. Geological Survey).

CHARLES KIRCHHOFF.

Anthrapurpurine: See ALIZARIN.

Anthraquinone: a hydrocarbon obtained by the oxidation of ANTHRACENE (*q. v.*). Alizarin is produced from it. See ALIZARIN.

Anthrax [in Fr. *charbon*; Ger. *Milzbrand*): a name formerly applied by surgical writers to ordinary carbuncle, but now restricted to an acute infectious disease caused by a specific micro-organism, the *bacillus anthracis*. It is also known as splenic fever, in its external manifestations as malignant pustule, and sometimes incorrectly as malignant œdema. Wool-sorter's disease is the same. It is especially interesting as being the first disease in which the causation by bacteria was demonstrated.

The *bacillus anthracis* appears as rods 5 to 20 micromillimeters (μ) long and 1 to 1.25 broad, square at its ends. At certain stages of its development it forms egg-shaped spores, and when growing in artificial cultures is commonly seen as long threads, often twisted or plaited together. On agar-agar (Japanese gelatin) it forms a characteristic, dry, cotton-like growth; it liquefies gelatin (ordinary bone gelatin) and forms flaky masses in bouillon. It grows rapidly on potato, forming dry, whitish colonies, which do not extend much beyond the points of inoculation. It is aerobic, non-motile, and grows best at about 98° F. It stains readily. The spores have a very persistent vitality, which in some instances is not destroyed by boiling for five minutes nor by freezing, and they retain the power of germinating and producing the characteristic bacilli for many years. When the bacilli gain admission to the sub-epithelial tissues of the body, they pass into the blood and multiply rapidly, producing the specific disease. Anthrax affects chiefly the herbivora, and especially cattle and sheep—being most prevalent among cattle in Russia, where it has been called the Siberian plague. In the U. S. it is comparatively rare. It occurs in man as the result of accidental inoculation through the skin, as in butchers or others who come in contact with the blood of infected animals, or through the alimentary canal, by eating infected meat, or through the air-passages, by inhalation of spores in the dust from hides, wool, etc. In animals it is conveyed chiefly through infected localities, such as pastures or stables, or by infected food, such as hay. External anthrax, or malignant pustule, in man usually occurs on the hands, arms, or face, following the inoculation with infected blood at a period varying from a few hours to ten days. Malignant pustule usually begins with a small, hard, red papule, which itches and soon forms a vesicle containing blood-stained serum. Around this there forms a raised ring of purplish, brawny, indurated tissue, on which successive crops of vesicles appear, while the central point forms a brown or black eschar, which becomes depressed. There is no suppuration, and comparatively little pain. The constitutional symptoms are chill, fever, headache, and in fatal cases collapse. Death may occur in from three to five days; in non-fatal cases the disease lasts from six to ten days.

Another form of the disease, which occurs on the eyelids, and occasionally on the face and neck, is an extensive œdema, resulting in gangrene, but without papules or vesicles. In the intestinal form of the disease the symptoms are those of acute poisoning, with vomiting, diarrhœa, and fever. Often several persons are attacked at once from eating infected flesh—in one case, out of twenty-five persons

thus affected, six died in from two to seven days. In the form known as wool-sorter's disease the symptoms are those of acute bronchitis, with much constitutional disturbance. The diagnosis in the internal forms is often difficult, and can be made certain only by bacteriological study and inoculation of susceptible animals with the blood of the patient. In the external forms the treatment is the destruction of the initial papule or vesicle by excision, by the actual cautery or by caustics, the free use of bichloride of mercury on the fresh surfaces thus made, and the subcutaneous injection of 5 per cent. carbolic acid into the surrounding œdema. The *bacillus anthracis* appears to produce its peculiar effects through the formation of poisonous albumoses, which are in some respects analogous to serpent venom, and probably also of a poisonous alkaloid belonging to the ptomaine group. By the injection of these products into the blood of an animal it is possible to produce a certain amount of immunity against subsequent inoculation with the organisms by which they were produced. When cultivated at a temperature a little higher than that most favorable to the normal growth of this organism, the products of its development, and indeed the organism itself, undergo a modification that robs them of the whole or a part of their virulence. When thus modified it is employed in lower animals as a vaccine to protect them against the inroads of virulent organisms.

J. S. BILLINGS and A. C. ABBOTT.

Anthrenus Scrophulariæ: See CARPET-BUG.

Anthropol'atry [from Gr. *ἀνθρωπολατρεία*, man-worship; *ἄνθρωπος*, man + *λατρεία*, worship]: the worship of man.

Anthropol'ogy [from Gr. *ἀνθρωπολόγος*, treating of man; *ἄνθρωπος*, man + *λόγος*, discourse, *λέγειν*, speak]: the science of man (see MAN). It may be divided into three departments. (1) *Somatology*; (2) *Psychology*; (3) *Ethnology*.

Somatology, or the biology of man, includes the study of man as an animal, and the classification of mankind in the zoölogical system. *Somatology* deals with man in so far as he is considered an animal in the origin and development of the human race. It also deals with the development of the individual from the germ to the adult state. It includes anatomy and physiology, the origin and nature of disease, and the methods of averting premature death.

By the new school of biology, of which Darwin is the great leader, it is maintained that man has developed from some lower form or forms of the animal kingdom; that, in fact, there is a serial development from the lowest form of animal life to man, who stands on the highest round of the ladder of evolution. This theory is accepted by a very large number of scientific men, and is rapidly spreading among all classes of authors. Many who accept the Darwinian theory of development, however, maintain that it applies to man only as an animal; that there has been a development of the animal man, but that at some stage in this development man has been endowed by the Creator with an immortal spirit, the science of which belongs to theology, or, as many maintain, to philosophy.

Psychology, as an integral part of anthropology, is the science of the human soul, though comparative psychology includes the subject of the minds of the lower animals. There is great diversity of opinion in relation to this science, but authors and investigators therein may in a broad way be grouped in two grand classes: those who believe that mental operations are functions of the brain and nervous system; and those who believe that mental operations are the functions of a spiritual soul, and that the nervous system, including the brain, is the organ of the spirit, the agency by which spirit is connected with animate matter.

By the first school psychology is claimed to be a natural science. Their methods of investigation are in part physical and physiological, and in part introspective; for as organic chemistry is the basis of biology, so the physiology of the nervous system is the basis of psychology. Plants exhibit sensitiveness to external agencies. Certain parts of the germinating plant seek the darkness, others the light. Some flowers open or close to conditions of moisture, heat, and light. Many plants are exceedingly sensitive even to touch. The lower animals have a higher degree of sensitiveness, and this increases in the scale of animal life, until man seems to be endowed with it in the highest degree. The psychologists of this school see in these facts an unbroken series of development in sensation, and in like manner an unbroken series of consciousness from a rudimentary condition to that highest state exhibited in man and represented by reason, emotion, and ethical volition.

The second school, which is the earlier in history, and still the larger, claim for the mind a spiritual and immortal existence; that it is self-active and unconditioned by time and space, and that it is thus a *causa sui*. They also cultivate physiological psychology, as the nervous system is the mediator between mind and matter. The method of investigation and exposition is metaphysical, or, as it is sometimes called, philosophical. In so far as the science is physiological, it belongs to natural science; but in so far as it is spiritual—and in chief part it is spiritual—it belongs to philosophy.

Ethnology treats of man as he engages in the arts of life, amusement, and decoration; as he employs the arts of society, by which conduct is regulated in the industries or employments of man in tribes, and nations, and in social or family life; the arts of language, by which men hold communion with one another; the arts of literature, by which they express opinions; and the arts of natural religion in which human conduct is regulated in its relation to mythical beings.

The study of man has occupied the attention of many of the greatest minds since the dawn of civilization, and many and diverse theories have been advocated from time to time. One theory represents man in a state of nature as highly intellectual and moral, and affirms that the lower tribes of mankind have become such by degeneracy, wandering away from truth and rectitude, and lapsing from a primeval stage of innocence into abhorrent degradation. The advocates of this theory are numerous, and it has been propounded in many forms. Another school, claiming to be scientific, holds that man has been profoundly under the influence of physical environment, and by it has been lifted or degraded; that the various phases of human culture exhibited throughout the earth are the effects of physical causes. Buckle is a noted advocate of this doctrine. A still more modern theory takes man where he is left in the philosophy of Darwin, as developed from lower animal life, and accounts for the evolution of mankind through the lower phases of culture to the highest exhibited in modern times by the laws of development—or of evolution, as they are called by this school—which govern in the animal domain, the chief of which is called "the law of the survival of the fittest in the struggle for existence." The leading philosopher of this school is Herbert Spencer, whose voluminous works on synthetic philosophy are chiefly devoted to the exposition of this theory. The Spencerian theory has obtained a wide popular acceptance; but among scientific men his doctrines are held to be too narrow. It is claimed that he has failed to discover the more important laws of human culture, and the active part which man himself takes in his own progress toward a higher life. Still others believe that he has failed properly to recognize the spiritual element in man, and that his doctrines are opposed by the fundamental maxims of philosophy.

On the subject of the distribution of mankind over the earth much has been written, and much speculation has been developed. The migrations of mankind have proved a prolific theme, but no real progress in the solution of the question has been made—at least no conclusions have been reached which command widespread assent. By many authors it has been held that mankind were dispersed by waves of migration from some region in Central Asia. Again, it has been held that this is true of the Aryan stock, to which the more highly cultured nations belong. Still again it has been affirmed and advocated with great skill that the Aryan stock had its primeval home somewhere in Europe. But the most general conclusion is that nothing can yet be affirmed with certainty on this subject. Many attempts have been made to prove that aboriginal America was peopled from Asia by way of Bering Straits, and a vague belief of this nature has spread widely, but little scientific evidence exists to sustain it. On the other hand, investigations in archaeology have now made it clear that man was distributed throughout the habitable earth at some very remote time or times in the lowest stage of human culture, when men employed stone tools and other agencies of industry of a like lowly character, and that from this rude condition men have progressed in culture everywhere, but some to a much greater degree than others. The linguistic evidence comes in to sustain the conclusions reached by archaeology, for a study of the languages of the world leads to the conclusion that they were developed in a multiplicity of centers; that languages of distinct stocks increase in numbers as tribes of lower culture are found; and that probably man was dis-

tributed throughout the world anterior to the development of organized or grammatic speech.

The Races of Mankind.—Many attempts have been made to classify men as animals are classified, by their biotic characteristics. The unity of the human race as one species is now generally, perhaps universally, accepted; though attempts are still made from time to time to classify mankind in varieties or races, but no such system of classification has attained to universal or even general acceptance. The facts seem to be these: that man in his primeval condition as an animal, but little lifted above the highest brute, was still subject to the laws of specialization, due to the survival of the fittest in the struggle for existence, and that in this condition varieties were developed, as shown in the color of the skin, the structure of the hair, the attitude of the eyes, the proportions of the skeleton, the conformation of the cranium, and in other biotic particulars; but that with advancing culture, tribes coalesced with tribes until nations were formed, and nations with nations; and by migrations, and the general intermixture of peoples through commerce and war, and the flux of national dominion forever expanding and contracting, such an admixture of streams of blood has been produced as in part to obliterate primeval characteristics and in part to blend them, so that no well-marked planes of demarkation can now be discovered; the black grades into the white, the curly haired into the straight haired, the black eyed into the blue eyed, the oblique eyed into the horizontal eyed, the long skull into the short skull; until in the same burial-mound skeletons are found which baffle the science of anthropometry.

J. W. POWELL.

Anthropology, in the THEOLOGICAL as distinguished from the physiological sense, is that part of the Christian system which treats of man in distinction from God. In its entire extent it includes the description of man both as created and as fallen, and therefore properly includes both the holiness and the sin of the human race. It begins with the creation of man as composed of body and soul, and thus supposes a basis in physical anthropology. It then considers the soul as created in the image of God, and thus discusses the nature of holiness and the happiness of an un-fallen creature in the paradisaical state. But inasmuch as man continued in his primitive holy condition but a brief time, his history is made up mainly of his apostasy and its consequences, so that practically the subject of anthropology relates to such topics as original and actual sin, the free and the enslaved will, the relation of the human to the divine efficiency in regeneration, and the related doctrines. The great controversies which have resulted in the several anthropologies that have a place in the history of religious opinions were concerned almost exclusively with sin, and it is in this reference that we shall examine the subject.

In the primitive Church of the first three centuries the fact of apostasy was universally acknowledged, but only in a general form. The doctrines of sin and grace in their more difficult and scientific aspects did not seriously engage the attention of the Church. The theological mind was occupied with the doctrine of the Trinity and the great controversy concerning the deity of Christ. The statements of Scripture concerning the fall of Adam and its consequences were taken without much discussion, and no acute and powerful exegesis was expended upon them for the purpose of answering the more difficult questions respecting the nature and depth of human depravity. When, however, these latter points were presented, and any direct response was given, sin in its nature was referred, to a considerable degree, to a sensuous ground, and its intensity was not regarded as so great as to deprive the human will of all power to good. The origin and development of human corruption was traced to the body full as much as to the activity of the spirit itself, and hence a remainder of energy was assumed to exist in the fallen will, by which it could co-operate with the Holy Ghost in regeneration. This view appears particularly in the writings of Clement of Alexandria and Origen, and colors the anthropology of that Alexandrine school which acknowledged those theologians as its great leaders.

It would be a mistake, however, to regard Clement and Origen as the only representatives of the anthropology of the primitive Church. In Tertullian and Cyprian a tendency appears toward that theory which was afterward elaborated by Augustine. While the part which the sensuous nature has in determining the origin and nature of sin is still asserted, yet more weight is attached to the self-determination

of the human will itself—to the purely mental and spiritual energy that originates and perpetuates it. This naturally leads to more assertion of the bondage of the will, and a more profound conception of sin as enfeebling and ruining the moral power of the soul. This tendency was strengthened by the adoption by Tertullian of the traducian view of the origin of the individual. This North African Father, in a somewhat crude and materializing manner, held that both the body and soul are propagated. Both the immaterial essence of the soul and the material substance of the body are individualized portions of human nature as created in Adam. There is no creation from nothing after the creative act on the sixth day, when "God created man male and female, and blessed them, and called their name Adam" (Gen. v. 1, 2). There is only procreation, or the deduction of individual after individual from this original unity. Such a theory of the propagation of the soul, however difficult in itself, yet made the propagation of sin more intelligible, and prepared the way for the subsequent doctrine of the propagation of sin itself, and not of mere physical evil.

The anthropology indicated in this brief statement of the views of the early Church received a subsequent modification in the later Alexandrine and Antiochian schools. The best representatives of the first were Athanasius, the two Gregories, and the two Cyrils; of the second, Theodore of Mopsuestia, Theodoret, and Chrysostom. The influence of Origen upon these Greek theologians is apparent, but they receded from his extreme positions and modified his anthropology, (1) by the adoption of creationism instead of pre-existence; (2) by recognizing more distinctly the effects of the Adamic transgression upon the soul itself, including the will; and (3) by making a more guarded assertion of power to good in the fallen man. They agreed, however, with the earlier anthropology in affirming that original sin, or inherited corruption, is not culpable. It is only a propagated disorder of the sensuous nature seen in exorbitant physical appetites, from which temptation issues, and to which every human individual yields without exception. But until this act of the individual will there is no sin, properly so called, no sin in the sense of guilt, in any man. The mortal Adam could beget mortal descendants, but the sinful Adam could not beget strictly sinful and guilty descendants. "What, then," says Chrysostom, "is the meaning of the phrase 'were made sinners?' (Rom. v. 19). It seems to me to denote liability to suffering and death." In this exegesis Chrysostom put a secondary meaning upon the verb "to sin," which has come down to the present time, and which has unquestionably exerted an influence upon many theologians who would agree with the golden-mouthed in most of his positions, and also upon many who would be unwilling to adopt his anthropology.

The question as to the guilt of original sin, and the justice of imputing that "disobedience of one man whereby many were made sinners" (Rom. v. 19), is, in truth, the hinge upon which the whole subject of anthropology must turn. And the way in which it is answered constitutes the dividing line between the two great dogmatic divisions which from Augustine down to the present day appear in the history of the Church. Augustine, in his controversy with Pelagianism, but still more with Semi-Pelagianism, maintained that the first sin of Adam is imputable to the posterity as guilt, and is a just ground of condemnation, because the posterity existed in the progenitor, and in some real but inexplicable manner acted in him in the first transgression. "We were all," he says, "in that one man, since we all *were* that one man. The particular form in which we were to live as individuals had not been created and assigned to us, man by man, but that *seminal nature* was in existence from which we were to be propagated" (*De Civitate Dei*, xiii. 14). If the mystery of such a generic existence and such a natural union between the progenitor and the posterity could be believed, and the fact conceded, then the imputation of Adam's sin to his descendants would be made upon the same principle that it is imputed to Adam himself—upon the principle, namely, of attributing to every real and veritable agent every real and veritable act of the agent. The consequence of this primal act of apostasy was the total depravation of the entire human species, then existing in the progenitors, and consequently every individual produced out of this species is born entirely depraved. Beginning in the higher parts of the soul, the reason and will, sin penetrates and poisons the lower powers, and vitiates the bodily appetites and propensities. Sin is spiritual evil in

its very outset, and becomes sensuous corruption in its final issue. The soul itself falls from God, and carries the body with its sensuous nature along with it. Unlike the anthropology of Origen, that of Augustine explains the disordered appetites of the flesh by the rebellion in the spirit, and not the rebellion in the spirit by the disorder of the flesh.

Another point of difference between Augustine and his Semi-Pelagian opponents relates to the question as to the amount of power to holiness in man after apostasy. Pelagianism, as defined and defended by its ablest advocate, Julian of Eclanum, contended for plenary power in every man to keep the moral law. The apostasy still left the will free, and freedom means the liberty of indifference, or the power of choosing either good or evil at any instant. This view was deemed to be extreme by those who would find a middle view between Pelagius and Augustine. Cassian and Faustus of Rhegium, the best representatives of the so-called Semi-Pelagianism, maintained that by the fall of Adam his posterity were greatly weakened, but not made absolutely impotent to good. There still remained a minimum of goodness, which is capable of co-operating with God, and therefore regeneration is a joint product of grace and free will. Neither can do without the other. In opposition to this, Augustine contended that there is no power to good, not even a minimum, left in the human soul since apostasy. The heart and will are wholly determined to evil, and there is no remainder, however small, of either inclination or affection that is friendly to God and holiness. The carnal mind is enmity toward God, and nothing but enmity. Hence man can not co-operate with God in regeneration. Not until the sinner is made willing (Ps. cx. 3; Phil. ii. 12, 13) can he will the right.

The Pelagian anthropology, which was the occasion of forcing out the systematic statements of Augustine, denied that any physical or moral corruption of human nature resulted from the Adamic transgression, interpreted the statements of the fifth chapter of Romans as teaching the influence of bad example, and asserted that sin is not strictly universal, but that some have lived without transgression. Pelagianism itself never exerted much influence within the Church. It contained too few elements of truth, and was too utterly at variance with the Scripture representations of sin and grace to get the advocacy of any who possessed an evangelical experience. It was rejected as heresy. But the middle view of Semi-Pelagianism held its ground by reason of its recognition of the injurious effects of Adam's apostasy upon his posterity, and its acknowledgment of the need of grace in order to recovery therefrom. Moreover, the *degree* of power to good which many of the Semi-Pelagians asserted was much less than that asserted in the Alexandrine anthropology, and in some instances it was reduced to so low a minimum as to border closely upon the Augustinian impotence. Wiggers compares the three systems with each other as follows: Augustinianism asserts that man is morally *dead*; Semi-Pelagianism maintains that he is morally *sick*; Pelagianism holds that he is morally *well*.

The Augustinian and Semi-Pelagian anthropologies (that of Pelagius being rejected by all parties within the Church) continued to hold their ground with varying success. The Augustinian theory of sin and grace was adopted by the Western Church at the Councils of Orange and Valence, in 529, as the catholic orthodoxy, not merely in opposition to Pelagianism, but also to Semi-Pelagianism and all grades of the synergistic theory of regeneration. But it would be an error to suppose that the Western Church as a body continued to adhere to the views of the venerated North African Father. Theologians like Leo and Gregory in the fifth and sixth centuries, and like Bede, Gottschalk, and Alcuin in the eighth and ninth centuries, propagated the teachings of Augustine respecting the corruption of human nature and the agency of the Holy Spirit in regeneration, but the middle theory found increasing currency in the mediæval Church. Its less rigorous character, together with its comparative silence upon the more difficult parts of the doctrines of original sin, predestination, and the enslaved will, recommended it to a large class of minds; while the element of human efficiency which it introduced into the doctrine of regeneration was thought to render it a more intelligible and practical doctrine. It was not strange, consequently, that in course of time the Latin Church, though holding the name of Augustine in the highest veneration, and claiming not to depart from his teachings, should have lapsed very generally into Semi-Pelagianism. It came thus upon

the same doctrinal position with the Greek Church, which, during all the controversy at the West respecting sin and grace, continued to adopt the views of Chrysostom and the Greek Fathers generally. In the eleventh century the wonderful intellect and saintly piety of Anselm maintained the Augustinian view with great power and depth of reasoning, but was not able to turn the current which was sweeping with an increasing flood in the other direction. Schoolmen like Bernard and Aquinas were nearer to Augustine than to any other great authority of the past, but the main influence of Scholasticism as a whole tended to undermine his positions. The dawn of a new era at the Reformation opened the old questions. Luther, Calvin, and the Protestant theologians generally not only adopted the Augustinian anthropology, but stated the doctrines involved in it with still greater clearness, and defended them with still closer reasoning. The papal Church took the opposite view. The Council of Trent enunciated Semi-Pelagianism, and endeavored to give it currency under the great authority of Augustine, whose opinions were in some instances honestly misconceived, and in others knowingly misrepresented.

Wherever Protestantism prevailed, Augustinianism prevailed also. Augustine's theory of sin and grace pervaded and molded the symbols of the Reformation almost without an exception, and from them passed into the heart and life of the Protestant Church. But in process of time the same transition occurs in Protestantism which we have seen taking place in the Latin Church. The more rigorous type gives way to the milder in some quarters. The Arminian controversy in reality turned upon the same points that were discussed between Augustine and the monks of Adrumetum, between Prosper and Cassian. Calvinism is the revived Augustinianism, and Arminianism is the revived Semi-Pelagianism. These two types of doctrine in reality exhaust and include all the varieties of doctrinal opinion that prevail in modern evangelical Christendom. There are minor differences, but churches and individuals are either Calvinistic or Arminian, as in the Patristic period they were either Augustinian or Semi-Pelagian. There is no real mid-point between these two, although schools and theologians have frequently attempted to find one.

The difference between these anthropologies is due to logic rather than to practical experience. The follower of Arminius agrees with the adherent of Calvin in holding the fundamental doctrines of the Trinity and the incarnation, of apostasy and redemption, and the religious experience of both alike is evangelical; that is, it springs out of faith in the atonement of the Son of God. The difference between them relates not to the general facts and truths of the New Testament, but to the more specific and exact definition of them. The modern Arminian, like the ancient Semi-Pelagian, while confessing sin and trusting in the blood of Christ, urges what he believes to be a valid argument against the doctrines of predestination and irresistible grace, and that particular form of the doctrine of original sin out of which the doctrines of predestination and irresistible grace issue as necessary corollaries. And his opponent shows his respect for this belief by entering into the debate, and defending what he thinks to be the more exact and self-consistent and self-comprehending statement of that same evangelical system. The issue of a controversy that originates in logic must therefore be left to logic. The closest reasoner from the scriptural premises and the evangelical experience must be adjudged to be the victor. If the Arminian anthropology shall in the course of time prove itself to be the more scientific and self-consistent system of the two, it will be recognized and accepted as such. But if in the same calm and cool atmosphere the Augustinian statements shall evince their superiority, they must pass for Christian science.

Anthropology, CRIMINAL: The subject of the criminal, his offenses and their consequences to society has been treated of, from a very early period, from the standpoint of jurisprudence. The jurist was chiefly concerned with the crime and the various degrees of punishment it deserved. Elaborate codes defined offenses and penalties, and torture was legally applicable to extort a confession. In modern times governments and benevolent associations have made strenuous efforts, largely unsuccessful, to reform the ill-doer, to lead him to repentance and to habits of honest industry. Both lawgiver and philanthropist regard criminals as varying only in degree of depravity. The care of the one was to provide adequate punishment for the offense; the other believed that religious teaching was the sole means of reform.

A new school, known as the School of Criminal Anthropology, or, as it is sometimes termed, the Neo-criminalistic School, may be said to have come into existence in 1876, when Prof. Cesare Lombroso, of Turin, published a work entitled *L'uomo delinquente*.

Three schools may be described as engaged in these investigations: (1) The classic or spiritualistic school, which denies that congenital development, race, or climate are factors in the production of crime; (2) the socialist school, which declares the physical and moral surroundings, the *milieu*, to be the sole cause—hence they are sometimes termed mesologists; and (3) the positivist criminal school, the school of Lombroso, which insists that crime is the result of three orders of factors—namely, anthropologic, physical, and social. If social causes alone produce crime, why is it, they inquire, that of 100 persons living under the same conditions of abject poverty, only five will become thieves? The social factor is the same for all, but the impulse to crime, born of the surroundings, becomes decisive only when the anthropologic and physical factors are found—the organic constitution and the abnormal brain. Crime, therefore, they emphatically assert, is the accumulated result of the individual constitution, bodily and mental, and of the physical and social surroundings.

"Criminal anthropology," then, is the study of the being who, in consequence of physical conformation, hereditary taint, or surroundings of vice, poverty, and ill example, yields to temptation and begins a career of crime. It is to study the anatomy, the physiology, the hygiene of the criminal, his productivity, his capability of amendment, to examine into his condition, and to recognize his rights.

At the outset it is necessary to define what constitutes crime. A distinction is made between "natural crime" and "statute crime," the latter varying with the codes in which it is found. Natural crime is that which is at variance with our "moral sense." Admitting the existence of the latter, it is obvious that, like other psychical sentiments, it may be subject to change, to disease, or, in extreme cases, it may be absent from birth, as in analogous cases of congenital physical monstrosity. It is asserted that certain characteristics of this "moral sense" are common to all nations and all ages, and that, therefore, violations of this universal sense constitute "natural crime."

Since crime is a violation of the common sentiments of compassion or probity, it follows that in the criminal there is either absence or temporary relapse, or weakness of one or other of these sentiments; but these sentiments form the substratum of the average morality of society, and the man who violates them is in a condition of incompatibility with that society. For the great mass of mankind the sentiment of compassion or tenderness which abhors bloodshed, and of probity which condemns theft, suffices.

It is assumed, then, that there are two varieties of our race who answer physically to the idea of these two crimes—men who are destitute of all feeling of pity, or of all sentiment of honesty. The adherents of the positivist school differ among themselves as to whether the criminal is an instance of regressive atavism or of physical and mental degeneration. They differ still more as to the existence of an anatomical type of the criminal. Lombroso emphatically asserts its reality. The supposed peculiarities are briefly these: In the brain the confluence of many of the primary fissures, the existence of four horizontal gyri, and a relative shortening of the occipital lobes which results in the cerebellum not being entirely covered. This last-named

condition is a characteristic of the inferior apes. The most common abnormalities of the criminal skull are:

1. Persistence of the metopic or median frontal suture.
2. Precocious synostosis or bony union of the other sutures.
3. A greater simplicity in the dentitions of the sutures, the edges being smoother.
4. The frequency of wormian bones in the region of the posterior fontanelle.
5. The strong development of the superciliary ridges, the effacement, or even depression, of the glabella or nasal eminence between the eyebrows, and large cavernous orbits.
6. The posterior situation of the foramen magnum.

The head and face of the criminal present an unusual number of asymmetries, so that a collection of portraits of criminals has all the effect of a series of caricatures. The lemurean jaw is of frequent occurrence. Large flat ears standing out prominently from the sides of the head—what are technically termed "winged ears"—are very common. The mean height of the criminal and his girth of chest are above the average, but the muscular force is below it. The length from finger-tip to finger-tip when the arms are extended horizontally (Fr. *le grand envergure*) is greater than in the non-criminal. While it is not true that this dimension corresponds exactly to the height in normal man, any decided excess is regarded as a reversion to the simian type. Other peculiarities of less importance have been noted. Lombroso, in a recent work, stated that he had compared 26,886 criminals with 25,447 normal persons.

It has been objected that the peculiarities named are also found in epileptics and insane persons, and, indeed, in persons neither criminal nor insane. To this it is replied that to show that the proportion of abnormalities is much greater in a given number of criminals than in an equal number of non-criminals is the vital point.

The physiological, pathological, and psychological conditions of the criminal, modified as they must be by his abnormal structure, form an important part of the researches of the criminal anthropologist. The sensibility of the criminal, tested by the electric apparatus of Du Bois-Reymond, averages 49.6, and in the honest class 64.2. In acuteness of the senses of smell, taste, and hearing, he is also inferior. The observations upon which these conclusions are based were made both upon men and women.

Diminished sensibility to pain—disvulnerability, as it is termed—enables the malefactor to recover rapidly from wounds which would be long in healing or of fatal result in normal man. Some hypnotic experiments by Delbœuf tend to confirm the belief that the rapidity of cure depends largely upon the absence of pain. This comparative insensibility to physical pain in the criminal has been pointed out by numerous observers, and it is not surprising that it should be accompanied by an equal indifference to the sufferings of others.

A French physician, Alphonse Bertillon, has devised an ingenious anthropometric system of identification of criminals. It has been formally adopted in Paris, Lyons, and other large cities with excellent results.

Ferri, who is Professor of Criminal Law at the University of Rome, and who belongs to the positivist school, proposed the following classification of criminals, which has been generally adopted:

(1) *The criminal by instinct*—the born criminal. He is distinguished by an entire absence of the moral sense and an utter heedlessness of the consequences of his acts. The prominent types of this class are the murderer and the robber. The suggestion of crime meets with ready acceptance, and the consequences to the victim—the destruction of life, the agony of the family, the loss of property—are regarded by him with imperturbable indifference. This insensibility is evinced also in endurance of pain in surgical operations and in his stolid demeanor at the place of execution.

(2) *The passionial criminal*, who commits crime under the influence of passion. He is, in most respects, the opposite of the instinctive criminal. The moral sense, which is strongly developed, is obscured for the time being by the overwhelming passion, but is speedily restored to its habitual predominance. The sense of guilt and the repentance that follows are in striking contrast to the sullen indifference of the born criminal or to his clumsy affectation of penitence.

(3) *The criminal from chance*. He is a reduced type of the instinctive criminal. In him the absence of the moral sense assumes the form of weakness, and it is more to his

surroundings than to any active disposition that his embarking in a career of crime is due.

(4) *The criminal from habit.* This is an intermediate type without marked psychologic characters. From continued relapses he acquires more and more the character of the instinctive criminal, until, from frequent prison experience, there is but little distinction observable between them.

(5) *The insane criminal.* The adherents of the new school are generally agreed in declaring that the insane criminal's condition is the result of psychological degeneration, or abnormal development, and is therefore incurable. He is, anthropologically, identical with the instinctive criminal in a great many cases of insanity, and in a large proportion of cases of epilepsy, but differs from him in the confusion of his ideas and many other psychological characters.

Jurists say that without a crime there is no criminal; anthropologists, that the criminal is here with the intent to commit crime; though his attempt may fail, he is as much the assassin or the thief as if the act had been completed, and he must be hanged or secluded accordingly. They regard any graduated scale of penalties as only a temptation to crime. The limitation of the punishment leads to a commercial view of the offense. They insist that the criminal shall merely be sent to prison. His coming out should depend, not upon a sliding scale in supposed proportion to the gravity of his crime, but upon the proof of his amendment. We do not send a sick man to the hospital for a definite period, but for treatment and for discharge *when cured*, as pronounced by competent authority. The criminal should have the right to demand from this competent authority an examination into his case, and a decision based upon regard to the safety of society. They insist, also, that the criminal should, by his labor, discharge his indebtedness to his victim as far as it would be possible to ascertain its extent. At present the State locks up the thief and appropriates to its own use the product of his labor while in prison. At the end of his imprisonment the offender is said to have "expiated" his crime—to have paid his debt to society—when, in truth, it is society who has paid his debt for him by housing, feeding, and clothing him, and not always even demanding the poor equivalent of his labor.

The spiritualistic view of punishment is that there must be expiation for crime. By suffering, the expiation of those who feel remorse is completed, and by it remorse is awakened in those who are as yet insensible. To this it is replied that long experience has shown that the ordinary criminal is incapable of remorse, although he may feign it for his own purpose. It is difficult to separate the idea of vengeance from that of expiation. What society really demands is the elimination or the segregation of the abnormal man, unassimilable with his social surroundings.

It is a biological principle that a being disappears who can not live in unison with his surroundings. The difference between the biologic and moral law is that under the first the selection takes place spontaneously by the death of the individual unsuited to his surroundings; in the second, the selection must take place artificially—that is to say, by the social power which acts in its own defense as nature operates in biologic order.

The opinion is generally entertained by those who have had to do with the inmates of penal institutions that repentance and reform are very rare among them. Mr. Bruce Thompson declares that among all the murderers he had known, amounting to nearly five hundred, only three were known to have expressed any feeling of remorse.

The positivist school is at variance with the psychiatrists as to the existence of moral insanity. Exclusively moral abnormality characterized by the perversion or absence of all moral instincts is not, they contend, a disease. If there be no disturbance of the faculty of ideation, the absence of the moral qualities can not justify the denomination of insanity. If the latter distinction were permitted, every slight peculiarity of character would be, on the same ground, pronounced to be pathological, and health would become a mere ideal standard. When there is no derangement of the psychical functions accompanying the perversity, it is not a case of disease. In the born criminal the mental process is in accord with the external impressions. If the motive was vengeance, the injury really had been inflicted. If the crime was to bring profit, the profit was real. If to obtain a certain pleasure, the pleasure was tangible. The hope of obtaining the desired end is logical, but the process is criminal, and reveals the absence of the moral sense.

Two international congresses of criminal anthropology have been held; the first at Rome in 1885, and the second at Paris in 1889. Seven journals relating exclusively to this subject are now published. ROBERT FLETCHER.

Anthropometry [from Gr. *ἄνθρωπος*, man + *μέτρον*, measure]: the measurement of the human body and of its different parts. The term is also often used to include the discussion of the results obtained by such measurements. The determination of the physical proportions and weight of different individuals, and of the force, rapidity, range and completeness of the performance of function of certain parts of their bodies, is made for very various purposes, and with corresponding differences in the scope of the methods employed. It may be used to ascertain the changes due to growth and development under various circumstances, and thus to determine the effects of exercise or special physical training, of occupation, or of habits of various kinds upon the organism or upon special parts of it, and for this purpose a series of observations of the same persons at intervals of time is especially useful. It may be used to determine the probable fitness of an individual for a particular occupation, as in the measurement of recruits, or his prospects for health and long life, as in examinations for life-insurance. It may be used for purposes of identification of an individual, such as a suspected criminal or deserter, or of a dead body in certain cases of jurisprudence. Considered as a branch of anthropology, it may be used as one means of classifying men into different race groups, or of investigating the probable affinities of one group to another. The measurements made by physicians and surgeons for purposes of diagnosis or for answering pathological problems are not usually considered under the head of anthropometry, nor are those measurements of internal organs which can only be made after death included in this subject.

The history of anthropometry begins with the use of the dimensions of certain parts of the human body as the first standards of measure. The length of the foot, of the forearm or cubit, the hand's breadth, the width of the thumb (Fr. *pouce*), or inch, are examples of such standards. Necessarily, as men differ in size, it became necessary to settle the length of the average cubit or foot, and in doing this no doubt the question as to what should be considered a properly proportioned human body may have arisen. The mathematicians and artists of Egypt and India seem to have agreed at a very early period that there must be some one part of the body whose length should be the modulus or standard of dimension for all other parts. The length of the face from the chin to the roots of the hair appears to have been the favorite modulus of sculptors, so that the height of the figure would be from nine to ten faces, the length of the arm from the shoulder to the point of the middle finger would be four faces, and so on. For an account of the various attempts to establish a canon of proportion of the human body, consult the paper of Dr. Robert Fletcher entitled *Human Proportion in Art and Anthropometry* (Cambridge, 1883).

As no two men are alike in all dimensions, and as the number of dimensions which might be taken on a given body is almost infinite, it becomes a matter of importance to decide as to precisely what measurements shall be made in a given case, and how they shall be stated. For anthropological purposes, and in the study of growth and development, it is important to have the data of as many individual measurements as possible, so stated that they can be compared with each other; and hence it is important to make the same measurements that have been made and published by others, and then to make such additional measurements as may seem desirable and expedient, bearing in mind that the more numerous and complicated the measurements the more time, labor, and skill are required to obtain them with such accuracy as to make them useful, and therefore the less probable it is that such elaborate work can be obtained from travelers, school-teachers, etc., or that such measurements can be made by experts in sufficient numbers to make them of real value.

To obtain reliable data but few measures should be asked for. It is also to be remembered that certain dimensions have little or no interest or value in themselves, but may be significant when compared with other dimensions; hence if these last are not taken, the first are of no use. This is especially the case in craniometrical work, which, however, will not be considered in detail in this article.

The most important points for registration for each indi-

vidual in a series of anthropometrical observations to determine race characteristics are sex, age, birthplace, supposed race, variety or tribe, height of body standing (taken from sole to vertex), weight, girth of chest, color of eyes and hair, breathing capacity, span of arms, strength of arm, and acuteness of vision and of color perception. To these it is desirable to add the height when sitting and when kneeling, the maximum length and breadth of the head, the length and breadth of the face, the length and breadth of the nose, and the length of the forearm and middle finger. If the measurements are to be made for the purpose of determining progress in growth and development, as in school children, or in those taking special forms of exercise, many other measurements, especially of girths and breadths, will be of interest; and in such cases there is usually a much better opportunity to obtain such data than there is in anthropological work.

Uniformity in methods and instruments is in all cases very desirable; these are discussed in the various manuals on the subject, and in the reports of the Anthropometric Committee of the British Association for the Advancement of Science (1878 to 1883). Often a slightly inaccurate method is the only one available, as, for example, in measuring the height of the body, which should be taken while the person is barefooted, but must often be taken while he is wearing shoes, and the height approximated by deducting the height of the shoe-heels.

Having obtained the individual data, the next step is to tabulate them in such a way as to show their relations to each other and to the results obtained by others; and the selection of the combinations by which this can best be effected, and the best methods of estimating and eliminating probable errors, and of presenting the results in a clear, reliable, and usable form, requires a considerable knowledge of statistical methods. In the first place, the difference between an average and a mean should be borne in mind, using these words in the sense in which they are used in the results obtained by the Anthropometric Committee of the British Association. As defined by Mr. Roberts, a member of this committee: "An *average* is obtained by dividing the sum of the values observed by the number of observations, while the *mean* is the value at which the largest number of observations occur ('the value of greatest frequency'). An average is influenced by exceptional cases, but a mean disregards exceptional cases, and is entirely dependent on the predominating numbers; hence the *mean* is employed to distinguish the racial type, and the *average* the variations to which the race is subject by the modifying influences of local and exceptional causes. To determine the radical type of a nation by means of an *average* it would be necessary to have all classes of the community represented in their due proportions; but the unequal distribution of occupations renders this impossible, unless a general census were taken. Even within narrow limits it is almost impossible to obtain observations of all the individuals of a class, as the taller and better-developed members readily submit to measurement, while the shorter and imperfectly developed evade examination, and the sick and deformed are passed over altogether. On the other hand, the determination of the racial type by the *mean* is free from these sources of error, as we disregard both the ill-developed and the over-developed individuals, and depend entirely on those which represent the medium development of the class or nation."

As the reliability of both the mean and the average depends largely upon the number and accuracy of the observations from which they are derived, we have very few of them relating to savage and barbarous tribes which are of much value. In some few cases, such as the Andamans and two or three African tribes, the stature and weight are so decidedly below the average of other peoples that they may be accepted as race characteristics without question; but for the great majority of tribes the data which we have are only sufficient to form a basis for hypotheses which must be accepted or rejected on other grounds.

Even in civilized countries the results thus far obtained, although derived from large numbers, are in many cases not comparable, owing to the age or other groupings according to which they are presented. The data derived from measurements of recruits in different countries are not comparable unless the minimum limit of stature is the same in each, nor unless they are given by uniform age groupings. As the height continues to increase to different ages in different races, this distinction is an important one.

The following table shows the average height by years of 189,216 American-born white men examined at draft stations between 1862 and 1863, and found fit for military service:

TABLE SHOWING THE MEAN HEIGHT BY YEARS, AND BY GROUPS OF FIVE YEARS, FROM THE AGE OF SEVENTEEN TO FORTY-FIVE, OF 189,216 AMERICAN-BORN WHITE MEN FOUND FIT FOR MILITARY SERVICE.

AGE.	BY YEARS.		AGE.	BY YEARS.

Bosjesmans (Bushmen and South Africa).....	Various.....	1·341	4	4·78
Difference between the tallest and shortest races.....		0·421	1	4·55
Average stature of man according to the above.....		1·658	5	5·25

Tables similar to those for height are given also for weight, and for various dimensions of the body, with distinction of sex, age, and race. Among the most important anthropometric tables are those which show the relative proportions of different parts of the body to each other and to the weight, with distinctions as above. There are several different ways of calculating these ratios, which may be made more or less complex according as the individual items are grouped by twos, by threes, etc. For example, the ratio obtained by dividing the length by the breadth of the face may be compared with the height, or with the ratio of height to weight, and the results of this comparison may be in turn compared with the length of the forearm in different races at different ages. Theoretically the variety of

ratios which might thus be obtained, and which might be of value, is very great; but practically the probable error in the use of a small number of sets of individual observations, and the impossibility of obtaining more than a few details in such sets, make such calculations of doubtful utility. Anthropometrical data in anthropological studies furnish very important aid in attempts at race classification; but they are not the only things to be considered in such work, and should not be relied upon to the exclusion of consideration of language, customs, and other points belonging to ethnological studies.

The use of anthropometrical data for the identification of criminals was commenced in Paris in 1832, on a plan suggested by Alphonse Bertillon, and is employed in connection with a collection of photographs of known criminals. These photographs are divided and subdivided into groups, according to the size of the head, the height, the length of the middle finger of the left hand, the length of the foot, the length of the forearm, etc.; and these, in connection with the sex and color of the eyes, form groups so small that for any suspected individual there will be only five or six photographs to examine to determine whether he is among the number. In the U. S. army the identification of deserters is effected by cards grouped according to tattoo marks, vaccination marks, and other scars, pigmented naevi, etc., taken in connection with color of eyes and hair and height.

The following works may be consulted with reference to anthropometrical methods and data:

Statistics, Medical and Anthropological, of the Provost-Marshal-General's Bureau, compiled by J. H. Baxter (2 vols., Washington, 1875); *A Manual of Anthropometry*, by Charles Roberts (London, 1878); *Reports of the Anthropometric Committee*, in Reports Brit. Assoc. for Adv. of Science (Lond. 1878-84); A. Weisbaeh, *Körpermessungen verschiedener Menschenrassen* (8vo, Berlin, 1878); F. Jagor and G. Koerbin, *Messungen an lebenden Indiern*. *Ztschr. f. Ethn.* (Berl. 1879, xi. 1-116. 2 Tab.); P. Topinard, *De différents instruments d'anthropométrie* (Bull. Soc. d'Anthrop. de Paris, 1880, 3. s. iii. 269-277); P. Topinard, *Observations upon the Methods and Processes of Anthropometry* (J. Anthropol. Inst., Lond. 1880-81, x. 212-224); P. Peli, *Sulle misure del corpo nel Bolognesi; ricerche antropometriche; con un' appendice storica sull' antropometria del Cesare Taruffi* (Mem. Accad. d. sc. d. Ist. di Bologna, 1881, 4. s. ii.); J. Bertillon Taille, *Dict. Encycl. d. sc. méd.* (Paris, 1885, 3. s. xv. 581-649); F. Galton, *On Recent Designs for Anthropometric Instruments* (J. Anthropol. Inst., Lond. 1886-87, xvi. 2-9); D. A. Sargent, *Anthropometric Apparatus, with Directions for Measuring and Testing the Principal Physical Characteristics of the Human Body* (8vo, Cambridge, 1887); A. Lacassange, *De la mensuration des différentes parties du corps dans les cas de dépeçage criminel* (Arch. de l'anthrop. crim., Paris, 1888, iii. 158-163); W. Health, Mass., 1889-90, Bost. 1891, xxii. 479-522); F. Galton, *Retrospect of Work done at my Anthropometric Laboratory at South Kensington* (J. Anthropol. Inst., Lond. 1891-92, xxi. 32-35); Seggel, *Brustbau und Körpergewicht im Verhältniss zur Körperlänge* (Verhandl. d. x. internat. med. Cong. 1890, Berl. 1891, v. 18. Abth., 162-174).

J. S. BILLINGS.

Anthropomor'phism [from Gr. ἀνθρωπόμορφος, having the form (μορφή) of a man (ἄνθρωπος)]: the representation of the Deity under a human form or with human affections; the figurative application to God of terms which properly relate to human beings. Also the heresy of the ANTHROPOMORPHITES (*q. v.*).

Anthropomor'phites, or Anthropomor'phists: persons who believe or imagine that the Deity has naturally a human form, as the ancient Greeks and other pagans. This error has been also entertained by some Christians, especially the Audæans or Audians, a Syrian sect formed about 350 A. D. The tendency to anthropomorphism arises from the inability of man to form any conception of a divine person except by imagining that there is some similarity between the human and the divine nature.

Anthu'rium [from Gr. ἄνθος, flower + οὐρά, tail]: a genus of aroids including 160 species, natives of tropical America. The spathe is large and leaf-like, and the spadix is usually cylindrical and sessile. Many species are grown in greenhouses, and are remarkably beautiful. C. E. B.

Antibes, ān'teeb' (anc. *Antip'olis*): a fortified seaport-town in the S. E. of France; in the department of Alpes Maritimes; on the Mediterranean, 17 miles by rail S. W. of Nice (see map of France, ref. 8-1). Its port is small but deep, and is furnished with a lighthouse, lat. 43° 35' N., and lon. 7° 81' E. It has a college, and a considerable trade in olives, fruits, oil, salt fish, etc. Here are some remains of great antiquity. It was founded by a Greek colony about 340 B. C. Its Provençal name, *Antiboul*, readily recalls the ancient Greek appellation. Its coins, the remains of its theater and of certain Roman constructions, have excited the interest of antiquaries, but its ancient history is obscure. Pop. (1891) 7,401; (1896) 9,329.

Anti-burgher: See BURGHHER.

An'tichlore: a name given by paper-makers to substances which are employed to remove from the pulp the chlorine which, in the form of chloride of lime, had been used to bleach it, and which, if allowed to remain in the pulp, would not only damage the machinery, but injure the strength of the paper. Sulphite and bisulphite of soda were first employed, but at present hyposulphite of soda is almost invariably used. Sulphide of calcium, proto-chloride of tin, and coal-gas have been used. See BLEACHING.

An'tichrist [Gr. Ἀντίχριστος; ἀντί, against + Χριστός, Christ]: a name which has been variously applied by Christian writers to a supposed powerful individual or institution destined to arise in opposition to Christianity, and to obtain a partial or temporary triumph over it. This idea has been traced back beyond the Christian era by some writers, who cite in favor of this view the prophecy of Ezekiel concerning Gog and Magog. The word Antichrist occurs in the Scriptures only in the First and Second Epistles of John. He says "that every spirit that confesseth not that Jesus Christ is come in the flesh" is Antichrist. The "Man of Sin" and "Adversary" of Paul's Second Epistle to the Thessalonians are commonly identified with the Antichrist of John. Many writers, both before and since the Protestant Reformation, have made the pope, or the papaey, Antichrist. Many writers, both Roman Catholics and Protestants, have suggested one or another of the persecuting emperors, such as Nero or Diocletian. Others say a succession of Roman emperors.

Anticlei'a (in Gr. Ἀντίκλεια): a daughter of Autolycus; was married to Laertes, and became the mother of Odysseus. According to Homer, she died of grief at the long absence of her son, but on his visit to Hades he met her and spoke with her. According to other traditions, she put an end to her own life on account of a false report of the death of her son. Euripides calls Odysseus a son of Sisyphus (*Iphig. Aul.*, 524), referring to a tradition, communicated by Hyginus, that Anticleia lived on intimate terms with Sisyphus before she married Laertes.

Anticlei'des (in Gr. Ἀντίκλειδης): a Greek historian; lived shortly after the time of Alexander the Great, and is often referred to by later writers, but of his works only fragments have come down to us. He wrote a history of Alexander the Great, which contained an elaborate sketch of the previous history of Egypt, but his principal work was his *Περὶ Νόστων*, containing, according to Strabo, an account of the return of the Greeks from their ancient expeditions.

Anticli'max [for etymology, see CLIMAX]; in rhetoric, a sentence which descends from great to little, and is the reverse of a climax, as in this verse of Pope: "Die and endow a college or a cat"; and this line from Horace: "Parturiunt montes, nascetur ridiculus mus."

Anti-Corn-Law League: an association founded in 1839 by a number of manufacturers in Manchester, England, who aimed at the abolition of all fiscal imports on grain. Sev-

eral local associations of like purpose had preceded it; one in London, 1836, and another in Manchester in 1838. The manufacturers of the latter city had sought a hearing through Parliament in vain, and when the House of Commons, Mar. 12, 1839, rejected a motion for a commission to inquire into the operations of the corn-laws, the Manchester men in attendance at once assembled in Herbert's hotel, London, and under Richard Cobden's (*q. v.*) leadership organized the League. During the seven years that its triumph was delayed he was its presiding genius. His great coadjutor was John Bright. Its secretary was W. A. Paulton; among its celebrated adherents were Joseph Hume, Sir William Molesworth, George Thompson, C. P. Villiers, Ebenezer Elliott, who wrote political verse for it, Milner Gibson, and W. J. Fox. Its methods were those of a propaganda, and its arguments were from the standpoint of the moral iniquity and economic folly of taxing food. Its career was energetic, fiery, and expensive, and its functions ended when Sir Robert Peel (*q. v.*) carried the repeal of the corn-laws in 1846, thus, in his words, "giving the people bread, no longer leavened by a sense of injustice." See CORN-LAWS.

Anticos'ti: a large island of the province of Quebec, Dominion of Canada; in the Gulf of St. Lawrence, between lat. 49° 04' and 49° 58' N., and lon. 61° 45' and 64° 35' W. Area, more than 2,600 sq. miles; length, 135 miles; greatest width, 40. It was exploited by the "Anticosti Company," which in 1873 divided into twenty counties, and eventually attracted a considerable colony. The soil proved to be sterile and the climate cruel; the colonists suffered from starvation, and were removed to the mainland. In 1896 Menier, the chocolate manufacturer of Paris, purchased it for a private park and game preserve, and claims sovereign rights over it. Ellis Bay (the chief settlement) and Fox Bay are the only tolerable harbors.

Anticyclone, ān-ti-sī-klōn' (i. e. the opposite of a cyclone; also called a *high*, alluding to the culmination of pressure on the weather-map): an atmospheric or weather condition covering a large territory, and characterized by a high barometer, gently outflowing winds, clear skies, and dryness. Such areas of high barometer usually appear, in middle latitudes, in the W., and move eastward slowly, though with varying speed. When they follow close on a storm-area (a technical cyclone or "low"), they usually produce cooler weather, and in winter cold waves result when they follow closely behind the storm. In summer the clear skies make the weather hot by day and cold at night. Unseasonable frosts usually occur during the prevalence of an anticyclone. The humidity is low, making the weather dry and fair, or clear. The long continuance of an anticyclone is one of the accompaniments of drouths.

Meteorologically, an anticyclone is an area over which wind is gently descending at the center, and flowing out at the sides. As the upper air is relatively dry, this gives the low humidity and cloudlessness characteristic of the phenomenon, while the coolness of the upper air gives the lower temperatures, and the clearness of the sky permits uninterrupted sunshine in the daytime and uninterrupted radiation to the sky at night, thus causing the great daily range of temperature. A "high" brings calm, pleasant weather, but also danger of frost and drouth. A "low" brings cloud, wind, and storm, but also a moist atmosphere, and rain or snow.

MARK W. HARRINGTON.

Antieyra, ān-tis'i-ra: an ancient city of Thessaly, on the river Sperchius. Another Antieyra was a city of Phocis, with a harbor on the Corinthian gulf. Still another was in Loeris, on the left side of the entrance to the Corinthian gulf. All were noted for the production of hellebore.

An'tidote [Gr. ἀντίδοτον, remedy; ἀντί, against + δότης (διδόναι), given]: a medicine given to overcome or prevent the injurious effects of poisons. Antidotes are chemical or physiological. The first act by neutralizing the poison, converting it into an insoluble or harmless substance. Physiological antidotes produce action within the body which enables it to resist the effect of the poison. Thus belladonna and opium, both poisonous, are physiological antidotes or counter-poisons to each other. Alcohol or ammonia is the physiological antidote of certain snake-poisons. The more important antidotes are mentioned in this work under the name of the poison for which they are administered. See TOXICOLOGY.

Antie'tam, BATTLE OF: battle; fought on Sept. 16 and 17, 1862, between the Union troops, under Gen. McClellan, and the Confederates, under Gen. Lee; taking name from Antie-

tam creek, which enters the Potomac about 6 miles above Harper's Ferry. It was called by the Confederates the battle of Sharpsburg.

After the second battle of Bull Run the Confederates crossed the Potomac above Harper's Ferry and pushed on to Frederick, Md., with a view to invading Pennsylvania. Upon McClellan's approach from Washington, they fell back and occupied the passes of the South Mountain between Frederick and the Hagerstown road. Jackson, with his own troops and those of McLaws and Walker, meanwhile marched upon Harper's Ferry, invested it, and captured its garrison of about 12,000 men, the surrender being made Sept. 15, and then marched to join Lee at Antietam, reaching there in time to take part in the battle. McClellan, marching from Washington, forced the passes of South Mountain Sept. 14, and, marching on toward Sharpsburg, found Lee's army occupying a position behind Antietam creek. McClellan's army came up and was massed in front of this position by the evening of the 15th, except Franklin's corps, which arrived about 10 A. M. of the 16th. Burnside was placed on the left, Sumner in the center, and Hooker on the right, with Porter in reserve. On the afternoon of the 16th Hooker's corps crossed the creek with a view to turning the enemy's left. Here he commenced the action which lasted until dark, and recommenced at early dawn on the 17th. During the night Mansfield's corps crossed in support of Hooker, and joined in the battle at about 7 A. M., and Sumner reached the front an hour or two later, extending the Union line to the left. Hood's division on the Confederate left met Hooker's attack of the 16th, and was driven back, but during the night was relieved by Jackson, with Ewell's troops, who had arrived from Harper's Ferry in time to meet the attacks of Hooker and Mansfield. McLaws and Walker also came on the field just in time to strike in flank the right division (Sedgwick's) of Sumner's corps, which was somewhat in advance of the others. Sumner's two remaining divisions (French's and Richardson's), supported by part of Franklin's corps, however, pushed back the Confederate line some distance, joined with the troops on their right, and succeeded in holding their ground for the rest of the day. The battle in this part of the field was virtually ended at 1 P. M. The fighting on the Union right had been most desperate, and the losses on both sides very great, including Gen. Mansfield killed, Richardson mortally wounded, and Hooker, Sedgwick, and Crawford wounded. On the Confederate side Gens. Branch and Starke were killed, and R. H. Anderson, Lawton, Gregg, and Jones wounded. It will be observed that the battle on the right commenced at early dawn, and that the different corps came into action in succession instead of simultaneously. Meanwhile Burnside, who commanded the left wing, did not cross the creek until about 1 P. M. Consequently the Confederates were able to strengthen their left, to meet the attack made upon it, by withdrawing troops from their right and center.

At about 10 A. M. Burnside commenced to move. He sent one division (Rodman's) to cross the creek by a ford well to the right of the Confederate line, and made an effort to force a passage at the stone bridge in his front, subsequently known as "Burnside's bridge." The first two assaulting columns were repulsed, but the third was successful, and carried the bridge and the wooded bank on the other side at about 1 P. M., just before Rodman's troops came up and joined them. The remainder of the Ninth Corps crossed and formed on the other side.

At about 3 P. M. Burnside's troops, under urgent orders from McClellan, made a vigorous and gallant attack, and drove the enemy before them until the right division (Willcox) reached and entered the village of Sharpsburg. As the direction of the advance inclined to the right, Rodman's division necessarily fell to the rear of Willcox's, and was thus exposed to a vigorous attack upon its left by A. P. Hill's division of six brigades, which had just arrived from Harper's Ferry. Rodman was mortally wounded, and one of his brigades thrown into confusion. The left of the corps being thus unprotected, the whole line was retired somewhat toward the creek, and a good position taken up, which was held against the Confederate assaults of the afternoon, and during the night and the following day (the 18th). During the night of the 18th the Confederates recrossed the Potomac at Shepherdstown.

McClellan's strength by official reports was about 87,000; his losses 12,469, including 2,010 killed. The most reliable reports place Lee's strength at about 40,000 men, and his losses at about 12,000.

The discussion of the tactical features of this battle is beyond the scope of this article. For full descriptions from different standpoints, see *The Battles and Leaders of the Civil War* (The Century Co.); *The Antietam and Fredericksburgh*, Scribner's War Series, etc. See also McCLELLAN and CONFEDERATE STATES.

JAS. MERCUR.

Antifeb'rin (*Acetanilide, Phenylacetamide*): a white crystalline substance, slightly soluble in cold, much more so in hot water, which is much used in medicine for the reduction of temperature and the relief of pain. When given to persons suffering from fever, in doses of from ten to fifteen grains, it usually produces in about an hour a fall of temperature which is often but not always accompanied by a profuse sweating, but which is not dependent upon that sweating. In doses of ten to fifteen grains in health, it usually causes no distinct symptoms; in larger doses, or when the dose is repeated, it occasions headache, malaise, some somnolence, ringing in the ears, dilatation of the pupils, cyanosis of the face and extremities, and sometimes an eruption of bright red spots. In poisonous doses, it causes fall of temperature, disturbance of respiration, wide-spread paralysis with convulsions, and death in collapse. Its general action is very similar to that of antipyrin, but there is a wide-spread belief in the medical profession that it is less apt to cause collapse than is antipyrin. That it has a very great effect upon the general nutrition is shown by the fact that it decreases the production of animal heat; that is, lessens the activity of the chemical changes in the body. It is not efficient against pain which is the result of distinct local inflammations, diseases, or injuries, such as a boil or broken leg; but it often affords a great relief in nervous pains, such as nervous or sick headache, the lightning-like pains of locomotor ataxia, or other spinal disease. Dose, ten to fifteen grains.

H. C. WOOD.

Anti-Federalists: party in the U. S. opposed to centralizing tendencies in the administration of government and interpretation of the Federal constitution; its first great leader was Thomas Jefferson. It first opposed the adoption of the Constitution, but when defeated on that point favored the strictest construction. The name went out of use soon after 1793, and the party it represented has been successively called Republican, Democratic Republican, and (at present) Democratic. See ALEXANDER HAMILTON, THOMAS JEFFERSON, DEMOCRACY, REPUBLICAN PARTY, and UNITED STATES.

An'tigo: city (founded in 1880); on railroad; capital of Langlade co., Wis. (for location of county, see map of Wisconsin, ref. 3-E); 207 miles from Milwaukee; has electric lights; 6 churches; 6 public schools, 1 Roman Catholic parochial school, and 2 German Lutheran schools. Principal industries are lumbering and agriculture. Has 1 flour and 3 saw mills, 2 planing-mills, machine-shop, a foundry, and a brewery; and chair, hub, broom-handle, veneer, excelsior, and other factories. Pop. (1890) 4,424; (1900) 5,145.

EDITOR OF "REPUBLICAN."

Antig'one (Gr. Ἀντιγόνη): a daughter of Œdipus, King of Thebes, and his own mother, Jocasta. She attended her father in his exile into Colonos in Attica, remaining with him till he died, when she returned to Thebes, and afterward buried her brother Polynices in defiance of the edict of the tyrant Creon, who, for her disobedience, immured her alive. Her tragic story was a subject of the Greek poets, particularly Sophocles, whose plays of *Antigone* and *Œdipus at Colonos* are still extant, and Euripides, whose *Antigone*, though not extant, is known from extracts by later writers, and in his play of the *Phœnissæ*.

Antig'onns (Gr. Ἀντίγονος): King of Asia, surnamed CYCLOPS (i. e. one-eyed); a Macedonian general; b. about 382 B. C. He took part in Alexander's campaign against Persia, and became satrap of Phrygia in 333. In the division of the empire which followed the death of Alexander, Antigonus received the provinces of Lycia, Pamphylia, and the Greater Phrygia. Having become an enemy of Perdiccas, he formed an alliance with Antipater and Ptolemy in 321 B. C. After the death of Perdiccas (321 B. C.), Antigonus waged war in Asia Minor against Eumenes, whom he defeated and put to death in 316. He obtained by conquest several provinces in Asia, and indulged an immoderate ambition, to restrain which Ptolemy, Cassander, Seleucus, and Lysimachus formed a league against him in 315 B. C. In the long war that ensued, Demetrius Poliorcetes, the son of Antigonus, defeated Ptolemy in a naval battle in 306, soon after which Antigonus took the title of king. He encountered the united armies of the allies

at Ipsus in Phrygia, where he was defeated and killed in battle in 301 B. C.

Antigonus: King of the Jews; son of Aristobulus II.; b. about 80 B. C. After the death of his father he was expelled from Judea by Antipater and Herod. He was restored to the throne by the Parthians about 39 B. C., but the Roman senate refused to recognize him as king. Mark Antony took Jerusalem and put Antigonus to death about 36 B. C.

Antigonus Do'son (Gr. Ἀντίγονος Δάσων): King of Macedonia; was a descendant of Antigonus surnamed CYCLOPS, and a nephew of Antigonus Gonatas. He became regent or king in 229 B. C., during the minority of Philip V., who was heir to the throne. He was an ally of the Achaean League in a war against Sparta, and he defeated the Spartan Cleomenes in 221 B. C. He died in the same year, and left the throne to Philip V.

Antigonus Gona'tas (Gr. Ἀντίγονος Γονατᾶς): son of Demetrius Poliorcetes; b. about 320 B. C. at Gona, or Gonni, in Thessaly, whence his surname. Having defeated an army of Gauls who under Brennus had invaded Macedonia, he became king of that country in 277 B. C. He was expelled from his kingdom by the famous Pyrrhus, King of Epirus, in 273, but he recovered the throne after the death of Pyrrhus in 271. He died about 240 B. C., and was succeeded by his son, Demetrius II.

Antig'orite: a species of serpentine in which a portion of the silica is replaced by alumina. It has a weak luster, and feels smooth but not greasy. It is found in the Antigorio valley in Piedmont.

Antigua, ān-tee'-ga: a British West India island; the most important of the Leeward group (see map of West Indies, ref. 6-M); first settled in 1632. It is 22 miles S. of Barbuda. The capital, St. John's, is in lat. 17° 8' N., lon. 61° 52' W. The surface is diversified, the climate dry and healthy, and the soil of the interior is fertile. Sugar, molasses, and rum are the chief articles of export. English Harbor can receive very large vessels. Pop. (1891) 36,700, including the small islands of Barbuda and Redonda. Combined area, 108 sq. miles.

Antilegom'ena [Gr. pres. pass. partic. of ἀντιλέγειν, speak against]: literally, "spoken against," a theological term applied in ancient times to certain books of the New Testament, the authority of which was questioned by some biblical critics—namely, the Second Epistle of Peter, those of James and Jude, the Epistle to the Hebrews, the Second and Third of St. John, and the Apocalypse. They were, however, ultimately admitted into the canon.

Anti-Lib'anus, or **Anti-Leb'anon**: a mountain-range of Palestine and Syria, extending about 90 miles in a N. E. and S. W. direction nearly parallel with Lebanon, from which it is separated by the valley of Cœle-Syria. It is of Jura limestone formation. The highest summit of this range is Mt. Hermon, which has an altitude of about 10,000 feet. The valley of Cœle-Syria, between the two ranges, now called *Būkā'a*, is from 4 to 6 miles wide. See Robinson's *Physical Geography of the Holy Land* (1865).

Antilles [supposed by some to be corrupted from Lat. *ante*, before + *insula*, islands, because they seemed placed before the continent, which was only reached after the islands had been passed; also attributed to a mythical *Antilla* island]: all the West India islands except the Bahamas. They lie between the Atlantic Ocean and the Caribbean Sea, and extend from the Gulf of Mexico nearly to the Gulf of Paria. They are divided into three groups—the Greater Antilles, the Virgin islands, and the Lesser Antilles, or Caribbean islands, which are the most eastern. The Greater Antilles comprise the four largest islands of the archipelago—namely, Cuba, Hayti (or St. Domingo), Jamaica, and Porto Rico, with the small islands along their coasts. They are situated in the torrid zone, and are subject to frequent hurricanes and earthquakes. In the central parts of these islands rise high mountains of granitic formation. The staple products are sugar, rum, tobacco, cotton, and coffee.

The Lesser Antilles are small in size, but very numerous, and are arranged in a long curved line or row like a crescent, the convex side of which is toward the east. They are divided into two groups—viz., the Windward, or South Caribbee islands, and the Leeward, or North Caribbee islands. The Windward islands are Barbadoes, Grenada, the Grenadines, Martinique, St. Lucia, St. Vincent, Trinidad, and Tobago. All these belong to Great Britain, except Martinique, which is a French colony. The Leeward islands are Anguilla, An-

tigna, Barbuda, Descada (French), Dominica, Guadeloupe (French), Marie Galante (French), Montserrat, Nevis, Saba, St. Bartholomew (Swedish), St. Christopher, St. Eustatius, St. Martin (French and Dutch), Santa Cruz. For Virgin islands, see these words. The Leeward islands are British, except those otherwise designated, and three of the Virgin islands. Many of the Lesser Antilles are of volcanic origin, and some are of coral formation. The staple productions are similar to those of the Greater Antilles. A large portion of the population of the Antilles are Negroes and mulattoes, who are free. Slavery was abolished in the island of Cuba in 1886, and in Porto Rico in 1873. Area of Greater Antilles, 83,636 sq. miles; pop. 4,342,000: Virgin islands, area 268 sq. miles; pop. 39,000: Lesser Antilles, area 4,359 sq. miles; pop. 1,000,000.

Revised by M. W. HARRINGTON.

Antilocapra (i. e. antelope-goat): the generic name of the prong-horned antelope (*Antilocapra americana*), which inhabits the drier portions of the North American continent W. of the Mississippi. With the exception of the so-called Rocky Mountain goat (*Mazama*), this is the only antelope

Prong-horned antelope.

found in America, and it differs widely from all the Old World antelopes in this, that the sheaths of its horns are shed annually, like the deciduous horns of the deer. In this respect the prong-horned antelope stands quite alone, and forms the type of a distinct family, the *Antilocapridæ*.

Revised by D. S. JORDAN.

Antimachus (in Gr. Ἀντίμαχος): poet and scholar of Colophon; lived about 400 B. C. He was a forerunner of the Alexandrian period, and, being in advance of his times, was not popular. Audience fit he found in Plato, who admired his poems. More successful than his epic *Thebais* was his *Lyde*, a cycle of elegies, in which he undertook to console himself for the loss of his love by recounting like sorrows. Only scant fragments remain. See Couat, *La poésie Alexandrine*. p. 62 foll.

B. L. G.

Anti-Masonry: opposition to secret societies (that is, societies which conserve secrets) in general; but more particularly opposition to the order known as Masons or Freemasons, for which a high antiquity and wide influence are claimed. This order early excited the suspicions of European governments, some of which regarded it as a mask for conspiracies against throne and altar. Some of them protected themselves, so far as they might, by procuring the election of princes or other eminent personages to the chief offices of the order.

In the summer of 1826 a thriftless tailor, named William Morgan, living in the village of Batavia, in Western New York, it was whispered, was engaged in preparing a revelation of the secrets of the Masonic order, whereof he was a member. Other Masons, including the editor of the village gazette, were understood to be engaged with him in the enterprise. Morgan disappeared suddenly one evening, and it was soon proved that he had been forcibly abducted. Ex-

citement naturally arose, committees of vigilance and safety were organized, and he was traced westward to Fort Niagara, near Lewiston, N. Y., where he was temporarily imprisoned, and whence, it was ultimately testified, he was taken out into deep water in Lake Ontario and there sunk, though this was strenuously denied, and various stories from time to time affirmed that he was subsequently seen alive at Smyrna in Asia and other places. Such reports did not allay the excitement, which deepened and diffused itself, finding vent in a political party, which cast 33,000 votes in the State of New York in 1828, about 70,000 in 1829, and 128,000 in 1830; but of this last a fraction were not Anti-Masons, but only Anti-Jackson. The party spread into other States, and nominated William Wirt for President and Amos Ellmaker for Vice-President in 1832, when they were heartily supported in several States, but carried Vermont only. They probably diverted votes enough from Clay to give the States of Ohio and New Jersey to Jackson. They nearly elected Joseph Ritner Governor of Pennsylvania in 1832, and did elect him in 1835, through a split in the Democratic ranks. The excitement gradually died out, and absorbing questions of finance and political economy soon dissolved the Anti-Masonic party. See the article UNITED STATES (*History*).

Anti-Mission Baptists, called by themselves **Old-School Baptists**: a denomination of hyper-Calvinistic Baptists of the U. S. who have no Sunday-schools, missions, colleges, or theological schools, holding that these things make the salvation of men to depend on human effort and not upon divine grace.

Antimo'rial Wine: a solution of tartar emetic in sherry or other wine.

Antimony [from Mediev. Lat. *antimonia*; etymol. obscure]: a brittle metal, of a silver-white color and of a peculiar taste; atomic weight 120; chemical symbol Sb (from Lat. *stibium*). It occurs in nature native, combined with other metals, as nickel, silver, etc., with oxygen and with sulphur. The sulphide, "stibnite" or "gray antimony," is the source of all the antimony of commerce. The most abundant supplies of this ore are obtained from Borneo. It also occurs in considerable quantities in Hungary, Cornwall, New Brunswick, California, and Nevada. The sulphide, being very fusible, is often separated from the accompanying gangue-rock by heat, and cast in blocks or loaves. The metal, or "regulus of antimony" as it is called in commerce, is separated from the sulphide in various ways, such as heating with metallic iron, sodic carbonate, and charcoal, or cream of tartar and niter. The extraction of antimony from its ores is mainly carried on at Linz, in Germany, where the sulphide of antimony is found extensively, and in Great Britain, which receives its supply of ore from Singapore and Borneo, commonly as ballast. The process consists in heating the crude ore, covered with charcoal, on the bed of a furnace, when the sulphide of antimony fuses, leaving unmelted the earthy impurities; and thereafter the liquid is drawn off into iron molds, where it solidifies into cakes or loaves. The latter are reduced to coarse powder, placed on the bed of a reverberatory furnace, and heated with access of ordinary air containing oxygen, when the sulphur passes away as gaseous sulphurous acid, SO₂, leaving behind the antimony as the trioxide, Sb₂O₃. The roasted mass is now mixed with one-sixth of its weight of powdered charcoal, the whole moistened with a solution of sodium carbonate, and raised to bright redness in crucibles, when the metal antimony trickles to the bottom, and the impurities are left above in the spent flux or scoria, which is known in the arts by the name of *crocus* of antimony. The antimony thus prepared is more or less contaminated by sulphur, copper, arsenic, iron, lead, etc. It may be freed from all these metals except lead by reducing it to a coarse powder and fusing with one-sixteenth of gray sulphide and one-eighth of dry sodic carbonate. The resulting metal must then be pulverized and fused with one-tenth of dry sodium carbonate, and the process repeated.

Owing to the extensive use of antimony preparations in medicine, the removal of arsenic is of special importance. This can be effected by mixing 4 parts of powdered antimony with 5 parts niter and 2 parts dry sodium carbonate, projecting the mixture into a red-hot crucible. The semi-fused mass is boiled with water, and the insoluble potassium antimoniate is reduced to metal by fusion with cream of tartar. Several successive fusions of pulverized antimony with one-eighth of niter are said to completely remove the arsenic.

Antimony is a brilliant metal of a bluish-white color and highly crystalline or laminated structure. Its density is 6.7 to 6.86. It is extremely brittle, and may be easily pulverized in a mortar. Heated in the open air, it burns with a bluish-white flame, and forms copious fumes of antimonous oxide (Sb_2O_3), or "flowers of antimony." A peculiar *amorphous* antimony was prepared by G. Gore (*Proc. Roy. Soc.*, ix. 70 and 304) by electrolyzing certain solutions of the metal. A mass having the appearance of polished steel, with a bright, metallic, amorphous fracture, was obtained of a density of 5.78, which, on being broken or heated, suddenly passed into the crystalline form, with the evolution of sufficient heat to make it take fire. Antimony is oxidized by nitric acid, with the formation of antimonous oxide (Sb_2O_3), antimonie oxide (Sb_2O_5), or antimonoso-antimonie oxide ($\text{Sb}_2\text{O}_3 \cdot \text{Sb}_2\text{O}_5$). Antimony forms with acids or chlorous radicals two classes of compounds: (1) antimonous or tri-compounds, as the trichloride SbCl_3 ; trioxide or antimonous oxide, Sb_2O_3 ; trisulphide, Sb_2S_3 . (2) Antimonie or pentacompounds, as pentachloride, SbCl_5 ; pentoxide or antimonie oxide, Sb_2O_5 ; pentasulphide, Sb_2S_5 .

Antimonous chloride, or *trichloride* (SbCl_3), called *butter of antimony*, is obtained by dissolving antimonie sulphide in hydrochloric acid. In its concentrated form it appears as a yellow oily liquid of the consistence of melted butter. Poured into water, it produces a buttery white precipitate of oxychloride (*powder of algaroth*), $\text{SbCl}_3 \cdot \text{Sb}_2\text{O}_3$, or $\text{SbO} \cdot \text{Cl}$. Mixed with olive oil, butter of antimony is used for bronzing gun-barrels. Powdered antimony poured into a jar of chlorine takes fire, forming SbCl_3 or SbCl_5 .

Antimonie chloride, or *pentachloride* (SbCl_5), is a colorless volatile liquid, prepared by heating antimony in an excess of chlorine. By the action of water it is changed to antimonie acid and hydrochloric acid.

Antimonous hydride, or *antimonetted hydrogen* (SbH_3), a colorless gas produced by the action of zinc and sulphuric acid on a solution of antimony. It burns with a greenish flame, evolving fumes of Sb_2O_3 . Passed through a red-hot tube, it is decomposed, with the formation of a black deposit of Sb. A similar deposit is formed on cold porcelain held in the flame. When the gas is passed into a solution of argentic nitrate, a black precipitate of antimonide of silver (SbAg_3) is formed. This gas (SbH_3) is the analogue of ammonia, NH_3 , phosphine, PH_3 , and arsine, AsH_3 ; as is also the silver compound, SbAg_3 . A class of organic bases, represented by triethyl stibine, $\text{Sb}(\text{C}_2\text{H}_5)_3$, belongs to the same group.

Antimonous, or *trioxide* (Sb_2O_3), found native in beautiful crystals, as *valentinite* and *senarmontite*. Boiled with cream of tartar ($\text{K.H.C}_4\text{H}_4\text{O}_6$), antimonous oxide dissolves, with the formation of *potassio-antimonyl tartrate*, or *tartar emetic* ($\text{K.SbO.C}_4\text{H}_4\text{O}_6$). An impure oxide is manufactured for the preparation of this salt, by roasting the powdered sulphide, and fusing the product at the end of the process. It is known as *glass of antimony*.

Antimonie, or *pentoxide* (Sb_2O_5), is formed by heating powdered antimony with excess of strong nitric acid, by decomposing SbCl_5 with water, or by fusing powdered antimony with niter. Potassium antimoniate is the only reagent for the precipitation of soda. There are two modifications of this acid, known as antimonie acid, HSbO_3 , and metantimonie acid, $\text{H}_4\text{Sb}_2\text{O}_7$.

Tetroxide, or *antimonoso-antimonie acid* (Sb_2O_4 or $\text{Sb}_2\text{O}_3 \cdot \text{Sb}_2\text{O}_5$), occurs native as *cervantite*. It is the ultimate product of the action of heat and air on the metal.

Trisulphide, or *antimonous sulphide* (Sb_2S_3), the ore *stibnite*, or *gray antimony*, prepared artificially by fusing antimony with sulphur, or as an orange precipitate by passing sulphuretted hydrogen through a solution of tartar emetic. This sulphide is a sulphur-acid, which unites with basic sulphides, forming salts in every way analogous to the oxygen salts. Such are $3\text{K}_2\text{S} \cdot \text{Sb}_2\text{S}_3$; zinkenite, $\text{PbS} \cdot \text{Sb}_2\text{S}_3$; miargyrite, $\text{AgS} \cdot \text{Sb}_2\text{S}_3$; pyrargyrite, $3\text{AgS} \cdot \text{Sb}_2\text{S}_3$.

Pentasulphide, or *antimonie sulphide* (Sb_2S_5), is also a sulphur-acid, forming sulpho-antimonates, analogous to the ortho-phosphates. The sodic sulpho-antimonate is $\text{Na}_3 \cdot \text{SbS}_4$. Precipitated from a mixture of antimonie pentachloride and tartaric acid, it appears as a yellowish-red powder, the golden sulphuret.

Kermes is an oxysulphide ($\text{Sb}_2\text{O}_3 \cdot 2\text{Sb}_2\text{S}_3$) which occurs native as the beautiful cherry-red kermesite.

ALLOYS OF ANTIMONY.—*Type-metal* is composed of antimony 1, lead 4 parts, and when used for stereotype plates receives an addition of one-eightieth to one-fiftieth of tin.

This alloy is not only hard, but, owing to the fact that it expands at the moment of solidification, it takes a very sharp impression of the mold. *Britannia* is composed of antimony 1, tin 9 parts. *Peuter* is another alloy of antimony and tin. Antimony also enters into the composition of some of the *anti-friction* alloys. Tartar emetic is the most important preparation of antimony used in medicine; in large doses it is very poisonous. The old-fashioned "family pill" was a small bullet of metallic antimony, which was swallowed for certain difficulties, and carefully preserved for future occasions.

Revised by IRA REMSEN.

Antino'mians [from Gr. *ἀντί*, against + *νόμος*, law]: those who maintain that the Law is of no use or obligation under the Gospel dispensation. They took their rise from JOHN AGRICOLA (*q. v.*), who was originally a disciple and friend of Luther, and who contended that his views were the legitimate deductions from the principles taught by Luther himself. He taught, among other things, that good works do not promote our salvation, nor evil ones hinder it. Luther attacked the Antinomian heresy with great zeal, and at length, in 1540, Agricola recanted his more obnoxious tenets. The controversy, however, having been reopened by Poach, of Erfurt, in 1556, led to the full statement and decision concerning the entire subject in the *Formula of Concord*, arts. v. and vi. Similar views were afterward charged against Dr. Tobias Crisp (1600–42) and others in England.

HENRY E. JACOBS.

Antinoöpolis: See BESA.

Antinous, än-tin'ō-ūs: a beautiful youth, a native of Bithynia, became a favorite and attendant of the Emperor Hadrian. Having accompanied that emperor to Egypt, he was drowned in the Nile, near Besa, in 122 A. D. As a monument to him, Hadrian built the city of Antinoöpolis, in Upper Egypt, and established an annual festival. Statues almost innumerable were also erected to perpetuate his memory and his form, by artists whose emulation gave a new impulse to the fine arts. Some of these statues are still extant. He is the subject of the romances of George Taylor (Hausrath), *Antinous* (1880), and Georg Ebers, *The Emperor* (1881).

An'tioch [from Lat. *Antiochi'a*; Gr. *Ἀντιόχεια*; Turk. *Antakia*]: an ancient city and the former capital of Syria, situated on a fertile and beautiful plain, on the left bank of the river Orontes, 57 miles W. of Aleppo; lat. $36^\circ 11' \text{ N.}$, lon. $36^\circ 9' 30'' \text{ E.}$ (see map of Turkey, ref. 6–G). It was founded in 301 B. C., by Seleucus Nicator, and named in honor of his father, Antiochus. It was the favorite residence of the Seleucid Kings of Syria, was called "Antioch the Beautiful," and was widely celebrated for the splendor of its luxury and the magnificence of its palaces and temples. The population in the time of its greatest prosperity is supposed to have been 400,000 or more. The Romans gave it autonomy; it was the capital of the Roman governor of Syria, the center of West Asiatic trade, and until the imperial residence was removed to Constantinople it ranked after Rome and Alexandria among the cities of the empire. Antioch has been several times nearly ruined by earthquakes. The most destructive of them occurred in 526 A. D., and is said to have caused the death of 250,000 people, there being at that time an assembly of Christians there. On Apr. 3 and 10, 1872, the city was again visited by severe earthquakes, which destroyed many houses and caused the death of a considerable portion of the population. The disciples of Christ were first called Christians in Antioch (Acts xi. 26), which occupies a prominent position in the history of the primitive Church as the scene of the labors of the apostle Paul, and the starting-point of his missionary journeys. In the fifth century the bishops of Antioch received the title of patriarchs, and ranked equal to the patriarchs of Rome, Constantinople, and Alexandria. In the Greek Church the patriarchs still retain this rank. In the Roman Catholic Church four prelates (of the Greek, Syrian, Maronite, and Latin rites) have the title of patriarch of Antioch, but none of them at present resides in Antioch. The Jacobite patriarch of Antioch is the head of that Church. Many councils of the Church were also held here. The crusaders took Antioch from the Saracens in 1098, after which it was the capital of a Christian principality until 1269. Among the remains of its former grandeur are the ruined walls and aqueduct. On the south bank of the Orontes, about 5 miles S. W. of Antioch, is the site of the famous ancient grove of Daphne and temple of Apollo. The modern town, Antakia, is

meanly built, but has some manufactures of pottery and cotton stuffs. The culture of silk is the chief branch of industry. It has become a center of Protestant missionary labors. Pop. estimated at 17,500.

ANTIOCH was also the name of an ancient city of Asia Minor, in Pisidia, visited by the apostle Paul (see Acts xiii. 14. and xiv. 21), who planted a church there. Of this city extensive ruins exist. Besides the above, there were at least six other Oriental towns of this name.

Revised by S. M. JACKSON.

Antioch, Bay of: is a part of the Mediterranean, at the mouth of the Orontes river, between lat. 35° 50' and 36° 20' N., and in lon. about 36° E., and lies between high mountains on the N. and S., by which it is mostly well sheltered. The waters are deep, and free from rocks. Some ruins are situated on the north side, which are described as those of Seleucia Peiria, the ancient port of Antioch.

Antioch College (Yellow Springs, Greene co., O.): founded in 1852, and opened in the following year. This college is designed to be free from sectarian influences, and to develop good character as well as mental excellence in its pupils. The sexes are educated together with the best results. The college was established with a view of diffusing education at the lowest possible cost. It has a music school and a preparatory department. Its first president was Hon. Horace Mann, LL. D. (1852-59). Rev. D. A. Long, D. D., LL. D., is the present incumbent. Its principal patrons are members of the Christian Church. The number of instructors is twelve, and of students 100. There are 5,000 volumes in the library.

Antiochian School: a school which held doctrinal views in opposition to the Alexandrian school; flourished in Antioch during the fourth and fifth centuries. It rejected allegorizing, maintained the freedom of the will, the conjunction rather than the union of the two natures in Christ, and in general practical rather than speculative views. The great names of the school are Cyril of Jerusalem, Theodore of Mopsuestia, and Chrysostom. See Her-genröther, *Die antiochenische Schule* (Würzburg, 1866).

S. M. JACKSON.

Antiochus I., surnamed SOTER (i. e. saviour): a King of Syria, of the dynasty Seleucidæ; a son of Seleucus I. Nicator; b. about 324 B. C. He commanded the cavalry which fought against Antigonus at Ipsus, in 301. Having succeeded his father in 280 B. C., he gained a victory over the Gauls, who had invaded his dominions, from which victory he derived the surname *Soter*. He was killed in battle by the Gauls in 261 B. C.

Antiochus II., THEOS: King of Syria; son of the preceding; began to reign in 261 B. C. The people of Miletus, who had received a favor from him, gave him the title of *Theos*, "God." In his reign the Parthians revolted with success, and Arsaces became King of Parthia, which was previously subject to the King of Syria. A war which he waged against Ptolemy of Egypt was ended in 252 B. C. by a treaty, in accordance with which he married Berenice, a daughter of Ptolemy, and repudiated his first wife, Laodice. After the death of Ptolemy he reinstated Laodice, who poisoned him in 246 B. C.

Antiochus III., surnamed THE GREAT: a grandson of the preceding, and a son of Seleucus Callinicus; b. about 238 B. C. He succeeded his brother, Seleucus Ceraunus in 223 B. C. His capital was Antioch, and his kingdom comprised Syria Proper, Babylonia, Media, and a part of Asia Minor. For the possession of Palestine he waged war against Ptolemy of Egypt, by whom he was defeated at Raphia, near Gaza, in 217 B. C. While he was suppressing a revolt of Aehæns in Asia Minor in 214, the Parthians occupied Media, but, after a successful campaign against Arsaces of Parthia, Antiochus reconquered Media in 212. He afterward conducted a victorious expedition across the mountains of Hindu Koosh into India, and, having formed an alliance with several Indian princes, returned to Antioch, from which he had been absent seven years. He took Palestine from the King of Egypt in 198 B. C., and invaded Thrace in 196. By this movement he provoked the hostility of the Roman senate. He led an army into Greece, was defeated at Thermopylæ in 191 by Acilius Glabrio, and retreated into Asia Minor. The Roman army, commanded by L. Cornelius Scipio, passed over into Asia in 190 B. C., and gained a decisive victory over Antiochus at Magnesia. The war was then ended by a treaty dictated by the Romans, who re-

quired him to cede all the provinces W. of Mt. Taurus, and to pay about 15,000 talents. In order to raise this sum he plundered a temple in Elymais, for which act the populace killed him in 187 B. C. He left the throne to his son, Seleucus Philopator. This Antiochus, and the second and fourth of the name, are supposed to be referred to in Dan. xi. See Polybius, *History*. Revised by S. M. JACKSON.

Antiochus IV., surnamed EPIPHANES (the illustrious): son of the preceding. He passed about twelve years in captivity in Rome, whither he was sent as a hostage in 188 B. C. He became king on the death of his brother, Seleucus Philopator, in 175 B. C. He invaded Egypt in 170, and captured the king, Ptolemy Philometor, but was constrained by the Roman senate to retire from that country in 168 B. C. About this date he endeavored to supplant Jewish institutions and usages by Hellenic arts and culture; he plundered the temple of Jerusalem and persecuted the Jews, who rose in arms and were led by Judas Maccabæus, who defeated the Syrian armies in several battles. (See 1 Maccabees ii.) D. in 164 B. C.

Antiochus VII., surnamed SIDETES: a son of Demetrius Soter; b. about 164 B. C.; became King of Syria in 137. He defeated the Parthians in several battles, but was killed in battle by them in 129 B. C.

Antiochus VIII.: second son of Cleopatra (the wife, first of Alexander Balas, then of Demetrius II., and then of Antiochus VII.); reigned over Syria with his mother from 126 to 122 B. C., and then alone till 114 B. C., when his authority was disputed by his half-brother, Antiochus Cyzicenus (Antiochus IX.). He was assassinated by an officer of his court, 96 B. C.

Antiochus IX., surnamed CYZICENUS: son of Cleopatra by Antiochus VII., survived Antiochus VIII., and committed suicide 95 B. C.

Antiochus X., surnamed EUSEBES: son of the preceding, succeeded his father in 95 B. C., but was soon after expelled, and died in obscurity.

Antiochus XIII., surnamed ASIATICUS: the twentieth and last king of the dynasty of the Seleucidæ. He began to reign about 69 B. C., and was deposed by Pompey in 65 B. C., when Syria became a Roman province. He was executed at Rome, 29 B. C.

Antiocho: an island in the Mediterranean, near the west coast of Sardinia. The soil is fertile. Area, 42 sq. miles. Pop. about 2,200.

Antioquia, ăn-tē-ō-kē-a: a department of Colombia; centrally located, on the west side of the Magdalena river, with Bolivar on the N., Santander on the E., Tolima on the S., and Cauca on the S. W. and W. It abounds in forests and in the ores of the precious metals. Area, 22,800 sq. miles. Pop. (1884) 464,887. The chief towns are: Antioquia (pop. 8,640, elevation 1,887 feet), on the Cauca river; Medellin, the capital (pop. 40,000, elevation 6,140 feet). A railroad a few miles in length extends westward from Puerto Berrio on the Magdalena. More than half of this department is under cultivation. M. W. H.

Antiparos, Oliaros, or Olearos: a Grecian island in the Ægean Sea, about a mile W. of Paros; is one of the Cyclades (see map of Greece, ref. 17-M). It is 8 miles long and 2 or 3 miles wide, and consists of a mass of marble, covered with soil which produces some grain, wine, etc. Here is a celebrated stalactitic cavern called the Grotto of Antiparos, which is about 300 feet long and 80 feet high. The roof and sides are adorned with white incrustations of great splendor and beauty. This grotto was discovered by M. de Nointel in 1673. It was probably not known to the ancients. Pop. about 800.

Antipas: See HEROD ANTIPAS.

Antipater (in Gr. Ἀντίπατρος): a Macedonian general; a pupil of Aristotle; held a responsible position under Philip of Macedon. He was appointed regent of that kingdom by Alexander the Great in 334 B. C., when he departed to invade Persia. He defeated Agis, King of Sparta, in a battle near Megalopolis in 330. After the death of Alexander, his generals or successors agreed that Antipater should govern Macedonia and Greece. The Athenians, in alliance with other Greek states, made an effort to regain their independence in 322, and defeated Antipater near Lamia, but, having been reinforced by Craterus, he gained a decisive victory in the same year. The Lamian war was then ended by a treaty dictated by Antipater, who required the Athenians to deliver Demosthenes to him. He joined Antigonus

in a league against Perdiccas, and on the death of the latter, in 321, succeeded him as regent of the empire. He died in 319 or 318 B. C., and left a son, Cassander. See Thirlwall, *History of Greece*; Diodorus Siculus, *History*.

Antipater: a son of Herod the Great and Doris; notorious for his wickedness. Having procured the death of his half-brothers Aristobulus and Alexander, and conspired against his father, he was put to death in 1 B. C.

Antipater of Tarsus: a Stoic philosopher who lived about 140 B. C.; wrote several works on philosophy and morality. He opposed the skepticism of Carneades. Cicero represents him as a man of remarkable subtlety.

Antipater the Idumean: son of Antipas, and the father of Herod the Great; became governor of Idumea. Having assisted Julius Cæsar in his war against the Egyptians, he was rewarded with the office of procurator or governor of Judea, about 46 B. C. D. in 43 B. C.

Antiph'anes (in Gr. Ἀντιφάνης): Greek poet of the Middle Comedy, who flourished about 368 B. C., was, like Alexis (*q. v.*), a prolific playwright. Indeed, one account gives him no less than 365 comedies. Of these we have specimens of some 130. The fragments have mainly to do with the giving of dinners and the uttering of "sentiments." Meineke, iii. 590 foll.; Kock, ii. 451 foll.

Antiph'ilus (Ἀντίφιλος): Greek painter; b. in Egypt; supposed to have flourished about 330 B. C. He was distinguished for facility of execution. Among his works were *Cadmus and Europa*, and a portrait of Alexander the Great. He was perhaps the most successful and celebrated painter of the Alexandrian epoch, except Apelles.

Antiphlogis'tic [from Gr. ἀντί, against + φλογιστός, burnt up; φλογίζειν, set on fire, φλέγειν, burn]: adapted to subdue inflammation or excitement of the system in inflammatory diseases; applied to such remedies are purgatives and blood-letting.

Ant'iphon (Ἀντιφῶν): one of the ten Attic orators; b. at Rhamnus in Attica about 480 B. C.; gained great repute as a teacher of rhetoric, and as a composer of orations for politicians and for those who were accused of capital offenses. The praise bestowed on him by Thucydides is accountable for the notion that the historian was the pupil of the orator. He took an active part in the oligarchical reaction of the Four Hundred (see GREEK HISTORY), was convicted of treason, and executed in 411. Of the fifteen speeches extant, all murder cases, twelve are mere skeletons for fictitious trials, three have more life, and one of these three (*On the Murder of Herodes*) a certain historical interest. Antiphon is important as an exemplar of early rhetorical art, the stiffness and formality of which do not disguise acuteness and force. See Blass, *Attische Beredsamkeit*, i. 91 foll.; Jebb, *Attic Orators*, i. 1 foll. Ed. with elaborate commentary by Mactzner, 1838. Text ed. by Blass, 2d (1881).

B. L. GILDERSLEEVE.

Antiphon [from Gr. ἀντίφωνος, sounding in response; ἀντί, against + φωνή, voice]: a piece of music performed in cathedral service by choristers, who sing alternately; a short verse which was sung in the ancient Church before the psalms and other portions of the service.

Antiph'ony: a species of musical accompaniment in the octave by instruments or voices.

ANTIPHONY is also a sacred song sung by two parties, each responding to the other; the answer of one choir to the other when an anthem is sung alternately. This practice prevailed among the ancient Hebrews and in the early Christian Church. Ignatius, Bishop of Antioch, is said to have introduced it into the Eastern Church in the second century.

Antip'odes [from Gr. plur. of ἀντίπους, having the feet opposite; ἀντί, against + πούς, foot]: in geography, people who live on opposite sides of the globe, and whose feet point against each other. The antipodes of any place are those who live at the other end of a straight line drawn from that place through the center of the earth to its opposite surface. Thus the antipodes of London, which is in lat. 51° 30' N. and lon. 0°, must be in lat. 51° 30' S. and lon. 180° E. or W. The noon of any point corresponds with the midnight of its antipodes, and the summer of one coincides with the winter of the other.

Antipodes: a small island in the South Pacific Ocean, S. E. of New Zealand; lat. 49° 32' S., lon. 178° 42' E. It is so called because it is the nearest land to the antipodes of London. See map of World, ref. 8-D.

An'tipope: one who assumes or usurps the office of pope, but is not regularly elected or generally recognized as such. The Emperors of Germany in several instances, having quarreled with the pope, appointed another person to the office. The Emperor Henry IV. in 1080 appointed the antipope Clement III. in opposition to Pope Gregory VII. In some cases two rival popes have been elected by different parties of cardinals. The great Western schism began in 1378, when the Italian party chose Urban VI., and the French cardinals voted for Clement VII., who held his court at Avignon, and was recognized by France and Spain. This schism was continued after their death by another double election, but in 1415 the Council of Constance deposed both of the popes, and elected Martin V. The last antipope was Felix V. (originally Amadeus VIII. of Savoy), who was elected in 1439, and abdicated in 1449.

Antipy'rin [from Gr. ἀντί, against + πυρ(ετός), fever]: chemically, dimethoxyquinizine; a compound prepared by a patented process, and much used in medicine, in the dose of ten to twenty grains, for the purpose of reducing temperature in fever and for relief of pain. The fall of temperature in fever is due to lessened heat production, and not to the excessive sweating which accompanies it. Pains dependent upon inflammations are not relieved by antipyrin, but nerve-pains, such as many headaches and neuralgias, are greatly affected by it. Antipyrin is also a useful remedy in epilepsy, especially in combination with bromides. The symptoms produced by an overdose, or the too long-continued use of the remedy, are languor, malaise, a peculiar livid pallor of the face, failure of the pulse and of the general strength. An eruption upon the surface resembling measles is not uncommon. Sometimes the eruption is accompanied by much œdematous swelling, and it may resemble urticaria or be replaced by a furious inflammation of the skin. The full effect of antipyrin is usually reached in from one to two hours, and continues from three to ten hours.

Antipyrin is not, unless in very large doses, depressing to the heart, and the collapse which has occasionally followed its use in fever has probably been due to some indirect influence rather than to the direct action of the drug. The free habitual use of antipyrin is certainly deleterious to the general health, and the livid color which the drug produces (when in large dose) is due to its altering the hæmoglobin of the red blood corpuscles into methæmoglobin.

H. C. WOOD.

An'tiquaries, Society of: the title of several associations of learned men, formed to promote the study of antiquities. The London Society of Antiquaries was founded in 1572, and reorganized in 1707, but received its charter in 1751. The Scottish Society of Antiquaries was founded in 1780. The American Antiquarian Society was organized in Massachusetts in 1812.

Antiquary [from Lat. *antiquarius*, pertaining to antiquity; *antiquus*, ancient]: originally a person who copied old books in convents before the invention of printing. In modern language an antiquary is one who studies and collects ancient monuments and remains, such as medals, coins, statues, manuscripts, and inscriptions; or who makes researches into the history, manners, and customs of former generations. The antiquary renders an important service to society by collecting materials for history and rescuing many documents from the ravages of time.

Antiq'uities [Lat. *antiquitates*, deriv. of *antiquus*, ancient]: an important department of learning, comprises all memorable facts, ideas, and things which relate to or illustrate the origin, early institutions, and development of nations. Thus the study of antiquities, in the largest application of the term, includes a knowledge of the religion, laws, language, arts, traditions, manners, and customs of ancient peoples, as well as a cognizance of ancient monuments of architecture, sculpture, and other arts. In a more restricted and perhaps more popular sense the study of antiquities is limited to the discovery, collection, verification, description, and explanation of the relics of antiquity, such as medals, statues, inscriptions, manuscripts, ruined buildings, bas-reliefs, and hieroglyphics. About the time of the revival of learning after the Dark Ages the study of classical antiquities became a distinct branch of research, which was pursued by many eminent scholars. Grævius published a valuable work on Greek antiquities, entitled *Thesaurus Antiquitatum Græcarum* (12 vols. fol., 1697 et seq.); and Roman antiquities were amply illustrated by Gronovius in his

Thesaurus Antiquitatum Romanarum (13 vols. fol., 1697). Champollion, Young, Bunsen, Lepsius, and Brugsch are the highest authorities in Egyptian antiquities. Among the best antiquarian works may be mentioned Montfaucon, *Antiquité Expliquée* (15 vols., 1719-24); Heeren, *History of Ancient Commerce*; Dr. W. Smith's *Dictionary of Greek and Roman Antiquities*; Montfaucon, *Monuments de la Monarchie Française* (5 vols., 1725). For the difference between archaeology and antiquities, see ARCHÆOLOGY.

Anti-rent'ers: those inhabitants of several counties in Eastern New York who refused to pay the rents and feudal services required of them by the so-called lord-patrons, the owners of the land. This disturbance, which at one time nearly amounted to insurrection, was at length ended by the triumph of the Anti-rent party in the constitutional convention of 1846, in which a clause was inserted abolishing thenceforth all feudal tenures and incidents.

Antiscorbu'tics [from Gr. *ἀντί*, against + Late Lat. *scorbutus*, scurvy, from Low Ger. *schorbock* or *scorbut*]: remedies of *scorbutus*, or scurvy (*q. v.*). Onions, lime-juice, potatoes, lemons, horseradish, scurvy-grass, etc., are the best antiscorbutics. Diet, and not medicine, is needed to effect the cure.

Anti-Semitic Movement: a movement against Jews as Jews, based on popular prejudice and helped by the undeniable success of the Jews in those branches of trade and manufacture in which they compete with Christians. The hatred of Jews has been a glaring inconsistency in the Christian world for many centuries, but of late all over Europe there has been a more or less organized effort to put the Jews back into the political bondage from which they have lately been delivered. In this disgraceful movement Russia has played the chief part among nations, and among individuals the ex-court-preacher Stöcker in Germany. See JEWS, PERSECUTION OF. S. M. J.

Antisept'ic [from Gr. *ἀντί*, against + *σηπτικός*, putrefying; from *σῆπειν*, to rot]: opposed to or preventing putrefaction. Antiseptics are substances which prevent or check the decay and putrefaction of organic matters. As air, moisture, and heat are necessary conditions of putrefaction, the exclusion of one of these from the animal or vegetable matter is an antiseptic process. The common practice of preserving fruit in air-tight cans of tin or glass is an illustration of this principle. Generally speaking, so long as the air is excluded no decomposition or decay can take place. Cold is a powerful antiseptic; intense cold will prevent change even in those substances which putrefy most readily. To render timber more durable and less liable to decay, corrosive sublimate, chloride of zinc, and heavy oil of tar are sometimes used. For this purpose the wood is placed in a steam-box, its pores are filled with steam, and a vacuum is formed in the pores by the condensation of the steam. The pores are then filled with the antiseptic substance.

The more important chemical antiseptics are—alcohol, wood-spirit (or pyroxylic acid), creosote, carbolic acid, heavy oil of tar, sugar, glycerin, many aniline derivatives, sulphurous acid, common salt, charcoal, niter, alum, chloride of zinc, sulphate of copper (blue vitriol), cresylic acid, sulphate of iron, aluminum chloride and acetate, other aluminum compounds, corrosive sublimate, and arsenic. Sulphurous acid acts by deoxidizing the substance; sugar acts by combining with the water of the substance to be preserved; creosote, tannic acid, alun, chloride of zinc, sulphate of copper, corrosive sublimate, and arsenic form compounds with the organic matter which are not liable to become putrescent; alcohol, salt, and niter act both by combining with the water of the putrescible substance, and by combining with the substance itself. See DISINFECTION, FERMENTATION, PRESERVATION OF FOOD, and PRESERVATION OF TIMBER. Revised by R. PARK.

Antispasmod'ics: medicines which cure or alleviate spasm. The name is frequently limited to a small class of drugs which have usually a strong and often an unpleasant odor, and which in some cases act as diffusive stimulants. Such are valerian, assafœtida, myrrh, musk, camphor, ether, etc. Others are sedatives, as hydrocyanic acid. The term might well include the other nerve-sedatives or depressors of reflex action, like bromide of potassium, belladonna, Calabar bean, curari, etc. The best treatment for spasmodic symptoms aims, however, at the restoration of health by proper food, good air, and correct habits of life, and by such special treatment as may be required to remove the cause.

Antis'thenes [in Gr. *Ἀντισθένης*]: an eminent Greek Cynic philosopher, called the founder of the Cynic sect or school; b. at Athens, and flourished about 400 B. C. He was a young man when he served at the battle of Tanagra, 426 B. C. He was a pupil and friend of Socrates, whose death he witnessed. After this event he opened a school at Athens in the gymnasium of Cynosarges, where the famous and witty Diogenes became one of his pupils. He was a man of temperate habits and simple mode of life, inculcating a contempt of riches and sensual pleasure. He maintained that virtue is all-sufficient for happiness and directed his attention chiefly to practical morality. His works on various subjects are lost, but several of his sententious and pithy sayings have been preserved. Socrates reproved the poverty of his dress and his neglect of the conventional by saying: "I can see thy pride through the holes in thy robe." Antisthenes was living in 371 B. C. See Zeller's *Socrates and the Socratic Schools*. Revised by W. T. HARRIS.

Antitox'in: a substance having the power to combat the poison of micro-organisms. It has been found that infection of the animal body with bacteria gives rise to the production of certain toxins which occasion most of the symptoms of infectious diseases, and which differ widely in their action with the different micro-organisms. Subsequently the organism produces other substances having antagonistic powers, and these have been called the antitoxins. Both the toxins and the antitoxins are found in the blood, and the preparations now used in medical practice are obtained from the blood of animals which have been gradually placed under the influence of increasing doses of toxins of the various bacteria. In this way an increasing quantity of antitoxin is produced in the blood of the animals, and is finally obtained by bleeding the animal and separating the serum from the solid constituents of the blood.

Antitoxins have been successfully employed only for diphtheria and tetanus, though experimentation with other micro-organisms has been performed. The results have been partially satisfactory. See SERUM THERAPEUTICS.

WILLIAM PEPPER.

Anti-Trinitarians: See UNITARIANISM.

An'tium (in It. *An'zo*): an ancient city of Latium, on the seacoast, 34 miles S. S. E. of Rome; was a favorite resort of opulent citizens of Rome, in whose villas famous works of art have been discovered. Among these was the Apollo Belvedere, and the Borghese Gladiator, mentioned under AGASIAS (*q. v.*). The Emperors Caligula and Nero were natives of Antium, the site of which is now occupied by a village called Porto d'Anzo (i. e. the port of Antium).

Antiv'ari: the only seaport of Montenegro, on the Adriatic; 14 miles N. W. of Scutari, acquired as a result of the Russo-Turkish war of 1877-78. The harbor is shallow, and admits only small vessels. It exports oil, etc., and has, with its suburbs, about 1,000 houses. Pop. about 5,000.

Ant-lion: the larva of several species of *Myrmeleon*, and other cognate genera, insects of the order *Neuroptera*,

Ant-lion.

found in sandy tracts in different parts of the world. The perfect insect is similar in appearance to the dragon-fly.

The larva is remarkable for the curious and insidious mode in which it catches the ants and other insects on which it feeds. It excavates a funnel-shaped cavity in the sandy soil, and lies in wait at the bottom until an insect comes so near to the edge of the pit that the loose sand gives way and the insect falls down the slope. Several species of antlion are found in the U. S.

Antofagas'ta: a province in the northern part of Chile; occupying the entire width of the state from Tarapaca on the N., from which it is separated by the Rio Loa (mouth in lat 21° 30' S.), to Atacama on the S., boundary the parallel of 26°. The area is 60,968 sq. miles, making it the largest province in the state, except the comparatively uninhabitable Magellan territory in the extreme S. Pop. (1891) 35,317. This province comprises the territory ceded by Bolivia as a result of the war of 1879-82. Bolivia has the right to free transport of goods over the state to her own custom-houses. Much of the province lies in the desert of Atacama, which is a rocky, not a sandy, waste. It is not generally suitable for agriculture, but it is one of the richest regions in the world in the ores of the precious metals. Antofagasta, the capital and principal port, has a population of 8,000 or 10,000. It is the littoral terminus of a railroad which reaches the rich mining districts to the N. E. (see map of South America, ref. 6-C). It has silver-smelting works, and ships much bullion, ore, and nitrate of soda. Toltal is the littoral terminus of a railroad extending to Cachinal, while the Antofagasta road sends a branch to the thriving port of Morro Mejillones. M. W. H.

Antommar'chi, FRANCESCO: Italian anatomist; b. in 1780; a native of Corsica; became in 1812 anatomical dissector to a hospital of Florence, attached to the University of Pisa. In 1819 he was sent for to attend Napoleon at St. Helena. The ex-emperor was so well pleased with him that he left him a legacy of 100,000 francs. He published *The Last Moments of Napoleon* (2 vols., 1823). In 1836 he settled in New Orleans as a homœopathist. He died at St. Antonio in Cuba, Apr. 3, 1838.

Antonel'li, GIACOMO: Italian cardinal and politician; b. at Sonnino, Apr. 2, 1806. He became grand treasurer of the two apostolic chambers in 1845, and was appointed minister of finance by Pius IX. soon after his election (1846). In 1847 he was made cardinal-deacon. He acquired much influence with the pope, and opposed the liberal movement of 1848. In 1849 he was appointed papal secretary of foreign affairs (i. e. prime minister), which place he occupied when Rome, in 1870, was incorporated with the kingdom of Italy. He strenuously opposed the cause of Italian unity. He left property to the amount of 100 million lire. D. in Rome, Nov. 6, 1876.

Antonel'lo, or **Antonelli**, ANTONIO (surnamed *Da Messina*, from the place of his birth): painter; b. at Messina in 1414. He is reputed to be the first Italian who painted in oil, having visited Bruges and obtained from J. van Eyck the secret of oil-painting. He returned to Italy about 1445, after which he worked at Milan, and removed to Venice about 1470. He gained distinction by the brilliance of his coloring. D. in Venice, 1493.

Anto'nia, MAJOR, or the ELDER: a Roman lady; daughter of Mark Antony the Triumvir; b. in 39 B. C. Her mother was Octavia, a sister of Augustus Cæsar. She was married to L. Domitius Ahenobarbus, and was the grandmother of Nero.—Her sister, ANTONIA MINOR (the younger), was born 36 B. C. She was the wife of Claudius Drusus Nero, and mother of the famous Germanicus and of the Emperor Claudius. She is said to have been virtuous and fair. D. in 37 or 38 A. D.

Anto'nides van der Goes: See GOES, ANTONIDES VAN DER.

Antoni'us, MARCUS AURELIUS (usually called *Marcus Aurelius*, and sometimes surnamed *The Philosopher*): a Roman emperor highly distinguished for his wisdom and virtue; b. in Rome, Apr. 26, 121 A. D. He was a son of Annius Verus and Domitia Calvilla, and his original name was Marcus Annius Verus. He became a disciple of the Stoic philosophy, with the principles of which his habitual conduct was consistent. Having been adopted as a son by the Emperor Antoninus Pius in 138 A. D., he assumed the name of M. Ælius Aurelius Verus Cæsar. He then admitted Lucius Commodus (or Lucius Verus) to a share of the imperial power, but the latter died in the year 169. Before this date the Roman army gained several victories over

the Parthians. Although the temper of Marcus Aurelius was pacific, he was involved in frequent wars by the aggressions of northern barbarians and the revolts of his subjects. He conducted in person an expedition against the Marcomanni, which was successful, in 168 A. D., and afterward drove them out of Pannonia. In 174 A. D. he gained over the Quadi a famous victory, which was reputed miraculous. According to Dion Cassius and other writers, the Romans, who were suffering with thirst, were refreshed by a shower of rain, while their enemies were demoralized by a violent storm of hail. In 176 the emperor visited Syria and Egypt, and displayed great clemency toward those who had been implicated in the rebellion of the previous year, headed by Avidius Cassius, one of his generals, who had obtained possession of Egypt and part of Syria, but who had been killed by his own officers. On his homeward journey he passed through Athens, where he founded a chair of philosophy for each of the four sects, Platonic, Stoic, Peripatetic, and Epicurean. His ardent love of learning continued unabated in advanced age, and he cherished constantly, amid the turmoil of war and the distractions of public life, his philosophic and philanthropic aspirations. No monarch was ever more warmly and generally beloved by his subjects. It is a strange anomaly in his character and conduct that he persecuted the Christians, but explicable on the ground that he considered them atheists and fomenters of political dissension. During a campaign against his inveterate enemies, the Marcomanni, he died at Sirmium or at Vindebona (Vienna), Mar. 17, 180 A. D., and was succeeded by his son Commodus. He was author of an excellent ethical work in Greek, called *Meditations*, a good English version of which, by George Long, appeared in 1862, under the title of *Thoughts of M. Aurelius Antoninus*. Besides, we have some Latin letters of his, edited by Naber (Leipzig, 1867), among the works of Fronto. See Farrar's *Seekers after God* (London and New York, 1869); Renan's *Marc Aurele* (Paris, 1881).

Revised by C. K. ADAMS.

Antoninus, Column of: a pillar in the Piazza Colonna in Rome. It is a combination of the Corinthian and Doric orders, and is adorned with bas-reliefs of the victories which Marcus Aurelius gained over the Marcomanni, in memory of which it was erected by the Roman Senate.

Antoninus, Itinerary of: valuable geographical work, the date and author of which are unknown. It contained the names of all places and stations on the roads of the Roman empire, with their distances in Roman miles.

Antoninus Pius (or, more fully, **Titus Aurelius Fulvius Boio'nus Ar'rius Antoninus**): a Roman emperor; b. at Lanuvium, Sept. 19, 86 A. D., was a son of Aurelius Fulvus. He was chosen consul in 120 A. D., and married Anna Galeria Faustina. Having, as proconsul in Asia, distinguished himself by his wisdom and equity, he was adopted by Hadrian in 138 A. D., and he ascended the throne on the death of Hadrian in July of that year. He adopted as his successor Marcus Aurelius. His reign was so peaceful and prosperous that it furnishes but scanty materials for history. Antoninus promoted literature, and treated the Christians with mildness. As a man he was temperate, humane, learned, and eloquent. The name of "Pater Patriæ" (father of his country) was given to him by the vote of the Roman Senate. He had two sons, whom he survived. He died in Rome, Mar. 7, 161 A. D., and was succeeded by Marcus Aurelius. His memory was greatly venerated by the Romans of his own and later ages. See Bossert und Müller, *Zur Geschichte des Kaisers Antoninus* (Leipzig, 1868); Lacour-Gayet, *Antonin le Pieux et son temps* (Paris, 1888).

Revised by S. M. JACKSON.

Antoninus, Wall of (in Lat. *Antoni'ni Vallum*): a rampart or intrenchment raised in Scotland by the Romans under Lollius Urbicus, in the reign of Antoninus Pius, in 139 A. D. It extended from the Clyde to the Frith of Forth, was 36 miles long and 20 feet high, and was built of earth and stone. Its remains are called "Græm's dyke."

Anto'nio, NICOLAS: Spanish critic and bibliographer; b. at Seville in 1617. He published *Bibliotheca Hispana Nova* (2 vols., 1672), and *Bibliotheca Hispana Vetus* (2 vols., 1696), which contain catalogues of all the Spanish books, with biographical notices, and are highly esteemed. He was Spanish agent at Rome 1659-81. D. Apr. 13, 1684.

Anto'ninus, CAIUS HYBRIDA: Roman consul; son of M. Antonius the Orator, and an uncle of Mark Antony the Triumvir. He was chosen consul as the colleague of Cicero

in 63 B. C. He was a profligate politician, and did not earnestly co-operate with Cicero in opposing the conspiracy of Catiline. D. in 44 B. C.

Antonius, MARCUS (called *The Orator*): an eminent Roman orator and lawyer; b. in 143 B. C.; was grandfather of the famous Mark Antony. He became prætor in 104, and consul in 99 B. C., and was attached to the aristocratic party. Having become an adherent of Sulla in the civil war, he was assassinated by the order of Marius in 87 B. C. He was perhaps the most eloquent Roman orator of his time. His eloquence is highly eulogized by Cicero in his treatise *De Oratore*, and in his *Brutus*. The orations of Antonius are not extant. See II. Meyer, *Oratorum Romanorum Fragmenta* (ed. ii., 1842, p. 280).

Antonius, MARCUS (surnamed **THE TRIUMVIR**, and commonly called in English **Mark Antony**): a celebrated Roman general and politician, b. in 83 B. C.; was a son of M. Antonius Creticus. His mother, Julia, was a daughter of L. Julius Cæsar, who was consul about 90 B. C. He obtained about 57 B. C. command of the cavalry of Gabinius, in Syria and Egypt. Having been elected quæstor in 53 or 52, he served in Gaul as legate of Cæsar, and displayed superior talents in several campaigns. Through the influence of Cæsar he was elected augur and tribune of the people in 50 B. C. As tribune he promoted the interest of Cæsar, and vetoed a decree of the Senate which ordered Cæsar to disband his army. Early in 49 B. C. he fled from Rome to Cæsar's camp. After the civil war began, and Cæsar passed into Spain, he appointed Antony commander-in-chief of his forces in Italy. The latter commanded the left wing at the battle of Pharsalia, 48 B. C. In the year 47 he became master of the horse to Cæsar, who was now invested with the office of dictator. He negotiated with Brutus and Cassius, and temporized with the Senate, whom he induced to ratify the acts of the late dictator. His eloquent funeral oration over the body of Cæsar excited such popular indignation against the conspirators that they were compelled to retreat from Rome. In 43 B. C. Antony was defeated in battle by the consuls Hirtius and Pansa at Mutina (now Módena). About this time he was denounced by Cicero in a series of famous orations, called "Philippics." Before the end of the year 43, Antony, Octavius, and Lepidus united to form a league (triumvirate) against the Senate and the republicans, many of whom were put to death by the myrmidons of the triumvirs. At the instigation of Antony, Cicero was proscribed and killed. It was the military skill of Antony which defeated Brutus and Cassius at the decisive battle of Philippi (42 B. C.), which rendered the triumvirs masters of the Roman world. This victory was followed by another bloody proscription. Antony, who received for his share of the empire the Asiatic provinces and Egypt, now gave himself up to pleasure and luxury. He was so captivated by Cleopatra, Queen of Egypt, that he neglected public affairs, while Octavius was marching with stealthy steps toward supreme and undivided power. Antony and Octavius were involved in a quarrel in the year 41, but they were formally reconciled in 40 B. C., and Antony then married Octavia, the sister of his rival or colleague. He soon divorced Octavia and returned to his dalliance with Cleopatra. The conflict which had been postponed now became inevitable, and Antony was defeated at the naval battle of Actium, in Sept., 31 B. C. He then retreated to Alexandria in Egypt, and was deserted by his fleet. Reduced to a desperate extremity, he killed himself in 30 B. C. He left two sons, Iulus and Antyllus. See Plutarch, *Life of Antony*; Drumann, *Geschichte Roms*; Appian, *Bellum Civile*.
Revised by C. K. ADAMS.

An'tony, or Anthony, SAINT (surnamed *Abbas*): an eminent anchorite, called the founder of monachism; b. at Coma, in Upper Egypt, in 250 A. D. He reduced himself to voluntary poverty, and retired to a desert, where he passed many years in ascetic devotion and solitude. About 305 he founded a monastery near Fayoum (or Phaiûm). He was an opponent of Arianism, and was venerated as a saint and oracle by his contemporaries. During the persecution of the Christians in 311 he went to Alexandria in the hope of obtaining the crown of martyrdom, but he was disappointed, and returned to the desert. He had an interview many years later with Athanasius, to whom is attributed the well-known account of his life, but there is grave doubt whether he really did write it. Some of the letters of St. Antony are extant. D. near the Red Sea, Jan. 17, 356 A. D.

Antony, or Anthony (SAINT), of Padua: b. at Lisbon, Aug. 15, 1195. He became a Franciscan monk, and preached

at Toulouse, Bologna, and Padua, where he died June 13, 1231. According to a legend, he once preached to the fish in the sea an eloquent sermon, because men would not listen to him, which attracted the devoted attention of his finny auditors. This sermon is extant. An abstract of it may be seen in Addison's *Remarks on Italy*. He was canonized in 1232. He is the patron saint of the animals.

Antony of Bourbon (in Fr. *Antoine de Bourbon*): Duke of Vendôme and King of Navarre; b. in Picardy, Apr. 22, 1518. He was a brother of the Prince of Condé. He married, in 1548, Jeanne d'Albret, the only child of the King of Navarre. In 1560 he was appointed lieutenant-general of France. Soon after that date he formed a coalition with the Duke of Guise and Constable Montmorency, and became a Roman Catholic. He commanded the royal army in the civil war, and was mortally wounded at Rouen, and died Nov. 17, 1562. He was the father of Henry IV. of France.

An'trim: the extreme N. E. county of Ireland; province of Ulster; bounded N. by the Atlantic, E. by the Irish Channel, S. by the Lagan river, and W. by the river Bann. Area, 1,237 sq. miles (see map of Ireland, ref. 4-I). The surface near the seacoast is hilly, and the soil is mostly light. The rock which underlies it is basaltic trap, with some new red sandstone. Lignite of good quality is mined. On the north coast is the famous Giant's Causeway, one of the most perfect examples of columnar basalt in the world. Oats and flax are the staple products of the soil. The county has extensive manufactures of linen and cotton. The earliest known inhabitants of this county were of Celtic origin. It was exposed to the inroads of the Danes and the Northern Scots, who finally made permanent settlements here. It has numerous ancient cairns, mounts or forts, cromlechs, round-towers, castles, etc. The noble castle of Carrickfergus is the only one perfectly preserved. Antrim is one of the most decidedly Protestant counties in Ireland. Chief town, Belfast. Pop. (1881) 423,171; (1891) 427,968. A battle was fought near the town of Antrim in this county between the English and Irish, in the reign of Edward III., and on June 7, 1798, a severe conflict took place there between the British army and a large body of rebels (United Irishmen), in which the latter were defeated.

Revised by M. W. HARRINGTON.

Ant-thrush: See the Appendix.

Ant'werp (Fr. *Anvers*): a province of Belgium; bounded N. by Holland, E. by Limbourg, S. by South Brabant, W. by the river Scheldt. Area, 1,093 sq. miles (see map of Holland and Belgium, ref. 9-E). The river Dyle forms part of its southern boundary. The soil is generally fertile, and produces grain, hemp, madder, hops, and pine timber. Capital, Antwerp. Pop. (1880) 577,232; (1896) 784,975.

Antwerp (Dutch *Antwerpen*, i. e. *aent werp*, on the wharf; Lat. *Antuer'pia*; Fr. *Anvers*, an'-vâr'; Sp. *Ambéres*): the chief commercial city of Belgium and capital of the province of same name; on the right bank of the Scheldt; 26½ miles by rail N. of Brussels; lat. 51° 13' N., lon. 4° 24' E. (see map of Holland and Belgium, ref. 9-E). It is strongly fortified, and has among its defenses a citadel built by the Duke of Alva in 1567. The magnificent public buildings, the numerous churches, the stately and antique houses, and the profusion of ornamental trees, render the general appearance of the city very picturesque. The streets are tortuous and irregular, but one of them, called the Place de Meir, is scarcely surpassed in beauty by any street in Europe. Foremost among the public buildings is the cathedral, one of the largest and most beautiful specimens of late and florid Gothic architecture in Europe, and has a tower and spire of extraordinary beauty. It is 500 feet long and 240 feet wide (having five aisles), and contains the principal masterpieces of Rubens. Among the other public edifices are the exchange and the marble hôtel de ville. The principal institutions are the Academy of Sciences, the Academy of Painting and Sculpture, a rich gallery of pictures, a public library, a zoölogical garden, and a botanic garden. Antwerp has a good harbor, which will admit the largest vessels, and has excellent railway connections with all parts of Europe. It has an extensive trade, and is an important market for hides. Here are manufactures of black silk stuffs, cotton, linen, lace, carpets, sewing-silk, and printer's ink. Antwerp was a city as early as the eighth century, and in the fifteenth and sixteenth was the great center of European commerce. It is stated that 509 vessels daily entered its port. It was besieged and taken by the Prince of Parma in 1585, soon after which much of its commerce was transferred to Amsterdam.

By the treaty of Paris, Antwerp, with the rest of Belgium, was annexed to the kingdom of Holland in 1814. In the popular rising of 1830 against that Government the citadel was held by Dutch troops under command of General Chassé. The resulting siege of Antwerp by the French was a fine practical example of the science of sieges, which excited the interest of military amateurs of all nations. The defense exhibited a conspicuous example of fortitude and endurance. The capitulation took place Dec. 24, 1832, the trenches having been opened Nov. 30. During recent years Antwerp, the true military capital of Belgium, has been fortified under a very distinguished engineer, Colonel Brialmont, as the central point of a great intrenched camp on the Scheldt, by a system of works "unrivaled in Europe in the intelligent application of the true principles of art to a great practical example." The most remarkable feature, however, in the recent history of the city is the marvelous development of its commerce during the last few years. About 4,500 vessels, of some 4,000,000 tons burden, enter the harbor annually, which places it at the head of all continental ports of Europe, far exceeding Bilbao, Genoa, Havre, Hamburg, etc., and ranking immediately after London, Liverpool, and New York. The causes of this unexpected development were the abolition in 1863 of the entrance-toll on the Scheldt and the construction in 1877 of magnificent quays and docks, at a cost of some \$20,000,000. Pop. (1896) 267,902.

Revised by C. K. ADAMS.

Antwerp: village; on Rome, Watertown and Ogdensburg R. R., Jefferson co., N. Y. (for location of county, see map of New York, ref. 2-G); the seat of the Northern New York Conference Seminary. Two hundred thousand tons of iron ore are raised from beds in this vicinity per year. Pop. (1880) 731; (1890) 912; (1900) 929.

Antwerp: village; Paulding co., O. (for location of county, see map of Ohio, ref. 2-C); on Wabash R. R. and on Maumee river, 72 miles S. W. of Toledo; has iron and clay industries. Pop. (1880) 1,275; (1890) 1,331; (1900) 1,206.

Anu'bis, or **Anepu**: a god of the Egyptians; represented as a son of Osiris, and as having the form of a jackal, a dog, or a man with a jackal's head (the Greeks took this for a dog's head). His worship commenced in the earliest times of Egyptian history, and was continued in some form till superseded by Christianity. The Greeks confounded him with Hermes, and called him Hermanubis. His worship spread to Rome. Among the Egyptians he was the god of embalming and of funeral rites, and was the escort of the soul to the under-world. He was also called *Ap-heru*, signifying "the opener of the paths supposed to lead to heaven."

Anu'ra [from Gr. *ἀ-*, not + *οὐρά*, tail]: the order of tailless batrachians, typified by the frog and toad. Striking characters are the loss of the tail and gills in the process of development, and the acquisition of strong hinder limbs. The young are called tadpoles. See SALIENTIA.

An'varī, or **An'wari**, **AUHAD UD-DĪN**: Persian poet; b. at Khorassan in the twelfth century. He is classed with Firdausi, Hafiz, and Saadi as one of the masters of the Persian Parnassus. He enjoyed the favor of the Seljukide Sultan Sanjar, at whose court he passed many years. He wrote numerous lyrical poems; also some longer panegyrics. His elegy on the capture of Sanjar by the Ghaurians has been translated into English. Having turned his attention to astrology, and having predicted that a great hurricane would occur in 1185 or 1186, he fell into disgrace when his prediction was not fulfilled. D. about 1200.

Revised by A. V. WILLIAMS JACKSON.

Anville, **JEAN BAPTISTE BOURGUIGNON, d'**: a French geographer; b. in Paris, July 11, 1697. He devoted his whole life to the study and improvement of geography, and is recognized as the first who raised geography to the rank of an exact science. He was appointed geographer to the king, and became a member of the Academy of Sciences. Among his works are *Orbis Romanus* (Roman World); *Orbis Veteribus Notus* (The World known to the Ancients); and a *Compendium of Ancient Geography* (in French, 3 vols., 1768). He published 211 maps and plans, which embrace nearly every country in the world. Although he never traveled, he delineated various foreign countries with remarkable accuracy. The correctness of his map of Egypt was confirmed by the French survey of 1798-99. D. in Paris, Jan. 28, 1782. See Condorcet, *Éloge de M. d'Anville* (1762).

An'yte (*Ἀνύτη*) of **Tegea**: a famous poetess of her day (290 B. C.); "a female Homer." We have twenty-two epi-

grams under her name that give some warrant for her reputation.

Anziu, *ān'zāi'*: a town of France; department of Nord; a mile N. W. of Valenciennes (see map of France, ref. 2-G). It has iron-foundries and glass-works, and is the center of the greatest collieries of France. Pop. 10,043.

Ao'nia: a district of ancient Greece; in Bœotia; contained Mt. Helicon (the Aonian mount) and the fountain Aganippe. These were celebrated as the favorite resorts of the Muses, who were called *Aon'ides*.

A'orist [Gr. *ἀόριστος*, unlimited; *ἀ-*, not + *ὀρίζειν*, define, limit; *ὄρος*, boundary]: a form of the Greek verb which simply names an action as an occurrence, and was so called by the Greek grammarians because it did not further define the action of the verb, e. g. with reference to its continuation, or its present or past completion. The Greek grammarians also used the term of the pronouns which we call "indefinite," as *ὅστις*, *ὅποιος*, *ὅπόσος*, "whoever," etc.

BENJ. IDE WHEELER.

Aor'ta [from Gr. *ἀορτή*, something suspended; *ἀείρειν*, raise, suspend; because it is supported or suspended from the heart]: the large arterial trunk arising from the left ventricle of the heart, and giving origin directly or indirectly to all arteries except the pulmonary and its ramifications. The curve that it makes in the upper part of its course, during which it sends off the innominate and the left carotid and subclavian arteries, is called the arch of the aorta. The *thoracic* aorta extends from the third dorsal vertebra to the diaphragm, where it takes the name of *abdominal* aorta, which in the lower part of the abdomen, about opposite the fourth lumbar vertebra, divides into the two iliac arteries, going to supply the lower extremities. The thoracic aorta gives off two or three bronchial arteries to supply the tissue of the lungs and intercostal arteries to the chest-walls. The abdominal aorta gives off two phrenic arteries to the diaphragm and a number of branches to the abdominal organs. See CIRCULATION OF THE BLOOD.

Aosasaguntacooks, or **St. Francis Indians**: See ALGONQUIAN INDIANS.

Aos'ta (anc. in Lat. *Augusta Prætoria*): a town of Italy, in the province of Turin; on the river Dora, in a valley 50 miles N. N. W. of Turin (see map of Italy, ref. 2-B). It has a Gothic cathedral, the remains of a Roman amphitheater, and a fine triumphal arch. The valley of Aosta produces large forests of pine, and has mines of copper, silver, iron, and lead. Cheese, leather, wine, and hemp are exported. Pop. (1881) 7,437.

Apaches, a-pach'ēes: See ATHAPASCAN INDIANS and YUMAN INDIANS.

Ap'afi, **MICHAEL** or **MIHALY**: Prince of Transylvania; b. in 1632. He began to reign in 1661, and was for many years an ally of the Turkish sultan. In 1687 he became tributary to the Emperor of Germany. D. April 15, 1690. He was succeeded by his son Mihaly, under whom Transylvania was invaded by the Turks, who took several towns. He sold his principality to Austria for a pension. D. Feb. 11, 1713.

Apalachicola, Fla.: See APPALACHICOLA.

Apame'a: an ancient city of Syria, on the river Orontes, which here expands into a lake named Apamea, about 75 miles S. of Antioch. It was probably named in honor of Apame, the wife of Seleucus Nicator. The place was called *Famieh* in the time of the crusades. Its extensive ruins still exist. There were several other ancient cities of this name in Asia.

Ap'anage, or **Ap'panage** [Fr. from *apaner*, furnish with food; from Lat. *ad*, to + *panis*, bread]: in feudal law, an allowance to the younger sons of a sovereign or prince out of the revenues of the country, generally joined with a grant of the public domain. In England the Duchy of Cornwall is an apanage of the Prince of Wales, but the younger sons of the sovereign are dependent upon the liberality of Parliament.

Apartment-house: a building containing more than three families under one roof. Tenement-houses are classed in the same way, but usually have more than one family on a floor. Such buildings have been common in Scotland, and in the large cities of the Continent of Europe for a century or more, but are of recent introduction in the U. S. They are mainly the result of the increased cost of living, the enhanced value of building-lots, the greater profit to be ob-

tained from high rather than from low buildings, and the relative economy of living in flats.

By the introduction of many labor-saving devices in apartment-houses, such as automatic door-openers, speaking-tubes, passenger and freight elevators, ash-shoots, trunk-rooms, combined laundries, and restaurants on the catering system, it is now possible to erect buildings ten, and even thirteen, stories high, which will comfortably provide for several hundred persons under one roof, and at less rental than in a proportionate number of single dwellings, yet with a higher profit to the owner.

Great ingenuity has been shown in planning apartment-houses so as to economize space to the greatest advantage, and to obtain light and ventilation for every room. Under the amended law recently passed by the New York State Legislature apartment-houses and tenements are prevented from occupying more than 65 per cent. of the building-site, and ample space is required to be left between them and adjacent houses in the rear. In European cities modern apartment-houses are usually built around a central court, with a driveway entrance for carriages, but in U. S. cities many are built upon a single or double city lot, 25 by 100, so that the suites of rooms of necessity extend from end to end, and, unless the building is on a corner, they must be lighted by narrow courts on either side or by light-shafts from above, and often wholly inadequate for the purpose. Few of these flats are fireproof, and several conflagrations have occurred in them.

There has been much agitation in regard to the necessity of limiting the height of buildings of this kind, which are found to be destructive to the value of adjoining property, and also objectionable from a sanitary point of view. One building of this class in New York is fourteen stories high, and the roof is 170 feet above the sidewalk. The Chicago Real Estate Exchange has recommended restricting apartment-houses to 100 feet in height, and a similar regulation is favored in New York. In Berlin such buildings are limited to five stories.

Some of the most notable apartment-houses in New York are remarkable for their size. The Dakota is estimated to have cost nearly \$2,000,000, and is said to be fireproof. It is 200 feet square and 9 stories in height. There are 65 suites, containing 8 to 20 rooms each, or 623 rooms in all. The suites rent from \$1,000 to \$5,600 per annum. There are 4,000 electric lights, 300 electric bells, and 12 water-tanks with a supply of 2,000,000 gal. per month. The annual expenses, including taxes, exceed \$50,000 per year. The Central Park flats constitute eight buildings, each 130 feet high and with 9 stories, having each 16 apartments. The whole cover half a city block on Fifty-ninth Street; the land cost \$1,000,000, and the buildings \$4,000,000 additional. The latter are considered fireproof. The Chelsea, Berkshire, Florence, and Van Corlear are other notable buildings of this class. Recently bachelor flats, to accommodate single gentlemen, have been erected, and have proved very popular.

Some apartment-houses have been erected on the co-operative plan, the occupants of each floor being independent owners of the same, while the title to the land is held in common by the associated owners, who manage the building the same as the affairs of any other corporation. Special laws have been passed by the Legislature of New York regulating the control of such associations and to facilitate their management, but the experiment has not proved a financial success.

Flats have never been popular in England; a few have been erected in London, but they have not become fashionable. They are common in Scotland, and Edinburgh and Glasgow have long been famous for their lofty tenements, some of them 13 and 14 stories high, with tortuous and interminable flights of stairs, which are the wonderment of visitors.

In Parisian apartment-houses persons of quite different social position may reside under the same roof, the *premier étage* or principal story being the home of wealthy people, while the stories above diminish in elegance and expensiveness as they are placed higher; but in the U. S. the use of elevators does away with such distinctions, so that there is a tendency toward a gradual and marked separation of classes, and the greater exclusiveness of the apartment-houses is one reason of their popularity with fashionable people.

CHAS. F. WINGATE.

Apatin': a town of Hungary; county of Bacs-Bodrog; on the left bank of the Danube; 60 miles S. of Baja (see

map of Austria-Hungary, ref. 8-H). It has a trade in silk, madder, and hemp. Pop. 12,821.

Ap'atite [from Gr. *ἀπάτη*, deceit + suffix *-ite* (Gr. *-ίτης*; as in Eng. *siderite*, Gr. *σιδηρίτης*); so called because it deceives the observer by its resemblance to other minerals]: the native phosphate of lime, which is extensively used as a manure in both Great Britain and the U. S. It usually occurs in crystalline rocks, such as granite and greenstone, but is also found in granular limestone and serpentine. The most abundant supplies, however, are derived from beds of animal remains, bones, etc. When crystallized it appears in six-sided prisms, sometimes of a greenish color, and containing calcic phosphate, with a certain proportion of calcic chloride and fluoride, $\text{Ca}_3(\text{PO}_4)_2 + \text{Ca}(\text{ClF})_2$. The amorphous apatite which is used in the preparation of artificial manure is imported from Spain and Norway, and from Sombrero, Navassa, Swan, and some other small islands in the West Indies. Before it is applied to the soil it is ground to powder and subjected to the action of sulphuric acid, which renders the phosphoric acid of the apatite soluble in water. The efficacy of apatite as a fertilizer of the soil depends on the presence of phosphoric acid, which is essential to the growth of such plants as wheat, barley, and oats. It is often mixed with guano, bones, and other manures to make a complex fertilizer, which is better than the simple mineral phosphate. A rich deposit of apatite in the form of nodules has been found in the Postpliocene marls of South Carolina, near the Ashley, Stono, and Edisto rivers. Large quantities of these nodules, which contain 25 or 30 per cent. of phosphoric acid, are converted into "superphosphate of lime" at Charleston, S. C., and at Camden, N. J. It is stated that about 13,000 tons of apatite (otherwise called phosphatic guano) were imported into the U. S. in 1868. Apatite occurs in large crystals, associated with white limestone, in St. Lawrence co., N. Y. Massive apatite is found in England, Ireland, Spain, and other countries. See AGRICULTURAL CHEMISTRY, BONE, FERTILIZERS, and GUANO.

Revised by IRA REMSEN.

Apcheron: See APSHERON.

Ape (synonymous with *monkey*): any of the Primates, excepting the lemurs and man; in a more restricted sense, any of the Old World tailless members of the family *Simiidae*, which includes the chimpanzee, orang-utan, gorilla, and gibbons. These apes are the most highly organized of the Quadrumana, and approach in structure nearest to man, from whom they differ principally in the smaller size of brain and brain-case, the larger canine teeth, the relatively greater length of the arms, and the shorter great toe, which is opposable to the other toes. Their structure is better adapted for climbing trees than for walking on the ground, and accordingly in the forest they swing from tree to tree with great agility and ease, but on the ground they are slow, often walking on the knuckles of the closed hand and on the outer side or the knuckles of the foot. Their food consists mainly of fruit and vegetables, varied in some species with insects. Apes are natives of Africa, India, Borneo, etc. See CHIMPANZEE, GORILLA, and ORANG-UTAN.

DAVID S. JORDAN.

Ap'eldorn, or **Apeldoorn**: a beautiful village of Holland; in Gelderland; on the river Grift; 16 miles N. N. E. of Arnhem (see map of Holland and Belgium, ref. 6-H). Here are an agricultural school and manufactures of paper, blankets, and coarse woolen fabrics. Pop. with adjacent hamlets (1879) 15,053; (1890) 19,190.

Apell'es: a Greek painter of the second half of the fourth century B. C.; probably a native of Colophon; studied his art at Ephesus, but at Pella, in Macedonia, formed that acquaintance with Alexander the Great which was so profitable to him in fame and wealth. He is noted especially as the painter of an *Aphrodite Anadyomene* and an *Artemis in the Chase*. His portrait of Alexander was put in the temple at Ephesus. Of it Alexander made the oft-quoted remark: "There are only two Alexanders, the invincible and the inimitable." See A. Houssaye, *Histoire d'Apellès* (Paris, 1867).

S. M. J.

Ap'ennines (It. *Apenni'no*; anc. in Lat. *Mons Apenni'nus*): a long chain of mountains extending through the whole length of the Italian peninsula, and forming the watershed between the Adriatic Sea and the Mediterranean. This chain belongs to the system of the Alps, from which it branches off near the Col de Tenda. The northern portion, called the Ligurian Alps, is nearly parallel to the Gulf of

Genoa, and is in close proximity to the coast. The entire length of the chain is about 800 miles, and its general direction nearly southeastward. None of its summits rises to the limit of perpetual snow. The highest summit in the peninsula is Monte Corno, which has an altitude of 9,546 feet, but Mt. Etna, regarded by some as a part of the Apennine system, is 10,935 feet high. The average height of the chain is about 4,000 feet. The geological formations of the Apennines are either metamorphic or secondary, and limestone is the predominant rock. They are remarkable for their rich quarries of marble of various colors, but are poor in metals. Rocks of volcanic origin abound in the former kingdom of Naples. The mineral riches of these mountains consist chiefly in the celebrated marbles of Carrara, Seravezza, and Sienna. The Apennines are somewhat deficient in sublime and magnificent scenery, and their general aspect is that of a wall, with few projecting peaks to break the monotony of the scene. The higher parts of these mountains are mostly dry, rocky, and destitute of trees, but below the altitude of 3,000 feet they are covered with forests of the evergreen oak, chestnut, beech, and other trees. The olive, orange, and palm also flourish near their base, especially where they are in close proximity to the sea, as near the Gulf of Naples and at the Riviera of Genoa. Some geographers divide this chain into four parts: 1. The Northern Apennines, extending from the Col de Tenda to the Pass of Borgo San Sepolero, near Arezzo; 2. The Central Apennines, from Arezzo to the valley of the Pescara, which separates the provinces of Teramo and Chieti; 3. The Southern Apennines, from the Pescara to Cape Spartivento; 4. The Insular Apennines, in the island of Sicily. In Central Italy the western or southwestern side presents a very gradual descent, but in the northern part of the range, which approaches the coast, there is a very steep declivity next to the sea.

Apenra'de: a seaport-town in Schleswig, on a fiord of the same name in the Little Belt, 35 miles N. of Schleswig (see map of German Empire, ref. 1-E). It has a good harbor and beautiful environs. Ship-building is carried on here. Near this town is the castle of Brundlund, built by Queen Margaret about 1410. Pop. 6,069.

Ape'rients: remedies employed to act upon the bowels in habitual or chronic constipation. They may be divided into two sets: salines; vegetable aperients. The most used of the saline aperients are the various mineral waters, such as Bedford water, Saratoga water, Hunyadi Arpad and Hunyadi Janos water, and Fredrickshalle water. These all depend for their activity upon the sulphates of sodium, magnesium, or lime, either alone or mixed together. The difference in the action of waters depends chiefly upon their strength. Sulphate of sodium, or Glauber's salts, sulphate of magnesium, or Epsom salts, tartrate of sodium and potassium, or Rochelle salts, may be substituted for the more costly natural waters. A very close imitation of these natural waters may be made by mixing an ounce each of the sulphate of sodium and magnesium, and half a drachm of the bicarbonate of sodium, and dissolving in water as needed. In order to act kindly, salines should be taken when the stomach is empty, and are therefore usually preferred on rising, at least half an hour before breakfast. The dose of the salines varies almost indefinitely; the amount taken should be increased until the desired effect is produced. Of the mixture given above, from a heaped teaspoonful to a heaped tablespoonful may be taken in half a glass of water.

The vegetable aperient compounds in use are legion. Probably the best of the single vegetable aperients is the cascara sagrada, given in the form of the fluid or solid extract, of which the dose is respectively 5 to 30 minims and 2 to 5 grains. A most excellent combination, and one which on account of the smallness of the dose can be taken in granules, is one-sixth of a grain of aloin, one-eighth of a grain of extract of belladonna, with one-sixtieth of a grain of strychnine. Of these granules, one to three may be taken at a dose. A vegetable laxative acts slowly, and should always be taken at bed-time; or in severe cases of constipation may be taken in minute doses after the mid-day and evening meals.

When habitually used, aperients lose their power over the individual, and it is essential that they should be changed from time to time. It is also an invariable rule that the use of aperients in chronic constipation is to be avoided as long as possible, the constipation being overcome by the use of proper food and the formation of proper

habits of life. All foods which contain a large proportion of non-nutritious material act as laxatives, by their bulk distending and stimulating the intestines. Thus bran bread, oatmeal porridge, whole-wheat flour, and cracked wheat are all distinctly laxative, while milk and meat are distinctly constipating. Water, by its softening influence, has some laxative power, and in many individuals a pint of hot water, taken on going to bed at night or getting up in the morning, acts most happily. General exercise is of great service in maintaining the normal condition of the alimentary canal, and all persons of costive habit should make an absolute rule of setting aside a fixed time in each day to respond to the calls of nature. Enemata of simple water may often be used with advantage from time to time to replace medicines. The habitual use of glycerine suppositories or of enemata of glycerine is not proper. H. C. WOOD.

Apet'alous Plants (*Apetalæ*): one of the divisions of dicotyledons, according to the usual system of classification. It includes many families, often with little if any relationship, agreeing only in wanting petals. While this division is recognized by most British, French, and American botanists, it is unquestionably artificial. In all or nearly all cases the petals have disappeared by a reduction from the petal-bearing type. Many apetalous plants belong to families containing choripetalous or gamopetalous flowers, and it is probable that all apetalæ should be considered as the reduced or degraded relatives of the plants of these higher groups. CHARLES E. BESSEY.

Aphanop'tera, or **Aphanop'tera** [from Gr. ἀφανής, invisible + πτερόν, wing; i. e. with wings not apparent]: a sub-order of wingless insects containing a single family, the *Pulicidae*, or fleas. There are many species, of which the common flea (*Pulex irritans*) may be regarded as the type. The female deposits her eggs, generally about a dozen in number, in any favorable situation; and in about six days the larvæ are hatched, attaining their full size in ten or twelve days more. At the end of this time the larva spins itself a little silken cocoon, in which it passes into the pupa state, and in about twelve days afterward emerges a perfect flea. The chigoe (*Sarcopsylla penetrans*) is a native of South America and the West Indies, and is an exceedingly annoying and sometimes even a dangerous insect. It penetrates the skin of the foot in man and various other mammals, and there lays its eggs. The larvæ often form troublesome ulcers which, if neglected at first, are very difficult to heal. Revised by D. S. JORDAN.

Apha'sia [from Gr. ἀφασία, speechlessness; from ἀφασος, speechless; ἀ-, not + φάσαι, speak]: disorder or loss of the power of speech due to brain disease, as distinguished from aphonia (*q. v.*), the loss of phonation of external disease, as of the vocal cords or larynx. There is a portion of the left side of the brain especially devoted to the function of speech, and whenever this becomes in any way diseased, as most frequently by apoplectic hæmorrhage in the brain, aphasia results. There are many grades of the condition, from entire speechlessness to the slightest, almost imperceptible, hesitation. Moreover, there are different types of aphasia, widely different in nature. In one there may be plain speechlessness; in another inability to speak correctly, the words of a sentence being confusedly misplaced; in a third, words are improperly applied (a table being called a knife or the like), not from want of intelligent appreciation, for the patient is at times painfully aware of his inability to express himself; and finally there may be a curious form in which any attempt to speak thoughts is futile, though the patient is able to repeat poems or declamations, or sing songs without the least hesitation. The last-mentioned phenomenon is due to the existence of an "automatic speech-center," which is operative when words once committed to memory are re-spoken, and this center lies on the opposite side of the brain from the "volitional speech-center." Disease of the latter may therefore be present while the automatic center remains intact. There are many other varieties of aphasia which can only be understood when the physiology of the brain is carefully considered. Aphasia must not be regarded as a disease, but as a symptom of many diseases. Therefore the question of its cure is involved in the consideration of the diseases which brought it about. In cases in which the speech-center has become irreparably damaged, it has happened that by a process of re-education, other parts of the brain assuming the function, the power of speech has been partially regained. See SPEECH. WILLIAM PEPPER.

Aphe'lion [from Gr. ἀπό, off + ἥλιος, sun]: that part of a planet's orbit which is the most distant from the sun, and is opposite to the perihelion, or the point nearest the sun.

Aph'ides (sing. *a'phis*, a plant-louse) [etymology uncertain]: the name applied to numerous hemipterous insects of the family *Aphididae*,

Aphides.

men, through which the saccharine fluid is exuded. In some of the aphides wings are present, but in others they are not. Many of them secrete a sweet fluid known as "honeydew," produced by a pair of small tubes near the hinder end of the body. Ants have a special fondness for this substance, and often frequent plants on which it is deposited. They may sometimes be seen milking the aphides, as it is termed—that is, stroking the sugar-tubes with their antennæ to induce them to furnish them the saccharine fluid more abundantly. Hence the aphides have been termed the milk cows of the ants. Some species of this genus are very destructive to vegetation, as the hop-fly (*A'phis hu'muli*), and the aphid of the turnip-cabbage (*A'phis bras'sicæ*), which have sometimes destroyed whole crops. Here also belong the *Phylloxera* or vine-louse. The aphides are often infested by certain minute parasites, which, by laying their eggs in the bodies of those insects, cause the death of great numbers. It is remarkable that one of these parasites (*Aphid'ius*) has itself still more minute ichneumon parasites, whose eggs are deposited in its body.

Revised by D. S. JORDAN.

Aphis: See APHIDES.

Apho'nia [from Gr. ἀφωνία, voicelessness; ἀ-, not + φωνή, voice]: loss of speech, in which the patient more or less completely loses power to utter sounds. This may arise from disease of the larynx, from direct paralysis of that organ, or from some functional disease, as hysteria or chorea. The treatment varies with the disease of which the aphonia is a symptom. As a general rule, these cases are temporary, unless there is a destruction or serious organic change in the tissues of the larynx.

Aphrodite, ἄφ'ρō-dī'tēē: See VENUS.

Aph'thæ (sing. *aphtha*) [from Gr. ἄφθα, ulcer, thrush]: ulcers of the mouth, beginning with numerous minute vesicles and terminating in white sloughs. Aphthæ are usually the seat of microscopic vegetation, but whether the growth is an essential or only an accidental element is a disputed point. Aphthæ resemble "thrush" in appearance, but in the latter disease no vesicles are formed.

Aphthar'to-Doce'tæ [from Gr. ἀφθαρτος, incorruptible + δοκεῖν, think]: literally, "believers in [that which is] incorruptible," the name of the followers of Julian of Halicarnassus, who lived about 520 A. D., and taught that the body of Christ was divine and incorruptible.

A'pia: the chief town of the Samoan islands; on the island of Upolu; lat. 14° 2' S., lon. 171° 21' W. There is a small but safe harbor. Since 1879 it has been a municipality governed by an elected council of six members, responsible to the consuls of Germany, Great Britain, and the U. S. Considerable foreign trade is carried on here, but it is for the most part in German hands. Copra (i. e. dried cocoanuts) is the most important article of trade, but cotton, cocoanuts, and breadfruit are also exported. Pop. 3,750. M. W. H.

A'pian, or Appian, PETER: German astronomer and mathematician; b. at Leisnig, Saxony, 1495. His proper name was BIENEWITZ. He became Professor of Mathematics at Ingolstadt about 1527, and gained distinction by his writings, among which is a work on cosmography (1524). He first proposed the method of ascertaining the longitude by lunar observations. He was ennobled by the Emperor Charles V. (1540). D. at Ingolstadt, Apr. 21, 1552. See Günther, *Peter und Philipp Apian* (Prag, 1882).

Apiary: See BEE.

Apicius, a-pis'i-ūs, MARCUS GABIUS: a celebrated epicure who lived at Rome in the reigns of Augustus and Tiberius. His name became proverbial for gluttony and luxury in eating. According to Seneca, he expended more than \$3,600,000 in the indulgence of his taste for rare dishes, and then discovering that his fortune was reduced to 10,000,000 sesterces (about \$360,000), he poisoned himself, because he could not continue his expensive style of living. Apicius composed a work on cookery, but the extant work *De re coquinaria*, in ten books, containing a large number of recipes, can not in its present form be attributed to Apicius, being compiled in part as late as the third century. See edition by C. T. Schuch (Heidelberg, 1874).

M. WARREN.

A'piculture: the rearing of bees. This industry is now represented by something over 300,000 beekeepers in the U. S. alone, some of the most extensive apiarists owning from 300 to 3,000 colonies; and, as a consequence, honey is produced by the ton and car-load in nearly all sections of the country. While the majority carry on apiculture in connection with some other rural pursuit, there is a considerable number who make beekeeping their sole means of livelihood.

Prior to 1850 beekeeping was carried on in the old-fashioned way, and but little practical results were obtained. In 1852 the Rev. L. L. Langstroth made the great invention which revolutionized apiculture throughout the world. This consisted in making the first practical movable-frame hive, an invention that made it possible to take out and put back with facility the combs, so that the exact condition of the colony could be easily ascertained. Although great improvements have been made since the date of Mr. Langstroth's invention, nearly all hives and frames are still made essentially on the Langstroth principle, the only difference being that the frames are self-spacing; and the hives, instead of having porticos, are simpler, stronger, and lighter. The illustration shows an eight-frame Langstroth hive, with the "super," as it is called, for the storage of the surplus or box honey.

Improved Langstroth eight-frame hive.

Honey is put upon the market both in the comb and liquid form. The former is put up in little square boxes which hold about a pound. These boxes are put in the hive, containing a little piece of embossed wax, which the bees draw out into comb, fill with honey, and cap over.

Extracted honey is the liquid product without the comb. It is sometimes incorrectly called "strained" honey. To obtain the former the combs are first cleared of bees, and then uncapped with a thin knife—that is, the film of wax that covers the cells is sliced off; the combs are next put into the revolving basket of an extractor, and the honey thrown out by centrifugal force. In this way there is no mutilation of the combs, and the same are put back into the hive to be filled again by the bees. While extracted honey is clear and wholesome, strained honey is the product from mashed-up combs; and the result is it is often befouled by

the juices from mashed-up bees, larvæ (or grubs), and bits of wax, propolis, etc.

Bees usually swarm during the honey harvest; and this swarming is simply nature's method of increase. It is not even yet decided how swarming may be controlled or prevented, but it is generally admitted that the first swarm should be allowed, and that all subsequent swarming should be stopped. The first one should be hived in a new location, and given empty combs or section honey-boxes, so that the bees may commence storing honey at once, because the first swarm is usually very active, and will do better work than the parent colony—at least for a time. In the meantime, all second or third swarms should be controlled in the parent colony as far as possible by cutting out the queen-cells in eight days after casting the first swarm, leaving, of course, one cell for one virgin queen to hatch.

Where the climate is cold enough bees are wintered either in the cellar or in double-walled, chaff-packed hives outdoors, the upper story filled with chaff or leaves. In the very coldest climate the cellar plan is preferred; but in localities where the winters are somewhat open, occasionally interspersed with warm days, so the bees can fly, the outdoor method is preferable. Each colony should have from 15 to 20 lb. of sealed stores in the fall. If, upon examination, the bees are found to be lacking, they should be fed up with sugar-sirup made in the proportion of one-third water and two-thirds sugar by weight, the same to be made into a sirup over a slow fire, being very careful not to burn it. If the bees are to winter in the cellar, the hives should have large entrances, or, better, the bottom-board should be removed. In that case the hives should be set in a row upon a pair of scantling in such a way that the bottoms of the hives are left entirely open, with a space of 4 inches between each hive. The next lot of hives should be piled on top of the lower row, each hive right over the space between the two hives below. The purpose of this is to give the bees plenty of bottom ventilation, and allow old bees, as they become superannuated, and die, to drop out of the way, and not to befoul the hive. If double-walled hives are not available for outdoor wintering, the single-walled hives may be placed in covered boxes large enough so as to give a space of 3 or 4 inches all around the hive. This space should then be filled with leaves, chaff, or any other packing, leaving, of course, a passageway from the hive entrance to the outside.

There are two kinds of bees in the U. S. The first are the black (or German) bees, and these seem to be more widely disseminated than any other race. But the bees that are preferred by the large practical beekeepers are the yellow-banded, or Italians, or, at least, a cross between them and the black bees. The Italians are proof against mothworms, and, in general, are better honey-gatherers.

Fortunately, the diseases of bees are hardly worth mentioning. There is only one disease that beekeepers are at all afraid of, and that is what is called foul brood. Colonies so affected become more or less demoralized, the brood dies in all stages of growth in the comb, and the cappings of the sealed brood are usually perforated and sunken. The affected larvæ are shriveled, and of a light coffee color, and the odor is very much like that of an ordinary glue-pot. To treat, shake the bees into a clean hive, put them on frames of foundation, and cause them to build them out into combs; and then the old combs should be burned, and the old hive boiled in water for some minutes, to be sure that all germs have been killed.

For further particulars in regard to bees, the reader is referred to Langstroth on *The Honey-bee*, revised by Dadant; the *Beekeepers' Guide*, by Prof. A. J. Cook; *Quinby's New Beekeeping*, by L. C. Root; or the *A B C of Bee Culture*, by A. I. Root.

A'pion (Ἀπίων): Greek grammarian and rhetorician of the first century A. D.; foster-son of Didymus, and head of the philological school at Alexandria. He is chiefly known by Josephus's tract *Against Apion*, a reply to the charges which he brought against the Jews in an address to Caligula.

A'pios Tubero'sa: a papilionaceous plant of the family *Leguminosæ*. It is a native of the U. S. east of the Rocky Mountains, has a twining stem, pinnate leaves, and tuberous roots, which are used as food, and resemble the potato. The roots are commonly called ground-nuts.

A'pis (in Gr. ἄπῖς): the name of the bull of Memphis, the favorite object of worship of the ancient Egyptians, as early as the second dynasty. According to some authorities, he

was sacred to Osiris, or was a symbol of Osiris, and was not permitted to live more than twenty-five years, at the end of which time he was secretly put to death by the priests. During his life he was kept in the temple of Ptah in Memphis, and served by a retinue of priests. His death was followed by a general mourning until a calf with the requisite color and marks was found to supply his place. The principal of these required marks were—black color with a white square on the brow, the figure of an eagle on the back, and a peculiar knot under the tongue.

Aplanat'ic Lens: in optics, a lens which causes all the rays of light that fall on it to converge to a single point or true focus. In order to be aplanatic, the lens must not only have the true geometrical figure necessary to destroy aberration, but must be formed of different media, so as to be achromatic. These conditions can not be accurately fulfilled in practice.

Apoc'alyptse [from Gr. ἀποκάλυψις, revelation; ἀπό, off + καλύπτειν, cover]: literally revelation, usually the last book of the New Testament, which contains discoveries or predictions respecting the future of Christianity. See REVELATION, BOOK OF.

Apocalyptic Number: the mystical number 666 spoken of in the book of Revelation: "Let him that hath understanding count the number of the beast: for it is the number of a man" (xiii. 18). Some critics interpret this to be an enigmatical expression of the word *Latinus*, the Greek characters of which, taken as numerals, amount to 666. The connection between *Latinus* and the Roman power has given Protestants a reason, or pretext, to apply this passage to the Roman Church, and the Roman Catholics retort by making the same number stand for Luther, Calvin, and other Protestants. It is frequently interpreted, according to its value in Hebrew characters, as meaning Nero.

Apocren'ic Acid [from Gr. ἀπό, from + κρήνη, fountain, so called because derived from some fountains or springs]: an extractive or brown matter found in some spring water, and in ordinary vegetable mould. It is a product of the natural decay of wood and other vegetable tissue.

Apoc'rypha [from neut. pl. of Gr. adjec. ἀπόκρυφος, hidden, spurious; ἀπό, away + κρύπτειν, hide]: a collection of writings which have been regarded as an appendage to the Old Testament, and sometimes as a part of it. They are valuable chiefly as historical records, and for the light they throw on the religious condition of the Jews from the close of the Old Testament to the Christian era. They are divided into three classes: (1) those which originated in Palestine, such as the book of Jesus, son of Sirach, first book of Maccabees, and book of Judith; (2) those of Egypto-Alexandrian origin—the book of Wisdom, second of Maccabees, and the addition to Esther; (3) those which show traces of Chaldaic or Persian influence, as Esdras, Tobias, Baruch, and the additions to Daniel. The Council of Laodicea in Phrygia, between 343 and 381 (commonly referred to cir. 360), condemned the use of "uncanonical books"; but the list of canonical books which follows is now generally thought to be an interpolation. The third Council of Carthage (Aug., 397), in the forty-seventh of its fifty canons, gives a list which includes Ecclesiastical, Wisdom, Tobit, Judith, First and Second Maccabees. There are in all fourteen apocryphal books, or portions of books, all but three of which were pronounced canonical by the Council of Trent in 1546. The Roman Catholic Church calls these books deuterocanonical or antilegomena, and applies the name "apocryphal" to those books which have been refused a place in the canon of the books of the Old Testament. By Protestants these books are generally called PSEUDEPIGRAPHA (*q. v.*). The Church of England in her Articles mentions the Apocrypha as books which "the Church doth read for example of life and instruction of manners, but yet doth it not apply them to establish any doctrine." In the Protestant Episcopal Church, lessons from the Apocrypha are included in the latest revision of the Lectionary. They are entirely rejected from public worship by other Protestants in the U. S., and by the dissenting churches in Great Britain. Besides the Old Testament there are many New Testament Apocrypha. See PSEUDEPIGRAPHA.

Revised by WILLIAM S. PERRY.

Apocynaceæ, or **Apocynææ**, a-pos-i-nā'scē-ee, or äp-ō-sin'ē-ee [from *Apoc'ynum*, the name of one of its genera]: an order of exogenous herbs, trees, and shrubs. The calyx is usually five-partite, persistent; the corolla monopetalous

and hypogynous; the stamens are five, inserted on the corolla. Many of the species have a poisonous milky juice, and others are used in medicine. The whole number of the species is said to be more than 1,000. This order comprises the oleander; the *hya-hya*, or cow-tree, the milk of which is wholesome; the *Cerbera*, which produces the Tanghin poison of Madagascar; the *Carissa edulis* of Arabia; and the *Apocynum cannabinum*, or Indian hemp, which grows in North America.

Ap'odal Fishes, or **Ap'odes** [apodes is from Gr. *ἄπους*, pl. *ἄποδες*, footless; *ἀ-*, not + *πούς*, foot]: fishes destitute of ventral fins or homologues of the posterior extremities. In the Linnaean system, *Apodes* was the name of an order of such fishes. Modern writers have restricted the group, till it now contains only the eels, which are further characterized by the elongate body and narrow gill openings, and the fact that the shoulder-girdle is not in contact with the skull.

D. S. J.

Ap'ogee [Fr. *apogée*, from Lat. *apogæum*, from Gr. *ἀπόγειον*, away from the earth; *ἀπό*, off + *γῆα*, earth]: the point of the moon's orbit most remote from the earth; the point which is opposite to the perigee. The apogee of the lunar orbit advances eastward among the stars, and completes a revolution in nine years.

Apol'da: a town of Central Germany; near the river Ilm, in the grand duchy of Saxe-Weimar; on the railway from Berlin to Weimar, 11 miles by rail N. E. of Weimar (see map of German Empire, ref. 5-F). It has manufactures of hosiery, cloths, etc. Here are mineral springs. Pop. (1880) 15,630; (1890) 20,880.

Apollina'ris, or **Apollina'rius**, THE YOUNGER: a learned bishop and philosopher; was a son of a grammarian of the same name. He became Bishop of Laodicea in 362 A. D., and gained distinction as an orator and writer. Among his works were *Thirty Books against Porphyry*, and commentaries on the Bible. He was an opponent of Arianism, and in 375 founded the sect of Apollinarians, who were regarded as heretics. The heresy of which he was accused was the denial of the human soul in Christ, the place of which, he taught, was supplied by the *Logos*. His heresy was condemned at Alexandria in 362, and at Rome in 374. At the Council of Constantinople, in 381, he was condemned by name. He died in 390, and by the middle of the subsequent century the sect he founded was extinct. Some of his writings have been recently discovered among those of other Fathers. See Wernsdorff, *Dissertatio de Apollinare Laodicensi* (1694).

Apollina'ris Sido'nus, GAIUS SOLLIUS. Saint: Latin poet and ecclesiastic: b. at Lugdunum (Lyons), in Gaul, about 430 A. D. He was a son-in-law of Avitus, who was Emperor of Rome for a few months in 455-456 A. D. Anthemius, who became emperor in 467, appointed him prefect of Rome in 468. About 470 he was elected Bishop of Clermont (Augustonemetum). He wrote *Carmina* and *Epistole*, which are extant, and have some historical value. D. about 480 A. D. Best ed. by C. Luetjohann (Berlin, 1887).

Apollinaris Spring: the source of true Apollinaris water; in the valley of the Ahr, near Remagen, Rhenish Prussia. The water is drawn from a deep rocky source at a depth of 50 feet, and the carbonic acid it contains is that contained by water at that depth. A London company undertook the export of the water in 1874. The bottles filled at the spring in 1888 numbered 12,720,000; in 1889, 15,822,000. In 1891 it was probably between 18,000,000 and 20,000,000. See MINERAL WATERS.

M. W. H.

Apollina'ris Sulpi'cius, GAIUS: Latin grammarian of the second century of our era; b. at Carthage, and famous as the teacher of Aulus Gellius and the Emperor Pertinax. He wrote metrical arguments (which are still extant) to the plays of Terence, and to the twelve books of the *Æneid*. The non-acrostic arguments preserved for five plays of Plautus (*Amphitruo*, *Aulularia*, *Miles*, *Mercator*, and *Pseudolus*) are commonly ascribed to him.

M. WARREN.

Apoll'o (in Gr. *Ἀπόλλων* and *Ἀπέλλων*): among the Lycians, Greeks, the Italic peoples, and the Etruscans, a god, primarily of light, secondarily the deity who presided over the annual stages of the sun. Hence he was regarded as an increaser and preserver of vegetable, animal, and human life. He is the protector of crops and flocks, the friend of the wild creatures of field and flood, and the maintainer of physical health, vigor, manly spirit, and masculine beauty, which he illustrates in his own person. The association of

Apollo with athletics and war, and with the healing of disease, comes under this head; the god's anger naturally has power to cause the disease and death which his mercy can ward off and check. The ritual prescribed for the worship of Apollo laid great stress on physical and moral purity. He removed the stain and the disabilities ensuing on moral guilt, such as bloodshed, by special expiatory rites. Another of his attributes is a knowledge of hidden things. Prophecy was dispensed in the name of the god at many of his sanctuaries. In this regard the ancient Pythian oracle at Delphi, on Mt. Parnassus, acquired a commanding pre-eminence. Finally Apollo, as the god of whatever is bright and fair, was considered to be the author of musical inspiration. As such he is the inventor of the lyre and the leader of the nine Muses. His largest Greek temple was at Miletus in Ionia. The Ionians made him the progenitor of Ion, the founder of their race. The island of Delos was represented to be the place of his birth, with his twin sister Artemis (Diana). Their parents were Zeus (Jupiter) and Leto (Latona). Delos remained sacred to Apollo, and was spared by the Persians, who must have identified the Delian Apollo with their own Ahuramazda (Ormuzd). The official recognition of the worship of Apollo in Rome dates from 429 B. C.

Apollo in Art.—Augustus, who ascribed his victory at Actium to Apollo's favor, erected a magnificent temple on the Palatine Hill. It contained one of his most spirited and widely famed statues, the work of the celebrated Skopas. A copy of it in the Vatican Museum shows the god in long robes, striking the strings of his lyre with both hands. The delicacy of the features causes many visitors to take the statue for a female figure. It is possible that the beautiful Pourtalès head, in the British Museum, with its rich topknot of luxuriant hair, and its perfect oval face suffused with a tender melancholy, better reproduces the exquisite original of Skopas. That a kindred conception of Apollo obtained from the earliest times is shown by the Homeric hymn to Pythian Apollo, and by a relief many times reproduced with studied quaintness, on which Apollo appears in the garb of the Pythian lute-player, welcomed by the goddess of victory. An early relief from Thasos, now in the Louvre, exhibits Apollo with the lyre, and clad in long garments, crowned victor by one of the Graces. The date is about 475 B. C. Even earlier are paintings on Greek black-figured ware, on which Apollo appears in the same ornate dress, bearded, and with long curls, striking a huge lyre. Totally different is the conception of the early statues, in which the god is represented as the patron of athletic exercises. A considerable number of these, dating from the sixth century B. C., has been unearthed on the islands and mainland of Greece, as at Thera and Naxos (Cyclades), Tenca (near Corinth), and Orchomenos (Bœotia); also elsewhere in Bœotia, and at Actium. These nude figures, of rigid pose, awkward execution, and little facial expression, mark the struggle of the Greek chisel with the great difficulties of the nude male form. In the absence of any attributes they have been held to portray human athletes; the dedication is, however, commonly to Apollo. Akin to these was the bronze Apollo of the artist Kanachos, at Miletus. The nude god stood with a bow in one hand and a stag or doe on the other. The Payne Knight statuette in the British Museum is a reproduction of this, as indicated by types on the coinage of Miletus. The Strangford marble in London and another discovered in the theater at Athens show the skillful transformation of this type by Attic artists at the beginning of the fifth century. Pythagoras of Rhegium in Italy modeled an Apollo as the divine archer in combat with the Pythian serpent. A notable extant figure of Apollo, which tradition ascribes to Alkamenes, occupied the center of the western gable of the temple of Olympia. Here Apollo is quelling the wild and ruthless Centaurs in behalf of his *protégés* Peirithoös and Theseus. A Neapolitan bronze of affected primitive quaintness shows Apollo as the "far shooter" of prayers and hymn, advancing with bow in hand and arrow strung. His only garment is a light hunter's cloak. The taste and skill of the fourth century found its expression in the above-mentioned statue by Skopas and in a number of graceful creations by Praxiteles. Such were his Apollo at rest and Apollo in action, of which good copies exist; the latter shows the god in the act of piercing a lizard which is crawling up the tree trunk against which he leans; the former, known as the Apollino, represents his exceedingly youthful figure in a pose full of languid grace, also leaning against a laurel tree. Several

temple statues by Praxiteles grouped Apollo with Leto and Artemis, his mother and sister. The third century, while no doubt elaborating and reproducing the types already crystallized, was stimulated to a more heroic conception of Apollo by the stirring event of an invasion of Greece by the Gauls under Brennus, in 278 B. C. The original of the much admired Apollo of the Belvedere in Rome was fashioned and dedicated at this time. It is proved by two bronze statuettes that Montorsoli's restoration of the god as an archer is wrong. He really held an ægis with which he terrifies the enemy exactly as described in the *Iliad*. Of similar character is the splendid figure of Apollo among the Pergamene bas-reliefs recently set up in the Berlin Museum. Attention should also be called to the figures and heads of Apollo on Greek coins, many of which are of great beauty. The ordinary attributes of Apollo are lyre, bow and quiver, laurel branch or wreath, and among animals the swan. In modern art Apollo figures as the leader of the Muses (so in Raphael's Vatican fresco), and as driver of the solar chariot (so in Guido Reni's equally celebrated ceiling fresco of the Rospigliosi Palace). His pursuit of Daphne, and her transformation into a bay-tree, is also a favorite subject of Italian art. The figure of Apollo is nowadays frequently used as a personification of art or music, and sometimes appears coupled with one of Minerva as the patroness of science.

ALFRED EMERSON.

Apollo: borough; Armstrong co., Pa. (for location of county, see map of Pennsylvania, ref. 4-B); on Pa. R. R. and Kiskiminetas river; in coal-mining district; has rolling-mills, foundry, steel-works, etc. Pop. (1880) 1,156; (1890) 2,156.

Apollodo'rus (Gr. Ἀπολλόδωρος): a celebrated Greek painter, surnamed THE SHADOWER; was b. at Athens about 440 B. C. He was a rival of Zeuxis, the founder of a new school, and the reputed inventor of chiaroscuro. His works are highly praised by Pliny, who says he was the first who painted objects as they really appear.

Apollodorus of Athens: grammarian and historian of the second century B. C.; was a pupil of Aristarchus. Only fragments of his numerous works remain. See Müller, *Fragmenta Historicorum Græcorum*, i. 428-469. To Apollodorus is attributed a manual of mythology entitled *Bibliotheca*, a large part of which is extant, and which has its value. Others assign it to a compiler of the second century A. D. Edited by Heyne (2 ed. 1803), and by Westermann in his *Mythographi Græci*.

B. L. G.

Apollodorus of Damascus: architect; b. at Damascus; lived about 100 A. D. He was patronized by Trajan, and erected in Rome numerous works, among which were the Basilica Ulpia, the Forum of Trajan, and the Column of Trajan, which is still extant. His capital work was a noble bridge over the Danube, near the mouth of the Aluta, built in 105 A. D. He was put to death about 128 A. D. by Hadrian, whom he had offended by criticising a temple which that emperor had designed.

Apollo'nia (Gr. Ἀπολλωνία): an ancient city of Illyricum, on the Adriatic Sea, about 40 miles S. of Dyrrhachium. It was founded by colonists from Corinth and Coreyra, and became an important city. The site is now occupied by a village called Polina or Pollina, and some ruins of temples.

Apollo'nus: Athenian sculptor; son of Nestor. His date is unknown, and nothing is known about him but that he executed the marble statue of Hercules, of which a large fragment, called the Torso of the Belvedere, is now in Rome. From the style of the work, and the form of the letters inscribed upon it, this statue may be ascribed to the first century A. D. It is one of the most important pieces of ancient sculpture existing.

Apollonius (surnamed DYSCOLUS the Crabbed): an eminent Greek grammarian of Alexandria (120-160 A. D.), was the father of Ælius Herodian. Of his many works a *Treatise on the Syntax of the Parts of Speech* and three others are extant. He had rare insight for his times, and Priscian calls him *maximus auctor artis grammaticæ*. Recent edition by Schneider and Uhlig. See Egger, *Apollonius Dyscole* (1854).

Apollonius (surnamed PERGÆUS): Greek geometer; b. at Perga, in Pamphylia, about 250 B. C. Little is known of his life, except that he resided in Alexandria in the reign of Ptolemy Philopator (222-205 B. C.). His most important work is a Greek *Treatise on Conic Sections*, in eight books,

which is extant except one book. He wrote other works, which are lost. He was also distinguished as an astronomer.

Apollonius Mo'lon: Greek rhetorician; b. at Alabanda, in Caria. He taught rhetoric at Rhodes and Rome, which he visited in 81 B. C. Cicero and Julius Cæsar were his pupils soon after that date.

Apollonius of Rhodes (280-203 B. C.): the most eminent of the Alexandrian epic poets. B. at Alexandria or Nau-cratis, he became the pupil and afterward the enemy of Callimachus. In consequence of this feud he betook himself to Rhodes, whence his surname. After the death of his rival he returned to Alexandria, where he finally became chief librarian. His *Argonautica*, or Story of the Argonauts, in four books shows great learning, great ingenuity, and a remarkable command of epic diction. Apollonius is rich in new expressions, new figures, new comparisons; he describes vividly, and his portrayal of emotions has elicited great applause, so that he was not unworthy of the admiration and imitation of the Romans, in spite of his lack of unity and his lack of reality. Ed. by Merkel (1854). See Couat, *La Poésie Alexandrine* (p. 293 foll.).

B. L. GILDERSLEEVE.

Apollonius the Sophist: a grammarian of Alexandria; about 100 A. D. His lexicon of Homeric glosses, based on Aristarchus and Apion, is extant. Ed. by Bekker (1833).

Apollonius of Tralles: Greek sculptor; lived probably about 200 B. C. Aided by his brother Tauriscus, he executed a group of Zethus and Amphiion tying Dirce to the horns of a bull. Some persons identify this with the group called *Toro Farnese* which is now at Naples.

Apollonius of Tyana (Gr. Ἀπολλώνιος Τυανεύς): a Pythagorean philosopher; b. at Tyana, in Cappadocia, lived about 30-70 A. D. He performed a journey to India in order to learn the doctrines of the Brahmans, and after his return gained a high reputation as a sage, an oracle, and a worker of miracles. He is considered by some authors as an impostor, and by others as a prophet or magician of extraordinary powers. He traveled extensively in Europe and Africa, and is said to have passed his latter years at Ephesus. But to disengage the real Apollonius from the romance of Philostratus (*q. v.*) is quite impossible. In addition to Baur (1832) and J. H. Newman (1853), see the authors cited in Gildersleeve's *Essays and Studies*, p. 251. Also L. Dyer, *The Gods in Greece* (1891), p. 257. The 100 letters under his name in Hercher's *Epistolographi Græci*, pp. 110-130, are doubtless spurious.

Apollonius of Tyre: See ROMANCES.

Apol'los: an eloquent preacher among the early Christians; was originally a Jew and a native of Alexandria. He is said to have been ordained Bishop of Corinth. See Acts xviii. 24; 1 Corinthians i. 12; iii. 4.

Apol'lyon [Gr. Ἀπολλύων, from ἀπολλύω, destroy]: the destroyer. The name answers to the Hebrew *Abaddon* (*q. v.*), and to the *Asmodeus* of Tobit.

Apologetics [from Gr. ἀπολογητικός, fit for defense; ἀπό, off + λέγειν, speak]: that branch of learning which treats of *Apology*. In this use the term apology does not, as in its popular use, imply an acknowledgment of error, but simply denotes the formal defense of a person or a doctrine that has been attacked. It is principally employed as the name of a branch of Christian theological learning, namely, the literary defense of Christianity and its doctrines. Some distinguish between apologetics as concerned with the methods of this defense and apology the defense itself, but it is more in accord with usage to speak of the two as theoretical and practical apologetics.

Its Place among the Departments of Theological Study.—There is a sense in which it is true that apologetics precedes dogmatics and practical religion. That is, there is a sense in which Christianity should be proved to be true, in order to justify its being systematically studied and practiced. But as a matter of ordinary fact, Christian people accept their religion as an element in life and society, on the testimony of others who have previously accepted it, combined with evidence from their own observation and experience, and are not interested either to define the doctrines of Christianity, or to study the literary defense of it, until after they have been thus convinced of its truth. In other words, they treat this problem as men of good sense treat other great problems of life, accepting evident truth as true, even

when they have to postpone the logical definition and demonstration of it.

Classifications.—Treatises in general apologetics take up the defense of Christianity as a whole; work in special apologetics is the discussion of the objections to each particular doctrine, as a part of the discussion of that doctrine. With all advance in thorough study, special apology gains in relative importance.

With reference to the materials used, apologetics may be classified as philosophical and historical or critical, though, in a large part of the field, the two kinds of material are used in combination. Purely philosophical are the arguments drawn from psychological and metaphysical considerations in proof that man is capable of knowing God and the supernatural. Partly philosophical and partly historical are the various arguments in proof that, as a matter of fact, God actually is known to exist and to reveal himself. In this class are included, notably, arguments from manifestations of design in nature, arguments from natural analogies, arguments from the comparative study of religions. More strictly historical are the arguments drawn from the history of the Israelitish and Christian religions (or, better, religion), as compared and contrasted with other religions, and the whole body of argument by which the character of the Bible, as a divine revelation, is vindicated.

With reference to its practical methods, apologetics may be classified as polemic or scientific, without implying, however, that one of these classes necessarily excludes the other. The principal aim of the polemic apologist is to defeat adversaries whom he has directly in mind. He attacks that which attacks Christianity. He lays out his strength in disproving accusations, or in showing some adverse position to be untenable. The scientific apologist, on the other hand, undertakes to vindicate positively the truth of Christianity, without so much regard to particular attacks upon that truth. He aims to establish the position of the Christian religion in the great cycle of possibly knowable truth, aware that, just in proportion as this is recognized, all particular attacks will fail of themselves. In proportion as an apologist is merely polemic, he avoids definitions, lest an adversary should take advantage of some imperfect definition. In proportion as he is scientific, he defines carefully, knowing that tenable positions are made stronger by abandoning untenable positions.

The History of Apologetics.—The defense of Christianity, particularly its polemic defense, changes character with the changing attacks made. Three periods, however, may be distinguished in the history of Christian apologetics, apology beginning in each period in polemic form, and advancing by stages to a more scientific form. The first period is that of the APOLOGETIC FATHERS, extending through the first five centuries. First come such men as Aristides and Justin Martyr, refuting the charges brought against Christians by Jews and pagans, then such men as Tertullian, Origen, and Clement of Alexandria, adding a constructive element to the mere negative apology, and then men like Eusebius and Augustine, giving the apology the form of a full theory of Christianity, according to the scientific standard of those times. The second period extends from the sixth century to the fifteenth. As the church is established by law, and its authority is undisputed, it has no great need of literary defense. But during these centuries such men as Agobard of Lyons and Rainund Martins wrote elaborate polemics against Jews and Mohammedans, and such men as Thomas Aquinas developed a new statement of the philosophy of Christianity. In these two periods apologetics had chiefly to do with attacks on Christianity from without. But during the third period, beginning with the Reformation of the sixteenth century, the defense has been mainly against skepticism, agnosticism, or other forms of adverse criticism from within. Apologetic writings have abounded, and group themselves according to the various controversies that have raged, such as the deistic controversy in Great Britain and others. In the latter part of the nineteenth century apology, though still abundantly polemic, is yet strongly tending toward forms more strictly scientific than have hitherto prevailed.

Literature.—A library of Christian apologetics would include many thousands of volumes and smaller works. The great works on theology all include treatments of apologetics. In these, and in the articles in special encyclopædias (for example, the Schaff-Herzog *Encyclopædia of Religious Knowledge*, or the *Cyclopædia* of McClintock and

Strong), lists of works are given, the lists in some instances covering several pages. For the earliest period see any set of the Patristic writings. Perhaps the greatest works of the middle period are Agobard, *De Insolentia Judæorum* (822); Martius, *Pugio Fidei* (1278, accessible in Ugolino); Abelard, *Dialogue between a Philosopher, a Jew, and a Christian* (early in the twelfth century); and works of Alexander de Hales, Albertus Magnus, Duns Scotus, and Thomas Aquinas. Among the multitude of apologetic works of the eighteenth century few have been more widely read than Bishop Butler's *Analogy* and Paley's *Natural Religion; Evidences of Christianity*; and *Hore Paulinae*. It is hardly possible to mention a few more recent works without seeming invidious. Dr. Herrick Johnson's little book, *Christianity's Challenge* (1881 and later eds.), is a particularly good popular treatise. In philosophical apologetics, Bushnell's *Nature and the Supernatural* (1858); G. P. Fisher's *Supernatural Origin of Christianity* (revised ed. N. Y., 1870); Flint's *Theism*; and *Antitheistic Theories* (Edinburgh, 1877-78), deserve mention, along with works, perhaps equally important, by McCosh, Schaff, Christlieb, and others. Albert Barnes, Stanley Leathes, and many others have newly presented the historical evidences. Kurtz, Hugh Miller, Sir William Dawson, Tayler Lewis, and many others have treated of the proofs from astronomy and natural science. And more voluminous than all the others are the recent works of critical authors of different schools touching the character of the Bible, and thus touching the domain of historical apologetics. A compendious and comprehensive treatise is A. B. Bruce's *Apologetics* (Edinburgh and New York, 1892). WILLIS J. BEECHER.

Apology of the Augsburg Confession: one of the symbolical books of the Lutheran Church, written by Melancthon in answer to the *Confutation of the Augsburg Confession* by the Roman Catholic theologians Eck, Faber, Wimpina, and Cochlaeus. It was written in Latin and first published in April, 1531. A German translation by Justus Jonas appeared six months later. It is a more elaborate treatment of the topics contained in the *Confession*, and combines clearness of definition and vigor of argument with a mild and conciliatory spirit, and a chaste and classical style. A translation from the Latin is found in Jacobs's *Book of Concord* (Philadelphia, 1882); one from the German translation in the Henkel edition of *Book of Concord* (New Market, 1854). The best commentary is *Die Apologie der Augustana geschichtlich erklärt von Gustav Plitt* (Erlangen, 1873). HENRY E. JACOBS.

Apophyllite [from Gr. *ἀπό*, off + *φύλλον*, leaf]: a zeolitic mineral with a lamellar structure; is so called because it exfoliates before the blowpipe. It is a hydrated silicate of lime and potash occurring in square prisms, the solid angles of which are sometimes replaced by triangular or rhombic planes. It is brittle, and has a white or grayish color, often tinged with green, yellow, blue, or red. It is found in beautiful crystals in the Hartz Mountains, in Poonah, and in the Bergen tunnel at Jersey City.

Ap'oplexy [from Gr. *ἀποπληξία*: *ἀπό*, off (to completion) + *πλήσσειν*, strike; cf. Eng. *stroke* (of apoplexy or of paralysis)]: a disease marked by the sudden failure of volition, sensation, motion, and mental action, the symptoms being caused by a pressure upon the brain, or disturbances of the circulation, originating within the cranium. Apoplexy is produced in various ways, though the symptoms are similar. The typical form is characterized by hæmorrhage into the substance of the brain. The rupture itself may be caused (1) by a non-inflammatory, fatty degeneration of the blood-vessel, caused by bad nutrition, etc.; (2) by a brittle condition or aneurismal dilatation of the vessel, resulting from an inflammatory process. These causes may be supplemented by a full habit of body or by a hypertrophied heart, or both; and it is easy to see how such secondary causes might assist in the rupture of a weakened blood-vessel. Apoplexy may, however, be produced by an extravasation of blood between the meninges, by a sudden serous effusion into the ventricles of the brain, by stoppage of circulation, by emboli or thrombi in the blood-vessels, or even by a congestion (hyperæmia) of the brain. The apoplectic stroke may end in partial recovery or in speedy death. Cases not fatal generally result in permanent or temporary paralysis of one side of the body (hemiplegia), often on the side opposite that in which the mischief has occurred.

The symptoms of apoplexy are often unexpected. The patient falls suddenly (with or without an outcry), his respi-

rations are long, slow, and stertorous, the pulse is slow, one or both the pupils usually small. If the patient does not die during the attack, a secondary inflammation follows which may destroy life. Bleeding may be resorted to if the pulse be strong, and the heart and lungs in good condition, but it is often injurious. Mustard to the extremities and frictions of the skin should be resorted to, and the bowels should be moved by enema. Persons having reason to fear apoplexy should avoid excesses of all kinds, yet live upon nutritious food, paying special attention to hygienic conditions.

Revised by WILLIAM PEPPER.

A Posteriori and **A Priori**: Before the time of Kant the former of these terms denoted a reasoning from effect to cause, and the latter a reasoning from cause to effect. Since Kant's time, and owing to his influence and that of his school, these terms are generally used more in relation to the doctrine of knowledge; a *posteriori* knowledge being empirical knowledge, or knowledge through experience, and a *priori* knowledge being rational knowledge, or a knowledge through the reason of that which is prior to experience. See ONTOLOGY and PHILOSOPHY.

Apos'tle [from Gr. ἀπόστολος, one sent forth; ἀπό, away + στέλλειν, send]: literally, "one sent," especially a "delegate"—e. g. in care of a collection; so Philo calls the persons sent to carry the tithes of the Dispersion to Jerusalem "apostles." In the New Testament the term is applied (1) to men divinely sent before Christ (Luke xi. 49); (2) to Christ himself (Heb. iii. 1); and (3) to church delegates—very much in the Philonian sense (Rom. xvi. 7; 2 Cor. viii. 23; Phil. ii. 25). The commonest application, however, is (4) to the twelve whom Jesus chose and sent to preach his religion (Luke vi. 13), viz.: Simon Peter, Andrew, James, John, Philip, Bartholomew (Nathanael), Thomas, Matthew, James the son of Alphæus, Thaddeus, Simon the Canaanite, and Judas Iscariot. There was no express command to keep up their number, yet it was doubtless approved of all to elect one to fill the vacancy caused by the suicide of Judas Iscariot. No successors of the twelve were in the nature of the case possible. When Paul had demonstrated his capacity as a preacher he was allowed to call himself the apostle to the Gentiles. Paul claimed that his commission was as much from Jesus as that of any of the other apostles. But this is really to use the term in a sense divergent from the primitive one. In this latter sense (5) Paul and Barnabas (Acts xiii. 1-3) were both apostles, sent by the Holy Spirit, and are so called afterward. The term was still further extended (6) to include the seventy disciples, and even Clement of Alexandria and others. Among the first disciples the chief requisites for an apostle were (1) that he should be the personal choice of Christ and (2) be a witness to the resurrection of Jesus. So Matthias was an apostle, as the use of the divinely directed lot rendered him the choice of the Lord, and he could testify to the empty tomb and to the appearance of the risen Lord.

Apostles, Acts of the (Gr. Πράξεις τῶν Ἀποστόλων): fifth book of the New Testament, written by Luke, containing the history of the period from the ascension of our Lord to the first captivity of Paul in Rome; that is, in all probability, from 30 to 63 A. D. It is proper to observe that though this portion of the Scriptures is styled the Acts of the Apostles it treats only of the acts of Peter, Paul, and James; and of these, only Paul's career is narrated fully and connectedly. The book is avowedly a continuation of the third Gospel, and, though restricted within such narrow limits, may be said to give those great events in the history of the apostles in which the Christian Church would naturally feel the greatest interest. It is a history of the founding of the Christian Church among the Jews (the work chiefly of Peter) and among the Gentiles (the work chiefly of Paul). Among these events the pouring out of the Holy Spirit at Pentecost, the martyrdom of Stephen, and the conversion of St. Paul, as well as most of his subsequent journeys and labors, are fully related. The best commentaries on Acts are by Lechler (in Lange's *Biblework*), Meyer, Hackett, and Gloag.

Apostles' Creed (Lat. *Symbolum Apostolicum*): called also the Creed or Confession of Faith; the most universal creed of the Christian Church. It is as follows: "I believe in God the Father Almighty, Maker of heaven and earth: And in Jesus Christ his only Son our Lord: Who was conceived by the Holy Ghost, Born of the Virgin Mary: Suffered under Pontius Pilate, Was crucified, dead, and buried: He descended into hell [or hades], The third day he rose again from the dead: He ascended into heaven,

And sitteth on the right hand of God the Father Almighty: From thence he shall come to judge the quick and the dead. I believe in the Holy Ghost: The Holy Catholic Church; The Communion of Saints; The Forgiveness of sins; the Resurrection of the body; And the Life everlasting. Amen." According to a tradition prevailing in the fourth century, but now generally discredited, this creed was composed by the apostles themselves, each contributing one of the articles. Some churches omit the clause, "He descended into hell," asserting that it was not a part of the original creed. In the American Prayer-Book (Standard of 1892) the rubric is as follows: "*And any churches may instead of the words, He descended into hell, use the words, He went into the place of departed spirits, which are considered as words of the same meaning in the Creed.*" See CREED.

Apostles' Islands, or the Twelve Apostles: a group of twenty-seven islands in Lake Superior, 70 miles W. of Ononagon (see map of Wisconsin, ref. 1-C). The principal islands are Ile au Chêne, Madeline, Bear, Stockton, and Outer island. The islands belong to Wisconsin. They are covered with fine timber, and their cliffs have been worn into strange forms by the action of the waves. The land area is estimated at 200 sq. miles. Brown sandstone is quarried and exported from the islands. La Pointe, on Madeline island, was formerly the capital of Ashland co., Wis. This place was settled by the French in 1680. The Jesuits established very early several missions on these beautiful islands.

Apostolic, or Apostolical: a general epithet applied to everything directly derived from, or bearing the character of, the apostles. The Roman Catholic Church styles itself the Apostolic Church, and the papal chair is called the Apostolic chair, because the pope is supposed to be the legitimate and lineal successor of Peter, the chief apostle. The Church of England claims to be apostolic in virtue of regular episcopal ordination from the Church before the Reformation; so also do the Protestant Episcopal churches in Scotland and the U. S. Several churches of Jerusalem, Antioch, Ephesus, Corinth, and Rome, which were the special scenes of the labors of the apostles, were called apostolic churches. With the increasing power of the Roman Catholic Church the word apostolic was more exclusively applied to whatever belonged to that Church, as Apostolic See, Apostolic Canons, etc.

Apostolic Canons and Constitutions: notes of ecclesiastical customs regarded as apostolic. The Apostolic Constitutions (*Constitutiones Apostolicæ*) consist of eight books, the first six of which contain a comprehensive rule for a Christian life. These are supposed to have been written about the end of the third and beginning of the fourth century. The Apostolic Canons (*Canones Apostolici*) were composed at a later period. The first fifty, translated from Greek into Latin by Dionysius Exiguus, were acknowledged by the Latin Church alone. The Greek Church accepted the thirty-five canons put forth early in the sixth century; and this became a point of dissension between the Eastern and Western churches. The Apostolic Constitutions have been ascribed by some writers to Clement of Rome. In them, as Bishop Lightfoot (*Apostolic Fathers*, pt. i. S. Clement of Rome, i. 100, 101) states, "the apostles are represented as communicating to Clement their ordinances and directions for the future administration of the Church." The Apostolic Canons "may be regarded as a corollary to the Constitutions."

Revised by W. S. PERRY.

Apostolic Fathers: the disciples and fellow-laborers of the apostles, especially those who have left writings. They are Barnabas; Clement of Rome; Ignatius, Bishop of Antioch; Polycarp, Bishop of Smyrna; Hermas; and Papias of Hierapolis. Some also include the author of the epistle to Diognetus among these Fathers. Cotelerius (Paris, 1672) issued an edition of the works of the Apostolic Fathers, which was improved by Clericus in 1698, and again in 1724. Of recent editors, the best are Jacobson (1838; 4th ed. 1866), Hefele (1839; 5th ed. 1878), and Dressel (1857; reissued 1863). Another edition, by Gebhardt, Harnack, and Zahn (1876, 1877, 1878). The late Bishop of Durham, Dr. Lightfoot, published (1890) *The Apostolic Fathers*, a revised text, with introductions, notes, dissertations, and translations, in five octavo volumes. The translations were reprinted in one volume (1892). Another translation is found in the Ante-Nicene Christian Library, vol. i.

Apostol'ici, or **Apostolic Breth'ren**: a sect of religious reformers who originated in Italy in the latter part of the thirteenth century, and had for their leader Gherardo Segarelli, of Parma. They traveled over Italy, France, and Switzerland, preaching the duty of renouncing worldly ties, property, etc. Having denounced popery, they were condemned by Pope Honorius IV., and Segarelli was burnt at the stake (1300). His place was filled by Dolcino, formerly a priest of Milan, who, after a brave resistance, was, with his adherents, taken by the forces of the pope, and perished at the stake in 1307.

Apostolic Majesty: a title of the Kings of Hungary; first conferred on the Duke of Hungary by Pope Sylvester II. in 1000 A. D. The title was renewed in 1758 by Pope Clement XIII. in favor of Maria Theresa.

Apostolic Par'ty: a party of fanatical Spanish Catholics, formed about 1820 for the promotion of an absolutist political policy. Their leaders were priests. In 1830 they merged themselves into the Carlist party.

Apostolic Succession: the uninterrupted succession of bishops, priests, and deacons (the apostolic orders) from the first apostles down to the present day. The Roman Catholic, Greek, Oriental, and Anglican churches consider this historical and essential. See ROMAN CATHOLIC CHURCH, ENGLAND, CHURCH OF, and GREEK CHURCH.

Apostool', SAMUEL: Dutch Mennonite theologian; b. in 1638. He became in 1662 a minister of a Waterlandian congregation in Amsterdam. He and Galenus engaged in a doctrinal dispute which divided the Church into two sects, Apostoolians and Galenists. D. about 1700.

Apos'trophe [Gr. ἀποστροφή, a turning away; ἀπό, away + στρέφειν, turn]: in rhetoric, a digressive address; a figure of speech by which the orator suddenly changes the course of his oration, and addresses with emotional emphasis a person present or absent, or some inanimate object. Frequent examples of it occur in the speeches and writings of great orators and poets.

Apoth'ecary [from Lat. *apotheca'rius*, storekeeper, from *apotheca*, loan, from Gr. ἀποθήκη, storehouse]: a person who compounds and sells medicines, and makes up medical prescriptions. The profession of an apothecary in England may be not incorrectly described as an inferior branch of the medical profession. He is legally entitled to attend sick persons and prescribe for them, as well as to make up and dispense medicines. It is not, however, usual for him to prescribe medicines to be prepared and supplied by others. But, although he may attend sick persons and prescribe for them, he can not charge both for his attendance and his medicines, but must make his election between the two. Although, therefore, the apothecary is inferior in professional rank and authority to the physician and surgeon, he is considered to be of a higher grade than the chemist and druggist, who merely vends drugs and medicinal compounds, but whose qualification, beyond the payment of a small annual tax by way of license, does not necessarily offer any test or guarantee of skill. The rules of the Pharmaceutical Society of Great Britain, incorporated in 1843 by royal charter, and the powers of which were considerably enlarged by a statute passed on June 30, 1852, operate as some restraint on ignorance and want of skill. Apothecaries and grocers (like surgeons and barbers) were in England and other countries formerly members of the same guild, and hardly distinguishable from each other. They were chartered as one company in London in 1606, but in 1617 James I. granted the apothecaries a charter as a separate corporation.

In the U. S. the vocation of the apothecary is mostly quite distinct from that of the medical practitioner. Among physicians it is generally regarded as contrary to professional ethics for a practitioner, in large cities at least, to be directly interested in the retailing of medicines. The education of pharmacists in the U. S. has greatly advanced of late years. Many of them are now graduates of colleges of pharmacy (the most important of which are in New York and Philadelphia), wherein excellent scientific and practical training is obtained. There is also a well-organized national pharmaceutical association. To limit the danger connected with the unskillful dispensing of drugs, a law has been put in force in New York and other States requiring all apothecaries to pass a rigid examination.

Apothe'osis [Gr. ἀποθέωσις, deification; ἀπό, off (to completion) + θεῖν, make into a god (θεός)]: a Greek word meaning deification, or the practice of raising a human be-

ing to a place among the gods. This practice was common among the ancient Greeks, who deified and worshiped heroes and benefactors after their death. Among the Romans, Romulus was the first who received such an honor, and Julius Cæsar appears to have been the second. Alexander the Great sent to all the states of Greece an order that they must recognize his divinity, and received from Sparta this laconic answer: "Since Alexander desires to be a god, let him be (or become) a god!" Several Roman emperors apotheosized themselves and their favorites.

Appalach'ee Bay: a large open bay near the northern part of Florida; is a part of the Gulf of Mexico, and is about 30 miles S. of Tallahassee. It extends inland about 50 miles.

Appalachees: See MUSKHOGEAN INDIANS.

Appalachian Mountains: the chain of mountains traversing the eastern part of the U. S. from Maine to Alabama. It is composed for the most part of a large number of ridges or small ranges, parallel with one another, with the Atlantic coast, and with the axis of the chain. The general trend is S. W. Prominent members of the chain are the White Mountains of New Hampshire, the Green Mountains of Vermont, the Adirondack and Catskill Mountains and the Highlands of New York, and the Alleghany Mountains of Pennsylvania and West Virginia. In part of Pennsylvania and in Virginia the most easterly range is called the Blue Ridge, and in North Carolina this region adjoins a broad mountain mass, the Great Smoky range, including the highest peaks of the chain. The culminating points are Mt. Mitchell, N. C., 6,688 feet, and Mt. Washington, N. H., 6,293 feet. S. of New York the subordinate ridges are remarkably uniform in outline and height, and in general long and closely parallel; and they are separated by valleys equally long, parallel, and simple in configuration. One valley, broader than the others, is of great length, extending from Alabama to Pennsylvania. It is locally known as the Coosa valley, the Great valley of Tennessee, the Great valley of Virginia, and the Cumberland valley, and is sometimes called collectively the Great Appalachian valley.

The constituent geological formations range in age from the Archean to the Coal-Measures, including representatives of each of the Paleozoic periods. In a general way, the older rocks lie nearer the coast and the younger toward the N. W., but to this there are exceptions. In New England all the Paleozoic rocks are metamorphic, and have not yet been fully discriminated from the older crystallines. From Pennsylvania southward the great valley divides the chain into two belts, of which the northwestern contains Paleozoic strata with little metamorphism, but greatly folded and faulted, and the southeastern contains crystalline rocks, of which a portion are metamorphic Paleozoic, and other portions are of greater age. The principal folding of the strata took place during and at the close of the Paleozoic era, when they were crowded together by forces acting in a N. W. and S. E. direction. The amount of compression in that direction is believed to have been from 5 to 15 miles, and the rocks were not only forced into a parallel system of huge wrinkles, but were in many places fractured and made to slide over one another. The resulting mountains may have had great magnitude, but in the geologic ages that followed they were almost completely worn away by the untiring action of rains and rivers, the country being reduced to an approximate plain, above which projected a few low ridges, marking the outcrops of the most enduring rocks. Subsequently the whole region was upraised bodily, apparently without renewal of the folding process, and from the plateau thus formed the rains and rivers of the last geologic periods have carved the existing chain. Wherever a soft or a soluble rock was exposed at the surface a valley was made, and the outcrops of hard rocks were left as the existing ridges. The great Appalachian valley marks the position of a broad belt of Cambrian and Silurian limestones. If we date the Appalachians from the folding of their strata, they are among the older of the mountain systems of the earth; if we date them from the time of their relifting and final sculpture, they are comparable in age with the Sierra Nevada, the Alps, and the Rocky Mountains.

The leading minerals derived from the chain are coal, iron, manganese, copper, zinc, marble, and slate. See *Physical Structure of the Appalachian Chain*, by H. D. and W. B. Rogers (*Amer. Jour. Science*, 1st ser., vol. xlv.); and *The Appalachian Mountain System*, by Arnold Guyot (*Amer. Jour. Science*, 2d ser., vol. xxxi.). G. K. GILBERT.

Ap'palachico'la: a river, formed by the union of the Chattahoochee and Flint, at the S. W. extremity of Georgia. It flows southward through Florida, and after a course of 100 miles enters Appalachicola Bay, a part of the Gulf of Mexico. It is navigable for steamboats.

Appalachicola: city and port of entry; 85 miles S. W. of Tallahassee; capital of Franklin co., Fla. (for location of county, see map of Florida, ref. 3-E); on river of same name, at its point of entrance into St. George's Sound, a part of the Gulf of Mexico. It has a large trade in timber and fish. Pop. (1880) 1,336; (1895) 3,061.

EDITOR OF "TIMES."

Appalachicola Bay: in the State of Florida; is situated in the N. E. part of the Gulf of Mexico, between St. George's island and the mainland, at the mouth of Appalachicola river.

Appanage: See APANAGE.

Appara'tus Sculpt'oris (the *Sculptor's Workshop*): a constellation situated immediately east of the large star Fomalhaut. It hardly rises above the horizon in the northern hemisphere.

Appa'rent [from Lat. *appa'rens*; part. pr. from *appa'reo*, appear]: that appears to the eye, in distinction from true or real. This word is used in astronomy to express several important distinctions, as "apparent time," which is indicated by the sun, and differs from true time. The apparent magnitude of a heavenly body is the dimension of the angle formed by two lines drawn from the ends of its diameter to the spectator's eye. The apparent diurnal motion of the sun and moon is an optical illusion caused by the rotary motion of the earth, and the real motion of the moon is contrary to its apparent motion. An heir-apparent to a throne is a person whose title is better than any other except the actual occupant of the throne, and whose succession does not depend on any contingency if he survive the reigning monarch.

Appari'tion [Lat. *appari'tio*, an appearance; see APARENT]: literally an appearance or appearing; in common language a specter, a ghost, a visible spirit. In astronomy it means the first appearance of a heavenly body after it has been eclipsed or obscured. Stars which appear to revolve around the pole, and which never set below the horizon, are said to be within the circle of perpetual apparition, which circle grows larger and larger in proportion as the spectator approaches the pole.

Appar'itor [Lat., attendant, from *appare're*, wait upon]: among the ancient Romans one of the officers or public servants who attended the magistrates and judges, including heralds, lictors, scribes, etc. In England the term is applied to the officer of an archiepiscopal, episcopal, archdiocesan, or other ecclesiastical court whose duty it is to summon persons to appear before the judge. It is also applied to the beadle of a university, who carries the mace, as well as to a messenger of a spiritual court, who serves its process.

Appeal [from Lat. *appello*, call]: in law, an accusation of a private citizen against another of some heinous crime, demanding punishment for the peculiar injury suffered, rather than for the offense against the public. This proceeding has been entirely abolished in England, and does not exist in this country. The word also means the removal of a cause from an inferior to a superior court for the purpose of obtaining a review and retrial of the case. It differs from a *writ of error* and a *certiorari*, inasmuch as they merely bring up for review the questions of law involved in the proceedings in the lower court, while by an appeal the questions both of law and fact may be re-examined. In a popular sense, the word signifies the removal of a cause, or of a proceeding in a cause, from an inferior to a superior court for the purposes of review, by whatever means effected. Codes of procedure in a number of States abolish writs of error in civil cases, and establish a review by appeal in all actions, whether of a common-law or equity nature. The word "appeal" is used in parliamentary law to indicate the mode of questioning the decision of the presiding officer as to a parliamentary rule.

Appear'ance [ultimately from Lat. *appareo*, be seen]: in law, the act by which a party to an action brings himself, or is brought, into court, usually applied to the defendant. Appearance is either voluntary or compulsory. It is said to be voluntary when no process has been served. It is also special or general. It is said to be special when made for

special purposes, not extending to the entire subject of litigation. It is general when absolute and unconditional. A notice of appearance will suffice, or the performance of some act from which an appearance can be inferred, such as serving a pleading. In civil cases it may be made by an attorney as well as by a party. In criminal cases personal appearance of the accused is frequently requisite, particularly in cases of felony.

Appel, THOMAS GILMORE, Ph. D., D. D., LL. D.: minister of the (German) Reformed Church in America; b. in Easton, Pa., Nov. 14, 1829. After graduating from Marshall College he served for some years as teacher, and afterward as pastor. He was president of Mercersburg College, 1865-71, and from 1871 has been Professor of Church History and New Testament Exegesis in the Theological Seminary at Lancaster, Pa. In addition to this work he was president of Franklin and Marshall College, 1877-90, and has edited the *Reformed Quarterly Review* from 1867. He has written much for the press, and has been active in the public work of his Church, in the movements for bringing the two Reformed churches into closer relations, and in the alliance of the Presbyterian churches of the world. W. J. BEECHER.

Appendici'tis: inflammation of the vermiform appendix resulting from obstructions at the mouth of the appendix or from extension of inflammation from the colon. Foreign bodies, such as grape-seeds, are much less important in its causation than was formerly believed. The appendix becomes swollen and filled with pus, and tends to rupture, when general peritonitis may result. Very often, however, inflammatory exudations around the appendix limit the inflammation, even though rupture has occurred.

The onset of appendicitis is usually abrupt, and the patient complains of pain in the right flank, of constipation, and of fever. Vomiting is usually present and may be a distressing symptom. The occurrence of chills and marked fever may indicate the beginning of suppuration, and sudden collapse may denote the occurrence of rupture of the appendix into the peritoneal cavity. A majority of the cases if left to themselves recover, but there is a constant tendency to relapses of the disease. Removal of the appendix by surgical operation is justified in cases of oft-repeated appendicitis, and during acute attacks is often proper or necessary. Medicinal treatment if begun early enough aborts many cases. W. P.

Ap'penzell [i. e. *des Abts Zelle*, the abbot's (of St. Gall) cell]: a canton in the N. part of Switzerland; bounded on every side by the canton of St. Gall (see map of Switzerland, ref. 3-I). In consequence of religious differences it was divided in 1597 into two half cantons—Appenzell Inner Rhodes (Catholic) and Appenzell Outer Rhodes (Protestant). Inner Rhodes has an area of 61 sq. miles, and had in 1894 a population of 12,899. Outer Rhodes has an area of 101 sq. miles; pop. in 1894, 55,616. It consists entirely of a wild mountain country, intersected by narrow valleys. Capital of Inner Rhodes, Appenzell; and of Outer Rhodes, Trogen. The canton was formerly subject to the abbey of St. Gall, gained its independence early in the fifteenth century, and joined the confederation in 1513.

Apperception: as used by Leibnitz, a knowledge that brings with it a reflection of the mind upon itself by which we know such objects as the ego, the soul, self-existence, true substances, spiritual being—in a word, immaterial things and truths. HERBERT (*q. v.*) used apperception to mean the act of recognition, identification or interpretation with which we assimilate what we perceive. In the works of Herbart and his followers this idea becomes of great importance for the philosophy of education. Apperception stands for what we understand and perception for what we only see. It is not what we perceive but what we apperceive that educates us. Kant found in the mind a transcendental act of apperception, while Herbart investigated the apperception which arises through the recognition of what has been formerly perceived in the object before us. W. T. H.

Appian of Alexandria (in Gr. Ἀππιανός): Greek writer of Roman history; came to Rome under Hadrian and was made a procurator by the influence of FRONTO (*q. v.*). In his *Roman History* (Ῥωμαϊκά), written about 160 A. D. in twenty-four books, he forsook the annalistic plan for the method of groups, of which we have those that pertain to the Spanish, Hannibalic, Punic, Syrian, Mithridatic, Illyrian, and Civil wars, about half of the whole. Appian is not critical; his style has no elevation and swarms with Latin-

isms. Ed. by Schweighäuser (1785); critical ed. by Mendelsolm (1881).

Appia'ni, ANDREA: Italian painter; b. at Bosizio, May 23, 1754; imitated the style of Correggio. He is thought to have excelled all the artists of his time in fresco-painting. About 1805 he was appointed court-painter to Napoleon, whose portrait he painted. Among his masterpieces are the frescoes on the ceiling of the royal palace of Milan, and those in the Church of Santa Maria Vergine, in the same city. D. in Milan, Nov. 8, 1817. See G. Longhi, *Elogio Storico di A. Appiani* (1826).

Ap'pian Way (in Lat. *Via Appia*): one of the great highways leading from ancient Rome, and the most famous of all because probably the first that was well and thoroughly constructed, and because it was lined with tombs and monuments for several miles outside of the walls. It extended originally from Rome to Capua, 125 miles, but was eventually continued to Brundisium. It was built in a very thorough manner, and was paved with large polygonal blocks of the hardest stone, accurately fitted to each other, so as to appear like a solid mass. The substructure was solidified by cement. The road has been partially restored by excavation, and is found to be in a remarkable state of preservation.

Revised by RUSSELL STURGIS.

Applause [from Lat. *applau'dere*, *applau'sum*, strike upon, clap]: a shout of approbation; an approving acclamation; a public expression of approbation and praise by striking upon the floor or the clapping of hands. This custom prevailed among the ancient Greeks and Romans. The Roman comedians usually terminated their performances with a request that the audience would applaud, *valet et plaudite!* Three species of applause were used by the Romans—namely, *Bombus*, a confused hum, like the buzzing of bees, produced by the mouth or the hands; and *Imbrices* and *Testæ*, which were sounds made by striking vessels placed in the theater for this purpose. The last was like the sudden crash produced by the fall and fracture of a set of chinaware.

In modern times, French politicians and dramatists often

small, hard apples, useful only for culinary purposes, and which are offspring of *Pyrus baccata* or are supposed hybrids between that species and *Pyrus malus*.

The apple is the most important fruit of temperate climates, and is peculiarly adapted to a large area of North America, where it occupies a larger acreage probably than any other fruit. In 1890 the number of acres devoted to the growing of apple-trees in nurseries was 20,232.75; and the total number of trees then growing in these nurseries was 240,570,666. The leading apple districts of North America are those comprising the Middle and Southern New England States, New York and Michigan, the Annapolis valley of Nova Scotia, a large area of the Province of Ontario, the middle altitudes of the Alleghanies in Virginia and southward in the Carolinas, the central area comprising Missouri, Kansas, and Northwestern Arkansas, and a large area in the Pacific Northwest, including the States of Oregon and Washington. The apple is profoundly influenced by latitude and climate. In the Northeastern States and Canada the fruit is very firm, highly colored, of high flavor and long-keeping quality. As the apple regions extend southward the fruit takes on a duller or less intense color, and loses much of its sprightliness or flavor, has a tendency to become larger, and the keeping qualities are very greatly diminished. Thus the Tompkins King, which is one of the standard winter apples of the northernmost States, becomes a fall apple in Kentucky. A knowledge of these influences of the climate upon the apple has come to be of great importance to apple-growers, in consequence of the growing export trade which demands apples of great firmness and of long-keeping qualities. Apple cultivation is rapidly assuming a new importance in the New England States, New York, and Canada, because of the trade which is opening up in the European countries. So long ago as 1845 apples were shipped to Scotland in small quantities, but it was not until 1880-81 that the export trade assumed great importance. It is now one of the established lines of international trade. The table on this page, showing the apple exportations during the last decade in barrels, will give some idea of the importance of this industry.

avail themselves of the services of hired applauders, called *claqueurs*, who cry *Bis, bis!* (twice, again, encore), or *Bien, très bien!* The audiences of English actors signify their approbation by the cry of *Encore!* but in the British House of Commons applause is expressed by cries of *Hear! hear!*

Apple: the fruit of a tree belonging to the rose family, and known botanically as *Pyrus malus*. It is supposed to be a native of Southwestern Asia and of a large part of Europe. De Candolle thinks "it probable that the tree was indigenous in Europe as in Anatolia, the south of the Caucasus and Northern Russia, and that its cultivation began early everywhere." It has been cultivated from time immemorial. The Siberian crab-apple is *Pyrus baccata*, which is characterized by very hard, dense wood, long-stalked and nearly smooth leaves and flowers, and a hard and austere small fruit from which the calyx drops before the fruit is fully ripe. Several varieties of this species are in cultivation in this country, but they are of minor importance. There are a number of species of wild apple in America, two of which (*Pyrus coronaria* and *P. Ioensis*) appear to possess some value as possible fruit-plants. Another type of native apple, which has already gained some prominence, is that represented by the Souldard crab, which has been recently described under the name of *Pyrus Souldard'i*, but which may be a hybrid between the common apple and *Pyrus Ioensis*. The term *crab-apple* is applied somewhat loosely to any small and inferior apple, whether belonging to *Pyrus malus* or to other species. Among pomologists, however, the term is often technically used to designate a class of

This export trade is confined almost entirely to shipments to England and Scotland, but there is reason to believe that other European markets may be opened with profit. There is probably no country in the world which can compete successfully with the U. S. and some parts of Canada in the production of apples.

In Europe apples are grown extensively in the central countries, in Denmark and throughout Great Britain, but there are few places in which apple cultivation is carried on so extensively and with such uniform commercial results as it is in the U. S. Very lately Tasmania and New Zealand have gained prominence as apple-growing countries, and they now ship considerable quantities of fruit to Great Britain and some to the Western U. S. Tasmanian apples were shipped to England as early as 1870, but only recently has this exportation become important. In 1890 there were shipped from Tasmania to Great Britain some 80,000 cases of apples, each holding about 40 lb. of fruit. These sold at prices ranging from 10s. to 20s. Tasmanian apples began to attract attention in San Francisco in 1890, and in 1891 shipments were received there from Australia and New Zealand. The Tasmanian and New Zealand apples, however, do not compete with the U. S. product, as they are received at a season of the year when domestic fruit is growing. They begin to arrive in the San Francisco and London markets in April and early in May.

The soils which are thought to be best adapted to apple cultivation are the higher and more rolling lands which contain more or less gravel, and are possessed of both atmospheric and water drainage. Those lands which are well

adapted to wheat and corn ordinarily make good apple lands. Soils which are warm and comparatively dry, and which admit of frequent and timely cultivation, are most desirable, both for the good of the tree and for the quality of the fruit.

The varieties of apples are very numerous, reaching undoubtedly four or five thousand; but the number of varieties actually grown for profit in the U. S. is probably not over 200, and in any one locality the number of profitable varieties will not ordinarily exceed a dozen or twenty. The varieties differ widely in different parts of the country, especially between the North and South, and there are few of the apples which are adapted to New England and New York which are grown so far S. as Maryland and Virginia. During recent years a great effort has been made to extend the apple regions northward in the northern parts of New England and into the colder parts of the Mississippi valley, as Wisconsin, Iowa, and Minnesota. This has been done by the origination of varieties of great hardiness, and by the importation of varieties from Russia. The apples grown in these cold regions nearly always possess great delicacy and beauty of surface and texture, but so far there are comparatively few of them which possess very high quality. There is every reason, however, to hope for the best results in the future.

New varieties of apples are produced by sowing seeds. As a rule, all the seedlings are different from each other, but it is only rarely that a meritorious variety is obtained. When such a variety is procured, however, it is readily propagated by grafting or budding it upon other seedling stocks, or in some cases it is grafted into the tops of old trees. The seedling trees or stocks, upon which the varieties are budded or grafted, are obtained by sowing the apple seeds in drills in early fall or spring; and the resulting trees are taken up at the end of the first season's growth, when they are ready to be set in nursery rows. In practice these seedling stocks are stored in cellars during the first winter, and the next spring they are set in the nursery into rows about 3 or 4 feet apart, and about a foot apart in the row. If the stocks are to be budded (see GRAFTING), the operation is performed during the following July and August. If they are to be grafted, they are taken up in the following fall and stored in cellars, and the grafting is performed during the winter season. During the following season, which is two years from the sowing of the seed, the trees, whether budded or grafted, grow rapidly, and make at the end of that year what the nurseryman calls the yearling trees. Apple-trees are rarely set in the orchard, however, until they are two or three years old—that is, two or three years from the bud or the graft. In the orchard, the larger growing varieties should be set as far as 40 feet apart each way; some of the smaller growing varieties may be put as close as 30 feet. Good cultivation during the first ten years of the orchard is advisable, during which time the soil should be well fertilized; but annual cultivated crops, such as corn and potatoes, may be grown in the same land in the meantime with good results. Trees should be pruned regularly and judiciously every year from the time of setting. Pruning produces the best quality of fruit, promotes the healthfulness of the tree, and renders it amenable to the best cultivation and treatment.

Numerous insects prey upon the apple-tree and its fruit. The most important is the codlin-moth, a small lepidopterous insect which lays an egg in the apex or blossom end of the apple soon after the petals fall. The larva soon hatches from this egg and bores directly downward into the fruit. In recent years this insect is being kept within almost entire control by spraying, as soon as the last blossoms fall, with some arsenical poison, as Paris green or London purple. One lb. of the poison to 200 or 250 gal. of water is used. (See INSECTICIDES.) This is sprayed thoroughly upon the tree as soon as the last petals fall, and again at an interval of a week or ten days. The arsenic lodges in the small cup-like cavity of the apex of the apple and destroys the young larva. No danger to health may be feared from this operation of spraying, for all traces of the poison are washed away by the rain long before the apple reaches maturity. The apple-scab is a well-known fungous disease of the apple, which causes the fruit to become distorted and scabby (see cut), but one which can be controlled by a spray of copper solutions, especially by the ammoniacal carbonate of copper. This disease is also common upon the leaves, producing discolored or blighted patches. (See FUNGICIDES.) For further information, see Downing's *Fruits and Fruit Trees of Amer-*

ica; Warder's *Pomology*; Barry's *Fruit Garden*; Thomas's *Fruit Culturist*; Fitz's *The Apple*; Strong's *Fruit Cul-*

Apple scab.

ture; Todd's *Apple Culturist*; Bailey's *Field Notes on Apple Culture*; Wickson's *California Fruits*. L. H. B.

Apple Blight: a disease of apple-trees, caused by a species of aphid (*Aphis lanigera*). This little insect penetrates the chinks in the bark, extracting the sap, causing diseased excrescences, and ultimately the death of the tree.

Apple Diseases: See BLIGHT, ROT, RUSTS, and SCAB.

Appledore: a small seaport and watering-place in the parish of Northampton, Devonshire, England; at the mouth of the river Torridge and on Barnstaple Bay, about 2 miles N. of Bideford (see map of England, ref. 13-D).

Apple Oil (artificial): a solution of valerianate of amyl in six parts of alcohol.

Apples of Sod'om: a fruit mentioned by Josephus and other ancient writers as growing near the Dead Sea. It was fair in appearance, but when grasped in the hand collapsed into dust and ashes. Some modern writers have supposed that it was the fruit of *Solanum Melongena* (nightshade), but Robinson identifies it with the *Asclepias gigantea*, the fruit of which looks like an orange, but disappoints those who touch it by its nauseousness in an immature state, and its emptiness when fully ripe.

Appleton: city; capital of Outagamie co., Wis. (for location, see map of Wisconsin, ref. 5-E); on the lower Fox river, 30 miles S. of Green Bay. The river is navigable for steamboats, and has here a constant fall of 49 feet, furnishing inexhaustible water-power. The city is the seat of Appleton Collegiate Institute and of Lawrence University. Pop. (1880) 8,005; (1890) 11,869; (1900) 15,085.

THE "POST" PUBLISHING CO.

Appleton, DANIEL: founder of the publishing house of D. Appleton & Co.; b. in Haverhill, Mass., Dec. 10, 1785; became a dry-goods merchant there and later in Boston, removing in 1825 to New York, where he combined the business of importing English books with the sale of dry goods, but soon abandoned the latter and gave his attention solely to books and publishing. *Daily Crumbs from the Master's Table* (1831) was the first of the many thousands of valuable works in literature, science, and art which have been issued from the press of D. Appleton & Co. He retired in 1848, and died Mar. 27, 1849. His eldest son, William II. (b. Jan. 27, 1814; d. Oct. 19, 1899), a partner from 1838, carried on the business in partnership with his brothers (now all deceased) and later with his son William W. and the sons of his brothers John A. and Daniel Sidney. It has now attained enormous proportions; its growth necessitating many removals—from Exchange Place about 1830 to Fifth Avenue in 1894.

Appleton, JESSE, D. D.: theologian; b. at New Ipswich, N. H., Nov. 17, 1772, and settled over the Congregational Church in Hampton, N. H., in Feb., 1797. In 1803 he was one of the most prominent candidates for the chair of theology in Harvard University. In 1807 he was chosen president of Bowdoin College, Brunswick, Me., and there died Nov. 12, 1819. A man of rare abilities and high classical culture, he was distinguished also for saintliness of character and singular dignity and grace of manners. His works, with a memoir prefixed, were published by his son-in-law, Prof. Alpheus S. Packard, in 1837.

Appleton, JOHN, LL. D.: jurist; b. in New Ipswich, N. H., July 12, 1804; graduated at Bowdoin College in 1822. In 1852 he became a justice of the Supreme Court of Maine, and in 1862 chief justice, being reappointed in 1869 and 1876. He published two volumes of *Maine Reports*. D. at Bangor, Me., Feb. 7, 1891. HENRY WADE ROGERS.

Appleton, JOHN: b. at Beverly, Mass., Feb. 11, 1815; graduated at Bowdoin College in 1834; became a lawyer and prominent Democratic editor in Portland, Me., where he settled in 1837, became chief clerk of the U. S. Treasury Department in 1845, and afterward held a similar position in the State Department; was *chargé d'affaires* to Bolivia (1848-49), member of Congress (1850-59), secretary of legation in London (1855-56), U. S. minister to Russia (1860-61). D. at Portland, Me., Aug. 22, 1864.

Appleton, NATHAN, LL. D.: merchant; b. at New Ipswich, N. H., Oct. 6, 1779; became a partner of his brother Samuel in Boston. He was one of the founders of Lowell, Mass., was several times in the Massachusetts Legislature, and was chosen a member of Congress in 1830 and again in 1842. Wrote speeches and essays on banking, currency, and the tariff. He was a member of the Academy of Sciences and Arts, and of the Massachusetts Historical Society. D. in Boston, July 14, 1861.

Appleton City: village; on Mo., Kan. and Tex. R. R.; St. Clair co., Mo. (for location of county, see map of Missouri, ref. 5-E); has various manufactures. Pop. (1880) 1,034; (1890) 1,081; (1900) 1,133.

Appoggiatura, ap-pod-ja-too'ra, literally, a support [Ital. from *appoggiare* (Fr. *appuyer*) < Lat. *appodia're*, lean upon; *ad*, to + *podium*, support, from Gr. *πόδιον*, base]; an Italian musical term indicating a form of embellishment by insertion of one or two "passing notes" in a melody. These notes are printed in a smaller character than the notes of the melody itself.

Appointment [remotely from Lat. *ad*, to + *punctum*, point]; in law, a disposition of property made by one authorized by a power contained in a deed, will, or other instrument to direct its use; an instrument executed pursuant to a power of appointment directing the disposition of property agreeably to such power (see POWERS). The word is also used to indicate the designation by lawful authority of some person to hold an office or to perform a public duty. Under the U. S. Constitution the President has the power to nominate, and, with the consent of the Senate, to "appoint," persons to hold certain specified offices.

Ap'pold, JOHN GEORGE, F. R. S.: English mechanician; b. in London in 1800; the inventor of a celebrated centrifugal pump, of machinery for paying out marine telegraph cables, and of a process for dressing furs, which last gave him the control of that business. His house was a museum of wonderful mechanical devices, which opened and closed doors, shutters, and gates, and performed many other surprising acts by automatic machinery. D. in London, Aug. 31, 1865.

Apold Centrifugal Pump: See PUMP.

Appomat'tox: a river of S. E. Virginia; rises in Appomattox County, flows in a general easterly direction, and enters the James river at City Point. Length, estimated at 150 miles. It is navigable for large vessels to Petersburg, 20 miles from its mouth.

Appomattox Court-house: former capital of Appomattox co., Va. (for location, see map of Virginia, ref. 6-F); here Gen. R. E. Lee, with the Confederate army of Northern Virginia, surrendered to Gen. Grant, Apr. 9, 1865.

Appor'tionment [ultimately from Lat. *ad*, to + *portio*, a share]; in law, the division of a thing into parts; the distribution of a claim or charge among different persons in proportion to their interests in the subject-matter to which it attaches. The leading cases concern—1, Incorporeal rights in land, such as commons and rents; 2, Encumbrances upon land; 3, Contracts. 1. The principal case under this division is that of rents. The question of apportionment may arise as to the rights of different owners either of the rent or of the land to which the burden of the payment of the rent attaches, or it may occur in case of a partial failure of the title as to the territorial extent of the land rented, or because the right of the tenant to hold the land ceases before the time agreed upon, on account of the expiration of the landlord's estate. Thus a landlord, after a lease of two houses by one contract for a specified rent, may sell one of them. The purchaser would be entitled to collect a propor-

tionate part of the rent. So, if the lessee should assign to a stranger all his rights in one of the houses, the latter would during his ownership be bound to pay a proportionate part of the rent. In case the title to a portion of the premises failed, as if in the case supposed the landlord did not own one of the houses that he assumed to lease, and the tenant was accordingly evicted, he would pay a proportional part of the rent for the remaining house. By the common law there was no apportionment where there was a failure as to time. This case is illustrated by a lease made by a life-tenant for a specified period—e. g. a year. Should he die before the time expired, the lease would of course instantly terminate, and the tenant would pay no rent for the time intervening since the last payment of rent fell due. This defect in the law has been remedied by statute. It should be added that there is by common law no apportionment where the property leased is simply diminished in value. Should a house and lot be hired and the house be destroyed by fire, no deduction can be claimed, as the rent is deemed to be paid for the land, which still remains. This rule may be obviated by agreement of the parties. 2. *Encumbrances.*—It is a general rule that several owners of land must bear the burden of an encumbrance upon it in proportion to their respective interests. Thus if land were mortgaged, and then conveyed to A for life, and, subject to A's estate, to B, the respective owners should share between themselves the burden of payment; while the mortgage remained, A should pay the interest. If it became necessary to pay the mortgage, A would need to raise a sum equivalent to his entire duty to pay the interest during his life. His probabilities of life are estimated by well-known tables indicating longevity, such as the Northampton, Carlisle, and others. On a similar principle, if mortgaged lands be sold in parcels, the duty to pay the mortgage is apportioned among the owners of the respective parcels. This is clearly the rule where the sales are contemporaneous; but if successive in point of time, the better opinion is that there is no apportionment, but that the lots must be taken to satisfy the mortgage in "the inverse order of alienation." By this is meant that the lands last sold by the proprietor must be first resorted to as a means of paying the mortgage. As soon as enough money is thus realized the remaining lots are discharged. 3. *Contracts.*—As a general rule, there is no apportionment of contracts. In other words, a party to a contract must completely fulfill his own obligation before he can enforce the agreement against the other party. Thus if a servant agreed to labor for a year at a specified salary, and should work for a portion of the time, and leave without cause, he could collect no portion of his wages. There are special cases where a contract is apportioned. One is where, after it has been partly performed, it is dissolved by mutual consent. So also in a contract for personal service there is an implied understanding that the contract is not to be completely fulfilled unless life should continue. Accordingly, if the servant should die before the expiration of the time specified in the contract, his wages would be apportioned according to the time of actual service. Some jurists have objected to the severity of the general rule, and would allow an apportionment, even where a contract is deliberately broken by a party, corresponding to the benefit received by the other party; but the prevailing opinion of courts is, and the better philosophy would seem to be, to adhere to the rule as modified by the special cases referred to. T. W. DWIGHT.

Apportionment Bill: an act of Congress which determines the total number of members sent by all the States of the Union, and also the number that each State shall send, to the House of Representatives. A new apportionment is made after each decennial census. The same term is applied to the act by which a State Legislature distributes among the counties their respective portions of representation. A populous county often forms a district by itself, and elects several members, while another district is formed by the union of two or three thinly populated counties. Those of the dominant party of the State sometimes so contrive the apportionment that they gain an advantage in the election, by forming districts in each of which a county that gives a majority against them is joined to one that gives a larger majority for their side. This is called *gerrymandering*.

Appraise'ment, or Apprize'ment [from vb. *praise*, fix a price for < O. Fr. *preiser* < Lat. *pretia're*, from *pretium*, price]; the act of estimating the value of property; the

valuation of property made by an authorized person who is called an appraiser. The mode of appointing appraisers varies in the different States of the Union. The law of the U. S. requires that there shall be an appraisal of the inventoried property of decedents and insolvent debtors, of property appropriated to public use, and of real estate seized upon execution. In Great Britain, appraisal, as a legal term, signifies a valuation of goods taken under a distress for rent by two appraisers, who are sworn by the sheriff or constable. The appraisers must be licensed for the office.

Appren'tice [O. Fr. *aprentis*, from *aprendre*, learn < Lat. *apprendere*, grasp]: a person, ordinarily a minor, bound in due form of law, usually by indenture, to another for a certain time to learn some art, trade, or business. In most of the States of this country statutes borrowed from English legislation allow minors, with their own consent, and with that of their father, mother, or guardian, to be bound out to service—if males, till the age of twenty-one; if females, till the age of eighteen, or for a shorter time. When the child is a pauper, he may be bound without his consent by public officers or by orphan asylums, houses of refuge, or of industry. The same rule is followed in the case of children charged with petty crimes. Apprenticeship is thus to some extent a mode of penal discipline, and is reformatory in its nature, particularly where some central authority oversees from time to time the conduct both of the apprentice and the master. The master in many respects stands in the relation of a parent. It is his duty to instruct the apprentice in the art which he has undertaken to teach him, to give him a reasonable support, and to provide for him in case of sickness. The apprentice, on his part, is bound to render faithful service and obedience to his master, who may administer for misconduct reasonable corporal punishment. This relation is not regulated by the ordinary rules governing master and servant, but depends upon special grounds of public policy. It may usually be dissolved by magistrates where the object of the apprenticeship has failed, and in special cases the apprentice may be punished by them for willful neglect to perform his duties. The contract of apprenticeship is of a personal nature, and is not assignable. T. W. DWIGHT.

Apprentice System (U. S. navy): See NAUTICAL SCHOOLS.

Approach'es: in military usage, the entire system of works employed in the methodic *approach* by siege of a fortification. The works consist of enveloping trenches called *parallels*, and trenches of communication called *boyaux* or *zigzags* (terms indicating the tortuous or *zigzag* form given them, in order to screen from the fire of the place), *places of arms*, etc. The earth removed is thrown upon the side toward the besieged place, by the height of which and the depth of the trench itself adequate cover is gained for the passage of troops, and even of artillery. Approaches sometimes acquire great development, as at Sebastopol, where, as is stated, the allies dug 70 miles of trenches. Recent changes in artillery and small-arms have rendered almost obsolete the methodic rules for the location and construction of approaches laid down in text-books on sieges.

Appropri'ation of Payments: in law, the application of money paid by a debtor to his creditor to one of several debts. The general rule is that when the payment is voluntary, and not under process of law, the debtor has a right to direct the application of the money. If he does not exercise this right, the creditor may elect to which debt to apply it; and in case of the failure of both parties to make such election the law will apply the money in accordance with certain rules, so as best to promote the rights of the parties. When the payment is not voluntary, but is made under compulsion, the rules as to election give way, and the money should be applied ratably to all the claims. Where a debt bears interest, that is extinguished before application to the principal.

Appui, ap'pwee' [for etymology see APPOGGIATURA]: a French word signifying "support." In military language the phrase *point d'appui* is applied to a base or position fitted to give support to troops; a fixed point at which troops form, and on which operations rest. Lakes, marshes, hills, or steep declivities sometimes serve as *points d'appui*.

Appur'tenances [viâ Fr. from Late Lat. *appertinentia*; *ad*, to + *pertine're*, belong]: in law, something belonging or appertaining to another thing as principal, as a right of way appurtenant to land. In a conveyance of land with

the "appurtenances," all easements and privileges in use and necessary to the enjoyment of the estate granted will be included. Land itself will not be considered as appurtenant to land. It is often a difficult question of construction to determine whether land can be regarded as a *part* or *parcel* of the thing granted; in which case it will pass, while it would not be embraced in the word "appurtenances." Thus in the conveyance of a "mill" or a "mansion-house," land which in the narrow acceptance of the terms "mill" or "mansion-house" would not be included might be in a comprehensive sense, since there could be no complete enjoyment of the mill or mansion-house without them.

Aprax'in, FEODOR MATVEIEVITCH: Russian admiral; called the creator of the Russian navy; b. in 1671. He was one of the principal coadjutors of Peter the Great in his efforts to civilize Russia, and enjoyed his confidence in a high degree. He built several ships of war, became an admiral and president of the admiralty in 1707, and took Viborg from the Swedes in 1710. In 1713 he ravaged the coasts of Finland, and commanded a fleet in the war against Sweden. D. Nov. 10, 1728.

Apraxin, STEPAN FEODOROVITCH: Russian general; grandson of the preceding; b. in 1702. He served in a war against the Turks, rose rapidly, and became a field-marshal. Having the command of a large army in the Seven Years War, he defeated the army of Frederick the Great at Gross-Jägerndorf in Aug., 1757. He neglected to improve the victory by marching to Berlin, and was recalled and tried by a court-martial, but before the trial was finished he died, Aug. 26, 1760.

A'pricot [Fr. *abricot*, Span. *albaricoque*, from Arab. *al-birquq*; *al*, the + *birquq*, from Gr. *πραϊκόκιον*, perhaps a loan from Lat. *præcoquum*, early-ripe]: a fruit (*Prunus armeniaca*) intermediate between the peach and the plum in character, having a small, thin, slightly furrowed stone, a firm, sweet flesh, and a pubescent exterior. The apricot has been cultivated from the earliest times, and is probably a native of China. The apricot is considered to be one of the most delicious fruits of temperate climates. It is grown throughout temperate Europe, where, especially in England, it is commonly trained on walls. In America, apricot culture has assumed great importance in California, and many portions of the country are adapted to it. Little attention has been given to the apricot in the Eastern States, because of the early blooming of the tree and the consequent danger from frosts, the injury by the plum-curculio, and the erroneous impression that the tree is very tender. The apricot is as hardy as the peach, while the Russian varieties—which are only extra hardy strains of the same species, *Prunus armeniaca* — are often still hardier. Even in New York orchard apricot culture is now receiving some attention. Grown upon the north or west side of walls—where the blossoms are retarded—apricots form one of the choicest fruits for the home garden. The general cultivation of the apricot is much like that of the peach. Plum stocks are commonly used for the apricot in the Northern States, especially if trees are to be placed upon heavy soil. Peach stocks are generally used elsewhere in this country, except in California, where apricot stocks can now be obtained. The apricot will also grow upon the almond, although this stock is not liked by orchardists. There are something like 100 varieties of apricots described. Among the best known are Breda, Moorpark, Royal, Early Golden, and Hemskirke. The Russian apricots are not esteemed except in regions where the better varieties are not hardy. L. H. BAILEY.

Apricot.

A'pries (in Gr. Ἀπρίης): a King of Egypt of the twenty-sixth dynasty, called in the Bible PHARAOH-HOPHRA; a son of Psammetichus II., whom he succeeded about 588 B. C. He attempted the relief of Jerusalem (587), but was defeated by Nebuchadnezzar. See the biblical account, Jer. xxxvii. 5-8; Ezek. xvii. 11-13; 2 Kings xxv. 1-4. His subjects revolted and killed him about 568 B. C., and Amasis then obtained the throne.

A'pril (Lat. *Aprilis*): the fourth month of the year; derived from the Romans, but in the early age of the Roman republic it was the second month.

April Fool's Day: the name given to the 1st of April, from the custom of playing tricks upon people or sending them upon bootless errands on that day. Some have derived it from some ancient pagan custom, such as the Holi festival (Mar. 31) among the Hindus, or the Roman Feast of Fools. Probably it was observed as the octave of Mar. 25, which used to be New Year's day. In France the person tricked is called *poisson d'Avril* (April fish), and in Scotland he is called a *gowk* (cuckoo).

A Priori: See A POSTERIORI.

A'pron: in former times, a piece of sheet-lead which covered the vent of a cannon. In ship-building the apron is a piece of curved timber fixed behind the lower part of the stem, and just above the foremost end of the keel, to fortify the stem. Apron is also a platform or flooring of plank at the entrance of a dock. In the Authorized Version of Gen. iii. 7 *apron* is used to render the Heb. *chagorah* (which is rendered "girdle" in 2 Sam. xviii. 11): "And they sewed fig-leaves together, and made themselves aprons"—in the margin, "or, things to gird about." In the Geneva (Barker) Bible (1599) it is rendered, "And they sewed figge tree leaves together, and made themselves breeches"—in the margin, "Ebr. things to gird about them to hide their privities." Because of the translation "breeches," this is called "the Breeches Bible." In Acts xix. 12 *apron* is the rendering of *σικκινδιον*, from the Latin *semicinctium*, a half-girdle, or belt covering half the person—an apron worn by workmen, servants, etc.

Apsheron', Apcheron, or Abcheron: a peninsula which extends into the Caspian Sea at the S. extremity of Daghestan. It forms the eastern termination of the Caucasian chain of mountains. It is famous as the place of the sacred flame which is venerated by the fire-worshippers (Ghebers), and is produced by inflammable gas rising from the soil. Large quantities of naphtha are procured here.

Ap'sides, plural of **Apsis** [from Gr. ἀψίς, -ίδος, loop, bow, arch]: the two points in the orbit of a primary planet which are at the greatest and the least distance from the sun, corresponding to the aphelion and perihelion. The term is also applied to the extreme points in the orbit of a satellite, which in the case of our moon are the same as the apogee and perigee. The straight line connecting them is called the line of the apsides.

Apteryges, āp-ter'i-jěz [for etymol. see **APTERYX**]: an order of birds comprising only the species of *Apteryx* of New Zealand. So named because the very short wings are hidden in the long loose feathers, and the birds appear wingless. See **APTERYX**.

F. A. LUCAS.

Ap'teryx [Gr. ἀ-, without + πτέρυξ, wing]: a genus of flightless birds, peculiar to New Zealand. The term is used as a common name quite as much as the native name, kiwi-kiwi. The birds of this genus represent also the family *Apterygidae* and order *Apteryges*. They have a keelless sternum, no clavicles, rudimentary wings, with a claw on the second digit, which is the only one present except in the embryo. The bill is long and the nostrils open near the end, a unique feature among birds. There are no distinct tail-feathers, and the plumage is loose and somewhat hair-like. Five species are known; one (*Apteryx maxima*) only from the feathers in the dress of a Maori chief. *A. mantelli* inhabits the North island, *A. australis* and *A. haastii* the South island, *A. owenii* both islands. These birds are nocturnal in their habits, feed on worms, nest in holes, and lay a single egg, enormous when compared with

Apteryx.

the size of the bird. They are rapidly decreasing in numbers, largely on account of dogs and cats introduced by the settlers.

F. A. LUCAS.

Ap'thorp, EAST: a clergyman of the Church of England; b. at Boston, Mass., in 1733, and educated at the Boston Latin School and afterward at Cambridge University, England, where he became a fellow of his college. Returning to America, he became a missionary of the Society for Propagating the Gospel in Foreign Parts, and was stationed at Cambridge, Mass., where he built Christ church, still one of the finest models of church architecture in New England, and became distinguished as a controversialist, an author, and a divine. He was supposed to be thought of by the ecclesiastical authorities in England as a possible American bishop, and his stately home in Cambridge was called in the pamphlets of the time a "palace" on this account. Rendered uncomfortable by the bitterness of the controversy aroused by the proposed introduction of bishops into America, Mr. Apthorp returned to England, was made D. D. by Archbishop Cornwallis; was collated to the Church of St. Mary-le-Bow, London; was appointed Boyle lecturer; was collated to a prebend of St. Paul's Cathedral; was tendered the bishopric of Kildare, Ireland, and finally received the valuable living of Finsbury (London). He was a voluminous author, and no American of his time attained greater celebrity in letters or as a divine. His four letters to Gibbon in defense of Christianity (1778) were very favorably received. D. in London, Apr. 17, 1816.

WILLIAM STEVENS PERRY.

Apuleius, ap-yu-lee'yūs, LUCIUS: Latin Platonic philosopher and satirical writer; b. at Madaura, in Africa. He lived about 150 A. D., traveled extensively, and was distinguished for his learning and eloquence. After he had spent his fortune in travel, he married a rich widow, and was involved in a lawsuit with her relatives, who accused him of using magical arts to gain her affection. He defended himself with success by an *Apology*, which is still extant. He became popular as an orator at Carthage, the senate of which raised statues in his honor. His chief work is a fantastic and satirical romance entitled the *Metamorphoses, or the Golden Ass*, which is of importance for the history of manners. Among other episodes, it contains the charming story of Cupid and Psyche. It has been translated into English by T. Taylor (1822), by Sir George Head (1851), and by several others. Some of his works are lost. See G. F. Hildebrand, edition of complete works (Leipzig, 1842), and F. Eyssenhardt, ed. of *Metamorphoses* (Berlin, 1869).

Revised by M. WARREN.

Apulia, a-poo'leē-a [in It. *La Puglia*]: province of Southern Italy, bounded N. E. by the Adriatic Sea, and was a portion of Græcia Magna (see map of Italy, ref. 6-G). It was bounded on the S. W. by Lucania and Samnium. Among the chief towns of this once populous and famous region were Canusium, Arpi, Luceria, and Arpinum. The battle of Cannæ, and most of the important events of the second Punic war, occurred in Apulia. Many of its cities aided Hannibal, by whom it was occupied until B. C. 207, when it was abandoned to the Romans. It was conquered by C. Cosconius, B. C. 89, and by the Normans about 1042 A. D. Apulia was united to the Sicilian monarchy in 1127, and is included in the modern provinces of Foggia, Bari, and Lecce. The present province has the Abruzzi e Molise on the N. W. and Campania and Basilicata on the W., and consists of the compartments Bari delle Puglie, Foggia, and Lecce. Area, 8,541 sq. miles. Pop. (1890) 1,759,396.

Apure, āā-poo'rā: a river of Venezuela, rises in the Andes near lat. 7° N. and lon. 72° W. It flows eastward, and enters the Orinoco in lat. 7° 36' 43" N. and lon. 66° 45' W. Length, estimated at 736 miles.

Apurimac, a-poo'rēe-mak': a river of South America; one of the head-streams of the Amazon, rises in the Andes, in Peru, about lat. 15° 38' S., and about 75 miles from the Pacific Ocean. It flows nearly northward, and unites with the river Urubamba about 8° 38' S. The stream thus formed is called the Ucayale. Its length from its source to the Ucayale is estimated at 600 miles.

Apurimac: a department of Central Peru, the second in size in the state, Cuzco being the first. It is inclosed between Cuzco and Ayacucho, the former being on the N. and W., the latter on the S. and E. The river Apurimac (a tributary of the Ucayale, and hence of the Amazon) and its branch, the Pampas river, form the northern boundary, while the southern is the Cordillera de Huanzo. The area is 62,325 sq. miles. Pop. approximately 120,000.

M. W. H.

A'qua, plu. **Aquæ** [Lat., water]: in pharmacy, spring-water, or natural water in its purest attainable state. It is a compound of oxygen and hydrogen; symbol H_2O , or *Aq.* The principal varieties of water are distilled water (*aqua destillata*), river-water (*aqua ex flumine* or *aqua fluvialis*), sea-water (*aqua marina*), rain-water (*aqua pluvialis*), and spring-water (*aqua fontana*). These terms are used in pharmacy, in which various watery solutions are also called *aquæ*.

Aqua For'tis (i. e. strong water): a name given to nitric acid by the alchemists; is still the common commercial name of that compound. See **NITRIC ACID**.

Aqua Marine: sea-green or blue-tinted **BERYL** (*q. v.*).

Aqua Re'gia (i. e. royal water): a mixture of nitric acid with hydrochloric (muriatic) acid. The usual proportion is one of the former and two of the latter acid. This is remarkable for its power of dissolving gold, regarded as the king of metals. The product is auric trichloride, $AuCl_3$. See **GOLD**.

Aqua Regi'næ (i. e. queen's water): a mixture of concentrated sulphuric acid and nitric acid, or of sulphuric acid and niter. It has been used as a disinfectant.

Aqua'rians [from Lat. *aqua*, water]: those ascetic persons who used water in the sacrament instead of wine, because they had scruples against the use of the latter. This practice is said to have originated with Tatian in the second century.

Aqua'rium (pl. **Aquaria**), or **Aquaviva'rium**: a glass tank or vessel containing either salt or fresh water, in which living aquatic animals and plants are kept for scientific study. It must contain both animals and plants in something like a due proportion, as the animals depend for breath on the oxygen which is given out by the plants, and the latter are nourished by the carbonic acid gas which the animals exhale. The water should be often aerated by agitation, which may be effected by dipping up portions of it and pouring them in again from a small height. *Aquaria* are stocked with mollusca, algæ, conifers, crustacea, zoöphytes, goldfish, sticklebacks, minnows, and other fish, sea-anemones, etc. The presence of molluscous animals is necessary for the consumption of the vegetable matter which is about to decay and the numerous spores of the conifers, unless the water be continually renewed, as in the "fountain aquarium." No dead animal or decaying plant should be permitted to remain in the aquarium, the temperature of which should be kept between 50° and 70° F. See P. H. Gosse, *Handbook of the Marine Aquarium* (1855). The great aquarium situated at the Jardin d'Acclimation at Paris is 50 yards long and 12 yards wide, and was constructed in 1860.

Aqua'rius [from Lat. *aqua*, water]: the Water-Bearer; the eleventh sign of the Zodiac, into which the sun enters about Jan. 20. It is represented by ♒. *Aquarius* is also the name of a constellation which coincided with that sign at the time when the signs were named, but in consequence of the precession of the equinoxes it is now in juxtaposition with the sign *Pisces*.

Aquat'ic An'imals: those animals which live constantly in the water, as fishes, and those which frequent the water to swim on its surface or dive in search of food, as ducks and other web-footed birds, otters and beavers among quadrupeds, etc. Among the aquatic animals are the majority of the grand division of *Mollusca*; numerous tribes of the *Articulata*, as crabs, lobsters, and shrimps; and a large portion of the *Radiata*. Whales and dolphins are examples of aquatic animals of the class *Mammalia*. The total number of aquatic animals is greater than that of all terrestrial animals (exclusive of insects). Those which live partly on land, and can not breathe under water, are called amphibious. The peculiarities of structure by which they are fitted for swimming, wading, etc., are very admirable. Some water-fowls have long legs for wading; others have webbed feet which enable them to swim with ease, and have waterproof plumage adapted to their mode of life. In aquatic animals of the higher vertebrate classes provision is made for the maintenance of the proper degree of animal heat by a coat of blubber, fur, or plumage, as in the case of otters, ducks, etc. The air-breathing animals that inhabit salt water have an organic structure greatly modified, and their extremities resemble the purely aquatic type more than the terrestrial.

Aquatic Plants, or **Water-plants**: vegetable organisms that grow in water. All vegetation must have been originally aquatic, later some plants became terrestrial. Nearly

all the lower green plants are aquatic, even mosses and ferns show strong aquatic tendencies, while the flowering plants as a rule are terrestrial. It is true, however, that many of the latter live in water, but most of these root in the mud, and bring their leaves above the water. A few only are entirely immersed in the water. It appears that many of the higher plants which now grow in the water are really terrestrial, but have been crowded into the water by their stronger rivals.

CHARLES E. BESSEY.

Aquatics: See **ROWING**.

Aquatint: See **ENGRAVING**.

Aqua Tofa'na: a secret poison, the invention of which is ascribed to a Sicilian woman, a notorious poisoner, named Tofana. She lived about 1650–1730. It is said that there was, about 1660, a society of young married women in Rome who used this aqua Tofana to poison their husbands. It was sold in vials marked "Manna of St. Nicholas of Bari." Some suppose it to have been a solution of arsenic.

Aqua Vi'tæ (i. e. water of life; in French, *eau de vie*): a Latin term applied to brandy, and sometimes to other ardent spirits.

Aq'ueducts [from Lat. *aquæ ductus* (*du'cere*, lead), leading of water]: artificial constructions for bringing water from a distance for the supply of cities or which serve to convey the water of canals of navigation and of irrigation, and of mill-races, at an elevation across deep valleys or streams.

Works for supplying large communities with water appear to have been constructed at a very early date. There are remains in Persia and Syria of structures which are supposed to have been intended for aqueducts, but there is nothing definite in existence regarding their history. Recent discoveries of wells and conduits cut in the rock in the neighborhood of Jerusalem appear to establish the fact of there having been a system of water-supply for that city from the neighborhood of Bethlehem and Hebron. Portions of this conduit are composed of earthen pipes of about 10 inches diameter, eased with two stones hewn out to fit them, and covered over with rough stones cemented together. In the island of Samos there have been discovered remains of a tunnel 5,000 feet long, containing water-pipes about 9 inches in diameter, which are supposed to have been constructed about the year 900 B. C. A very ancient aqueduct of unknown date exists near Patara. This consists of an embankment of rough stone, 250 feet high and about 200 long, with archway at the center of the valley for the passage of a stream underneath. The conduit for water consists of stone blocks about 3 feet in each dimension, with a hole 13 inches in diameter through the center. The blocks are connected together by annular projections on one stone fitting into recesses on the adjoining stone, the joints being filled with cement.

The Romans appear to have been the first to construct extensive and durable aqueducts, first for the supply of Rome itself, beginning about 500 years before the Christian era, and continuing until the fall of the Roman empire, and at the present day the city of Rome is amply supplied with water, the greater part of which is brought over ancient aqueducts repaired by the popes. The Appian aqueduct, attributed to Appius Claudius Cæcus, is said to have been completed 311 years before the Christian era, after the building of the Appian Way. Its length was about 6 miles, and it brought by a devious course to Rome the waters of a spring whose fountain-head was 5 miles from the city, near Rustica on the Via Collatina. The Aqua Augusta was at a later period added to this aqueduct. It supplied the most ancient portion of the town and the Transtiberine city.

The Anio Vetus was built B. C. 272 by Manius Curius Dentatus. It brought its supply from near Augusta, in the valley of the Anio, 43 miles from Rome. It was almost entirely subterranean, and the only fragment now visible lies below the road and under the Aqua Marcia, outside the Porta Maggiore.

The Aqua Marcia (B. C. 145), built by the prætor Quintus Martius Rex, was 37 miles long, of which 6 miles were on arches still visible, crossing the Campagna by the Fraseati and Albano roads. This aqueduct is crossed by the Claudian aqueduct, which for some distance runs parallel to it. It has been restored.

Aqua Tepula (B. C. 126), the work of Cneius Servilius Cæpio and Cassius Longinus, is 10 miles long. Its channel or *specus* can still be seen at the Porta San Lorenzo and

Porta Maggiore in connection with the channels of the Aqua Marcia and Aqua Julia.

Aqua Julia (B. C. 34), by Augustus, named in honor of Julius Cæsar, 12 miles long. Its water was brought to the city in a *specus* or conduit above the Tepula, and, like that, upon the arches of the Aqua Marcia, which thus brought the waters of three different sources separately to Rome. Its channel is still to be seen at the gate of San Lorenzo and at the Porta Maggiore.

Aqua Virgo, also by Augustus. Its source is said to have been pointed out by a young girl, whence its name. Its course is mostly subterraneous, about half a mile only being on arches. It was restored by Pope Nicholas V. as the Aqua Vergine, and it still supplies Rome with its cool water. The fountains in the Piazza di Spagna, Piazza Navona, and the magnificent fountain of Trevi are supplied by this aqueduct, as are many others. On the fountain of Trevi, the virgin, pointing out the source to the soldiers sent by Augustus, appears among many other marble reliefs and statues. This is perhaps the finest fountain in the world. An inscription, still legible, in a cellar of No. 12 Via del Nazareno, near the Palazzo del Bufalo, states that it was repaired A. D. 52 by Claudius, after having been disturbed by Caligula in the construction of his wooden amphitheater.

Aqua Alsietina, 30 miles in length, built by Augustus; restored by Trajan, who added to its waters those of several springs along the hills to the W. of Lago Bracciano. Its original sources were around the smaller Lake Alsietinus, now the Lago de Martignano. It was restored by Paul V., and now supplies the fountains of the great Piazza of St. Peter's and the magnificent fountain Paolina, and turns the wheels of many flour-mills on the slopes of the Janiculum. It is known indifferently as the Aqua Alsietina and the Aqua Paolina.

Aqua Claudia, built by Caligula and Claudius (A. D. 36 to 50). Its sources were near Agosta, about 38 miles from Rome. Its devious course was over 46 miles in length, of which 36 were below the surface and 10 were on arches. Six miles of arches stretching across the Campagna still attest the power and liberality of the Roman empire. Repaired by Septimus Severus, by Caracalla, and by Pope Sixtus V., its arches now bring to Rome the Aqua Felice

obstructed the channels of many of these ancient aqueducts, especially those from the valley of the Anio.

It is estimated that Rome received daily 377,000,000 gal. of water. The Acque Vergine, Felice, Marcia, and Paola, having their sources in volcanic districts, supply a pure and delicious water, which does not obstruct its channels, and at this day they bring into Rome 160,000,000 gal. of water daily. By channels of masonry the water is led to fountains in every part of the city, and by pipes of metal and of burned clay it is distributed to most of the great houses or palaces, in each of which it flows constantly into a basin, frequently an ancient sarcophagus, of stone or marble. The water is rarely carried by pipes to the upper stories.

The Romans also constructed extensive aqueducts for the large cities in their provinces. Carthage before its destruction by the Romans had been supplied by an extensive system of underground reservoirs retaining the water from the roofs and paved areas of the city. After it was rebuilt by the Romans the supply was deficient for several years until about A. D. 120, when the Emperor Hadrian constructed the magnificent aqueduct of Zaghuan, about 60 miles in length, across valleys by one and sometimes two tiers of arches, in some places of stone, and in others of concrete made from the surrounding soil. Portions of this aqueduct are still in existence, and are used for the supply of water to the city of Tunis. Several arches still remain of an aqueduct supplying Constantine in Africa, 60 miles from the seacoast and midway between Algiers and Tunis. Another fine aqueduct was built in the third or fourth century at Nîmes in the south of France. This aqueduct is still in a good state of preservation, and consists of three tiers of arches of masonry with a rectangular channel 6 by 4 feet at the top. The lower tier consists of 6 arches, the second of 11 arches of the same span, and the upper tier of 35 arches of smaller span. The whole structure is 180 feet high and 873 feet long. The Roman aqueducts of Segovia and Seville in Spain still supply those towns with water. The former is about 2,400 feet long and 100 feet high, and is composed of two tiers of arches of uncemented stone. In the lower tier, which is 65 feet high, there are 42 arches of 15 feet span, and in the upper tier, 27 feet high, there are 119 arches. At Lyons and at Metz in France are remains of fine Roman structures.

For several hundred years after the fall of the Roman empire there do not appear to have been many extensive aqueducts constructed. In England the first important structure of the kind was that for bringing the New river to London, built in 1613. Water was brought a distance of 20 miles, crossing valleys by timber aqueducts, the water-way or trough of which was lined with lead. These wooden aqueducts have since been replaced by embankments. In 1738 an aqueduct was built for supplying Lisbon.

It is about 9 miles long, and for part of the way is in excavation, but near the city it is carried over a deep valley for a length of 2,400 feet by several arches, the largest of which is 250 feet high and has a span of 115 feet.

The aqueduct of Caserta, built in 1753, supplies water to Naples. This aqueduct is 37 miles long, and is a channel of masonry 5 ft. 3 in. wide by 7 ft. 6 in. high. In tunnels it is circular in section and of 7 ft. 6 in. diameter. Twenty valleys are crossed by masonry structures, the conduit of which is 4 ft. 9 in. wide and 7 ft. 4 in. high. One structure consists of three tiers of arches, 724 feet on top and 190 feet high. For 15 miles, from the end of the aqueduct to the city, the water is carried in iron pipes.

Ruins of the Aqua Claudia.

from the springs near the Osteria dei Pantani, on the road to Palestrina. They supply the Fontana dei Termini, near the railroad dépôt in the Baths of Diocletian, the fountain of the Triton, that of Monte Cavallo, and some twenty-four others in different parts of the city.

Anio Novus, also by Claudius, from the forty-second mile of the Via Sublacensis. This was the longest of the ancient aqueducts, having a course of 62 miles, 48 of which were underground. Its channel or *specus* is still visible above the Aqua Claudia on the arches of the Porta Maggiore. It is also visible at the Villa Braschi, near Tivoli, where it is 9 feet high by 4 feet in width, but is choked up by a calcareous deposit, which incrusts, and finally, unless removed,

The city of Constantinople was supplied for several years by an aqueduct built by the later Roman emperors. Since 1885 the water has been furnished by an aqueduct built by

Pont du Gard, Nîmes.

a French company, taking the supply from Lake Derkos, whence the water is pumped 358 feet into a reservoir, and then flows 27 miles to the city through an aqueduct of rubble masonry 3 ft. 5 in. wide by 5 ft. 3 in. high. Fifteen valleys are crossed by siphons of cast-iron pipe.

The city of Otumba in Mexico was supplied for 125 years by the aqueduct of Zempoala, which was built by a Spanish friar in 1554-71. This aqueduct is about 27 miles long, and 7,677 feet above the sea-level. Three valleys are crossed by masonry having, respectively, 13, 46, and 68 arches. In the last named the valley is 124 feet deep. The conduit is 8½ inches by 12 inches in dimensions, with a flat bottom and arched top. The flow of water through this aqueduct was discontinued about 1700, but it is said that slight repairs would enable it to be used again.

The discovery of the method of manufacturing cast iron into water-pipes has obviated the necessity of the construction of such enormous masonry structures for conveying water across valleys, but there are several fine examples of modern aqueducts of masonry, such as the High Bridge across the Harlem river in New York city, which is 120 feet high and 1,460 long, and was constructed in the year 1840. The Cabin John Bridge of the Washington, D. C., aqueduct, which is 101 feet high and has a single span of 220 feet, is the longest stone arch in existence.

The tendency of engineering at the present day is to construct aqueducts below the surface of the ground as far as possible, and where valleys have to be crossed to pass them by inverted siphons of iron pipe, rather than by elevated structures.

Among the best examples of modern aqueducts may be mentioned that of Vienna, which is 59 miles long and has a conduit of masonry varying in size from 5 ft. 8 in. by 6 ft. to 2 ft. 9 in. by 4 feet.

Glasgow is supplied through the Loch Katrine aqueduct 26 miles long, of which about 13 are in tunneling and about 4 of iron pipe across valleys. This was constructed in 1859. The conduit is of brick and is of a horseshoe cross-section 8 feet wide and 8 high.

In the U. S. the first important aqueduct was that for supplying water to New York city from the Croton river, a distance of about 40 miles. The first aqueduct was built in 1837-41 and is still in use. It is a covered masonry channel of horseshoe form, 7 ft. 5 in. wide and 8 ft. 6 in. high. In 1885-90 an additional aqueduct was constructed from the Croton river to New York city. By following a direct line and constructing the aqueduct principally in tunneling, the length of the aqueduct was reduced to 33 miles. In tunnels the conduit is circular, of 12 ft. 3 in. diameter. Where constructed by opening the surface of the ground it is of horseshoe form, 13 ft. 7 in. wide and 13 ft. 6½ in. high. The Harlem river is crossed by an inverted siphon of masonry lined with iron, in a tunnel 150 feet below the bed of the river.

The Washington aqueduct was constructed by the U. S. Government in 1855-60. It is a circular conduit of brick and rubble masonry 9 feet in diameter, and 11 miles long

from the Great Falls of the Potomac to the distributing reservoir.

The first aqueduct for supplying Boston with water was built in 1846-48, conveying water from Lake Cochituate, a distance of about 15 miles. The conduit is oviform in cross-section with the large end down, 6 ft. 4 in. high and 5 feet wide. In 1876-78 a new aqueduct was constructed from the Sudbury river to Boston. This aqueduct is generally in excavation, but with two fine bridges across the Charles river and the Waban valley. The conduit is of horseshoe cross-section, 9 feet wide and 7 ft. 8 in. high.

High Bridge, Harlem river.

Brooklyn, on Long Island, is supplied with water by an aqueduct constructed in 1856-59, about 10 miles long, leading from a series of lakes formed by damming streams. This aqueduct is entirely in excavation through a level country and below the surface of the ground-water. It is of horseshoe cross-section, 10 ft. wide and 9 ft. 8 in. high.

Baltimore receives its supply of water from Lake Roland through a brick aqueduct of elliptical cross-section, 5 feet wide and 8 ft. 10 in. high, constructed in 1857-62. There is an additional supply from the Gunpowder river, conveyed through a circular brick aqueduct 12 feet in diameter and about 8 miles long. This conduit is in a tunnel from 65 to 300 feet below the surface, and was constructed in 1875-80.

In California the use of wrought-iron pipes for aqueducts was first introduced to any great extent in the construction of the water-supply of San Francisco about the year 1865. Large additional works were constructed in 1878. At present the city is supplied through several conduits of wrought-iron pipe of from 22 to 40 inches diameter, laid following the undulations of the ground.

In the Eastern States, the first large wrought-iron conduit built was that at Rochester, N. Y., constructed in 1872-76, which is 36 and 24 inches diameter and 28 miles long. The aqueduct follows the surface of the ground, which in some places is 340 feet below the hydraulic grade line.

In 1890-92 an aqueduct of wrought-iron pipe was constructed to supply Newark, N. J., from the Pequannock river, about 15 miles. This pipe is 30 inches in diameter and is laid following the surface of the ground.

We defer till we treat of WATER-SUPPLY OF CITIES remarks upon the reservoirs and pipes for the distribution

through them of the water brought by the aqueduct from the source to their confines, noting only that the modern practice makes reservoirs much more extensive and capacious than the ancient. The Romans brought large supplies through aqueducts of rapid flow. A small portion only was stored in reservoirs, generally of masonry covered with arches, and the surplus was allowed to flow out through great fountains and cascades in constant streams.

Reserve Reservoirs.—The moderns provide large reservoirs in which the water not used is stored up to compensate during the periods of scarcity for the scanty supply of the original source. These reservoirs are sometimes covered with brick arches, as in London, but generally they are open ponds or lakes of many acres. Such magnificent cov-

cred reservoirs as that for the Roman fleet at Baie, and the arched reservoirs of Constantinople, supported on stone columns, are no longer constructed. They remain among the most stately monuments of the Roman empire. See the article WATER-WORKS.

Revised by J. JAMES R. CROES.

Aqueous Humor: See EYE.

Aquifolia'ceæ [from *Aquifolium*, a former name of the holly]: a family of exogenous plants, all trees or shrubs with simple leaves, and mostly natives of America. The ovary is superior, with two or more cells, each of which contains a solitary anatropal ovule, and generally becomes bony as a stone in the fruit, which is fleshy. Among the species of this order is the holly (*Ilex*). The flowers are white or greenish, and the species are quite numerous in the U. S.

Aq'uila (the *Eagle*): a constellation of stars in the Milky Way near the equator, and on its north side. It may be seen on the meridian during the evenings of August and September.

Aquila: a genus of birds. See EAGLE.

A'quila: a fortified town of Italy, capital of the province of Aquila; is situated on the Pescara, near the Apennines, 58 miles N. E. of Rome (see map of Italy, ref. 5-E). It contains several interesting churches. Here are manufactures of paper, linen, and wax. It was much injured by earthquakes in 1688, 1703, and 1706. Aquila was built by the Emperor Frederick II. about 1240, on or near the site of the ancient *Amiternum*. It contains a citadel built in 1534, and has a large trade in saffron, which is extensively cultivated in the surrounding territory. Pop. 19,027.

Aquila (usually *A. degli Abruzzi*): a province of Italy, formerly called Abruzzo Ulteriore II.; bounded N. E. by Ascoli, E. by Teramo and Chieti, S. by Campobasso and Caserta, W. by Rome and Perugia, and N. W. by Perugia. Area, 2,510 sq. miles. The chief products are grain, vegetables, rice, wine, oil, and fruits. Pop. (1879) 356,371; (1890) 372,710.

Aq'uila of Pontus: author of an extremely literal Greek translation of the Hebrew scriptures (about A. D. 130). His version was embodied by Origen in his *Hexapla* (q. v.). For the fragments now known, see Field's ed. of the *Hexapla*.

C. H. TOY.

Aquilaria'ceæ [so called from *Aquila'ria*, one of the genera]: a family of exogenous plants, all of which are trees and natives of the tropical parts of Asia. The leaves are entire; the perianth coriaceous, turbinate, or tubular; the stamens usually ten; the ovary two-celled, with two ovules; the fruit a drupe or capsule. The order comprises only ten known species, one of which produces the fragrant ALOES-WOOD (q. v.).

Aquile'ja, **Aquileia**, or **Aglar**: an old town of Austria; in the littoral provinces, near the Adriatic or Gulf of Venice, with which it is connected by a canal; is 22 miles W. N. W. of Trieste (see map of Austria-Hungary, ref. 8-C). During the Roman empire it was an important city, was called the second Rome (in Lat. *Roma Secunda*), and was the chief emporium of the trade between the north and south of Europe. The Emperor Augustus often resided here, and here were held several councils of the Church, the first of which was in 381 A. D. The bishops of Aquileja in the sixth century took the title of patriarch, and assumed the rank next to the pope. Aquileja was burned by Attila in 452 A. D., at which time it is said to have had 100,000 inhabitants. Pop. about 2,000.

Aqui'nas, **Saint THOMAS**: celebrated scholastic doctor and theologian, surnamed THE ANGELIC DOCTOR; b. in the castle of Rocca Sicca, near Aquino, in the neighborhood of Naples, in 1227. He was a grand-nephew of the Emperor Frederick I., Barbarossa. About 1243 he joined the order of Dominican monks, and became a pupil of Albertus Magnus. After he had studied theology and scholastic philosophy, he began to teach and preach at Paris with great applause. Having acquired a European reputation by his talents and learning, he left Paris in 1261, and was induced by Pope Urban IV. to remove to Rome, where he taught philosophy. He was distinguished for his modesty, and refused the offer of a bishopric, but he had great influence in the Church. The greatest of the Schoolmen were the Dominican Thomas Aquinas and the Franciscan Duns Scotus. They were founders of rival sects, which wrangled with each other for

two or three centuries. Aquinas wrote a number of works, the most important of which is his *Summa Theologiae* (Sum of Theology), which was regarded as the most complete compendium of scholastic divinity. He died at Fossanuova, in Naples, Mar. 7, 1274. His disciples were called Thomists. Aquinas was a great admirer of the philosophy of Aristotle, and all of his writings may be regarded as commentary designed to interpret Aristotle's doctrines to the support of Christian views of God, Freedom, and Immortality. He was canonized in 1323. Pope Leo XIII. is devoted to him, and has patronized an edition of his works (Rome, 1882, *sqq.*). See Renn D. Hampden, *Life of Thomas Aquinas* (1848); Maffei, *Vita di Tommaso d'Aquino* (1842); Tholnek, *Dissertatio de Thoma Aquinate* (1842); P. S. Carle, *Histoire de la Vie et des Écrits de Thomas d'Aquin* (1846); *Philosophie de Thomas d'Aquin*, par Charles Jourdain (Paris, 1857); *The Life and Labors of S. Thomas of Aquin*, by the Very Rev. Roger Bede Vaughan (2 vols., 1871-72). See the articles DUNS SCOTUS, PHILOSOPHY, and SCHOLASTICISM.

Revised by W. T. HARRIS.

Aquita'nia (in Fr. *Aquitaine*): the ancient Latin name of the most southwestern of the three divisions of Gaul. It originally included the country between the Pyrenees and the Garonne, but Augustus added to it the territory between the Garonne and the Loire. The ancient inhabitants were Iberian tribes. In the fifth century the country was conquered by the Visigoths, and thus brought in close connection with Spain. It was taken from the Goths and added to the possessions of the Franks by Clovis. It was an independent duchy under the feeble princes of the Carolingian dynasty, and became an English possession in 1152 by the marriage of Henry II. with Eleanor of Guienne, who was the heiress of the Duke of Aquitaine. It was united to France in 1451.

Arabesque, ar-a-besk': in the Arabian style or manner; an epithet applied to the fantastic decoration which was profusely employed in the architecture of the Arabs and of the Moors in Spain. Among the most beautiful specimens of Moorish arabesques are the decorations of the famous palace of the Alhambra. The name arabesque was applied to this mode of decoration because it had been long known and admired in the works of the Arabs before the discovery of the beautiful paintings in the Baths of Titus, by Raphael and his pupil Giovanni da Udine, made the world acquainted with a magnificent specimen of Roman work in the same style. The early Italian painters and sculptors, however, had always taken delight in this style of decoration as they found it in the antique Roman sculpture, where scrolls, flowers, fruit, and leaves are mingled with animals and genii. Raphael painted his famous arabesques in the Loggia of the Vatican in direct imitation of the frescoes on the Baths of Titus. He was largely assisted by Giovanni da Udine.

Arabgir', or **Arabkir'**: an important city of Asia Minor, on the Arabgir-Su, and on the road from Aleppo to Trebizond, 100 miles E. S. E. of Siwas (see map of Turkey, ref. 5-H). It has considerable trade, and a large community of Protestant Armenians. Pop. estimated at from 25,000 to 30,000.

Ara'bia [Arab. *Jeze'ret* (or *Jezi'ret*) -*el-A'rab*, i. e. the isle or peninsula of the Arabs; Turk. and Pers. *Arabistan*; Lat. *Arabia*]: a peninsula forming the extreme S. W. part of Asia; encompassed by the sea on all sides except the N. It is bounded N. by Asiatic Turkey, N. E. by the Persian Gulf and Sea of Oman, S. E. by the Indian Ocean, and S. W. by the Red Sea. It extends from lat. 12° 35' to 34° N., and from lon. 32° 10' to 59° 40' E. Its area is now estimated at 1,230,000 sq. miles. It is connected with Africa by the Isthmus of Suez at the N. W. corner. The Euphrates forms a part of the N. E. boundary of Arabia, the southern part of which is included in the torrid zone.

Topography.—The topography of the interior of this peninsula is imperfectly known to European geographers. We know, however, that it is generally arid and sterile, destitute of forests, has no large rivers, and few permanent streams. The surface is diversified by hills of naked rock, plains of sand, and ranges of mountains of no great elevation. The central part of Arabia appears to be occupied by an elevated table-land. A long range of mountains extends through the W. part nearly parallel with the Red Sea, from which it is not more than 80 miles distant, and in some parts less than that. The peaks of these mountains are from 5,000 to 8,000 feet high. In the vicinity of the

mountains, and of the torrents which flow from them, are a number of fertile valleys called *wadys*. Among the remarkable features in the geography of Arabia is Mt. Sinai, which is 7,497 feet high. Ancient and foreign geographers divided this country into three parts—namely, ARABIA FELIX, the Happy; ARABIA PETRÆA, the Stony; and ARABIA DESERTA, the Desert. The first comprises the southeastern part, bordering on the Persian Gulf, the Indian Ocean, and part of the Red Sea; Arabia Petraea includes the northwestern part, bordering on the Red Sea; and Arabia Deserta, the interior and northern portions.

Climate.—The climate is hot and extremely dry. Muscat and Mocha, both on the seacoast, are among the hottest inhabited spots on the earth. The temperature of the plains is often 100° in the shade. In many parts of Arabia rain never falls in the course of the year, and the sun is rarely obscured by a cloud. On the coasts of the Red Sea there is a rainy season of two or three months in summer, but on the southern or southeastern coast the scanty supply of rain falls in the winter, so that the hottest months of the year are also the driest. To the extreme dryness of the atmosphere may be ascribed the remarkable degree of cold sometimes felt in Arabia, for ice and snow frequently occur on mountains ranging from 6,000 to 8,000 feet in height in the part of the peninsula which is in the torrid zone. Among the remarkable phenomena of the climate is a hot south wind called *simoom*, the poisonous quality of which has been exaggerated by travelers.

Productions.—The soil, where it is irrigated, produces cotton, coffee, indigo, tobacco, tamarinds, the date-palm, barley, rice, sugar, and many aromatic plants. The flora of Arabia comprises the characteristic plants of its neighboring countries. Among the wild plants are the mimosa, the Euphorbiaceæ, lavender, jasmine, the aloe, and the trees which yield gum-arabic and olibanum. The animal kingdom is here represented by the camel, the antelope, the ibex, hyena, wolf, jackal, wild-ass, wild-boar, the jerboa, monkey, ostrich, eagle, etc. The Arabian horse is celebrated, and perhaps unrivaled, for docility, endurance, beauty, and speed. Among the mineral resources of Arabia are copper, iron, lead, coal, emeralds, carnelians, agate, onyx, alabaster, marble, sulphur, and saltpeter.

Trade.—Few nations of the world have been more nearly stationary or have made such little progress in industrial arts. The division of the Arabs into numerous independent and unsettled tribes, with consequent absence of national unity, is a great obstacle to their improvement and organization. The government is neither a monarchy, a republic, nor an aristocracy, but each tribe is subject to a chief called an emir, sheik, or inâm. Having the advantage of occupying the coasts between India on the east and Africa and Europe on the west, the Arabs distribute the cotton goods of India among the peoples of Africa and carry back ivory, guns, dye-woods, etc. Merchandise is conveyed across the deserts by large caravans of camels. The principal exports are dates, coffee, gum-arabic, myrrh, aloes, pearls, balsam, etc.

Population.—The population, formerly estimated at from 10,000,000 to 15,000,000, amounts, according to recent calculations, to little over 5,000,000, and is divided into two classes—the nomadic Bedouins, who have no habitations but tents, and have loose notions of the rights of property, and agricultural and mercantile Arabs, who live in towns and villages. The chief towns are Mecca, Medina, Loheia, Mocha, Aden, Muscat, Yembo (or Yambo), and Rostak.

Weights and Measures.—(1) Weight.—The unit of weight is the maund = 3 lb. av. = 1.3608 kilogs. Multiples, 10 maunds = 1 frazil; 15 frazils = 1 bahar. Sub-multiples, $\frac{1}{2}$ maund = 1 rattle; $\frac{1}{5}$ rattle = 1 vakia. At Mocha the maund of coffee contains but 29 vakias. Egyptian weights are also used.

(2) Length.—There are several measures which are not multiples of each other. The guz = 25 in. = 634.98 mm.; the cobido = 19 in. = 482.6 mm.; the kassaba = 4.1 yards = 3.75 meters.

(3) Surface.—The feddan = 400 cassabas (the cassaba for this purpose = 3.84 meters = 12.5986 feet) = 1.4782 acres = 0.589824 hectare.

(4) Volume.—For liquid capacity, the gudda or cuddy = 1.999 gallons = 7.567 liters. Sub-multiples, $\frac{1}{2}$ cuddy = 1 noosfia; $\frac{1}{6}$ noosfia = 1 vakia. Dry measure, the teman or toman = about $2\frac{1}{4}$ pints or 2 liters. Its value is not well ascertained; $\frac{1}{40}$ teman = 1 mecdema or kella. The teman of rice-weight, 168 lb. avoirdupois = 76.2 kilogs.

History.—Owing to the sterility of its soil, Arabia was

never touched by any of the great conquerors of ancient times. After the death of Alexander the Great the Arabians conquered a part of Chaldæa, and founded the empire of Hira. Another tribe founded the empire of the Ghassanides, on the river Ghassan. In 107 A. D. the Roman Emperor Trajan was the first to penetrate to the interior. With the advent of Mohammed the different tribes began to unite and act in concert, and, leaving their peninsula, founded large and powerful empires in three continents. (See MOORS and CALIPHS.) At the time of the conquest of the caliphate of Bagdad in 1258, and the expulsion of the Moors from Spain in 1492, the Arabian rule in Europe and Asia Minor came to an end. In the sixteenth century the Turks conquered Yemen, but were driven back in the seventeenth, but again gained the nominal authority over the holy cities and Hejaz. From 1508 to 1609 Muscat was subject to Portugal. The most important event of recent times in the internal history of Arabia is the advent of the WAHÂBĒES (*q. v.*) in 1770, and their defeat by Mehemed Ali in 1811. At present the only European power having possessions in Arabia is Great Britain, which has taken possession of Aden. In consequence of an attack made on the Christians in Jidda in 1858, the city was bombarded by the British. See CRICHTON, *History of Araby* (1852); SÉDILLOT, *Histoire des Arabes* (1854); MÜLLER, *Beiträge zur Geschichte der westlichen Araber* (1868); WEIL, *Geschichte der islamitischen Völker* (1868); MALTZAN, *Wallfahrt nach Mekka* (2 vols., 1865); *Annals of the Early Caliphates from Original Sources*, and *The Rise and Decline of Islam*, by W. Muir (4 vols., 8vo, Lond. 1858–61); Wrede, *Reisen in Hadhramaut* (1870); and the accounts of Niebuhr, Burckhardt, Burton, Palgrave, and others.

Revised by C. K. ADAMS.

Arabian Architecture: the style of architecture which prevails in or is characteristic of the Arabs. In their native land they had no architecture of importance. After their conquests of the former Roman provinces of Egypt, Syria, and Asia Minor, they caused mosques and other buildings to be constructed in the Byzantine style, as modified in accordance with their acquirements. This style was developed in richer and larger buildings at a later time, and was flourishing from the eleventh to the sixteenth century of the Christian era. The most important monuments that remain are in Cairo. The buildings erected in Persia since the Arab conquests are not often considered as Arabian, because the Persian art has always been of great importance and independent value; but, in fact, the ornamentation derived from Persia was the strongest influence, except the Byzantine method of building, and the style might well be called Perso-Byzantine. The Moorish architecture is a late and inferior modification of this style. See SARACENIC ART.

RUSSELL STURGIS.

Arabian Gulf: See RED SEA.

Arabian Language and Literature: (1) The *language:* Arabic belongs to what is termed the Semitic (or Shemitic) family of languages (see SEMITIC LANGUAGES), and is closely related to the Hebrew, which it resembles in its general grammatical structure, as well as in the form of many of its words. Like the Hebrew, it is written from right to left, and like it, also, the vowels are not written in the body of a word or name, but are indicated (if indicated at all) by certain marks placed above or below the consonants to which they belong (see below). The alphabet consists of twenty-eight letters, as follows:

Number.	Unconnected.	Final connected.	Medial.	Initial.	Name.	Transliteration.
1.	ا*	ا	ا	ا	alif,	'
2.	ب	ب	ب	ب	bâ,	b.
3.	ت	ت	ت	ت	tâ,	t.
4.	ث	ث	ث	ث	thâ,	th.
5.	ج	ج	ج	ج	jîm, gîm,	j, g.
6.	ح	ح	ح	ح	hâ,	h.
7.	خ	خ	خ	خ	khâ,	kh.
8.	د*	د	د	د	dâl,	d.
9.	ذ*	ذ	ذ	ذ	dhâl,	dh.

* The letters thus marked ought never, according to the rules of Arabic orthography, to be connected with those that follow them.

Number.	Uncon- nected.	Final con- nected.	Medial.	Initial.	Name.	Transliteration.
10.	ر*	ر	ر	ر	râ,	r.
11.	ز*	ز	ز	ز	zây,	z.
12.	س	س	س	س	sîn,	s.
13.	ش	ش	ش	ش	shîn,	sh.
14.	ص	ص	ص	ص	şâd,	ş.
15.	ض	ض	ض	ض	đâd,	đ.
16.	ط	ط	ط	ط	ţâ,	ţ.
17.	ظ	ظ	ظ	ظ	zâ,	z.
18.	ع	ع	ع	ع	'ain,	'.
19.	غ	غ	غ	غ	ghain,	gh.
20.	ف	ف	ف	ف	fâ,	f.
21.	ق	ق	ق	ق	kâf,	k.
22.	ك	ك	ك†	ك†	kâf,	k.
23.	ل	ل	ل	ل	lâm,	l.
24.	م	م	م	م	mîm,	m.
25.	ن	ن	ن	ن	nûm,	n.
26.	ه	ه	ه	ه	hâ,	h.
27.	و*	و	و	و	wâw,	w.
28.	ي	ي	ي	ي	yâ,	y.

* The letters thus marked ought never, according to the rules of Arabic orthography, to be connected with those that follow them.

† Written also, .

‡ Written also, .

All the foregoing characters are regarded by Arab grammarians as consonants. Alif has been compared to the soft breathing (*spiritus lenis*) of the Greeks; 'Ain is a strong guttural of which the pronunciation is very difficult for foreigners.

When a consonant is doubled, this doubling must be brought out clearly and distinctly in the pronunciation.

VOWELS.

In Arabic there are three short vowels. These are indicated by signs called—1. *Fet'ha* (a*); 2. *Kes'ra* (i, sometimes ě); and 3. *damma* (oo or u †). Fet'ha is written over the consonant to which it belongs, thus ; kesra is placed beneath its consonant, thus ; damma (which is in fact a minute ʾ) is written over its consonant, thus . These vowels are always pronounced after the consonant above or below which they are written.

There are three long vowels, ā, ī, ū ‡, and to indicate these the Arabic makes use of the consonants alif, yâ, wâw, respectively, preceded by the marks of the corresponding short vowels. There are two diphthongs, ai and au, which are indicated by the consonants yâ and wâw, respectively, preceded by the fet'ha.

The vowel-signs are usually omitted in Arabic manuscripts and printed works (but not the consonants used to indicate the long vowels), and they are scarcely needed by the native Arabs, who are already familiar with the language; but they are of the utmost importance to foreigners in learning Arabic. The same may be said of the *jâzm* or *jëzm* (◌), a mark placed over a consonant to show that it has no vowel following it, as  (*azrak*, "blue," which without the *jâzm* might be pronounced *azrârk*), and the *teshdeed* or *teshdîd* (◌), placed on a consonant to show that it is to be doubled in pronunciation; as  (*Mohammed*).

It is proper to observe that when the Arabic article *al* or *el* is followed by the letters *t*, *th*, *d*, *dh*, *r*, *z*, *s*, *sh*, *ş*, *đ*, *ţ*, *z*, *n*, the sound of the *l* is changed to that of the letter following; thus *el-Deen* becomes *ed-Deen*; *el-Dowlah*, *ed-Dowlah*; *al-Rahman* or *el-Rahman*, *ar-Rahman* or *er-Rahman*; *al-Temeeme*, *at-Temeeme*, and so on.

* Often represented by *e*, and sometimes (in English) by *u* short.

† Often represented by *o*, as in the name of Mohammed.

‡ The long vowels in Arabic are to be pronounced very full and long.

The Arabic alphabet belongs to the Aramean family of alphabets. With the exception of the Latin alphabet it is used over a greater extent of territory than any other. By means of diacritical points and minor changes it has been adapted to such languages as Turkish, Persian, etc. There are two principal forms of the Arabic alphabet, the Kufic and the Neskhi. The Kufic is so called from the town of Kufa on the Euphrates, where, it is said, the transcription of the Koran was carried on extensively. It is a square character, not well adapted for ordinary use, but well suited for inscriptions on coins, etc., and for ornamental texts. It has long since fallen into disuse. The Neskhi, which is given above, is the form which is used in books and newspapers. On the history of this alphabet, see Isaac Taylor's *The Alphabet* (Lond. 1883).

The Arabic is one of the most extensively diffused languages in the world. It not only prevails in Arabia, in Syria, and in a part of Mesopotamia, but it is spoken in its various dialects (which are more or less corrupted) throughout a large part of Northern Africa, from the shores of the Atlantic to the Red Sea. It is the language of Egypt, which, since its conquest during the caliphate of Omâr, in 641 A. D., has been one of the principal centers of Arabian culture. From about the ninth to the twelfth or thirteenth century it was the prevailing tongue of a large part of the Spanish Peninsula, and its traces are still seen, not merely in many of the names, but in the language of Spain at the present day.

The Arabic, together with the Ethiopic, belongs to the South Semitic family of languages. Of the Arabic tongue there are two principal dialects, the northern or prevailing dialect, in which the Koran is written and which has come to be known as the Arabic language, and the southern or Sabean (formerly called Himyaritic), originally spoken in Yemen and in the extreme southern part of Arabia. The earliest distinctively Arabic writing dates from the early part of the sixth century, but there have been found in the northern part of Hijâz inscriptions written in an Arabian dialect and of a much earlier date. There seems little doubt that in the sixth century practically one and the same dialect was spoken over the larger part of Arabia. As time passed on, however, and the language began to be used in places far away from its original home, dialectical differences increased and were accentuated; new and different conditions required new and different words, till now each of the countries where Arabic is spoken has its own dialect, which differs not a little from the other Arabic dialects and from the classical Arabic. The local dialect is used in ordinary conversation even by the learned, but for books, letters, public speeches, or documents a classical or pseudo-classical Arabic is used, which does not vary greatly in the different countries. When one speaks of the Arabic dialect of a country it must not be forgotten that not only does the speech of different towns betray differences, but such differences have been detected in the language of the different quarters of the same large city.

The large number of gutturals in the Arabic, while making the pronunciation difficult for a foreigner, makes the language, especially when spoken by an uneducated person, rather harsh. When used by a master, however, it is by no means unpleasant.

The Arabic has a very large vocabulary. The life of the Arabs was necessarily rather monotonous, and their opportunity for observation limited, but within their narrow range they noted and named everything with great care and accuracy. Every feature of their life, every phenomenon of nature, every point of their horses and their camels, had its own individual name. Of course, when the desert Arab became acquainted with the culture of the lands he conquered he had to borrow or invent new words, and thus add to his already large stock. Arabic has proved itself admirably adapted for the discussion of abstract subjects, and Arabic journals and books seem to be able, with the help of some borrowed words, to express all modern ideas. On the Arabic and its relation to the other Semitic languages, cf. Nöldeke's *Die semitischen Sprachen* (Leipzig, 1887).

For the study of the classical Arabic, Wright's *Arabic Grammar* (Lond. 1874-75) is a standard work. The grammars of Sorin and of Lansing may also be mentioned. Lane's *Arabic Dictionary* (Lond. 1864) is a work of great value. Cuhe's *Vocabulaire Arabe-Français* (2d ed., Beirut, 1888) is an extremely valuable little book. Other dictionaries of value are: Freytag's *Lexicon arabico-latinum* (Halle, 1830-37); Cherbonneau's *Dictionnaire Arabe-Français* (Paris,

1876); Steingass's *Student's Arabic-English Dictionary* (Lond. 1884); Wortabet's *Arabic-English Dictionary* (Cairo, 1884).

For a study of two of the modern dialects, the following works will be found of value: Spitta Bey's *Grammatik des Arabischen Vulgärdialectes von Aegypten* (Leipzig, 1880); Vollers's *Lehrbuch der Aegyptio-Arabischen Umgangssprache* (Cairo, 1890); Hartmann's *Arabischer Sprachführer* (Leipzig); Landberg, *Proverbes et Dictons du Peuple Arabe* (Leyden, 1883).

(2) ARABIAN LITERATURE is very rich, especially in poetry and other productions of the imagination. Even before the time of Mohammed the Arabs had celebrated poets who sang the praises of heroes and the charms of beautiful women. During the great fairs at Okâz, near Mecca, poetic contests were held in much the same manner as at the games of ancient Greece. It was a great honor to be victorious in one of these conquests. These pre-Mohammedan poets "represent the highest pitch of the Arabic poetic imagination," and they were much imitated by the Moslem writers.

The Arabs have produced no epic or dramatic poems. It is in lyric and romantic composition that they most excel.

There is one kind of poetical fiction, called *Assemblies* (Arab. Maḳâmât مقامات), which may be said to be peculiar to Arabic literature. The *Assemblies* may be regarded as the first step toward dramatic composition. The author of this species of writing was Hamadânee (or Al-Hamadânee), who flourished toward the close of the tenth century. He imagined a witty and unscrupulous improviser, wandering from place to place and living on the presents which the display of his marvelous talents procured from his hearers, and a narrator or story-teller who should be continually meeting with the other, should relate his adventures and repeat his excellent improvisations. He gave to these compositions the name of *Assemblies*, because the improviser was always introduced as making his appearance in some company or assembly of strangers, where the narrator also happens to be, and is sure to be greatly astonished at the tricks, wit, and genius of the other, which he afterward relates in his own language, and these relations constitute the *Assemblies* as they are presented to us. Of this species of composition the *Assemblies* of Hareeree (Harîrî) furnish, perhaps, the best specimen. Hareeree is regarded by the Arabs as a consummate master of diction, and the highest authority in the use of language. "For more than seven centuries," says a recent writer, "his work (the *Assemblies*) has been esteemed as, next to the Koran, the chief treasure of the Arabic tongue. Contemporaries and posterity have vied in their praises of him. His *Assemblies* have been commented on with infinite learning and labor in Andalusia and on the banks of the Oxus." See Introduction to the *Assemblies of Al-Harîrî*, translated by T. Chenery (Lond. 1867).

In romance especially the Arabs may be said to excel. Among the works of this class we may name the *Feats of Antar*, the stories or fables of Ibn Arabshâh, etc. But perhaps the most universally popular, not merely of Arabian fiction, but of all fiction of which we have any knowledge, is the famous collection of tales known as the *Arabian Nights* (q. v.).

In philosophy, mathematics, history, geography, medicine, and physics, the Arabs, during the period of their power, rendered important services to science and civilization; the Arabic terms still found in the language of science, such as *alcohol*, *algebra*, *almanac*, *azimuth*, *nadir*, *zenith*, etc., sufficiently attest their influence on the early intellectual culture of Europe. During the period known as the Dark Ages the scientific works of Aristotle and other Greek philosophers were translated for the most part by Christian scholars who resided as physicians at the courts of the caliphs in great numbers. These works were diligently studied in the Mohammedan capitals of Bagdad, Damaseus, and Cordova, and served to diffuse a knowledge of those great writers among nations who otherwise would have remained in utter ignorance of them and of their writings.

The study of rhetoric and of grammar was pursued with great diligence and success, and an enormous amount of labor was devoted to the expounding of the Koran, the result of which may be seen in the numerous works dealing with the Koran and its exegesis.

The most glorious period of Mohammedan culture extended from about 750 to 1200 A. D. During this period the Abbasside caliphs, Haroun-al-Rashid, Mamoon, and Motassem, reigned at Bagdad, which, under their auspices, became

a magnificent center of science, letters, and the arts. In the far East, Mahnood of Gazna (about 990-1030), though a sanguinary conqueror, was ambitious of the distinction of a patron of literature. At his court flourished Firdousee (Firdausi), the greatest not only of all Persian* but of all Moslem poets, Mohammed only excepted. In Spain, under the caliphs of the Omeyyade dynasty, the period of Arabian culture was not less glorious, and was of much longer duration, than that under the Abbassides. Al-Hakem, Caliph of Cordova (961-76), had, it is said, a library of 600,000 volumes. The high reputation for learning of the Spanish Arabs is shown by the fact that some of the best students of Christendom visited Cordova in order to study the philosophy of Aristotle, medicine, and mathematics under Arabian professors. To the Arabs we are indebted for the preservation of many works from classical antiquity, which without their care and zeal would in all probability have perished during the long period of darkness and semi-barbarism that followed the overthrow of the Western Roman empire.

Among the most distinguished Arabian authors, besides those already mentioned in this article, we may name—(1) In poetry, Khansâ, a female poet contemporary with Mohammed; Ibn-Doreid (838-933); Al-Mootenabee (about 900-965); and Booseeree (or Busîrî), who flourished in Upper Egypt (about 1250). (2) In philosophy, Alchindus flourished under the Caliph Mamoon (about 820); Alfarabius, who lived at Damaseus (about 950); Avicenna (980-1037), who was even more celebrated as a physician than as a philosopher; Averroes (about 1120-98), wrote at Cordova, in Spain, a commentary on Aristotle, to which Dante alludes. (3) In medicine the Arabs excelled all the nations of that period; they are commonly regarded as the earliest experimenters in chemistry (alchemy). Among their celebrated physicians were Razes (or Rhazes)—870-930—who is said to have been the first to describe the smallpox accurately; Avicenna (Ibn Sînâ), already mentioned, the most famous of all the Arabian physicians; Averroes was also distinguished as a physician; Abuleasem (Abulcasis), the most distinguished of Arabian surgeons, is supposed to have practiced in Cordova (about 1050-1110); he left a treatise on surgery, the most valuable that has come down to us from early times. (4) In mathematics the labors of the Arabs were not less useful than in other branches of science, though they can not perhaps boast of so many famous names as in philosophy and medicine. They contributed greatly to simplify and improve the science of numbers by the introduction of the Indian numerals, with the decimal notation. They appear to have been the first to introduce the knowledge of algebra (which had been previously cultivated by the Greeks and Hindus) into Western Europe. Mohammed Ibn Moosa (who flourished at Bagdad from about 810-833) is said to have been the first of his countrymen who wrote on algebra. He also wrote on optics and astronomy. Albatēgnius (Albatenî), who died at Bagdad in 929, wrote some valuable works on astronomy; Abulfeda combined mathematics and astronomy with geography. (5) In history and geography, Masoodee, one of the first of Arab historians, was born at Bagdad, and died at Cairo in 956. His *Meadows of Gold and Mines of Gems* comprises the history, the politics, the religion, and the geography of many Oriental and European nations. Abulfeda (1273-1331) has left works of great value in this and other departments of knowledge. His *Description of the Countries* is considered the best work on geography which the Arabian writers have bequeathed to us. Abulfaragius or Elmaein (or Elmakin), though Christians, wrote valuable general histories in the Arabic language. Ibn Khaldoon (1332-1406) wrote a valuable history of the Arabs, Persians, and Berbers. Makreezee flourished at Cairo (1360-1442), and wrote some excellent historical works. Mak-karee, or Al-Makkari (1585-1631), wrote a history of the *Mohammedan Dynasties of Spain*, which has been translated into English by Gayangos (Lond. 1840).

Those who seek for a general view of Arabian literature are referred to Hammer-Purgstall's *Encyklopädischen Übersicht der Wissenschaften des Orients* (Leipzig, 1804), and his *Literaturgeschichte der Araber* (7 vols. 4to, 1850-56); Renan, *Averrhoes et l'Averrhoisme*; Whewell, *History of the Inductive Sciences*. Revised by J. R. JEWETT.

* Not only was the genius of the poetry of the modern Persians greatly modified by the influence of Islamism, but the Persian language itself includes a very large mixture of Arabic words and phrases. This is especially remarkable with respect to some of the later poets. To understand thoroughly the works of Saadi, for example, a very considerable knowledge of Arabic is absolutely requisite.

Arabian Nights, sometimes called **The Thousand and One Nights**: the title of a collection of wild and fanciful Oriental tales, first brought to the notice of Europe in the early part of the eighteenth century by Antoine Galland, a French Orientalist. These fascinating fictions are probably more widely diffused and read than almost any other production of the human mind. The origin and author of this collection are still unknown. According to some authorities the *Arabian Nights* may be properly divided into three portions, which may be respectively traced to a Persian, an Indian, and an Arabian origin. Throughout the entire work, however, everything appears to be conformable to the character and customs of the Arabian people, and to the Mohammedan faith. The fact that Haroun-al-Raschid figures in several of the stories goes to prove that they, at least, must have been written after his death; while the omission of any mention of coffee and tobacco (except in two or three instances where the names are supposed to be interpolations) shows that the work must have been composed before the introduction of those articles into Western Asia (in the latter half of the fifteenth century). "Many of the tales," says Mr. Lane, referring to this remarkable work, "are doubtless of different and early origins, and its general plan is probably borrowed from a much older production bearing the same title." After some further remarks, he states it as his opinion that the composition in its present form was probably commenced in the last quarter of the fifteenth and completed in the first quarter of the sixteenth century, and that the author or authors must have been Egyptian, because the description of Arab life as it is seen in Cairo is so minutely accurate in all respects. But respecting the date and place of its composition, Oriental critics are far from being agreed. It is noteworthy that the tales differ considerably in various Arabic texts. The work has been translated by W. Beaumont (1811), Macnaghten, Scott, Torrens, E. Foster (1802), and Lane (1839). Most of these translations were from the French. Among the best translations are those of Lane (already mentioned), Payne's literal translation (9 vols., 1882-84), and Sir Richard Burton's (10 vols., "Benares," 1885-87; with 5 supplementary volumes, issued in 1887-88), a slightly expurgated edition of which was published by Lady Burton in six volumes (London, 1886-87). The *Arabian Nights* has given rise to many imitations, among the best of which in English is *Tales of the Genii*, by Rev. James Ridley.

Revised by J. R. JEWETT.

Arabian Numerals, or Figures: the characters 1, 2, 3, 4, 5, 6, 7, 8, 9, 0, which Europeans received through the Arabs from the Hindus. The use of these numerals was not general in Europe before the invention of printing.

Arabian Sea: the N. W. part of the Indian Ocean, lying between India, Arabia, Persia, and East Africa, anciently called *Mare Erythreum*. It has considerable commerce, mainly by virtue of being connected by the Red Sea and the Suez Canal with the Mediterranean.

Arab'ici (i. e. Arabians): a heretical sect which arose in Arabia in the third century, the founder of which was Beryllus, Bishop of Bostra. They denied Christ's divinity, and believed that the soul dies, and is raised again with the body. They were confuted by Origen.

Ara'bi Pasha' (AHMED-EL-URABY): the leader of the Egyptian rebellion of 1882; b. about 1835 on a state farm at Tantah, on the delta of the Nile, where he worked till he was twenty-six, and where his father was a laborer. Arabi received no education while young, but afterward learned to read and write a little Arabic. He was a private soldier in the Egyptian army for twelve years; but later was rapidly advanced to lieutenant, colonel, minister of war, and then pasha. The khedive had pledged all of Egypt and every possible source of revenue to the bondholders. The taxpayers refused to pay; the interest of the foreign loans could not be paid. Great Britain and France semi-officially interfered; the khedive was compelled to allow all high positions of trust to be filled by men sent from the British and French foreign offices; the natives were excluded, and thousands of them joined Arabi's party. Arabi proclaimed to the troops that he was inspired by the Prophet to fulfill a holy mission, the motto of which was "Egypt for the Egyptians," and he became the leader of a great rebellion. The massacre by his forces at Alexandria soon followed. The British intervened, and the forts at that place were bombarded and dismantled by their fleet July 11 and 12, 1882. The war lasted but a few months, and Arabi's army was

totally defeated at Tel-el-Kebir, Sept. 13, 1882, by the British under Gen. Wolseley. Arabi soon after surrendered himself to them, and was sentenced to death Dec. 3, 1882; but his sentence was commuted by the khedive to exile for life, and he was soon after sent to Ceylon.

Aracan: See ARAKAN.

Araca'ri, or **Aricari**: a bird of the genus *Pteroglossus*; a native of tropical South America, and nearly allied to the toucan, but smaller, with longer tail. The bill of one species of this genus is white, with a blood-red stripe along the middle. One of the most remarkable is the curl-crested aracari, having the feathers upon its head beautifully curled.

Araca'ty: a port in Ceara, Brazil; has three churches, several schools, and a trade in hides and cotton. It is on the river Jaguaribe; lat. 4° 31' S., lon. 37° 48' W. (see map of South America, ref. 4-II). There is a dangerous bar at the river's mouth. Pop. 6,000.

Ara'ceæ: a family of endogenous herbaceous plants, natives of temperate and especially of tropical countries, so named from *Arum*, one of its genera. The leaves are sheathing at the base, convolute in the bud; the flowers are naked, arranged on a spadix, which is usually inclosed in a spathe; the male flowers at the upper part of the spadix, and the female at the base. The genus *Arum* is the type of this order, which is characterized by an acrid juice and a nutritious amylaceous substance which is used for food. The *Amorphophallus* is cultivated in India for its roots (or corms), which are edible. See ARUM and AROIDS.

Arachis: See PEANUT.

Arach'nida [from Gr. ἀράχνη, a spider]: a class of arthropodous animals, characterized by having eight pairs of appendages adapted for eating and walking, by having the body divided into an anterior unjointed region* (cephalothorax), and a jointed or unjointed abdomen. They differ from the true insects in many particulars, among which may be mentioned the absence of antennæ, the situation of the sexual openings near the middle of the body, the development of the respiratory organs on the abdomen in connection with legs which disappear after the embryonic stages. They have rather more affinities with the Crustacea, and are to be closely associated with the living horse-shoe crabs (*q. v.*), and the extinct trilobites and enypterans. Seven orders are recognized: (1) *Scorpionida*, the scorpions; (2) *Solpugida*, or cylinder scorpions; (3) *Pseudoscorpia*, or false scorpions; (4) *Pedipalpi*, or whip-scorpions; (5) *Phalangida*, or "daddy long-legs"; (6) *Araneida*, the true spiders; and (7) *Acarina*, the mites. Almost all of the group are carnivorous, and many of them are well provided with poison organs. In some cases they may produce severe and even dangerous injury to man. J. S. KINGSLEY.

Arach'noïd [from Gr. ἀραχνοειδής, cobweb-like]: resembling a spider's web, applied to the second or middle membrane of the brain.

Arachnoid Membrane (sometimes called *me'ninx me'dia*): the fine cobweb-like serous membrane situated between the dura and pia mater of the brain or spinal cord. It

* In Galeodes and Solpuga the cephalothorax is three-jointed.

Aracari.

covers both brain and spinal cord. It is a closed sac, disposed in two layers.

Arad': a county of Hungary; bounded N. by Bihar, E. by Zarand and Transylvania, S. by Temes and Krasso, and W. by Csanad. Area, 2,488 sq. miles. In the E. it consists of high mountain-ranges, but the W. is a fertile plain, traversed by the White Körös. Grain of all kinds, wine, and tobacco are produced here in large quantities of an excellent quality. Chief town, Arad. Pop. 303,964.

Arad, NEW (Hun. *Uj-Arad*): town of Hungary; county of Temesvár; on the left bank of the Máros (see map of Austria-Hungary, ref. 7-1). Here is an extensive fortress, which is one of the strongest in the Austrian empire, and is used as a prison for political offenders. Pop. about 5,000.

Arad, OLD (Hun. *O Arad*): open town; capital of the county of Arad; on the right bank of the Máros; 35 miles E. of Szegedin (see map of Austria-Hungary, ref. 7-1). It is a bishop's see, has a Greek theological seminary, a normal school, and manufactures of tobacco, etc. It is an important cattle market, and has a considerable trade in grain. Pop. (1880) 35,556; (1891) 41,945.

Ar'adus [the *Arvad* or *Arpad* of the Bible]: one of the chief cities of ancient Phœnicia; was built upon the island now called *Rvad*, which is small and rocky, and is situated 35 miles N. of Tripoli, and 2 miles from the mainland. It long continued to be a place of great population and importance. It was supplied with water from submarine springs. It was destroyed and depopulated by the Moslems in the seventh century. Many relics of its former greatness remain. It has still a small population.

Arafat', Mount. or Jeb'el-er-Rahm' (i. e. the mountain of mercy): a granite hill of Arabia, 15 miles E. of Mecca, rises about 200 feet above the plain. To facilitate its ascent, steps have been cut in the rock or built of solid masonry. It is visited annually by a great multitude of Mohammedan pilgrims, who believe that this is the place where Adam and Eve first met after they had been expelled from Paradise and had been separated 120 years. It has a chapel on its summit, which is said by the Mohammedans to have been built by Adam.

Arafu'ra: an aboriginal or non-Malay race of the Spice islands, Celebes, Papua, etc., according to some ethnologists embracing the native race of Australia, and indeed all the Melanesian tribes, including the extinct Tasmanians and the black forest tribes (Negrillos) of Malacca and the Philippines. These people are all exceedingly rude. To cut off a human head plays the same part among their moral institutions as confirmation in many Protestant countries; a young man is not allowed to marry unless he has performed the deed. A white man's head is considered the greatest trophy, and is treasured up in the family sanctuary as the most valuable piece of property. Generally the people have black or very dark skins, and for the most part crisp or woolly hair; but from the character of their languages they are considered quite distinct from the black races of Africa. From this people the sea N. of Australia and S. of the Malay Archipelago is called the Arafura Sea. The name is of Portuguese origin, and originally meant "foreigners."

Ar'ago, DOMINIQUE FRANÇOIS: French astronomer and savant; b. at Estagel, near Perpignan (Eastern Pyrenees), Feb. 26, 1786; entered the Polytechnic School in 1803, and became in 1805 secretary to the Bureau of Longitudes. In 1806 Arago and Biot were employed by the Government to perform the measurement of an arc of the meridian from Barcelona to the Balearic isles, in order to complete an important operation which Delambre and Méchain had commenced. While he was engaged in this arduous work among the mountains, war broke out between the French and Spaniards. Arago escaped from the violence of the Spaniards, who suspected him to be a spy, but on his voyage toward home was driven by a tempest to Algiers, where he was held as a slave. He was finally liberated, and returned to France in July, 1809. In consideration of his services and sufferings he was elected a member of the Institute in 1809, although he was under the age the rules required. About the same time he was appointed Professor of Analysis in the Polytechnic School, where he lectured for many years. He afterward devoted much attention to optics, astronomy, and magnetism. In 1812 he began a course of lectures on astronomy, which were rendered very popular by a brilliant style added to their other merits. Arago and Gay-Lussac founded in 1816 the *Annales de Chimie et de*

Physique. He advocated the undulatory theory of light, and made several discoveries in the science of electro-magnetism. For his discovery of the development of magnetism by rotation, he received the Copley medal of the Royal Society of London in 1825. He became in 1830 director of the Observatory of Paris, and perpetual secretary of the Academy of Sciences. His reputation as a writer was increased by the eulogies which he composed on Condorcet, Ampère, and Carnot, and other members of that academy. He displayed a remarkable faculty of popularizing science in his writings and lectures. He promoted the revolution of 1830, and was elected in 1831 to the Chamber of Deputies, in which he acted with the *extrême gauche*, the advanced republicans. He was a member of the provisional government formed by the republicans in Feb., 1848, and co-operated with Lamartine in resistance to the socialists and in the maintenance of order. He officiated as Minister of War and the Marine for several months, and was one of the executive committee of five elected by the Assembly in May, 1848. About this time the voters of his native department elected him to the National Assembly. He opposed the election of Louis Napoleon to the presidency, and refused the oath of allegiance after the *coup d'état* of Dec., 1851. The emperor recognized his eminent services by accepting him from the enforcement of the law on this point. Arago died in Paris on Oct. 2, 1853, leaving a son, Emmanuel, noticed below. He was a friend of Alexander von Humboldt and of Faraday; was a man of a generous disposition, an ardent temperament, and great energy of character. A statue of him was unveiled at Perpignan in 1879. His works were edited by Barral with a biography, and appeared in Paris (1854-62, 17 vols.; 2d ed. 1865, *sqq.*). D. F. Arago's *Histoire de sa Jeunesse* (1854); J. A. Barral's *F. Arago* (8vo, 1853); Bertrand's *Arago et sa Vie Scientifique* (1865); Audiganne's *François Arago* (1869).

Arago, FRANÇOIS VICTOR EMMANUEL: politician; b. at Paris, June 6, 1812. He studied law, and gained distinction as an advocate and counsel for the defense in political trials. Like his father, D. F. Arago, he was a keen republican, and took an active part in the revolution of 1848. In this crisis he was selected by the republicans to protest in the Chamber of Deputies against the appointment of a regency. He was sent as commissary-general to Lyons in March, was elected to the Constituent Assembly in April, and was sent as minister to Berlin in May, 1848. He resigned in December in consequence of the election as president of Louis Napoleon, whose designs he constantly opposed. The *coup d'état* of Dec., 1851, and the *régime* that followed, excluded Arago from the public service. On the formation of a provisional government by the republicans in Sept., 1870, he became a member of the same. He was elected a member of the National Assembly in 1871, and to the Senate 1876 and 1891. D. in Paris, Nov. 26, 1896.

Arago, ÉTIENNE: dramatic author; brother of the great savant, D. F. Arago; b. at Estagel, near Perpignan, Feb. 9, 1802; produced a number of successful comedies and vaudevilles, which exhibit a talent for satire. Among his works is *The Aristocrats* (1847), a comedy in verse. He fought for the popular cause in the revolution of 1830, and founded the *Reform*, a daily republican journal, in 1834. He was director-general of the post-office from Feb., 1848, until December of that year, and in that position acted with much vigor and ability. As a member of the National Assembly he voted with the *gauche* and opposed the policy of Louis Napoleon. He was exiled in June, 1849. After the proclamation of the republic in Sept., 1870, he was appointed mayor of Paris, which position he held until November. In Feb., 1871, he was elected a member of the National Assembly, but soon resigned on account of his age. He became conservator of the Luxembourg Museum, 1879. D. in Paris, Mar. 5, 1892.

Arago, JACQUES ÉTIENNE VICTOR: French *littérateur*; brother of Étienne Arago; b. at Estagel, Mar. 10, 1790. He accompanied the exploring expedition of Freycinet as draughtsman in 1817, and on his return in 1821 published a *Tour Round the World in the Uranie*, etc. (2 vols., 1822). Among his works are several dramas. Although he had become blind, he joined a party that went to California in 1849 to dig for gold, and published *Travels of a Blind Man in California*, etc. (1851). D. in Brazil, Jan., 1855.

Ar'agon: a former kingdom of Spain; bounded N. by France, E. by Catalonia, S. by Valencia, and W. by Navarre and the Castiles. Length from N. to S., about 200 miles.

Area, 17,976 sq. miles. It is now divided into the provinces of Huesca, Saragossa (Zaragoza), and Teruel. The Pyrenees, which extend along the northern border of Aragon, rise to the height of 11,000 feet. The surface is diversified by several ranges of mountains and many fertile and beautiful valleys. Aragon is intersected by the river Ebro, which flows southeastward and divides it into two nearly equal parts. A considerable portion of the soil is sterile. Among the mineral resources of this region are copper, iron, lead, cobalt, quicksilver, marble, stone, coal, alum, and salt. Aragon was conquered by the Moors in the eighth century. The Christian kingdom of Aragon, founded in 1035, became a powerful state, which was united with Castile by the marriage of Ferdinand of Aragon and Isabella of Castile in 1469. The chief towns are Saragossa and Huesca. Pop. (1887) 910,830. See Schmidt, *Geschichte Aragoniens im Mittelalter*.

Arago'na: a town of the island of Sicily, in the province of Girgenti, 8 miles N. of Girgenti (see map of Italy, ref. 9-E). It has a ruined castle and large sulphur mines. Pop. 13,520.

Ar'agonite, or **Ar'ragonite**: a variety of carbonate of lime, first found in Aragon. It crystallizes in hexagonal prisms, or in crystals of which the primary form is a rhombic prism. It resembles calcareous spar in composition, but differs from it in the form of its crystals, and is reduced to powder by a heat in which calcareous spar remains unchanged. Satin spar is a variety of aragonite.

Aragnay, ăă-răă-gwī, or **Aragnay'a**: a large river of Brazil; rising in the mountains about lat. 18° 10' S., and lon. 51° 30' W. It flows northward; forms the boundary between Goyaz and Matto-Grosso, and after a course of 1,300 miles joins the Tocantins at São João. It is navigable for about 1,100 miles. About midway from its source to its mouth it incloses the island of Santa Anna, or Bananal, 210 miles long. The stream on the east side of this island is called *Furo*.

Arakan, or **Aracan** (called by the natives **Rakhaing'**): a province of Burma, extending along the east side of the Bay of Bengal. The greatest length from N. to S. is about 280 miles, and the area is 14,526 sq. miles. The surface is diversified and extensively covered with forests. The chief productions are rice, tobacco, indigo, cotton, salt, oil, ivory, hides, and timber. Arakan was conquered from the Burmese by the British in 1826. Chief town, Akyab. The principal rivers are the Naf estuary in the N., forming the boundary between the province and Chittagong, the Myu, the Koladyne, running into the Bay of Bengal and navigable for 40 miles, and the Lemyhu, a few miles S. of the Koladyne. Farther S. the rivers are short, and are unimportant except the Gwa, whose mouth forms a harbor. Pop. (1891) 669,540. See Hay, *Arakan: Past, Present, Future* (1892).

Arakan', or **Aracan**: a town of Burma, in province of same name; on the river Arakan; about 50 miles from its entrance into the Bay of Bengal, about lat. 20° 45' N., and lon. 93° 15' E. (see map of India, ref. 2-K). It was formerly the capital of the province and a populous town, but it is now much reduced. Pop. estimated at 10,000.

Ara'lia: a genus of plants of the family *Araliaceæ*, natives of the U. S., of the Himalaya Mountains, and other regions. It comprises a number of species which are used in medicine, as the ginseng, *Aralia quinquefolia*; *Aralia nudicaulis*, called wild sarsaparilla, which grows in the U. S.; *Aralia spinosa*, a native of Virginia, which is a stimulant diaphoretic, called angelica-tree, or toothache-tree; and *Aralia racemosa*, or American spikenard, which produces an aromatic gum-resin. Chinese rice-paper is cut from cylinders of the pith of *Aralia papyrifera*.

Araliaceæ, a-ră-li-ă'se-cē (so called from *Ara'lia*, one of its genera): a natural order of exogenous plants, natives of tropical, temperate, and cold regions in various parts of the globe. It comprises about 375 known species (trees, shrubs, and herbaceous plants), generally possessing stimulant or aromatic properties. The fruit consists of several one-seeded cells. The leaves of several species are used as fodder for cattle in India. One species of this order, the ivy, is a native of England.

Ar'al, SEA OF: a large inland sea in Asiatic Russia, about 150 miles E. of the Caspian Sea. It is included between lat. 43° and 47° N. Length, estimated at 262 miles; breadth, about 184 miles. Area, 26,900 sq. miles. Next to the Cas-

pian, it is the largest inland sea of Asia. Having no outlet, it is saline or brackish. The S. W. part, called Lake Landau, is shallow, and not more than 5 feet deep in the deepest part. The Aral is fed by the large river Oxus or Amu, which enters the sea at its south side; it also receives the river Sihon or Sir-Daria from the E. The latest measurements make it 157 feet above the level of the sea. Seals, sturgeons, and other fish are found in it.

A'ram, EUGENE: an English felon; b. at Ramsgill, Yorkshire, in 1704. He had not the advantage of a liberal education, but he acquired a good knowledge of the Latin, Greek, Hebrew, Chaldee, Arabic, and Welsh languages. He became a schoolmaster at Knaresborough, where he was intimate with a shoemaker named Daniel Clarke. The latter, having purchased some goods on credit, suddenly disappeared, leaving his debts unpaid. Aram was suspected of being an accomplice of Clarke in an attempt to defraud. A portion of the goods which Clarke had purchased was found in the garden of Aram, who was tried, but acquitted, after which he removed from Knaresborough. In 1759 a man named Houseman having confessed that he was accessory to the death of Clarke, whom Aram had killed, Aram was tried for the murder, and made an elaborate argument in his own defense, but was convicted, and afterward confessed his guilt. He was hanged at York, Aug. 6, 1759. His story forms the subject of one of Bulwer's novels, and of a poem by Hood. See Scatcherd, *Memoirs of Eugene Aram* (1832).

Aramæ'a [from *A'ram*, the son of Shem]: the ancient name of a region of Asia, the boundaries of which are not well defined. It extended from Mt. Taurus on the N. to Arabia on the S., and coincided nearly with the countries called by the Greeks Syria, Babylonia, and Mesopotamia. The Aramaic language, a branch of the Semitic, was divided into two forms or dialects—the Syriac or West Aramaic, and the Chaldee or East Aramaic. The former was the language commonly spoken by the Jews in Palestine at the Christian era.

Aramaic, ăr-a-mă'ik: geographically the middle member of the North Semitic group of languages. The original seat of Aramaic is unknown; but in historical times it was spoken over the somewhat indefinite area called ARAMÆA (*q. v.*). Its formal characteristics are as follows: In phonetic decay it has advanced about as far as Hebrew, somewhat farther than Assyrian. In both verb and noun the univocalic form predominates in trilaterals. The roots usually have simple dentals where Hebrew has sibilants and Arabic spirants. In the declension of the noun it employs the termination 'a to denote the emphatic or definite state; and its plural termination is *n*. It forms passives by the prefix 'eth. In vocabulary it is similar in part to Assyrian and in part to Hebrew. In syntax it is marked by great flexibility.

Aramaic is naturally divided into two branches—West or Palestinian Aramaic, and East or Mesopotamian Aramaic.

West Aramaic has for its most striking peculiarities the preformative *y* in the third person of all imperfects, and the preformative *h*, or more rarely 'a, in the causative stem of the verb (Haphel and Hophal). About 1000 B. C. (and doubtless long before this) it was used in Syria proper, and thence down into the region E. of the Sea of Galilee. In some way it came into use in Western Asia as the medium of international intercourse during the Assyrian supremacy, and so continued even under the Persian dominion. Thus the oldest West Aramaic, and indeed the oldest Aramaic, writing is that found on weights, seals, gems, pottery, and clay contract-tablets, from Assyria-Babylonia, and dating from the period between the first year of Shalmanezar, King of Assyria (727 B. C.), and the nineteenth year of Darius Nothus (407 B. C.). In Nabataea also this use of Aramaic as an international language has left inscriptions on stone of about the sixth century, and in Egypt inscriptions on gems, seals, stones, pottery, and papyri of the fifth to third centuries. All of these are written in the old Phœnician character. The language of these inscriptions presents the West Aramaic peculiarities, but has borrowed words from the languages of the foreigners by whom it was used. The religious character of some of the Nabataean and Egyptian inscriptions moreover shows that Aramaic was known rather more intimately than as a mere medium of intercourse.

The most extensive and important part of the old West Aramaic literature is the Aramaic portion of the Old Testament: Ezra iv. 8-vi. 18; vii. 12-26; Dan. ii. 4 b-vii. 28; Jer. x. 11; Gen. xxxi. 47. The language used in these places

has been falsely called Chaldee on the supposition that it was spoken in Chaldea (that is, Babylonia), and had been brought thence by the Jews. But Aramaic was the native language of the people living in the region just N. of Israel. And it was after the exile that this dialect, owing, perhaps, to its phonetic simplicity and its syntactical flexibility, began to work its way down among the Hebrews as the common speech of the people. By the third century B. C. Aramaic was known and used alongside of the Hebrew, and this parallel use of the two may account for the sudden changes in Daniel and Ezra from one to the other. For it seems probable that here parts of the Hebrew text had been lost, and were replaced from Aramaic translations which had been made for a certain class of Jews. From the end of the third century the Hebrew began to yield to the Aramaic, becoming first the language of learning, and then in the first century merely that of the public worship.

Of this biblical Aramaic the portion in Genesis (consisting of but two words) and that in Jeremiah (a later interpolation) require no comment. The difference between the Aramaic of Daniel and that of Ezra is almost entirely lexical, with the exception of a few pronominal forms. Both present the West Aramaic characteristics, except that in the third person imperfect of the verb "to be" they have the preformative *l*, apparently an East Aramaism. This *l*, however, may be merely the particle *l*, used as in Assyrian without precative force to avoid writing the imperfect in *y*, which for this verb "to be" has the same Aramaic form as the sacrosanct divine name Yahweh. In general, the Aramaic of the Bible seldom differs from that of the Targums of Onkelos and Jonathan, and then mostly in orthography. Further, in some of the greatest of these differences biblical Aramaic is found to agree with the Palmyrene and the later Nabataean inscriptions (9 B. C.—300 A. D.). It also contains a number of Persian and Greek words, and some of these latter are not found in Greek earlier than Aristotle. So, as nearly as can be made out, the Aramaic of the Bible is that of the third, second, or even first century B. C. In agreement with this, from other considerations, it seems probable that the passages in Ezra were written between 250 B. C. and 300 B. C., and that in Daniel about 165 B. C.

The Targums of Onkelos, Jonathan, and those known as Jerushalmi i. and ii., the Mishna, the Gemara of the Jerusalem Talmud, and scattered places in the Babylonian Talmud and the Midrashim, are also written in West Aramaic. See TALMUD and TARGUM.

During the supremacy of West Aramaic in Palestine that language came into use in Nabataea also. The remains found there consist of tombstone inscriptions dated from 9 B. C. to 75 A. D. The script is a square cursive development of the old Phœnician. The language is formally the same as the biblical Aramaic, and, like the latter, contains Greek words. But the predominating influence is Arabic. Arabic words and constructions abound; and as the proper names are almost entirely Arabic, it seems that Aramaic had here made its way among an Arabic people nearly as it did among the Hebrews.

About this time in Syria itself, at Palmyra (Tadmor), Greek had crept in alongside of the Aramaic. Near that place have been found a number of Aramaic inscriptions on stone, usually accompanied by Greek translations, and dated in the first three centuries of the Christian Era. They are votive, dedicatory, memorial, and political, the last sort giving decrees of the Senate and the people of Palmyra. The language is about the same formally as the biblical Aramaic and the Nabataean; but shows a much greater Greek influence.

The people about Samaria also used a West Aramaic dialect which came in time, at least in the written language, to be mixed with Hebrew. See SAMARITANS.

West Aramaic, though hard pressed by Greek and Syriac, maintained itself in Palestine down to the Arabic period. A number of Aramaic words and phrases occur in the New Testament; see Kautzsch's *Grammatik*, p. 7. And between 300 A. D. and 600 A. D. a West Aramaic translation of the New Testament was produced which has come down to us under the name of *Evangelium Hierosolymitanum*. This translation shows a strong Syriac influence. But after the Arabic conquest, Arabic gradually took the place of Aramaic and the other languages in the lowlands and the cities. In the mountains, however, Aramaic lingered on, and to-day is still spoken, along with Arabic, in Ma'lula and two other villages of Anti-Lebanon, but in fragmentary form and rapidly decaying condition.

Eastern Aramaic, while it seems to have been spoken for centuries in Northern Mesopotamia, is not known to have been used as a written language previous to the Christian Era. It is characterized formally by the preformative *n*, and its variation *l*, in the third person imperfect of the verb, by the preformative 'a in the causative stem ('Aphel) and by the absence of the Hophal as the passive of the causative. It is divided into several dialects, of which the principal are Syriac, Babylonian Aramaic, Mandæan and Modern Syriac. The differences between these dialects are mostly lexical and orthographic, except that the later Aramaic shows numerous phonetic and grammatical changes.

The earliest East Aramaic, Syriac, first came into prominence at Edessa, where a cursive script called Estrangelo (*στρογγύλος*) was developed from the old Phœnician character. At this city, in the second century A. D., the translation of the Bible known to us as the Pēshīttā (the simple) was made. Through the influence of this translation Edessa became the center of Aramaic Christendom; and this Edessene literary language spread, especially eastward among the Aramaeans of the Tigris region, in which at Nisibis another center of learning was soon established. Then from the name of that whole indefinite region, which was called Assyria, or Syria, by the Greeks, this language written in the Edessene script came to be called Syriac. By 700 A. D., Syriac literature, fostered by the schools of Edessa and Nisibis, had passed its prime and produced its greatest writers, such as Ephrem Syrus (306-73), Narses (d. 496), James of Sarug (522), and Philoxenus of Mabug (d. 520). During this time, owing to theological controversies, Syriac Christendom split into three parts. The most of the Eastern Syrians were Nestorians, while the most of the Western were Jacobites (Monophysites). A small third part remained orthodox Catholics. In 489 the academy at Edessa was closed for heresy; and from that time Nisibis was the center of religion and learning among the Eastern Syrians, or Nestorians. The two sects produced two sets of writings, scarcely two dialects. The greatest difference was in the script. The Nestorians continued to use the old Estrangelo, with slight changes, so that indeed it came to be called Nestorian, while the Jacobites used a development pointed with Greek vowels, and called after them Jacobite. Largely on account of this division a literal translation of the New Testament from the Greek was made for the Jacobites by Philoxenus, Bishop of Mabug, about 500 A. D. and revised by Thomas of Harkel at Alexandria in 616 A. D. In 617 Paul of Tella, also for the Jacobites, made a very close translation of Origen's text of the Septuagint. Both translations are useful for textual criticism, and together with the Pēshīttā are the most valuable of the Syriac productions of the period.

After the Arabic conquest, Syriac remained for some centuries the spoken language of Northern Mesopotamia; but Arabic gradually came in, especially as the language of commercial and official intercourse. Syriac became more and more the language of the school and the church until, in the eighth century, it was practically dead. The identification of Syriac with the Christian Church, however, served to maintain it in use among the learned. Even in the present century the Nestorians have used books written in the now half-understood literary Syriac, and the Maronite College at Rome has kept up a special cultivation of it. During this period a great number of writers were busy producing a mass of literature, mostly theological and ritualistic. The most original and important of these was Bar Hebraeus, or Gregory Abul Faraj (1226-86), whose chronicles are the main source of information for the civil and ecclesiastical history of the time. Probably the most notable work of the Syrians under Moslem rule was the transmission to the Arabs of the knowledge of Greek literature. And in general it may be said that the ablest of the Syriac writers were mere translators and adapters and the most useful, bare chroniclers. From the time of the Assyrians their country was overrun and held by enemies. The separate Aramaic communities never had a chance to unite in peace, and develop a national character; and so they never produced any distinctly original literature.

East Aramaic was adopted by the Jews of Babylon as West Aramaic was by those of Palestine; and the Babylonian Talmud was written in an East Aramaic dialect closely resembling Mandæan. See TALMUD.

In Southern Babylonia and on the shores of the Persian Gulf a dialect of East Aramaic was developed by the sect of the Mandæans, so-called from Manda d' Hayye (*γνώσις ζωής*), whom they think to be the Saviour. They call them-

selves Nazeraye, or Nazarenes, and hold to a queer mixture of Christian and heathen ideas. Their oldest literature consists of three religious works dating from the period between 650 and 900 A. D.; and, being written at a time when the dialect was still a living speech, they present it in its greatest purity, though it already shows a general phonetic decay. From 900 on, several astronomical and ritualistic works are known, whose language shows a greater and greater breaking down in grammar and orthography. But the modern dialect of the sect still contains Aramaic elements mixed with Persian and Arabic.

The region between Lake Urmi, the district of Salamas, and the Tur Abdin Mountains is inhabited at the present time by a mixed population of Moslem Kurds and Christian Aramaeans. These Aramaeans, while the priests own and to some extent understand books written in the old literary Syriac, speak a division of Aramaic called Modern Syriac, which is "not exactly the daughter of the old Syriac" (Nöldeke). It is rather a descendant of the folk-speech from which literary Syriac itself was developed. The language, however, shows great phonetic change and strong foreign influence, especially in vocabulary. It is divided into a number of minor dialects due to varying foreign and religious influences. Modern Syriac has been made known to European scholars mainly by American missionaries, who for religious purposes have made a literary language out of the Urmi dialect, and have printed in it translations of the Bible and of other books.

BIBLIOGRAPHY.—Only a short list of books can be given here; for fuller list, see Nestle, *Syriac Grammar*.

Lexicons.—Abul' Hassan, *Isa bar Bahlul* (963), the best native lexicon and basis of all modern lexicography, in MS. in Bodleian; Georg Hoffman, *Syrisch-arabische Glossar*, Bar-Ali, from Alaf to Mim (Kiel, 1874); Cardahi, *Al-Lobab, Dict. Syro-Arab.* (Beirut, 1887); C. Schaaf, *Lexicon Syriacum Concordantiale* (2d. ed. Leyden, 1717), best for the New Testament and valuable as concordance; *Castelli Lexicon Syriacum*, revised by J. D. Michaelis (Göttingen, 1788); R. Payne Smith, *Thesaurus Syriacus*, now publishing in Oxford.

Grammars.—A. G. Hoffman, *Gram. Syriaca* (Halle, 1827), the most exhaustive, but not always reliable; revised and enlarged (but not improved) by A. Merx, *Gram. Syr. quam post opus Hoffman refecit A. Merx*, two parts, all that have appeared (Halle, 1867-70); an abridged translation is B. H. Cowper's *Syriac Grammar*. Fr. Uhlemann, *Grammatik der syrischen Sprache, etc.* (2d ed. Berlin, 1858), most serviceable, but by no means scientific; translated by E. Hutchinson (2d ed. New York, 1875); Th. Nöldeke, *Syrische Grammatik* (Leipzig, 1880); do., *Mandäische Grammatik* (1875); E. Nestle, *Syriac Grammar*; R. Duval, *Grammaire Syriacque* (Paris, 1887); F. Bähgen, *Syr. Gram. des Elias von Tirkhn* (Leipzig, 1880); R. J. H. Gottheil, *Syr. Gram.*, by Elia of Soba (Berlin, 1887); E. Kautzsch, *Aram. Grammar* (Leipzig, 1884); I. Löw, *Aram. Pflanzennamen* (Leipzig, 1881); *New Syriac*, Stoddart; Nöldeke, *Grammatik der neusyrischen Sprache* (Leipzig, 1863).

Chrestomathies.—G. W. Kirsch, *Chrestom. Syr.*, revised by Bernstein (Leipzig, 1832), the lexicon extremely valuable; Rödiger, *Chrestomathia Syriaca* (2d ed. 1868).

West Aramaic Literature.—Besides the biblical passages, the *Targums*, the *Talmud*, and the *Evangeliarium Hierosolymitanum*, a late Palestinian lectionary (Verona, 1861-64), see *Corpus Inscriptionum Semiticarum*; De Vogüé's *La Syrie Centrale*; Euting's *Nabatäische Inschriften*.

East Aramaic Literature.—The Babylonian *Talmud*, and the Mandæan and Modern Syriac works are mentioned above. The principal classical Syriac works are as follows:

FIRST PERIOD.—Up to the Mohammedan conquest A. D. 636.

Bible Versions.—A. The *Peshiftā* or *Peshito* (i. e. the simple) edition, the oldest Syriac literature that has come down to us. It exerted an immense influence in molding the language, as well as all the subsequent literature, and has remained the accepted version among all parties of the Syrian Church. (a) *New Testament.*—Made at Edessa in the second century. Editions: Widmannstadt and Moses of Marden (2 vols., 1555), *editio princeps*, best, but very rare. Serviceable is Henderson's edition of Gutbier's text, published by Baxter. Cureton has published in his *Remains of a very Ancient Recension of the Four Gospels in Syriac*, etc. (London, 1858), a text of the Peshito different from that of the MSS. on which our printed editions are based. (b) *Old Testament.*—Valuable translation,

made directly from Hebrew. It is the work of Christian editors, and probably contemporaneous with the version of the New Testament. Editions: *Vet. Test. Syriace*, S. Lee (Lond. 1823); also many editions of the Psalter. Ceriani, *Photolithograph of Cod. Ambrosianus* (Milan, 1876-79).

B. *Philoxenian Version* of the New Testament. Editions: White (Oxford, 1778-1803, 4to); Bernstein, *Evang. des Johannes* (Leipzig, 1853).

C. *Hexaplar Version of O. T.* (formerly called *Figurata*). MS. is in Milan. Various portions of it have been edited by Norberg, Bugati, Middeldorpf, Ceriani, De Lagarde, and a photolithograph of MSS. has been published.

Authors.—See Land, *Anecdota*, vol. iv. (Leyden, 1875). Ephrem Syrus, *S. Ephraem. Syri Opera omnia* (Rom., 1732-46, 6 vols. folio), edited by Petrus Benedictus and S. E. Assemani. Narses (d. 496); James of Sarug (522), *De Vita et Scriptis S. Jacobi Sarugi*, etc., ed. by Abeloos (Louvain, 1867); Isaac the Syrian; Xenagas or Philoxenus of Mabug (d. 520).

SECOND PERIOD (636-1318 A. D.).—Period of decay of Syriac; Arabic and Syriac spoken languages. James of Edessa (d. 708), learned scholar, celebrated grammarian, and linguist. Barhebraeus: (a) *Chronicon Syriacum*, ed. Bruns and Kirsch (Leipzig, 1789, 2 vols.). (b) *Chronicon Ecclesiasticum*, ed. Abeloos and Lamy (Louvain, 1873). Besides this he wrote a number of grammars, treatises, commentaries, etc. Ebed Jesus (d. 1318).

THIRD PERIOD (1318).—Arabic the spoken language; Syriac cultivated only as a learned and ecclesiastical language, chiefly in the Maronite College in Rome. Amira (1644), grammarian; the Assemanis. (a) Joseph Simon: *Bibliotheca Orientalis* (Rom., 1719-28, 3 pts., 4 vols. fol.), a complete history of Syrian literature, and the source from which our knowledge of it is largely derived. (b) Stephan Evodius: *Acta Sanctorum Martyrorum* (Rom., 1748, fol.).

SYRIAC MSS.—The chief collections of Syriac MSS. are in the British Museum, the Vatican, the Bibliothèque Nationale in Paris, and the Bodleian in Oxford. The oldest MSS. are of the fifth century. Wright, *Catalogue of Syriac MSS. in British Museum* (1870-72); Zotenberg, *Catalogues des MSS. syriaques, etc., de la Bib. Nat. Paris* (1874).

PRINTED BOOKS.—See list in *Conspectus Rei Syrorum Lit.*, ed. G. Bickell (Münster, 1871). *Festal Letters of Athanasius* (London, 1848); *Corpus Ignatianum—Complete Collection of Ignatian Epistles* (London, 1845-49); *History of Martyrs in Palestine, by Eusebius* (London, 1861), etc.; Samuel Lee, *V. T. Syriace* (see above); *Theophany of Eusebius* (1842); Paul Anton de Lagarde, *Libri Veteris Test. Apocryphi Syriace* (Leipzig, 1861); *Analecta Syriaca* (Leipzig, 1858); *Geoponica Syriaca* (Leipzig, 1858); *Clementis Recognitiones Syriace* (Leipzig, 1861); *Didascalia Apostolorum Syriace* (Leipzig, 1854); William Wright, *Homilies of Aphraates* (London, 1869); I. P. N. Land, *Anecdota Syriaca* (Leyden, 1862); W. Wright, *Apocryphal Acts of the Apostles* (Lond. 1871); Martin, *Œuvres grammaticales d'Abou' Faradg di Bar Hebraeus* (Paris, 1872); articles in *Journal asiatique*; *Zeitschrift der deutsch. Morgenländ. Gesellschaft*, etc.

C. II. TOY.

Aran'ida, JOSÉ JIMENEZ: a Spanish genre-painter; b. at Seville in 1832; well known in the U. S. First class medal, Paris Exposition, 1889; studio in Paris. W. A. C.

Aranda, DON PEDRO PABLO ABARACA DE BOLEA, Count of: Spanish statesman; b. of a noble family at Saragossa, Dec. 21, 1718. He served many years in the army, and rose to the rank of general. In 1765 he became president of the council of Castile and prime minister. He used his power to promote reform and a liberal policy, and procured the expulsion of the Jesuits from Spain in 1767. In 1773 he was removed from power by the intrigues of the clergy, but was sent as an ambassador to France, where he remained until 1787. He was again prime minister for a short time in 1792, and was driven from power by Godoy. He died on his estate in Aragon in 1799.

Arane'ida [from Lat. *ara'nea*, a spider]: the order of *Arachnida*, which includes the SPIDERS (*q. v.*).

Aranjuez, āar-āan-khweth' (in Lat. *A'ra Jo'vis*, i. e. altar of Jupiter): a town and royal residence of Spain, in New Castile, in the modern province of Toledo, and situated on the left bank of the Tagus, 30½ miles by rail S. S. E. of Madrid (see map of Spain and Portugal, ref. 16-E). It is situated in a beautiful valley, has spacious streets, elegant squares and a royal palace, and gardens laid out by Philip II. Here are also a theater, a hospital, and several summer-

houses in the royal gardens. Aranjuez suffered severely from the French during the Peninsular war. The treaty of 1772 between France and Spain was concluded here. It was the scene of the insurrection which ended in the abdication of Charles IV. in Mar., 1808. Pop. (1881) 8,154.

Arau'sas Bay, sometimes called **Arausa'zua**, or **Arausaso, Bay**: on the coast of Texas, in the N. W. part of the Gulf of Mexico, about 15 miles N. by E. of Corpus Christi Bay, and is about 18 miles long and 8 miles wide in its broadest part.

Arausas Pass: the principal inlet to Aransas Bay and Corpus Christi Bay, Tex., between St. Joseph and Mustang islands. It is becoming commercially important, but has a troublesome shifting bar. The lighthouse is of brick, 40 feet high, and stands on Low island, inside the pass; lat. 27° 51' 51" N., lon. 97° 2' 58" W. The Confederate works at this pass were captured by the Federal troops, with 100 prisoners and some guns, Nov. 20, 1864.

Ar'any, JÁNOS: a popular Hungarian poet; b. Mar. 7, 1817; became in 1851 professor at Nagy-Körös, in 1859 member of the Hungarian Academy, and in 1860 director of the Kiszaludy Society at Pesth. His first work was a humorous poem called *The Lost Constitution of the Past* (1843), which gained a prize. He wrote, among other poems, *Buda Halála*, which in 1874 was crowned by the Hungarian Academy. D. at Budapest, Oct. 22, 1882.

Arapahoes: See ALGONQUIAN INDIANS.

Arapai'ma: a genus of fresh-water fishes found in the rivers of South America, and highly esteemed for food. They are the largest fresh-water fishes in the world, and are allied to the *Clupeidæ* or herring family. Some of them measure about 15 feet long, and weigh 400 lb. or more. The body is covered with strong, bony, compound scales.

Arapiles, aar-a-pee'les: a small village of Spain, situated 4 miles S. E. of Salamanca; was the scene of a severe engagement which was called "the battle of Salamanca," between the allies under Wellington and the French under Marmont, July 22, 1812, in which the latter were defeated.

Ararambo'ya: the dog-headed boa or bojobi, a green snake most abundant in Brazil.

Ar'arat: a celebrated mountain of Western Asia; rises from the plain of the Aras (or Araxes) about 33 miles S. W. of Erivan. It is called by the Persians Koh-i-Nooh, "Mountain of Noah." It is on the boundary between Persia, Asiatic Turkey, and the Russian possessions. The highest peak is in lat. 39° 42' N. and lon. 44° 35' E., is covered with perpetual snow, and has an altitude of 17,212 feet above the level of the sea, or 14,200 feet above the plain of the Aras. It is a volcano, the last eruption of which occurred in July, 1840, when a great earthquake shook the surrounding country. See James Bryce's *Transcaucasia and Ararat* (1877).

Ararat, LITTLE: a peak S. E. of the preceding, and rises in the form of a cone to the height of 12,840 feet above the level of the sea. The summits of these two mountains are 7 miles apart in a direct line, but their bases are nearly in contact. According to the eighth chapter of Genesis, the ark rested "upon the mountains of Ararat."

Ararat, or **Pilot Mountain**: a hill in Surrey co., N. C., between the Ararat and Dan rivers, is 3,000 feet high. It is visible at a distance, and serves as a landmark to travelers.

Arari, THE SERRA: a low mountain range between the Brazilian states of Piahy and Ceara; part of a general range which nearly crosses Brazil from the coast near Parnahyba, southward. It forms the watershed between the Parnahyba river and the coast streams to the E.—principally the Jaguaribe and San Francisco. It takes on several names in its course. Beginning at the N., these are the Serra Grande, the Serrania, the Serra Arari, the Serra dos Irmaos, and Serra do Piahy. M. W. H.

Aras' (the ancient *Arax'es*): a river of Armenia; rising in the Turkish pashalic of Erzurum. It flows eastward, passes near the northern foot of Mt. Ararat, and traverses the Persian province of Adzerbijan. It afterward turns toward the N. E., and enters Georgia or the Russian dominions, and unites with the river Kur about 60 miles from its entrance into the Caspian Sea. Its whole length is about 500 miles.

Arat'us (in Gr. *Ἀρατος*): a Greek poet and astronomer; b. at Soli, in Cilicia; flourished about 290–260 B. C.; contemporary and friend of Theocritus and Callimachus. He lived

as physician at the court of Antigonus Gonatas, at whose instance he composed the poem which is his title to a place in literature, *Phænomena* (*Φαινόμενα*), or *Aspects of the Heavens*, an astronomical poem, in 1,154 verses based on Eudoxus and Theophrastus. The concluding portion, *Signs of Weather* (*Διοσημεία*), is called by Cicero *Prognostica*. The versification is smooth, the language is an imitation of Homer, the plan an imitation of Hesiod. The poem was much admired and highly valued. The astronomer Hipparchus wrote a commentary on it, which is still extant, and it was translated into Latin by Cicero and Germanicus among others. Elaborated ed. by Buhle (1793–1801); critical ed. by I. Bekker (1828). B. L. GILDERSLEEVE.

Aratus of Sicyon: a Greek general and statesman; b. at Sicyon in 271 B. C.; son of Clinias, who was assassinated about 264. Aratus then escaped to Argos, where he was liberally educated. In 251 B. C., with the aid of other exiles, he liberated Sicyon from the tyrant Nicocles, and united it with the Achaean League, of which he was chosen general (*strat'egos*) in 245. An important object of the league was to maintain the independence of the Greek states against the King of Macedonia. He expelled a Macedonian garrison from Corinth in 243 B. C., was many times re-elected general-in-chief, and managed the affairs of the league with much ability. About 226 the league was involved in a war against Cleomenes, King of Sparta, who defeated Aratus in several battles. Aratus formed in 222 an alliance with Antigonus of Macedon against the Spartans. He died in 213 B. C., leaving the reputation of a true patriot. Philip V. of Macedon is said to have procured his death by poison. He left thirty books of memoirs, which were drawn upon by Polybius and Plutarch.

Arauca'nia, or **Arauca'ua**: once an independent state in the S. of Chili, bounded E. by the Andes and W. by the Pacific. It extended from the river Bio-Bio on the N. to Valdivia, or to lat. 40° S., being about 190 miles long. The physical features, climate, and productions are like the rest of Chili. The Araucanians are remarkable for their independent spirit and their successful resistance to foreign domination. The Spaniards made an unsuccessful attempt to subdue them in 1537 and at several subsequent periods. On this subject Ercilla, a Spaniard, wrote a celebrated epic poem called *Araucana*. It is said that they possess many noble qualities, and cultivate poetry, but abhor the restraints of civilization. They recognize a Supreme Being and a future state, but build no temples. The government was administered by four hereditary *toquis*, each of whom ruled over one of the provinces into which their country was divided. The most important national questions were decided by the grand council composed of these *toquis*, or by a general assembly. In 1860 a French lawyer, De Tonneins, who had gained considerable influence among the Araucanians, proclaimed himself, under the name of Orélie Antoine I., constitutional King of Araucania. He was in 1861 taken prisoner by the Chilians and sent back to France. In the treaty of Jan. 22, 1870, the Araucanians promised to recognize the authority of Chili. See Molina, *History of Chili*; Edward R. Smith, *The Araucanians*, etc. (New York, 1855). Only some 50,000 of the original inhabitants are left at the present time.

Arauca'ria [derived from ARAUCANIA (*q. v.*), name of a territory in Southern Chili]: a genus of plants of the natural order *Coniferae*, natives of the southern hemisphere; all evergreen trees, distinguished by having the male and female flowers on separate trees, the pollen contained in from ten to twenty scales pendent from the apex of each scale, the female flowers two under each scale, each having one ovule. The *Araucaria imbricata*, or Chili pine, a native of the Chilian Andes, attains the height of 150 feet, and produces a seed which is an important article of food; also a fragrant resin in abundance. The timber is hard, heavy, and suitable for the masts of ships. This tree is cultivated as an ornament of landscapes. The Norfolk island pine, which is about 200 feet high, is *Araucaria excelsa*, a noble tree, and Australia has two or three fine species.

Arauco: a marine department of Chile, forming the bold projection into the Pacific Ocean called Punta de Levapie, the south wall of Arauco Bay. On the E. are the departments of Concepcion, Bio-Bio, Malleco, and Cautin. The territory bearing this name was formerly much more extensive. It is now a strip of coast. Area, 4,248 sq. miles. Pop. (1891) 70,064. Principal towns, Arauco and Lebu, ports, and Nacimiento and Tucapel.

Araujo d'Azevedo, a-row'zhō-daã-zā-vā'dō, ANTONIO (Count da Barca): Portuguese statesman; b. at Ponte de Lima, May 14, 1754. He negotiated at Paris, and signed, a treaty of peace with France in 1797, but the French Directory annulled it. He became Minister of Foreign Affairs in 1806. After Napoleon had invaded Portugal and captured Lisbon, Araujo accompanied the king, John VI., to Brazil in 1808. He was appointed Minister of Marine in 1814, and in 1817 sole minister. He was a man of various accomplishments; he wrote poetry and gained distinction by his scientific attainments. D. at Rio de Janeiro, June 21, 1817.

Araujo Porto Alegre, MANOEL, de: Brazilian poet; b. at Rio Pardo, Nov. 29, 1806; first attracted attention as a painter, and, in fact, continued throughout his life to devote himself largely to the fine arts. His fame, however, rests chiefly upon his poems and plays. Of the latter, few have been published, in spite of the fact that they may be said to have brought into being the modern Brazilian drama. Of his poems, most noteworthy are: *As Brazilianas* (1843, *seq.*), lyrics upon Brazilian themes, and *Colombo*, an epic poem of some length.

A. R. MARSH.

Arau're: a city in Zamora, Venezuela; on the Acarigua, a branch of the Portuguesa; on the northeastern flank of the Cordillera de Merida (see map of South America, ref. 1-C). It is in a fertile district, yielding cotton and coffee, and pasturing many cattle. Pop. 10,000.

Aravali, or **Aravalli**, āa-ra-vū'li: a mountain range of Hindustan; traverses Ajmir, and is about 300 miles long. The highest summits are about 5,000 feet above the level of the sea. It constitutes the watershed between the Arabian Sea and the system of the Ganges. The general direction of the range is N. N. E. and S. S. W.

Ar'bases (Gr. Ἀρβάκης): a Median general who revolted against Sardanapalus, captured Nineveh, his capital, and on the ruins of the Assyrian empire founded the kingdom of Media, about 876 B. C.

Arbe'la, now **Arbeel** (**Arbil** or **Erbil**): a small town of Asiatic Turkey, in Kurdistan, about 40 miles E. of Mosul (see map of Turkey, ref. 6-J). The modern town has some large mosques and bazaars. Arbela gave its name to the battle in which Darius was finally defeated by Alexander the Great, in 331 B. C., but it was fought at Gaugamela. Pop. about 6,000, mostly Kurds.

Ar'biter (Lat., supreme judge): a person chosen by parties in a controversy to decide a question; sometimes applied to a person who has the power of judging and determining, or who is able to control the destiny of others. Some cases among the ancient Romans were decided by an arbiter, especially when the parties differed in respect to the amount of money which one of them should pay to the other.

Arbitra'tion [from Lat. *arbitrari*, act as arbiter or judge]: a submission of some matter in dispute to the judgment and decision of a person called an "arbitrator." It applies to civil cases only, and may be either oral or written. It is voluntary in its nature, as any party has a legal right to have an adjudication upon his case by a court of justice. Statute law sometimes makes arbitration compulsory, as where the investigation of a long account is necessary. Even after parties have agreed to submit a controversy to arbitration, one of them may withdraw his consent against the will of the other at any time before the hearing is closed. The only remedy of the other party is to bring an action for damages, which would usually be nominal. However, when parties enter into a contract, they may stipulate that no rights of action shall accrue under its provisions unless there is a submission on their part to arbitration; in which case the duty to submit becomes a condition precedent, and can not be avoided. The result of the arbitration is termed an *award*. It is not, however, equivalent to a judgment of a court, and if not performed the regular course of the successful party would be to bring an action upon the award, and thus make it a judgment of a court. To avoid this inconvenience, statute law frequently provides that on reducing the submission to writing a clause may be inserted that the award may be entered on the records of a specified court as a judgment, whereupon it shall have the like force and effect. Having the characteristics of a judgment, the award falls under the control of the court, and modes are provided by which mistakes and errors may be rectified by judicial action. As a general rule, there is no review of the result of an arbitration. There are no methods of appeal provided, as the theory of

the proceeding is that the arbitrator is to be the judge of the difference between the parties. This rule does not prevent the rectification of mistakes in matters of fact, nor does it include the case of fraud or the violation of the first principles of justice; as, for example, the act of hearing one party, and not the other.

Revised by HENRY WADE ROGERS.

ARBITRATION as a means of settling labor disputes may be either voluntary or compulsory. In the former case it has much in its favor. The French courts of conciliation (*conseils de prudhommes*), dating from 1791, which provide a means for talking over the points at issue between employers and workmen, have done a great deal in preventing trouble, and there have been similar experiences on a smaller scale in Great Britain, especially in Nottingham (1860) and Wolverhampton. The efforts of Parliament, in 1824 and 1872, to provide official facilities for arbitration on the French models have not been very successful, and the same thing may be said of similar efforts at State boards of arbitration in New York and other parts of the Union. It is hard to make compulsory arbitration of any avail, because the workmen can always, and the employers can generally, avoid obeying an arbitrator's award. See STRIKES AND LOCK-OUTS and TRADES-UNIONS.

ARTHUR T. HADLEY.

ARBITRATION between states. Between the breaking out of an international difficulty and a final recourse to war there are several methods of settlement which should be first resorted to. These are, in the language of the publicists, amicable conference, mediation, and arbitration. The first is hardly to be distinguished from that diplomatic negotiation which always attends a quarrel, and which in a majority of cases is able to settle it. Mediation is the decision of a dispute by some third power which offers its services, but whose award is recommendatory, not binding.

Arbitration is a voluntary submission of certain definite points in dispute to the decision of a third party, whether an individual, a number of individuals forming a court, or simply the representative of a friendly power. It is essential that the exact questions to be submitted be definitely agreed upon in advance, since a failure to pass judgment upon the points submitted is a fatal defect in the award. This was the flaw in that award given by the King of the Netherlands in 1831 in our northeastern boundary question. Instead of deciding which of the two lines claimed was the one intended by a certain treaty, he recommended a third line as a compromise. This was very properly rejected by both parties.

International arbitration thus far has been used to settle particular questions. It has been suggested, but not often adopted, as an obligatory method of deciding *all* the controversies which may arise between two or more states. (See PAN-AMERICAN CONGRESS.) Being intended to meet a particular known exigency, its adoption will usually be the result of a convention negotiated for the purpose, in which all the details of the arbitration will be formally laid down, the composition of the court, its place of meeting, the character and method of award, even sometimes the rules to be applied in judging national conduct. For a most instructive example, see ALABAMA CLAIMS.

In default of rules to govern the award, in the agreement to arbitrate, the rules of the Roman law are held to apply. Thus unless unanimity in the court is necessary, a majority vote decides. There was, therefore, no ground for the protest in the U. S. Senate against the Halifax fishery award, which was made by a majority vote. The decision of a court of arbitration is binding upon the contestants, save and except only in these cases: (1) If the award is outside of the questions submitted; (2) if there is proof that fraud or corruption has influenced it; (3) if it involves an impossibility; (4) if it is equivocal or unintelligible; (5) if (according to some writers) it is an open denial of justice. But in this last case the defeated litigant will be judge in his own behalf, and this exception should be held doubtful.

That arbitration is a fair and valuable method of settling what may be called business controversies between nations is beyond question. Under INTERNATIONAL LAW are given many instances of its successful employment, particularly in recent times. In 1883 Switzerland proposed a general arbitration agreement to the U. S. and other American republics. This principle was actually incorporated into several commercial treaties between Italy and other powers. A general treaty of arbitration was framed also between the U. S. of Colombia and the republic of Honduras. Of sixteen cases of arbitration between Great Britain and other

states prior to 1880 seven were in the last decade. But when we ask whether some general international court of arbitration may not be established to settle *all* international disputes, the answer is not a simple one. The advocates of some such substitute for war have been many. They urge the immense evil of war, its economic waste, its destruction of productive human lives, its suffering, cruelty, barbarity. They point to the many and constantly increasing instances of happy resort to arbitration by differing powers. They suggest tribunals or courts of arbitration made up in various ways, but all needing, to be effective, (1) a code of law recognized by the powers, (2) a body of arbitrators to apply this code, (3) the military power of Europe to enforce their decision. This discloses the weakness of the advocates of such a measure. Without the three essentials given, no general arbitration scheme could be made applicable to *all* controversies between states. An international court, like a court of civil or criminal law, must know the law and have the power of execution behind it. Now, as yet there exists no international code, nor is there any sign of one. Bluntschli and Field have codified the body of international law provisionally, but no single state has moved for its adoption. Nor can one easily conceive of a body of arbitrators who would be acceptable to all nations. The states of Europe, for instance, are not, have never been, can not be practically equal. Still more is this true with the republics of this continent. A powerful state will continue to be powerful through its influences with such a court, otherwise it could not afford to consent to the arrangement. To assume the contrary presupposes the millennium, when quarrels would never arise. And again the award of such a court to be effective must be capable of enforcement. Here is the crucial difficulty. The scheme if entered upon bids fair either to be impotent, from inability to execute its judgments, or, if such execution is attempted, might lead to a general embroilment, perhaps war. The truth is that there may come crises in the life of a nation when the national honor or the national life can not be jeopardized before a court. Great Britain could not surrender the control of the Suez Canal to Russia, the North could not have settled its struggle with the South, in accordance with the award of arbitrators. There are differences which words can not settle.

Setting aside all such questions as *could* not be submitted to arbitration, it is desirable and conceivable that all others concerning damages, limits, the rights of individuals, and so on, should be arbitrated. But even here it is wiser to submit each case to such a method of settlement separately, rather than strive for a general standing court, or consent to a general agreement to arbitrate, for a state ought not to be expected to go into such a scheme blindfold. In arbitrating a particular case, it knows the worst which may happen in consequence. It still retains its liberty of choice. There are other projects, approaching the same ideal from other standpoints, which perhaps promise better results. The growth of neutral trade, the growing importance of neutral states, limit the effects of war upon commerce. The spread of a humane system of warfare lessens its hardships. All minor quarrels between states to-day are settled without recourse to war. We should look to the changed spirit of our age, rather than to a mechanical device, for the maintenance of that dream of all ages—perpetual peace.

THEODORE S. WOOLSEY.

Arbois, aăr'-bwăă': a town of France; department of Jura; about 25 miles S. W. of Besançon (see map of France, ref. 5-H). It is celebrated for its wine, and has manufactures of paper and earthenware. Here are some Roman antiquities. Pop. about 4,900.

Arbois de Jubainville, MARIE HENRI, d' (däär-bwăă' de-zhü'-bän-veel'): French palæographer and Celtist; b. at Nancy, Dec. 5, 1827; became professor in the Collège de France, 1882. He has published much upon the early history of France, the origins of the French language, and the literary history of the Celtic race. Among his works are: *Histoire des ducs et des comtes de Champagne* (7 vols., 1859-69); *La Déclinaison latine en Gaule à l'époque mérovingienne* (1872); *Études grammaticales sur les langues celtiques* (1881); *Les Celtes et les langues celtiques* (1882); *Introduction à l'étude de la littérature celtique* (1883); *Essai d'un catalogue de la littérature épique de l'Irlande* (1883); *Le Cycle mythologique irlandais et la mythologie grecque* (1884); *Recherches sur l'origine de la propriété foncière et des noms de lieux habités en France* (1890); *Les noms gaulois chez César et Hirtius* (1891).

A. R. MARSH.

Arbole'da, JULIO: South American statesman, soldier, orator, and poet; b. in New Granada, June 9, 1817. Educated in England and on the Continent, he carried home with him a wide knowledge of English, French, and Italian, as well as of Spanish literature. In 1839 he was editing the journal *El Independiente* when the revolution led by José M. Obando broke out. During this and the many subsequent upheavals in New Granada, Arbole'da took always the line of liberal conservatism, opposing both ultra-socialistic and anarchistic doctrines, then very prevalent among his countrymen. In his journal, *El Misoforo*, founded in 1850, he advocated law, order, and the pursuit of legitimate prosperity, but without much success. He was several years a member of the legislature of New Granada, and more than once refused the vice-presidency of the republic. As a poet he is well known in Spanish America for a small number of poems full of passionate love of liberty and justice. Among these are *Al Congreso Granadino*, *Estoy en la Cárcel*, and an unfinished epic entitled *Gonzalo de Oyón*.

A. R. MARSH.

Arbor Day: a day set apart in most of the States and Territories of the U. S. for the voluntary planting of trees by the people. The object is to encourage the planting of trees, and to stimulate public interest in forestry. The importance of the day has been greatly increased by interesting the children of the public schools in its observance. The day is made a school holiday, and special and often elaborate programmes of exercises are carried out. Arbor day was inaugurated by the Nebraska State Board of Agriculture, which in 1874 recommended that the second Wednesday in April of each year be dedicated to the work of planting trees. The following States and Territories have since then established an annual Arbor day: Alabama, California, Colorado, Connecticut, Florida, Georgia, Idaho, Illinois, Indiana, Iowa, Kansas, Kentucky, Maine, Maryland, Massachusetts, Michigan, Minnesota, Montana, Missouri, Nebraska, Nevada, New Hampshire, New Jersey, New Mexico, New York, North Dakota, Ohio, Oregon, Pennsylvania, Rhode Island, South Dakota, Tennessee, Texas, Vermont, West Virginia, Wisconsin, and Wyoming. See LEGAL HOLIDAYS.

C. K. ADAMS.

Arboriculture [from Lat. *ar'bor*, tree + *cullu'ra*, cultivation]: the art and science of growing trees. See FORESTRY, NURSERY, and discussions of the various fruit-trees under their proper heads.

Ar'bor Vi'tæ (Lat., tree of life): the thick mass of white substance in either hemisphere of the cerebellum. This mass, on section, presents a tree-like appearance.

Arbor Vitæ: a plant of the genus *Thuja*, and family *Conifera*. *Thuja* consists of evergreen trees or shrubs, with compressed or flattened branchlets, and small, scale-like, and imbricated leaves. The *Thuja occidentalis* is a native of the U. S., and is often planted as an ornamental tree in the parks and pleasure-grounds of America and Europe. It is one of the trees known as white cedar. The Chinese arbor vitæ (*Thuja orientalis*), a native of China, has larger cones and more upright branches than the preceding. It is cultivated in Europe and the U. S. as an ornamental tree, and produces a resin which has been supposed to possess medicinal virtues. The genus comprises several other species.

Ar'broath, Ab'erbroth'wick, or Ab'erbroth'ock: a seaport-town of Scotland; in Forfarshire; at the mouth of a small stream called the Brothock; 16 miles N. E. of Dundee, with which it is connected by railway (see map of Scotland, ref. 10-J). It has a public library, and manufactures of coarse linens, canvas, leather, etc. About 100 vessels (tonnage 13,896) belong to this port. Here are picturesque ruins of a richly endowed abbey, founded by William the Lion in 1178. Robert Bruce and the Scottish nobles met in this abbey in 1320 to organize a resistance to Edward II. Pop. (1901) 22,372.

Arbuthnot, JOHN, M. D., F. R. S.: author and physician; b. at Arbuthnot, near Montrose, Scotland, in 1667. He studied at Aberdeen, where he graduated, and settled in London. His first work was an *Examination of Dr. Woodward's Account of the Deluge* (1697). His reputation was increased by his *Tables of the Greek, Roman, and Jewish Measures, Weights, and Coins* (1705). He was appointed physician to the queen in 1705, and obtained an extensive practice. He was an intimate associate of Pope, Swift, and Lord Bolingbroke. In 1712 he published a humorous political

allegory entitled a *History of John Bull*, in which the great powers then involved in war were personated by John Bull the clothier, Nick Frog the linen-draper, and Louis Baboon (Louis XIV.). This work displays a great talent for satire. He produced another humorous and ironical work, called *The First Book of the Memoirs of Martinus Scriblerus*. This was part of an unfinished work which Pope, Swift, and Arbuthnot projected in partnership, and which was designed to be a satire against pedantry and the abuse of learning. In 1723 he was chosen second censor of the Royal College of Physicians, and in 1727 was made an elect of the college. D. in London, Feb. 27, 1735.

Arbutin: a principle found in the leaves of the red bearberry (*Arctostaphylos uva ursi*).

Arbutus: a genus of plants of the family *Ericaceae*, mostly natives of America and Southern Europe. They are evergreen shrubs, bearing a fleshy fruit which has five cells and many seeds. The arbutus mentioned by Vergil was the *Arbutus unedo* or strawberry-tree, which bears bright red and yellow berries, with beautiful foliage, and is cultivated as an ornamental evergreen. The fruit has narcotic properties, and is used for making wine in Corsica. Another species, the *Arbutus andrachne*, a native of the Levant, is admired as an ornamental plant, and bears an esculent fruit. The *madroña* of California is a species of this genus; but the *manzanita*, and also the bearberry (or *Uva ursi*, a trailing shrub of the northern hemisphere, the leaves used as an astringent tonic in medicine) belong to the related genus *Arctostaphylos*, although formerly included in *Arbutus*. "Trailing arbutus" is *EPIGÆA REPENS* (*q. v.*).

Revised by CHARLES E. BESSEY.

Arc [from Lat. *arcus*, a bow]: a portion of a line, the straight line being excluded. The length of an arc, when the nature of the curve is given, may be found by the integral calculus. (See RECTIFICATION.) The length of an arc is always greater than that of the straight line joining its extremities, which is called the chord of the arc. The word is most commonly used in the case of the circle; and the principal properties of circular arcs are given in Euclid's works. The length of a circular arc divided by the entire length of the perimeter is equal to the angle subtended at the center, expressed in degrees, minutes, etc., and divided by 360.

Arca: a genus of bivalve mollusks, the type of a family called *Arcadeæ*. The hinge is straight, and is coextensive with the whole breadth of the shell, the breadth being greater than the length. Numerous species are known, some of them fossil.

Arca'dia (in Gr. Ἀρκάδια): a celebrated state of ancient Greece; the most central part of the Peloponnesus (now called the Morea). It was bounded N. by Achaia, E. by Argolis, S. by Laconia and Messenia, and W. by Elis. The area was about 1,600 sq. miles (see map of Greece, ref. 17-J). It was inclosed on nearly all sides by mountains, and a large part of it was occupied by fertile valleys and verdant mountain-ridges. The principal river was the Alpheus. It was also watered by the Helisson, the Ladon, the Erymanthus, and several smaller streams, which cut their way in numerous instances by underground channels through the limestone rocks. There were a number of lakes in the E. The Arcadians were a simple, pastoral people, inferior to most of the other Greeks in genius and culture. This inferiority may be ascribed to their isolated position, which deprived them of the influence of the sea and of the advantages of commerce. The chief towns of Arcadia were Mantinea, Tegea, Orchomenos, and Megalopolis. The Arcadians resembled the Swiss in their love of freedom and money, and in their tendency to enlist as mercenaries in foreign armies. Among the Ten Thousand whose famous retreat Xenophon described, more than two thousand were Arcadians. This country was a favorite of ancient pastoral poets, who praise the peaceful and happy life of the Arcadian shepherds. At present, Arcadia is one of the sixteen nomarchies of the kingdom of Greece. Area, 2,020 sq. miles. Pop. (1889) 148,285.

Arca'dius (in Gr. Ἀρκάδιος): Emperor of the East; eldest son of Theodosius the Great; b. in Spain in 377. In 395 Theodosius died, after he had divided his empire between Arcadius and Honorius, the latter of whom received the western part. The eastern empire, of which Byzantium was the capital, included Thrace, Asia Minor, and Syria, and extended from the Adriatic to the Tigris. During the

minority of Arcadius, Rufinus and Eutopius successively acted as regents of the empire. The Empress Eudoxia acquired the control over Arcadius, who was a feeble and indolent prince. He died May 1, 408, and was succeeded by his son, Theodosius II.

Arca'ni Disciplina (i. e. instruction in the mystery): a term for the first time used by the Protestant theologian Dalaus in 1666 for the secrecy observed in the early Church with respect to certain doctrines; as, for example, those of baptism, the Eucharist, and some others. These doctrines were withheld from candidates until after they had been received into full communion with the Church, and they were only alluded to in the public preaching by some such phrase as "the initiated knows." After the sermon the uninitiated were shown out by the deacons, and the doors closed. Then the Eucharist was celebrated. Thus the Christians imitated the heathen mysteries. The practice is not primitive. It first comes up in the middle of the second century and disappeared in the sixth century, being, in fact, synchronous throughout with the institution of the catechumenate. It is defensible upon the two grounds—(1) that truth should be given no faster than it can be assimilated. So it is proper that a heathen should gradually be instructed in Christianity. (2) The danger of irreverent speaking of the deeper truths of Christianity if they were discussed in mixed assemblies. But the practice is not to be taken as proof that there was any body of secret teaching which was primitive but publicly revealed only in a later period. The secret instruction related to those truths which are taught in the New Testament. The only novelty was the way in which they were defended. Soon after the introduction of the term, the subject gave rise to a very animated controversy between Roman Catholic and Protestant theologians, which has continued ever since. The former used it to account for the silence of the early Church writers as to certain doctrines and practices of their Church. Protestant writers generally regard it either as a natural outgrowth of the oppressed condition in which the Church found itself at that time, or a degeneration of the simple forms of primitive Christianity in the interest of the hierarchy. The best modern treatises on the subject are: On the Roman Catholic side, J. A. Toklot, *De arcani disciplina, quae antiqua in ecclesia fuit in usu* (Cologne, 1836); Adalbert Weiss, *Die altkirchliche Pädagogik dargestellt in Katechumenat und Katechese des ersten sechs Jahrhunderte* (Freiburg, 1869); on the Protestant side, Th. Harnack, *Der christliche Gemeindegottesdienst* (Erlangen, 1854); G. v. Zezschwitz, *System der Katechetik* (Leipzig, 1863); Huyskens, *Zur Frage über die sogenannte Arcandisciplin* (Münster, 1891). For a comprehensive study, see Bonwetsch's art. *Wesen, Entstehung und Fortgang der Arcandisciplin* in *Zeitschrift für historische Theologie* (1873, ii. 203, sqq).

Revised by S. M. JACKSON.

Arca'num (plu. *Arca'na*): a secret, a mystery; sometimes applied to a medicine the composition of which is kept a secret. This term was much used by the alchemists, whose object was to discover the grand arcanum, the philosopher's stone.

Arcanum: village; Darke co., Ohio (for location of county, see map of Ohio, ref. 5-C); on the Peoria Division of the "Big Four" and the D. and U. R. R.; 26 miles from Dayton. It has good graded schools, fine city buildings, an opera-house, and two banks. The village is surrounded by a thriving agricultural country. Chief industry, tobacco. Pop. (1880) 778; (1890) 1,134; (1900) 1,225.

Ar'ce, MANUEL JOSÉ: a general who in 1824 was chosen president of the republic of Central America for four years. He favored the clerical party, at whose instigation he arrested Barrundia, governor of Guatemala, in Sept., 1826. This act provoked a popular revolt and a civil war, in which Arce was defeated in 1827. He was expelled in 1829.

Arcesila'us (Ἀρκεσίλαος): Greek philosopher; b. at Pitane, in Æolis, about 315 B. C.; founder of the New (or, as it is sometimes called, the Middle) Academy. He was a pupil of Theophrastus, and was an admirer of Plato, but taught a modified form of Platonic philosophy. He was eloquent, witty, and ingenious in argument, revived the Socratic method of teaching, and recommended an abstinence from dogmatism. It appears that he left no written statement of his doctrines, which are known to us only through the medium of his pupils and successors. Among the sayings ascribed to him is that "he knew nothing, not even his own ignorance."

D. in Athens in 241 B. C. See Erehmann's *History of Philosophy*.

Arch [O. Fr. *arche* < Lat. *arca*, chest; it has, however, assumed the meaning of Lat. *arcus*, a bow]: a curved structure of stone or brick intended to cover the space between two piers or two columns, and to support at the same time a superincumbent weight. The wedge-shaped pieces of which the arch is composed are called *voussoirs*. The middle stone of the arch is called the *keystone*, and the lowest stone on either side is the *springer*. The highest part is the *crown*, the sides are termed *haunches*, the inner curve is the *intrados*, and the exterior or upper curve is the *extrados*; while the base which supports the lowest *voussoir* or

springer on each side is the *impost*. The impost-stones are a part of the *abutments*, which support the structure at each end, and also resist its horizontal thrust. The arch probably originated in Egypt. The great pyramid of Cheops (2170 B. C.) has a false room above the ceiling of the sarcophagus-chamber, whose roof is formed of large inclined stones acting like rafters. In pyramids built several hundred years later similar roofs have been found having two inclined stones, and one placed horizontally between them, thus forming a rude arch of three *voussoirs*. A tomb of the date 1550 B. C. contains a brick arch of 11 feet span, formed of four courses, and having a total thickness of nearly 4 feet. The arch was also known to the Ethiopians, the Assyrians, the Greeks, and the Etruscans, though no one of these peoples made any extensive use of it, since the lintel system met all their wants. The Grecians did not allow curved lines in any important visible parts of their structures; hence their magnificent buildings retarded rather than encouraged the development of arches.

The Romans used the arch extensively, not only in buildings, but also for drains, aqueducts, and bridges. A great sewer called Cloaca Maxima, still seen in Rome, is believed to be one of the oldest of the Roman arches, dating from about 500 B. C. As shown in the cut, it consists of two arches, one within the other, the inner one being 13 feet in diameter. These were built of large blocks of tufa about 5½

Mouth of Cloaca Maxima at Rome.

feet long and 3 feet thick, laid without cement. The Roman arches were of the most simple form, usually semicircular or of a segment of a circle.

Gothic or pointed arches, introduced during the ninth century, were quickly developed in numerous forms, such as the equilateral arch, the ogee, and the foiled arches, so ex-

tensively used for the windows of churches. For bridges these forms are not well adapted, the sections employed being arcs of circles described from three or four different centers, or sometimes ellipses.

Cabin John arch.

The use of the arch for bridges originated with the Romans, and many monuments of their skill are still to be seen in different parts of the ancient Roman empire. Near Narni, in Italy, four stone arches were built in the time of Augustus, one of which now remains; the spans of these were 75, 114, 135, and 142 feet. Trajan's famous bridge over the Danube (A. D. 105) was 4,770 feet in length, and consisted of 22 wooden arches, some of which were 180 feet in span. During the Middle Ages a number of stone bridges were erected. Perronet mentions one built at Verona in 1354, consisting of 3 arches, one being nearly 160 feet in span, and another, erected in 1454, of 184 feet span and 71 feet rise.

Only 2 stone arches exceeding 184 feet in span now exist. One of these, built in 1820 over the river Dee at Chester, in England, has a span of 200 feet and a rise of 42 feet. The other, constructed by Gen. M. C. Meigs in 1861 to carry the Washington aqueduct over the Cabin John creek, has a span of 220 feet, a rise of 57 feet, and a width of 20 feet; the arch stones are 4 feet thick at the crown, and 6 feet at the springing lines. The keystone was laid in cold weather, so that in summer the crown rises. One of the most beautiful stone structures in the U. S. is High bridge, built in 1840 by J. B. Jervis, to carry the Croton aqueduct over Harlem river; this has 8 arches of 80 feet span, and 7 of 50 feet span.

The largest stone arch ever constructed was built in the latter part of the fourteenth century over the river Adda, in Northern Italy, and was 251 feet in span. This arch is not standing, but it is said that the *voussoirs* were of granite and in two courses, the inner one 3 ft. 3 in. thick and the outer one 9 inches thick.

When the face of an arch is oblique to the direction of its axis it is called a skew arch. Owing to the necessity of making the joints of stone perpendicular to the directions of the pressures that come upon them, many radial joints, which in an ordinary structure are plane surfaces, become warped surfaces in the skew arch, and the *voussoirs* are laid in spiral instead of horizontal courses. Skew arches are rarely constructed, and none of large span have been built. Falls bridge, over the Schuylkill river near Philadelphia, completed in 1856, had 6 arches of 83 feet span and 24 feet rise, each arch consisting of 8 square-built ribs of 3 by 3 feet in section, and each rib being placed 18 inches back of its fellow, thus making a skew of 12 feet in a width of 24 feet. Skew arches without ribs are, however, those usually built. One of the finest in the U. S. is the structure at Reading, Pa., which consists of a central span of 40 feet over a roadway, and two side spans of much less width over the sidewalks.

No complete theory of the stone arch exists, but several theories, more or less approximate, enable computations to be made with sufficient accuracy. For a linear arch, that is an imaginary arch ring without thickness, the formulas given by Rankine furnish the means of fully discussing parabolic and circular forms under certain conditions of load-

ing. The *horizontal thrust* of an arch is that force, acting at the crown in a horizontal direction, which would hold one half of the structure in equilibrium were the other half removed. As the point where this is applied is generally indeterminate, the thrust itself can not be precisely computed for a real voussoir arch. The tables of Woodbury (*Treatise on the Well-proportioned Arch*, New York, 1858), are useful for segmental and circular forms. Among the best short theoretical discussions are *Vousoir Arches*, by William Cain (New York, 1879), and *Skew Arches*, by E. W. Hyde (New York, 1876).

The word ARCH is also applied to curved structures of timber, iron, or steel, used for roofs or bridges. The distinctive feature of an arch, as opposed to a girder or truss, is that it exerts horizontal pressures upon the abutments or points of support. Arched roofs are often provided with

river at Rochester, N. Y., designed by L. L. Buck, and completed in 1890, is formed by a three-hinged arch span of 428 feet span and two approaches of 103 and 93 feet; the roadway is 212 feet above the bed of the river.

The Washington bridge, completed in 1890, over the Harlem river at 181st Street, New York, has two of its spans composed of two-hinged arches of 508 feet span, which have solid web-plates connecting the ribs instead of diagonal bracing; the radial depth of these arches is 13 feet, and the hinge-pin at each end is 18 inches in diameter. The chief engineer of this bridge, William R. Hutton, has written a book describing its construction in detail.

The great bridge over the Mississippi river at St. Louis has three main spans of 497, 515, and 497 feet, respectively, the central one being the largest arch in the U. S. In each of these spans there are four arches composed of steel tubes

9 inches in exterior diameter, and connected by lateral bracing. Each section of tube between the joints is straight, the joints being formed by wedge-like plates which give the necessary curvature. In the construction of this bridge many difficulties were encountered and overcome, particularly in the founda-

tions. The chief engineer was James B. Eads. A history of the construction of this bridge was written by C. M. Woodward, and published at St. Louis in 1889. The cut shows only about one-third of one of the steel spans. The arch is a structure without hinges, and its ends are rigidly fixed to the abutments.

The theory of the equilibrium of braced arches with three hinges is quite simple, since the horizontal thrust must pass through the center hinge, and thus can be readily determined. The arch with two hinges and the arch with fixed ends require the elastic properties of the material to be known before the reactions and stresses can be found, and the computations are often quite intricate. The most complete development of the theory of the subject is given in Weyrauch's *Theorie der elastigen Bogenträger* (Munich, 1879). The methods of Winckler are also good, and these may be seen in Du Bois's *Elements of Graphic Statics* (New York, 1875).

The arch of longest span yet constructed is on the Garabit viaduct in Central France. It is a metal structure of

Rock creek arch, Washington, D. C.

horizontal tie-rods in order to prevent the outward motion of the walls which support them. Cast-iron arches were first built in England—one of 100 feet span and 45 feet rise in 1779, one of 130 feet span and 27 feet rise in 1795, and a bolder design of 240 feet span and 30 feet rise in 1796. This last, known as the Sunderland bridge, is probably the longest cast-iron arch ever built, it being equaled but not exceeded by the Southwark bridge, erected in 1818. A unique construction is the Rock creek bridge in Washington, D. C., whose arches are formed of two cast-iron pipes, through which the water from the Potomac aqueduct enters the city; these arches are 200 feet in span and 20 feet rise, each being formed of sections of water-pipe 4 feet in diameter and $1\frac{1}{2}$ inches thick. The Rock creek bridge was built in 1861, and since that date the only cast-iron arch worthy of mention is that over the Schuylkill river at Chestnut Street in Philadelphia, which was completed in 1866, consisting of two spans, each of 150 feet.

Wrought-iron and steel arches formed of parallel ribs, braced together with diagonal members, and hence often called "braced arches," have been built both in Europe and America since 1850, some of which rank among the boldest bridge structures. In order to eliminate stresses due to temperature, hinges or pins are sometimes used to connect them with the abutments, in which case they are called two-hinged arches. A third pin added at the crown renders the stresses more determinate still, and these receive the name of three-hinged arches. If no hinges exist the arch is very stiff, but extra material must be used to resist the stresses due to temperature.

A three-hinged arch of 64 feet span and 12 feet rise carries railway tracks across Thirtieth Street in Philadelphia, and one of about the same span forms a highway bridge over Mill river in New Haven, Conn. The highway viaduct over the Genesee

Approach and steel arch, St. Louis bridge.

541 feet span and 169 feet rise, erected by M. Eiffel in 1885. Next to it ranks the Douro arch, on the Oporto viaduct in Portugal, which is 525 feet in span and 123 feet in rise. A

vague statement concerning a stone arch of 600 feet span, built long ago on the line of the Chinese wall, found in several books, can not be traced to any reliable authority.

A stone arch is always built upon a timber framework (see CENTERING). A metal arch is, however, sometimes built out from the abutments, panel by panel, being sustained by suspension guys and cables, until the two arms meet at the center of the span. See ARCHITECTURE, BRIDGES, ROOF, TUNNELS, FOUNDATION.

MANSFIELD MERRIMAN.

Arch, Triumphal [in Lat. *arcus triumphalis*; in Fr. *arc de triomphe* or *arc triomphal*]: a monumental structure erected in honor of a victorious general or in commemoration of some important event or victory. It was usually placed at the entrance of a city or over a grand avenue. The ancient Romans built numerous triumphal arches at Rome and elsewhere. Scipio Africanus erected one on the Capitoline Hill, about 190 B. C. Magnificent structures of this class were raised by Augustus at Rimini and Ancona, the latter of which stands at the head of a great pier stretching out into the sea; it is in perfect preservation. Several structures of this sort have been erected in the U. S. as gateways to parks and cemeteries or as memorial structures. In 1891-92 a marble arch was erected at the foot of Fifth Avenue, New York city, in commemoration of the hundredth anniversary of Washington's inauguration, which had been celebrated in 1888, when a similar structure in wood had been put up for the temporary purpose. Three large triumphal arches at Rome are still extant—namely, the Arch of Titus, which commemorates the conquest of Judea; the Arch of Septimius Severus; and the Arch of Constantine, a beautiful and imposing structure adorned with bas-reliefs. There are also several smaller ones. The most magnificent of modern triumphal arches are those of Paris, and the finest among these is the Arc de l'Étoile, erected by Napoleon I. at the Barrière de Neuilly. It has three arches, the central one of which is 95 feet high. The whole structure, which is equal in grandeur and splendor to the ancient Roman arches, is about 160 feet high and 150 feet in length.

Arch, JOSEPH: founder and first president of the National Agricultural Laborers' Union of England; b. at Barford, Warwickshire, England, Nov. 10, 1826. He was brought up as a farm-laborer, educated himself as best he could, and became a Primitive Methodist preacher. When the union movement arose among the agricultural laborers he became its recognized leader. In 1872 he founded the National Agricultural Laborers' Union, of which he became president. In 1873 he visited Canada to inquire into the labor and immigration questions. In 1885 he was elected to Parliament for Northwest Norfolk, but was defeated for re-election after the dissolution of 1886; was re-elected in 1892, and again in 1895. He has been the recognized leader of the movement for the elevation of the rural laborers. See Heath's *English Peasantry* (1874).

C. H. THURBER.

Archæology [Gr. *ἀρχαιολογία*; *ἀρχαῖος*, ancient + *λέγειν*, discuss]: literally the science of antiquities. Dionysius of Halicarnassus gave the title of *Roman Archæology* to a work of general history, and the Jewish history of Josephus was likewise entitled "*Ἰουδαϊκὴ Ἀρχαιολογία*." The term in its widest sense includes the knowledge of origins, language, religion, laws, institutions, literature, science, arts, manners, customs—everything, in fact, that can be learned of the ancient life and being of mankind. Archæology may thus be made to comprehend a part of many branches of knowledge which are recognized as distinct or independent pursuits; but in its narrower and perhaps more popular significance it is understood to have reference to the *materials* from which a knowledge of the ancient condition of a country is to be attained. These materials are written, monumental, and traditional. Written archæology includes both the science of ancient writings and the knowledge of printed books. The second, monumental archæology, admits of almost endless subdivisions, according to the character of the remains to be studied, which may be works of art, such as buildings, sculptures, paintings, inscriptions, coins, armorial bearings, furniture, enamels, glass, porcelain, etc.; works of engineering, such as roads, canals, aqueducts, mines, etc.; articles of dress, armor, or personal ornament; tools, weapons, utensils, habitations, etc.; forms of sepulture; vestiges of man and animals, such as bones, etc. The third, or traditional archæology, may be said to include the oral literature of a people, their dialects, legends, proverbs, ballads, as well as their sports, customs, and superstitions.

In regard to the application of the words archæology and antiquities, it may be remarked that the latter has reference properly to the objects studied, the former to the study itself. And though archæology in its more limited signification refers to the materials studied, those materials are considered not as individual specimens, but in their totality. Thus while we might say a "collection of antiquities" (i. e. of antique objects), we could not so properly say "a collection of archæology," though we might say "an archæological collection." The study of archæology was long almost exclusively confined to the antiquities of the Greeks and Romans, but about the middle of the sixteenth century attention was turned to the antiquities of other ancient nations and of the Middle Ages. Since the discovery of the Rosetta Stone, which gave a key to its hieroglyphics, the archæology of Egypt has made astonishing progress; while the discoveries of Layard, Rawlinson, and others have already far advanced that of Assyria. Within the last few years the archæology of India and that of China have been successfully prosecuted. The rude and scanty remains of the aboriginal inhabitants of North America have occupied the attention of men of letters in this country; while the more stately and instructive monuments of Central and South America have fully rewarded the investigations of antiquaries. Prehistoric archæology, or the study of the relics of man as he existed before the dawn of history, is of late attracting much attention. The Royal Society of Antiquaries at Copenhagen has given this branch of the subject especial attention, Northern Europe being peculiarly rich in remains of the prehistoric ages.

In Great Britain, too, prehistoric remains of the most ancient origin have been abundantly found, and there can be but little doubt that many ancient relics which have been regarded as Druidical are in reality ante-Celtic. But in France and Belgium, especially, have the labors of Boucher de Perthes, Lartet, De Vibraye, and others been rewarded by the discovery of very ancient human relics. In Switzerland (see LAKE-DWELLINGS), in Italy, Greece, Turkey, etc., the study of these profoundly interesting prehistoric remains has aroused much enthusiasm. But the work is as yet in its early infancy. The cyclopean walls of the southern peninsulas of Europe are now generally assigned to the prehistoric ages. The fruits of the discoveries near the supposed site of ancient Troy are by many referred to prehistoric times. The later heroic age of Greece has left many undoubted relics, the most remarkable of which are associated with the discoveries of Dr. Schliemann (see MYCENÆ). The discovery of Phrygian ruins of similar character is interesting, although it does not appear that the civilization of Mycenæ in Greece can be referred to Phrygian origins. The deeply interesting discoveries in Cyprus (see CYPRUS and CESNOLA, DI) have shown us unquestionably the works of historic times. The discovery in 1873 of the key to the reading of the strange inscriptions in the syllabic alphabet of Cyprus has thus far given no evidence of their being of very remote origin, and the inscriptions themselves are in Greek of a very marked dialect.

While prehistoric archæology opens to us a world of mystery and wonder, the archæology of later times serves to dispel mysteries; the resulting effect of the two being to remove the mysterious age farther backward into the past. Much that has hitherto been unexplained is receiving light from the labors of archæologists in the valley of the Euphrates-Tigris, as well as in that of the Nile. Biblical archæology is greatly forwarded by the labors of the English and Americans in the Holy Land. The Asiatic societies find abundant material for examination in Southeastern India, a new and almost untrodden field. Oslander, Fresnel, and other Semitic scholars would appear to have solved the riddle of the Himyaritic inscriptions in Arabia; and the wonders of the semi-civilizations of America before the time of Columbus have been much diminished by the simple and yet admirable generalizations which have been of late brought forward with regard to them. But an interest hardly less intense than attaches to the above-mentioned works is, and long has been, felt in the antiquities of the Middle Ages, both ecclesiastical and social. The civilizations of ancient Rome and Greece are quite clearly marked off from ours, while the Christian civilization that sprang up on the ruins of the old is our own civilization, and must possess for ever a deep interest to the student of modern humanity. The French and Italians have given special attention to this department.

Among other recent archæological investigations may be

mentioned the labors of Mariette Bey, Lepsius, Brugsch Bey, Maspero, and Flinders Petrie in Egypt, extending from the delta of the Nile up to the Sudan; the excavations at Carthage and Cyrene (Greek Africa); at Ephesus, Pergamon, and Assos in Asia Minor; on the island of Delos, on the Acropolis of Athens (see ATHENS); at Eleusis, Epidaurus, Olympia, and Delphi in Greece; and chiefly at Rome and Pompeii, and among the Etruscan cemeteries, in Italy. The monumental archæology of Brazil, Ecuador, Peru, and the rest of South America has been studied with important results.

The quite modern science of "folk-lore," which examines and compares the traditions, legends, superstitions, and immemorial customs of existing peoples, links itself inseparably with some departments of archæology; and it is from the study of long-overlooked traces of the old Aryan and Sanskrit traditions, legends, superstitions, and customs that they receive much of the light which has lately been shed upon them—a light which shows very plainly that a common, if very remote, kinship unites all the Indo-European peoples. Such considerations show that the true archæologist is no mere antiquarian curiosity hunter, but a student of matters which have a very wide and deep interest to nearly every thoughtful mind.

The foundership of archæological research has lately been claimed in behalf of Rienzi, the Roman tribune, who was an enthusiastic antiquarian (1313–54). But classical archæology appears to have worn the aspect of a collector's hobby until a vitalizing spirit was infused into the science of the concrete remains of antiquity by Winckelmann. The interpretation and illustration of ancient art, as one of the principal fields of mental activity and production, has since been the leading idea of archæologists, more particularly in France and Germany. These countries were the first to establish schools of archæology in Rome and Athens; their example has since been followed in Athens by the U. S. and Great Britain, and by the Italians themselves in Italy. There is also a French school of archæology on Egyptian soil, while the science is systematically taught at most of the continental and some of the British and American universities. The proper correlation of the fragmentary literary testimony of antiquity is perhaps the most interesting and difficult problem with which archæologists are constantly occupied.

The science of archæology has been greatly promoted by the publication of chronicles, records, catalogues, etc., by the formation of clubs and societies, and by the establishment of museums for the collection and classification of antiquities. Among the societies formed for this purpose may be mentioned the Society of Antiquaries of London, which was founded in 1572, but was not incorporated by royal charter until 1751; the Society of Antiquaries of Scotland, chartered in 1780; and the Royal Irish Academy, for promoting "the study of science, polite literature, and antiquities," which was chartered in 1786. The last two have good museums of national antiquities. Among the most celebrated antiquarian collections are those of the British Museum in London, which contains, besides a great collection of early manuscripts, galleries of Assyrian, Egyptian, Etruscan, Greek, Roman, British, and mediæval antiquities; the museums of the Louvre and the Hôtel de Cluny in Paris, which contain an unrivaled collection of mediæval in addition to more ancient antiquities; the collections at Florence and Rome, and the Royal Museum at Naples, which contains most of the objects recovered during the last one hundred years from the ruins of Herculaneum and Pompeii. Among the best works on classic antiquity are those of Montfaucon, particularly his *Antiquité Expliquée* (10 vols., 1719), and Winckelmann's *Geschichte der Kunst des Alterthums* (1766), and his *Monumenti antichi inediti* (1766). On Egyptian archæology, see the works of Champollion and Bunsen. Among the recent works on archæology those by Westropp, *Handbook of Archæology* (1867); J. H. Parker's *Archæology of Rome* (vol. i., 1874); Newton, *Essays on Art and Archæology*; Waldstein, *Essays on the Art of Phidias* (1856); Lanciani, *Ancient Rome in the Light of Archæology* (1887); and J. H. Middleton's *Remains of Ancient Rome* (1892) deserve to be here mentioned. On prehistoric archæology see Lubbock, *Prehistoric Times* (2d ed. 1869); Baldwin, *Prehistoric Nations* (1869), and *Ancient America* (1872); C. C. Jones, *Antiquities of the Southern Indians* (1873); Foster, *Prehistoric Races of the United States* (1873); Nadaillac, *Prehistoric America*. Among the writers upon Scandinavian prehistoric remains

we may mention N. M. Petersen, Finn Magnusen, and Worsaae. The *Journal of Hellenic Studies* and the *American Journal of Archæology* are the best periodical repositories of archæological news and investigation published in English. Revised by ALFRED EMERSON.

Archæology, Biblical: the science which treats of those things which illustrate the public and private life of the people and places mentioned in the Bible. Our knowledge of these subjects is obtained from the ancient literature both of the Jews and Gentiles, and from the monumental and other remains of ancient nations, such as inscriptions, ruins, coins, etc. The principal literary sources of archæological knowledge of this kind are the Bible, Josephus, Philo, the rabbinical and Arabian writers, Herodotus, the writings of the Christian Fathers, the later classical authors, and a great number of modern works of travel and literary research. The monumental sources of knowledge include the interesting literary and other remains of ancient Egypt, the coins of the Phœnicians, of the Maccabees, and of the Syrians, the cuneiform inscriptions of Babylon, Assyria, and Persia, the Moabite Stone, the catacombs of Rome, and the remains of the ancient cities of Palestine and the neighboring countries.

Among the immense numbers of older treatises upon this subject we may mention J. D. Michaelis, *Commentary on the Laws of Moses* (1770, 2d ed. 1775; Eng. trans., London, 1814, 4 vols.); J. Jahn, *Biblical Archæology* (1796–1805, Eng. trans., Andover, 1823; 5th ed. 1849); J. L. Saalschütz, *Archæologie der Hebräer* (Königsberg, 1855–56, 2 vols.); Edward Robinson, *Biblical Researches* (Boston, 1841–56, 4 vols.). More recent works are Ewald's *Die Alterthümer des Volkes Israel* (3d ed. 1866; Eng. trans., London and Boston, 1876); Keil's *Handbuch* (2d ed. 1875); E. C. Bissell's *Biblical Antiquities* (Phila., 1888); the *Transactions and Proceedings* of numerous archæological societies; the Bible dictionaries of Smith, Kitto, Riehm, and Schaff, and the general religious encyclopædias of Herzog and Plitt, the Schaff-Herzog, the Wetzer and Welte (n. e. Kaulen), and McClintock and Strong. Revised by W. J. BEECHER.

Archæop'teryx [from Gr. ἀρχαῖος, ancient + πτέρυξ, bird]: a remarkable fossil bird found in the lithographic limestones (Jurassic) of Solenhofen, Bavaria. It is the oldest bird of which we have any record, and is in many points of structure intermediate between birds and reptiles. It had, however, undoubted feathers. As in some of the eretaceous birds, the jaws were furnished with teeth. The wing was very bird-like, but three fingers being present. These were, however, terminated with claws. One of the most striking features is the long, reptile-like tail, composed of many vertebrae, from which feathers diverge on either side. Two specimens are known, representing two species.

Archaic Art: art in its earliest stages, characterized by a striving after ideals as yet unrealized and only imperfectly discerned, with a resulting uncouthness and stiffness of expression which disappear as the ideals become more clearly defined, and experience and developing taste bring with them greater facility of expression and an improved technique. In this early and immature stage the arts are the objects of careful study on the part of archæologists and artists, not merely because of the light they throw upon the influences of, and the relations between, the older civilizations and the rising one, but also because of the simplicity, sincerity, and naïf charm of many of the works themselves.

Singularly enough, the oldest of all civilizations—that of Egypt—has left us practically no traces of its archaic stage, and but little has come down to us from the Euphrates-Tigris valley that can properly be called archaic. The art of Greece, on the other hand, and that of the neighboring Asiatic peoples have bequeathed to us an extraordinary number of vases, sculptures, rock-carvings, and architectural fragments belonging to the archaic periods of their several civilizations, while the arts of Cyprus and Etruria seem never to have emerged from the immaturity and uncouthness of archaism.

The archaic vases of Greece have little of the grace of the later more perfect ceramic art; the most ancient are adorned with concentric rings or circles in black, with zig-zags and ernde frets, and sometimes with rows of what appear like caricatures of beasts and human figures. The later archaic vases, belonging to the sixth century B. C., display more decorative skill; are adorned with pictorial compositions, elaborate honeysuckle ornaments of rather Asiatic character, and other decorations in black and white

upon the light yellow or nearly white clay of the vase itself. The archaic sculptures of Greece, starting from the *Xoana* or log-idols of prehistoric times, show a gradual and steady advance in anatomical knowledge, truth to nature, and action. The transition from archaism is marked by the disappearance of the "archaic smile" of the countenance, by the mastery of the expression of perfect and dignified repose, by the horizontal position and more truthful modeling of the eyes, and by the freedom and naturalness of the pose, especially of the feet and hands, with a corresponding freedom and boldness in the drapery.

In the later periods of Greek and Roman art the practice was introduced of imitating the archaic formalism of the earlier ages. These counterfeitings are easily detected by experts, and are called *archaistic*, to distinguish them from their genuine prototypes.

The nascent art of early Christian and mediæval times is not usually called archaic, nor is the term applied to the productions of savage and barbarous or primitive races or tribes, elaborate and beautiful as these often are. The element of a *developing* civilization is usually understood to underlie the application of this term. A. D. F. HAMLIN.

Archangel, or **Archangelsk'** (referring to *Archangel Michael*): a government or province of European Russia; bounded N. by the Arctic Ocean, E. by the Ural Mountains, S. by Wologda and Olonetz, and W. by Finland. It comprises Russian Lapland, and is divided into two parts by the White Sea. The surface is flat and the soil mostly barren, but produces valuable timber. The climate is very severe. Area, 331,640 sq. miles. Pop. (1897) 347,560.

Archangel: a seaport of Russia; capital of the province of that name; on the Dwina, about 20 miles from its entrance into the White Sea; lat. 64° 32' N., lon. 40° 33' E. (see map of Russia, ref. 4-E). The houses are mostly of wood. It has about twelve churches and an ecclesiastical college. The harbor is closed by ice except about three months, from July to September, during which period it is visited by many foreign vessels. The chief articles of export are fish, furs, lumber, tallow, flax, linseed, tar, iron, and bristles. This place, which was founded in 1584, was for a long time the only seaport of Russia. Pop. 19,702.

Archbish'op [from Lat. *archiepiscopus*; Gr. ἀρχι-, chief + ἐπίσκοπος, overseer. See BISHOP]: the chief bishop of an ecclesiastical province containing several dioceses, who has also a diocese of his own. The title came into use in the fourth century, and is said to have been first employed by Athanasius. It was hardly known in the Latin Church before the seventh century after Christ. The Church of England has two archbishops—one of Canterbury, who is Primate of all England and ranks next to the princes of the blood-royal; and the other of York, who is Primate of all England and ranks next to his brother of Canterbury.

Arch'dale, JOHN: an Englishman and member of the Society of Friends; became Governor of Carolina in 1695. He introduced the cultivation of rice, and in several respects promoted the prosperity of the colony. In 1707 he published a *Description of the Province of Carolina*.

Archdea'con [from Lat. *archidiaconus*, from Gr. ἀρχιδιάκονος; ἀρχι-, chief + διάκονος. See DEACON]: an ecclesiastic whose jurisdiction is immediately subordinate to that of a bishop. An archdeacon was originally an assistant of the bishop, and an overseer of the deacons and younger clergy. The archdeacon is called the *oculus Episcopi*, "the eye of the bishop." The importance and authority of the archdeacons gradually increased, although neither the name nor the office is mentioned in the Apostolical Constitutions. The office practically became distinct from that of the bishops, so that in the twelfth century they were recognized as influential as prelates. Since that time the power and influence of archdeacons have been much reduced. The Church of England has seventy-one archdeacons, who have a limited vice-episcopal territorial jurisdiction. In the Episcopal Church in the U. S., archdeacons have been introduced in a number of the dioceses, e. g. New York, Connecticut, Maryland, Chicago, Iowa, and elsewhere. These archdeacons are generally charged with the supervision of the missionary work, though in some cases they are also connected with the cathedral. See DEACON.

Archduke' and **Archduch'ess**: titles assumed by all the sons and daughters of the Emperor of Austria, and inherited by their descendants through the male line. The title of archduke was first taken by the dukes of Austria in the

fourteenth century, or earlier, but their claim to that mark of precedence over the other dukes of the German empire was not recognized by the emperor and the electors until 1453.

Arche'an E'ra, or **Archean Pe'riod** [*archean* is from Gr. ἀρχαῖος, ancient]: the earliest division of geologic time. Crystalline rocks of this era were formerly called Primitive in the belief that they constituted part of the original crust of the earth, before the formation of sedimentary strata. The name *Azoic* (without life) was afterward applied to all rocks older than the Cambrian, and to the time occupied in their formation, in the belief that life began with the Cambrian. Still later, structures supposed to be organic were found in the oldest rocks (see Eozoön), and the name *Eozoic* (pertaining to, or marking the dawn of life) was proposed for the pre-Cambrian era. With the progress of investigation it became known that some of the crystalline rocks were originally sedimentary, but had been metamorphosed to a crystalline condition; great doubt arose as to the possibility of distinguishing portions of the original crust, if they exist at the surface, from metamorphic strata; and the name Primitive no longer seemed appropriate. With the progress of evolutionary ideas it came to be believed that animals so highly organized as those of the Cambrian must have a long ancestry, and thus the name Azoic ceased to be an appropriate title for pre-Cambrian time. Not all were agreed that the obscure structures discovered in the oldest rocks were really fossils, but most students thought them inorganic. It still seemed possible that part of pre-Cambrian time was zoic (marked by the presence of life) and part azoic, and so the term Eozoic did not represent the prevalent opinion of geologists. Thus each title proposed for the pre-Cambrian era proved unsatisfactory by reason of the theory it implied, and need was felt for a term free from theoretic implication. In 1872 J. D. Dana proposed the name *Archean*, and it was immediately adopted by nearly all geologists.

Complicated structure, metamorphism, and the lack of fossils made the classification of Archean rocks a matter of great difficulty, but the fact that they contain important deposits of iron ore and of other economic minerals secured for them patient study, and substantial progress has been made in the discovery of their sequence and history. It has been found in several districts that one or more series of sedimentary rocks antedate the Cambrian, separated from one another by unconformities, and usually exhibiting different degrees of metamorphism. There occur also extensive bodies of rock older than the series just mentioned, and in these older bodies metamorphism has gone so far that it has not been found possible to determine whether they were originally igneous or sedimentary. In 1887 R. D. Irving proposed to restrict the term Archean to these fundamental crystalline rocks, and establish a new category from the various series of sedimentary rocks intermediate between them and the Cambrian. His proposition was widely accepted by American geologists, and the newly recognized period was named Algonkian (see ALGONKIAN).

As thus restricted, the Archean includes a complex aggregate of gneisses and allied schists, traversed by igneous dikes and veins of many ages and kinds. Its rocks occur in the Grand Cañon of the Colorado, in various mountain ranges of Arizona, Nevada, and Utah, in Southwestern Montana, in Texas, in the Lake Superior region, north of Lake Huron, about Hudson Bay, in Newfoundland, and probably in the Laurentian Mountains, in New England, and in the southeastern belt of the Appalachian Mountains. Similar rocks occur also in Scandinavia, Scotland, Central Europe, India, Australia, and New Zealand. The literature of American Archean is summarized by C. R. Van Hise in *Archean and Algonkian* (Bulletin 86, U. S. Geological Survey, 1892). See GEOLOGY, HISTORIC. G. K. GILBERT.

Archegone, or **Archegonium** [from Gr. ἀρχέγονος, original, founder of a race; ἀρχε-, first + γόνος, race]: the female reproductive organ in mosses, ferns, and their relatives. It is a flask-shaped, many-celled structure, containing a germ-cell which must be fertilized by an antherozoid from the ANTHERID (*q. v.*). CHARLES E. BESSEY.

Archegosau'rus [from Gr. ἀρχηγός, leader + σαῦρος, lizard]: a fossil animal, so named because it was supposed to have been the beginning of reptilian life. It is found in the Bavarian coal-measures. Goldfuss in 1847 described three species discovered in the coal-field of Saarbrück, and gave them the generic name of *Archegosaurus*. Prof.

Owen considers this animal as a remarkable connecting link between reptiles and fishes. Agassiz and Dana regard it as a ganoid fish, while others class it with salamandroid batrachians.

Archela'us: a Greek philosopher, surnamed **Physicus**, because he applied himself chiefly to physical science; was a native of Miletus, or, as some say, of Athens. He was a pupil of Anaxagoras, and flourished about 450 B. C. Socrates was one of his pupils. Archelaus taught that there were two principles of generation—heat, which moves, and cold, which remains at rest. His works are preserved only in fragments, quoted by Diogenes Laertius, Simplicius, Plutarch, and others.

Archelaus: King of Macedonia; son of Perdiccas II., whom he succeeded in 413 B. C. He patronized Euripides and Zeuxis and other Greek poets and artists. Socrates was invited to his court at Pella, but did not go. This king promoted the prosperity of Macedonia by roads and other internal improvements. Murdered in 399 B. C.

Archelaus: an able general of Mithridates the Great; was a native of Cappadocia. He commanded a large army which that king sent to oppose the Romans in Greece in 87 B. C. He captured a number of islands and occupied Athens, where he was attacked and besieged by Sulla. Having been forced to evacuate Athens, he retired to Thesaly in 86 B. C., and was defeated by Sulla at Charonea and Orchomenus. He signed a treaty of peace with Sulla in the year 85, and deserted to the Romans in 81 B. C. and commanded on their side in the second Mithridatic war. He is last heard of in 74 B. C.

Archelaus: a son of the preceding; became high priest of Comana about 63 B. C. He pretended to be a son of King Mithridates, and by that imposture induced Berenice, Queen of Egypt, to marry him. After he had reigned about six months in Egypt, he was defeated and killed by the Romans in 55 B. C. He left a son, Archelaus, who was high priest of Comana until he was deprived of that office by Cæsar in 47 B. C.

Archelaus: son of Herod the Great by Malthace, a Samaritan woman. On the death of his father (4 B. C.) he became ethnarch of Judea, Samaria, and Idumea; his full brother Antipas and his half-brother Philip receiving the rest of the kingdom. Fear of him sent the parents of Jesus into Galilee. In 7 A. D. he was deposed by Augustus, and banished to Vienne, Gaul, where probably he died.

Archencephala, ar-ken-sel'a-la [from Gr. ἀρχε-, first, chief; ἐγκέφαλος, brain]: the highest division of the class Mammalia, to which the order *Bimana*, composed of the solitary genus *Homo*, belongs.

Archenholz, aär'-khen-hölts, JOHANN WILHELM, Baron von: German historian; b. at Langfuhr, near Danzig, Sept. 3, 1743; took part in the Seven Years war, and afterward traveled extensively. He wrote a number of historical works, among which his *Geschichte des siebenjährigen Krieges* is the most celebrated and popular. D. at Oyendorf, Feb. 28, 1812. JULIUS GOEBEL.

Archers and Archery: An archer is one who shoots with a bow. In ancient times archers formed an important portion of the armies of most Oriental and of all barbarous or semi-barbarous nations. Among the ancients, the Cretans, Parthians, and Thracians, and in the Middle Ages the English, were especially distinguished for the skill and efficiency of their archers. The use of the bow and arrow in war was probably first introduced into Britain by the Romans, but it was under the Norman rule in England that archery was extensively practiced and greatly improved. Her archers became superior to those of all other nations. The English archers decided the fate of the day in the important battles of Crécy, Poitiers, and Agincourt. Among the Asiatic Turks, the Persians, the Tartars, and other nations of the East, as well as certain native African tribes and some American Indians, the bow and arrow are still used as weapons of war. In England archery is now no more than a pastime; it is promoted by archery clubs or societies. During the reign of Charles II. of England archery was much patronized by the court. After his reign archery fell into disuse for about a century. Toward the latter part of the eighteenth century it was revived as a fashionable pastime, even ladies often taking part in the trials of skill. The exercise, especially in the form of target-shooting, is still popular.

Archer, BRANCH T., M. D.: b. in 1790 in Virginia; studied medicine in Philadelphia, and was long a prominent physician and politician in Virginia. He went to Texas, in 1831 took part in the revolution, was in 1835 president of the "Consultation," and was sent as a commissioner to the U. S. He was a member of the first Texan Congress, and Speaker of the House of Representatives and Secretary of War 1839-42. D. in Brazoria co., Tex., Sept. 22, 1856.

Archer, JOHN, M. D.: b. in Harford co., Md., June 6, 1741; graduated at Princeton in 1760; was the first person who received the degree of M. D. in America. This degree he received from the Philadelphia Medical College in 1768. He served as an officer in the Revolutionary war, and was a member of Congress (1801-07). D. in 1810.

Archer, FREDERIC: See the Appendix.

Archer-fish: a small East Indian fish of the family of *Toxotidae*. The archer-fishes are said to project drops of water at insects, which they thus cause to fall from the air

Archer-fish.

into the water, and then devour them. *Toxotes jaculator*, one of these archer-fishes, is a native of Java, and about 6 inches long. The only remarkable peculiarity in the form of this fish is its elongated lower jaw, which may aid it in directing the liquid missile upon which its subsistence partially depends, as does that of the hunter on the accuracy of his rifle. "So powerful," says Wood, "is the projectile force, and so marvelously accurate is the aim [of the *Toxotes jaculator*], that it will strike a fly with certainty at a distance of 3 or even 4 feet."

Arches, Court of: a court of ecclesiastical law in England; the chief court of appeal from the courts of the several bishops or ordinaries within the province of Canterbury, which includes nearly all England. The dean of arches has long been the Archbishop of Canterbury's principal official, and in this capacity his jurisdiction, originally confined to the thirteen London parishes belonging to the see of Canterbury, has been extended to the "peculiar," i. e. the fifty-seven parishes which, though situated in various dioceses, are subject only to the archbishop. This court is so called because it was anciently held in the Church of St. Mary-le-Bow (*de Arcubus*). Abolished by act of Parliament, 1874.

Archetype [from Gr. ἀρχέτυπον, pattern: ἀρχε-, first + τύπος, stamp]: the original pattern or model of a work; the original type on which others are formed. Among Platonic philosophers the term archetype was applied to the original patterns or ideas existing in the Divine mind before the creation.

Archiac, ÉTIENNE JULES ADOLPHE DESMIER DE SAINT-SIMON, Vicomte d' (dar'shee-ak'): French geologist and author; b. at Rheims, Sept. 24, 1802. He published, besides

other works in French, a romance entitled *Zizim, or the Chivalry of Rhodes* (3 vols., 1828), and a *History of the Progress of Geology from 1834 to 1863* (8 vols., 1847-62). The latter was published at the expense of the state. D. in Paris, Dec. 24, 1868.

Ar'chias, AULUS LICINIUS: a Greek poet; b. at Antioch about 120 B. C.; became a resident of Rome in 102 B. C., and obtained the right of citizenship. Having been accused of assuming citizenship illegally, he was defended by Cicero in his famous *Pro Archia*, about 60 B. C.

Archia'ter, or **Archiator** [from Gr. ἀρχίατρος, ἀρχι-, chief + ἰατρός, physician]: a title given by the Roman emperors to some of their medical attendants; also to certain officials who were paid by the state or city, and were expected to give gratuitous medical treatment to the poor.

Archibald, SIR ADAMS GEORGE, LL. D.: Canadian statesman; b. at Truro, Nova Scotia, May 18, 1814; educated at Pictou Academy; admitted to the bar in 1838; represented Colchester in N. S. Assembly 1851-67; in Dominion Parliament 1869-70, and re-entered that body in 1888. He was a member of the Executive Council of Nova Scotia; a delegate to Great Britain on the subject of mines and the union of the provinces in 1857; to the Quebec union conference in 1864; and to the final conference in London to complete the terms of union 1866-67. He was Secretary of State for the provinces 1867-68; Lieutenant-Governor of Manitoba and Northwest Territories 1870-73; Lieutenant-Governor of Nova Scotia 1873-83. He was one of the directors of the Canadian Pacific R. R.; president of the board of governors of Dalhousie College, Halifax; and was knighted in 1885. D. at Truro, N. S., Dec. 14, 1892.

NEIL MACDONALD.

Archibald, ANDREW WEBSTER, D. D.: Congregational minister; b. at New Kingston, N. Y., Apr. 10, 1851; graduated at Union College, Schenectady, N. Y., in 1872 at the head of his class, and in the theological department of Yale College, New Haven, Conn., in 1876. His pastorates have been in Iowa and at Hyde Park, Mass. He has been a trustee of Iowa College at Grinnell since 1888. He is the author of *The Bible Verified* (1890), which in eighteen months passed to its third edition, and of *The Trend of the Centuries* (Boston, 1901).

Archida'mus II., became King of Sparta about 470 B. C. He waged war against the Messenians, and commanded the army which invaded Attica in 431 B. C., but the Athenians declined a battle. This was one of the earliest campaigns of the Peloponnesian war. He was the father of the famous Agesilaus. D. in 427 B. C.

Archidamus III.: King of Sparta; grandson of the preceding and son of Agesilaus II. He defeated the Arcadians and Argives in 367 B. C. in a battle which was called the "scarless" or "tearless," because no Spartan was killed in it. In 362 he defended Sparta with success against Epaminondas. He began to reign on the death of his father, 361 B. C., and was an ally of the Phocians in the Sacred war. Having led an army to Italy to aid the Tarentines, he was killed in battle near Manduria, on Aug. 2, 338 B. C.

Archidamus V.: the last king of the Proclid line. He was a brother of Agis IV., whom he succeeded in 240 B. C. He was soon killed by the parties that murdered Agis.

Ar'chil, **Or'chil**, or **Orseille** [from O. Fr. *orchel*, from Ital. *orcella*: of unknown origin]: a reddish purple dye obtained from various species of lichens, among which are the *Lichen roccella* or *Roccella tinctoria*, *Roccella fuciformis*, and *Lecanora tartarea*. These are gathered from rocks near the shores of the Canaries, the Azores, the Cape de Verde isles, Sardinia, Corsica, Ceylon, Madeira, Lower California, Auvergne, the Pyrenees, Sweden, and many other countries. The lichens do not contain the coloring-matter ready formed, but they contain colorless acids, *erythric*, *lecanoric*, *orsellinic*, *evernic*, etc., which readily change to ORCIN (*q. v.*). By the action of air and ammonia the colorless orcin changes to purple *orcein*, which is the coloring-principle of archil. To produce the archil, the weeds are reduced to pulp, a little putrid urine or ammoniac carbonate is added, and the whole is allowed to putrefy or ferment. In a week or ten days the color is fully developed. By adding potassium or sodium carbonate, as well as ammonia, a blue color, LITMUS (*q. v.*), is obtained instead of archil. *Cudbear* is a variety of archil made at Glasgow. Archil produces beautiful shades of purple, violet, mauve, red, etc., but, unfortunately, they are not, as generally employed, permanent. Dr.

Stenhouse suggested some improvements in the manufacture of archil, which were in 1856 put in practice by M. Marnas, of the firm of Guinon, Marnas & Bonnet, of Lyons. He treated lichens with milk of lime, filtered, precipitated the color-producing principles by hydrochloric acid, washed them on a filter, dissolved them in ammonia, and subjected the solution to a temperature of from 153° to 160° for twenty or twenty-five days. The color being at this time fully developed, he precipitated it by adding calcic chloride. The purple lake thus obtained was sold as *French purple*. To dye with this lake it is mixed with oxalic acid and water, boiled, and filtered. The color all goes into solution, a little ammonia is added, and on introducing the silk, wool, or mordanted cotton (mordanted with albumen, or as for Turkey-red), they become dyed with magnificent fast shades of purple. Unfortunately for M. Marnas, in the same year that he developed his *French purple* (1856) Mr. Perkin discovered his *mauve*, which was the starting-point in the great aniline-color industry. Archil has therefore a comparatively limited application. C. F. CHANDLER.

Archil'ochus of Paros: a famous Greek poet, ranked by ancient critics as second only to Homer; flourished about 650 B. C. A soldier, he was in battles often, and showed a soldier's philosophy at the loss of his shield in a fight between men of Thrace and men of Thasos, to which island he had emigrated in his youth. A soldier, he met a soldier's death in a war between Paros and Naxos. A pioneer in poetical art, he is said to have invented or perfected the elegiac verse and the iambic; and other lyric measures still bear his name. He was a master in odes, in elegies, in the fable, but his great and formidable gift lay in satire; and his lampoons are said to have driven his fickle love, Neobule, and her false father, Lycambes, to suicide. He opened the world of realism to song; and his intense passion made the unheroic heroic and gave wings to the language of everyday life. His name is a proverb for remorseless bitterness, but his works have perished save the few fragments in Bergk's *Poetae Lyrici Graeci* (4th ed. 1878-82).

B. L. GILDERSLEEVE.

Archima'gus: the chief of the ancient Persian magi. This title and office belonged to the reigning King of Persia after the time of Darius I., who, having ordered a general massacre of the magi, directed that it should be recorded on his monument that he was the master of the magi. Archimagus is also the name of a powerful and wicked magician in Spenser's *Faerie Queene*.

Archiman'drite [from Gr. ἀρχιμανδρίτης; ἀρχι-, chief + μάνδρα, inclosure, monastery]: an ecclesiastic who presides over monasteries of the Greek Church. The Russian bishops are chosen from the archimandrites. The title is retained in the Greek rite of the Roman Catholic Church.

Archime'des (in Gr. Ἀρχιμήδης): the greatest of ancient geometers; b. at Syracuse about 287 B. C. He was of Greek extraction, and is said to have been a pupil of Conon and a kinsman of Hiero II., King of Syracuse, by whom he was patronized. He enriched geometry, mathematics, and mechanics with important discoveries, and invented several useful and powerful machines. King Hiero, suspecting that a goldsmith had mixed alloy with a golden crown which he had made for him, applied to Archimedes to detect the fraud. The solution of this problem suggested itself to him as he entered a full bathing-tub, and perceived that his body must displace a volume of water equal to its own bulk. Greatly delighted with the discovery, he ran out of the bath, without having dressed (as the story goes), exclaiming "Eureka!"—"I have found it!" He discovered the proportion which a sphere bears to a cylinder by which it is inclosed. He was the author of a celebrated saying, "Δὲς ποῦ στῶ καὶ τὴν γῆν κινήσω"—"Give me where I may stand and I will move the world" (or universe). When Syracuse was besieged by the Roman general Marcellus, Archimedes exerted his ingenuity in the invention and construction of powerful machines or engines for the defense of that city. The tradition that he burned the Roman ships by mirrors is not confirmed by Polybius and Plutarch, and is discredited by many writers. He was killed, it is said, at the capture of Syracuse, in 212 B. C., by a Roman soldier, who would have spared his life if Archimedes had not been so absorbed in a problem that he would not comply with the soldier's summons to surrender or to follow him. He wrote numerous works, of which eight are extant, namely: *On the Sphere and Cylinder*; *The Measurement of a Circle*; *On the Equilibrium and Center of Gravity of Planes*; *On Conoids and*

Spheroids; On Spirals; The Quadrature of the Parabola; The Arenarius; and On Floating Bodies. According to his direction, a cylinder inclosing a sphere was engraved on his tombstone, to commemorate his discovery of their relation. The latest edition of his extant works is by J. L. Heiberg (Leipzig, 1880-81, 3 vols.). There is a complete French translation (Paris, 1807), and one in German (Stralsund, 1824). "He possessed," says Prof. Donkin, of Oxford, "in a degree never exceeded, unless by Newton, the inventive genius which discovers new provinces of inquiry, and finds new points of view for old and familiar objects, and the power and habit of intense and persevering thought, without which other intellectual gifts are comparatively fruitless." See *Journal of the American Oriental Society* (vol. vi., 1860).

WILLIAM JACOBS.

Archimedes: a genus of *Bryozoa* of the family *Fenestellidae*, quite common in certain limestones of the lower Carboniferous in the Mississippi valley, to which the name "Archimedes limestone" has been applied. The part of the fossil more frequently met with is the central screw-like axis around which, in the perfect form, was spirally wound a reticulated lamella very similar to the *Fenestella*. Pieces of such lamellæ are often found in place upon the central axis, showing the structure and arrangement of the pores from which the true nature of the fossil has been determined. Several species have been described from the rocks of Iowa and Illinois and elsewhere. The genus is not known outside the carboniferous system.

H. S. WILLIAMS.

Archimedes, the Principle of: an important principle in the science of hydrostatics, the discovery of which is ascribed to Archimedes. It is this: "A body immersed in a fluid loses exactly as much of its weight as is equal to the weight of the fluid which it displaces."

Archimedes's Screw: an engineering appliance, said to have been invented by Archimedes, for the purpose of lifting water. A tube is wound like a screw around a cylinder, the ends of which are fixed on pivots. The cylinder is placed in an inclined position, with its lower end beneath the surface of the water to be raised, and is then rotated by means of a handle at its upper end. As the cylinder turns round the water in the lower part of the tube rises above the water, and continues to rise from bend to bend as a fresh charge is taken in at the lower mouth, until it reaches the upper mouth and flows out. This contrivance is also sometimes called *spiral pump* and *water-screw*.

Archine: a measure of length in Russia, exactly equal to 28 English inches.

Archipel'ago [from Ital. *areipelago*, the Ægean; *arci-* (from Gr. ἀρχι-, chief) + *pelago*, pond, from Gr. πέλαγος, sea]: a name originally applied to a part of the Mediterranean called the Ægean Sea, which lies between Greece and Asia Minor and incloses numerous islands. They are mostly arranged in two groups, the Cyclades and Sporades. The principal islands of the former group are Melos or Milo, Naxos, Paros, Andros, Tenos, Delos, Seripho, Syra, Cythnos, and Thera. These islands, with Negropont, which is the largest island in the Archipelago, belong to Greece. Some writers include Crete in the Archipelago. Among the Sporades, which belong to Turkey, are Rhodes, Samos, Scio (Chios) Lemnos, Metelin, or Mitylene, Imbro, Samothraki, and Thasos. The islands of this sea are generally of calcareous formation, and have a fertile soil, beautiful scenery, and a pleasant climate. Many of them have produced famous philosophers, artists, and poets, and have been the scenes of interesting events of ancient history. (See ÆGEAN SEA.) In modern times the term is applied to any sea or expanse of water which contains many islands, or to a group of islands, as the Malay or Eastern Archipelago.

Archipelago, EASTERN: See EASTERN ARCHIPELAGO.

Arch'itecture [from Lat. *architectu'ra*, deriv. of *architectus*, master-builder, a translation of Gr. ἀρχιτέκτων; ἀρχι-, chief + τέκτων, builder, carpenter; Sanskr. *tákshan-*, builder]: Although sometimes applied to building showing systematic and scientific design without intended decorative effect (as military architecture), and so used even of the work of certain animals (as beavers or honey-bees), architecture, strictly speaking, denotes the art, as distinguished from the science, of constructive design. It is the highest of the industrial arts, and the most useful of the fine arts, having for its object to produce effects pleasing to the eye and mind, as well as to satisfy the requirements of conven-

ience and stability. Vitruvius defines its essential qualities as "*firmitas, utilitas, venustas*" (stability, utility, beauty),

FIG. 1.—The Greater Temple at Ipsambul.

and the most perfect architecture is that which most completely reconciles these requirements without sacrificing one

to another. The architect may impart to his work sublimity, splendor, grace, playfulness, variety or solemnity, and beautify it by grace of proportion, picturesque outline, play of light and shade, richness of carving and detail, or splendor of color, at the same time that he consults and satisfies the demands of durable construction and convenient arrangement; so that architecture, arising out of the humblest necessities of man, may minister to his highest aesthetic emotions, and rank as a fine art with painting and sculpture.

As an art of design, architecture comprises *planning*, or the distribution of the parts and divisions of each floor of a building; *composition*, or the general arrangement and proportioning of its voids and solids, outlines and masses; *constructive design*, by which the supporting and supported parts of its constructive framework are scientifically disposed; and *decoration*, or its embellishment by carving, sculpture, color, or other ornament. As a *profession*, it involves

the preparation of working drawings for the erection of the building, and the superintendence of its actual construction; besides much semi-legal business, in which the architect stands as the legal agent of the proprietor. The superintendence of the construction requires familiarity with several branches of engineering and of the mechanical trades; so that architecture has become one of the most complex of modern professions, instead of the simple industrial art of the master-builder of ancient days.

FIG. 2.—Plan of Great Temple at Karnak.

As architecture more than any other art reflects the political, religious, social, and aesthetic conditions out of which it has grown, we find its history falling into divisions more or less sharply outlined by limitations both of time and space. Different nations, provinces, and races, having invented or adopted each a particular principle or system of design, have developed their architecture along the lines of these various dominant principles until it has reached perfection, in which case decline has finally supervened; or until the influx of new ideas and principles, or conquest by a foreign race, has crowded out the old system and effected a revolution in the forms and methods of the art. Thus only have *styles*—i. e. the customary and characteristic systems of form and methods of design of given peoples and epochs—arisen and passed away by a law of evolution, and not by any mere caprice of fashion or scintillation of genius. To

EGYPTIAN.—The valley of the Nile, as the seat of the oldest civilization known to history, may be called the birthplace of historic architecture. Long before any known appearance of permanent buildings in Europe or Asia, the

FIG. 7.—Tomb at Beni-Hassan.

pyramids of Ghizeh, near Cairo, had been reared as tombs for kings who died at least 3500 years B. C. They attest the advanced civilization and mechanical skill of that early age; that of Shufu or Cheops is the most colossal work ever reared by man. From a base 760 feet square, covering 13 acres, it rises 480 feet into the air, built mainly of huge limestone blocks, with intricate passages and chambers of polished granite, in one of which is the royal sarcophagus, long since rifled of its mummy. The other two pyramids of the trio that dominate the group at Ghizeh are smaller than "Cheops"; one was built by Shafra and the other by Menkeres, both of the fourth dynasty. Nearly a hundred others are scattered in groups between Abu-Roash and Illahouh, some of stone, others of brick, but none rivaling the three giants of Ghizeh. Near the latter is the Sphinx, a colossal, rock-cut, symbolic figure, lion-bodied and human-headed, supposed by some authorities to antedate the pyramids; and a small, sand-buried temple, of nearly equal antiquity, built of square piers and lintels of granite, imposing in spite of its diminutive size.

The monuments of Egyptian architecture are almost wholly religious, consisting mainly of tombs and temples; the domestic architecture of Egypt has wholly perished, owing, probably, to its use of wood and sun-dried brick as building materials, and to its relative unimportance architecturally. The houses, as shown in the reliefs, were but one or two stories high, and comprised several rooms surrounding an open court, with verandas and porches of wood. But the religious architecture of the Egyptians was of the most imposing and enduring character, building up colossal combinations of columns, lintels, and pictured walls; or cutting the solid rock itself into architectural caverns of surpassing magnificence. Of the latter sort are the two temples at Ipsambul, whose gigantic sculptured façades and gloomy halls are thus hewn in the side of the mountain. The funeral temple of Hatasu at Deir-el-Bahari combined the two systems, being partly structural and partly excavated in the rock.

We can not delay to mention particularly even such great temples as those at Luxor, Medinet Abu, and Abydos, belonging to the great age of the Rameses and Setis of the nineteenth dynasty (1450 B. C.); nor the magnificent temples at Edfou, Denderah, and Philae, belonging to the Ptolemaic period when Egyptian architecture underwent an extraordinary revival. Even the vast temple at Karnak, which embodies all the characteristic features of Egyptian temple architecture on a colossal scale, can only be summarily described. It covered 420,000 sq. feet, measuring some 1,200

FIG. 3.—Egyptian column.

FIG. 4.—Egyptian column.

FIG. 5.—Capital at Beni-Hassan.

the different styles, according as we wish to indicate national or epochal characteristics, we give special names, as Arabian, Greek, French architecture; classic, mediæval, modern architecture.

Of the historic development of architecture only the broadest outlines can be given in a short article; for details, the reader is referred to the numerous histories of the art, or of special periods of its development, by Rosengarten, Fergusson, Lübke, Reber, Perrot and Chipiez, Viollet-le-Duc, and others.

Although architecture has grown up from the crude efforts of primitive man to provide a shelter for himself and his gods, these primitive and uncouth works—wigwams, huts, tents, and caverns—are destitute of true art, and do not enter the domain of architectural history. Moreover, the

FIG. 6.—Temple of Chensu at Karnak.

transitional structures which would reveal the successive stages by which a noble art was evolved from these rude beginnings have all perished. The most ancient existing edifices display the well-developed art of a high civilization, so that the origins and early stages of the art can only be conjectured. The rude monuments attributed to the Druids (see Fergusson's *Rude Stone Monuments*), and even the megalithic walls and fortifications of Greece, have no connection with the architecture of subsequent ages, and will therefore be passed over with only casual mention in this article.

FIG. 8.—Osiris Pier: Temple of Medinet Abu.

feet in length by 350 feet in width; and was begun by Osirtasen I. of the twelfth dynasty. It was continued and extended by many subsequent monarchs, especially Thothmes III., Amenophis III., Seti I. and II., and Rameses I. and II., of the "great age."

FIG. 9.—The Lion-gate at Mycenæ.

Like the other temples, its oldest portion was also the smallest and the most sacred—the sanctuary; to which were added through the centuries successive halls, chambers, and open courts, each addition fronted by a huge double pylon, i. e. a gateway between twin truncated pyramidal masses, and usually flanked by colossal sitting figures of the king. Each addition surpassed in size the earlier structures; so that, entering the first (really the latest) pylon, one traverses successively diminishing courts and halls up to the small, solemn, and gloomy *sekos* or sanctuary, surrounded by the chambers of the priests. The whole was inclosed by a massive and unpierced wall, covered with incised sculptures, and again by a second circuit-wall of brick. But the most imposing feature was the *hypostyle hall*, near the center of the group, measuring 342 by 170 feet, its stone ceiling supported by 134 columns in sixteen rows, those in the two central rows being 11½ feet in diameter and 62 feet high. (A model of this hall to the ½ scale is in the Metropolitan Museum in New York.) This and the other lesser halls and courts were made gorgeous with symbolic and decorative carvings and pictures, covering every available surface and richly colored. In the dim light which entered through the doors, or through clerestory windows, the effect must have been most solemn and impressive.

The structural forms used were few and simple. Round columns of sturdy proportions, carrying capitals imitating the buds or blossoms of the lotus, or swelling into bell-shaped forms simple or compound, and square piers fronted by figures of Osiris, were the supports chiefly used. The architraves were plain, and the pylons and walls externally were crowned with a simple, overhanging eavetto cornice. Colored symbolic pictures were the chief decorative resource.

FIG. 11.—Greek Doric order.

a, Plinth or abacus; b, echinus or ovolo; c, fluted shaft; d, neck; e, groove; f, architrave or epistylium; g, metope; h, triglyph; i, cornice.

ASSYRIAN.—Assyrian architecture was developed under the limitation of poor and scanty building materials; sun-dried and burnt brick, alabaster slabs, and wood being chiefly used. The ancient temples of Chaldæa, dating from a very remote antiquity

(perhaps 2000 B. C.), and the elaborate palaces of Assyria were alike built of these perishable materials. Immense terraced mounds, held by retaining walls of stone (as at Khor-sabad), or of brick, were the only means of attaining the altitude made necessary by the flatness of the land; and enameled brick and alabaster slabs carved in low relief were almost the only available resources for decoration. Nevertheless the Assyrians and Babylonians were able to produce results of great splendor in spite of these limitations; but, as was natural, their construction was far inferior to their decorative art. The latter borrowed much from Egypt, and invented much besides; many of its forms, perpetuated in part by the Persian art which succeeded it, and in part by that of neighboring Asiatic races which borrowed from it, were by them transmitted in more or less modified shape to the Greeks, who developed them into a wholly new and vastly superior art of exquisite beauty. See articles ASSYRIA, ASSYRIAN ART, and ASSYRIAN EXPLORATION.

The Persians, who conquered Babylonia in the sixth century B. C., adopted the Assyrian ornamental forms and symbols, and adapted them to a columnar architecture derived, apparently, from earlier wooden prototypes of their own. The ruins of Persepolis and Susa exhibit the singular but imposing results of this combination.

GREEK.—The beginnings of Greek art are lost in obscurity. The "cyclopean" walls of Greece and Southern Italy, the subterranean "treasuries" of Mycenæ and Orcho-

FIG. 10.—Plan of Temple of Theus.

FIG. 12.—Doric construction.

menos, the Mycenæ "lion-gate" and fortifications, and the walls of Tiryns, belong to a prehistoric age, and have little or nothing to do with the architecture of later times. The oldest remains of historic Greek architecture are the ruins of the temple at Corinth, erected about 650 B. C., and those of a temple at Selinous, in Sicily, of not much later date. These, like all the known Greek temples previous to the Persian wars, are in what is called the *Doric* style, and differ from the most perfect temples of the fifth century B. C. only by their less refinement of detail and proportion, and by the absence of sculptural decoration. The efforts of Greek architects seem to have been concentrated for two hundred years upon the perfecting of the proportions, profiles, and decorations of this their national style, and not upon the altering of its fundamental elements or the invention of new forms. The question naturally arises, Whence

came this style, and how and where was the temple-form developed which we find so complete and well understood even in these early shrines of Corinth and Selinous? This can only be answered by conjectures; and it must be confessed that none of the theories hitherto advanced quite satisfactorily accounts for the apparently sudden appearance on Greek soil of so well developed an architectural style, for no vestige remains of the experimental stages which must have preceded it. As in Egypt, so here, all the buildings of a transitional age and character seem to have been demolished to make way for the superior products of later days. Some would explain the Doric order as borrowed from Egyptian models like the tombs of Beni-Hasan; but this does not account for the temple-plan, which is utterly un-Egyptian. Others ingeniously account for Doric forms by a supposed translation into stone of forms developed in an earlier and long-vanished architecture of wood. This may have a grain of truth in it, but, even so, only partially explains the enigma. Prof. Melani, the Italian savant, argues for an Etruscan origin of the Doric system, both as to plan and details; but here again evidence seems scanty for the theory, and the question still remains in debate.

The typical Greek temple consisted of a windowless hall, called the *cella*, often divided into two unequal chambers, the *naos* containing the statue of the deity and the *thesauros* or treasury; the whole standing on a platform in two or three steps, and surrounded by a colonnade or *peristyle*, whose front portion (usually to the E.) was called the *pronaos*, and the opposite end the *opisthodomus*. The columns

FIG. 13.—Ionic order.

forming each end of the colonnade supported a low gable or *pediment*, usually filled with sculpture; and according as there were four, six, eight, or ten columns in the end row, the temple was called *tetrastyle*, *hexastyle*, *octastyle*, or *decastyle*. The ceiling of the colonnade was of stone slabs and beams; that of the *cella*, with the whole roof, was of wood covered with tiles. In the larger temples the roof required additional support internally, which was afforded by two rows of columns in the *cella*, usually in two superposed ranges, to avoid the encumbrance of very large and heavy shafts. The temple is now by many supposed to have been lighted only through the doors at the ends or by artificial light. The existence of *hypæthral* (partially open-roofed or roofless) temples, such as Vitruvius vaguely describes as "*sine tecto et sub divo*," is now seriously questioned. Many ingenious theories have been proposed by Fergusson, Chipiez, and others to remove the many obvious difficulties and objections incident to any hypæthral system, but so far without really satisfactory or convincing results. That of Chipiez, shown in the splendid model of the Parthenon in the Metropolitan Museum at New York city, seems the most plausible of them all.

The Doric order, which was the exclusive national style for two hundred years at least, employed alike for temples and civic buildings, is characterized by sturdy shallow-fluted columns without bases, and having simple capitals, consisting of a spreading circular cushion or *echinus* and a plain square cap or *abacus*. It employs a plain architrave or lintel, a frieze divided into square panels or metopes by vertical grooved or channeled blocks called *triglyphs*, and a cornice with a plain shelf-like corona, decorated on the under side with slightly projecting panels or *mutules* ornamented with rows of peg-like projections or *guttae*. Above the corona are two or three small moldings, and (except along the sides of the temple) a *cymatium* or gutter-molding. The moldings were decorated with patterns painted in brilliant colors; the metopes, or their backgrounds when they were filled with sculpture, were painted a dark red, and the triglyphs blue; and color was liberally used on all parts of the architecture, though the precise tints and shades employed are no longer known.

After the Persian wars the ascendancy of Athens and the prosperity of the Ionian cities of Greece and Asia Minor brought about the introduction of the *Ionic* style, characterized by its voluted capitals, slender columns deeply fluted, and rich bases; by the substitution of carved for painted ornament on the moldings; by the use of *dentils* in the cornice; by the absence of triglyphs; and by a general richness and elegance very different from the sober dignity of the Doric. It seems to have originated in Asia Minor, and to have been strongly affected by Persian and Lycian influences; but its precise history is as uncertain as that of the Doric. About the time of Alexander (333 B. C.) a modification of the Ionic came into use called the *Corinthian*, its chief innovation being in the capital, which was composed of two rows of richly carved acanthus leaves, and sixteen scrolls meeting in pairs under the four corners and four middle points of the abacus, the whole disposed around a tall bell-shaped core. This order it was reserved for the Romans to adopt and perfect, enriching greatly its base and cornice, as will be noticed later.

FIG. 14.—Great Temple of Agrigentum.

The Greeks out of these elements developed an architecture very unlike that of Egypt. They sought after perfection and a sunny grace rather than colossal size or gloomy solemnity; and the richest aspect of their buildings was

that which they presented externally to the public. Their carved ornament, and, above all, their decorative sculpture, was infinitely richer and more perfect than that of the Egyptians, while the execution of their masonry has never been equaled. They excelled in temple-building, but achieved also notable triumphs in the building of tombs, theaters, gates, and colonnades, all marked by the same spirit of refinement and simplicity, of dignity and grace.

FIG. 15.—The Erechtheion, Athens.

that which they presented externally to the public. Their carved ornament, and, above all, their decorative sculpture, was infinitely richer and more perfect than that of the Egyptians, while the execution of their masonry has never been equaled. They excelled in temple-building, but achieved also notable triumphs in the building of tombs, theaters, gates, and colonnades, all marked by the same spirit of refinement and simplicity, of dignity and grace.

It is impossible within our brief limits to mention more than a small number of these structures; for particulars one must consult the works of Stuart and Revett, Reber, Penrose, Durm, and the various publications of archæological societies in Europe and the U. S.

The earlier temples are mostly found in Southern Italy and Sicily, at Selinous, Agrigentum, Paestum, Segesta, Metapontium, and Syracuse. These for the most part have somewhat heavy columns and entablatures, and retain the primitive triglyph-frieze around the external wall of the cella. They date mostly from the sixth century B. C., and one of those at Selinous shows the uncouth beginning of decorative sculpture in the metopes. The finest is the temple of Poseidon (Neptune) at Paestum. The Basilica near by—probably an open hall for public assemblies—has no cella-walls, but has nine columns in the ends and a central row from end to end; while at Agrigentum is a very large *pseudo-peripteral* temple, whose massive columns were connected by a continuous wall. These are almost the only departures from the typical temple-plan. To the first half of the fifth century are ascribed the elegant temple at Ægina, whose striking pediment-groups enrich the museum at Munich; the clumsy provincial temple at Assos (explored by the American Archæological Institute); and the beautiful hexastyle temple of Theseus, so called, in Athens, the most perfectly preserved of all. As we advance toward the time of Pericles (440 B. C.), we find in these Doric temples an increasing refinement and delicacy in the moldings as well as in the proportions, more slender columns, and greater subtlety of design and execution, as in the temple of Zeus at Olympia.

The age of Pericles, made glorious by the names of Ictinus, Callicrates, and Phidias, marks the acme of Greek art, when, by her successful deliverance of Greece from the Persians. Athens had reached the headship of all Hellas, and grown rich to boot. Her wealth she expended upon her public and religious monuments, especially those in the Acropolis, which were rebuilt with a splendor and perfection impossible at any other period. The Propylæa, by Mnesicles; the Parthenon by Ictinus and Callicrates, adorned with the sculptures of Phidias; the triple temple of Erechtheus, and the tiny shrine of the Wingless Victory, with many altars, statues, and small shrines, formed on the Acropolis an unrivaled group of architectural triumphs. Among them all the Parthenon—the temple of Athena (Minerva) Parthenos—stood supreme, the master-work of Hellenic genius. Built of fine Pentelic marble, laid up without mortar, but so perfectly jointed that the blocks seem almost to have united into a monolithic whole, it stood a little to the S. of the general axis of the Acropolis, an octastyle peripteral temple, with 17 columns laterally and with 6 additional columns in the pronaos, and as many in the opisthodomus, or 58 in all. The temple measured 228 by 101 feet; the columns were about 6 feet in diameter and 36 high, supporting an architrave of mighty blocks of marble, above which were the triglyphs and metopes, the latter filled with groups in high relief, presumably by Phidias and his scholars, representing fights of centaurs and Lapiths; masterly works, though inferior to the magnificent groups in the gables. These two unrivaled compositions, representing the birth of Athena and her contest with Poseidon for the mastery of Athens, respectively, were composed of colossal figures standing free on the shelf of the horizontal cornice of the pediment, and are the grandest achievements of decorative sculpture in any age. Removed by Lord Elgin to London early in the nineteenth century, they are now the chief treasure of the British Museum, together with a large portion of the glorious frieze which once surrounded the cella just under the ceiling of the colonnade. This frieze represented the Panathenaic procession, and was treated in relatively low relief with masterly skill. All these sculptural adornments so fitted into the architectural framework of the temple that, without losing their intrinsic importance, they seemed rather a part of the temple itself

than independent sculptures added to adorn the fabric. Equally remarkable with this sculptural decoration were the refinements of the lines and execution of the temple. All the seemingly straight lines were slightly curved, to impart to them a fullness and strength of which their great length would otherwise have deprived them by a species of optical illusion; but these curves were so subtle as to remain

FIG. 16.—The Parthenon.

long undetected by archæologists. In like manner the seemingly vertical surfaces were all slightly inclined; the columns leaned imperceptibly inward, and those at the corner were less widely spaced than the rest. Only the most delicate æsthetic perceptions could have devised such refinements; the Parthenon, built as if by giants, seems finished like a jewel.

The entrance to the Acropolis was through the propylæa of Mnesicles, an imposing composition, showing, to one approaching it from the plain below, a noble hexastyle Doric colonnade surmounted by a pediment, and flanked by two projecting wings or chambers fronted by lesser colonnades of the same order. Behind the main façade two rows of Ionic columns supported the roof, and formed three aisles leading to five doors in the rear wall, behind which was another Doric portico looking upon the Acropolis. The whole was of the purest and most refined design and perfect construction, and shows us an early example of the Ionic order. The neighboring Erechtheion, however, displays this order in its most splendid form, having two Ionic porticoes to the north and east, besides a remarkable porch supported on

FIG. 17.—Caryatid porch of Erechtheion.

female figures, or Caryatides, the only example of the kind in Greek architecture, but fully worthy of the splendid age to which it belongs. Besides the singularity of this porch, this little temple is remarkable for the irregularity of its plan, which Greek genius knew how to reconcile with perfect dignity and monumental balance. Among other Ionic temples are the little shrine of the Wingless Victory on a bastion of the Acropolis; the temple on the Ilissus in Athens; the temple of Apollo at Phigalæa, Doric externally, but in-

ternally Ionic; and that of Athena at Priene. But the chief triumphs of this style were in the Ionian cities of Asia Minor; the Mausoleum (tomb of Mausolus) at Halicarnassus, and the great dipteral temples of Apollo at Miletus and of Artemis (Diana) at Ephesus.

FIG. 18.—Plan of temple of Olympian Zeus.

But two distinctively Corinthian monuments are recognized in Greece; the first is the Choragic monument of Lysicrates at Athens. This is a charming circular structure on a square pedestal; six Corinthian columns support a slightly domical roof terminating in a magnificent finial, on which once stood the tripod won by Lysicrates in the choral contests. The whole is but 27 feet high. The second example is the great temple of the Olympian Zeus at Athens, whose gigantic ruins represent but a small fraction of the original structure. It was a decastyle dipteral temple, i. e. flanked by double lateral colonnades, and measured 354 by 170 feet, with 120 columns 60 feet high, and a little over 6 in diameter. Begun as a Doric temple in the time of Pisis-

tratus, continued by Cossutius, a Roman architect in the second century B. C., it was terminated only in the time of Hadrian, and should therefore rank as a Roman rather than Greek building, especially as its cornice was adorned with

FIG. 19.—Decorated Roman molding.

modillions, which were a distinctively Roman feature of the order.

We can not delay to describe other monuments of Greek architecture. It must suffice to observe that the theaters, excavated in the hillside and furnished with permanent stage-settings of marble or stone architecture; the *stoa* or porticoes for public assemblies and promenades; the propylæa or city gates; the arsenals, tombs, and sepulchral monuments erected by the Greeks, everywhere display the same high qualities of design, the same minute attention to details and striving after absolute purity and perfection of form. Of the houses of the Greeks we know little; their remains are scanty and trivial, and it is probable that domestic architecture received from them but little attention compared with that bestowed on it by the Romans. The Greek was essentially a public man and lived out of doors, and the public architecture of his cities was his chief concern.

FIG. 20.—Corinthian order.

After the Macedonian conquest, Greek art began to decline in purity and dignity. Ostentation and triviality took the place of these qualities, and, in spite of the magnificence of some of the later temples in Asia Minor, it becomes evident that the age of Alexander was one of general decadence. Yet the spark of Greek genius was not extinguished; under Roman dominion it kindled the flame of art among the warlike Italians, and helped

create the triumphs of Roman architecture. Even in the fifth century A. D. it still burned, and under new conditions was able to originate still another architecture, the Byzantine, with whose passing away it finally vanished.

ROMAN.—Nothing could differ more widely from the Greek than the Roman taste and system of building. Masters of engineering, and of the art of planning the most complex and difficult structures, the Romans preferred to employ a massive system of vaults and arches, clothed with a merely decorative apparel of columns and entablatures, rather than to limit themselves, like the Greeks, to the simple system of the post and lintel. Their works are impressive by size, massiveness, and splendor rather than by those finer æsthetic qualities which we find in Hellenic work.

The Romans were consummate organizers, but indifferent artists; they knew, however, how to put to use the artistic abilities of conquered races, while by a quasi-formulation of architectural design they imparted a certain impressive unity of style to all their buildings, from the Pillars of Hercules to Palmyra, and from Britain to Alexandria; a unity which must have ministered strongly to the impression of an omnipresent Rome. And if the Romans distinguished, as none had done before them, between their construction and their decorative apparel of architectural forms, they were at least enabled thereby to utilize the unskilled hands of slaves and barbarians for the bulk of the work of construction, leaving to skilled artisans and artists only the finishing of the details and decoration. It should not, moreover, be forgotten that the vast number and mass of the buildings undertaken by the Romans would have made it absolutely impossible to bestow upon them all the minute exactitude and refinement of execution of Greek work. Considering all the circumstances, the Romans did wisely to substitute for such unattainable refinement (which, indeed, they were not likely to appreciate) a splendor and lavishness

FIG. 21.—Section of exterior wall, theater of Marcellus.

they were at least enabled thereby to utilize the unskilled hands of slaves and barbarians for the bulk of the work of construction, leaving to skilled artisans and artists only the finishing of the details and decoration. It should not, moreover, be forgotten that the vast number and mass of the buildings undertaken by the Romans would have made it absolutely impossible to bestow upon them all the minute exactitude and refinement of execution of Greek work. Considering all the circumstances, the Romans did wisely to substitute for such unattainable refinement (which, indeed, they were not likely to appreciate) a splendor and lavishness

FIG. 22.—Plan of the theater of Marcellus.

FIG. 23.—The "Maison Carrée" at Nîmes.

of ornament and material better suited to the character of their buildings.

From the foundation of Rome until the fall of Greece (146 B. C.) the Romans made almost exclusive use of the uncouth and undeveloped architecture of the Etruscans, to whom they

owed the arch and vault, which became as characteristic of their later architecture as the column and entablature were of the Greek. The conquest of Greece, however, with the consequent influx both of Greek artists and works of art, revolutionized Roman taste, and established Greek art as the fashion of the day. The craving for splendor and the

FIG. 24.—Elevation of Pantheon.

FIG. 25.—Plan of Pantheon.

accession of wealth which resulted from the Greek conquests combined to foster the development of a new architecture, in which the orders of the Greeks were married to the Roman arch; and to Greek artists are doubtless due the skill and success with which these Greek members were adapted to Roman plans and systems of construction. This adaptation involved radical changes in the details of the

FIG. 26.—Section of Pantheon.

orders. The profiles of the moldings were modified, as well as their succession and proportions in the entablature. The Doric order received a base, and was often unfluted and crowned with a cornice much like the Ionic. The Tuscan order, a simplified form of the Doric, and the Composite, a modification of the Corinthian, were added to the three orders borrowed from Greece; and the Corinthian

FIG. 27.—Arch of Titus.

was elaborated and perfected, receiving a new base and a new cornice with modillions. Out of all these changes there was gradually developed a sort of canon of proportions for the various parts of the orders. Not that these rules

were established at once, or arbitrarily by the dictation of authority, or as absolute and unchangeable laws; but the systematic, organizing, mathematical turn of mind of the Romans gradually led them into practically uniform ways of doing each thing, and imposed these methods upon the Greeks who worked for them. In the same way, while they used the orders as did the Greeks for porches and colonnades, they also used them in the form of engaged columns and pilasters, to decorate their façades and triumphal arches, placing them between the arches, where they performed no really constructive function, but served to constitute a most imposing system of decorative form. Carved decoration was no longer confined to the moldings, but applied to every possible surface; and instead of the sculptured groups and processions of the Greek temples (which would have been an absurd extravagance on friezes like those of the Colosseum, for instance), they adorned their friezes with magnificent compositions of acanthus-leaved scrolls mingling with genii, griffins, garlands, and symbolic forms.

FIG. 28.—Half-plan of Colosseum.

The Romans were not pre-eminently temple-builders, though they produced several notable temples. These all retained Etruscan peculiarities of plans, in spite of their Grecian columns and pediments. They were usually *prostylar* instead of *peripteral*, having generally a nearly square cella prefaced by a deep porch (e. g. the temples of Antoninus and Faustina, of Vespasian, etc.). Sometimes the flanks of the cella were adorned with engaged columns, giving them the name of *pseudo-peripteral*, as in the case of the temple of Virile Fortune; and the temple of Venus and Rome near the Forum offers a singular example of two cellas placed back to back, and surrounded by a *pseudo-dipteral* colonnade, i. e. one in which the width of the lateral colonnade is equal to two intercolumniations of the front. They built also a considerable number of circular temples, a form exceptional in Greek work (e. g. the Philippeion at Olympia), but evidently a favorite with Etruscans and Romans. Some of these were surrounded by colonnades, as in the two so-called temples of Vesta, one in Rome, and the other at Tivoli, and the actual temple of Vesta at one end of the Forum; others, like the unrivaled Pantheon, had columnar porches over the entrance. But the Roman genius was much better exemplified in such complex and elaborate structures as the amphitheatres and *thermæ*, into whose construction engineering entered largely. Their enormous size and mass, the majesty of their arches and vaulting, the ingenuity and dignity of their plans, constitute the soundest title of the Romans to architectural fame. Roman love of splendor also found abundant scope in the monumental disposition and design of the *fora*, with their colonnades, statues, and altars; and in the erection of triumphal arches and memorial columns, with which they recorded throughout Europe and the Mediterranean lands their feats of conquest. They developed furthermore the architecture of the *basilica*, which was destined in later ages and in Christian hands to become the germ of nearly all church architecture, the cathedral included. In the basilicas and *thermæ* was moreover evolved that splendid system of internal decoration by paneled incrustations of marble in various colors, by elaborate marble pavements, by monolithic shafts of porphyry, verd antique,

FIG. 29.—Section of Colosseum.

was elaborated and perfected, receiving a new base and a new cornice with modillions. Out of all these changes there was gradually developed a sort of canon of proportions for the various parts of the orders. Not that these rules

and other precious materials, and by mosaic and wall-painting, which the architects of Byzantium in after years made the basis of the decoration of their gorgeous church interiors.

Little remains to us of the architecture of the republic; the little temple of Virile Fortune and the temples of Vesta,

FIG. 30.—Plan of Ulpian Basilica.

so called, at Rome and at Tivoli are of Greek workmanship, though on Roman plans. The most important monument of this period is the great theater of Marcellus (13 B. C.), built of stone with engaged columns in superposed orders, the Ionic over the Doric, between the arches

FIG. 31.—Plan of Basilica of Maxentius and Constantine.

of the exterior (see Fig. 19). The most noble of all Roman temples, the "Pantheon of Agrippa," so called from the inscription upon the portico, has until very recently been ascribed to this period, as the work of M. Vipsanius Agrippa (27 B. C.). Very recently, however (summer of 1892), a French architect, M. Chédanne, made the important discovery that while the portico and the temple to which it belonged were built by Agrippa, the circular domed hall is of

FIG. 32.—Plan, Basilica St. Paul beyond the Walls.

a later date, having been either constructed new or rebuilt from the foundation in the time of Hadrian. The portico, of twelve monolithic Corinthian columns, arranged in three aisles after the Etruscan fashion, admits to a vast circular structure, 140 feet in diameter, covered by a noble hemispherical dome, and lighted by a single circular opening in the summit of

the dome, 28 feet in diameter and 140 feet above the marble pavement. The circular wall, 20 feet thick, which supports the dome is lightened by eight alternately semicircular and rectangular niches, in one of which is the entrance-door; these niches are arched and decorated with columns. The whole interior was originally adorned with a splendid veneering of marble, with statues and with bronze enrichments, and the deeply coffered vault of the dome was also richly ornamented. A conjectural restoration of the original interior is shown in the fine model of the Pantheon in the Metropolitan Museum in New York. The Pantheon is now used as the Church of S. Maria della Rotonda; it has been internally altered by successive restorations, and the bronze ceiling of the portico was long ago removed; but even in its present condition it is one of the most majestic and impressive buildings in existence. The ruins of Agrippa's baths, of which it was once thought to have formed the *laconicum*, are still to be seen in the rear of the temple.

Of the architecture of Imperial Rome the ruins are almost countless. The Forum Romanum retains many of the columns of splendid temples, e. g. of Vespasian, Saturn, Antoninus and Faustina, and Castor and Pol-

lux ("Jupiter Stator," so called); and in or near it are the arches of Septimius Severus, Titus, and Constantine. That of Titus, in the Composite order, is the most elegant, though not the largest or richest of these; and other examples of this sort of monumental architecture are to be seen at Ancona, Benevento, Orange, Reims, and other Italian and provincial cities, some with one, some with three arches. Of somewhat similar character are the city gates, like the *Porta Maggiore* at Rome, and the gates at Verona, Athens ("Arch

of Hadrian"), Nîmes, Autun, etc. The column of Trajan, in the forum of that emperor at Rome, was erected both to mark the height of the hill removed to create an area for the forum and to commemorate the Dacian campaigns of Trajan. It is some 90 feet high, and enwrapped by a continuous spiral bas-relief picturing the victories of its builder, whose statue crowned its summit. The Antonine column of Marcus Aurelius is almost precisely similar; and Constantinople, Alexandria ("Pompey's Pillar"), and other cities were likewise adorned with columns of victory by the Roman conquerors or rulers.

In the building of amphitheaters the Romans excelled, and the Flavian amphitheater of Vespasian, commonly called the Colosseum, is not only the finest of these, but the greatest in size and bulk of all Roman structures. Its circuit-wall of travertine, pierced by 240 arches, rises in three stories of superposed Doric, Ionic, and Corinthian columns and entablatures, with a fourth range of pilasters, to a height of 150 feet, inclosing a vast ellipse, 606 feet long by 500 wide. The seats, rising in tiers around the arena, could accommodate over 80,000 spectators, and even in its present ruinous condition it is one of the most tremendous and impressive piles ever reared by man, its very size converting the monotony of its architecture into sublimity. Less in dimension, but still imposing, are the amphitheaters of Pompeii, Verona, Capua, Nîmes, and Arles. The Romans also built theaters of stone on the same general principle as their amphitheaters, but inclosing a little more than a semicircle, somewhat

FIG. 33.—Interior view, San Apollinare Nuovo, Ravenna.

after the Greek fashion. The theaters of Marcellus (see *ante*), of Pompeii, Taormina, and Orange are among the finest examples extant. The Odeon of Herodes Atticus at Athens belongs to the same class.

Of the *thermæ* or baths, which share with the amphitheaters the glory of displaying the highest resources of Roman engineering skill and architectural genius, only shapeless ruins exist; but these are sufficient to show their plan and general design. In the center of a vast inclosure, surrounded by small bath-rooms, lecture-rooms, gymnasia, and exedrae, was situated the principal edifice, which contained, besides one or two open courts and various smaller chambers, a series of enormous halls of the greatest magnificence, planned with consummate skill, vaulted with simple but massive vaults, and decorated with the greatest possible splendor of marble incrustations and mosaic. One of these halls, the *tepidarium* of the baths of Diocletian (the largest of the *thermæ*, ac-

commodating 3,600 bathers at once), remains to-day almost intact, except for the alterations which were required to convert it into the Church of S. Maria degli Angeli. Of the baths of Caracalla imposing masses of brickwork still remain, from which it has been possible not only to restore quite completely the plan of the baths, but also to prove that the Romans were the first to use iron beams with brick or concrete for the construction of fire-proof floors.

The ruins of the Flavian palaces on the Palatine hill, the excavations at Pompeii and Herculaneum, the picturesque

FIG. 34.—Pillar, Church of St. John, Constantinople.

remains of Hadrian's villa at Tibur, and other similar vestiges on the Campagna and elsewhere, furnish us with a very clear notion of the Roman domestic architecture, private and imperial. The private houses and villas were less remarkable for their external architecture than for the beauty of their gardens and surroundings and the splendor of their interior decoration, in which wall-painting of the most brilliant and fanciful description, largely executed by Greek painters in encaustic, played an important part. The houses themselves had mostly but one or at most two stories, and presented little in the way of architectural embellishment to the street. The imperial palaces were, of course, far more splendid; the magnificence of Nero's "Golden House," as preserved in the narratives of contemporary writers, almost passes belief, and the palace of Diocletian at Spalatro preserved in its massive and imposing architecture the dispositions of the typical Roman camp.

This summary account of the building-art of the Romans must be brought to a close with a brief sketch of the basilicas. These were civic buildings, serving at once as auction-marts, exchanges, and palaces of justice, and comprised generally a great hall, sometimes open to the sky, as at Pompeii, more often roofed with wood, rarely vaulted, as in that of Maxentius and Constantine at Rome: two or more side aisles, lower than the nave or hall, from which they were separated by ranges of columns, and an *apsis* or tribune at the end opposite the entrance. In the *apsis* was the seat of the *quaestor*, with an altar in front of it, and sometimes a species of transept

FIG. 35.—Plan of S. Vitale, Ravenna.

between it and the nave. The side aisles were sometimes two-storied, with galleries; above their roofs the walls of the nave, supported on the columns below, rose to form a clerestory, with windows to light the hall; and the whole structure was preceded in many cases by a *narthex* or porch across the front (Basilica Julia, Basilica Ulpia, Basilica of Fano, etc.). The last of the pagan basilicas was erected by Maxentius and Constantine (328 A. D.) after the model of the tepidaria of the baths, vaulted and fire-

proof. It was in the reign of this monarch that Christianity was first freely permitted to erect for itself suitable places of worship. The early Christians, disdaining to convert to their own use the temples of paganism polluted by heathen worship, and unfitted by their size and plan for Christian uses, saw in the basilicas precisely what they needed. When they built new churches they followed the same plan and arrangements, often using the materials—columns, architraves, etc.—of ruined or demolished Roman buildings, and adopted the same general scheme of decoration by marble incrustations and mosaic, using, however, the forms of Christian symbolism in place of the pagan representations in their prototypes. Thus arose Early Christian architecture on the ruins of Roman art, and for a thousand years continued to furnish Rome with churches of the same unchanging type. Meanwhile Western Europe was developing out of the same elements a totally new and sublime architecture, evolving from the Roman basilica the matchless fabric of the Gothic cathedral; and the architects of the East, out of prototypes furnished by the *thermae* and the basilica of Constantine, were at the same time developing the very different but still splendid domical forms of Byzantine architecture.

BYZANTINE.—As Rome declined, Constantinople advanced in splendor and importance to the first place in Christen-

FIG. 36.—Plan of St. Sophia, Constantinople.

FIG. 37.—Section of St. Sophia.

dom. Inheriting the traditions and constructive methods of Roman architecture, the Byzantine Greeks blended with them many Oriental elements, due to their relations with Asia Minor, Syria, and the far East, and developed therefrom a new and distinctively Christian architecture. To the Roman systems of vaulting they added the dome, and developed out of the marble incrustations and mosaics of Roman art a complete system of gorgeous but harmonious color-decoration, the vaults and domes being made especially magnificent with glass-mosaic on a gold ground. The details of Roman architecture, already much modified in the basilicas and in provincial works, as in Dalmatia and Syria, underwent further alterations. Arches were supported on columns, capitals and profiles were changed, and for the Roman carving in strong relief was substituted a rich incised decoration of patterns which blended the acanthus leaf with Christian symbols and monograms. Byzantine architecture flourished from the fifth to the end of the twelfth century, and was the parent of several styles,

FIG. 38.—Plan of St. Mark's church, Venice.

including that of the modern Greek Church, many of the Mohammedan styles, and the earlier mediæval architecture of Venice. In France, along the highway of the Oriental commerce of the Middle Ages, the cities of Angoulême, Périgueux, and others betray in their churches of the eleventh

FIG. 39.—Interior, Cathedral of Speyer (Spire).

century the Byzantine influence. Ravenna was in the sixth century a part of the Byzantine empire, and is full of splendid monuments of the style, among which the domical Church of San Vitale is the most important. It was completed by Justinian, who during his long reign (527-565 A. D.) built an extraordinary number of magnificent churches in Constantinople and the provinces. But it was far surpassed by the great basilica which he dedicated in Constantinople in 537 to the Divine Wisdom (*ἡ Ἁγία Σοφία*, mis-called "Santa So-

phía"). and by many considered to be internally the most beautiful church ever erected. The magnificence of its decorations, together with the unrivaled majesty of its interior, elicited from the emperor the historic and perhaps justifiable boast: "Solomon, I have surpassed thee!" Its church, measuring 253 by 115 feet, is covered by a masterly combination of two half-domes with a central dome 107 feet in diameter and rising 180 feet into the air. This dome was the first pendentive dome ever attempted on a large scale, and for internal effect has never been surpassed. (The pendentive dome is supported on four arches by means of spherical triangles of masonry, called *pendentives*, which fit in between the adjacent halves of each pair of arches.) Side aisles, 60 feet wide, in ten stories forming galleries, are separated from the nave by magnificent arcades with polished columns of precious materials. Abundant light enters through clerestories above the gallery-roofs and through a great circle of windows at the base of the dome; and whether we regard the whole from the point of view of its engineering design or its decoration, it appears a masterpiece, unrivaled in its way, and marks an era in the history of architecture. It is now a Turkish mosque.

FIG. 41.—Plan, Notre Dame du Port, Clermont-Ferrand

A few of the other Byzantine churches in the Turkish empire have been spared by the Mohammedans, and of the Church of the Apostles, which ranked next to that of the Divine Wisdom in size and beauty, the almost exact counterpart exists in Venice, though the original was long ago demolished. This copy is the famous Church of St. Mark, erected by Byzantine architects in the latter part of the tenth century, though not completed till much later. It is a five-domed cruciform church, and though it lacks the majesty of Santa Sophia it is hardly less magnificent in the

general plan seems to have been suggested to Anthemius and Isidorus, its architects, by the basilica of Maxentius at Rome, which, however, it greatly surpasses in scale; while, instead of its groined vaulting, the immense nave of this

FIG. 42.—Fan vaulting, Henry VII. chapel, Westminster.

splendor of its internal color-decoration. In Athens are a number of small but interesting Byzantine churches, and in the monasteries of Mt. Athos the traditions of Byzantine art are still maintained. But the vitality of Byzantine architecture was exhausted with the decay of the Eastern empire, which never fully recovered from the Latin conquest in 1204.

ROMANESQUE.—Contemporaneously with the later phases of Byzantine art in the East the spread of Christianity through Western and Northern Europe was calling into existence a new architecture, varying in detail according

to locality, but marked everywhere by certain common characteristics, which have given it the name of *Romanesque*. While in Italy the early Middle Ages show a strange confusion of styles, with the Lombard in the northwest, the Byzantine in the northeast, the basilican in Rome, and Norman and Arab and Byzantine mingled picturesquely in Sicily and the south, all Western Europe was endeavoring to solve one and the same problem—the conversion of the three-aisled Roman basilica into a vaulted structure. This problem is the key to the whole history of mediæval architecture in Western Europe, of which the Romanesque styles are simply the first stages, the magnificent cathedrals of the thirteenth and fourteenth centuries the consummate achievement. Everywhere in Europe the three-aisled basilica, with its apse, transepts, and clerestory, was accepted as the type-plan for church architecture; and so long as classic traditions prevailed, or the columns and architraves of Roman ruins were accessible for use in church-building, the type underwent little modification. But with the lapse of time local and climatic influences asserted themselves in a progressive modification of this type, until it could hardly be recognized except in the main disposition of the plan. These changes were mainly motivated by two considerations: first, the difficulty of procuring or executing the fine classic columns of marble required by the typical basilica, and the rich marble revetments and mosaic pictures with which it was adorned; and, secondly, the desire to cover the wide nave as well as the aisles with a fire-proof vault of stone. As a combined result of both these considerations, heavy round or clustered piers were substituted for the columns, and

FIG. 43.—Buttness and flying arch.

space spaced much more widely apart; the clerestory wall was made extremely heavy and thick, and the nave reduced in width; while for the costly revetment of marble and mosaic was substituted the dignity of simple but harmonious architectural lines, with a limited amount of strong carving of moldings, capitals, and door porches. The Lombard churches of Northern Italy, like S. Ambrogio at Milan, S. Zeno at Verona, and S. Michele at Pavia; the magnificent abbeys of the Rhenish provinces, like Laach, Worms, Mayence, etc.; the French churches of the eleventh and twelfth centuries, as, for example, the great abbeys at Caen

FIG. 44.—Plan of Sainte Chapelle, Paris.

FIG. 45.—Section of Sainte Chapelle, Paris.

and Vézelay; and the Norman churches of England, like Durham, St. Albans, Peterborough, Romsey, etc., are exam-

ples of the various national phases of Romanesque architecture. In all of these the heavy piers, the massive walls, the round arch strongly molded, the revival of Roman groined or quadripartite vaulting, and of the Roman system of buttressing the points of special thrust or strain, are characteristic features. Deeply recessed portals,

FIG. 49.—Flamboyant tracery, St. Saviour, Dinan.

capitals utterly unlike the Roman, and the zigzag, billet beak, and other characteristic molding-ornaments, are also found in nearly all Romanesque churches. Changes in the ritual, moreover, introduced changes in the plan; the head of the cross was lengthened to form a choir, and flanked by side aisles like the nave; chapels dedicated to various saints were added wherever convenient; and the use of bells made necessary detached campaniles (as in Italy) or towers, usually at the west end of the church, to which spires were added to give them loftiness and grace.

GOthic.—What is commonly called Gothic architecture is simply a continuation of the Romanesque, from which it can not be separated by any sharply defined line: for the pointed arch, which is usually considered its distinguishing mark, was no sudden innovation, and involved no abrupt breaking with the methods of Romanesque building, of which it was the outgrowth and result. Its form had been known from the earliest antiquity. The Assyrians, the Arabs, and the French Provençal architects had used it in successive ages; but its general adoption came about only when the exigencies of

FIG. 50.—Façade of Notre Dame, Paris.

the problem of vaulting demanded its use, and this seems to have first occurred in France, perhaps (as Viollet-le-Duc

terms formed by the ribs, among the finest examples of which may be instanced the choir-vaults of Gloucester and Christ Church cathedrals, the retro-choir of Peterborough, and the vaults of Henry VII.'s chapel at Westminster and St. George's chapel at Windsor. The French never produced any vaults to compare with these in beauty, though French vaulting is superior from a scientific point of view. It was they, however, who developed the constructive fabric of the Gothic cathedral to its highest perfection. Their constant aim was to increase the height of the nave and clerestory and the size of the windows in order to secure better light, and to allow of a greater splendor of stained glass, which in the thirteenth century had become a decorative resource of great importance, and continued through the fourteenth century to stimulate the increase in the size of the windows. The use of lofty clerestories, together with the constant effort to lighten the massiveness of the

FIG. 51.—Interior of Amiens Cathedral.

suggests) in the great porch of Vézelay. It is impossible within the limits of this article to explain what were the difficulties encountered

in the effort to solve the problem of vaulting the nave, and how the pointed arch contributed to its solution (for such particulars, consult Moore's *Gothic Architecture* and the articles *Construction* and *Voûte* in the *Dictionnaire Raisonné* of Viollet-le-Duc). It must suffice to say that these difficulties were partly constructive, resulting from the intersection of vaulting surfaces of different spans, due to the discrepancy between the width of the nave and of the pier arches; and partly æsthetic, some of the possible solutions of the constructive problem being objectionable because of their ugly appearance. But the pointed arch, having been once adopted for the pier arches and vaulting-ribs, was almost of necessity made use of for all the openings and spans; so that while in transitional works of the close of the twelfth century and beginning of the thirteenth century we find the round and pointed forms occurring side by side, the

FIG. 52.—Plan of Amiens Cathedral.

former finally disappears after those dates except in a few isolated instances.

Very early in the course of these efforts to devise a suitable form for the vaulting, the church-builders began to use plain or molded ribs of stone as a sort of framework for the vaults. This feature the English architects developed into a decorative as well as constructive element of the greatest splendor. The different stages of this development are called *lierne*, *star*, and *fan* vaulting, according to the pat-

FIG. 53.—West front of Cologne Cathedral.

masonry, led to the adoption of flying buttresses, by which the enormous thrust of the vaults was conveyed outward and downward to buttresses of great transverse depth built against the external walls of the side aisles (see BUTTRESS). Where side aisles were omitted the flying arches became unnecessary, and the buttresses directly resisted the vault-thrust, as in the Sainte Chapelle in Paris. By these means, the germs of which may be found in Roman and Byzantine buildings, the side walls of the aisles and clerestory became of little importance, and were in large part replaced by immense windows of stained glass, furnishing a color-decoration even more gorgeous than that of the Byzantine mosaics. But such walls of leaded glass required multiple supports to stiffen them, and these were afforded by the graceful stone traceries with which the window opening was filled. The changes in the character of these traceries mark

the stages of development of Gothic architecture in France and England, and in measurably in Germany, and have given to them, as well as to the several periods in which they occur, the names of lancet, geometric, and perpendicular for the English styles, respectively, of the thirteenth, fourteenth, and fifteenth centuries; and of early pointed (or early French), rayonnant, and flamboyant to the corresponding phases of French architecture.

By these successive steps the Gothic cathedral was developed into a structural organism, each of whose parts fulfilled a definite constructive function. All the members of this framework of stone, piers, arches, ribs, etc., received forms originating not in caprice or mere æsthetic fancy, but in the demands of stability, lightness, and convenience; and every radical variation in their shapes and proportions may be traced to the effort to meet more perfectly the special requirements of each case. Especially is this true in France, where a sure and unerring logic seems to have guided the mediæval builders in every step they undertook. At the

FIG. 54.—Orvieto Cathedral, west front.

same time they were ever controlled by an equally unerring artistic taste, so that the splendid engineering of their structures is clothed in forms of undying charm and ever-fresh beauty and loveliness. For their ornamental details they ranged the whole universe of vegetable and animal forms, and, under the influence of a fervid imagination, compounded therefrom a marvelous world of grotesque, symbolic, and conventionalized ornament, or, as in the later stages of their art, copied nature with realistic fidelity. Thus was the æsthetic marvelously blended with the constructive in extraordinary creations, whose vaults, like that of Amiens, soar 150 feet into the air, or stretch into long vistas extending, as in some of the English cathedrals, 500 feet from porch to apse. Never were the demands of use and beauty more perfectly reconciled and satisfied than in these structures, which unite the æsthetic charm which the Greeks strove after with the splendid engineering and impressive magnitude of Roman architecture, adding thereto a religious symbolism and a glory of carved and colored picturing, full of poetry and far more inspiring than Egypt ever produced.

Our limits will not permit of attempting to specialize upon the various national phases of this development except in the briefest manner. France was the birthplace of every important step in its advance, and created its most perfect examples. Conspicuous among many others are the cathedrals of Paris (Notre Dame); Chartres, with its unrivaled stained glass; Rouen; Amiens, the largest and internally

the richest of all; Reims, with its magnificent front and exterior; and Tours, Sens, Auxerre, and Orléans among the later examples, besides many splendid abbeys and parish churches. In England the cathedrals were less lofty, but longer, than in France, usually terminating in square east ends instead of the French *chevet*; Durham, Peterborough, Norwich, and Ely among the earlier built, Lincoln, Canterbury, Salisbury, and York among those of the thirteenth and fourteenth centuries may be mentioned.

FIG. 55.—Florid Gothic carving.

In Germany the finest are the earliest works, like the minsters at Worms, Mayence, Limburg, Laach, etc., which exhibit the round arch in its glory. Strassburg, Freiburg, and Cologne (the largest of all) are of later date, splendid with elaborately minute tracery, especially in their magnificent open-work spires. Spain copied indiscriminately from other countries, and mingled with this copying many features of Moorish origin in most fanciful combinations (Seville, Burgos, Toledo, etc.). Italy never adopted the constructive principles of the West, and the pointed arch, introduced by French Cistercian monks and by German architects, was used without constructive meaning. Vaults were

FIG. 56.—Florid Gothic doorway, Rochester Chapter-house.

tied by iron rods, buttresses omitted, and façades designed as mere decorative screens, though as such often singularly beautiful (Sienna, Orvieto, Ferrara, Milan, etc.).

Two chief causes led to the decay of Gothic architecture. In the first place the constructive development, which was its life, could not continue forever; the main problem of the vault once solved, it could only busy itself with proportions and details. The striving after height and lightness and ingenuity of construction became its chief concern and its bane. Decoration assumed an undue importance, and the elaborate naturalistic ornament of the fourteenth century preluded the extravagant but often dry and unmeaning carving and paneling of the fifteenth; while the somewhat stiff but noble figure-sculpture of the thirteenth century degenerated into an art of overcrowded and realistic carved pictures. In the second place, mankind was undergoing a religious and intellectual revolution, which was loosening the hold of that mediæval mysticism which so powerfully influenced the Gothic builders. Men were becoming practical, independent, lovers of splendor and luxury, and fashions changed in building as in all else. There was no longer need of new cathedrals, and civic architecture was replacing religious architecture in interest and importance, as in the town-halls of Flanders and Italy. In other words, the Renaissance was approaching, bringing in its train the revival of classic tastes and of classic forms, with palace-building and domes, with the individualism of great builders like Brunellesco and Bramante and Michel Angelo, in place of the consistent and ubiquitous advance of all architecture along the same general lines through the combined efforts of countless unknown designers. A new architecture arose, of courtiers and princes, of municipalities and guilds, of burghers and common citizens, of merchants and corporations, to be succeeded by the philistinism of the eighteenth century, and that again by the artistic revival of which we of the last decade of the nineteenth century are the witnesses. This revival, still chaotic and uncertain in its tendencies, is not marked by those lofty impulses and strong currents of feeling which we note in all the great epochs of architecture in the past, but by that more general diffusion of taste and knowledge which to-day in intellectual as in artistic matters produces perhaps fewer giants and great master-works, but infinitely more of general and common excellence of performance.

For the architecture of the East, see ARABIAN ARCHITECTURE, ASSYRIA, CHINA, INDIA, and MOHAMMEDAN ARCHITECTURE; and for its progress after the decay of Gothic art, see RENAISSANCE (*Architecture*). Other subdivisions of the subject are covered by special articles under the appropriate heads. The general reader is also referred to the handbooks of architectural history already cited, and to the volume on *The Fine Arts* in the history of *The Renaissance in Italy*, by J. A. Symonds.

A. D. F. HAMLIN.

Architecture of the American Aborigines: See INDIANS OF CENTRAL AMERICA, INDIANS OF NORTH AMERICA, and INDIANS OF SOUTH AMERICA.

Archon [Gr. ἄρχων, ruler, deriv. of ἄρχειν, be first]: the title of the highest magistrates or rulers of Athens. On the death of Codrus, King of Athens (1068 B. C.), the title of king was abolished, and Medon, the son of Codrus, became the first archon, with limited power. The office was at first hereditary and held for life, but in 752 B. C. the term of office was limited to ten years, and in 714 it ceased to be hereditary and became open to all patricians. In 683 the number of archons was increased to nine, who were elected annually. One of the nine was called archon *eponymus* (ἐπώνυμος), because his name was used to designate the year; the second, who was styled *king* (βασιλεύς), had charge of religious affairs; the third was called *potemarch* (commander-in-chief), and originally had the command of the army. The other six, who were styled *thesmothetæ* (θεσμοθέται), law-givers, conducted criminal trials, and had power to ratify treaties with foreign states. In the latter period of Athenian history all citizens were eligible to the office of archon. The word archon (translated *ruler*) occurs in the New Testament as the title of members of the SANHEDRIN (*q. v.*), among whom was Nicodemus (John iii. 1). Among the Gnostics the word is the designation of two beings who ruled the several heavens. A sect of Gnostics bore the title *Archontic*. It arose in the fourth century, rejected baptism and the Lord's Supper, and identified the God of the Old Testament with the devil.

Archytas (Ἀρχύτας): Greek philosopher, general, and mathematician; b. at Tarentum. He flourished about 400-350 B. C., was a Pythagorean in philosophy, and was an intimate friend of Plato, whose life he is said to have saved

when the tyrant Dionysius was about to put him to death. As general of Tarentum, to which office he was elected seven times, he commanded with success in several campaigns. He was also employed in important civil affairs, for which he displayed excellent capacity. His virtue was as conspicuous as his ability. He is reputed the first that applied geometry to practical mechanics, and the first to solve the problem of the doubling of the cube. He was drowned on the coast of Apulia. Only fragments of his works are extant. See Zeller's *Pre-Socratic Philosophy* and Mullach's *Frag. Philos. Græc.*

Arcis-sur-Anbe, ar'see'-sür-õb: a town of France; department of Anbe; on the river Anbe; 16 miles N. by E. of Troyes (see map of France, ref. 4-G). It has manufactures of cotton hosiery. On Mar. 20 and 21, 1814, an indecisive battle was fought here between Napoleon and Prince Schwartzburg, who commanded a portion of the allied army. Pop. about 3,000.

Arc-lamp: See ELECTRIC LIGHT.

Arco'la: a village of Northern Italy; on the Alpone, near its entrance into the Adige; 15 miles E. S. E. of Verona (see map of Italy, ref. 2-D). Here Napoleon gained an important victory over the Austrian general Alvinzy. The French commenced the battle on Nov. 14, 1796, by an attempt to cross a bridge over the Alpone, but were repulsed. The action was renewed on the 16th, and ended on the 17th, when Alvinzy retreated. Pop. 5,259.

Arcola: city on railroad; Douglas co., Ill. (for location of county, see map of Illinois, ref. 6-F); 158 miles S. of Chicago; has a high school, 8 churches, a city hall, electric lights, 2 newspapers, a broom-factory, and 2 tile-factories. Pop. (1880) 1,515; (1890) 1,733; (1900) 1,995.

Arcou, JEAN CLAUDE ELÉONORE LEMICEAU, d': French engineer; b. at Pontarlier, 1733; invented (1780) the celebrated floating batteries for attacking Gibraltar; directed successful operations against several fortresses in Holland; author of *Considérations Militaires et Politiques sur les Fortifications*. D. July 1, 1800.

Arcona: See ARKONA.

Ar'cos de la Fronte'ra: a town of Spain, in Andalusia, on the right bank of the Gaudalete, 30 miles N. E. of Cadiz (see map of Spain and Portugal, ref. 20-D). It is called Arcos, because it is built in the form of a bow. Its site is a high rock, which commands an extensive and beautiful prospect. Here are celebrated manufactures of tanned leather. This town was once strongly fortified. In 1519 Magelhaens started from here for the first circumnavigation of the globe. Pop. 16,280.

Arcot': two districts and a city of Madras presidency, British India; near the southern end of the peninsula, on the east side, just W. of Madras city and Pondicherry. *North Arcot* is between latitudes 12° and 14° N. It is flat and uninteresting in the eastern and southern parts, but the western extends to the foot of the Eastern Ghats, and is agreeably diversified. This part abounds in minerals, especially the ores of copper and iron. Four railways pass through the district. Grain, cotton, sugar-cane, and indigo are largely grown, and cotton-cloth is manufactured. Area, 7,256 sq. miles. Pop. about 2,000,000.

South Arcot lies immediately S. of the preceding, and is similar to it. Both districts are poorly watered, especially in the dry season. Area, 4,873 sq. miles. Pop. about 2,000,000.

Arcot City, also called *Arcuaty*, is the principal town of North Arcot; lat. 12° 54' N., lon. 79° 24' E. (see map of S. India, ref. 6-E). It is a railway station and military cantonment. Arcot was taken by Clive in the middle of the eighteenth century with an inconsiderable force of men. Its siege in 1751 by the natives was a memorable incident in the history of the Carnatic. It became British in 1801. Pop. 50,000.

MARK W. HARRINGTON.

Arctic [Lat. *arcticus*; Gr. ἀρκτικός, belonging to [the constellation of] the Bear (ἄρκτος), which is near the North Pole]: "northern," or, rather, "far to the north," "near the North Pole."

The ARCTIC CIRCLE is a circle drawn around the North Pole of the earth, 23° 27½' from the pole and 66° 32½' from the equator. It forms the boundary between the north temperate and the north frigid zones. Within this circle the sun does not set at the summer solstice nor rise at the win-

ter solstice. The ARCTIC CURRENT is supposed to originate in the ice of the Arctic seas, whence it runs along the eastern shore of Greenland, and round Cape Farewell to the western shore of Greenland, in N. lat. 66°, where it turns southward, forming the *Hudson's Bay Current*. Thence it passes near the Bank of Newfoundland, and, meeting the Gulf Stream, passes beneath it. Other portions follow the eastern coast of North America for various distances, cooling the land, and eventually pass beneath the Gulf Stream. Both at the surface and after descending, the Arctic is a return current, compensating in part for the northward transfer of water by the Gulf Stream.

Arctic Discovery: See POLAR RESEARCH.

Arctic Ocean: the ocean which surrounds the North Pole, washes the northern shores of Europe, Asia, and America, and is nearly coextensive with the Arctic Circle. It communicates with the Pacific by Bering's Strait, and with the Atlantic by a wide passage between Greenland and Norway. The navigation of this ocean is obstructed by perpetual congelation, but it has been supposed that a portion N. of 80° is an open polar sea. The Arctic Ocean incloses many large islands, and comprises large bays and gulfs, which deeply indent the adjacent continents, as Baffin's Bay, the White Sea, and the Gulf of Obi. The water of this ocean is extremely pure and clear, and the ice is remarkable for the beauty and variety of its tints. Those parts of this sea which have been explored are occupied by large fields of floating ice and icebergs in almost perpetual motion. Capt. Ross measured an iceberg which rose 325 feet above the water in which it floated. There are masses that present a front of 200 feet in height, and fields from 10 to 40 feet thick sometimes extend over 100 miles. Icebergs often have a violent rotation, and are dashed against each other with a tremendous force. Fogs, storms, and almost endless night add to the dangers which beset the explorer. Among the navigators who have explored it in search of a northwest passage are Parry, Ross, Sir John Franklin, and Kane. Dr. Hayes and Dr. Hall, and various Scandinavian and Dutch navigators, are among the recent explorers. Parry in 1827 reached lat. 82° 45' N., lon. 19° 25' E., and found there floes of ice, with open water between. In 1854 Kane penetrated to lat. 81° 22' in lon. 65° 35' W. He argued that there is an open sea, not frozen, around the pole. For further details, and for account of later explorations by Nares, Nordenskjöld, De Long, Greely, Peary, etc., see POLAR RESEARCH. There are valuable whale-fisheries in the Arctic Ocean.

Arcturus [from Gr. ἀρκτοῦρος; ἄρκτος, bear + οὔρος, keeper]: a fixed star of the first magnitude in the constellation Bootes. It is situated behind the Great Bear, and may readily be found by continuing the curve of the tail of the Bear. It is designated in catalogues as α Bootis.

Arcuation [Lat. *arcuatio*, from *arcuare*, curve like a bow (*arcus*)]: a mode of propagating trees; the shoots of the trees, cut off near the ground, are bent over and partly covered with earth, which causes them to take root. It is now generally called *inarching*.

Arcueil, ar'-küel': a village of France; 3 miles S. of Paris; on the railway from that capital to Sceaux; has a fine aqueduct constructed by Marie de Médicis; also the remains of a Roman aqueduct built by the Emperor Julian. It is a place of resort on holidays for the Parisians. Pop. (1896) 7,064.

Arcus senilis [Lat., bow of old age]: the hazy zone seen around the outer zone of the cornea with advancing years. It is rarely a complete circle, but may become so in extreme cases. When seen in persons at middle life it is an indication of premature decay or actual disease, being due to fatty degeneration from disease of the blood-vessels, and very probably associated with similar fatty change elsewhere, as in the heart.

WILLIAM PEPPER.

Arey, GROTTO OF: an ancient limestone quarry in France, in the department of Yonne, remarkable for its size and the beauty and extent of its stalactites and incrustations, which have almost completely obliterated all traces of the labor of man.

Ardavan: See ARTABANUS.

Ardebil', or **Ardabil'**: a town of Persia; province of Azerbaijan; on the Karasū; 40 miles from the Caspian; 90 miles E. by N. of Tabriz (see map of Persia, ref. 1-F). It is visited by the trading caravans from Tiflis, Derbend, and

Ispahan. Its salubrity is celebrated, and there are warm mineral springs in the vicinity. Pop. 10,000 to 15,000.

Ardèche, ar-dāsh: a river of France; rises among the mountains of Cévennes, flows southeastward through the most magnificent and romantic scenery, and enters the Rhône a mile from Pont Saint-Esprit, after a course of 45 miles. Near its mouth is a natural curiosity called the Bridge of Arc.

Ardèche: a mountainous department in the S. E. of France; bounded N. by the department of Loire, E. by Drôme, S. by Gard, and W. by Lozère and Haute-Loire, and drained by the Ardèche. Area, 2,136 sq. miles. The surface is diversified by extinct volcanic peaks, deep craters, ranges of basaltic columns, and romantic valleys, forming combinations of scenery which are highly magnificent and picturesque. The valleys near the Rhône produce good wine, olives, figs, almonds, and Spanish chestnuts, the annual crop of which latter is about 400,000 bushels. Mines of copper, iron, lead, antimony, and coal are worked in this department. It is subdivided into three arrondissements. Capital, Privas. Pop. (1896) 363,501.

Arden (commonly written ARDENNES, *q. v.*): a forest in which Shakspeare places the scene of his play called *As You Like It*. There was formerly a forest of this name on the western borders of Warwickshire, which is believed to have occupied a great part of the midland counties, and it is noteworthy as the maiden name of Shakspeare's mother.

Ardennes, or **Arden** (anc. *Arduenna Sylva*): a hilly and densely wooded tract which includes a part of Belgium and of France, and is situated on both sides of the river Meuse. The forest of Ardennes in Cæsar's time was more extensive, and occupied nearly all the space between the Sambre, Moselle, and Rhine. The highest points of the Ardennes are about 2,200 feet above the sea. The predominant rocks are clay-slate, grauwacke, and limestone. The channel of the Meuse presents rugged and precipitous rocks about 600 feet high. Many important military events have occurred among the Ardennes, at Rocroi, Sedan, Mézières, etc. Its chief wealth is in its minerals, wood, cattle, and sheep.

Ardennes: a department in the N. E. of France; bounded N. by Belgium, E. by the department of Meuse, S. by Marne, and W. by Aisne; was part of the old province of Champagne. Area, 2,020 sq. miles. It is intersected by the Meuse, which flows northward, and by the Aisne, which flows westward. The surface is partly hilly, and covered with the forest of Ardennes. The valley of the Aisne is fertile and produces much grain. Among the mineral resources of this department are iron, lead, marble, and slate. The canal of Ardennes, connecting the Meuse and the Aisne, affords facilities for trade. Here are manufactures of glass, metallic wares, woolen cloths, shawls, firearms, earthenware, etc. It is subdivided into five arrondissements. Capital, Mézières. Pop. (1896) 318,865.

Arditi, LUIGI, loo-ee-'jěe aar-dee'těe: musician and composer: b. at Crescentino, Piedmont, Italy, July 16, 1825. He received a musical education at the Milan Conservatory, where he remained six years. Soon after he made his first public appearance as a violinist and conductor in concerts and operatic performances at the small town of Vercelli; was engaged as conductor at the Teatro Re, Milan. In 1846 he went to Havana, and subsequently in company with an opera troupe visited the principal cities of the U. S. In 1856 Arditi returned to Europe and conducted Italian opera in Constantinople, producing Verdi's opera of *Traviata* in that city for the first time; settled in London in 1858 as conductor, first at Her Majesty's theater and afterward at Covent Garden, then managed by Gye and Mapleson. He has also conducted Italian opera in Russia and at Vienna. Arditi's name has been associated professionally with the most famous artists, such as Mario, Grisi, Piccolomini, and Patti. He is principally known as a composer by his opera *The Spy*, produced in New York in 1856, and *Il Bacio*, a waltz song. He frequently visits the U. S. to conduct operatic performances. B. B. VALLENTINE.

Ardmore: village; Montgomery co., Pa. (for location of county, see map of Pennsylvania, ref. 6-J); on Pa. R. R.; 7 miles N. W. of Philadelphia; has several yarn-factories. It has many beautiful private residences and fine roads. Pop. (1880) 519; (1890) 2,205; not returned separately in 1900.

Ardoch: a small village of Scotland, in the county of Perth, 8 miles S. S. W. of Crieff (see map of Scotland, ref.

10-G). Here is an ancient Roman camp, the most entire now in Britain. The intrenched works form a rectangle 500 by 430 feet, the north and east sides of which are protected by five ditches and six ramparts.

Ardovan: See ARTABANUS.

Ardshir', or **Ardsheer'**, BABEGAN: a King of Persia; founder of the dynasty of the Sassanides; a man of obscure origin who raised himself by his courage and energy. He revolted against Artabanus (or Ardovan), King of Persia, whom he defeated and killed. He extended the boundaries of Persia by conquests, and afterward reigned in peace for many years. He was celebrated as a sage and a legislator, and was the author of maxims which are still preserved by the Persians. The Greeks called him Artaxerxes. He died about 260 A. D., and was succeeded by his son Shapur (or Sapor).

Are [Fr., from Lat. *area*, space]: in the metric system of weights and measures, the unit of measure of surface. It is the square of 10 meters = 119·60332 sq. yards. The *are* is not practically employed, the hectare = 100 ares, or 2·47114 English acres, the deciare (one-tenth of an are), and the centiare (one-hundredth of an are), being the only agrarian measures practically used in this system.

A'rea [Lat., orig. an open space, a courtyard, a threshing-floor]: any plane surface. In geometry it means quantity of surface, the surface included within any given lines. The calculation of areas is one of the ultimate objects of geometry, and the measuring units employed are a square inch, a square foot, etc. The area of a rectangle is equal to the product of the length and breadth. That of a circle is found by multiplying the square of the diameter by the decimal ·7854.

Are'ca: a genus of palm-trees having pinnate leaves and double spathes; a fruit which is a one-seeded drupe, or nut, with an outer fibrous husk. The *Areca catechu*, called pinang-palm or betel-nut palm, is a native of the East Indies, and grows to the height of 40 or 50 feet. It bears a fruit called areca-nut or betel-nut, which is astringent and tonic, and is extensively used in the East as a masticatory. (See BETEL.) It also yields a part of the catechu of commerce.

Areci'bo: a port of Porto Rico, Spanish West Indies; on the north side of the island; 45 miles W. of San Juan (see map of the West Indies, ref. 5-J). It is at the mouth of the Rio Arecibo, but is a poor port, being shallow and exposed to the north winds. It is the capital of a province of the same name. Pop. about 11,000.

Are Frode, THORGILSSON: the father of Icelandic (that is, of Scandinavian) history; b. in Iceland in 1067; d. in 1148. Snorri Sturlason, in his *Heimskringla*, says of him that "he was the first man in the north who wrote down in the Norse language narratives of events both old and new"; that "he wrote principally about the first settlements in Iceland, the laws and government, and next of the lawmen, and how long each had administered the law"; and that "he added many other subjects, such as the lives and times of kings of Norway and Denmark, and also of England." Are Frode is the Herodotus of Scandinavian history-writing. See ICELAND.

R. B. ANDERSON.

A'remberg', or **Arenberg**: the name of a noble family of Germany, which adhered to the Roman Catholic Church and to Philip II. of Spain. They own large estates in Hanover and Prussia.

Arenberg, LEOPOLD PHILIPP KARL JOSEPH VON LIGNE, Duke of: b. at Mons, Belgium, in 1690; became a field-marshal in the Austrian army and commander-in-chief in Flanders in 1737; distinguished himself at the battle of Malplaquet in 1709, and at that of Belgrade in 1717. D. in 1754.

Are'na: a Latin word signifying sand; was anciently applied to an open space of ground strewed with sand on which athletes and pugilists contended for mastery, and to the open central part of the amphitheater where gladiators and wild beasts fought. This was usually covered with sand. In modern language *arena* signifies any scene of contest or field of intellectual exertion; any public place in which men display their talents or contend in debate.

Ar'endal: a city of Norway; 41 miles N. E. of Christiansand; on the Cattegat; in lat. 58° 23' N., lon. 8° 53' E. (see map of Norway and Sweden, ref. 12-B). It is partly built on the mainland and partly on islands, giving it the

name of "Little Venice," and has considerable trade in iron and timber. Pop. 5,800.

Arends, LEOPOLD ALEXANDER FRIEDRICH: founder of a famous German system of stenography; b. Dec. 1, 1817, near Milma; removed to Berlin, 1844; d. Dec. 22, 1882. Author of *Introduction to Rational Shorthand* (17th ed. 1888).

Arenicola [literally, sand-dweller; from Lat. *arena*, sand + *colere*, dwell]: a genus of annelids containing the lug-worms. See LUGWORM.

Arens, FRANZ XAVIER: See the Appendix.

Arensberg: See ARNSBERG.

Arensky, ANTON STEPANOVITCH: See the Appendix.

Arenswalde: See ARNSWALDE.

Arent'zen, CHRISTIAN AUGUST EMIL: Danish poet and literary historian; b. at Copenhagen, Nov. 10, 1823. His most important work is *Baggesen og Oehlenschläger: Litteratur-historisk Studie* (8 vols., 1870-78). See his *Recollections (Fra yngre og ældre Dage: Livs-Erindringer)*, 1886.

Areoi: See ARREOY.

Areom'eter, or **Aræometer** [From Gr. *ἀραιός*, thin + *μέτρον*, measure]: an instrument used to measure the specific gravity of fluids and ascertain the strength of spirituous liquors, usually called HYDROMETER (*q. v.*).

Areop'agus (in Gr. *Ἄρειος πάγος*, i. e. hill of Mars): a hill in Athens W. of the Acropolis; also a celebrated court of justice which held its sessions on the same spot in ancient times. This court or council was remarkable for its high character and great antiquity, having been organized before the first Messenian war, the date of which was 740 B. C. It was merely a criminal tribunal before the time of Solon, who made important changes in its constitution, and extended its jurisdiction to political and moral affairs. He ordained that this court should be composed of those archons who had performed their official duties faithfully, and who had passed with credit the scrutiny to which all archons were subjected at the expiration of their term of office. Its influence was conservative, and tended to restrain the excesses or the progress of democracy. The political power of this court was much reduced by Pericles about 458 B. C., but it maintained a high reputation long after that date. The name of the Areopagus occurs in the history of the apostle Paul, who uttered a memorable discourse on Mars Hill. See Acts xvii. 22-31.

Arequipa, a-rä-kee'pa: a department of Peru; bordering on the Pacific Ocean; bounded N. by Ayacucho and Cuzco, E. by Cuzco and Puno, S. by Moquega, and W. by the ocean. Area, estimated at 27,744 sq. miles. The eastern part is mountainous. The soil is fertile, and produces chiefly wine. Gold, silver, zinc, lead, and coal are found here. Capital, Arequipa. Pop. 160,282.

Arequipa: a city of Peru; capital of department of same name: finely situated about 40 miles from the Pacific Ocean, on the river Chili and on the plain of Quilca, 7,850 feet above the level of the sea; lat 16° 24' 28" S., lon. 71° 37' 30" W. (see map of South America, ref. 5-C). It is reputed one of the best built and most beautiful towns of South America. It is the seat of a bishop, and has a cathedral, a college, and several convents. The public edifices and private houses are built of stone, one or two stories high. It has been ruined by earthquakes several times. It has an active trade, facilitated by a railroad which extends from Puno on Lake Titicaca to Mollendo on the Pacific. Gold and silver are found in the vicinity. The adjacent country is fertile. Here occurred a great earthquake, Aug. 13 and 14, 1868, destroying property worth more than \$12,000,000, and said to have caused the death of more than 500 persons. Harvard College observatory has established a station at an elevation of over 8,000 feet near this place, which is exceptionally favorable for astronomical observations. Pop. 35,000.

Arequipa, VOLCANO OF: a volcanic peak of the Peruvian Andes; about 14 miles E. of the city of Arequipa. It rises to the height of 20,300 feet above the level of the sea, and has the form of a regular truncated cone, with a deep crater, from which ashes and vapor continually issue.

A'res (Gr. *Ἄρης*): the god of war in the Greek mythology, corresponding to the Roman MARS (*q. v.*).

Aretæ'us (in Gr. *Ἀρεταῖος*): an able Greek medical writer of Cappadocia; supposed to have lived between 50 and 150 A. D. The events of his life are not known, but he is considered by some persons to rank next to Hippocrates. He wrote a work in eight books on the causes, symptoms, and

cure of acute and chronic diseases, which is still extant and is highly esteemed. The style is singularly elegant and concise. The Greek text has often been printed, and has been translated into English by T. F. Reynolds (1837); Greek with English translation by Dr. F. Adams (1856).

Arethusa (in Gr. Ἀρέθουσα): in classic mythology, one of the Nereids, of whom Alpheus was enamored. Also the name of a fountain situated near Syracuse, into which it is said she was transformed. (See ALPHEUS.) Arethusa was invoked by Vergil as a source of inspiration in his tenth eclogue.

Arethusa: the name of two ancient cities, one on the river Orontes, in Syria, and the other in Macedonia. The Syrian city (now called *Restan*) was rebuilt by Seleucus Nicator, the first King of Syria. Its inhabitants persecuted Marcus, a Christian bishop, who is now honored as a martyr by the Greek Church. The Macedonian city was the site of the tomb of the Greek poet Euripides.

Arethinian Syllables: the syllables *ut, re, mi, fa, sol, la*, which Guido d'Arezzo used to designate his notes in his musical system of hexachords.

Aretno, PIETRO, pee-ā'trō āā-rā-tee'nō: satirical and licentious Italian writer; b. at Arezzo, Apr. 20, 1492. He was the son of a cobbler, and was not liberally educated. He became a resident of Venice in 1527, and found several powerful patrons, among whom were the Emperor Charles V. and Francis I. Among his numerous works were comedies, dialogues, sonnets, and letters (6 vols., 1538-57). He gained by his writings great applause and large sums of money. His satires, which were personal and bitter, procured for him the surname of THE SCOURGE OF PRINCES. His habits were extremely licentious. D. in Venice, Oct. 21, 1556. See P. Chasles, *L'Arélin, sa vie et ses écrits* (1879); Sinigaglia, *Saggio di un studio su P. A.* (1882); Samosch, *Pietro Aretno* (Berlin, 1881).

Aretno, SPINELLO: See SPINELLO DI LUCA SPINELLI.

Aretnus, LÉONARDO BRUNI: b. in Arezzo, the birthplace of Petrarch, of low parentage, in 1369; orphaned at an early age, the precocious boy was educated by the famous Salutato, and the two remained in close companionship until 1405, when Bruni secured the position of apostolic secretary to Pope Innocent VII. In 1410 he was elected chancellor of Florence, with very limited powers, which caused him to resign and to return to the papal court. In 1427 he was again appointed chancellor of Florence with the same prerogatives that Salutato had possessed, and he remained in this office, universally esteemed and admired, until his death on Mar. 9, 1444. He is remembered chiefly for his elegant and justly famous translations of Greek writers into Latin, to which he was inspired by Chrysoloras. Among the best of these may be mentioned the speeches of Demosthenes and Aeschines, the biographies of Plutarch, Plato's *Phædo*, *Gorgias*, *Kriton*, *Apology*, *Phædrus*, and some of the works of Aristotle. See G. Voigt, *Wiederbeleb. des class Alterth.* (i. 309-314; ii. 165-174); J. A. Symonds, *Renaissance in Italy* (ii. 182-186). ALFRED GUDEMAN.

Arezzo, a-ret'sō: a province of Tuscany, Central Italy; bounded on the N. by Florence, on the E. and S. by Perugia, and on the W. by Sienna. Area, 1,279 sq. miles. The country is chiefly mountainous, and is traversed by the rivers Arno and Chiana. The chief town is Arezzo. Pop. (1881) 238,707; (1890) 242,506.

Arezzo (anc. *Arretium*): a city of Italy; capital of the province of same name; on the Chiana; 55 miles by rail S. E. of Florence. It is a very ancient town, having been founded by the Etruscans several centuries before the Christian era. It has two colleges, a seminary, a lyceum, a school of technology, an academy of sciences and arts, and many silk, cloth, iron, and other factories. Among the public edifices are a cathedral, several churches rich in works of art, a museum, and the famous *Loggie* of Vasari. Arezzo is remarkable for the great number of eminent men who were born in it—namely, Mæcenas, Petrarch, Vasari, Pietro Aretno, Guy d'Arezzo, Redi the physiologist, and Cesalpino. Pop. 39,447 (commune). Ancient Arretium was celebrated for the manufacture of terra-cotta vases. The cathedral contains rich sculptures by Giovanni Pisano, and some of the finest glass windows in Italy.

Argæus, Monnt (in Turk. *Arjish-Dagh*): the highest mountain in Asia Minor; in the pashalic of Karamania, about 12 miles S. of Kaisariyeh, and connected with a branch of Mt. Taurus. Its height is 13,100 feet.

Argali (*Ovis ammon*): the large wild sheep of Central Asia and Siberia. A closely related species is the bighorn of the Rocky Mountains (*Ovis montana*).

Argali.

Argand Lamp: a lamp (patented in 1787) invented in 1782 by A. Argand (a Swiss chemist who lived in England; b. 1755, d. 1803), and intended for burning oil. His invention consisted, first, in using a wick in the form of a hollow cylinder, through which a current of air ascends, so that the supply of oxygen is increased, preventing the waste of carbon (which in the old lamps escaped in the form of smoke), thus greatly increasing the amount of light; and, second, in adding the glass chimney, by which a draft is created and the flame is rendered more steady.

Argelan'der, FRIEDRICH WILHELM AUGUST: German astronomer; b. at Memel, Mar. 22, 1799; was a pupil of Bessel. He became in 1823 director of the observatory at Åbo, in Finland, where he made observations for a well-known catalogue of stars. In 1832 he became professor at Helsingfors. In 1837 he was appointed Professor of Astronomy at Bonn. Published a celestial atlas entitled *Uranometria Nova* (1843), and was one of the first to raise the study of variable stars to the rank of a science. His greatest work was a catalogue of all the stars north of the equator, from the first to the ninth magnitude inclusive, the number exceeding 300,000. D. at Bonn, Feb. 17, 1875.

Revised by S. NEWCOMB.

Argemo'ne [through Lat. from Gr. ἀργεμόνη, a kind of poppy]: a genus of plants of the family *Papaveraceæ*. The *Argemone mexicana* is an annual herbaceous plant, with yellow flowers and sinuated spiny leaves, a native of Mexico and the U. S., now naturalized in India, Africa, South America, etc. It has seeds which are emetic and purgative, and have been used as a substitute for ipecacuanha.

Argens, dar'zhan, JEAN BAPTISTE DE BOYER, Marquis d': French writer; b. at Aix, in Provence, June 24, 1704. He served in the army in his youth, and gained distinction by his *Jewish Letters* (*Lettres Juives*, 6 vols., 1738-42), and *Chinese Letters* (6 vols., 1739-42). These procured for him the favor of the Crown Prince of Prussia, afterward Frederick the Great. He went to Berlin, and became an associate of that prince, who after his ascension appointed him director of the Academy of Fine Arts. Among his works is *Histoire de l'Esprit Humain* (14 vols., 1765-68). D. at Toulon, Jan. 11, 1771.

Argenso'la, BARTOLOMÉ LEONARDO, de: Spanish poet; b. at Barbastro, in Aragon, Aug. 26, 1562. Having entered the Church he became a canon of Saragossa, and historiographer of Aragon. He published a number of poems and a *History of the Conquest of the Moluccas* (1609). He and his brother (see below) were called the Horaces of Spain. D. at Saragossa, Feb. 26, 1631.

Argensola, LUPERCIO LEONARDO, de: popular poet; b. at Barbastro, Dec. 14, 1559; was a brother of the preceding. He was appointed historiographer of Aragon by Philip III., and Secretary of State by the viceroy of Naples in 1610. He produced tragedies, entitled *Filis*, *Isabela*, and *Alejandra*; also lyric poems which were very successful. The poems of these two brothers display much similarity. D. in Naples, March, 1613. Bouterwek commends his true poetic feeling, and recognizes in his works an imagination more plastic than creative. See Ticknor's *History of Spanish Literature*; N. Antonio's *Bibliotheca Hispana Nova*.

Argenson, d', dar'zhan-soi': a French family which has produced many men eminent in letters and in public affairs.—MARC RENÉ DE VOYER D'ARGENSON (1652-1721) was a prominent academician and public officer.—His son RENÉ LOUIS, Marquis d'Argenson (1694-1757), was a foreign minister and an author of distinction.—MARC PIERRE, Count d'Argenson (1696-1764), a brother of the foregoing, was an able statesman and a patron of letters.—MARC ANTOINE RENÉ DE PAULMY D'ARGENSON (1722-87), a son of the Marquis René Louis, was an academician and the collector of a famous library.—MARC RENÉ, b. in Paris, Sept. 10, 1771, served as the adjutant of Gen. La Fayette, and fought afterward for the republic. Throughout his life he was a prominent leader of the ultra-republicans. D. in Paris, Aug. 2, 1842.

Argenson, Pierre de Voyer, Viscount d': b. in France in 1626; was governor of Canada in 1657-61, and made some discoveries near Lake Superior and Hudson's Bay. He was of noble ancestry, served honorably at the siege of Bordeaux and the battle of Sens, and was afterward reeve of Touraine. D. in France about 1709.

Argentan: a town in the N. W. of France; department of Orne; on a railway which connects Alençon with Caen; 16½ miles by rail N. N. W. of the former (see map of France, ref. 3-D). It is well built, and has a fine Gothic church and a college; also manufactures of linen, and lace called *point d'Argentan*. Pop. 6,300.

Argenteuil, ar-zhan-tü: a town of France; department of Seine-et-Oise; on the Seine; 11½ miles by rail S. W. of Paris (see map of France, ref. 3-F). Here was a convent to which the celebrated Héloïse retired about 1120. It is now in ruins. Pop. (1896) 15,116.

Argen'teus Co'dex: an old uncial manuscript of fragments of the Four Gospels, written in the Mæso-Gothic dialect on vellum; is so called because the letters are in silver, except the initials. It is supposed that it was written in the sixth century. It is a copy of the translation made by Ulfphilas, Bishop of the Mæso-Goths, was found in the abbey of Werden, Westphalia, in 1597, and is now preserved as the most precious treasure of the University of Upsala, Sweden.

Argentina, aar-gen-tee'nää: the ARGENTINE REPUBLIC.

Argentine [from Lat. *argen'tum*, silver]: a variety of carbonate of lime, having a silvery-white luster.

Argentine: city; Wyandotte co., Kan. (for location of county, see map of Kansas, ref. 6-K); incorporated in 1880, and made a city of the second class in 1890; 4 miles from the mouth of Kansas river, on a level plot of bottom-land, almost surrounded with hills; the main terminal of the Santa Fé system of railroads. The "Argentine smelter" smelts gold, silver, copper, and lead, and employs about 1,000 men. Argentine has street-car lines extending to Kansas City, Mo., and Kansas City, Kan. (4 miles distant), electric lights, fine water-works, and two large grain elevators. Pop. (1890) 4,732; (1900) 5,878. EDITOR OF "REPUBLIC."

Argentine Literature: See SPANISH-AMERICAN LITERATURE.

Argentine Republic [Sp. *La República Argentina*, named from the *Río de la Plata*, i. e. the river of silver, *argentum*]: a South American federal republic; bounded N. by Bolivia and Paraguay, E. by Brazil, Paraguay, Uruguay, and the Atlantic Ocean, S. by the Atlantic Ocean, and W. by the Andes, which separate it from Chile. It extends from lat. 22° to 56° S., and lon. 53° 30' to 72° W. The area, including additions, in 1881, of most of Patagonia and a small part of Tierra del Fuego, is about 1,125,086 sq. miles. The population, including additions from Patagonia, etc., and including the "Federal District," which is practically the city of Buenos Ayres, according to the census of May 10, 1895, is 3,973,626, of whom over 2,000,000 are natives, 280,000 Italians, 100,000 Spaniards, 150,000 French, 40,000 British, 20,000 Germans, besides Uruguayans, Chilians, Swiss, Bolivians, Paraguayans, Portuguese, Asiatics, Africans, Oceanians, etc., in numbers of from 18,300 to about 2,000 each. The area and population of the 14 provinces and 9 territories into which the republic is divided are, according to the latest official reports, as follows:

PROVINCES AND TERRITORIES.	Area in sq. miles.	Pop. in 1895.	Capitals of provinces.
Coast.....	Buenos Ayres... ..	63,000	La Plata.
	Santa Fé.....	18,000	Santa Fé.
	Entre Rios.....	45,000	Paraná.
	Corrientes.....	54,000	Corrientes.
Andes.....	Rioja.....	31,500	Rioja.
	Catamarca.....	31,500	Catamarca.
	San Juan.....	29,700	San Juan.
	Mendoza.....	54,000	Mendoza.
Central....	Cordoba.....	54,000	Cordoba.
	San Luis.....	18,000	San Luis.
	Santiago.....	31,500	Santiago.
	Tucuman.....	13,500	Tucuman.
Northern..	Salta.....	45,000	Salta.
	Jujuy.....	27,000	Jujuy.
Territories.	Misiones.....	23,932	
	Formosa.....	125,612	
	Chaco.....	191,842	
	Pampa.....		
	Río Negro.....		100,000
	Neuquen.....		
Chubut.....	268,000		
Santa Cruz.....			
Tierra del Fuego.			

The chief cities with populations in 1895 are: Buenos Ayres (665,243), Rosario (124,305), La Plata (60,982), Cordoba (54,400), Santa Fé (35,288), Mendoza (28,709), Tucuman (25,000), Salta (20,000), Paraná (18,000), Corrientes (14,000), San Luis (17,827).

Physical Geography.—The country is divided into four regions, viz.: 1, the regions of the Andes, the western boundary; 2, "the Argentine Mesopotamia," situated between the Uruguay and the Parana; 3, the pampas or southern plains; 4, the northern or interior plains which extend far into Bolivia. The characteristic feature of the country, excepting the region of the Andes, is the plain. The true pampas are situated between the Rio Negro and the Rio Salado. About the mouth of the Rio Negro, beyond Buenos Ayres and some distance up the Parana, the ground consists of a fine deposit of sand and clay, which have been washed down from the mountains in the course of time. For hundreds of miles S. and W. of Buenos Ayres not a stone is to be found. In the pampas the principal vegetation consists of grasses, which serve as food for the numerous herds of cattle. In the interior cacti and thorny mimosæ are frequent. Timber trees are not met with. Toward the N. the vegetation becomes extremely varied; along the rivers it becomes luxuriant; the trees, however, are not extraordinarily high. Land capable of being cultivated is found only along the rivers. The strip of country between the eastern branches of the Andes and the Parana is more or less sterile and deserted, and even the western states are partly separated from each other by deserts. Large tracts in the interior are covered by volcanic ashes and pumice-stone. The southern plains are broken by several ranges of hills, some of which stretch 150 miles to the S. and S. W. of Buenos Ayres, and run from S. E. to N. W. Their elevation above the plain never exceeds 300 feet. Parallel to these are the Ventana Mountains, whose highest point is 3,500 feet above the level of the plain. These ranges mostly consist of granite, which in some parts is covered by quartz. In the lower diluvian strata many fossil remains of marine animals occur, which are also found occasionally in the mountains at a height of 14,000 feet. The next higher stratum to the one last mentioned is rich in fossil remains of extinct mammals of an enormous size, which have a striking resemblance to the present mammals of South America and Africa (e. g. the large armadillo, the giant sloth, the mastodon, fossil horses). The mountains, especially the Aconquija Cordilleras, which separate Tucuman from Catamarca, are rich in valuable metals, especially in gold, silver, and copper. In the Famatina range, in the province of Rioja, much iron ore is found. In the Gran Chaco it was ascertained by the expedition of Porter Cornelius Bliss in 1863 that the ground is covered for miles around with iron, which contains about 10 per cent. of nickel. A piece of this, weighing about 1,400 lb., was taken to the British Museum. Up to the present time, however, the republic imports the iron it uses from Europe. In the southwestern provinces extensive coal-fields have been discovered, while sulphur, alum, etc., are found in large quantities in the Andes.

Rivers, Lakes, and Swamps.—Almost all the rivers which come down from the Andes, the southern slope of the central Brazilian ranges, and the heights forming the watershed of Buenos Ayres, unite to form the Rio de la Plata, which has a wider mouth than any other river on the globe. Between the capes San Antonio and St. Mary it has a width of 170 miles; 50 miles farther up stream, at Montevideo, it has narrowed down to 75 miles, and the water becomes fresh. At Buenos Ayres, 150 miles farther up, the low shores can not be seen from the middle of the river. The current can be noticed as far as 100 to 200 miles out in the ocean, although the depth of the river is not very great. Above Montevideo, which is the only good port on it, its navigable channels are so obstructed by sand-banks that vessels of light draught, which go to Buenos Ayres, are compelled to anchor from 6 to 9 miles from the city. Even small boats have such difficulty in getting ashore that the passengers are generally landed by means of wagons with very high wheels. The chief branches of which the La Plata is formed are the Parana (with its affluent, the Paraguay) and Uruguay, which are respectively navigable for steamers for 1,000 and 250 miles. Many of the eastern tributaries, especially the Rio Vermejo and the Rio Salado, are navigable for smaller vessels for 400 to 500 miles. The smaller tributaries coming from the E. are generally unsuited to navigation by reason of their strong currents. Those coming from the Andes, however, slowly wend their

way through the endless plains, and are of the greatest importance for commerce. The rivers of the interior which do not belong to the system of the La Plata are mostly unimportant, as they are lost in swamps or temporary lakes, or entirely dry up in summer. These temporary lakes, lagoons, and swamps are found in great number, and are sometimes of considerable extent. Those to the E. of the Parana and Parana generally contain fresh water, while those W. of these rivers are brackish, almost without exception. Among the former the lake of Ybera in the province of Corrientes is the most important. Those to the W. of the great rivers usually dry up at the end of the rainy season, and leave the ground covered with a crust of saline matter several inches in thickness. The salts are of different kinds. In the plain around Fort Melincue, W. S. W. of Buenos Ayres, sulphates of magnesia are found which yield a profitable article of commerce. Good cooking-salt is found in large quantities S. of Buenos Ayres and in the neighborhood of San Luis.

Climate.—The most prominent characteristic of the climate of the Argentine Republic is extreme dryness. Although the territory W. of the Parana has plenty of rain, still the plains in the interior suffer extremely from drought, because the S. W. winds, being stopped by the Andes, discharge their rain in Chili, and the eastern equatorial winds have already exhausted their rain at the tropic. Buenos Ayres and the country immediately surrounding are often exposed to warm N. winds, which come down the valley of the Parana loaded with vapor. The mean temperature of Buenos Ayres is 64° F.; the mean for the summer 72°, for the winter 52°. In many places a warm and a cool season can be distinguished, the former lasting from October to May, the latter from May to September. The time of the change from one to the other is the chief rainy season. The heavy thunder-storms, sometimes accompanied by hail-storms, often produce very sudden changes of temperature. Nevertheless, the climate is very healthy. This is partly due to the pampero, a strong S. W. wind coming from the Andes. Also the nights, which are cool throughout the year, and which tend to make the heat of the day less felt, contribute much toward this end. In the plains of the interior the hot zonda, the strong and lasting N. wind, is very much dreaded. The republic has a well-organized meteorological service, and its climate has been studied with more care than that of any other South American country.

Animal and Plant Life—Products.—With very few exceptions, the animals of the present day have the same characteristics as the gigantic fossils found in the country, except that they are considerably smaller. The animal peculiar to the plains is the llama. The vicuña, related to the llama, is hunted in the W. Of other wild animals are found the puma, the tapir, the capibara, and the ounce. Among the birds the birds of prey, as the condor and the Caracara vulture, are especially numerous. The American ostrich and different kinds of humming-birds and parrots are also often met with. The vegetation of the plains of the La Plata is poor. Even in Entre Rios the lack of wood is often seriously felt. To the S. clumps of willows are found here and there. But the shores of the Parana are covered with beautiful forests, and both toward the tropics and the Cordilleras the vegetation becomes varied and luxuriant. The most characteristic plants of the Gran Chaco, as well as of the pampas, are mimosas and cacti, and not until the foot of the Cordilleras in Salta and Mendoza is reached are palms and the other ornaments of tropical forests met with. The native plants and animals of these regions are, however, mostly superseded by naturalized species. The apple-tree, which at the present day forms large woods in the S. of Chili and toward the sources of the Rio Negro, has been transplanted by the Indians farther N. on the eastern slopes of the Cordilleras. The peach-tree is largely cultivated on the islands at the mouth of the Parana. A wild species of artichoke and impenetrable thickets of thistles cover the ground for miles to the W. and N. W. of Buenos Ayres. Wine is extensively grown in Mendoza and La Rioja.

Agriculture, Industry, Trade.—It is only in late years that agriculture has been generally introduced, especially in the coast provinces. In the region of the Andes, where the ground is more easily irrigated, considerable wheat, wine, and fruits of all kinds have been produced for a long time. At present wheat, corn, oats, and other grain and vegetables are cultivated on a large scale. Sugar-cane, tobacco (especially in Corrientes and Tucuman, but also in Salta and Catamarca), cotton, peanuts, and flax are also cultivated,

but many of these plants are of comparatively recent introduction. Less than 1 per cent. of the total area is under cultivation. Cattle and sheep breeding, the old national occupation, is much more important than agriculture. The natives had at the time of the discovery no other domestic animal than the llama or guanaco. Mendoza introduced the horse in 1536; in 1550 goats and sheep were brought from Peru; in 1553 the ox was brought from the coast of Brazil. From these importations have descended the millions of cattle which now roam over the plains of the republic. The breeds are almost all good. The sheep have been greatly improved. In recent times the breeders of cattle have suffered considerable losses, as, in consequence of the high tariff of the U. S., they have no market for their products. Wild cattle are no longer to be found. All are inclosed, though often in very large ranges. The large *estancias* of former times are becoming things of the past, and they are cut up more and more into smaller estates. While the price of land has risen considerably (in some places it has doubled within twenty years), the increase of the cattle has been so large that the supply exceeds the demand largely, and manure is made of the unsold meat. About 3,000,000 hides of cattle are exported annually, and in the large slaughter-houses (*saladeros*) 310,700 cattle were killed in 1899. The herds of horses seem to diminish gradually, but are still so large that 250,000 horse-hides are annually exported. The pampa horse is small and of coarse build, but excels in fleetness and endurance. It roams about in herds of 6,000 or 8,000, and is caught by the gauchos with the lasso or the bolas. Mules are raised in large numbers, and are exported to Peru and other places. General industry and manufactures are unimportant in the La Plata states. The manufacture and export of "Liebig's extract of meat" is extensive. Besides this, tanning and the soap manufacture are carried on on a large scale. Valuable embroidered cloths, wearing apparel, gorgeous blankets, and ponchos are made of the finest wool. The Indian women of the S. also make wonderfully fine quilted ponchos, belts, horse-blankets, and harness. A laborer is paid from \$1 to \$3 in gold per day.

The commerce with the interior is unimportant: that with Chili and Bolivia is of more consequence. To these countries oxen, mules, and asses are exported in large numbers. The commerce by sea is about twenty times as large as that by land. It is limited almost entirely to Buenos Ayres and Rosario. The river-ports, Santa Fé, Parana, Corrientes, Gualeguay, Concepcion, and Concordia, supply themselves from Buenos Ayres. The inland trade is to a great extent carried on by caravans of thirty or forty wagons. The articles of export are, besides those obtained from the herds of cattle, horses, and sheep, chiefly ostrich feathers, Patagonian and artificial guano, furs, honey, copper, gold and silver bars. The development, however, of the vast resources of the country can as yet hardly be said to have commenced. Its greatest wealth is still represented by the herds of cattle and sheep which graze upon its plains. The manufactures and luxuries imported into the country are paid for with the proceeds from the flocks. The total exports amounted in 1899 to \$185,000,000, and the imports to \$117,000,000, both in gold dollars. The number of vessels entered in 1898 was 10,198, of 6,555,128 tons, of which 6,866, of 5,928,765 tons, were steamers, and 3,332, of 626,363 tons, sailing vessels. Of the exports 48 per cent. were animals or their products, 23 per cent. agricultural produce, 9 per cent. manufactures, and only $\frac{1}{10}$ of 1 per cent. mineral products.

In 1897 the post-office carried 110,217,576 letters and 80,289,287 newspapers and other packets. The length of railway in 1898 was 9,885 miles, carrying 16,044,389 passengers and 9,001,559 tons of freight. In 1898 there were 25,345 miles of Government telegraph line. A submarine telegraph from Buenos Ayres to Montevideo has been in operation since 1866. Buenos Ayres has now complete communication with Europe by telegraph.

Inhabitants.—The native tribes are divided into three different groups: 1, the Araneanians, who are found as far N. as the Rio Salado; 2, the Quichnas, who were formerly subject to the Incas of Peru, and spread E. of the Cordilleras as far as Santiago; 3, the Guaranis, who formerly ruled the Rio de la Plata region. These races were among the most civilized of the aborigines when first found, and have blended somewhat (the Guaranis especially) with the Spaniards, this mixed race constituting the larger part of the indigenous population of the republic. The number of the foreign-born population is very large. The number of im-

migrants amounted in 1888 to 155,632; in 1889, 289,014; in 1890, 138,407; in 1898, 95,190. Most of the immigrants are from Spain, France, and Italy.

Manners and Customs.—In Buenos Ayres, where the foreign population gains the ascendancy more and more, European dress and manners have been rapidly naturalized. The lower classes, which are chiefly mestizoes and half-breeds, combine the inclination of the higher classes for gaming and a dissolute life with the plain and rough mode of living of the gaucho of the pampas. The gaucho wears a jacket of coarse cloth or sheepskin, and pantaloons of the same stuff, which are open from the knee down. His poncho is a square piece of cloth with an opening in the middle for the head. His ornaments consist of spurs with large silver rowels, and a large knife, with the handle inlaid with silver, which is carried in the belt. The women are dressed almost exactly like the men, only they have the neck and arms bare. The rancho or hut of the gaucho consists of a trellis-work of brushwood, which is covered with mud. The roof is covered with straw or cow-hides, and in the place of a door is a horse-hide. The food of the gaucho consists almost entirely of meat and water. From 1850 to 1860 there was 1 marriage for every 140 inhabitants, 1 birth for every 22, 1 death for every 44, and 5 children for every family; one-fifth of all the children are illegitimate. The mean length of life in the country and the smaller cities is 40 years. Since 1780 the population has almost quadrupled itself. The predominating religion is the Roman Catholic; Protestants are only found among the immigrants. Under the Archbishop of Buenos Ayres are the Bishops of the Littoral (with his seat in Parana), of Cordova, of Cuyo (San Juan), and of Salta. There are very few monasteries, but a large number of nunneries. Since the accession of President Sarmiento much has been done to improve the education of the people. In 1887 there were 3,028 elementary schools with 6,241 teachers and 227,450 pupils; there were in 1885 15 lycées with 369 professors and 3,189 pupils; also 2 universities, a school of mines, 2 colleges of agriculture, a naval and a military school, 15 normal schools for females and 6 for males, a national observatory, a national museum, and a meteorological bureau. In 1886 the general Government and the 14 provinces contributed \$3,467,240 to the support of elementary education. In 1869 Congress passed a law that the new civil code (*codigo civil*) compiled by Dr. Sarsfield, at that time Minister of the Interior, was to be introduced throughout the whole republic on Jan. 1, 1871.

Constitution.—The constitution was adopted May 11, 1853, and was revised in 1860 and 1862. This is now nearly identical with that of the U. S. At the head of the republic is a President, elected for a term of 6 years by representatives of the 14 provinces. Congress consists of a House of Deputies with 86 members, and a Senate with two members for each province and the capital. In 1862 Congress transferred the seat of government to Buenos Ayres, and introduced several clauses into the constitution with regard to the relations of the city to the Confederation. The province of Buenos Ayres elects its own governor, but the city is under the direct jurisdiction of the President and Congress. The judiciary is entirely independent. There are a supreme court and tribunals in every state. The freedom of the press, of association, of education, and free disposition of property, as well as equality before the law, is guaranteed to everybody. The "provinces" are really states. The Roman Catholic religion is recognized in the constitution as that of the state, but all creeds are tolerated.

Army, Navy, and Finances.—The army consisted in 1891 of 1,129 officers with 789 artillery, 2,227 horse, and 2,331 foot. The militia comprises 236,000 men, besides 68,000 reserves. The navy includes several modern-built and ironclad vessels, and has 1,530 officers and men. In 1899 the financial position was as follows: Debt, \$449,680,000; revenue, \$107,096,000; expenditure, \$134,123,671. The paper dollar, which forms a large part of the currency, was worth 27½ cents in gold. A law of national banks similar to the banking law of the U. S. was published Nov. 3, 1887.

Weights and Measures.—The metric system is established by law, but the old Spanish weights and measures are still in use.

History.—The La Plata was discovered by Juan Diaz de Solis in 1516, who took possession of the country for the crown of Spain. Buenos Ayres was founded by Don Pedro de Mendoza, who became governor in 1535. The city was not, however, firmly established against the attacks of the

Indians until after its third rebuilding in 1580, and after Santa Fé, Mendoza, and other cities in the interior had been founded. The government of the countries of the La Plata was subject to the Viceroy of Peru until 1778, in which year a vicerealty was formed of the provinces of Rio de la Plata, Paraguay, Uruguay, and Bolivia, with Buenos Ayres as its capital. After 1806–07 Buenos Ayres and Montevideo were for a short time in the hands of the British, who, however, were not able to hold them. Soon after liberal ideas began to gain ground. The viceroy was expelled, and on May 25, 1810, a *junta gubernativa* was installed. Cordova, Paraguay, and Uruguay, however, did not recognize this junta, and a long succession of civil wars ensued. Soon after the districts in the interior also joined the Confederation. In 1813 a constituent assembly met in Buenos Ayres, the Spanish flag was given up, and the republic issued its own coin. In the previous year Montevideo, which had remained longest connected with Spain, had been taken. In 1816 the representatives of all the provinces assembled in congress at Tucuman, declared the La Plata states independent, and appointed Gen. Pueyrredon dictator of the republic. The Spanish troops were severely defeated at Chacabuco in 1817, and at Maypu in 1818. The last and decisive victory was gained in 1821. In the meanwhile the republic was the scene of serious encounters between several ambitious leaders. In 1825 the "Unitarians" (who favored a strong central government) succeeded in restoring unity and established a new constitution. But Rivadiva was their only President. Juan Manuel de Rosas, the leader of the gauchos, in connection with other malcontents, forced him to resign, and caused Dorrego to be elected governor of Buenos Ayres. After a counter-revolution under Lavalle, which was for a time successful, Rosas was elected governor in 1826, in which position he remained for six years. In 1835 he declined a re-election, but accepted the position of dictator of the republic with unlimited powers, which he held until 1852. During this entire period Congress did not assemble. The civil wars nevertheless continued uninterruptedly. The independence of Uruguay, which had assumed the title of "República Oriental del Uruguay," had been recognized in 1828. But Rosas did not relinquish his plans. He assisted Governor Oribe, while France took sides with his rival, Rivera. Peace was concluded in 1840, but in 1845 new difficulties arose, which led to an armed intervention of France and England. They blockaded Buenos Ayres and occupied the island of Martin Garcia, but were compelled to recall their fleets the next year. The provinces of Corrientes and Entre Rios seceded from Rosas soon after, and on Feb. 3, 1852, he was defeated by the united forces of Brazil, Uruguay, Paraguay, and Urquiza, the head of the opposition, in the battle of Monte Caseros, in consequence of which he was compelled to fly to England. After a short administration of Vincente Lopez, Urquiza declared himself President, and recognized on June 23, 1852, the independence of Paraguay. In September another revolution took place, and Buenos Ayres resolved to secede from the Confederation. In the meanwhile Congress had adopted a new constitution (May, 1853), and Urquiza was elected President. Buenos Ayres remained independent, but consented to the conclusion of two treaties in Dec., 1854, and Jan., 1855. The attempts at a reunion were not suspended, but several difficulties caused the suspension of the treaties. A war followed, and Buenos Ayres was defeated. Urquiza gained a victory at Cepeda on Oct. 23, 1859, and by the treaty of peace of San José de Flores of Nov. 10, 1859, and the union of Parana, Buenos Ayres again entered the Confederation. In 1861 new difficulties arose on account of taxation, and Gen. Mitre completely defeated the federal troops on the Pavon (a small tributary of the Parana) on Sept. 17, 1861. The President, Santiago Derqui, resigned in consequence of this, and Gen. Mitre was appointed President *pro tem.*, with the direction to call a Congress on May 25, 1862, at Buenos Ayres. Mitre was elected President of the reunited Confederation on Dec. 14 of the same year. In 1866 great dissatisfaction arose in several provinces in consequence of the war with PARAGUAY (*q. v.*). In several places, as Mendoza and Catamarca, serious disturbances arose, which were secretly encouraged by Peru, Chili, and Bolivia. In 1867 the disturbance, under the command of Videla, began to assume serious proportions in Mendoza, and even extended to La Rioja and San Juan. Gen. Pannero, although not till Mitre had joined him with 4,000 men, completely defeated the insurgents, and triumphantly entered Mendoza on May 14. Both houses of Congress passed a resolution to transfer the seat of government to Rosario, which was, how-

ever, vetoed by the President. In 1868 Sarmiento was elected President for a term of six years. Since that time the country has been rapidly increasing in prosperity. In 1870 a rebellion broke out in Entre Rios, at the head of which was Gen. Lopez Jordan, a son-in-law of Urquiza. This old patriot was murdered by the rebels in his palace at San José. The rebellion, although rapidly gaining, was opposed by almost all the other states. On Sept. 23 Jordan was completely routed at Santa Rosa, and lost all his infantry and artillery. In April, 1871, he was again completely defeated, and the rebellion was suppressed. In Mar. and Apr., 1871, the city of Buenos Ayres was visited by the yellow fever, and suffered terribly from its ravages. The citizens and the Government did their utmost to prevent its spread, but still the total of its victims was found to be 13,403—a figure which, although large, was still considerably below the estimate made by the press. In Feb., 1872, a revolution broke out in Corrientes, which, however, was soon ended. In Entre Rios, Lopez still continued to agitate in secret, but without success. On Jan. 1, 1872, a band of gauchos, under a Bolivian fanatic calling himself a *Dios medico* (God physician), entered the town of Tandil, and crying "Death to the Masons and Gringos!" massacred thirty-five persons. They were afterward captured; fourteen were put to death, fifteen imprisoned, and the *Dios medico* was shot by the populace.

In April, 1872, Gail Jordan was reported to be on the frontier of Brazil, at the head of 2,000, intending to revive the dream of Artigas and Urquiza concerning the establishment of an independent republic, to consist of the Argentine provinces of Corrientes and Entre Rios and the republic of Uruguay. At the beginning of the year the border provinces had to suffer from a new invasion of the Araucanian Indians under their chief Calfucura. In May, 1873, the province of Entre Rios was once more invaded by Lopez Jordan. Dr. Avellaneda became President in 1874, and served six years; in Sept., 1880, Gen. Roca was elected President, after another rebellion; Dr. Miguel Juarez Celman was elected President for six years, June 13, 1886. By treaty with Chili in 1881, all the country E. of the eastern crest of the Andes, including most of Patagonia and a small part of Terra del Fuego, was conceded to the Argentine Republic.

The enormous issues of paper money, and the improvidence and mismanagement of the administration of President Celman, caused a revolution, which began July 26, 1890. It began among the troops, was favored by the Unión Civica, a party opposed to financial excesses, and was soon joined by the navy. The fighting lasted several days, and President Celman remained master of the field, but public opinion forced him to resign on Aug. 5, 1890. Gen. Pelligrini, the Vice-President, became President on Aug. 9, and public confidence was restored. In Oct., 1891, the old National Bank was placed in liquidation, and a new bank was created with a capital of \$50,000,000. The financial crisis involved among other disastrous consequences the failure of the celebrated banking-house of Baring Brothers, London. Dr. Saenz Peña succeeded President Pelligrini in April, 1892. His administration was marked by several serious revolutions, and on Jan. 22, 1895, he was forced to resign, and was succeeded by Z. S. Uriburu. Gen. Julio A. Roca was inaugurated President, Oct. 12, 1898. The western boundary is a source of constant dispute with Chili, and in 1893, 1896, and 1898 almost led to war between these countries. By mutual agreement, Sept. 22, 1898, the question was submitted to the arbitration of the British Government.

LITERATURE.—Compare, besides the works of Nuñez, King, Mansfield, and Page, André's *Buenos Ayres und die Argentinischen Provinzen* (1856); Mannequin's *Les provinces argentines et Buenos Ayres* (1856); De Moussy's *Description géographique et statistique de la Confédération Argentine* (1861 and 1864); Burmeister's *Reise durch die La Plata Staaten* (1861); Ford's *La République Argentine* (1867); Trelles's *Registro Estadístico* (1867); L. Beck Bernhard's *Le Rio Parana, etc.* (1865); Mouchez's *Nouveau Manuel de la navigation dans le Rio de la Plata, etc.* (1865); Schnepf's *Mission Scientifique dans l'Amérique du Sud* (1864); the *Annales del Museo público de Buenos Ayres*, published yearly by Burmeister since 1864; Dominguez's *History of the Argentine Republic*, translated by G. Williams (1866); M. G. and E. T. Mulhall's *Handbook of the River Platte* (1869); Wappäus's *Argentinische Republik*, in Stein and Hörchelmann's *Handbuch der Geographie und Statistik* (7th ed. 1863-70); Hudson, *The Naturalist in La*

Plata (London, 1892); Turner, *Argentina and the Argentines* (1892); and Brackebusch's map (1891). Also, reference can profitably be made to the Argentine official publications, which are numerous and valuable; to the numerous Consular Reports; and to the *Handbook of the Bureau of American Republics* (2d ed. Feb., 1891). See also the article SPANISH-AMERICAN LITERATURE.

MARK W. HARRINGTON.

Ar'ges: a genus of small fishes of the family *Siluridae*, said to be thrown out sometimes from some South American volcanoes (16,000 feet or more above the sea-level) with hot, muddy water. One species, now called *Arges cyclopus*, has been described by Humboldt.

Argillite: See SLATE.

Ar'gives, or Argi'vi: the inhabitants of Argos and of Argolis, a state of ancient Greece. The name was also used by Homer and other ancient authors as a generic appellation for all the Greeks.

Ar'go: an extensive southern constellation named after the ship of the ARGONAUTÆ (*q. v.*). It is usually divided into four: Argo, Argo in Carina (in the keel), Argo in Puppi (in the stern), and Argo in Velis (in the sails). Canopus belongs to this constellation, part of which is invisible in our latitude.

Ar'gol: crude tartar; a salt which is deposited by wine in crystalline crusts on the interior of vats, barrels, and bottles. Being less soluble in alcohol than in water, the increasing proportion of alcohol during fermentation causes it to separate. It consists chiefly of potassic bitartrate, $\text{KHC}_4\text{H}_4\text{O}_6$, but contains also variable quantities of calcic tartrate, coloring, and mucilaginous matter. It is purified by solution in hot water, clarification by the addition of clay, and recrystallization. By repeating the process it becomes white, and is then sold under the name of *cream of tartar*, and extensively used in connection with sodic bicarbonate for raising bread. Cream of tartar is shamefully adulterated with gypsum, flour, etc., many samples containing two-thirds or more of such fraudulent admixtures. Argol is used for the preparation of tartaric acid, Rochelle salt, and potassic carbonate, or *salt of tartar*.

Ar'golis (Gr. Ἀργολίς): a state of ancient Greece, in the N. E. part of the Peloponnesus (Morea), bordering on the sea. It consists partly of a peninsula between the *Saronicus Sinus* (Gulf of Ægina) and the *Argolicus Sinus* (Gulf of Nauplia). It was bounded on the S. by Laconia and on the W. by Arcadia. The surface is diversified by mountains, which are about 5,000 feet high. Near the sea is the large plain of Argos, which is rendered unhealthy by marshes. Argolis was one of the most famous and powerful states of ancient Greece, and was the scene of many memorable events or myths in the heroic ages. Here Hercules was born, and the descendants of Pelops reigned. The inhabitants were called ARGIVES (*q. v.*). The chief towns were Argos, Mycenæ, Epidaurus, Hermione, Sicyon, and Trœzene, each of which was a separate kingdom. ARGOLIS AND CORINTH is the name of a nomarchy of modern Greece. Area, 1,447 sq. miles. Pop. (1889), 144,836. Capital, Nauplia.

Argon: a gas, somewhat heavier than nitrogen, found in the air in 1894 to the extent of less than one per cent. by Lord Rayleigh (see STRUTT) and Prof. Ramsay. It can be obtained (1) by passing air over heated copper, which combines with the oxygen, and then over heated magnesium, which combines with the nitrogen, leaving the argon; (2) by mixing air with oxygen, and passing electric sparks through the mixture contained in a vessel over an alkali. Its most marked property is its inactivity, to which it owes its name. It is not known whether it is an element or not. I. R.

Argonaut: a mollusk of the genus *Argonauta* and class *Cephalopoda*; commonly called "paper nautilus." The latter name is derived from the fragile nature of the boat-like shell in which the argonaut floats on the surface of tranquil seas. The shell is not chambered like that of the true nautilus, but has one spiral cavity, into which the animal can retire and be completely hidden. There is no organic connection between the body of the animal and its shell; the latter being formed as a secretion from the two broadly expanded dorsal arms, and thus not comparable to the shell of other mollusks. The shell is formed in the female only, and is for the purpose of protecting the eggs. Several species of *Argonauta* are known. They have eight arms, two of which are expanded into broad membranes. The latter were formerly believed to be sails, and the other arms were regarded as oars; but, though the fable is perpetuated

by the poets, it has long been known that the animal really propels itself by ejecting water from its funnel. It is a

Argonaut within its shell.

pelagic form, coming to the surface during the breeding season, at other times living on the bottom.

Revised by DAVID S. JORDAN.

Argonau'tæ (Gr. Ἀργοναῦται, i. e. the sailors of the Argo), in English **Ar'gonauts**: the famous Greek heroes who, according to tradition, lived before the Trojan war, and acquired celebrity by an adventurous navigation of unknown seas. This is the most ancient voyage of discovery mentioned by classic poets or historians. They derived their name from the ship Argo, in which, under the command of Jason, they performed the expedition to Colchis, on the Euxine, in order to recover the Golden Fleece, which was guarded by a sleepless dragon. Among the Argonauts were Hercules, Theseus, Castor, Pollux, and Orpheus. In the course of the voyage they landed at several points and passed through many perilous adventures. Among the obstacles which they encountered were the enmity and treachery of Æetes, King of Colchis, but they were aided by his daughter Medea, a powerful sorceress, and finally carried off the Golden Fleece.

Ar'gos: an important city of ancient Greece; situated in Argolis; about 3 miles from the *Argolicus Sinus*, or Gulf of Nauplia. It was considered the oldest city of Greece, and was supposed to have been founded by Inachus, the father of Io, about 1500 B. C. It was a famous city in the heroic age, and at the time of Trojan was the capital of Diomedes. Argos was the head of a league of Doric cities before Sparta acquired the supremacy in the Peloponnesus. Its site is occupied by a small modern town of the same name, 6 miles N. N. W. of Nauplia. Here are remains of ancient cyclopean structures, among them those of the theater and an extensive aqueduct.

Argos: town; Marshall co., Ind. (for location of county, see map of Indiana, ref. 2-E); situated at junction of Erie and Western and N. Y. C. and St. L. R. Rs.; 8 miles from Plymouth. Furniture, flour, and lumber are here manufactured. Pop. (1880) 622; (1890) 1,101; (1900) 1,307.

Argot, ar'gō: a word of uncertain derivation, applied in France to a peculiar language or gibberish invented for purposes of concealment by those whose pursuits make them dread the arm of the law. In all the countries of Europe a language of this kind prevails, and has prevailed perhaps to some extent from immemorial time. In England it is called "thieves' Latin," "St. Giles's Greek," "peddler's French," "flash," and other names; in Italian, "zergo" (or "gergo") and "furbesco" (from *furbo*, a rogue); in Spanish, "Germania"; in Germany, "Rothwelsch" or "Rothwälsch." An able French writer, M. Nodier, remarks that "argot, a language invented by thieves, often sparkles with imagination and wit." The following examples may serve to illustrate the truth of the foregoing remark: *Apôtre* ("apostle") applied to the fingers, because they are "sent forth." *Sans feuille* ("without leaf"), the "leafless" tree—that is, the "gallows." *Epouser la veuve* (to "marry the widow"), to "be hanged"; implying that those who had previously been joined in the same marriage were deceased. *Aspic*, (an "asp," or poisonous serpent), a "slanderer." *Sancho Panza*, "justice of the

peace," in allusion to Sancho Panza having been under Don Quixote magistrate of the isle of Barataria. *Sanglier* (a "boar," an animal having long teeth), applied to priests, in allusion to their frequent fasting; the phrase "having long teeth" was equivalent to "being very hungry." Sometimes the principle on which the word (in argot) is formed is a mere resemblance of sound: thus *arsenic* is used for "arsenal." In a somewhat similar manner *solir* is used for *ventre* ("belly"), because *sollir*, "to sell," in argot signifies the same as *vendre*, which resembles *ventre* in sound. Considerable attention has of late years been paid to the study of argot. Francisque Michel has written a large volume on argot (Paris, 1856), which is said to be by far the most complete work on the subject. Several distinguished novelists, including Bulwer, Dickens, and Victor Hugo, have introduced frequent specimens of this language into their works; it may suffice to refer the reader to *Pelham*, *Paul Clifford*, *Oliver Twist*, and *Les Misérables*.

Argout, ANTOINE MAURICE APOLLINAIRE, Count d' (an-twan mō-rēs' a-pol-in-âr dar-goo'): b. at Veissilien (Isère), Sept. 27, 1782. He became prefect of Gard in 1817, and a peer of France in 1819. In July, 1830, during the revolution, he negotiated between the popular party and the king, from whom he obtained concessions, but it was then too late. He was appointed Minister of Commerce in 1831, Minister of the Interior in 1833, and governor of the Bank of France in 1834. He retained that office many years. D. in Paris, Jan. 15, 1858.

Arguelles, ar-gwel'yēs, AUGUSTIN: a liberal Spanish statesman; b. at Ribadesella in the Asturias, Aug. 28, 1776. He was elected to the Cortes, and was a member of the committee which produced the liberal constitution of 1812. He gained distinction as an orator, and became very popular with the liberal party. On the restoration of Ferdinand VII., in 1814, he was imprisoned for several years, but was released by the revolution of 1820. He was Minister of the Interior for several months in that year, and was an exile from 1823 to 1832. After that date he was a leader of the moderate party in the Cortes, and in 1841 was appointed tutor to the young Queen Isabel. D. in Madrid, Mar. 23, 1844. See Evaristo San Miguel, *Vida de D. A. Arguelles* (1850).

Ar'gument: a reason offered for or against a proposition, opinion, etc.; a series of reasonings; a debate or disputation. In logic, an expression in which, from something laid down as granted (i. e. the premises), something else (i. e. the conclusion) is to be deduced. "Socrates," says Addison, "introduced a catechetical method of arguing. He would ask his adversary question upon question, until he had convinced him out of his own mouth that his opinions were wrong. . . . Aristotle changed this method of attack, and invented a great variety of little weapons called syllogisms. As in the Socratic way of dispute you agree to everything which your opponent advances, in the Aristotelic you are still denying and contradicting some part or other of what he says. Socrates conquers you by stratagem, Aristotle by force. . . . When our universities found there was no end of wrangling this way, they invented a kind of argument which is not reducible to any mode or figure in Aristotle. It was called the *argumentum basilinum* (others write it *bacilinum* or *baculinum*), which is pretty well expressed in our English word *club-law*. When they were not able to confute their antagonist, they knocked him down." (*Spectator*, No. 239.) In the tables used in the exact sciences, the term *argument* signifies the leading numbers, or quantities, arranged in order at the top or sides to guide to the tabular number sought.

Argumen'tum ad Hom'inem (i. e. an argument [applied] to [the particular] man [one is addressing]): an argument derived from the principles or conduct of an antagonist, or an appeal to the prepossessions or prejudices of a person to whom the argument is addressed.

Ar'gus (in Gr. Ἄργος): a fabulous personage who, according to an ancient Greek legend, had a hundred eyes, some of which were always awake. Having been employed by Juno to guard the heifer into which Io was transformed, he was killed by Hermes. Juno is said to have transferred his eyes to the tail of her favorite bird, the peacock. Another mythical Argus was King of Argos, and a son of Jupiter and Niobe.

Argus (named in allusion to the Argus of the Greek mythology, having a hundred eyes): a genus of gallinaceous birds remarkable for rich and brilliant plumage. The best

known species is the *Argus argus*, commonly called argus-pheasant. It is a native of Sumatra and other parts of the

Argus pheasant.

East Indies, and is about equal in size to a common barn-door fowl. Two of the tail-feathers of the male are about 4 feet long. The name argus is given in reference to the beautiful circular eye-like markings which adorn the plumage of the male, especially on the secondaries of the wings.

Argyle, or Argyll, DUKES OF: Marquesses of Lorne and Kintyre, Earls of Campbell and Cowal, Viscounts of Lochow and Glenilla, Barons of Inverary, Mull, Morven, and Tiry (1701), Earls of Argyll (1457), Barons Campbell (1445), Barons of Lorne (1470, in Scotland), Lords Sundridge and Hamilton (1766, in Great Britain).

Argyle, ARCHIBALD CAMPBELL, Marquis of: Scottish peer; b. in 1598; son of the seventh Earl of Argyle. In the civil war he fought against Charles I., and was a leader of the Scottish Covenanters. He was defeated in battle by Montrose in 1644. An adherent of Charles II., he took arms for him against Cromwell in 1651. After the restoration of 1660 he was convicted of submission to the usurpation of Cromwell, and was beheaded in Edinburgh, May 27, 1661.

Argyle, ARCHIBALD CAMPBELL, ninth Earl of: eldest son of the preceding; noted for his loyalty to the royal family, notwithstanding the fact that his father was a leader of the Covenanters. He fought for Charles II. at Dunbar in 1650, and when the Commonwealth was established he was imprisoned and was carefully watched till the Restoration. The estate of his father was restored to him, with the title of earl in 1663. When he took the test-oath, which was exacted in 1681, he added the phrase: "So far as consistent with the Protestant faith." For this offense he was imprisoned, tried for high treason, and condemned to death. The execution of the sentence being suspended, he escaped from prison, and, after remaining concealed for a while in London, fled to Holland, where he remained until the close of the reign of Charles II. He returned with a small body of armed men to Scotland on the accession of James II., to aid in the rising of the Duke of Monmouth, and was captured, and beheaded in Edinburgh, June 30, 1685.

Argyle, or Argyll, GEORGE DOUGLAS CAMPBELL, eighth Duke of: b. in Ardeneaple Castle, Dumbartonshire, Apr. 30, 1823; succeeded his father, the seventh duke, in 1847, before

which he was styled the Marquis of Lorne. He published in 1848 *Presbytery Examined*, in which he defends the Presbyterian system against prelacy. Having entered the House of Lords, he supported the Liberal party, and distinguished himself by his oratorical ability and soundness of judgment. He became Lord Privy Seal in 1852, and Postmaster-General in 1855. When the Tories obtained power in 1858 he resigned office, but he was reappointed Postmaster-General and Lord Privy Seal in 1860. In 1866 he published a philosophical work called *The Reign of Law*, one of the ablest of recent works advocating a theistic view of creation. He resigned with his colleagues in June, 1866, but was Secretary for India 1868-74; again was appointed Lord Privy Seal under Gladstone 1880, but resigned 1881 because of his differences with his colleagues on the Irish Bill. He married Elizabeth Gower, daughter of the Duke of Sutherland (d. 1878); married in 1881 the widow of Col. A. H. A. Anson. D. Apr. 24, 1900. His eldest son, the Marquis of Lorne, married H. R. H. the Princess Louise, daughter of Queen Victoria (1871), and was Governor-General of Canada 1879-83.

Argyle, JOHN CAMPBELL, second Duke of: b. Oct. 10, 1678; fought under Marlborough in 1706 in Flanders; defeated the Jacobites at Dumblane, Scotland, 1715; made an English peer 1718, with the title Duke of Greenwich. D. Oct. 4, 1743.

Argyle'shire, or Argyll (Gaelic, country of the Gael): a large county of Scotland; bordering on the Atlantic Ocean. It is bounded on the N. by Inverness-shire, E. by Perthshire and Dumbarton, S. and W. by the sea. It includes the islands of Mull, Islay, Jura, Tiree, Coll, Iona, Lismore, Colonsay, etc. Area, 3,270 sq. miles. The surface is rugged and mountainous, and presents some of the grandest and most picturesque scenery in Scotland. The highest peaks are Bidean nam Bian, 3,760 feet, and Ben Cruachan, 3,668 feet. The rocks which predominate here are granite, mica-slate, trap, limestone, and quartz. Long arms of the sea, called Loch Linnhe and Loch Fyne, extend into this county, which also contains Loch Awe, a fresh-water lake. The chief occupation of the farmers is the raising of cattle and sheep. The land is owned by a few proprietors, among whom are the Duke of Argyle and the Marquis of Breadalbane. Inverary and Campbellton are chief towns. Pop. (1901) 73,166. The United Diocese of Argyle and the Isles (Scottish Episcopal Church) comprises the counties of Argyle, Bute, part of Inverness, and the Hebrides. The see of Argyle was founded A. D. 1115, that of the Isles A. D. 1838.

Ar'gyro-Cas'tro (in modern Gr. *Arguron-Kastron*; Turk. *Ergree-Kastree*): a town of Albania, on the river Deropuli, 50 miles N. W. of Yánina (see map of Turkey, ref. 4-B). It is built on the steep declivity of a mountain. The best Turkish snuff is manufactured here. Pop. 11,000.

Argyrop'ulos, JOHANNES: b. in Constantinople in 1416; went early to Italy, where he contributed much to the revival of letters. He taught the Greek language and literature and Aristotelian philosophy at Padua 1434-56, Florence 1456-71, and Rome, where he died in 1473. Palla Strozzi, Politianus, and Reuchlin were among his disciples. He became a master of the Latin language, and translated several of the works of Aristotle directly from the Greek, thus finally displacing the mediæval translations which had come through the Arabic. Revised by A. R. MARSH.

Ari the Wise (Old Norse, *Ari Fróði*): "the father of Icelandic history"; b. in Iceland in 1067. He was a "goði" (chief), and was also in holy orders. Three works of his are mentioned: *The Book of Kings* (Konungabók), the *Book of Settlements* (Landnámabók), and the *Book of the Icelanders* (Íslendingabók). No one of these has come down to us in its original shape, and the *Book of Kings* is by many thought to be altogether lost, though Vigfússon holds that parts of it are preserved in the writings of Snorri Sturlason. The *Landnámabók*, which gives a record of the settlers of Iceland and of their descendants, is, in its present condition, the work of several hands; but the essential part of it is the work of Ari. It is a remarkable monument of genealogical labor. The *Book of the Icelanders* is preserved only in the form of an abstract. The *Kristni Saga*, a history of the conversion of Iceland, has also been ascribed to Ari. Ari is remarkable for his acumen and his power of historical criticism in an inaccurate and altogether uncritical age. His style served as a model for later Icelandic prose-writers. D. 1148. G. L. KITTEDGE.

A'ria [Ital. air < from Lat. **arius* for *aerius*, deriv. of *aër*, air]: in music, a rhythmical song, a tune, a measured lyrical piece for one or several voices; commonly applied to a song introduced into a cantata, opera, or oratorio, and intended for one voice supported by instruments.

Ariad'ne (in Gr. 'Αριάδνη): a daughter of Minos, King of Crete; became the lover of Theseus when he visited Crete. She gave him a clew of thread by which he was enabled to find his way out of the Cretan labyrinth. Her mythus is not uniform, but, according to one account, she was abandoned by Theseus at Naxos, and subsequently became the wife of Bacchus. Others say that Diana slew her at Naxos with her arrows. She bore twin sons to Theseus. Her name is given to the forty-third asteroid. See THESEUS.

Arial'dus: a deacon of the Church of Milan, noted for his zeal against the marriage of priests; was born in Lombardy. His preaching led to a schism in the Church, attended with violent tumults. Arialdus was killed June 28, 1066. See Muratori, *Annali d'Italia*.

Aria'na: the ancient name of a region in the west central part of Asia, inhabited by the Aryan or Arian race. It probably comprised ancient Persia and Bactriana.

A'rianism: the doctrines of the ARIANS (*q. v.*), who held that the Son was begotten of the Father, and therefore not eternal nor consubstantial with him, but created by and subordinate to the Father, though possessing a similar nature. See ARIUS.

Aria'no: a town of Italy, in Avellino, among the Apennines; 23 miles N. E. of Avellino, on a steep hill, 2,500 feet above sea-level (see map of Italy, ref. 6-F). It was founded by the Greeks, and was an important military post for many centuries. The district is volcanic, and the town suffered severely from earthquakes in 1456 and 1732. It is the seat of a bishop. It has a mountain-fortress, a fine cathedral, several churches, a gymnasium, a normal school, and considerable manufacture of silk. Wine and butter are exported. Pop. about 15,000.

Arians: friends and followers of Arius, and those who have from time to time held his or similar opinions (see ARIUS). After the death of Arius in 336, the strife between the Arians and Athanasians went on for nearly half a century in the Church, and after the councils of Constantinople and Chalcedon the Arians were a heretical sect till far into the seventh century. Eusebius of Casarea and Eusebius of Nicomedia, both Arians who had signed the Nicene Creed, were the principal opponents of Athanasius. The Emperor Constantius, who succeeded to the imperial throne in 337, inherited his father's sympathies with the Arian party, who would say that the Son was of the "same substance" with the Father, meaning of "like substance." In 360 the latter phrase was actually substituted for the former at the Council of Rimini, after which the controversy raged hotter than before, but complicated with other points of doctrine. The Arian doctrine had a great attraction for the Northern people pressing down upon the Roman empire. The Ostrogoths were unanimous in their adoption of it, and the Visigoths also, withholding their assent from the Nicene symbol until 589, when they declared for it at the Council of Toledo. The Vandals, the Suevi, and the Burgundians were all largely Arian, and the Lombards were the last to become orthodox. From the middle of the seventh until the middle of the sixteenth century there was no Arian party, and the individual Arians were unconscious of their lapse. The "adoption" heresy, by which certain Spanish teachers at the close of the eighth century endeavored to make their doctrine palatable to the Mohammedans, was more akin to the heresy of Nestorius than to that of Arius. Even when the Reformation period produced departures from the orthodox doctrine, they were not on Arian lines. Servetus certainly was not an Arian, for he wrote that Arius was "incapable of appreciating the glory of Christ"; "gloriæ Christi incapaximus." The Socini, Laelius, and Faustus were humanitarians in their Christology. Opinions of an Arian stamp were developed among the German Anabaptists, and passed over into England. The charge of Arianism was common in the seventeenth century, but investigation often shows that Socinianism is meant, as in the case of Bartholomew Legate, the Unitarian, who perished at the stake in 1611, and was the last person burned for heresy in England. Milton, and Locke, and Cudworth, and Sir Isaac Newton, and Isaac Watts were Arians with more or less decision. While the English Unitarianism of the eigh-

teenth century was generally Socinian (Richard Price, the friend of Franklin, against whom Burke wrote his *Reflections on the French Revolution*, was an exception), American Unitarianism in its earlier growth was generally Arian, though it may be doubted whether Channing or many of his coreligionists could have used the terms of Arius without qualification. But Christ was for them a unique being, of whose pre-existence they made cordial affirmation. Few if any Unitarians are now Arians, and there is a growing preference among them for the thought of Athanasius as compared with that of Arius, because the former insisted on the humanity of Christ, while the latter destroyed it altogether, making of Christ a being neither God nor man. But the modern Unitarian would make the particular of Athanasius a universal, declaring that all men are at once human and divine.

JOHN W. CHADWICK.

A'rias Monta'nus, BENEDICTUS: Spanish biblical scholar and Orientalist; b. in Estremadura in 1527. He was a member of the Council of Trent in 1562, and under the auspices of Philip II. edited a Polyglot Bible, which was published at Antwerp (1568-72, 8 vols. fol.), and is highly commended. He wrote, besides other works, *Jewish Antiquities* (1593). D. at Seville in 1598. See Lounmyer, *Vie de B. A. Montano* (1842); N. Antonio, *Bibliotheca Hispana Nova*.

Ari'ca: a maritime town of Chili; department of Tacna (see map of South America, ref. 6-C). It was formerly the principal port of Bolivia, and is yet the principal point of imports and exports for that country, Bolivia having the right of transporting goods across this strip of Chili in bond. A railroad extends to the town of Tacna. Pop., formerly put at 7,000, is now only 3,000 or 4,000.

M. W. II.

Arichat, ar-i-shat': a seaport; capital of Richmond co., Nova Scotia; on the south coast of Madame island, near the Gut of Canso, and on a small bay or inlet of the Atlantic; lat. 45° 28' N., lon. 61° W. (see map of Quebec, ref. 2-D). It owes its importance to fisheries. It is the seat of a Roman Catholic bishop. Pop., including West Arichat, about 2,500.

Aric'ia: an ancient and celebrated city of Latium, on the Appian Way, at the foot of Mons Albanus, 16 miles S. E. of Rome. It was an important town in the reign of Tarquin the Proud. The Aricians took part in a war of the Latins against Rome, which ended in their defeat at Lake Regillus, 498 B. C. Cicero speaks of it as in his time a wealthy and flourishing *municipium*. Here was a celebrated temple of Diana, and here is a beautiful lake called Lago di Nemi. The modern town, *La Riccia*, is on or near the site of the ancient Aricia.

Arid Region: that part of the U. S. in which the land is not sufficiently watered by rain for the successful cultivation of crops. It is approximately limited by the line of 20 inches mean annual rainfall, but in districts where the principal precipitation occurs during the agricultural season a less rainfall determines the limit. Between the arid region and the humid region—where rainfall meets the needs of agriculture—lies the sub-humid region, a belt of country in which ordinary farming is successful in relatively moist years, but fails in other years. The arid region includes the States and Territories of Montana, Wyoming, Colorado, Utah, Nevada, Arizona, and New Mexico, together with those parts of North and South Dakota, Nebraska, Kansas, and Northern Texas lying west of the 100th meridian, a belt of Southern Texas extending 100 miles from the Rio Grande, all of California south of the 37th parallel, the eastern half of Northern California, the eastern two-thirds of Oregon, the southeastern third of Washington, and nearly the whole of Idaho; a total area of about 1,340,000 sq. miles. In 1889 the irrigated portion of this amounted to about half of one per cent.

In this region are a few spots rendered fertile by perennial supplies of moisture from below, but in general agriculture is absolutely dependent on artificial irrigation. Fortunately, the face of the country is diversified by mountains, and the loftier of these receive in winter a supply of snow which does not melt until spring, and then nourishes streams which can be diverted to farms or neighboring lowlands (see IRRIGATION). Associated with the small rainfall is a dryness of the air, which causes rapid evaporation not only from bodies of water but from the leaves of plants. This is advantageous to irrigated plants, giving them a vigorous growth, but unfavorable to plants not supplied with water at the roots. The native vegetation is consequently scant. The lowlands

are destitute of trees, and but sparsely clothed with bushes and grass. See *Lands of the Arid Region*, by J. W. Powell (1878); 11th Ann. Rep., U. S. Geological Survey (part 2, Irrigation, 1891); 12th Ann. Rep., U. S. G. S. (part 2, Irrigation, 1892). See also articles DESERT and GREAT BASIN.

G. K. GILBERT.

Ariége, a'ri-āzh: a river of France; rises in the Pyrenees, flows nearly northward through the department of its own name, passing by Foix and Pamiers, and enters the Garonne a few miles south of Toulouse. Length about 90 miles.

Ariége: a department in the S. of France; bounded N. and W. by Haute-Garonne, E. by Aude and Busillon, and S. by Spain, from which it is separated by the Pyrenees. Area, 1,889 sq. miles (see map of France, ref. 9-E). The surface is mostly mountainous, the highest mountains being in the southern part. Among the highest summits are Montcalm, about 10,600 feet, and Serrère, 9,592 feet high. It is drained by the rivers Ariége and Salat. The soil of the lower lands is fertile. Here are rich iron mines, which furnish the chief article of export. It is subdivided into three arrondissements. Capital, Foix. Pop. (1881) 240,601; (1891) 227,491; (1896) 219,641.

Ariel: a word signifying lion of God, or altar of God; was sometimes applied to the city of Jerusalem (Is. xxix. 1). Among the Jews of a more recent date the name was given to a water-spirit.—ARIEL is also the name of one of the principal characters in Shakspeare's drama of *The Tempest*, where he is represented as a spirit of air.

Ariel Gazelle (*Gazella dorcas* or *arabica*): the gazelle of Western Asia, the true gazelle belonging to Northern Africa. The ariel gazelle is one of the most beautiful of antelopes, is 21 inches high at the shoulder, of a dark-fawn color, the belly white, with a black or brown band running along the flanks. It is a variety of the species to which the African gazelle belongs. It is hunted both for sport (by falconry) and for its flesh and skin, both highly prized. Gazelles are often hunted in *battue*, for they can not be successfully followed in the chase, their speed excelling that of the greyhound. They are great favorites in the East when tamed, and the beauty of their eyes is proverbial.

Aries [Lat., ram]: a sign of the Zodiac; the first thirty degrees of the Zodiac measured from the point at which the equator intersects the ecliptic—i. e. the vernal equinox. The sun enters this sign about Mar. 21. Aries is also the name of a constellation of the Zodiac which once coincided with that sign, but which now occupies the same place as the sign Taurus. Among the ancient Romans, *aries* was the name of a battering-ram—a machine with an iron head used to batter down the walls of besieged towns or forts.

Arikara: See CADDOAN INDIANS.

Ar'il: a membrane or peculiar covering of some seeds, formed by an expansion of the *funiculus* or of the placenta. Mace, for example, is the *aril* of the nutmeg. The aril never appears until after the seed is fertilized.

Arimaspi: a mythological one-eyed Scythian race which lived in continual warfare with treasure-guarding griffins.

Ari'on (in Gr. Ἀρίων): Greek musician and poet, who first gave the dithyramb (*q. v.*) an artistic form; was a native of Lesbos, and flourished about 625 B. C. Herodotus has preserved a curious legend, according to which he was returning from Lower Italy to Corinth by sea with much treasure, to get which the mariners resolved to kill him. Having obtained permission to play one tune, he threw himself into the sea, and was received on the back of a dolphin, which had been charmed by the music, and carried him to land. This dolphin is supposed to be the same as that which figures among the stars.

Arios'to, ΛΟΔΟΒΙ'CO: Italian poet; b. at Reggio, near Modena, Sept. 8, 1474. He was educated at the College of Ferrara, and afterward, in compliance with the wish of his father, studied law, which he disliked and soon abandoned. After the death of his father, who left many children younger than Lodovico, he devoted much time to the support and education of his brothers and sisters. His early lyrical poems procured for him the patronage of Cardinal Ippolito d'Este, whose service he entered in 1503. He was employed by this cardinal, and his brother, the Duke of Ferrara, in embassies to several Italian courts. In the intervals of his busy life he meditated and matured his great romantic poem, *Orlando Furioso*, which was published in 1516 and soon acquired universal popularity. In 1517 he entered the serv-

ice of Alfonso, Duke of Ferrara, in whom he found a liberal patron. He is said to have been a favorite associate of that prince, and to have enjoyed some ecclesiastical revenues. In 1521 he was appointed governor or commissary of Garfagnana, where he was required to enforce order among a turbulent and rude population addicted to brigandage and violence. In the latter part of his life he married privately a widow named Alessandra Benucci. He had continued to polish and revise his *Orlando Furioso*, of which he published an enlarged edition in 1532 in forty-six cantos. It was at once seen how fortunate the poet had been both in subject and in manner. The subject was the romantic history of Charlemagne and his peers, especially of Roland—a history which had first been elaborated in mediæval France and treated in a whole cycle of poems, some finely serious, like the *Chanson de Roland*, others trivial and tedious. From France the story had come to Northern Italy in the thirteenth century, and been enormously popular there, leading to the production of numerous works in verse and prose—some of them, like the famous *Reali di Francia*, long eagerly read by the lower classes. In the end of the fifteenth century the tradition had been taken up by two considerable poets—Pulci, in his *Morgante Maggiore*, and Boiardo in his *Orlando Innamorato*—who had treated it, the one grotesquely, the other satirically. Ariosto, who perhaps had never seen Pulci's work, frankly used Boiardo's as the basis of his own, continuing the story from the point where Boiardo stopped. He used a different manner, however; and though his irony continues the satiric strain of his predecessor, he manages to give his poem, as a whole, a certain loveliness of style which makes what is most fantastic in character or action yet plausible and interesting. He also produced, in Italian, five comedies in verse, seven satires formed on the Horatian model, a number of sonnets, and some Latin poems. "Ariosto," says Hallam, "has been, after Homer, the favorite poet of Europe. His grace and facility, his clear and rapid stream of language, his variety and beauty of invention, his very transitions of subject, so frequently censured by critics, but artfully devised to spare the tediousness that hangs on a protracted story, left him no rival in general popularity." D. at Ferrara, June 6, 1533. See Barrotti, *Vita di L. Ariosto* (4 vols., 1766); Carl L. Fernow, *Lebenslauf L. Ariosto's des Göttlichen* (1809); Bolza, *Manuale Ariostesco* (1866); Ferrazzi, *Bibliografia Ariostesca* (1881); Crescini, *Orlando nella Chanson de Roland e nei poemi del Boiardo e dell' Ariosto* (1880); P. Panizzi, *Boiardo, Orlando Innamorato; Ariosto, Orlando Furioso*: edited, with an essay *On the Romantic Narrative Poetry of the Italians* (London, Pickering, 1830); G. Carducci, *Delle Poesie latine edite e inedite di L. Ariosto* (1875). Revised by A. R. MARSH.

Ariovis'tus: a chief of the ancient Suevi or Marcomanni; was a German. Solicited by the Sequani to aid them in a war against the Ædui, he marched (72 B. C.) with an army into Gaul, and took possession of that part which was afterward Burgundy. The Gauls then applied to the Romans to liberate them from their new master. Ariovistus was defeated by Cæsar near Vesontium (modern city of Besançon, France) in 58 B. C., and fled across the Rhine.

Aris'ta, MARIANO: Mexican general; b. in the state of San Luis Potosi, July 26, 1802; entered the army in his youth. Having served in several civil wars, he was made general of brigade in 1833, and was banished in that year by Santa Anna. He returned in 1835, became a general of division in 1841, and commanded the army which was defeated by Gen. Taylor at Palo Alto in May, 1846. In June, 1848, he was appointed Minister of War, and in 1850 was elected President of Mexico. Under his administration Mexico was disturbed by the usual chronic revolts and anarchy, and Arista was driven from power by Santa Anna early in 1853. He died on the way from Lisbon to France, Aug. 7, 1855.

Aristae'netus (in Gr. Ἀριστάνετος): a Greek epistolary writer of the fifth or sixth century; a poor imitator of Alciphron and Achilles Tatius, who composed two books of love stories in the form of letters, prose transcripts of Alexandrian elegies. Ed. by Boissonade (1822).

Aristæ'us (in Gr. Ἀριστᾶϊος): a personage of classic mythology, represented as a son of Apollo and Cyrene. He married Autoonē, a daughter of Cadmus; was the father of Actæon, and a lover of Eurydice. He was worshiped as a divinity who presided over flocks and herds, and taught men the art of raising or managing bees. See Vergil, *Georgics*, book iv.

Aristæus of Alexandria: a fictitious person represented as a Jew who enjoyed the favor of Ptolemy Philadelphus (cir. 280 B. C.). His alleged letter to Philocrates, giving an account of the origin of the Septuagint, has been proved by Humphrey Hody and others to be spurious. See SEPTUAGINT.

C. H. TOY.

Aristar'chus (in Gr. Ἀρίσταρχος): Greek grammarian and critic; 222–150 B. C.; a native of Samothrace; pupil and successor of Aristophanes of Byzantium. He taught at Alexandria, where he educated the son of Ptolemy Philometor. In consequence of a difficulty in the royal household he withdrew to Rhodes, where he died at the age of seventy-two. His especial excellence lay in textual criticism, in which he showed great acumen, rare powers of divination, and soundness of method. His leading principle of exegesis was the explanation of the author out of himself. He was an inspiring teacher, and did much to insure the prevalence of the analogical school of grammar in opposition to the Pergamene school of anomaly. He published a large number of corrected texts, with critical signs; and the restoration of Aristarchus's text of Homer is still the ideal of a school of editors. The Homeric scholia derive much of their value from the preservation of the criticisms of Aristarchus. See Lehrs, *De Aristarchi Studiis Homericis* (3d ed. 1882); Ludwich, *Aristarchs Homerische Textkritik*. B. L. GILDERSLEEVE.

Aristarchus of Samos: Greek astronomer; supposed to have flourished about 275 B. C. The events of his life are unknown. Archimedes in one of his works states that "Aristarchus of Samos supposes that the earth revolves about the sun in the circumference of a circle." All of his writings are lost except a short treatise *On the Magnitudes and Distances of the Sun and Moon*. He calculated that the sun is twenty times farther than the moon from the earth. See Fortia d'Urban's *Histoire d'Aristarque de Samos* (1810).

Aristi'des, or Aristei'des (surnamed THE JUST): eminent Athenian statesman; son of Lysimachus; b. in Alopeke, a demos of Attica. His political tendencies were conservative or aristocratic. He was one of the ten generals who had the command of the army when the Persians invaded Greece in 490 B. C. Each general had a right to the chief command for one day, but Aristides persuaded his colleagues to resign or waive their claims, so that Miltiades commanded at Marathon when it was not his turn. Aristides became chief archon in 489, and a political adversary of Themistocles, the leader of the democracy. On the pretext that his influence was dangerous to the public interest, he was ostracized in 483 B. C. On this occasion a citizen who was personally a stranger to him, and who could not write, requested him to write *Aristides* on a shell to be used in voting. He asked this voter if Aristides had injured him. "No," replied the citizen, "but I am tired of hearing him always called Aristides the Just." When Xerxes, King of Persia, invaded Greece with a mighty army in 480 B. C., Aristides sought an interview with Themistocles, took a prominent part in the battle of Salamis, and recovered his popularity. He commanded the Athenian troops, which, aided by other Greeks, defeated the Persians at Plataea in 479. Aristides and Cimon were appointed in 477 B. C. commanders of the Athenian forces which co-operated with other Greek armies against the Persians. Pausanias the Spartan had the chief command of the allied army, but he offended the allies by his arrogance, while Aristides by mildness and prudence gained general favor, and promoted the supremacy or predominance of Athens among the states of Greece. He died poor in 467 B. C., leaving a son and two daughters, who received dowries from the public treasury. Few statesmen have left so pure and honorable a reputation as Aristides. See Plutarch, *Life of Aristides*; Cornelius Nepos, *Life of Aristides*. WILLIAM JACOBS.

Aristides, ÆLIUS: a Greek sophist and rhetorician; b. in Bithynia about 117 A. D.; was a pupil of Polemon and Herodes Atticus. He acquired an undue reputation for eloquence, and produced many orations and panegyrics. His emulation of Demosthenes had the unhappy effect of making his style labored and obscure. He resided at Smyrna when that city was ruined by an earthquake in 178 A. D., and persuaded the Emperor Marcus Aurelius to rebuild it. D. in 185 A. D. Principal edition by Dindorf in 3 vols., 1829. See Baumgart, *Ælius Aristides* (1874); Schmid, *Atticismus* (vol. ii.). B. L. G.

Aristides Quintilianus: a Greek grammarian (of the third century A. D. ?); author of an important work on music,

in which he holds fast to the great principles of Aristoxenus, though beclouded by Neo-Platonic mysticism. Ed. by Albert Jahn (1882).

Aristides of Thebes: an eminent Greek painter who lived about 350 B. C., and was a contemporary of Apelles. He had a brother, Nicomaehus, who was a skillful painter. According to Pliny, Aristides was the first who expressed on the countenance the passions and movements of the soul. He painted a battle between the Greeks and Persians, which the Roman consul seized among the spoils of war and took to Rome.

Aristip'pus (in Gr. Ἀριστιππος): Greek philosopher; founder of the Cyrenaic school; b. at Cyrene, in Africa, about 435 B. C. He was a pupil of Socrates, but did not adopt his principles or imitate his mode of life. He traveled extensively, indulged freely in sensual pleasure, was intimate with the courtesan Lais at Corinth, and flourished as a courtier and philosophic voluptuary at Syracuse in the reign of Dionysius the Elder. Though he recognized pleasure as a proper subject of pursuit, he appears to have observed some moderation in that pursuit, and to have been remarkable for self-control and equanimity as well as versatility, and a faculty of adapting himself to the vicissitudes of fortune. Plato is reported to have said that "Aristippus was the only man he knew who could wear with equal grace fine clothes and rags." He was celebrated for his witty sayings and repartees, some of which are recorded by Diogenes Laertius. His works, if he wrote any, have not come down to us. He despised or neglected mathematics and physical sciences. He died after 366 B. C., and left a daughter, Arete, who was distinguished as a philosopher. Wieland wrote in German a romance of *Aristippus and his Contemporaries* (4 vols., 1800–02). See G. H. Lewes, *Biographical History of Philosophy*; F. Mentz, *Aristippus Philosophus Socraticus, sive de ejus Vita* (1719); and Zeller's *Socratic Schools*.

Revised by W. T. HARRIS.

Aris'to, or Aris'ton, of Chios (surnamed THE SIREN): Stoic philosopher who lived about 275 B. C.; a disciple of Zeno. He taught at Athens, and confined his attention to moral philosophy. He maintained that the chief good consists in indifference to everything except virtue and vice.

Aristobu'lus (Gr. Ἀριστόβουλος): a Greek historian who accompanied Alexander the Great in his expedition against Persia, about 332 B. C., and wrote a history of the same, which is not extant. It was highly praised by Arrian for its trustworthiness.

Aristobulus: a Jew and philosopher who lived at Alexandria about 175–150 B. C. He was the reputed author of a Commentary on the Books of Moses, the aim of which was to show that the ancient Greek writers had borrowed much from the sacred books of the Hebrews.

Aristobulus I.: high priest of the Jews; son of Joannes Hyrcanus. He assumed the title of king in 107 B. C., and died in 105, when he was succeeded by his brother, Alexander Jannæus.

Aristobulus II.: nephew of Aristobulus I., and a son of Alexander Jannæus; became King of the Jews about 70 B. C. Jerusalem was taken in 63 by Pompey, who gave the throne to Hyrcanus, a brother of Aristobulus, and carried the latter as a captive to Rome. D. about 48 B. C.

Aristoc'raey [from Gr. ἀριστοκρατία: ἄριστος, best + κρατία (in comp.), rule; cf. κράτος, power]: signifies ideally a form of government controlled and administered by the best or noblest citizens. It is enumerated by Aristotle among the principal forms of government. Aristocracy is of very ancient origin, and in some countries of ancient times it prevailed as subsidiary to monarchy. The word may be defined as a government controlled by the nobility or privileged class, or a government in which a minority of adult males constitutes the ruling class. Such was the republic of Venice. The aristocratic element also predominated originally in the republic of ancient Rome, which was governed by patricians, whose power was hereditary. The feudal system of the Middle Ages favored the formation of powerful aristocracies. Among modern nations Great Britain is perhaps that in which the aristocracy is most influential and respectable. A title of nobility is the great prize for which British statesmen and soldiers compete, and the ranks of the ancient noble families are often reinforced by men of genius, who are raised to the peerage. There is probably no country where rank is more highly prized and ardently coveted. In modern language, this word is used to denote

nobility, or the higher class of society, without reference to government. See DEMOCRACY.

Aristogi'ton, or **Aristogeiton** (Gr. Ἀριστογείτων): an Athenian conspirator, an accomplice of Harmodius in the assassination of Hipparchus. He was put to death by Hippias in 514 B. C. He was regarded as a patriot by the Athenians, who erected statues to him and to HARMODIUS (*q. v.*).

Aristolo'chia [from, Gr. ἀριστολόχεια, an herb promoting childbirth; ἄριστος, best + λόχεια, childbed]: a genus of plants of the family *Aristolochiaceae*; are mostly natives of tropical countries, and have twining stems. The genus is characterized by a tubular oblique perianth, and by stamens adherent to the style. Some of the species climb to the tops of high trees and have handsome flowers. The *Aristolochia serpentaria*, or Virginian snakeroot, is a native of the U. S., possesses stimulant and tonic properties, and was once supposed to be a remedy for the bite of serpents. Similar virtues are ascribed to various species in different parts of the world. The root of this plant is exported from the U. S. to Europe, and is highly esteemed as a remedy in certain fevers. The *Aristolochia clematitis* (birthwort) is a native of Europe, a perennial plant, with cordate leaves, erect stem, and grows in waste places, hedges, and among rubbish. The roots of these and many other species, which possess powerfully stimulating properties, have been used in medicine.

Revised by CHARLES E. BESSEY.

Aristolo'chia'ceæ: a family of exogenous plants, of which *Aristolochia* (*q. v.*) is the type.

Aristom'enes (in Gr. Ἀριστομένης): a famous Messenian general who commanded the army of his state in the second Messenian war. He was renowned for personal valor and daring enterprises. Having been finally defeated in 668 B. C., he went with his daughter and son-in-law to Rhodes. See Jourdan, *Histoire d'Aristomène* (1749).

Aristoph'anes (in Gr. Ἀριστοφάνης): greatest of Attic comic poets; b. about 450, d. about 385 B. C. His birthplace is variously given; that he was a full-blood Athenian has been denied, but in character, endowment, and art he was an Athenian of the Athenians: his language is the norm of Atticism, his genius has the flavor of Attic soil and the light of Attic sky. An aristocrat by party allegiance, he was from the beginning in opposition to "democracy" and "progress," to "elevation of the masses," to "the career open to talent," to "free thought," to "finer art," to "art for art's" sake, to every form of sophistic phrase-making and humanitarian claptrap. Hence Aristophanes is to this day a powerful ally of conservative souls. He began early. His first two pieces, *Banqueters* (427) and *Babylonians* (426) are lost. Eleven out of about forty are left. *Acharnians* (425), a burlesque plea for peace; *Knights* (424), an attack on Cleon; *Clouds* (423), in ridicule of Socrates as the head sophist; *Wasps* (422), a caricature of the Athenian jury system; *Peace* (421), a frolic in anticipation of the close of the Ten Years war; *Birds* (414), in which the poet builds an airy cloud-cuckoo-town as a home for all manner of fancies. Then the shadow of the Four Hundred (see GREECE, HISTORY OF) falls over the poet. The *Lysistrata* and the *Thesmophoriazusæ* were acted in the same year (411). Both of them have to do with women and women's ways. In the *Lysistrata* the women seize the helm of state; in the *Thesmophoriazusæ* they band together against Euripides, the woman-hater. The truceless war against Euripides culminates in a formal siege in the *Frogs* (405). The *Ecclesiazusæ* (389 or 392) is a farce at the expense of women's rights and communism. The *Plutus* (388) is a manner of allegory and marks a transition to Middle Comedy (see GREEK LITERATURE). In wit, in humor, in inventiveness, in command of all the resources of language and rhythmical art, Aristophanes is one of the foremost masters of all time. Critical editions of all the plays by Bekker (*cum notis variorum*), Dindorf, Meineke, Bergk, Blaydes, Von Velsen (not yet complete). Annotated editions of single plays too numerous to mention. Famous translations by J. Hookham Frere. Noteworthy renderings by Mitchell, Rogers, Tyrrell, Kennedy. Droysen's German translation is a classic. See also Browning, *Aristophanes's Apology*.

B. L. GILDERSLEEVE.

Aristophanes of Byzantium: Greek grammarian; b. about 262 B. C.; studied at Alexandria, and succeeded Apollonius Rhodius as librarian. D. about 185. He did important service in connection with the Alexandrian canon; published valuable critical editions of Homer, Hesiod, the lyric poets, especially Alcæus and Pindar; wrote introduc-

tions to the plays of the tragic and comic poets, especially Aristophanes and Menander; made lexicographical collections; invented a series of critical signs; and developed the notation of prosody, including accent, breathing, and quantity. See Nauck's *Aristophanis Byzantii Fragmenta* (1848); Wilamowitz-Moellendorff, *Euripides Herakles*, vol. i. pp. 137-153.

B. L. GILDERSLEEVE.

Ar'istotle: Greek philosopher; b. at Stagira, a city of Thrace, but a Grecian colony, in the first year of the 99th Olympiad, or 384 B. C. His father was Nicomachus, a physician and friend of Amyntas, King of Macedon and father of Philip. The family of Aristotle was distinguished by the hereditary profession of medicine, and was wont to trace its origin to Machaon, son of Æsculapius. Left an orphan at an early age, he was brought up by Proxenus of Atarneus, in Mysia, to whose guardianship he seems to have been intrusted by his father, and whose memory Aristotle held so dear in after life that he erected a statue to him, and both instructed his son Nicanor in the liberal arts and adopted him as his heir. In his seventeenth year he went to Athens, and became a pupil of Plato, with whom he continued twenty years, and by whom he was called the reader and the intellect of the school, and likened, in his ardor and restiveness, to a colt which needed the bit more than the spur. Upon the death of Plato (348 B. C.) he accepted an invitation of Hermias, tyrant of Atarneus, his former fellow-pupil in the school of Plato, to take up his residence with him. Here Aristotle spent the three following years of his life, when Hermias, conquered by a Persian invader, was sent a prisoner to Persia, where he was put to death by Artaxerxes. To avoid a like fate, Aristotle fled to Mitylene, taking with him Pythias, whom he married, and who is variously described as the mistress, the sister, and the niece of Hermias. After her death he married his concubine Herpyllis, the mother of his son Nieomachus.

When Alexander of Macedon was born, Philip, his father, is said to have sent this letter to Aristotle: "Be it known unto you that I have a son, and that I am thankful to the gods, not so much for his birth as that he was born in your time. For if you will but take the charge of his education, I assure myself that he will become worthy of his father and of his future kingdom." The philosopher accepted the commission of the king, and there is evidence that he gave early directions respecting the care and culture of the infant prince. When Alexander was fifteen, Aristotle assumed the personal oversight of his instruction, taking up his residence at the court, and continuing there during the lifetime of Philip and for two years after his pupil had ascended the throne. When the conquest of the East was undertaken, Aristotle returned to Athens, and taught philosophy in the Lyceum, a temple dedicated to the Lycian Apollo, with walks ornamented by trees, fountains, and colonnades. From these shady walks (περίπατοι) his school received the name of Peripatetic. He here abode and taught thirteen years, when, after the death of Alexander, he was accused by the Athenians of impiety, and fled to Chalceis in Eubœa, the present Negropont, in order to escape the fate of Socrates, or, as he said, that Athens might not have the opportunity to sin against philosophy again. Here he died (B. C. 322) in his sixty-third year.

His Character.—Aristotle's was one of the most highly gifted intellects of all the ages. All agree that his wealth of scientific knowledge, his unbiased judgment, his constructive power, and his depth and breadth of speculative insight are unsurpassed in ancient or modern times. But the verdict is not so unanimous respecting his moral traits. By some of the ancients he is extolled for his patriotism, his reverence, his modesty, his moderation, his love of truth, and his attachment to his friends, while others hold him up as selfish, ungrateful, sordid, gluttonous, and impious. It must be owned, however, that few of the stories told in proof of either of these sides will bear a sharp look. They rest on frail grounds. But while we have little direct showing that can be trusted respecting the personal character of Aristotle, some points seem clear. The regard in which he ever held the memory of Proxenus, and the beautiful hymn to virtue which he composed in honor of Hermias, and which we still have, show that he was not incapable of gratitude or of love to his friends. The charge often made that he was jealous of Plato does not hang with the fact of Aristotle's continued intimacy with Xenocrates, Plato's devoted disciple and successor, nor with an elegy, some verses of which have come down to us, in which Aristotle calls Plato one whom the bad

might not even praise, and who first taught the world how a man could be at the same time good and happy. In his will he shows not only a judicious care, but an affectionate solicitude, for his family, while in his writings a lofty moral tone appears and a winning frankness and sincerity seem to shine.

His Writings.—These were very numerous, though only a small part, perhaps a fourth, remains, all of which probably differ more or less from the state in which Aristotle left them. Incompetent editors and ignorant transcribers have made almost as much mischief as the mold and mildew by which some of the original manuscripts are said to have been sadly injured, and some destroyed. But while the fragmentary and skeleton-like form which many of the so-called Aristotelian writings possess, joined to the evident omissions and the repetitions and contradictions which they contain, show the work of some other hands than those of the great master, there remains a solid nucleus of considerable size, whose purity of style and depth of speculative content bring us into the unmistakable presence of Aristotle himself. In 1890 one of the most interesting discoveries of the century was made. The constitution of Athens, one of the 250 constitutional histories that Aristotle wrote by way of preparation for his great work on Politics, was discovered and transcribed in the British Museum from Papyrus cxxxi.

His Philosophy.—Aristotle's method is exactly the reverse of Plato's, which he does not tire of making manifest. The attention which Plato had given to the unity of all being, Aristotle directs to the manifoldness of the phenomenal world. He is as analytic and discursive as Plato is synthetic and intuitive. While Plato finds in the universal the only light in which the particular can be seen, Aristotle sees the particular to be necessary in order that we may have any knowledge of the universal. So he gathers particulars from all quarters. History, the human mind, and all departments of nature furnish him contributions. He has no rival in the variety and extent of the facts which he has collected, and has never been surpassed in the patient industry of his investigations. But it is a great mistake, though one easily and often made, to judge thereby that Aristotle sought for nothing beyond experience, or that he and Plato represented only the opposite extremes of empiricism and idealism. The idea was as truly the object of Aristotle's search as it was of Plato's. Both Plato and Aristotle also agreed that the reality or the essence of individual things was in the idea. Aristotle also held as strongly as Plato to the objective existence of the idea. The doctrine of the Nominalists in the Middle Ages, that the idea or the universal is only a subjective product in which objects are represented, and by which they are named, though often ascribed to Aristotle, is but little less foreign to him than to Plato. But while to Plato the idea had an objective existence independent of the individual object which participated in it, to Aristotle the idea was immanent in the individual, and had no being separate from it. This accounts for the prodigious attention which Aristotle gave to individual facts. He collected these in such vast measure, not because they had any interest in themselves, and not because their collection and classification could give a satisfying science, but only for the sake of the idea which was immanent in them, and which was the only proper object in scientific inquiry, since it was the only object which could be truly known.

This immanence of the idea in the individual shows what was the most essential difference between Plato and Aristotle, and also what was the most characteristic and important doctrine in the Aristotelian philosophy. Aristotle criticises Plato because the Platonic ideas, being separate from and independent of phenomena, could not explain the existence of the phenomenal world. They are, in the Aristotelian view of Plato's doctrine, only potential, not actual, sources of individual things. But to the idea as universal Aristotle ascribes an activity which individualizes, but this individualization is not a change to anything without, nor because of anything without, but is wholly within the universal itself; it is a change thus into a difference which is at the same time an identity, a determining which is a self-determining, wherein the universal or the idea realizes or actualizes itself. This self-realizing of the idea is a conformity to an end which is at the same time a self-end, a true Final Cause, wherein is the living principle and rational explanation of individual things. This doctrine of the final cause, or sufficient reason, which it is the immeasurable merit of Aristotle to have introduced into philosophy, carries us back to a principle deeper than that of efficient causation, and

brings us from the world of necessity to that of freedom. Our modern physicists would gain a profounder view of nature and a more successful pursuit of science if they could know this principle as Aristotle taught it. They would find him, as the ancients called him, "the father of those who know." See Zeller, *Aristoteles und die Alten Peripatetiker*, and especially E. Wallace, *Aristotle's Psychology in Greek and English*; Stahr, *Aristotelia*; Lewes, *Aristotle*; Grant, *Ethics of Aristotle*; Trendelenburg, *Comm. ad "De Anima"*; Hegel, *Geschichte der Philosophie*; Thomas Davidson, *Aristotle and the Ancient Educational Ideals*; also Ritter, Ueberweg, Schwegler, Erdmann, etc.; also PHILOSOPHY, ITS HISTORY. Revised by W. T. HARRIS.

Aristotle's-lantern; the jaws of the sea-urchin, which are large in proportion to the size of the animal, and composed of five pieces, which form a lantern-shaped structure.

Aristoxenus of Tarentum: Greek philosopher; a pupil of Aristotle; lived about 350–320 B. C. He wrote numerous works which are lost, and a treatise on music (*Elements of Harmony*), which is extant and is accounted valuable. It was published by Meursius in 1616. He founded a school of musicians, who rejected the system of Pythagoras, and judged of the notes in the diatonic scale by the ear exclusively. See Zeller, *Aristoteles und die Alten Peripatetiker*.

Arith'metic [deriv. of Gr. ἡ ἀριθμητική (sc. τέχνη, art), art of counting, from ἀριθμεῖν, count]: the science which treats of numbers or the art of computation, is a branch of mathematics. In the ordinary use of the term it is the art of expressing numbers by symbols, combining these symbols, and applying to them rules of the greatest practical utility. Among the ancient Greeks, Pythagoras, Archimedes, and others cultivated the science of numbers, but they labored under the disadvantage of a clumsy mode of notation, and had no sign for zero or naught. The Roman numerals, I, V, X, L, C, etc., continued to be commonly used in Europe until the fifteenth century. The invention of the symbols called Arabian numerals, now in use, is attributed to the Hindus. The use of the cipher (0) gives the modern arithmetic a great advantage over the ancient.

Arithmetical Mean: See MEAN.

Arithmetical Progression: See PROGRESSION.

Arius, aa'ri-us (properly aā-rī'us): the founder of Arianism; an Alexandrian presbyter, theologian, and controversialist; one of the two principal figures in the first great controversy of the early Church; b. in Libya, in Africa, 256. He went as a layman to Alexandria, and there sided with Peter, Bishop of Alexandria, in the Meletian Schism; was ordained deacon by him, but subsequently excommunicated in consequence of his joining the schismatics. He repented, was restored, advanced to the priesthood and given sole charge of a church. He was so popular that when Peter's successor, Achilles, died, he came very near being elected to fill the vacant archiepiscopal throne. Alexander was, however, chosen. In 318 Arius first came into wide public notice. He was then an old man. He was probably trained in Antioch, imbibing there the doctrine of the Son's subordination to the Father which he afterward taught. While the historian Socrates represents him as assailed by his bishop, Alexander of Alexandria, as a Sabellian—i. e. as representing the Son to be a manifestation of the Father, as light is of the sun—the historian Sozomen relates that he had been for some time regarded as a heretic before Alexander, impelled by others, called him to account. His heresy—for as such his opinions were at last condemned—consisted in his denial that Jesus Christ was an unoriginated being. He would not say "there was a time when he was not," but only "there was when he was not," admitting that he was created before time. But he insisted that he was created, because a Son must be younger than his Father. This literalism appears in all the authentic records of his life, and notably in two of his letters that have come down to us. They deny that Christ was "unoriginate, or part of the Unoriginate, or made of any previously existing substance." They affirm that he was begotten before time, that he was perfect God (πλήρης Θεός), by whom all worlds were made. The controversy between Arius and Alexander widened till it included Egypt, Libya, and Palestine in its extent. A synod of Egyptian and Libyan bishops excommunicated Arius, but his followers steadily increased. He was a rigorous ascetic, a persuasive advocate, an ardent propagandist. Tall, gloomy, fanatical, with downcast eyes and tangled hair, he went about singing his doctrines, which he had set to the music of the theaters.

Before long they were being sung by priests, boatmen, bakers, and all sorts of people. Constantine, who had become sole emperor in 323 A. D., was ashamed to find the religion which he had just embraced rent by such a fierce dispute, and in 325 called the Council of Nicæa to settle it, with other matters affecting the peace and honor of the Church. It was the first œcumenical council, the first attempt to bring together all the bishops of the Church. There is abundant evidence that both parties were seeking the same end by different means—to steer clear of Ditheism, the doctrine of two Gods. To call the Son unoriginate, or eternally created, seemed to Arius to make him a second God. No, said his opponents, if one with God he can not be another. But a being created before time, the creator of all things but himself, was sure to be another God soon or late. Arius insisted that his “createdness” and his “moment when he was not” nullified the danger, but his opponents did not wish to be convinced. Their object was to fix upon a term that Arius and his party could not accept. It was furnished them by one of the Arian party, Eusebius of Nicomedia, who declared, in a letter that was produced in the council, that “to assert the Son to be uncreated would be to say that he was *homoïousian*, that is, consubstantial, of one substance, with the Father. Around this word the battle waged. The Arians would say that Christ was *homoïousian*, of like substance with the Father, but they would say no more. A creed offered by Arius was torn in pieces, and that he might not share its fate he was removed from the assembly. A second creed, which the emperor had approved beforehand, fared as ill. Then the creed since known as the Nicene was offered by the opponents of Arius, and prevailed. A young deacon of Alexandria, Athanasius, was its principal protagonist, and in the long controversy that ensued he was ever the most brilliant and picturesque and noble figure on the scene. Constantine, who cared much for unanimity and little for the diphthong, threw all his weight in favor of the creed, privately confessing to Eusebius that he understood *homoïousian* to mean *homoïousian*. The Arian bishops generally availed themselves of this understanding. Arius and two bishops who would not sign the creed were banished to Illyria, and Eusebius of Nicomedia, who, while accepting it, objected to its anathemas, was sent to Gaul. The Bishop Alexander went back to his see in triumph, and when he died, soon after, Athanasius succeeded to his throne. It was not in the nature of Arius to be easily suppressed. He gained the ear of Constantia, the sister of the emperor, and she persuaded her brother to recall him to the court. There he renewed the strife, but when Athanasius was ordered to reinstate him at Alexandria he stubbornly refused. In 336 Athanasius was banished and Arius went back to take his old place, but the popular uproar did not allow him to do so. Finally, the Bishop of Constantinople consented to receive him back into the Church, but on the eve of his reinstatement he was suddenly taken ill and died (336), whereupon there was great rejoicing in the enemy’s camp, and thanksgiving to God for his good providence. As we know Arius mainly through his opponents, some deduction must be made from their abuse. But that he had an arid mind, and a temper that grew harsher as the winds of controversy blew upon it, admits of little doubt. The Nicene creed as now used is longer than that adopted at Nicæa, by the clauses beginning “I believe in the Holy Ghost,” and the phrase “and the Son” was added by a Western council in 589. The new clauses were added at or before the Council of Constantinople in 381; probably before, to be officially ratified at the Council of Chalcedon (a suburb of Constantinople) in 451. J. H. Newman’s *Arians of the Fourth Century*, though described by an ardent eulogist, R. H. Hutton, as “dry almost to grittiness,” is useful for the period, and Dean Stanley’s *Eastern Church* gives a picturesque account of the Arian controversy and its culmination at Nicæa.

JOHN W. CHADWICK.

Arizo’na: a southwestern Territory of the U. S., between lat. 31° 20’ and 37° N., and lon. 109° and 114° 35’ W. Bounded by Nevada and Utah on the N., New Mexico on the E., Mexico on the S., California and Nevada on the W. Area, 113,020 sq. miles, 72,332,800 acres, which is about equal to that of New York, New Jersey, Pennsylvania, Delaware, and Maryland combined.

Topography.—Surface generally elevated, and composed of wide plateaus, descending gradually from 7,500 feet above the sea in the N. to 80 or 100 feet in the S. These plateaus are crossed by ranges of mountains with towering peaks ris-

ing to the height of 12,000 or 14,000 feet. They are riven by streams and rivers which have cut for themselves beds varying from 1,000 to 6,000 feet below the surface. The mountains have many local names; the longer and more important ranges are the Mogolon and Zuni Mountains in the E., the Pinaleno and Santa Catalina in the S. E., the Santa Aña and the Dragon Mountains in the S., the Gila range, the Black Mesa, and the San Francisco Mountains in the center, the Gerbat and Black Mountains in the W., and the great

mass rising above the Colorado plateau, the Northside Mountains, in the N. W. The San Francisco Mountains seem to have been a group of volcanoes, none of them now active; but centuries ago they poured out immense streams of lava, which flowed northward to the banks of the Colorado Chiquito. Extensive *mesas*, or table-lands, rise above the plains, with perpendicular sides, often 1,000 feet or more in height. The whole of Arizona is drained by the Colorado river and its tributaries. It is the most remarkable river in the world. Its own course in Arizona for 400 miles is through the Grand Cañon, from 5,000 feet to 400 feet below the surface of the plateau, and its actual fall in the 400 miles is over 3,000 feet. Nearly all its affluents, and particularly the San Juan, Little Colorado, Zuni, Salt, and Upper Gila rivers, pass through similar and perhaps deeper cañons. These cañons are among the greatest wonders of the world. It is said they expose to view geological strata of all the formations in their regular places to the thickness of 25,000 feet. The Colorado is navigable for about 550 miles.

Minerals.—Gold, silver, platinum, quicksilver, copper, tin, lead, nickel, iron ores of all sorts, bituminous coal, and perhaps anthracite, salt, sulphur, gypsum, loadstones, opals, garnets, sapphires, chalcedony. Many gold and silver mines had been worked by the Spaniards and Mexicans successfully for years before the Territory came into possession of the U. S., and they are still largely productive.

Soil and Vegetation.—The lava-covered and granitic sides of the mountains are sterile. Aside from these, the soil is fertile where irrigation (now extensively introduced) is possible, and yields large crops; elsewhere it is dry and barren. There are forests, generally of pine and spruce, in the mountains, but protracted drought kills many of the trees. Wherever there is water, flowers and shrubs are profuse and beautiful. On the dry and hot plains, mimosas and cacti of many forms are the only vegetation.

Zoölogy.—The elk is found in Arizona, though not abundant; two species of deer, antelopes, the big-horn, wild horses or mustangs, pumas, jaguars, ocelots, black and cinnamon bears, wildcats, lynxes, the red or gray wolves, the true coyotes, foxes, raccoons, opossums, and skunks are very numerous. Birds of prey, game-birds, and birds of fine plumage abound.

Climate.—In the mountains and plateaus a warm but healthy and very uniform temperature prevails. At Prescott, lat. 34° 29', the mean of the year 65.49° F.; summer mean, 84°; only two days above 100°. In Southern Arizona very hot and dry. Yuma (lat. 32° 43', but low) had, in 1877, 106 days of summer above 100° F., 30 days above 108°, and 12 days above 110°; the maximum is 126° F. Tucson is not quite so hot; only 51 days were above 100°. But the whole Gila valley is very hot, yet the air is dry and invigorating, and sunstrokes are rare. The lack of rain is very general. Yuma has but 2 or 3 inches in the year, Prescott about 10 inches, and Tucson not over 6 or 7.

Industries.—Mining is the most important of these. Gold is found, both in placers and in quartz-lodes, at various points, and the latter are often very rich; silver in galena, and combined with both lead and copper as sulphides and carbonates; copper as gray sulphuret; quicksilver as cinn-

bar, etc.; platinum and nickel nearly pure; iron in all kinds of ores, and coal where it is easily accessible. The mines of both gold and silver are very numerous in Southern Arizona, near and below the Southern Pacific R. R.; copper, gold, some silver and iron, as well as the other metals, in Central and Western Arizona, between lat. 33° and 35°. In both sections the scarcity of wood and water renders mining very expensive. The estimated value of products of gold and silver for 1899 was \$3,739,113.

Agricultural Productions.—The Agricultural Report shows a yield in 1899 of 342,139 bushels of wheat. The amount of corn and oats raised is insignificant. There are good pasturage lands in Central Arizona and in Apache County in the N. E., where the Navajo Indians keep a great many sheep. The irrigable lands yield under irrigation immense grain and root crops, and the semi-tropical fruits are plentiful.

Farm Animals.*—In 1899 there were in the Territory 52,431 horses, 1,031 mules, 381,861 cattle, and 1,024,430 sheep.

Manufactures.—In 1880 there were 66 manufacturing establishments, employing 220 persons. capital \$272,600; in 1890, 76 establishments, capital \$616,629.

Finances.—The assessed valuation was, in 1900, \$33,782,466. Territorial debt, 1898, \$1,045,972. County and municipal debt, \$1,634,027. Receipts, \$236,437; expenditures, \$127,782.

Railroads.—The Southern Pacific crosses Arizona from W. to E. between the 32d and 33d parallels. Another crosses from E. to W. near the 35th parallel. The total valuation of railways in 1900 was \$4,363,624. Silver, copper, lead, and iron ores, wheat, and cattle are the principal freights.

Education.—Arizona in 1900 had 398 public schools, with 16,504 pupils; 2 public normal schools.

Pop., 1900.—(White and colored, except tribal Indians) 122,212. Pop. 1870, 9,658; 1880, 40,440; 1890, 59,620.

The number of Indians (including the Navajo, most of whom are in Arizona) is nearly 35,000. These are of various tribes, the Apache, the most turbulent, numbering nearly 5,000, and the pueblo-dwelling Hopi or Moki, 1,976. The latter are an offshoot of the great Shoshonean linguistic stock and occupy a number of communal villages on three mesas in the northeastern portion of the Territory.

Cities and Towns, Pop. 1900.—Tucson, 7,531; Phoenix (capital), 5,544; Prescott, 3,559; Jerome, 2,861; Nogales, 1,761; Globe, 1,495; Yuma, 1,402; Winslow, 1,305; Flagstaff, 1,271; Tempe, 892.

History.—The Indians were originally Aztec or Toltec; these occupied the country long, and reared walled towns, of which there are now ruins; mostly dispossessed by more northern tribes; Spaniards and Jesuit missionaries came before 1600, and established many settlements in the seventeenth century. Arizona, as well as New Mexico, belonged to Mexico till 1848, when all N. of the Gila was ceded to the U. S.; the Gadsden Purchase made in 1853; Arizona made a separate Territory in Feb., 1863.

* On farms only.

† Reference for location of counties, see map of Arizona.

‡ Organized from part of Pima in 1899.

Arjish': a river of Roumania; rises in the East Carpathian Mountains; flows southeastward, and enters the Danube 42 miles S. S. E. of Bucharest. Length about 175 miles.

Arjish-Dagh: See ARGÆUS, MOUNT.

Arkadelphia: on railroad; capital of Clark co., Ark. (for location, see map of Arkansas, ref. 4-B); is situated at the head of steam-navigation, on the right shore of Washita river, 65 miles S. W. of Little Rock. Its chief products are lumber and cotton; it has water-power and an active trade. During the first two years of the civil war Arkadelphia was a principal military dépôt for the States of Arkansas, Missouri, and Louisiana. On Feb. 15, 1863, a skirmish took place here between a detachment of Union troops, under Capt. Brown, and a party of Confederates, in which the latter were defeated. Pop. (1890) 2,455; (1900) 2,739.

Arkansas: a river of the U. S., next to the Missouri the longest affluent of the Mississippi, rises in the Rocky Mountains and in the west central part of Colorado. Its general direction is eastward for more than 500 miles through extensive plains, large portions of which are sterile. Having crossed the eastern boundary of Colorado into the State of Kansas, and reached nearly the 98th degree of W. longitude, it turns and flows southeastward through Kansas and the Indian Territory to Fort Smith, on the western boundary of Arkansas; continuing thence in a southeastern course, it traverses the State of Arkansas, which it divides into two nearly equal portions, and enters the Mississippi in lat. 33° 54' N., lon. 91° 10' W.; length, 2,170 miles. It is navigable by steamers 800 miles from its mouth during nine months of the year; difference between high and low water in this river about 25 feet.

Arkansas (by act of its Legislature to be pronounced Ar'kan-saw): one of the southwestern States of the Mississippi valley; bounded N. by Missouri, E. by Missouri and the Mississippi river, S. by Louisiana, W. by Texas and the Indian Territory. It is between 33° and 36° 30' N. lat., and 89° 40' and 94° 42' W. lon. Area, 53,850 sq. miles, about the size of England without Wales. Arkansas, by census of 1900, ranked 24th in population, 21st in value of agricultural products, and 36th in value of manufactures.

Topography.—Eastern part of the State, from 30 to 100 miles west of the Mississippi, low, with lakes, bayous, and swamps; subject to overflow, except occasional bluffs. West of this, land rises by stages to the table-lands and hills of Ozark, Washita, and Black Hills, in N. W., W., and S. W. These rise 1,500 to 2,000 feet, and knobs 500 to 800 feet higher. The rivers are: Mississippi, eastern boundary; Arkansas, crossing diagonally; White, St. Francis, Washita, Red, and their affluents; 3,000 miles of navigable rivers in the State.

Minerals.—Gold, argentiferous galena, zinc, copper, manganese, iron (various ores), semi-bituminous coal, lignite, marble, novaculite or oilstone, millstone, kaolin, mineral paints, salt, and remarkably hot and other mineral springs. In 1899 279,584 tons of bituminous coal were mined.

Soil and Vegetation.—Arkansas has much good soil and some which is not productive. The lowlands are alluvial and highly fertile. Some of the table-lands are sterile, but are covered with scattered pines. The river valleys and some of the mountain slopes have a good and productive soil, and are largely covered with heavy forests. There are immense tracts of alluvial bottom-lands which might be made available for cultivation by a system of drainage. Oak, black walnut, hickory, red elm, maple, tupelo, gum trees (black and sweet), yellow poplar, American elm, white and blue ash, hornbeam, ironwood, Osage orange, red cedar, beech, pecan, sycamore, buttonwood, sassafras, persimmon, locust,

wild cherry, pine, cypress, and cottonwood are the principal forest trees. Wild and cultivated fruits of all kinds abound, and large portions of the uplands, particularly in the north, are adapted to the growing of apples of the best quality.

Zoölogy.—Wild game: Bears, deer of two species, rarely the buffalo and elk, peccaries and wild hogs, rabbits or hares, several species of squirrels and other rodents; cougars or panthers rarely, wolves, foxes, raccoons, opossums, skunks, Texan coyotes. Game-birds: Turkeys, ducks, partridges, quails, prairie-hens, etc.; eagles, vultures, hawks, owls, and many song-birds. The rivers, lakes, and bayous abound in fish, with an occasional alligator, serpents, and other reptiles.

Climate.—In the lowlands, mean annual temperature, 60°-6°; summer mean, 81°-4°; winter, average minimum, 9°; summer maximum, 98°; annual rainfall, 63°-42 inches. On the table-lands (Little Rock), annual mean, 62°-66°; maximum, summer, 96°; winter minimum, 4°; annual range, 92°; rainfall, 55 to 60 inches. Mountains in the west, annual mean, 60° F.; rainfall, about 58 inches. As a whole, the climate is very fine, and it has a high reputation for alleviation of pulmonary diseases.

Agricultural Productions, 1899.—Cotton, 919,469 bales; wheat, 1,953,361 bush.; Indian corn, 48,087,140 bush.; oats, 5,964,442 bush.; potatoes, 1,773,198 bush.; rye, 19,052 bush.; hay, 205,491 tons. Farm animals: horses, 234,127; mules, 142,594; cattle, 419,422; sheep, 108,957. Average wages of farm labor (1890), \$18.40, or, with board, \$12.55 a month.

Manufactures.—Principally of cotton-seed oil, flour and meal, lumber, leather, cotton and woolen goods, wagons, tobacco and cigars, and hones of novaeulite; amount moderate, but increasing. In 1880 there were 1,202 manufactories, \$2,953,130 capital, 4,557 employees, \$925,358 paid for wages, and \$6,756,159 in value of products. In 1890 there were 2,073 establishments with \$14,971,614 capital.

Railroads.—There were in 1885 2,146 miles completed, and in 1899 3,128°-44 miles in operation. The railway system of the State connects with the Texas and Southern Pacific lines.

Finances.—The State debt was in 1890 \$2,092,100 principal; past-due interest, \$2,884,897; total, \$4,976,997, exclusive of \$1,986,773 levee bonds (unconstitutional and invalid), \$5,350,000 railroad aid bonds (illegally issued), and \$1,370,000 other disputed debts. The assessed valuation in 1900 was: Real estate, \$127,062,908; personal, \$62,936,142; total, \$189,999,050; State tax, 50 cents on \$100. The commerce of Arkansas is wholly internal, there being no ports of entry.

Banks.—In 1900 there were 7 national banks with \$1,070,000 capital; and deposits, \$3,102,315.55. There were also 39 State banks—capital, \$1,243,509; deposits, \$4,464,013; and 3 private banks—capital, \$25,000; deposits, \$133,878.

Education.—Population of school age 1899 (six to twenty-one years), 472,508; enrolled in public schools, 296,785; number of school-houses, 2,535; number of teachers, 5,945; expenditure for public schools, \$967,609; amount of permanent school fund, \$458,888. There are normal departments in connection with colleges at Helena and Pine Bluff. There are 13 private schools and seminaries, with 64 teachers and 5,835 pupils. There are 5 universities and colleges, with 44 instructors, 1,023 students, and \$145,000 property. Included in these is the Arkansas Industrial University, with 524 students. There is also one school of medicine, with 14 teachers and 83 students.

Libraries, Newspapers, and Periodicals.—The number of public libraries in 1886 was 16, with 48,143 volumes, besides many school and college libraries. In 1900 the newspapers numbered 263, of which 26 were dailies.

Churches.—The Methodist and Baptist denominations are the most numerous, and, taking the various organizations of each, are of about equal numbers, having between 750 and 800 churches, and from 60,000 to 70,000 members each. The others, in the order named, were Presbyterians, Union, Episcopalians, Roman Catholics, Lutherans, etc.

Population.—In 1870 Arkansas had 484,471 inhabitants; in 1880, 802,525; in 1890, 1,128,179; in 1900, 1,311,564. The counties and county towns, with population of each, are as given in the table.

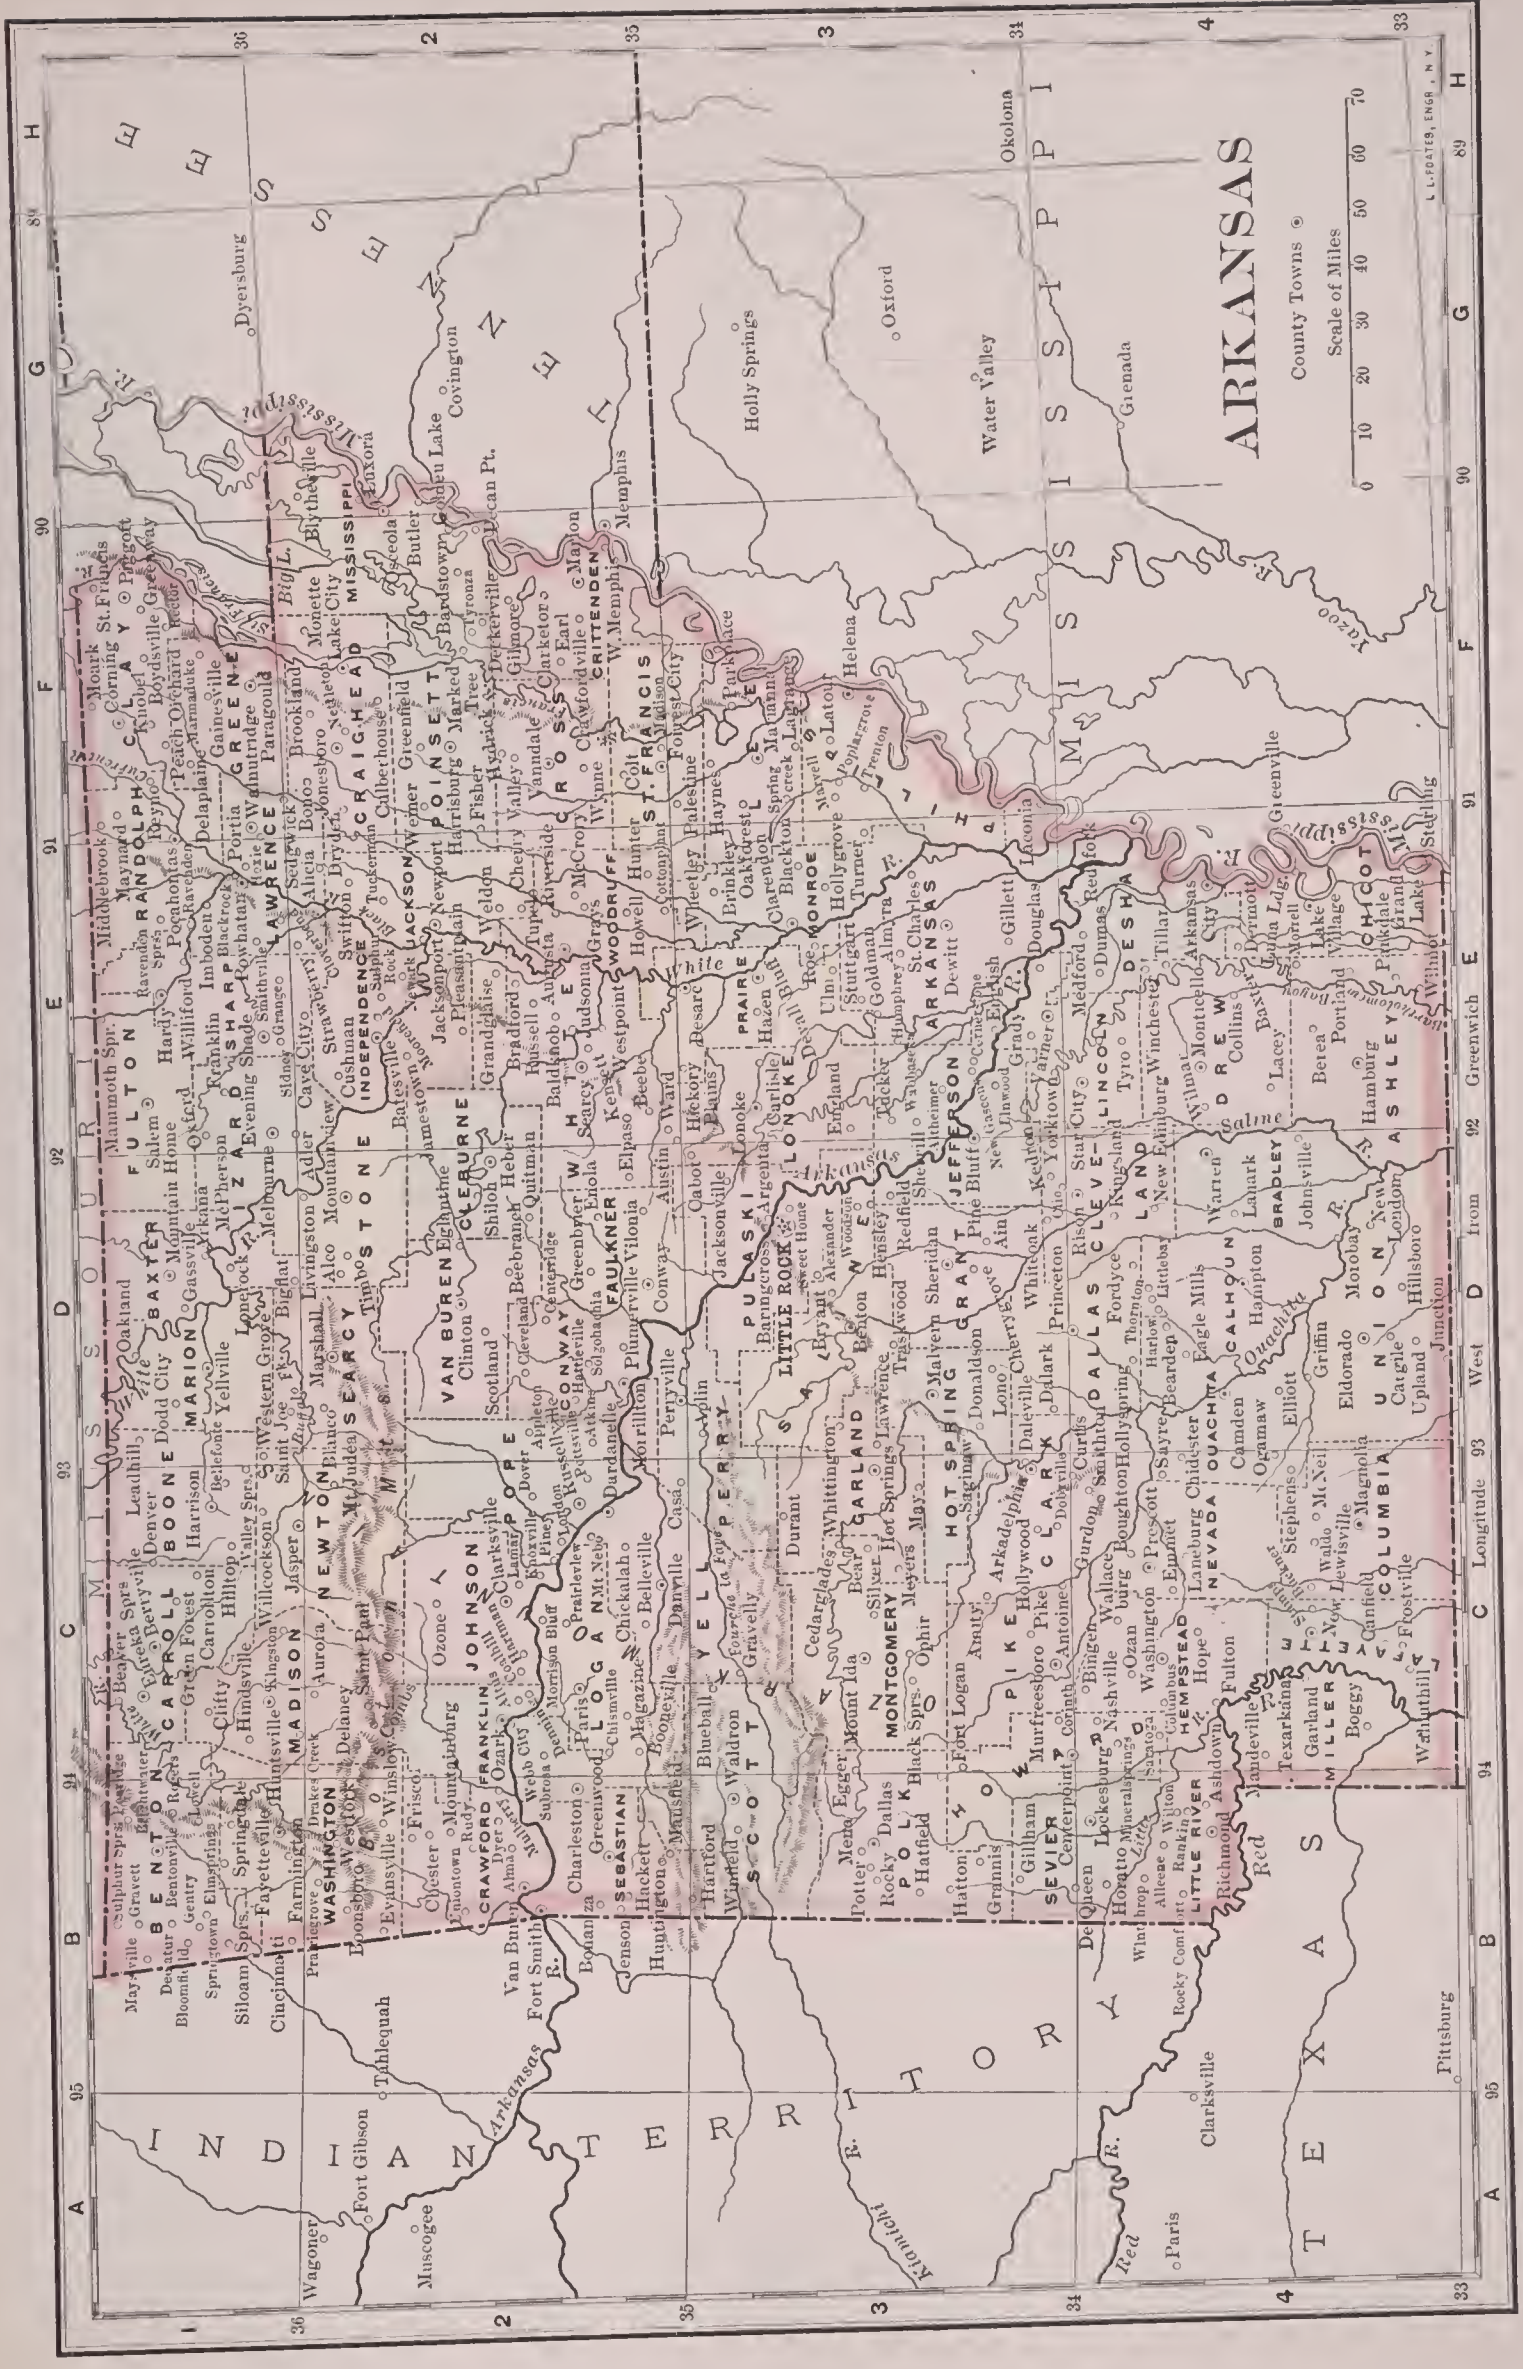

Principal Towns and Population in 1900.—Little Rock, capital, 38,307; Fort Smith, 11,587; Pine Bluff, 11,496; Hot Springs, 9,973; Helena, 5,550; Texarkana, 4,914; Jonesboro, 4,508; Fayetteville, 4,061; Eureka Springs, 3,572; Mena, 3,423; Paragould, 3,324; Newport, 2,866; Camden, 2,840; Arkadelphia, 2,739.

* Reference for location of counties, see map of Arkansas.

History.—First settled in 1670 by the French, near St. Francis river; part of Louisiana Territory in 1803, of Missouri Territory in 1812, and of Arkansas Territory in 1819; organized as a State in 1836, Indian Territory being set off; its growth at first slow—only 97,574 inhabitants in 1840, 209,897 in 1850; large increase from Southern immigration in 1850-60. Having been settled almost exclusively from the Southern States, its population entered heartily into the secession movement. The State convention assembled at Little Rock, and passed the ordinance of secession May 6, 1861. Arkansas was overrun by both armies several times, 1861-63; controlled by Federal troops after Dec., 1863; a new constitution was adopted Mar. 18, 1864, but not accepted by Congress, and the State was for four years under military control; a constitution was

Revised by A. R. SPOFFORD.

Arkansas City: on three railroads and the southern border of Kansas, in Cowley County (for location of county, see map of Kansas, ref. 8-H); at the confluence of the Arkansas and Walnut rivers. Pop. (1880) 1,012; (1890) 8,347; (1900) 6,140.

Arkansas Indians: See SIOUAN INDIANS.

Arkansas Post: a post-village of Arkansas co., Ark. (for location of county, see map of Arkansas, ref. 4-E); on the left bank of the Arkansas river, 50 miles from its mouth; settled by the French in 1685. During the civil war this post was garrisoned and fortified by the Confederates. On Jan. 11, 1863, a combined attack of the U. S. military and naval forces under Gen. McClelland and Admiral Porter was made upon the place, and its works were finally carried by storm. Pop. (1880) 37; township (1900), 1,010.

Arkansas Stone: a stone consisting of NOVACULITE (*q. v.*), which is quarried extensively in Hot Springs and Grant cos., Ark. It is a very beautiful and valuable stone, and is largely used for hones and oilstones.

Ark'ausite: a name given to the thick black crystals of brookite (titanic acid) found at Magnet Cove in the Ozark Mountains of Arkansas. See TITANIC DIOXIDE.

Arko'na, or Arcona: a promontory on the north side of the Prussian island of Rügen, in the Baltic. Here is a lighthouse on the site of the heathen temple of Swantewit, which King Waldemar of Denmark burned in 1168.

Ar'kose: See SANDSTONE.

Arkwright, Sir RICHARD: English inventor; b. at Preston, in Lancashire, Dec. 23, 1732. He learned the trade of a barber, which he soon abandoned, and applied himself to the invention of machinery for spinning cotton. At that time no machine could produce cotton yarn fit for warp. In 1768 he set up at Preston his first spinning-frame, for which he obtained a patent in 1769. He removed to Nottingham in 1769, and formed a partnership with Need and Strutt. His machine caused a great extension of the cotton manufacture, and greatly promoted the prosperity of the nation, and he may be called the founder of the factory system. He was knighted by George III. in 1786. D. at Cromford, Aug. 3, 1792. See Baines, *History of the Cotton Manufacture in Great Britain* (1835).

Arlberg: a mountain mass which forms the boundary between the two Austrian provinces of Tyrol and Vorarlberg; 5,400 feet above the sea (see map of Switzerland, ref. 4-J). In 1880-84 it was pierced, at an elevation of 4,030 feet, with a railway-tunnel, 6,720 yards long.

Arles (anc. *Ar'elas, Arela'te, or Arela'tum*): city of France; department of Bouches-du-Rhône; on the Rhône, 15 miles from the Mediterranean (see map of France, ref. 8-G). It has a cathedral of the seventh century, a museum, a college, and a public library. It was once the capital of the kingdom of Arelate. Important councils of the Church were held here in 314, 354, 452, and 475 A. D. Here are the remains of a grand Roman amphitheater, and an ancient granite obelisk which was dug out of the Rhône about 1389. Arles has manufactures of hats, silk, brandy, etc. Pop. (1881) 23,480; (1896) 24,567.

Arlington: on railroad, Middlesex co., Mass. (for location of county, see map of Massachusetts, ref. 2-H); 7 miles N. W. of Boston. It has national and savings banks, an elegant new library building costing \$200,000 (the gift of Mrs. Eli Robbins), gas and water works, electric cars to Boston, and sends a large supply of ice to market. There are im-

portant manufactures. The principal business is market-gardening. Pop. of township (1880) 4,100; (1890) 5,629; (1900) 8,603.

EDITOR OF "ADVOCATE."

Arlington, HENRY BENNET, Earl of; b. in 1618; served as a royalist in the civil war (1642-45); was knighted at Bruges (1658), became Secretary of State (1662), a baron (1664), a member of the "Cabal" (1667), received the Garter, and was sent as ambassador to the King of France in the same year; was impeached by the Commons, resigned, and was appointed Lord Chamberlain (1674). D. July 28, 1685.

Arlt, FERDINAND: German oculist; b. at Obergraupen, near Teplitz, Apr. 18, 1812. He wrote, among other works, *Krankheiten des Auges* (3 vols., 1851-56; 4th ed. 1867); *Pflege der Augen im gesunden und kranken Zustande* (3d ed. 1865).

Arm: in man and the higher animals, the upper or anterior limb, extending from the shoulder to the wrist. The human arm consists of the *brachium* or arm proper (sometimes called the upper arm) and the *antebrachium* or forearm. The former has one bone, the humerus; the latter two, the ulna upon the inside (as the hand lies with the palm upward) and the radius upon the outside. The humerus articulates with the shoulder-blade or scapula, forming the shoulder. This is a ball-and-socket joint, having universal movement. At the elbow-joint the inner bone of the forearm, the ulna, articulates with the lower end of the humerus, forming a hinge-joint. The upper end of the radius practically does not enter into the elbow-joint, but acts as a fulcrum upon which the radius swings as the hand is pronated and supinated, for an account of which see the article HAND. And the lower end of the radius and ulna are bound closely to each other with ligaments, and form an articulation with the upper row of the carpal bones of the hand—that is, turned palm upward or palm downward.

The muscles of the arm may be divided into separate groups; the shoulder-joint is covered over and rounded by the powerful deltoid muscle which springs from the shoulder-blade and clavicle, and is attached to the upper and outer part of the humerus, so that in its action the arm is moved from the side. It is opposed by the great pectoral muscle in front and the latissimus dorsi behind, the two latter in their action drawing the arm to the side and downward. On the front of the arm proper is the biceps, which

The bones of the upper extremity with the biceps muscle.

flexes the forearm upon the arm and behind the triceps acts in the opposite direction. The forearm has two groups of muscles, the one on the outer side surrounding the radius containing the extensor muscles for the wrist and hand, that on the inner or ulnar side being composed of the flexor muscles.

The blood-supply of the arm is mostly derived from the brachial artery, which is a continuation of the axillary artery. This vessel may be felt beneath the skin on the inner side of the biceps muscle of the arm, and especially at the elbow-joint, where it is quite superficial below the elbow before it divides into a radial and an ulnar branch, which continue downward into the hand. The nerves of the arm are branches of the brachial plexus. They accompany the axillary and brachial artery, giving off numerous branches in their descent.

W. P.

Arma'da, The Spanish: often called the "Invincible Armada," a great Spanish fleet or armament which was fitted out by Philip II. for the conquest of England in 1588. It

consisted of about 130 vessels, some of which were of enormous size, carrying in all 2,431 guns and more than 19,000 soldiers. The command of this armada was given to the Duke of Medina Sidonia, who was not a competent naval commander. Lord Howard of Effingham commanded the English fleet, which was greatly inferior in size. Among the subordinates were some of the best naval officers of the time, such as Drake, Hawkins, and Frobisher. The armada sailed from Spain about the end of May, 1588, and in passing through the English Channel was harassed by the English, who avoided a general engagement. During a night in August Lord Howard sent eight fire-ships against the armada, and produced a panic and great disorder, in consequence of which the English captured or destroyed about twelve ships early the next morning. This defeat induced the Spanish admiral to abandon the invasion of England, and he resolved to return to Spain by sailing around the Orkney islands, the passage of the English Channel being closed by the enemy. Many of the Spanish ships were wrecked on their circuitous voyage, and only fifty-three returned to Spain. See Fronde, *Spanish Story of the Armada* (London and New York, 1892).

Armadillo [Span. dimin. of *armado*, armed, one who is armed < Lat. *armatus*, partic. of *armare*, to arm]: the common name of the *Dasyproctidae* (*q. v.*), a family of edentate mammals, natives of South and Central America. They derive their name from a bony armor which covers the body, and consists of polygonal pieces united to form solid bucklers, one over the rump, one piece over the shoulders, and between them a dorsal cloak consisting of a number of plates disposed in transverse bands, which are movable and allow freedom of motion. The head is protected by a similar buckler, not continuous with that of the body. They have short legs and feet adapted to burrowing in the ground, in which, when pursued by enemies, they bury themselves quickly. These animals are nocturnal, and feed on insects, carrion, and vegetable food. Their flesh is often eaten by the natives, but, owing to its rank and strong flavor, it is not agreeable to European palates. The giant armadillo (*Priodon gigas*), the largest member of the family, is about 3 feet long, exclusive of the tail. The claw of the third toe of the forefoot is extremely large and much flattened, forming an admirable instrument for digging out the ants which constitute the animal's chief food. It is found in the forests of Surinam and Brazil, but is rare. Although it is quite commonly believed that all armadillos can curl up into a ball, the members of the genus *Tolypeutes* are the only ones which can do so, this feat being rendered possible by the arrangement of the back armor, which is divided into five portions, a large shield over the shoulders, another of the hinder portion of the body, and three narrow bands between. The fore and hind legs are drawn up under their respective coverings, the head and short tail filling in the little space left below. The peba (*Tatusia peba*) is one of the best known species, and is widely distributed, ranging from Southern Texas to the Argentine Republic. The GLYPTODON (*q. v.*) is an extinct gigantic relative of the armadillo.

Armadillos.

Armageddon (mount of Megiddo): the Plain of Esdraelon, the great battle-field of the Old Testament; used figuratively in Rev. xvi. 16.

Armagh, ar-maa': an inland county of Ireland, province of Ulster; bounded N. by Lough Neagh, E. by Down, S. by Louth, and W. by Monaghan and Tyrone. Area, 512 sq. miles. The surface is undulating or level, except the S. W. part, where Slieve Gullion rises to the height of 1,893 feet. The soil is mostly fertile. The chief rivers are the Bann, Blackwater, and Callan. Granite, trap, carboniferous limestone, and lower Silurian rocks underlie the county. Capital, Armagh. Pop. of the county (1881) 162,823; (1891) 143,056.

Armagh [Ard-magha, high field]: a city of Ireland; capital of county of same name; situated on high ground 36 miles by rail S. W. of Belfast (see map of Ireland, ref. 6-H). It is built of limestone quarried in the vicinity, and has a Protestant cathedral of red sandstone crowning the central eminence, down the sides of which the streets diverge. Armagh is the archiepiscopal seat of the primate and metropolitan of all Ireland, both in the Anglican and Roman

Catholic churches. It has a Roman Catholic cathedral, a college, a large public library, a famous astronomical observatory, and a lunatic asylum. It was the capital of Ireland in the sixth and seventh centuries, and was renowned as a school of theology, etc. On account of the Danish incursions and the English conquest and wars it fell into decay, but is now one of the best-built cities in Ireland. Pop. 10,070.

Armagnac, aar-maan'yak: a former name of a region in France, now comprised in Gers and parts of Haute-Garonne, Tarn-et-Garonne, and Lot-et-Garonne. Its ancient counts were feudal to the crown of France until the time of Henry IV., who united it in his own person to the crown. In later times the title of Count of Armagnac was an honorary one.

Armagnac, BERNARD, Count, d': constable of France; was an ambitious and turbulent nobleman. He became in 1407 the enemy of the Duke of Burgundy and the chief of the faction called "Armagnacs," who waged a civil war against the Burgundians. In 1415 he obtained the office of constable of France, the highest in the nation. Having excited the odium of the Parisians by his tyranny, he was killed by the populace June 12, 1418.

Armagnac, JEAN V., Count, d': a grandson of Bernard, noticed above; b. about 1420. He was notorious for his crimes (he married his sister), and was excommunicated by the pope, but subsequently absolved. As a party to the League of Public Good, he revolted against Louis XI. in 1465. He was put to death by order of that king in Paris, Mar. 5, 1473.

Armausperg', JOSEPH LUDWIG, Count von: an able German statesman; b. at Kötzing, in Bavaria, Feb. 28, 1787. He became a leader of the liberal party, Bavarian Minister of Finance in 1826, and Minister of Foreign Affairs in 1828. By the influence of the Roman Catholic priests he was removed from office in 1831. From Jan., 1833, to Feb., 1837, he governed Greece as regent or chief minister under King Otho, who was a minor. D. in Bavaria, Apr. 3, 1853.

Armatoli, or **Armatoles**: a body of Greek militia organized about 1500 A. D., or earlier. They lived and operated in mountainous regions that were difficult of access, and were very tenacious of their independence. They were employed by the Turkish sultan to protect the fertile plains from the raids of the *klephts* (mountain-robbers) of Thessaly. Northern Greece was divided into about sixteen districts, each of which was placed under the supervision of an armatol. In the war of Greek independence the armatols fought against the Turks, and distinguished themselves by daring exploits.

Armature [Lat. *armatu'ra*, armor]: a piece of soft iron which is placed in contact with the poles of a permanent magnet to preserve its magnetic power. To such an armature the name "keeper" is frequently applied. In dynamos the armature is the coil or set of coils of wires in which current is generated, either by revolution in the magnetic field of the machine or by periodical fluctuations otherwise produced in the number of lines of force which pass through the coils in question. See DYNAMO-ELECTRIC MACHINES, ELECTRIC MOTOR, and ELECTRICITY. E. L. NICHOLS.

Armenia (Turk. *Erminee'yeh*): an important country of Western Asia which has now no political existence, but is historically very interesting as the original seat of an ancient civilized people (Armenians), who have preserved their nationality to the present time. Armenia, the boundaries of which varied in different periods, was situated between Asia Minor and the Caspian Sea. It was mostly included between lat. 37° and 42° N., and between lon. 36° and 49° E. It was divided into Armenia Major and Armenia Minor, the former of which was bounded on the N. E. by the river Kur, on the E. by the Caspian Sea, and on the W. partly by the Euphrates. The Lesser Armenia was situated on the western side of the other. This country is an elevated table-land, inclosed on several sides by the ranges of Taurus and Anti-Taurus, and partly occupied by other mountains, the highest of which is the volcanic peak of Ararat. It is drained by the Euphrates and Tigris, which rise within its limits, and traversed by the river Aras (Araxes). Among its physical features are the large lakes of Van and Sevan, the former of which is saline. It abounds in romantic mountain scenery. The climate of Armenia is very cold in the highlands, while the summer heat of the valleys is intense. Here is a variety of soils, some of which in the valleys produce good crops of cotton, rice, tobacco, and grapes. Grazing

and cattle-breeding are more extensively followed than agriculture. Among its mineral resources are copper, iron, lead, alum, and salt. The chief towns of ancient Armenia were Artaxata, Anni, and Tigranocerta. The chief modern towns are Erivan, Erzroom, and Van. The Armenians call themselves *Haiks* or *Haikans*, a name derived from Haik, or Haig, represented as the first King of Armenia and a descendant of Japhet. Among the most famous of their ancient kings was Dikran or Tigranes, who lived about 550 B. C., and was a friend and ally of Cyrus the Great. The kingdom was conquered by Alexander the Great in 325 B. C., and recovered its independence about 190 B. C. It was afterward ruled by the Parthian Arsacidæ, among whom was Tigranes the Great, a son-in-law of Mithridates, King of Pontus. He waged war against the Romans, and was defeated about 63 B. C. The Armenians are physically a fine variety of the Indo-European race. They have excellent talents for business, and are especially skillful in banking and mercantile pursuits. Christianity is said to have been introduced into Armenia by the apostle Thaddeus. It became, through the influence of Gregory the Illuminator, the established religion of the state in 289. King Tiridates was baptized in 289, and Gregory the Illuminator made "hierarchy" in 302. Political troubles prevented the Armenian Church from taking part in the Council at Chalcedon (451). Hence a misunderstanding, which led the Armenians to set up a separate communion in 491, without ever having become really monophysitic. The Armenians believe in the worship of saints, but not in purgatory, and are especially rigid in the observance of fasts. A small portion of the Armenians in Turkey, Persia, Austria, and Russia have recognized the supremacy of the pope, and are called United or Roman Catholic Armenians; they date from 1316-34. Some years ago a split took place among the United Armenians of Turkey, on account of the changes which the pope made in the ancient constitution of their Church. They were excommunicated by the pope, and in 1872 entered into official communication with the Old Catholics of Germany. In 1830 a very successful Protestant mission among the Armenians was organized by the American Board of Commissioners for Foreign Missions, out of which grew the Evangelical Protestant Church in 1850.

Since 1894 the Armenians in Turkey have been subjected at the hands of the Kurds and Turkish soldiery and officials to atrocities which have shocked the whole civilized world, and called forth strong protests from the U. S. and the great powers of Europe. It has been estimated that during these years over 50,000 persons of both sexes have been massacred. Hitherto (1897), owing chiefly to international jealousies, the so-called "concert of the great powers" of Europe has failed to secure to the Armenians and other Christians in the Turkish empire the protection which they need and deserve, and to which they are entitled. Since the early years of the Christian era this country has been the subject and scene of many bloody contests between the Romans, Persians, Byzantine Greeks, Saracens, Turks, etc., who have successively been masters of it. It now belongs partly to Russia, partly to Persia, and partly to Turkey. The scourge of war and persecution for religious opinions drove great numbers of the Armenians from their native land, and they are now dispersed in various parts of Europe and Asia Minor. The number of Armenians is estimated at not more than 4,000,000, of whom 2,500,000 are in Turkey, and of these about 1,000,000 live in Armenia. See Saint-Martin, *Mémoire historique et géographique sur l'Arménie* (1818); Curzon, *Armenia* (1854); Creagh, *Armenians, Koords, and Turks* (1880); Gatteyrias, *L'Arménie* (Paris, 1880); Norman, *Armenia* (1896); *The Rule of the Turk* and *The Armenian Crisis in Turkey*, by F. D. Greene (1896); and Vartoogian's *Armenia's Ordeal* (1896). See also *Life and Times of St. Gregory the Illuminator* (trans. by Malan, 1868); and Hamachod, *Chronological Succession of the Armenian Patriarchs* (1865). Revised by R. LILLEY.

Armenian Language and Literature: The language of Armenia belongs to the Indo-Germanic family of languages, under which it forms an independent branch like the Greek and Albanian. This view regarding its independence is the generally accepted one, in accordance with Hübschmann's investigations; though the Armenian tongue, especially on the claim of De Lagarde and Fr. Müller, was formerly regarded merely as a subdivision under the Iranian group. We possess monuments of Armenian dating back to the fourth or fifth century of our era. Three stages are

recognized in its linguistic development: (1) the early period, prior to the fifth century; (2) the classical period, from the fifth century, or the date of Bishop Mesrob, to the twelfth century; (3) the later period, from the twelfth century to the present.

A statement preserved in Philostratus (about 200 A. D.) would point to the existence of an Armenian alphabet at the beginning of our era; but tradition usually ascribes the invention, or perhaps rather the reconstruction, of an Armenian alphabet on the Greek basis to Bishop Mesrob in the fifth century. Mesrob's alphabet consists of thirty-six letters, to which there were added two new characters, one for *f* and one for long *ō*, in the twelfth century. The writing runs from left to right.

In addition to the usual familiar sounds the Armenian phonology presents an indefinite vowel *ə* (cf. Eng. *but*), likewise affricatives *č* (*tsh*), *č'* (*thsh*), etc., and spirants (*š* = *sh*, *ž* = *zh*, etc.) and aspirates (*k'* = *k-h*, etc.). The accent of words is prevailing on the final syllable. The inflectional system does not distinguish grammatical gender; but in declension seven cases, including the instrumental, are recognized. A so-called "narrative" case and a "circumlocutory" are also formed by added prefixes. There is no dual. The adjective, moreover, is declined like the substantive, but it sometimes remains invariable. The comparative degree is usually formed by adding *guin* to the stem; the superlative has no special form, but is expressed by repeating the positive, or by emphasizing it by strengthening adverbs resembling *most*, *very*. The numerals, as well as the pronouns, show full declensions. The demonstrative pronouns present a characteristic formative element, *s*, *d*, *n*, which amalgamates with the stem-form to indicate nearness or less and greater remoteness, somewhat like Lat. *hic*, *iste*, *ille*. The verb-system distinguishes three persons, two numbers, three modes, namely, indicative, conjunctive, imperative, likewise an infinitive ending in *l*, and also participial forms. There are four tenses, a present, an imperfect, an aorist of twofold formation, and a future of two forms. Four conjugation classes, based on the characteristic vowels, *e*, *a*, *u*, *i*, are distinguished. The fourth or *i* conjugation may be generally regarded as a passive.

Armenian literature, like Anglo-Saxon, practically begins with the introduction of Christianity, about the fourth century, but there are only scanty remains until the fifth century. The fifth century, or the age of Mesrob, is one of the most flourishing periods in Armenian literary activity. Mesrob, like the great Gothic Bishop Ulfilas, practically invented an alphabet, and created an epoch by his work on a translation of the Bible. Aided by two of his pupils he joined the Patriarch Isaac in work upon a version. The translation was begun from the Syriac Peshito version, but was finally made from the Greek version. Its completion is assigned to the year 411, or perhaps rather about 431. To the same century belongs the famous historian Moses of Khoreni or Chorene (d. 488), who wrote the Armenian *Chronicle* (transl. by Lauer, Regensburg, 1869) from the time of Haig down to his own day. His contemporary, Bishop Eghishe, or Elisæus, recorded the events of the wars of Vartan with the Persians (transl. by Neumann, London, 1830). The succeeding six centuries all contain literary works, but there are no names of real importance till the twelfth and thirteenth centuries. To this era belong, among other names, the distinguished religious writer and poet Nerses Klayensis (d. 1173) and his nephew, Nerses Lampron. In the eighteenth century the Venetian Mekhitarists did much toward reviving and encouraging Armenian literary work, and the comparatively recent historical writings of Tschamtschean (3 vols., Vienna, 1786), for example, are of genuine value. Armenian literature shows almost unbroken continuity since its beginning, and it is of historical and philological importance, as well as of interest from the literary side.

Müller, *Armeniaca* (Vienna, 1860-92); Hübschmann, *Armenische Studien* (Leipzig, 1883); also Bedrossian, *New Armenian Dictionary* (Vienna, 1875-79); Neumann, *Geschichte der armenischen Literatur* (Leipzig, 1836). A. V. WILLIAMS JACKSON.

Armentières: a town of France; department of Nord; on the river Lys; 12 miles by rail N. W. of Lille (see map)

of France, ref. 1-F). It has manufactures of cotton, linen, lace, and sailcloth. Pop. (1896) 29,603.

Armes, PHILIP: musician; b. in Norwich, England, in 1836. He was first a chorister in Norwich cathedral, afterward going to Rochester. In 1857 he was appointed organist of St. Andrew's, Wells Street, London; Chichester cathedral, 1861, and Durham cathedral, 1862, where he still remains. Most important among his compositions are the two oratorios *Hezekiah* and *St. John the Evangelist*. He has composed largely in the field of church music, and his anthems and services are well known and appreciated.

D. E. HERVEY.

Arm'felt, GUSTAF MAURITZ: Swedish general and courtier; b. in the province of Åbo, Apr. 1, 1757. He became a favorite of Gustavus III., who, after he was mortally wounded by an assassin in Mar., 1792, appointed Armfelt governor of Stockholm. This appointment was nullified by the Duke of Sudermania, who was the enemy of Armfelt, and acted as regent during the minority of Gustavus IV. The regent sent him on a mission to Naples, and during his absence charged him with treason, for which he was sentenced to death. When Gustavus IV. began to reign in 1799 he restored Armfelt to honor and office. He became governor-general of Finland in 1805, and commanded the army in a war against Norway in 1808. Having entered the service of Russia in 1810, he obtained several high civil offices. D. at Zarskoje-Selo, Aug. 19, 1814.

Armi'da: the name of a beautiful sorceress in Tasso's poem of *Jerusalem Delivered*. She attempted to seduce Rinaldo and other crusaders. The former was fascinated for a time, but finally returned to the war against the infidels, and converted Armida to Christianity.

Ar'millary Sphere [*armillary* is from Lat. *armilla*, ring, circle, deriv. from *armus*, upper arm]: an ancient and obsolete astronomical machine; consisted of an assemblage of rings or circles fixed together, so as to represent the principal circles of the celestial sphere in their proper relative positions. These rings were movable round the polar axis within a meridian and horizon, as in the celestial globe. The observations of Hipparchus were made by means of the armillary sphere.

Arminius and Arminianism: (1) **ARMINIUS.**—The name of Arminius in his native language was **JACOBUS HERMANS**, identical with Herman, the name of the hero of Germany who destroyed the Roman legions under Varus. And as this name was transformed into Arminius by Tacitus and other Roman writers, so, in accordance with the custom of the age when Latin was the language of current literature, this name was Latinized, and has come down in modern English as **JAMES ARMINIUS**. He was born in 1560 at Oudewater (old water), a small town in the Southern Netherlands. He lost his father in early childhood, and, his mother being left in straitened circumstances, the promising intellect of the boy so attracted the attention of patrons that he was taken to school at Marburg. When fifteen years of age his native town, Oudewater, was taken by the Spaniards, and his mother, brother, and sister were all massacred, leaving him the sole survivor of his family. He was sent by his patrons to the new university at Leyden, where he remained six years. Such was his proficiency that the city of Amsterdam adopted him as her *vesterling* or foster-child, to be educated at the public expense, he being bound by a written obligation to be at the command of the city through life. He studied at Geneva under Beza, as well as at Basel under Gryneas. At the latter place he was offered a doctorate, but declined the honor on account of his youth. By Beza he was commended to Amsterdam in high terms. He then went to Italy to become accomplished in philosophy under Zarabella, and having visited Rome and the other principal cities returned to Amsterdam, where he was installed minister at the age of twenty-eight.

Arminius's ministry in Amsterdam, of fourteen years' duration, forms the second period of his life. His learning and eloquence were rapidly rendering him one of the leading theologians and preachers of his age. He was of middle size, had dark, piercing eyes, and voice light but clear, and possessing a winning mellowness. His manners were magnetic, and he had the power of fastening firm friends. He was condescending to the lowly and a sympathizing guide to the religious inquirer. At the same time he was an independent seeker and follower of truth.

In 1585 the extreme predestinarianism prevalent in the

Netherlands had been for ten years so effectively attacked by Richard Coornhert, an eminent patriotic and acute layman of Amsterdam, that Arminius was invited by the city to refute him. In a debate at Delft between Coornhert and two high Calvinistic clergymen, the latter were so hard pressed that they yielded, and took the lower or sublapsarian ground, and published a pamphlet against the higher view. The extreme Calvinists called upon Martin Lydius, Professor of Theology in Friesland, to refute them, but he handed over the task to Arminius, who had thus a double request on his hands. He bravely undertook the task, but was soon convinced of the untenableness of either the higher or lower predestination. At the expense of an ignominious failure in even *attacking* Coornhert, he resolved to pursue the light of honest conviction. Avoiding the entire subject in public, he prosecuted his investigations with earnest study. Yet, in lecturing on Romans vii., having given the non-Calvinistic interpretation, he found himself generally assailed by the high Calvinists as a Pelagian and Socinian. He was arraigned before the ecclesiastical courts, where he successfully defended himself on the ground that, though adverse to the prevalent opinions, his interpretation contradicted nothing in the standards—namely, the Belgic Confession and the Catechism. Being questioned as to predestination, he declined to answer, as no fact was alleged against him.

In prosecuting his inquiries he determined to consult privately the best theologians of the day. He commenced a confidential correspondence with Prof. Francis Junius of the University of Leyden, the most eminent of the Dutch theologians. He was delighted to find how far Junius coincided with him, but when he addressed to Junius the arguments for still more advanced views the professor kept the letter by him unanswered for six years, when he died. The friends of Arminius believed that this silence arose from the fact that Junius found more than he could answer or was willing to admit. Unfortunately, this correspondence was inadvertently exposed by Junius to discovery, and was used to the disadvantage of Arminius. Arminius also, having received a treatise in favor of predestination by Prof. Perkins, of Cambridge, prepared an epistle to him, but was prevented by Perkins's death from sending it. His letters both to Junius and Perkins are embodied in his published works, and, whatever may be thought of the validity of the argument, no one will deny that in candor, courtesy, and Christian dignity, they are hardly to be surpassed.

On the death of Junius the curators of the University of Leyden looked to Arminius as his successor. The reluctant consent of Amsterdam being at length gained, Arminius assented. But the predestinarians, led by Gomarus, senior Professor of Theology at Leyden, opposed his election. After a long series of strifes, Arminius offered to meet Gomarus and satisfy his objections. The meeting took place, and Gomarus, admitting that he had judged Arminius by hearsay, after Arminius had fully declared his entire opposition to Pelagianism and Socinianism, fully renounced his objections. So far as predestination was concerned, each professor was to deliver his own sentiments with moderation, and all collision with the other was to be avoided; and Arminius was thereupon elected.

The six years of his Leyden professorship closing with his death are the most important, yet troublous, period of his career. The terms of peace were broken within the first year by Gomarus, who delivered a violent public harangue on predestination in terms of insult to Arminius, who was personally present; to which the latter prepared a refutation clothed in terms of personal respect toward his opponent. Arminius was held as invalidating the Belgic Confession, and so was everywhere traduced by the clergy as a papist, a Pelagian, and a Coornherter. Yet, really, the doctrines he taught were essentially the doctrines of St. Chrysostom, Melancthon, Jeremy Taylor, and John Wesley. In regard to the Confession, he ever treated it with reverence, and only claimed the right of that same liberality of interpretation which Lutherans exercised with the Augsburg Confession. Arminius was proscribed by the clergy, harassed by irresponsible deputations, and his students were subjected to persecutions and exclusions from the ministry. The more intelligent laity, including the magistracy, and especially the chief magistrate, Olden Barneveldt, were favorable to Arminius, who at length appealed to the national legislature (called the States-General) for protection. That body appointed a committee or council, who, having heard both Gomarus and Arminius in full, reported that the latter

taught nothing but what could be tolerated. Before the States-General themselves Arminius delivered a full oration, expounding his entire views, given in full in the edition of his works published in the U. S. The clergy demanded the appointment of a national synod, consisting purely of ecclesiastics, but the States-General, well knowing what would be the fate of Arminius in their hands, refused. Under the constant pressure of these years of persecution the gentle spirit of Arminius at length sunk. He was taken from the bloody times that followed the Synod of Dort. His nervous system was prostrated, and, attended by his faithful pupil, the afterward celebrated Episcopius, he died in the faith he had maintained at Leyden, Oct. 19, 1609, a martyr to his views of truth.

(2) ARMINIANISM.—Arminianism, as the customary antithesis to Calvinism, is, within the limits of the evangelical doctrines, the theology that tends to freedom in opposition to the theology of necessity or absolutism. This contrast rises into thought among all nations that attain to reflection and philosophy. So in Greek and Roman thinking, Stoicism and all materialistic atheism held that mind, *will*, is subject to just as fixed laws in its volitions as physical events are in their successions. When, however, men like Plato and Cicero rose to a more transcendent sense of moral responsibility, especially of eternal responsibility, they came to say, like Cicero, "Those who maintain an eternal series of causes despoil the mind of man of free will, and bind it in the necessity of fate."

Theistic fatalism, or Predestination, consists in the predetermination of the Divine Will, which, determining alike the volitions of the will and the succession of physical events, reduces both to a like unfreedom; but those who hold Predestination very uniformly hold also to volitional necessity, or the subjection of will in its action to the control of strongest motive force. And as the Divine Will is held subject to the same law, so Necessity, as master of God, man, and the universe, becomes a universal and absolute Fate. This doctrine, installed by St. Augustine, and still more absolutely by John Calvin, in Christian theology, is from them called Augustinianism, or more usually Calvinism.

In opposition to this theology, Arminianism maintains that in true *responsibility, guilt, penalty*, especially *eternal penalty*, there must be in the agent a *free will*; and in a true responsible free will the freedom must consist in the power, even in the same circumstances and under the same motives, of *choosing either way*. No man can justly be eternally damned, according to Arminianism, for a choice or action which he can not help. If fixed by Divine decree or volitional necessity to the particular act, he can not be held responsible or justly punished. In all such statements, however, it is presupposed, in order to a just responsibility, that the agent has not responsibly abdicated or destroyed his own power. It is also to be admitted that there may be suffering which is not penalty—finite sufferings for which there are compensations, and for which every one would take his chance for the sake of life. But eternal suffering, for which there is no compensation, inflicted as a *judicial penalty* on the basis of *justice*, can be justly inflicted only for avoidable sin. If Divine decree or volitional necessity determine the act, it is irresponsible, and judicial penalty is unjust.

Arminianism also holds that none but the person who freely commits the sin can be guilty of that sin. One person can not be guilty of another person's sin. A tempter may be guilty of tempting another to sin, but then one is guilty of the sin, and the other of solely the sin of temptation. There can thus be no vicarious guilt; and as punishment, taken strictly, can be only infliction *for guilt upon the guilty*, there can literally and strictly be no vicarious punishment. If innocent Damon die for Pythias guilty of murder, Damon is not guilty because he takes Pythias's place in dying, and his death is not *to him* a punishment, but a suffering, which is a substitute for another man's punishment. The doer of sin is solely the sinner, the guilty, or the punished. These preliminary statements will elucidate the issues between Calvinism and Arminianism on the following points:

1. *Foreordination*.—Calvinism affirms that God does unchangeably and eternally foreordain whatsoever comes to pass. That is, God from all eternity predetermines not only all physical events, but all the volitions of responsible agents. To this Arminianism objects that the predetermination of the agent's volitions destroys the freedom of his will; that it makes God the responsible predeterminer and willer of

sin; and that it makes every sinner to say that his sin accords with the Divine Will, and therefore, so far as himself is concerned, is right. It makes God first decree the sin, and then punish the sinner for the sin decreed. The Arminian theory is this: God does from all eternity predetermine the laws of nature and the succession of physical and necessary events; but as to free moral agents, God, knowing all possible futurities, does choose that plan of his own conduct which, in view of what each agent will ultimately in freedom do, will bring out the best results. His system is a system of his own actions. And God's predeterminations of his own acts are so far contingent as they are based on his precognition of what the agent will freely do; yet as his omniscience knows the future with perfect accuracy, so he will never be deceived nor frustrated in his plans and providences.

Some Arminians deny God's foreknowledge, on the ground of the intrinsic impossibility of a future contingency being foreknown. As the performance of a contradictory act is impossible, intrinsically, even to Omnipotence, so, say they, the knowability of a future contingency, being an essential contradiction, is impossible even to Omniscience. A contradiction is a nothing; and it is very unnecessary to say in behalf of God's omnipotence that he can do all things, and all nothings too. So it is equally absurd to say in behalf of his omniscience that he knows all things, and all nothings too. The exclusion of contradictions does not *limit* God's omnipotence or omniscience, but *defines* it. Arminians do not condemn this reasoning, but generally hold that their theory is maintainable against Calvinism on the assumption of foreknowledge. They deny, as against the Calvinist, that foreknowledge has any influence upon the future of the act, as predetermination has. Predetermination *fixes* the act—foreknowledge *is fixed* by the act. In foreordination God determines the act as he pleases; in foreknowledge the agent fixes the prescience as he pleases. In the former case God is alone responsible for the creature's act; in the latter case God holds the creature responsible, and a just divine government becomes possible. Yet most Arminians probably would say: If the divine foreknowledge of the volitions of a free agent contradicts the freedom, then the freedom, and not the foreknowledge, is to be believed.

2. *Divine Sovereignty*.—Calvinism affirms that if man is free God is not a sovereign. Just so far as man is free to will either way, God's power is limited. Arminians reply that if man is not free, God is not a sovereign, but sinks to a mere mechanist. If man's will is as fixed as the physical machinery of the universe, then *all* is machinery and not a government, and God is a mechanist and not a ruler. The higher man's freedom of will is exalted above mechanism, so much higher is God elevated as a sovereign. Here, according to Arminians, Calvinism degrades and destroys God's sovereignty, and Arminianism exalts it; the freedom of man no more limits God's power than do the laws of nature by him established; in both cases, equally, there is simply a self-limitation by God of the *exercise* of his power; Arminianism holds to the absoluteness of God's omnipotence just as truly as Calvinism, and to the grandeur of his sovereignty even more exaltedly.

3. *Imputation of Adam's Sin*.—Calvinism affirms that Adam's posterity is truly *guilty* of Adam's sin, so as to be eternally and justly punishable therefor without a remedy. As *guilty* of this sin, God might have the whole race born into existence under a curse, without the power or means of deliverance, and consigned to eternal punishment. Arminians deny that guilt and literal punishment can, in the nature of things, be thus transferred. Their theory is that upon Adam's sin a Saviour was forthwith interposed for the race as a previous condition to the allowance of the propagation of the race by Adam, and a provision for inherited disadvantages. The race inherits the nature of fallen Adam, not by being held *guilty* of his sin, but by the law of natural descent, just as all posterity inherit the species-qualities, physical, mental, and moral, of the progenitor. The race in Adam, without redemption, is totally incapable of salvation; yet under Christ it is placed upon a new redemptive probation, is empowered by the quickening spirit given to all, and through Christ may, by the exercise of free agency, attain eternal life.

4. *Reprobation*.—Of the whole mass of mankind thus involved in guilt and punishment for sin they never actually committed, Calvinism affirms that God has left a large share "passed by"—that is, without adequate means of recovery, and with no intention to recover them—and this from the

“good pleasure of his will” and for a display of his “glorious justice.” The other portion of mankind God does, from “mere good pleasure,” without any superior preferability in them, “elect” or choose, and confers upon them regeneration and eternal life, “all to the praise of his glorious grace.” Arminians pronounce such a proceeding arbitrary, and fail to see in it either “justice” or “glorious grace.” The reprobation seems to them to be injustice, and the “grace,” with such an accompaniment, unworthy the acceptance of honorable free agents. Election and reprobation, as Arminianism holds them, are conditioned upon the conduct and voluntary character of the subjects. All, submitting to God and righteousness, by repentance of sin and true self-consecrating faith, do meet the conditions of that election; all who persist in sin present the qualities upon which reprobation depends. And as this preference for the obedient and holy, and rejection of the disobedient and unholy, lies in the very nature of God, so this election and reprobation are from before the foundations of the world.

5. *Philosophical or Volitional Necessity.*—Calvinism maintains the doctrine that all volitions are determined and fixed by the force of strongest motive, just as the strokes of a clock-hammer are fixed and determined by the strongest force. The will can no more choose otherwise in a given case than the clock-hammer can strike otherwise. There is no “power of contrary choice.” Calvinism often speaks, indeed, of “free agents,” “free will,” “self-determining power,” and “will’s choosing by its own power”; but bring it to analysis, and it will always, say the Arminians, be found that the freedom is the same as that of the clock-hammer—the freedom to strike as it does, and no otherwise. Arminianism affirms that if the agent has no power to will otherwise than motive-force determines, any more than a clock-hammer can strike otherwise, then there is no justice in requiring a different volition any more than a different clock-stroke. It would be requiring an impossibility. And to punish an agent for not performing an impossibility is injustice, and to punish him eternally an infinite injustice. Arminianism charges, therefore, that Calvinism destroys all just punishment, and so all free volition and all divine government.

6. *Infant Damnation.*—Holding that the race is truly *guilty*, and judicially condemnable to endless torment for Adam’s sin, Calvinism necessarily maintains, according to Arminians, that it is just for God to condemn all infants to eternal punishment, even those who have never performed any moral act of their own. This was held by Augustine, and wherever Calvinism has spread this has been a part of the doctrine, more or less explicitly taught. Earlier Calvinists maintained against the Arminians that there is actual reprobation—that is, a real sending to hell—as well as particular election, of infants. Arminianism, denying that the race is judicially *guilty*, or justly damnable for Adam’s sins, affirms the salvation of all infants. The individual man as born does, indeed, irresponsibly possess within his constitution that nature which will, amid the temptations of life, commence to sin when it obtains its full-grown strength. If born immortal, with such a nature unchangeable, he must be for ever unholy, and for ever naturally unhappy under the divine repugnance. Under such conditions Divine Justice would not permit the race, after the fall, to be born. But at once the future Incarnate Redeemer interposes, restores the divine complacency, and places the race upon a new probation. Man is thereby born in a “state of initial salvation,” as Fletcher of Madeley called it, and the means of final salvation are amply placed within the reach of his free choice.

7. *Pagan Damnation.*—On its own principle, that power to perform is not necessary in order to obligation to perform, Calvinism easily maintains that pagans, who never heard of Christ, are rightly damned for want of faith in Christ. They may be damned for original sin, and for their own sin, and for unbelief in Christ, without any Saviour. Arminianism, on the contrary, maintains that there doubtless are many in pagan lands saved even by the unknown Redeemer. They, not having the law, are a law unto themselves. Nay, they may have *the spirit of faith*, so that were Christ truly presented he would be truly accepted. They may have faith in that of which Christ is the embodiment, like the ancient worthies enumerated in Heb. xi. There may not be as great differences in the chances for salvation in different lands as Calvinism assumes. Where little is given, much is not required. Arminianism holds that no one of the human race is damned who has not had full chance for salvation. Mis-

sions are none the less important in order to hasten the day when *all* shall be converted. If that millennial age shall come, and be of long duration, Arminianism hopes that the great majority of the entire race of all ages may be finally saved.

8. *Doctrines of Grace.*—Calvinism maintains that the death of Christ is an expiation for man’s sin: first, for the guilt of men for Adam’s sin, so that it is possible for God to forgive and save; and second, for actual sin—that thereby the influence of the Spirit restores the lapsed moral powers, regenerates and saves the man. But these saving benefits are *reserved for the elect only*. Arminianism, claiming a far richer doctrine of grace, extends it to the very foundations of the existence of Adam’s posterity. Grace underlies our very nature and life. We are born and live because Christ became incarnate and died for us. All the institutes of salvation—the chance of probation, the Spirit, the Word, the pardon, the regeneration, the resurrection, and the life eternal—are through him. And Arminianism, against Calvinism, proclaims that these are for *ALL*. Christ died for all *alike*; for no one man more than for any other man, and sufficient grace and opportunity for salvation is given to every man.

Calvinism maintains the irresistibility of grace; or, more strongly still, that grace is *absolute*, like the act of creation, which is called *irresistible* with a sort of impropriety from the fact that resistance in that connection is truly unthinkable. Against this Arminians reply that will, aided by prevenient grace, is free even in accepting pardoning grace; that though this acceptance is no more meritorious than a beggar’s acceptance of an offered fortune, yet it is accepted freely and with full power of rejection, and is none the less grace for that.

9. *Justifying and Saving Faith.*—Faith, according to Calvinism, is an acceptance of Christ wrought absolutely, as an act of creation in the man, whereby it is as impossible for him not savingly to believe as it is for a world to be not created or an infant to be not born. And as this faith is resistlessly fastened in the man, so it is resistlessly kept there, and the man necessarily perseveres to the end. Faith, according to Arminianism, is, as a *power*, indeed the gift of God, but as an *act* it is the free, avoidable, yet really performed act of the intellect, heart, and will, by which the man surrenders himself to Christ and all holiness for time and eternity. In consequence of this act, and not for its meritorious value or its any way compensating for or earning salvation, it is accepted for righteousness, and the man himself is accepted, pardoned, and saved. And as this faith is free and rejectable in its beginning, so through life it continues. It is of the very essence of his probationary freedom that he is as able to renounce his faith and apostatize as to reject it at first.

10. *Extent of the Atonement and Offers of Salvation.*—Earlier Calvinism maintained that Christ died for the elect alone; later Calvinism affirms that he died for one and all, and so offers salvation to all on condition of faith. But Arminianism asks, With what consistency can the atonement be said to be *for all* when, by the eternal decree of God, it is foreordained that a *large part* of mankind shall be excluded from its benefits? How also can it be *for all* when none can accept it but by efficacious grace, and that grace is arbitrarily withheld *from a large part*? How can it be *for all* when God has so fastened the will of a large part of mankind, by counter motive-force, that they are unable to accept it? The same arguments show the impossibility of a *rightful offer* of salvation to *all*, either by God or by the Calvinistic pulpit. How can salvation be rationally offered to those whom God by an eternal decree has excluded from salvation? What right to exhort the very men to repent whom God determines, by volitional necessity, not to repent? What right to exhort men to do otherwise than God has willed, decreed, and foreordained they shall do? If God has decreed a thing, is not that thing right? What an awful sinner is the preacher who stands up to oppose and defeat God’s decrees? If a man is to be damned for fulfilling God’s decrees, ought not that imaginary God to be, *a fortiori*, damned for making such decrees? If a man does as God decrees, ought he not to be by God approved and saved? And since all men do as God decrees, wills, and determines they shall do, ought not all men to be saved, so that the true theory should be Universalism? How can grace be offered to the man whom God had decreed never to have grace? or faith be preached to those to whom God has made faith impossible? or conditions proposed to those from whom God withholds the power of performing conditions? Hence the Arminian affirms that in all

public offers of a free or conditional salvation to *all* the Calvinistic pulpit contradicts its own creed.

Basis of Morality.—Calvinism claims that the very severity of its system, its deep view of human guilt and necessary damnability by birth and nature, its entire subjection to divine absolutism irrespective of human ideas of justice, tend to produce a profound piety. Arminianism replies that this is missing the true ideal of piety. It seems to be basing Christian morality on fundamental immorality. For God to will and predetermine the sin, and then damn the sinner—for him to impute guilt to the innocent, and so eternally damn the innocent as guilty—are procedures that appear fundamentally unrighteous, so far as the deepest intuitions of our nature can decide. Thus first to make God in the *facts* intrinsically and absolutely bad, and then require us to *ascribe* holiness and goodness to his character and conduct, perverts the moral sense. It is to make him what we are in duty bound to hate, and then require us to love and adore him. Such adoration, secured by the abdication not only of the reason, but of the moral sense, and the prostration of the soul to pure, naked absolutism, naturally results in the somber piety of fear; just as children are frightened into a factitious goodness by images of terror. While the piety of Jesus is serene, firm, winning, and gently yet powerfully subduing, the piety of absolutism tends to be stern and Judaic-like. While thus apparently defective at the roots, it does nevertheless often present an objective character of rectitude, a practical hardihood and aggressive energy in the cause of morality and regulated freedom. Arminianism, in order to a true and rational piety, sees the ideal of rectitude in the divine character and conduct, not by mere *ascriptions* contradicted by *facts*, but both in the *facts* and the *ascriptions*. A harmony of facts and intuitive reason is produced, love to the Divine Being becomes a rational sentiment, and a piety cheerful, hopeful, merciful, and gladly obedient becomes realized.

Civil and Religious Liberty.—As the freedom of the individual, and his own intransferable responsibility for his own voluntary character and conduct, are fundamental principles with Arminianism, it is in its own nature adverse to civil or religious despotism. It has been said that when Romanism persecutes, it accords with its fundamental *principle*, the denial of right of private judgment, while when Protestantism persecutes, it contradicts itself. So when Calvinism persecutes, it obeys an intrinsic absolutism, while if Arminianism persecutes, it contradicts its own freedom and individualism. Yet *position* has often in history produced in all these parties palpable violations of, and discordances with, their *principle*. Romanists often become by *position* asserters of ultra-democracy, and Protestants of absolute despotism. And so Calvinism has, historically, been by *position* the advocate for revolution, and Arminianism the asserter of authority. In fact, as Arminianism has been, as above shown, the ruling doctrine of the Church, and Calvinism an insurgent specialty, so the historical *position* of the first has been favorable to the assertion of authority, and the normal position of the latter has been revolt. This may be called one of the *accidents of history*.

Nor was Calvinism, as Prof. Fisher truly affirms, the advocate of liberty of conscience. Not only did Calvin himself banish Bolsec, ruin Castellio, and favor the execution of Servetus, but he maintained, doctrinally, the *duty of the magistrate to punish heresy*. Beza, his learned successor, wrote a treatise in favor of punishing heretics. Bogerman, the president at the Synod of Dort, was the translator of Beza's essay. It is but too evident that the Protestant Calvinists differed with the Romanists not about the punishment of heretics, but about who the heretics to be punished were. In this respect the Calvinism of the new Church and the Arminianism of the old were nearly upon a par. The new Church, however, belonged to the progressive order of things; but whether, finally, the Calvinism or the Arminianism of the new Church first actually proclaimed toleration is a matter of question.

Comparative Morality.—Mr. Froude endeavors by comparison to show that Calvinism is superior to Arminianism in morals by selecting his own examples. But the Arminian may perhaps in reply make also *his* selections. Scottish Calvinism has an unquestioned severity of morals, but are Scotch character and history, as a whole, even ethically superior to the English? Is the morality of Presbyterianism in its entire aspect superior to that of Moravianism, Quakerism, or Wesleyan Methodism? Are Calvinistic Baptists more Christian in morals than the Free-will Baptists?

Is there any umpire qualified to decide that the devout Presbyterian is superior to the devout Episcopalian? Did Jonathan Edwards present a type of piety superior to that of Fletcher of Madeley? or John Calvin to that of James Arminius? Can Calvinism show a grander type of an evangelist than was John Wesley in England or Francis Asbury in America? Has she produced, in all her history, a system of evangelism as earnest, as self-sacrificing, as aggressive as the itinerant ministry of English and American Methodism? Taking the entire body of Calvinism since the Reformation, does it excel in purity, martyrdom, doctrine, and missionary enterprise the (Arminian) Church of the first centuries?

Comparative Republicanism.—Nor did, nor does, Predestination, as compared with Arminianism, possess any peculiar affinity with republicanism against monarchy. By its very nature Calvinism establishes an infinite and eternal distinction between different parts of mankind made by divine prerogative, by which one is born in a divine aristocracy, and the other in an eternal helpless and hopeless pariahism; while Arminianism, holding every man equal before God, proclaims an equal yet resistible grace for all, a universal atonement and Saviour alike to all, an equal power of acceptance in all, a free, unpredestined chance for every man to be the artificer of his own eternal, as well as temporal, fortunes. Caste, partialism, are the characteristics of the former; equality, universality, republicanism, of the latter. It is as plain as consciousness can make any fact that it is the latter that is the natural ally; not of monarchies, aristocracies, or hierarchies, but of regulated freedom. Augustine and Gottschalk were good papists, and Augustinianism was as entirely at home under the tiara of Gregory the Great as under the cap of Bogerman—in the court of Charlemagne as in the camp of the Covenanter. Irrespective of their Calvinism, the Reformers everywhere acted *according to conditions*. Where kings and nobles favored them, they favored kings and nobles; where (as was generally the case) they were rejected by rank and power, and had nothing to make royalty and aristocracy out of, they fashioned a theocratic Commune, out of which modern political experience has picked some aids and methods for voluntary government. Modern experience has eliminated the theocracy, the intolerance, and the predestinarianism, and added the elements to make republicanism. For all this it duly thanks the Reformers, but does not thank their Calvinism.

HISTORY OF ARMINIANISM.—The theology of freedom, essentially Arminianism, in opposition to predestination, necessitated volitions, and imputation of guilt to the innocent is universally acknowledged to have been the doctrine of the entire Christian Church through its most glorious period, the martyr age of the first three centuries. The Calvinistic historian of theology, Hagenbach, says (vol. i., p. 155): "All the Greek Fathers, as well as the apologists Justin, Tatian, Athenagoras, Theophilus, and the Latin author Minucius Felix, exalt the autonomy or self-determination of the human soul. They know nothing of any imputation of sin, except as a voluntary and moral self-determination is presupposed. Even Irenæus and Tertullian strongly insist upon this self-determination in the use of freedom of the will." Again (157): "Even the opponents of human liberty, as Calvin, are compelled to acknowledge this remarkable unanimity of the Fathers, and in order to account for it they are obliged to suppose a general illusion about this doctrine!"

Arminians contend that we know as well when predestination was introduced into the Church—namely, by Augustine—as we do when transubstantiation and image-worship were introduced; that it was in the fourth century, when Pelagius upon one extreme made free will dispense with divine grace, Augustine on the other extreme made divine grace irresistibly nullify free will, and thus both lost their balance; that both invented dogmas never before recognized in the Church; that, tried by the previous mind of the Church, both were equally heretical; that the heresy of one, pushed to extreme, becomes rationalism and pure deism—the heresy of the other, pushed to extreme, becomes presumptuous antinomianism. They assert that the Eastern Church maintained her primitive position, neither Pelagian on one side nor Augustinian on the other, essentially in the position of modern Arminianism; that hence Arminianism is not a *compromise*, but the primitive historical position, the permanent center, rejecting innovations and extremes on either side; that the Western Church, in spite of the great name of Augustine, never became Augustinian.

It is indeed customarily said by anti-Arminian writers that this was because the "age of systematic theology" had not then arrived. Arminians reply that a theology not only unrecognized during that best period of the Church, but, still more, a theology unanimously condemned as heretical by that period, has little right now to lay claim to pre-eminent Christian orthodoxy. The Eastern Church—namely, the churches of Asia, with whom the language of our Lord and his apostles was essentially vernacular; the Greek Church, to whom the language of the New Testament was vernacular; and the Russian Church, embracing many millions—all inherited and retain, firmly and unanimously, the theology of freedom, essential Arminianism. The learned Calvinistic scholar Dr. Shedd, in his *History of Doctrines* (vol. ii., p. 198), says: "The Augustinian anthropology was rejected in the East, and, though at first triumphant in the West, was gradually displaced by the semi-Pelagian theory, or the theory of inherited evil [instead of inherited guilt] and synergistic [or co-operative] regeneration. This theory was finally stated for the papal Church in exact form by the Council of Trent. The Augustinian anthropology, though advocated in the Middle Ages by a few individuals like Gottschalk, Bede, Anselm, slumbered until the Reformation, when it was revived by Luther and Calvin, and opposed by the papists." It will thus be seen, on a review of the universal Church in all ages, how small though respectable a minority Augustinianism or Calvinism, before the Reformation, ever was. With minor exceptions, Arminianism was the doctrine of the universal Church.

The accuracy of Dr. Shedd's statement of the general non-existence of Augustinianism during the Middle Ages is not invalidated by the fact of the great authority of Augustine's name, arising from the powerful genius and voluminous writings of the man. It was no proof that a man was truly Augustinian because he belonged to the "Augustinian order," or quoted Augustine's authority. Such Schoolmen as Bernard, Anselm, and Peter Lombard modified Augustine's doctrine materially; Bonaventura and Duns Scotus were essentially Arminians, and Hincmar of Rheims and Savonarola literally so. Gottschalk, the high predestinarian, was condemned for heresy, and Thomas Bradwardine, the "second Gottschalk," made complaints, doubtless overstrained, that in his day "almost the whole world had become Pelagian."

At the Reformation, however, we encounter the phenomenon that all the eminent leaders at first not only adopted, but even exaggerated the absolutism of Augustine. This might seem strange, for it was apparently natural that the absolute papacy should identify itself with the absolute, and that asserters of freedom would have stood on the free-will theology. The twin doctrines of the supremacy of Scripture and of justification by faith were amply sufficient, without predestination, for their purpose to abolish the whole system of popish corruption. The former dethroned alike the authority of tradition and the popedom; the latter swept away alike the mediations of Mary, saints, and priests. But the first heroic impulse of reform tends to magnify the issues to their utmost dimensions. The old free-will theology belonged universally to the old historic Church, and was identified by the first Reformers with its corruptions. Luther at first, in his reply to Erasmus *On the Bondage of the Will*, uttered fatalisms that probably had hardly ever before been heard in the Christian Church, and perhaps it would be hard to find a Calvinist at the present day who would adopt the trenchant predestinarian utterances of Calvin. Under the indoctrinations of these leaders, especially of Calvin at Geneva, the absolute doctrines were diffused and formed into the creeds of Germany, the Netherlands, France, England, and Switzerland. But in Germany the "second sober thought" of Melancthon, who at first coincided with Luther, receded from predestination, and Melancthon himself intimates that Luther receded with him. In the Netherlands the same "second thought," led by Arminius himself, was suppressed by state power. In France, Protestantism, which was Calvinistic, was overwhelmed in blood. In England the Calvinism was generally of a gentle type, and the same "second thought" was awakened by the Arminian writings of Grotius and Episcopius diffused through Europe. And as the English Church gradually inclined to the ancient high episcopacy of the old Church, so it adopted the ancient Arminianism. Calvinism, persecuted and oppressed, overthrew monarchy and Church, and for a brief period ruled with hardly less intolerance, until, over-

thrown in turn, Calvinism took refuge in America, and laid foundations here. Even here past sufferings did not teach tolerance, and that doctrine had to be learned from checks and lessons administered by surrounding sources. Calvinism has, nevertheless, here acted a noble part in our Christian civilization. It perhaps about equally divides the evangelic Church with Arminianism.

Arminianism, proper and Protestant, came into existence under the severe persecution by Dutch Calvinism, in which the great and good Arminius himself was a virtual martyr. The Synod of Dort, the standard council of the Calvinistic faith, made itself subservient to the unprincipled and sanguinary usurper Maurice; and even during its sessions the judicial murder of the great Arminian and republican statesman Olden Barneveldt was triumphantly announced at Dort to overawe the Arminians at the synod, who were bravely maintaining their cause under the leadership of the eloquent Episcopius. Then followed the banishment of Episcopius, the imprisonment of Grotius, the ejection of hundreds of Arminian ministers from their pulpits, and the firing of soldiers upon the religious assemblies of Arminian worshipers. The great Arminian writers of Holland, Episcopius, Grotius, and Limborch, are claimed by Arminian writers to be the first public proclaimers of the doctrine of liberty of conscience in Europe, as those two Arminian Puritans, John Milton and John Goodwin, were its earliest proclaimers in England.

Wesleyan Methodism is now by all admitted to be a great modern Arminian development. Beginning most humbly as a half-unconscious awakening amid the general religious chill of Protestantism, it has not only quickened the religious life of the age, but gathered, it is said, 25,000,000 of worshipers into its congregations throughout the world. Its theology is very definite, and very nearly the exact theology of James Arminius himself, and of the first three centuries. Cradled in both the Arminianism and High-Churchism of the English establishment, Wesley's maturer years earnestly approved the Arminianism, but severed it from the High-Churchism. The connection between Arminianism and High-Churchism is hereby clearly revealed to be historical and incidental rather than intrinsic or logical. Yet, even after adopting the doctrine that every church has the right to shape its own government, as a lover of the primitive, post-apostolic Church, as well as from notions of Christian expediency, Wesley preferred, and provided for American Methodism, an episcopal form of government. Arminian Methodism has apparently demonstrated that the Augustinian "systematic theology" is unnecessary, and that the primitive theology is amply sufficient for the production of a profound depth of piety, a free ecclesiastical system, an energetic missionary enterprise, and a rapid evangelical success. She exhibits in her various phases every form of government, from the most decisive system of episcopacy to the simplest congregationalism, all voluntarily adopted, and changeable at will. The problems she has thus wrought suggest the thought that the free, simple theology of the earliest age may be the universal theology of the latest.

THE LITERATURE OF ARMINIANISM.—The literature of the controversy of free will and predestination, beginning with Justin Martyr, Chrysostom, and the Greek Christian Fathers generally, is very extensive. Since the Reformation we may name the following: Arminius's *Works* (3 vols. 8vo. translated into English by Nicolls and Bagnall, Auburn and Buffalo, 1853); Episcopius, *Instit. Theol.* (Amsterdam, 1650); Episcopius's works, in two volumes folio, are mainly devoted to the maintenance of the Arminian views against the doctrines of the Synod of Dort; Stephen Curcellæus, *Opera Theologica* (1675, 1 vol. fol.); Limborch's *Theologia Christiana*, the first complete body of Arminian theology (1686), translated into English by Rev. William Jones, presbyter of the Church of England (London, 1702; 2d ed. 1713); Bishop Burnet's *Exposition of the Thirty-Nine Articles* (1699) furnishes what was intended as an impartial presentation of the argument on both sides, though expressing a preference for the Arminian in his preface; Whitby, *On the Five Points* (London, 1710, 1 vol. 8vo), a standard work on the subject in English theology; Wesley's *Works* (New York, 7 vols.); *Checks to Antinomianism* and other works, by Fletcher of Madeley (New York, 4 vols. 8vo); Richard Watson's *Theological Institutes* (New York, 2 vols.), a standard work in Methodist theology; Nicolls's *Calvinism and Arminianism Compared* (London, 1824, 2 vols. 8vo).

The maintenance of the Arminian view of the divine government has, during the present period, proceeded largely

from the Methodist body, and most of the productions have been furnished in America. We may enumerate the following: Dr. Wilbur Fisk's *Calvinistic Controversy* (New York, 1830, 1 vol.), a work which exerted much influence on Methodist theology in the U. S.; Bishop Randolph S. Foster's *Calvinism as it Is* (Cincinnati, 1840), and *Studies in Theology* (3 vols., New York, 1889); Dr. A. T. Bledsoe's *Theodicy* (New York, 1853); Whedon's *Freedom of the Will* (New York, 1864); *Bibliotheca Sacra* (April, 1862); Dr. William B. Pope, professor in the Wesleyan Theological School, Didsbury, England, has published in one large 8vo volume *A Systematic Theology* (London, 1875); Dr. Miner Raymond, professor in the Methodist Theological Seminary, Evanston, Ill., has published (New York, 1879) *A Systematic Theology* (in 3 vols.); Dr. Arnold Sulzberger, professor in the German Methodist Theological Seminary, Frankfurt-am-Main, has issued (1878, in 3 vols.) *Christliche Glaubenslehre vom Methodisten Standpunkt*; Dr. John Miley, Professor of Systematic Theology in Drew Theological Seminary, has published (2 vols. 8vo) *Systematic Theology* (New York, 1892-93). See CALVINISM.

Revised by JOHN F. HURST.

Ar'mistice [from Lat. *arma*, arms, war + *-stitium* (as in *sol-stitium*, etc.), a halt]: a truce; a suspension of hostilities between two armies or belligerent powers, which often agree to suspend operations for a definite time while the diplomatists are negotiating the preliminaries of a peace. During the third crusade Richard Cœur de Lion and Saladin made a truce for three years, three months, and three days. In modern times the duration of armistices is much less. After the Germans captured Paris, Jan. 30, 1871, the French people, having no regular Government, desired to elect a national assembly, for which purpose an armistice was granted by the Germans. The armistice, during which the armies on both sides were bound to remain stationary, ended in a treaty of peace, the preliminaries of which were ratified on Feb. 26, 1871. The definitive treaty of peace was signed at Frankfort in May of that year.

Armistie'io: a territory of Venezuela formed between 1881 and 1884 from parts of the states of Bolivar and Zamora. It lies between the Arauca and Caparra rivers, and includes the upper valley of the Apure river. It is a narrow strip of territory, with Colombia on the south and Zamora on the north. The separation of this territory appears merely nominal, and has perhaps been already abandoned. Area, 7,046 sq. miles. M. W. H.

Armitage, EDWARD, R. A.: painter of historical and other figure subjects; b. in London, May 20, 1817. Studied in Paris under Paul Delaroche; Royal Academician (London) 1872. Appointed professor and lecturer on painting at the Royal Academy 1875. Painted the fresco of *The Thames* in 1852, and in 1854 that of *The Death of Marmion*, in the Houses of Parliament. D. May 24, 1896. W. A. C.

Armitage, THOMAS, D. D., LL. D.: b. at Pontefract, England, Aug. 2, 1819; became in his youth a Methodist preacher. In 1838 he removed to New York, and entered the ministry of the Methodist Episcopal Church. In 1848 he became a Baptist, and settled as a pastor in New York; retired in 1888. He warmly advocated the movement for Bible revision, which led, in 1850, to the formation of the American Bible Union, of which organization he became an efficient officer, and subsequently the president. He occupies a high rank as a pulpit orator and as a writer of great power and elegance. His position as a leader in the denomination with which he was identified is generally acknowledged. D. at Yonkers, N. Y., Jan. 20, 1896. Author of *A History of the Baptists* (New York, 1887).

Armitage, WILLIAM EDMOND, D. D.: second Bishop of Wisconsin; b. in New York city, Sept. 6, 1830; graduated at Columbia College in 1849, and at the General Theological Seminary in 1852. Ordained deacon June 27, 1852, and priest Sept. 27, 1854, he ministered at St. John's, Portsmouth, N. H., St. Mark's, Augusta, Me., and at St. John's, Detroit, Mich. He was consecrated assistant to the venerable Bishop Jackson Kemper, Dec. 6, 1866, and succeeded to the episcopate of Wisconsin in 1870. D. in St. Luke's Hospital, New York city, Dec. 7, 1873.

Armor: garments of defense. The term includes all forms of shields. The materials usually employed are, beginning with the easiest to make and least costly, quilted and stuffed garments, which are often an excellent security against sword-cuts and arrows, and which also serve better

than metal the purpose of protecting the body from bruises and broken bones; secondly, leather; thirdly, metal used in small pieces, such as plates or rings, which are sewed to textile or leather fabrics, or very small rings, which are linked together as in a making of chains, but so as to cover a surface, and called chain mail or simply mail; fourthly, metal in larger pieces, as the strips or ribbons of steel, which form the body-armor of the Roman soldiers and that of the Japanese, and the larger splints or plates of steel used in large and elaborately made pieces such as the cuirass, the head-piece (see HELMET), the greaves, and the like. Armor in antiquity was nearly always light and manageable; it usually covered the body only in part, and was never allowed to interfere with ease of movement. The Roman and Greek warriors depended upon their helmet and shields for their chief defense; otherwise their armor was confined to the trunk, the tops of the shoulders, and the front part of the legs below the knees, the boots, however, affording some protection to the feet; even a Roman general or prince engaged in battle with the face, neck, arms, and thighs unprotected, except by the shield. In the Middle Ages, however, there was a general disposition to cover the person completely. As early as the tenth century the helmet had a long nasal, which protected the face, and the hauberk had long sleeves (even gloves attached at a later period), and protected the thighs to the knees. As the skill of armorers became greater the hauberk was reinforced by plates of steel applied to its surface, covering the back of the upper arm, the whole of the forearm, the shoulder, the legs, and afterward parts of the trunk. During the same epoch stuffed armor and armor made by quilting pieces of steel between two thicknesses of strong textile fabric were in constant use, and it was customary to combine many kinds of armor in one equipment; thus the hauberk was worn over the stuffed gambison. In the fourteenth century smithwork had been greatly developed, and suits of complete steel were worn. The head-piece in particular had become a complete covering closed in front and fitting closely at the neck, so that the wearer looked through small openings in the movable visor, and obtained air through minute holes in the movable beaver. At this time the armor of mounted men became extremely heavy and cumbersome, and when the heavy heaume was set upon the bascinet or steel cap as an addition of the defense in time of battle, the wearer was liable to suffocation. It must be remembered, however, that the tilting suits found in collections, and sometimes weighing 200 lb., were not worn in war. In fact, from the beginning of the fourteenth century the armor for the just and the tourney grew continually more and more unlike that intended for battle. The manufacture of armor reached the highest excellence about 1500. Soon after this it began to be given up, because only the most perfectly forged breast-plates could resist a musket-ball; but those who could afford to purchase the best work of the armorer continued to wear steel on the head and body down to the close of the seventeenth century. Moreover, as armies became national in character, so that their equipment was provided out of the national treasury, regiments of cuirassiers were established, some few of which were kept up even down to the Franco-Prussian war in 1870. As steel armor was gradually given up, leather replaced it to a certain extent; thus the buff or buff-coat was worn either to replace the cuirass or in addition to it. RUSSELL STURGIS.

Armor, in modern usage, is a metallic covering for ships or fortifications, intended to furnish protection against gun-fire. The introduction of shell-guns, and the signal instance of their effect in the annihilation of the Turkish fleet at Sinope, showed the necessity of providing protection against their destructive fire. To John Stevens, of Hoboken, N. J., belongs the credit of originating the idea of applying armor to the sides of ships, but the French first gave this idea practical shape in the floating batteries which on Oct. 17, 1855, silenced the Russian forts at Kinburn. For the moment the defense was ahead, but its superiority was short lived, and the introduction of new weapons of attack and the continued advance of artillery in weight and power forced a corresponding development of armor. For some years manufacture of armor was limited to plates of small area; and imperfect welds and steely spots, as well as great irregularity in quality, were necessary evils, owing to imperfect appliances for the production of thick plates. Laminated plating, when tried, was found greatly inferior to the same thickness in a single plate. In 1859, however, armor manufacture had so far developed

that French 4 $\frac{3}{4}$ -inch plating proved superior to the attack of the 68-pounder, then the most powerful naval gun, and in 1860 the British report "vessels clothed in rolled iron plates 4 $\frac{1}{2}$ inches thick are to all practical purposes invulnerable against any projectile that can at present be brought against them at any range." But the general adoption of rifled guns on the Continent and the introduction of the 11-inch and 15-inch smooth-bore guns in the United States called for renewed exertions on the part of the armor makers, and in 1867, it being still impossible to produce plates of reliable quality more than 6 or 7 inches thick, the plate-upon-plate system, in which several thick plates were superimposed, was tried and proved superior, in the then state of the art, to the solid plate of equal thickness. In 1868 plates over 8 inches thick were tested, and in 1872 12-inch plates were tested both in Great Britain and Prussia, and, though of good quality, were hardly a match for the guns brought against them. Such had been the development of the artillery with which armor had to contend that while as late as 1863 4 $\frac{1}{2}$ -inch plating made a ship invulnerable, in 1868 it took 9-inch plating, and in 1872 a 12-inch plate was pierced on the firing-ground. With the introduction of 12-inch plates the limit of regularity in manufacture with wrought iron seemed to be reached, and the cost of the plate-upon-plate system, owing to difficulty in making the plates fit each other, led to the trial and adoption of the sandwich system, in which layers of wood separate the two or more plates making up the complete target. The first application of this system was to the British ship *Dreadnaught*, whose turrets, built up of two 7-inch plates separated by 9 inches of teak and secured to a backing of 6 inches of teak and two $\frac{3}{4}$ -inch skin-plates, were considered more than a match for the 12-inch rifle. But the advent of the 14 $\frac{1}{4}$ -inch Krupp rifle in 1875 and the 81-ton Woolwich gun in 1876 marked the final supremacy of the gun. Wrought-iron armor had now reached its highest development in the *Inflexible*, whose armor consisted of two layers of 12-inch plates with 11 inches of teak between, backed by 6 inches of teak and two 1-inch skin-plates. Simultaneously with the adoption of this armor-disposition the Italian Government, desirous of building the most powerful ships in the world, called for competitive tests of 22-inch armor, and, two French and two English firms having submitted plates, in 1876 the famous Spezzia trials which revolutionized armor manufacture in Europe took place. The plates submitted were solid wrought iron, sandwich wrought iron, sandwich with wrought-iron face-plate and cast-iron rear-plate, and solid steel (the latter made by Schneider & Co., of France). The guns used were the 10-inch and 11-inch Woolwich rifles and the Armstrong 100-ton gun. The Italian commission condemned the types containing cast iron as of relatively feeble defensive qualities, stated that the remarkable advantages realized with the single plates left no doubt of the superiority of this disposition over the sandwich, and concluded that the most advantageous disposition of armor was embodied in the solid steel plate, this having kept out all shot, although wrecked thereby, while the iron targets were pierced by the shot from the 100-ton gun. Thin steel plates and iron plates faced with steel had ere this been tried in Great Britain with doubtful success, but it was now recognized that the day of wrought iron had passed, and attention was at once turned to the production of armor having the resisting qualities of the Schneider plate without its brittleness. In Aug., 1877, the first of what are known as compound plates was tested at Shoeburyness, England. This plate, made by casting a steel face upon a wrought-iron back and rolling the whole to a thickness of 9 inches, was tested with the 7-inch rifle, the penetration being but 3 $\frac{1}{2}$ inches, whereas in a wrought-iron plate it would have been fully 8 inches. In another year 9-inch compound plates, now adopted for the *Inflexible's* turrets, resisted the 9-inch rifle, so rapid was the development of the new system, and in 1880 the manufacture of both compound and steel armor had so progressed that they were brought into close competition. In 1882 the Italian Government again invited armor makers to submit plates to test in order to determine the best system for use on the *Lepanto*, and Cammel & Co. and Brown & Co., of England, the foremost makers of compound armor, and Schneider & Co., of France, the leading makers of steel armor, each submitted a plate 18.9 inches thick. Two shots from the 100-ton gun wrecked each compound plate, while the steel plate, after three, still covered the greater part of its backing. The commission concluded that the Schneider plate was superior to the compound

plates and better adapted to protect a ship's side. Steel plates were not always victorious, however, for in several trials, notably that at Ochta in 1882, the compound plate proved the better, and the less cost and more rapid development of this system in Great Britain led to its exclusive use there and its general adoption on the Continent during the next ten years. The demand for steel armor was, however, sufficient to continue its development, and its increasing superiority was so demonstrated by various tests that when the U. S., in 1886, had before it the task of domesticating the manufacture of heavy armor, the decision as to the preferable material was not doubtful, and steel armor was ordered for all the armored ships then authorized by law. In 1890 the first public trial of a new material for armor, steel alloyed with nickel, took place at Annapolis, Md., a competitive test of a Cammel compound, a Schneider steel, and a Schneider nickel-steel plate being held by the U. S. Navy Department. The compound plate proved inferior in a marked degree to the others, and the nickel-steel showed a remarkable resistance to cracking. In the same year a steel plate hardened on one face by a process of superficial carbonization was also tried at Annapolis, and showed phenomenal resistance to penetration. In 1891 the U. S. Navy Department tested three plates made by the Bethlehem Iron Company of Pennsylvania by the usual forging process, and three made by Carnegie, Phipps & Co. of Pennsylvania by rolling in a heavy plate mill erected for the purpose. Five of these plates were of nickel-steel and three had been surface-hardened, or *Harveyed*, as it was called from the inventor of the process. This test demonstrated that good armor can be produced by the rolling process, a fact of great importance, since enormous and costly hammers are thus unnecessary; that the nickel-steel plates made in the U. S. were markedly superior to any armor that had been publicly tested abroad; and that the process of surface-hardening offered a probable means, after some difficulties were overcome, of greatly increasing resistance to perforation. As a result of these trials it is now generally recognized that nickel-steel is the best material for armor yet produced, and that progress for the present at least lies in the direction of surface-hardening, with the object of breaking up projectiles before they can penetrate.

The armor applied to the protection of ships is also used on coast and frontier defenses, but another armor, ill adapted to naval use on account of its great weight, has also been developed for land fortifications. The Gruson system consists in building up ellipsoidal-shaped turrets of very heavy iron castings, chilled on the outer surface, and fitted together without bolts. This chilled cast iron was first tried in Prussia in 1868, and showed such remarkable resisting qualities in this and many subsequent tests that it has been largely adopted for land fortifications on the Continent.

Methods of Manufacture.—Gruson armor is made as follows: A plaster model of the plate is first made, and from this a chill mold of cast iron representing its outer face. Upon this a sand mold is built up corresponding to the other surfaces; and finally the plate is cast of specially selected iron. No machining is needed, and the use of bolts is avoided by hollowing the ends and running solder into the cavities thus formed between the adjacent blocks. Wrought-iron armor is made by piling a number of slabs or thin plates of wrought iron together, raising them to a welding heat, and either forging or rolling the mass into a solid plate. Rolled iron plates were considered better than forged ones.

Compound armor is made by Brown & Co. under the Ellis patents, as follows: Around three sides of a wrought-iron plate is fixed an iron or steel frame, to which is bolted a thin steel plate, its surface parallel to the iron plate and at the desired distance therefrom, and the sides of the frame having webs extending into the space between the two plates. Thus prepared it is heated to a high temperature, the exposed steel surfaces protected by gannister, and is placed upright in a pit, where a hydraulic ram pushes a movable iron plate against it and holds it firmly against another iron plate. The space between the iron and the thin steel plate is then filled with molten steel, and the top is covered with sand and weighted. After cooling, the compound plate is reheated, rolled to the desired thickness, bent, and machined as required. Cammel & Co. make compound armor under the Wilson patents, the process being as follows: A wrought-iron plate, prepared in the usual way by rolling, is heated to a high temperature and slid horizontally into an iron mold lined with refractory material; iron strips

are then placed along the sides of the plate, between it and the opposite face of the mold, so as to hold the plate firmly in place, and the mold is placed upright in a pit, where it is filled with molten steel, the top being then covered with sand and weighted. After cooling the mold is removed, the plate rolled to the required thickness, reheated, bent to shape, and machined. Compound plates are usually made with one-third the thickness steel and two-thirds iron.

Steel armor, as made by Schneider & Co. and the Bethlehem Iron Company, is of open-hearth steel. An ingot of approximately rectangular cross-section and about twice the weight of the finished plate is cast, and after cooling is stripped, reheated, and forged to the required thickness under a 100-ton hammer, the first operation being forging the upper end of the ingot into a porter-bar for handling, and the entire operation requiring several heats. The upper part of the forging is next cut off under the hammer, and the remainder, after cooling, is trimmed nearly to size either by a saw or a planer; it is then again heated, bent to shape under a hydraulic press, reheated to a high temperature, plunged in oil, where it is allowed to cool, again heated to a somewhat lower temperature in a closed furnace, and allowed to cool there slowly. Lastly it is machined to size, the bolt-holes are bored and tapped, and the curvature is rectified under the bending-press at a low heat not sufficient to undo the work of the previous oil tempering and annealing. The manufacture of steel armor by rolling is similar to the above, except that instead of being forged the ingot, after reheating, is passed back and forth through heavy rolls which reduce its thickness several inches at each pass, water or salt being thrown on the surface from time to time to break up the hard scale. The rolling operation reduces the ingot to a plate of the desired thickness in a single heat, but the temperature of rolling is higher than needed in the forging operation, where immense hammers are used, and it is on this account that it has been generally supposed that the resulting plate would have a coarser texture and be inferior to the forged plate. In making nickel-steel armor enough nickel is added to the furnace charge to give about 3 per cent. in the ingot, the remaining operations being the same as in making steel armor.

Backing and Fastenings.—Armor was first applied to wooden ships, but when iron and steel ships succeeded these it was found necessary to interpose a certain thickness of wood between the skin-plating of the ship and the armor to decrease injury to the ship's side from impact of shot, and to provide a surface that could be trimmed to exactly fit the plates as manufactured. This backing is of oak or teak, and in modern ship-design is usually of moderate thickness. In fortifications masonry has been used for backing with great advantage. From the first much trouble was experienced with fastenings, the through bolts originally used causing leaks, and snapping at the bottom screw-thread when the plate was struck. These defects were remedied by using bolts like wood-screws, extending not quite through the backing. The bolts now used are forged steel, pass through the skin-plating and backing, and screw into the plate from 2 to 3 inches. They have shanks of reduced diameter to prevent breaking at the thread; are packed with hard rubber to prevent leakage around them; and have rubber washers under the nut-heads. With steel armor one bolt is used to about every 4½ sq. feet of plate, and the diameters vary from 1½ inches for thin plates to 3½ inches for thick plates. With compound armor the bolts are larger and fewer in number.

Disposition and Uses.—The armor of modern ships has a twofold end: to prevent the effective use by an enemy of explosive shell containing large bursting charges, compelling resort to armor-piercing shell, which are practically solid shot; and to prevent destruction of a ship by a single blow from a heavy projectile. For the first purpose the armor need only be thin and should cover a wide area; to be effective for the second purpose it must be concentrated about the more vital parts. These systems are both used, and in the largest ships a combination of the two is found. At first sight it would appear that a means of greatly increasing the protective power of armor would consist in placing it so as to receive the shot at a sharp angle, but numerous experiments have shown that where a given area is to be covered with a fixed weight no advantage is gained by inclining the plates, since every increase of inclination requires a decrease of thickness to keep the total weight within the limit allowed. The principle of inclined armor is, however, largely used in protective decks which cover the propelling machinery and in shields for the defense of guns'

crews. The marked superiority of guns to armor on the firing-ground has led to the opinion that the use of armor will ere long be abandoned, but the circumstances of naval warfare are such as to greatly increase the value of armor over that shown in experiments, and it is probable that as long as ships of war are built armor will be used for one or both of the purposes described above. PHILIP R. ALGER.

Armor'ica [Lat.; supposed to be from Celtic *ar*, upon + *mor*, sea]: the ancient name of the northwestern part of Gaul, bordering on the ocean, and extending from the Seine to the Loire. The Armoricians had numerous ships, and were extensively engaged in maritime pursuits. About 400 A. D. Mariadec, a Briton, obtained the chief power in Armorica, which became an independent state. In consequence of the immigration of Britons or Welsh in the sixth or seventh century, the name of Armorica was changed to Bretagne. The language of the country is closely allied to the Welsh.

Arms [Lat. *arma*]: weapons of war; offensive weapons or instruments, which are divisible into two great classes—firearms and arms which are used without gunpowder or any explosive substance. The latter, which are the more ancient, are the sword, spear, dart, javelin, lance, arrow, battle-axe, cutlass, dagger, dirk, bayonet, scimitar, pike, sling, etc. The principal varieties of firearms are described under the heads ARTILLERY, ORDNANCE, MAGAZINE-GUNS, and SMALL-ARMS. Arms for both war and the chase have been used from the most remote time. Beautifully finished specimens of stone axes or tomahawks, arrow and spear heads, and stone knives or daggers have been found with the remains of prehistoric men. The bow and arrow seem to have reached a somewhat high state of perfection at a very early age. The most ancient sculptures show missile and cutting arms differing but little from the more modern forms.

A *stand of arms* is a complete set necessary for arming one soldier.

Arms, or Armorial Bearings: See HERALDRY.

Arm'strong**, DAVID MAITLAND:** genre and decorative painter; b. at Newburg, N. Y., June 12, 1837; pupil of Luc Olivier Merson. Member of the Society of American Artists and Architectural League, New York. Legion of Honor, 1878. Studio in New York. W. A. C.

Armstrong, GEORGE DODD, D. D., LL. D.: a brother of Dr. W. J. Armstrong; b. at Mendham, N. J., Sept. 15, 1813; graduated at Princeton in 1832, studied theology in Union Seminary, Prince Edward co., Va., was Professor of Chemistry and Mechanics in Washington College, Lexington, Va. (1838-51), and since then pastor of a Presbyterian church in Norfolk, Va.; became *pastor emeritus* 1891. He has been a large contributor to periodicals and has published *The Summer of the Pestilence* (Phila. 1856); *The Doctrine of Baptisms* (N. Y., 1857); *The Christian Doctrine of Slavery* (1858); *The Theology of Christian Experience* (1860); *The Sacraments of the New Testament* (1880); *The Books of Nature and Revelation* (1886).

Armstrong, GEORGE FRANCIS: poet; b. near Dublin, May 5, 1845; educated at Trinity College, Dublin; professor in Queen's College, Cork, 1871; author of *Poems, Lyrical and Dramatic* (2d ed. 1872); *Ugone* (1870); *Israel* (1872-76); and *Mephistopheles in Broadcloth* (1888).

Armstrong, JAMES: commodore U. S. N.; b. at Shelbyville, Ky., Jan. 17, 1794; entered the navy as a midshipman in 1809; was captured by the British while serving in the Frolic in 1814; received the regular promotions, becoming a captain in 1841, commanding the East India squadron (1855-58), and captured the Barrier Forts in the Canton river in 1857. Jan. 12, 1861, he was compelled to surrender Pensacola navy-yard to a greatly superior force of Confederates. D. Aug. 27, 1868.

Armstrong, JAMES: Canadian jurist; b. at Berthier, P. Q., Apr. 27, 1821. He was admitted to the bar in 1844, was appointed queen's counsel in 1867, and subsequently became chief justice of Tobago, W. I., which he held conjointly with the chief justiceship of St. Lucia till his resignation in 1882. He was instrumental in introducing the English criminal law into the islands. He was made a Companion of the Order of St. Michael and St. George in 1857. Since his return to Canada he has been president of the Montreal and Sorel Railway, and has written many valuable treatises on law. NEIL MACDONALD.

Armstrong, JOHN, M. D.: physician, poet, and miscellaneous writer; b. in parish of Castleton, Roxburghshire, Scot-

land, about 1709; received degree of M. D. from Edinburgh University in 1732, and went to London to practice. He was not famous as a physician, but he was popular as a poet. His best known poems are the *Economy of Love* (1737), and *Art of Preserving Health* (1744). D. in London, Sept. 7, 1779.

Armstrong, JOHN: soldier; b. at Carlisle, Pa., Nov. 25, 1758. He served in the Revolutionary war with the rank of major. He was the author of the anonymous and celebrated *Newburg Addresses*, written in March, 1783, in order to obtain from Congress a payment of the money due to the officers of the army. He was a member of the old Congress, and in 1800 was sent to the U. S. Senate from New York. He was sent as minister to France in 1804, and was appointed Secretary of War in January, 1813. He was censured because he failed to defend Washington in 1814, and resigned in September of that year. D. at Red Hook, N. Y., Apr. 1, 1843.

Armstrong, JOHN: b. in the north of Ireland in 1725; commanded successfully the expedition sent in 1756 against the Indian allies of the French at Kittanning; served as brigadier-general in the Revolutionary army at Fort Moultrie, and commanded the militia at Brandywine and Germantown. He was a member of Congress (1778-80 and 1787-88). D. at Carlisle, Pa., Mar. 9, 1795.

Armstrong, SAMUEL CHAPMAN: educator; b. at Wailuka, Maui, Hawaiian islands, where his father was a missionary, Jan. 30, 1839; educated at Oahu College and Williams College, Mass. (graduated 1862); after being chief clerk of the Department of Public Instruction, Hawaii islands, entered the Union army as captain, 1862; became brevet brigadier-general 1865; superintendent of ten counties in Virginia in Freedman's Bureau, 1866-68; principal of Hampton Normal and Agricultural Institute (1868), from which time he devoted his life with eminent success to the improvement of the Negro and Indian races. D. at Hampton, Va., May 11, 1893.

Armstrong, Lord (formerly Sir) WILLIAM GEORGE, C. B., LL. D., D. C. L., F. R. S.: mechanical engineer, etc.; b. at Newcastle-upon-Tyne in 1810. He was educated at the school of Bishop-Auckland, Durham, and articled to a solicitor of Newcastle, whose partner he subsequently became. A strong bent for scientific pursuits diverted him from the law. He early investigated the subject of electricity. In 1840 a workman of Newcastle, having put one hand in the steam blowing off from a high-pressure engine while his other hand was on the lever of the valve, received a powerful electric shock. The investigation of this case by Armstrong led to the invention of the hydro-electric machine, which far surpassed any ordinary machine in the quantity of electricity furnished in a given time. For this, while very young, he was elected a fellow of the Society of Arts. He then invented the hydraulic crane, and the "accumulator" to furnish an artificial head for working hydraulic machines, and he extended the application of hydraulic power to machines of every kind. He founded the Elswick engine-works for the construction of this machinery. In 1854 he invented the rifled ordnance gun that bears his name. In 1858 the gun was recommended for adoption, and upon presenting his patents to the British Government Mr. Armstrong was knighted, made a C. B., and appointed engineer of rifled ordnance. Between 1858 and 1870 the Armstrong gun underwent many changes; the breech-loading feature was abandoned, but the general principle of its construction—by which coiled bars are shrunk one over the other upon a tube made with the fiber lengthwise—was retained. The system is applied to all sizes, from the 6-pounder to the 600-pounder. Within three years he furnished 3,000 guns to the British service.

In 1863 Sir William resigned his position with the Government and rejoined the Elswick company, which has become one of the most important works of Europe, constructing not only guns but armor and armored ships for various governments. In 1863 he was president of the British Association at Newcastle-upon-Tyne, when he drew attention to the probable exhaustion of the coal of Great Britain at some future time. He was made a member of a royal commission to inquire into this subject and make report. He received the honorary degree of LL. D. from the University of Cambridge in 1862 and that of D. C. L. from Oxford in 1870. Lord Armstrong is a Knight Commander of the Bath, of the Danish order of Dannebrog, of the Austrian order of Francis Joseph, and of the Brazilian order of the Rose. He is also a Grand Officer of the Italian order of SS. Maurice

and Lazarus since 1876. Lord Armstrong is active in opposition to the patent laws of Great Britain, and has worked for their repeal. He has been president of the Institution of Civil Engineers, of the Institution of Mechanical Engineers, and of the Newcastle Literary and Philosophical Society. He was made a peer in 1887, the year of the queen's jubilee, under the title of Baron Armstrong.

WILLIAM RICH HUTTON.

Army [from O. Fr. *armee*, Mod. Fr. *armée*, ultimately from Lat. *armatus*, armed, *arma*, arms]: the entire organized land forces of a nation, or a force of considerable size so organized, armed, and equipped as to be able to act independently or in combination with others.

In the first sense we speak of the *army of the United States*, the *French army*, etc. In the second we include such forces as the Army of the Potomac, the first, second, or third German armies, etc., and also organized bodies sometimes of less size which take their names from their duties. For instance, a *covering army*, which interposes itself between the enemy and some place to be secured or protected; a *blockading army*, which surrounds a place and prevents ingress and egress; an *army of observation*, which is held in close proximity to an enemy, watching his movements, but generally avoiding an engagement; and many others whose names sufficiently indicate their duties.

The characteristic feature which separates an army from a mob is its organization, by which is meant that system of subordination which enables one man to control the entire mass and move it in accordance with his will. This implies a subdivision of the mass into units of such small size that the commander of each one can personally supervise, direct, and control the movements of each man in it. This is the *unit of combat*, whether called a tetrachia by the Greeks or a company, troop, or battery at the present time, and has varied in numbers at different epochs with the use of different weapons, from about 60 to 250 men.

These units of combat combine to form *tactical units*, which while small enough to be under the personal observation and control of one man are yet large enough to be an efficient factor in attack or defense, and when acting alone may use their subdivisions for successive attack, mutual support, etc. In modern armies the tactical unit of infantry is the battalion.

For administrative purposes, such as supplying clothing, food, arms, etc., and for recruiting and keeping records, the tactical units are united into *units of administration*, now called regiments.

The regiments are again united into brigades, the brigades into divisions, the divisions into corps, and the corps into armies. Each of these subdivisions in turn is controlled by its immediate commander, who holds those beneath him to a strict accountability, and is himself similarly held by his superiors.

It is evident that by this system of subordination in command, sometimes called the "military hierarchy," the commander of the army can control each and every man in the army, and that the relative command and responsibility of each subordinate can be fixed.

Coexistent with this organization, and absolutely essential to its existence, is a proper state of discipline in the army. This discipline is not limited (as is popularly supposed) to training the men in the use of their arms and the details of military drill, but includes thoroughly instructing both officers and men in their military duties, and in developing in them a respect for the authority of their superiors and a devotion to their duty which will cause them to implicitly obey the orders given them, even to the unhesitating sacrifice of their own lives. These elementary principles of army organization, which are the outgrowth of the experience of the world, being understood, the reader is at once enabled to decide to what extent the armed forces of a nation are entitled to be called an army as distinguished from a mob.

It must not be inferred that magnificent results have not been attained by the struggles of nations, who, actuated by patriotism, religious fervor, or some other strong emotion, have fought as individuals or in bands without being formed into armies properly so called; but such results have been possible only when every man of the nation was aroused, and even then at a much greater cost of life than would have been necessary with an organized army.

Before describing the organization of modern armies a short *résumé* will be given of ancient and mediæval ones,

sketching their development only, since the progressive growth of the different arms is given in more or less detail in the articles ARTILLERY, CAVALRY, INFANTRY, etc.

In the earliest stage of civilization armies, strictly speaking, did not exist; the active men of the tribes were all warriors, while the old men, women, and children looked after the supplies, etc., as among the savages and barbarians of to-day, the different bands fighting among themselves or uniting for a foray or common defense as circumstances might determine.

The Egyptian Army.—History points to Egypt as the first nation to establish a military organization which may be called an army. Under Sesostris the nation was divided into thirty-six provinces, in each of which a warrior-class raised a contingent, all of which when united gave an army, stated by Diodorus Siculus to consist of 600,000 infantry, 24,000 cavalry, and 27,000 chariots (probably an exaggerated estimate). The army was commanded by the king in person, assisted by his companions, who like himself had been trained for war by his father, Amenophis. With this army, which seems to have been well drilled, disciplined, and commanded, he, in a campaign of some nine years, made his extended conquests in Africa, India, Tartary, and Asia Minor.

After these conquests, however, the Egyptian army assumes no further prominence as an aggressive force.

The tactical formation of its infantry seems to have been in solid squares of 100 front and depth, or total of 10,000 men. But little is known of its cavalry, which was not a prominent arm.

Persian Army.—The Persian army, at first mainly cavalry, starting out from the sterile mountains, gradually extended its conquests through the more fertile surrounding regions, garrisoning the cities and occupying the country with the native Persians known as the "king's troops."

Each province was under a military commander who was responsible for the troops of his province, who were annually mustered and inspected.

These troops made up the standing army, efficient for defense against ordinary inroads and insurrections.

In case of foreign war this army was supplemented by the addition of a militia force collected from all the provinces and conquered nations, making up a mass of troops immense in numbers but of little organization or discipline.

The army which Darius led against Alexander was of this character and very large, stated by historians to consist of from 750,000 to 1,000,000 men. That it so easily fell before Alexander must be due to its heterogeneous character and lack of organization, rather than to the lack of fighting power of the Persians themselves, who, except as cavalry which retained its old efficiency, made up but a small part of this force.

The Greek Armies.—The armies of the Greek states consisted almost entirely of infantry, their leaders fighting either on foot with the men or in chariots. Their military system was rather that of a state militia than of a standing army, since but few garrisons were maintained and the men were called out only when needed, returning to their homes when the war was over.

Their frequent wars, however, domestic and foreign, together with their acceptance of service as mercenaries, kept them in constant familiarity with war. And the fact that it was the proud duty and privilege of every freeman to bear arms, while slaves only were called upon to work, led them to keep themselves fitted, by constant military training and physical exercise, to take their place and properly perform their duties in the phalanx.

The Athenian freeman was enrolled at the age of eighteen, and for two years was kept upon home service; from twenty to forty he was liable to service anywhere. But very few were exempt. The more wealthy were allowed to serve in the cavalry, but the mass of the army was infantry. The characteristic feature of the Athenian troops was the vigor and dash of their attack.

The Spartans, under the laws of Lycurgus, were subjected to rigid discipline, unquestioning obedience, endurance of pain and fatigue, and contempt of danger. They were under constant drill, training, and exercise, more so in peace than in war; since in war they were, so far as possible, relieved of labor and fatigue by slaves, baggage-wagons, etc., so that they might be fresh for battle.

Every citizen was called upon for military duty, and their term of service was between the ages of twenty and sixty.

Macedonia, although rising into civilization later than the

above-mentioned states, became the leading state of Greece. Under the reign of Philip she built up a standing army whose organization was developed from but improved upon that of the other states.

At Philip's death, just as he was about to invade Persia, he was succeeded by his son Alexander the Great, who with the army so provided commenced his wonderful career of conquest. His actual force at the outset was about 35,000 men, of which between 4,000 and 5,000 were cavalry, about 5,000 foreign mercenaries, 12,000 Macedonians, and 13,000 Greeks of other states and allies. Recruits subsequently sent to his army brought up its strength to about 60,000 men, constituting two grand phalanxes; the heavy troops armed with the sarissa or pike, 24 feet long, the light troops with the javelin, sling, etc. The formation of the Greek infantry was in the PHALANX (*q. v.*). The small size of this conquering army is the strongest proof of its excellence in individual courage and skill, and in its organization, discipline, and tactics.

The Roman army, like the Greek, was made up originally from free citizens only. Every Roman citizen was liable to military service between the ages of seventeen and forty-six. Yearly levies were ordered by the Senate, and from them were selected the new men required. They were thoroughly trained in the arts of fighting, camping, fortifying, and in marching, working, carrying their heavy arms, equipments, etc.

The cavalry was recruited from the families of rank. One regiment of ten turmae, each of thirty men, was attached to the legion, constituting about 6 per cent. of its entire strength. The earlier tactical formation of the infantry was the legion of ten maniples.

Under Marius we first find slaves fighting among the legionaries, and at about the same time the replacement of the maniple by the cohort.

These changes seem to mark the epoch at which that decadence of the Roman army began which ended in its succumbing to the barbarians of the north. The organization and arms of the legion, maniple, and cohort, are described in the article INFANTRY (*q. v.*).

Medieval Armies.—The Franks and Germans in their warfare against the Romans were organized by tribes and families united into larger masses, who, under the direction of some selected ruler, fought usually in their wedge-shaped columns of attack, aided by their cavalry and light infantry, the latter at the time a *corps d'élite*, but which at a much later date lost this character, and the foot troops became merely attendants upon the mounted men or knights.

All the freemen of these tribes were entitled to bear arms, and in peace claimed perfect liberty and a voice in deciding all public questions. In war, commanders were elected and given absolute power. The more ambitious of these commanders, uniting contiguous tribes for defense or conquest, gradually gathered around themselves bands of retainers, whom they rewarded by allotting to them booty and lands gained by conquest. Soon the acceptance of these gifts was made equivalent to a pledge of future service, and by this means they increased the number of their retainers, augmented their power, and subjected the freemen who were not among their followers to oppressions and exactions of all sorts, until they became in all things subject to the petty suzerains, and the feudal system was established.

The feudal armies were composed of knights, men at arms, and vassals, who were called out as needed, and when disbanded returned to their ordinary pursuits. The fighting power rested in the knights; the infantry, being poorly armed and equipped and almost without organization or training, were held in contempt.

About the middle of the fifteenth century, however, the victories of the Swiss pikemen over the chivalry of Burgundy, and the establishment by Charles VII. of a standing army, demonstrated the superiority of trained and organized forces over the feudal bands, and in a degree re-established the prestige of well armed and drilled foot troops. These changes marked the beginning of the downfall of the feudal system, which was completed by the almost universal establishment of standing armies and the general introduction of firearms at the beginning of the sixteenth century.

The standing armies of this date, and up to the French Revolution, were recruited by voluntary enlistment from the citizens or from foreign mercenaries. The organization and tactical development of the different arms being given under the heads ARTILLERY, CAVALRY, INFANTRY, TACTICS, WAR, etc., will not be repeated. Attention need be called here only to the progressive extension of front and diminu-

tion of depth of formation resulting from improvements in firearms, and to the successive subdivisions of the larger masses into smaller units, in order to increase the mobility of the whole by the greater freedom of movement of its components, at the same time retaining the control of the entire army under one head through the subordination of commanders, to which reference has already been made.

Under this progressive change the masses of the Swiss infantry disappeared, and by the time of Gustavus Adolphus, during the Thirty Years war (1618-48), were replaced by lines with a depth of six ranks, which with the introduction of the bayonet were still further reduced to four ranks.

Under the First Frederick, the "drillmaster of Europe," guided by Leopold of Dessau, was formed that army with which Frederick the Great won his battles. The infantry was reduced to three ranks in depth, and by its drill, still further perfected by the Second Frederick, the mobility of the army was increased, the volume of infantry fire very much developed, and that system of mathematical accuracy of movement was established which enabled him to strike with his army as a whole or by wings, and with a rapidity and dash that secured to him the victory in almost every case in which he could maneuver.

Frederick's successes led not only to the perpetuation of his system in Prussia, but also to its servile following by the other nations of Europe. Many traces of his drill still remain in the armies of to-day, and are only now disappearing, forced out by the requirements of modern methods and weapons.

Napoleon, applying under all varying circumstances that one great principle of tactics which he had learned by his studies of all previous campaigns—that success results from being stronger than the enemy at the point of actual conflict, irrespective of the total strength of the two armies—so modified the tactical handling of his armies that he was able to move the smaller units independently to the points at which they were to be used, and there combine them for the attack or defense. From his acts and writings have been developed the principles of the strategy and tactics which are accepted as the basis of the art of war, and which, while most simple in themselves, have been made to appear by pedantic military writers extremely abstruse and difficult of application.

The immense losses during the Napoleonic wars so depleted the armies that new methods of recruiting became necessary. In consequence the "conscription" was established, by which every male citizen was declared liable to military service for five years, and under which every citizen between twenty and twenty-five years of age was enrolled by name and called out as required.

This system has in recent years been adopted with some modifications by nearly all European nations, and has made possible the formation of the immense armies of modern times.

Under the terms of the Peace of Tilsit the Prussians were allowed to maintain a standing army of 42,000 men only; but under Scharnhorst and Gneisenau at this time was established the "short-service system," by which each man, so soon as he was trained in his military duties, was sent home and was replaced by a recruit. By this method it became possible to augment indefinitely the trained force of the kingdom.

This system once established became permanent in Prussia, and, with the necessary modifications due to the growth of the state and its relations to its neighbors, remains in force at the present time.

The other nations of Europe did not seem to fully realize the value of this system until they were awakened by the results of Sadowa and the Franco-German war. It is now adopted with slight modifications by almost all the nations of Europe. The German army has thus become the model upon which most modern armies are formed, and a *résumé* of its organization will be given first in order. Many details not included in this article will be found in the article WAR (*q. v.*).

German Army.—Under the military laws of Germany, 1867-90, every able-bodied citizen is liable to military service. Each year a muster is made of all young men who have reached the age of twenty-one years, together with those who have been previously mustered, found not fully qualified, and "postponed" for further examination. The annual contingent is selected by lot. Those who fail to pass the inspections for lack of physical development are postponed for the next year's examination. (Two postponements are allowed.) Those who are permanently disquali-

fied for active service are passed into the reserve, to be called upon for such service as they are able to perform. Those not drawn by lot pass into the Landsturm. The selected men serve three years with the colors, four years in the reserve, five years in the first ban of the Landwehr, and seven years in the second ban of the Landwehr. They then pass into the Landsturm, which includes in addition all men between the ages of seventeen and forty-six who are able to bear arms and who are not otherwise enrolled.

The term of service with the colors is shortened to one year for volunteers who pay their own expenses, and frequently to two years for men who are thoroughly trained in their duties by that length of service, the design being to have in the state the largest possible body of trained soldiers at the least expense.

The empire is divided into nineteen districts, each of which furnishes an army-corps. The Guard Corps is recruited from the entire kingdom of Prussia. The districts are divided and subdivided until each battalion, and even each company, is localized, receiving its recruits from its own locality, and returning its reserves to it. The typical organization of an army-corps in time of peace (departures from which are made in the Guard and Bavarian Corps, which will not be specified here) consists of two divisions made up of infantry and cavalry, a brigade of field-artillery, a regiment or less of foot-artillery, a battalion of pioneers, and a battalion of train.

Each division contains two brigades of infantry and one brigade of cavalry. Each brigade (infantry, cavalry, and artillery) consists of two regiments.

Each regiment of infantry contains three battalions, known generally as grenadiers, musketeers, and fusiliers, from their older arms and drill. They are now all armed and drilled alike. The battalion is made up of four companies, and its peace strength is about 588 enlisted men. There are also independent battalions of "Jägers," or rifles recruited from the foresters, gamekeepers, etc., who are specially skillful as riflemen.

The infantry arm is the Mauser rifle, model 1888, with fixed magazine carrying five cartridges (caliber, 7.874 mm. = 0.31 in.). Each regiment of cavalry consists of five squadrons of 133 men each, armed with the cavalry saber, lance, and Mauser carbine, model 1888. The cuirassiers carry the straight sword or "Pallasch" instead of the saber.

Each brigade of field-artillery is made up of two regiments, one consisting of three sections, each of three "mounted" batteries usually of six guns; the other regiment of three sections "mounted" and one section of two "horse-batteries." The total strength of the field-artillery is 277 six-gun and 110 four-gun mounted batteries, and 28 six-gun and 19 four-gun horse-batteries. To each artillery brigade there is attached a battalion of train of three companies. There are in addition fourteen regiments of foot-artillery divided among the army-corps (caliber of field-pieces, 88 mm. = 3.5 in.). Twenty battalions of pioneers, the railroad brigade, and the balloon-companies complete the organization of the combatants; to which must be added the non-combatant or supply departments.

The total strength of the army in time of peace in 1892 was as follows, viz.:

DIVISIONS.	Officers.	Men.
Staff and special troops.....	2,598	2,580
Infantry, 538 battalions.....	10,983	328,713
Cavalry, 465 squadrons.....	2,351	65,347
Field-artillery, 434 batteries.....	2,363	48,397
Train, 62 companies.....	299	6,842
Foot-artillery, 31 battalions.....	728	17,169
Pioneers, 101 companies.....	588	12,724
Landwehr, 277 districts.....	530	5,211
Totals.....	20,440	486,983

Organization during War.—The division into twenty army-corps is rigidly maintained; these corps are united into armies as required. Each corps contains two divisions, the infantry battalions of which are brought up to a strength of about 1,000 men; one regiment of mounted artillery of six six-gun batteries, one or two companies of pioneers, and a sanitary detachment.

The corps-cavalry consists of one brigade of two regiments, each of four squadrons of about 150 men. The remaining artillery makes up the "corps-artillery," as distinguished from that belonging to the divisions; and the trains containing artillery and infantry ammunition, pontoons, spare

horses, bakeries, provisions, ambulances, etc., complete the corps organization.

The remaining cavalry brigades are not attached to corps, but are united in cavalry divisions provided with horse-artillery, and these are again combined into cavalry corps, etc., as required.

The reserves of all arms are called out, armed, equipped, and formed into their proper divisions, etc.; the dépôts become centers of recruiting and instruction, under the charge of the officers of the dépôt battalions, companies, squadrons, or batteries respectively.

The strong places are garrisoned as needed by the Landwehr and Landsturm.

The following is given as the most reliable estimate of the effective war-strength in 1892, viz.:

Active army and reserve, less 10 per cent.....	1,081,550
First ban of Landwehr, less 20 per cent.....	605,890
Second ban of Landwehr, less 30 per cent.....	692,860
Officers of active army and reserve.....	36,000
Total	2,416,300

The armies of the other nations of Europe having been modeled upon that of Germany, it will not be necessary to describe their organization in detail. Attention will be called only to the marked departures from the German system.

Austrian Army.—Every male subject of the Austro-Hungarian empire is liable to military service, beginning on the first of January of the year in which he reaches the age of twenty-one.

The contingent each year is selected by lot; for the year 1893 it was 103,100 men for the army and navy, and 23,000 for the Landwehr. A few exemptions are made, as in the case of those preparing for special professions, etc.

The selected recruits serve for twelve years—three years in the line, seven in the reserve, and two in the Landwehr. Those not drawn by lot pass into the dépôt reserves for ten years or the Landwehr for twelve years. Those not able to bear arms pay an annual military tax during a corresponding number of years. All able-bodied citizens not otherwise enrolled constitute the Landsturm, of which there are two bans, the first including all between the ages of nineteen and thirty-seven years, the second those between thirty-eight and forty-two. The Landsturm can be called out only in time of war.

The empire is divided into fifteen military districts, each furnishing a corps, consisting usually of two divisions of infantry, each of two brigades of two regiments, one brigade of cavalry of two or three regiments, and one brigade of artillery consisting of one regiment of corps-artillery, two divisions of heavy batteries, and one to three battalions of fortress-artillery.

The two regiments of engineers and three of pioneers have each five battalions of four companies of 116 men, with their bridge-trains and other equipments. They are attached to the divisions as needed, generally by battalions.

The infantry regiment contains four battalions of four companies, each of ninety-five men, armed with the Mannlicher rifle (caliber, 8 mm. = 0.32 in.), fixed magazine carrying five cartridges.

The cavalry regiment has six squadrons of about 170 men each.

The artillery regiment is made up of two divisions of three mounted four-gun batteries each, one division of foot-artillery of three two-gun batteries, the necessary battery wagons, forges, etc.

Some of the regiments have in addition a division of horse-artillery of two six-gun batteries, and others a four-gun mountain battery. The guns are of Uchatius bronze (calibers, 87, 75, and 70 mm. = 3½, 3, and 2¾ in. nearly).

The methods of recruiting, mobilization, etc., resemble those adopted in Germany. The total strength of the army on a peace footing in 1891 was as follows, viz.:

DIVISIONS.	Officers.	Men.
Staff and special troops.....	5,485	18,830
Infantry, 450 battalions and 135 cadres.....	9,153	179,502
Cavalry, 258 squadrons and 43 cadres.....	1,982	46,864
Field-artillery, 241 batteries and 70 cadres.....	1,374	23,992
Fortress-artillery, 18 battalions and 18 cadres ...	420	7,346
Engineers, 81 companies and 16 cadres.....	584	9,564
Train, etc., 84 squadrons and 22 cadres.....	386	3,465
Landwehr, 171 battalions, 60 squadrons, and 134 cadres.....	1,977	26,495
Totals.....	21,361	316,058

In time of war this effective would be increased to about the following figures, viz.:

DIVISIONS.	Officers.	Men.
Staff and special troops.....	9,386	57,068
Infantry.....	12,435	635,118
Cavalry.....	2,475	71,580
Field-artillery.....	1,680	90,268
Fortress-artillery.....	648	21,798
Engineers, etc.....	705	46,914
Train.....	1,020	45,642
Landwehr, Austrian.....	3,129	252,960
“ Hungarian.....	4,178	174,062
Landsturm.....	9,582	431,540
Totals.....	45,238	1,826,940

French Army.—Under the French military law of 1872, and its modifications up to Nov., 1890, every Frenchman becomes liable to military service upon reaching twenty years of age, the service to consist of three years in the active army, seven in the reserve, six in the territorial army, and nine in the reserve of the territorial army. A certain portion of each contingent, however, is relegated to the reserve after two years' service in the active army, and for special reasons a limited number pass into the reserve after one year's service.

Those found to be not physically qualified for service and certain others partially exempt pay an annual military tax.

The methods of recruiting, mobilization, etc., do not differ materially from those of Germany.

There are eighteen military districts in France and one in Algeria, each furnishing and garrisoned by a *corps d'armée*. The typical corps, from which some variations exist, is made up of two divisions of infantry, a brigade of cavalry, a brigade of artillery, a battalion of engineers, a squadron of train, and a legion of gendarmes.

There are also six divisions of cavalry not attached to any corps.

Each infantry division consists of two brigades of infantry.

Each cavalry division contains one brigade of cuirassiers, one brigade of dragoons, and one brigade of chasseurs or hussars.

Each brigade of infantry, cavalry, and artillery is made up of two regiments.

The infantry regiment contains three battalions of four companies each, and a separate battalion or company for recruiting, etc.

The battalion on a peace footing contains about five hundred men.

The infantry is armed with the Lebel rifle (caliber, 8 mm., fixed magazine holding eight cartridges).

The cavalry regiments have each five squadrons of about one hundred and fifty men. The firearm of the dragoons, chasseurs, and hussars is a carbine, that of the cuirassiers a revolver.

The nineteen regiments of divisional artillery have each twelve mounted batteries, the nineteen regiments of corps-artillery have each nine mounted and three horse batteries. There are, in addition, twenty-four mountain batteries in Algeria, Tunis, Corsica, and attached to the Fourteenth and Fifteenth army corps.

All batteries have six pieces each, the calibers being 90 mm. for mounted, 80 mm. for horse, and 95 mm. for the foot batteries.

The strength of the army on a peace footing in 1891 was as follows, viz.:

DIVISIONS.	Officers.	Men.
Staff and special troops.....	4,000	3,473
Infantry, 564 battalions.....	11,712	318,502
Cavalry, 478 squadrons and 8 companies.....	3,326	73,006
Field-artillery, 480 batteries.....	3,046	54,238
Fortress-artillery, 100 battalions, 54 companies..	1,158	20,008
Engineers, 108 companies.....	483	12,623
Train, etc.....	3,336	16,134
Totals.....	30,341	508,686

In time of war the *corps d'armée* are united in armies according to the needs of the service, and all the organizations are recruited up to their full war footing from the trained reserves, bringing the effective strength of a regiment of infantry up to about 3,000 men, a regiment of cavalry to 650 men, and a mounted battery to about 192 men.

The probable effective in 1892 is estimated to be as follows, viz.:

Active and reserve army, less 10 per cent.....	1,395,000
Territorial army, less 20 per cent.....	740,000
Reserve of territorial army, less 33 per cent.....	815,000
Dépôt, etc.....	90,000
Total.....	3,040,000

The estimated total for 1893 is 3,254,000 men.

Spanish Army.—Under the laws of 1877–82 military service is made obligatory in Spain. Beginning at the age of twenty years it continues for three years in the active army, three in the first reserve, and six in the second reserve. Exemptions can be purchased.

The kingdom is divided into ten conscription districts; but no corps, division, or brigade organizations exist in time of peace. The infantry and engineer regiments consist usually of two battalions, each of four companies. There are also a certain number of dépôt battalions.

The cavalry consists of lancers, chasseurs, dragoons, and hussars; each regiment of four squadrons.

The field-artillery regiment contains from four to seven batteries, the battalion of fortress-artillery from three to six companies, and the regiment of siege-artillery four batteries.

The total strength on a peace footing is about as follows:

Infantry.....	90,327
Cavalry.....	13,968
Artillery.....	11,340
Engineers.....	4,671

besides the train-ambulance, etc., belonging to the active army, and the territorial troops, which bring the total up to about 120,000 men.

In time of war the strength would be increased to about—

Infantry.....	734,680
Cavalry.....	23,300
Artillery, 460 guns, etc.....	30,350
Engineers.....	7,500
Workmen, sanitary troops, and territorial troops.....	9,570
Total.....	805,400

The colonial troops are not included.

Russian Army.—Under the laws of 1874, 1876, and 1888, military service is obligatory. Christian clergymen are totally exempt. Mohammedans are exempt upon payment of a fixed tax, and certain artists and members of learned professions are exempt in time of peace. The remaining able-bodied men are subject to conscription upon reaching the age of twenty-one.

The annual contingent for 1892 was 262,400 men. The term of service in European Russia is five years in the active army, thirteen in the reserve, and five in the first ban of the territorial army. In the provinces these periods differ somewhat. Those able-bodied men between the ages of twenty-one and forty-one not otherwise enrolled constitute the first ban of the territorial army, and those not physically qualified for active service make up the second ban, used for local defense, etc. The first ban can furnish about 1,000,000 men for their annual drills.

The conscription for the Cossacks takes place at the age of nineteen. They serve three years in their native villages under instruction, four in active service in the first ban, four in the second ban, four in the third ban, and five in dépôt. All other Cossacks may be called out by the emperor for national defense in exceptional cases during war.

European Russia is divided into 13 conscription districts, some of which furnish two to four army corps, giving a total of 20 corps. Each corps is, as a rule, made up of 2 divisions of infantry, 1 division of cavalry, 2 brigades of mounted artillery, and 2 horse-batteries. Owing to variations in corps organization the total strength is 48 divisions of infantry, 18 divisions of cavalry, 48 brigades of mounted artillery, and 31 horse-batteries.

Each infantry division contains 2 brigades of 2 four-battalion regiments.

Each battalion has four companies, all armed with the Berdan rifle (caliber, 10.7 mm. = 0.42 in.).

The cavalry division is made up of 2 brigades of 2 regiments, each of 6 squadrons, armed with the dragoon rifle with bayonet and saber. There are included in the regular cavalry 16 regiments of Cossacks. Each brigade of field-artillery has 6 mounted batteries (2 heavy—caliber, 106.8 mm. = 4.2 in., and 4 light—caliber, 86.9 mm. = 3.4 in.), each in time of peace of 4 guns, increased to 8 in time of war. The horse-batteries have 6 light guns. The mountain-batteries have a still lighter gun (caliber, 63.5 mm. = 2.5 in.).

The special troops do not belong to the corps, but are assigned as needed. The infantry of the guard, the regiments of grenadiers and chasseurs, the cavalry, horse-artillery, artillery of the reserve, and the technical troops are recruited from the empire at large.

The strength of the army in 1892 on a peace footing is given as follows, viz.:

DIVISIONS.	Officers.	Men.
Infantry, 888½ battalions.....	15,764	429,383
Cavalry, 356 squadrons.....	2,262	59,916
Field-artillery, 350 batteries.....	2,073	60,787
Engineers, 44 companies.....	772	23,547
Train.....	428	7,254
Reserve, 125 battalions and 33 batteries.....	4,225	76,280
Garrison troops, 28 battalions of infantry, 54½ battalions and 5 batteries of artillery.....	1,742	40,501
Dépôt troops.....	202	4,836
Cossack infantry, 6½ battalions.....	150	4,956
“ cavalry, 11 squadrons and 275 sotnias.....	1,912	44,714
“ artillery, 20 horse-batteries.....	100	3,340
Caucasian militia, 26 sotnias, horse, 2 sotnias, foot.....	71	3,358
Custom or frontier guards.....	860	28,500
Totals.....	30,561	787,372
		818,033 combatants

Upon a war footing this force is increased as follows, viz.:

	Officers and men.
Infantry, 889 battalions.....	876,651
Cavalry, 360 squadrons, regulars.....	57,464
Field-artillery, 353 batteries, regular.....	77,594
Engineers, 121 companies.....	29,944
Train, etc.....	146,298
Reserve troops, 527 battalions, 92 batteries, and 46 companies.....	544,578
Garrison troops, 143 battalions of infantry, 57½ battalions of artillery, and 16 field-batteries.....	210,921
Dépôt troops, 205 battalions, 113 squadrons, and 48 batteries.....	290,493
Cossack troops, 868 sotnias and 38 batteries.....	154,014
Caucasian militia.....	3,429
Frontier guards.....	29,360
Total.....	2,420,746

Not counting the territorial army and the Cossack troops available for national defense.

Turkish Army.—Under the laws of 1880–88, military service in Turkey is compulsory. The term of service in the permanent army is three years for the infantry and four for the other arms; in the reserve three or two years, in the Landwehr (redif) eight, and in the Landsturm (moustahfiz) six. Conscripts assigned to dépôts serve only six months. Exemptions may be purchased after serving five months in the active army. The army is divided into seven corps of an organization similar to the German.

The Landwehr divisions are attached to and form part of the army-corps.

Each infantry regiment contains four 4-company battalions armed with the Mauser rifle (caliber, 11 mm. = 0.44 in.), with fixed magazine holding eight cartridges. There are also unattached battalions of rifles, zouaves, etc.

The cavalry regiments have five squadrons each, and the typical field-artillery regiment has 3 horse, 4 mounted, and 2 mountain batteries; or 3 sections, each of 4 mounted batteries.

The heavy artillery is organized in regiments, separate battalions, and companies, which will not be described here.

The engineer regiments contain either two or three battalions.

The enlisted strength (1891) is about as follows, viz.:

Infantry, 243 battalions of 400 men.....	97,200
Cavalry, 185 squadrons of 160 men.....	29,600
Field-artillery, 208 six-gun batteries of 100 men.....	20,800
Foot-artillery and lancers and 122 companies of 100 men.....	12,200
Engineers, 50 companies of 100 men.....	5,000
Train, 20 companies of 100 men.....	2,000
Landwehr, 352 cadres of 10 men.....	3,520
Total.....	170,420

To this must be added about 1,200 officers. The artillery has 1,248 field and mountain guns and 2,300 heavy guns. The troops not serving with the colors are 27,000 reserves on leave, 37,500 dépôt troops, 590,000 Landwehr, and 262,000 Landsturm; which, added to the active force, gives a total available for an European war of between 800,000 and 1,000,000 men.

Bulgarian Army.—Although under Turkish sovereignty, the Bulgarian army constitutes a factor in the European armaments.

Military service is obligatory, beginning at twenty years of age. The term is in the active army two years for the infantry and three for the other arms; then in the reserve eight or five years, in the first ban of Landwehr to the age of thirty-seven, and in the second ban to forty-five.

Mohammedans may buy an exemption, and some others are exempt by law. The annual contingent is about 16,000 men.

The Bulgarian principality is divided into six districts, each furnishing a brigade. The composition of brigades, regiments, etc., does not differ materially from that previously described. The infantry is armed with the Mannlicher repeating rifle (caliber, 8 mm.), the cavalry with the Berdan carbine, and the artillery with Krupp guns (of 8.7, 7.5, and 7 cm. caliber). The strength on a peace footing is about as follows, viz.:

	Officers and men.
Staff and special troops.....	68
24 regiments of infantry, 48 battalions.....	26,181
4 regiments of cavalry, 17 squadrons.....	2,981
6 regiments of artillery, 27 batteries.....	4,062
1 siege-battery and 2 dépôts.....	765
1 regiment of engineers.....	1,603
Total.....	35,650

In time of war the total force of trained troops available is estimated at 2,300 officers and 133,000 men, with an untrained force of Landwehr, etc., of about 150,000 men in addition.

Roumanian Army.—The army of Roumania, organized under the military laws of 1876–91, is recruited by a general conscription similar to those already described. It is divided into 4 army corps, containing 33 regiments and 4 separate battalions of infantry, 15 regiments of cavalry, 8 regiments of artillery, 2 regiments of engineers, and the train, administrative departments, etc., which in time of peace make up a total of about 3,000 officers and 49,000 men, besides the territorial army of about 71,000 men. On a war footing this strength may be brought up to a total of 3,500 officers and 149,000 men.

Servian Army.—Under the law of Jan., 1889, military service is obligatory at twenty-one years of age. The term of service is one year in the active army, of which cadres only are maintained in time of peace, nine in the reserve, ten in the first ban, and ten in the second ban of the national militia.

The kingdom is divided into five territorial divisions, in which the cadres of the active army are located, forming a force of about 1,000 officers and 20,000 men.

In case of mobilization these cadres filled out form five divisions, in addition to a force of unattached troops of all arms and the reserves and militia.

The total effective strength is about as follows:

ACTIVE ARMY AND RESERVE.			
	Men.		
75 battalions.....	70,000		
30 squadrons.....	3,500		
57 batteries, 282 pieces.....	7,000		
24 companies of engineers, etc.....	3,500		
Total.....	84,000	84,000	
NATIONAL MILITIA.			
120 battalions.....	70,000		
10 squadrons.....	1,000		
20 batteries with 120 pieces.....	2,000		
5 companies of engineers, etc.....	500		
Total.....	73,500	73,500	
Grand Total.....			157,500

Not including trains, etc.

Italian Army.—Under the laws of 1875–91, military service is compulsory in Italy. The age of conscription is twenty years. The conscripts generally serve three years with the colors, five in the reserve, four in the mobile militia, and seven in the territorial militia. The annual contingent is 82,000 men, one-third of whom, selected by lot, serve only two years with the colors. The cavalry contingent serves four years with the colors, five in the reserve, and ten in the territorial militia. Those who are not enrolled in the active army are formed into the second and third classes, and liable to such service as may be required, under the law, up to the age of thirty-nine.

The army is made up of twelve corps, whose organization does not differ materially from those already described. Its composition is as follows, viz.: Infantry, 96 regiments of the

line, 12 of bersaglieri (or rifles), 75 companies of Alpine troops, and 98 separate companies. The infantry arm is the Vetterli rifle (caliber, 10.388 mm. = 0.42 in.), with fixed magazine holding 5 cartridges. Cavalry, 24 regiments of 6 squadrons each; artillery, 24 regiments of 8 batteries each; engineers, 4 regiments of from 17 to 21 companies, beside the territorial troops and militia.

The total strength in 1891 was 276,013 men with the colors, 566,152 on leave of absence, 449,016 mobile militia, and 1,553,158 territorial troops, giving a grand total of 2,844,339 men.

Belgian Army.—The Belgian army is recruited by voluntary enlistment and by conscription by lot of an annual contingent, fixed by law, which will keep the strength of the active army at about 13,300 men. The conscription is made from the young men who have reached the age of nineteen, but many exemptions are allowed.

The term of service is eight years in the active army and five in the reserve.

The strength in time of peace is as follows:

DIVISIONS.	Officers.	Men.
Staff and special troops.....	602	869
Infantry, 58 battalions and 415 cadres.....	1,745	28,810
Cavalry, 4 squadrons and 8 cadres.....	304	5,744
Field-artillery, 34 batteries and 14 cadres.....	290	3,400
Fortress-artillery, 58 batteries and 4 cadres.....	244	4,518
Engineers, 17 companies.....	146	1,541
Train, 7 companies, 1 dépôt, etc.....	29	402
Totals.....	3,360	45,284

The *gendarmerie* and *garde civique* make up an additional force of 42,827 men. In time of war the strength is brought up to a total of 3,849 officers and 127,119 men, besides about 90,000 men of the local *garde civique*.

Swiss Army.—By the laws of 1874–87 every able-bodied Swiss is liable to military service from his twentieth to his thirty-second year in the *Anszug*, and from his thirty-third to his forty-fourth year in the Landwehr. Service in the *Anszug* includes a short course of training, followed by several weeks' drill each year. The Landwehr is designed to be eventually a trained army similar to the *Anszug*.

Those not rendering personal service pay an annual military tax.

The Landsturm includes every able-bodied man between the ages of seventeen and fifty who is not otherwise enrolled.

The army is divided into 4 army-corps. The peace strength is 32 regiments and 2 battalions of fusiliers and 8 battalions of carbineers, armed with the Rubin rifle (caliber, 7.5 mm. = 0.3 in.), with fixed magazine carrying 12 cartridges; 8 regiments of cavalry, each of 3 squadrons, and 12 companies of "guides"; 24 regiments of field-artillery, each of 4 batteries; 1 regiment of mountain-artillery of 2 batteries, 8 companies of foot-artillery, 8 battalions of engineers of 3 companies each, train, ambulance, etc.

The effective strength on a peace footing in 1891 was as follows, viz.:

Regular army, 127,973; Landwehr, 80,272: total, 208,245. This was without the Landsturm, which contains about 272,000 men.

Holland.—The army of Holland is composed one-third of men enlisted for six years and two-thirds of conscripts raised by an annual contingent of 11,000 militia. Service in the militia is obligatory from the age of twenty to that of twenty-five, but by frequent exchanges, etc., the active service of each man generally is limited to from six months to one year. In addition, every able-bodied citizen is enrolled in the *garde civile* between the ages of twenty-five and thirty-five, and all citizens capable of bearing arms in the Landsturm between the ages of nineteen and fifty.

The kingdom is divided into three military districts, which are expected to furnish an effective strength in time of war as follows, viz.:

DIVISIONS.	Officers.	Men.
Staff and special troops.....	158	693
Infantry, 46 battalions.....	1,060	42,908
Cavalry, 16 squadrons.....	143	3,988
Artillery, 21 batteries and 51 companies.....	503	13,843
Engineers, etc., 8 companies.....	98	1,614
Other troops.....	27	626
Totals.....	2,359	63,672

Add in all reserves except the Landsturm and civil societies of riflemen, etc., this sum is increased to about 185,600 men.

In peace the strength of the organizations is about one-third of that given.

Danish Army.—In Denmark military service is obligatory, beginning at the twenty-second year.

The service with the colors is limited to six months' instruction for infantry and nine months for cavalry, after which the recruits pass into the first ban for eight years, during which time they are called upon for several terms of service of thirty days each. They then pass into the second ban for eight years.

The annual conscription is about 11,000 men. The strength of the army in 1891 was as follows, viz.:

DIVISIONS.	Officers.	Men.
Staff and special troops.....	25	16
10 regiments of infantry.....	801	33,192
5 regiments of cavalry.....	139	2,420
2 regiments of field-artillery.....	175	4,755
2 battalions, not artillery.....		
1 regiment of engineers.....	61	1,366
Totals.....	1,201	41,749
Add during war—		
11 dépôt battalions.....	245	13,525
4 battalions and 6 companies of artillery.....	49	2,793
Totals on war footing.....	1,493	58,067

Sweden and Norway.—Military service is obligatory. Commencing at twenty-three years, it includes nominally five years in the active army, four in the Landwehr, and four in the first levy of the Landsturm. The service is limited, however, to an instruction of from two to four months for the first year and about one month the second year. All able-bodied men not otherwise enrolled belong to the Landsturm between their eighteenth and fiftieth years.

The Landwehr is available for national and the Landsturm for local defense only. The total strength of the army is about 40,000 men. In time of war, by adding the first levy of the Landwehr, it can be increased to about 800 officers and 18,000 men, maximum.

British Army.—The British army is recruited entirely by voluntary enlistment. The term of service in the regular army is twelve years, of which nine in the infantry of the guard and seven in the infantry of the line may be in the reserve. Any soldier of good habits may, however, enlist for a term of twenty-one years, which will entitle him to be "retired" at the expiration of his term.

The militia of the kingdom is recruited also by voluntary enlistment, but every able-bodied man between the ages of eighteen and fifty years, belonging neither to the regular nor volunteer forces, is liable to conscription for service in the militia. The term of this service is six years, which may be prolonged to twelve. The active service in the militia is limited to six months for the first year, and to three or four weeks for the following years. Those enrolled in the volunteers are exempt from militia service, but are called out for manœuvres of nine days each year.

The United Kingdom is divided into fifteen military districts, and these into sixty-seven sub-districts, each of which is expected to furnish a regiment of infantry, two or three battalions of militia, and to form a dépôt for instruction of recruits and for collecting the reserves, etc. The infantry of the guard and the rifles is recruited from the country at large, and the cavalry and artillery from special districts.

In time of peace no corps, division, or brigade organizations exist, and the regimental organizations differ very much among themselves. The typical infantry regiment contains two battalions, each of eight companies of from 100 to 130 men. The infantry arm is the Lee-Metford rifle (caliber, 0.30 in., with detachable magazine holding eight cartridges). The cavalry regiment is made up of eight troops of about sixty men each, two troops forming one squadron.

The artillery is organized in batteries of six guns each (calibers for horse-batteries, 3-inch 12-pounders; for field-batteries, 3½-inch 22-pounders; and for mountain-batteries, light 22-pounders, muzzle-loaders, pattern of 1882. The guns of the horse and field batteries are breech-loaders with interrupted screw ferreture), and the engineers into companies and battalions.

The strength in time of peace (1891-92) is as follows, viz.:

DIVISIONS.	Officers.	Men.
Staff and special troops.....	1,891	8,510
Infantry, 148 battalions, 71 dépôts, and 345 cadres.....	4,785	142,059
Cavalry, 186 squadrons, 11 dépôts, and 43 cadres.....	856	18,412
Artillery, 230 batteries and 89 cadres.....	1,445	35,446
Engineers, 70 companies and 24 cadres.....	933	6,620
Colonial troops, 3 battalions, 4 batteries, and 16 cadres.....	171	5,064
Totals.....	10,081	216,111
		226,192

In time of war the troops are united into brigades, divisions, and corps, and the cadres are filled to a war footing. The organization includes 2 army-corps, 1 division of cavalry, and the dépôt troops for foreign service; and for home defense 2 army-corps and 4 brigades of cavalry made up from the volunteers and militia. The army-corps, besides its staff and special arms, contains 3 divisions of infantry and 1 battalion of corps-infantry with 2 machine-guns. Each infantry division has its staff, 3 brigades, each of 4 battalions of infantry, each battalion of about 1,000 men with 2 machine-guns; 1 squadron of cavalry, 3 mounted batteries, and the proportionate force of engineers, ambulances, train, etc., with a strength of about 327 officers and 10,000 men.

Each cavalry division contains 2 brigades of cavalry, each of four 4-squadron regiments, 2 machine-guns, 2 horse-batteries, train pioneers, etc.; 4 battalions of mounted infantry with 2 machine-guns, a company of train, ambulances, etc., with a total strength of about 7,300 officers and men, and 18 pieces of artillery.

The estimated effective war strength is about as follows:

	Officers.	Men.
Militia.....	4,517	146,000
Volunteers.....	8,723	252,007
	13,240	398,007
Reserves of regular army.....		411,247
Regular army of United Kingdom.....		73,825
Total.....		117,211
		602,283

To this may be added the regular army:

In the colonies.....	108,981
Irish police, etc.....	13,000

The colonial troops are not included in this total, as they are organized principally for local defense, although they may contribute a contingent for foreign wars in some cases. Their strength in 1892 may be summarized as follows, viz.:

CANADA.		Men.
British troops at Halifax.....		1,494
Canadian standing army.....		1,200
“ militia.....		37,359
“ militia reserve.....		655,000
Total.....		695,053

AUSTRALIA, NEW ZEALAND, AND TASMANIA.	
Regular troops and volunteers, about.....	27,000

INDIA.	
British troops, about.....	72,500
British officers commanding native troops.....	26,400
Native troops.....	125,000
Police, partly officered by British.....	120,000

The United States Army.—The regular army of the U. S. is recruited by voluntary enlistment. The Act of Feb. 2, 1901, provides for the following organization: 30 regiments of infantry, each of 12 companies; 15 regiments of cavalry, each of 12 troops; 126 companies of coast artillery, and 30 batteries of field artillery; 1 battalion of engineers, of 12 companies; the signal corps, the officers and cadets of the Military Academy, unattached enlisted men, Indian scouts, hospital attendants, messengers, etc. Total enlisted strength, 75,787.

The staff and administrative departments consist of three major-generals, fifteen brigadier-generals with their aides, and the following departments, viz.: The adjutant-general's department, charged with orders, correspondence, etc.; the inspector-general's department, charged with inspecting the troops, etc.; the judge-advocate-general's department, charged with supervision of courts martial; the quartermaster's department, charged with transportation, quarters, etc.; the subsistence department, charged with provisioning the army; the medical and pay departments, chaplains and signal-corps, whose names indicate their duties; the corps of engineers, charged with the construction of fortifications,

military engineering, etc., and in time of peace with the improvements of rivers and harbors and other civil works; and the ordnance department, charged with the construction and repair of cannon, small arms, and military equipments and supplies.

No brigade division or corps organization exists in time of peace; but the U. S. is divided into military departments commanded by the general officers, who control the troops stationed in their respective commands.

The regular army is used in time of peace principally for suppressing Indian outbreaks, disorders upon the frontier, and enforcing the laws of the U. S. when necessary. It is officered from graduates of the Military Academy, supplemented by promotions from the ranks and selections from civil life. It is regarded rather as a training-school for educating officers and preserving military knowledge and traditions than as an efficient defense against foreign armies.

The main reliance of the nation in a great war is upon the volunteers and militia, the probable strength of which is indicated by the numbers called into service during the civil war, at the close of which there were in service 1,000,516 men, with an available reserve of 2,500,000 men.

The total number of men in the U. S. available for military service is now between 11,000,000 and 12,000,000. See MILITIA.

The trained militia is, however, relatively small in numbers, although in some States the organized regiments are well trained in drill, etc.

The drill, arms, equipments, etc., of the militia are very generally modeled on those of the regular army, and the efforts of the war department are directed to making this resemblance more complete, and to assisting in every way the more thorough instruction and discipline of the citizen soldiery.

The arms and equipments of the U. S. army are now in a state of transition from the older to the newer types, not yet fully adopted. They will not be described in this article.

For methods of educating the officers of modern armies see MILITARY ACADEMIES, ARTILLERY, SCHOOLS OF, and STAFF AND STAFF SCHOOLS.

JAMES MERCUR.

Army-corps: See CORPS D'ARMÉE.

Army-list: an official publication issued by the British War Office; contains the names of all the commissioned officers in the British army, arranged according to the dates of their commissions. Then come the officers of that portion of the queen's army which belongs exclusively to India. The bulk of the work is filled with an enumeration of all the regiments in the queen's army, and all the officers in each regiment.

Army-register is an annual register published by order of the Secretary of War, in compliance with an act of Congress, containing lists of the departments, regiments, and commissioned officers of the U. S. army, with the promotions and casualties for the year.

Army-regulations is the name of a volume published by the U. S. War Department, containing rules for the management of troops in camp and field, with instructions for keeping accounts and making returns to the army bureaus. It is based upon the Articles of War and other acts of Congress. See ARTICLES OF WAR.

Army-worm: in the Northern U. S. the larva or grub of a night-flying moth (*Leucania unipuncta*). It varies considerably in color and size with age and locality, but its markings are characteristic. It is usually from less than an inch to an inch and three-quarters in length; dark gray, with three narrow yellowish stripes above, and a broader one of nearly the same color on each side; thinly clothed with short hairs, especially about the head, which is of a dull yellow color. The ravages of these worms, which sometimes march over grain-fields in great numbers, are best prevented by plowing a double furrow around or across the field on which they are moving. Then they may be killed by setting fire to straw in the furrows or by turning pigs and fowls (after removal of the crop) into the field. Crows and blackbirds will also destroy them rapidly.

The army-worm of the Southern U. S., a near relative of the above, sometimes appears in countless hosts and devours the cotton. In the West Indies its ravages have led to a general abandonment of the cotton crop. Various other destructive larvæ are called by this name.

Arnald'o, or Arnold of Brescia: an eloquent Italian reformer; b. at Brescia about 1100. He was a pupil of the celebrated Abelard in France, and adopted the monastic life. As a preacher he boldly reprov'd the prevalent venality, luxury, and corruption of the clergy. He affirmed that the clergy ought not to possess temporal power or property. The second Council of the Lateran, in 1139, condemned Arnaldo as a disturber of the peace, and banished him from Italy. He retired first to France, where he encountered the hostility of St. Bernard, and next to Switzerland, where he gained many adherents. In the meantime there was formed in Rome a numerous party which favored the principles of Arnaldo and was friendly to civil liberty. These revolted against the pope, who fled or was driven out of the city. Arnaldo in 1146 returned to Rome, again raised his voice for religious reform, and endeavored to organize a republic. His success was hindered by the violence and excesses of the populace, which filled the city with disorder for nearly ten years. A reaction ensued, and Pope Adrian IV. reduced the Romans to submission by laying the city under an interdict in 1154. Arnaldo was arrested in Rome by the aid of the Emperor Frederik Barbarossa, and was hanged in 1155, his body burnt, and his ashes scattered on the Tiber. A statue to him at Brescia was unveiled Aug. 14, 1882. See Gregorovius, *Geschichte der Stadt Rom im Mittelalter*, and biographies by Clavel (Paris, 1868); Bonet-Maury (Paris, 1881); Bonghi (Rome, 1885).

Arnald'us Villanova'nus [It. *Arnald'o di Villano'va*], sometimes called ARNALDUS NOVICOMENSIS; an eminent physician; b. about 1235. He devoted much attention to alchemy, wrote treatises on medicine, alchemy, and religion, and was suspected of heresy. He was employed in diplomacy by the King of Naples. D. near Avignon, in 1312. His works, in Latin, with a life by S. Campegius, appeared in last edition at Basel, 1585, fol. See his life by Pierre Joseph de Haitze (Paris, 1719).

Arnauts: See ALBANIA.

Arnason, aar-na-son, Jón: Icelandic scholar; librarian at Reykjavik; b. Aug. 17, 1819; d. at Reykjavik, Nov. 13, 1888. His very important collection of Icelandic popular tales and legendary stories, *Íslenskar Þjóðsögur og Æfintýri*, was published at Leipzig in 2 vols. (1862-64). G. L. KITTREDGE.

Arnatto: See ANNOTTO.

Arnaud, aar-nō, HENRI: a pastor of the Waldenses and an able military commander; b. at Embrun, Hautes-Alpes, France, Sept. 30, 1641; educated at Basel and Geneva; licensed by the Waldensian Church 1670; was pastor in Tours at the time of the edict abolishing the Waldensian Church. This was the occasion of the daring resolve which eventuated in the famous "Glorious Return of the Vaudois." He was the commander of his brethren, who after defeating the French in several actions recovered their native valleys in France (August, 1689), from which they had been driven by persecution, as they were again later on. He served as colonel in the allied army in the war of the Spanish succession (1702-13), but in his closing years preached to the exiled Waldensians (Jan. 31, 1686) at Schönenberg, Würtemberg, where he died Sept. 8, 1721. He published an *Histoire de la glorieuse Rentrée des Vaudois* (1710; n. e. Nenchâtel, 1845), translated by Ackland (London, 1827). The Return was celebrated August and September, 1889.

Arnauld, ANGÉLIQUE, called also ANGÉLIQUE DE SAINT-JEAN: an eminent French nun; b. in Paris, Nov. 28, 1624; was a daughter of Robert Arnauld d'Andilly. She was educated at Port Royal by her aunt, Marie Angélique, and was a zealous Jansenist. In 1669 she was elected prioress of the convent of Port Royal. She acquired a high reputation for piety, learning, and courageous endurance of persecution. She became abbess of Port Royal in 1678, after which she was persecuted by the Jesuits. She wrote memoirs of her aunt, the abbess Marie Angélique Arnauld (1591-1661). D. in Paris, Jan. 29, 1684. She was the principal author of the *Mémoires pour servir à l'histoire de Port Royal* (Utrecht, 1742, 3 vols.). See Sainte-Beuve, *Port Royal*; also Beard, *Port Royal*.

Arnauld (formerly written *Arnaud*), ANTOINE, surnamed L'AVOCAT: a famous orator; b. in Paris in 1560; was the most eloquent French advocate of his time. He was also distinguished for his probity. He became procureur-général in 1585. His most memorable performance was his speech against the Jesuits in 1594, which resulted in their temporary banishment. He was the father of four distinguished

sons (the eminent Arnaulds of Port Royal) and of six daughters. D. in Paris, Dec. 29, 1619.

Arnauld, ANTOINE, called LE GRAND ARNAULD: a celebrated Jansenist theologian and philosopher; a son of the preceding; b. in Paris on Feb. 8, 1612. His mother was Catherine Marion. He was educated in the Sorbonne, ordained a priest in 1641, became a doctor of the Sorbonne in 1642, and engaged in the controversy between Jansenius and his opponents on the subject of grace. He published in 1643 a work *On Frequent Communion*, which was highly esteemed, but gave offense to the Jesuits, of whom he was a constant and strenuous adversary. This book promoted a reform in the style of French theologians. Having retired to Port Royal (1648), a convent near Paris, he passed there many years in seclusion, and wrote numerous works on theology and philosophy. In 1650 he published an *Apology for the Fathers (Apologie pour les Saints Pères)*. He was expelled from the Society of the Sorbonne in 1656 for maintaining that Jansen had been misunderstood and maligned, after which the Jansenists were generally proscribed and persecuted, both by the civil and ecclesiastical powers. He aided Pascal in his *Provincial Letters*, and Lancelot in a *Grammaire générale et raisonnée*. Among his other works are *Logic, or the Art of Thinking*, commonly called *The Port Royal Logic* (1662), written in collaboration with Nicole, and the only one of his books not entirely forgotten (the 10th ed. of the Eng. trans. appeared Edinburgh, 1887); *The Moral Theology of the Jesuits*; *The Perpetuity of the Catholic Faith touching the Eucharist defended against Sieur Ctaude* (1669); and *The Practical Morality of the Jesuits* (8 vols., 1683-94). To escape the persecution which the Jesuits instigated, he became an exile in 1679, and passed the remainder of his life in Flanders and Holland. He died near Liège, Aug. 8, 1694. Boileau, who wrote his epitaph, pronounced him the "most learned mortal who ever wrote." Arnauld was distinguished for his earnestness and simplicity of character, his industry, and his alacrity in controversy. His works occupy forty-five closely printed quarto volumes, which were published, Paris and Lausanne, in 1775-83. See P. Quesnel, *Histoire de la Vie et des Ouvrages de M. Arnauld* (Paris, 1697); N. de Larrière, *Vie d'Antoine Arnauld* (1783); Sainte-Beuve, *Port Royal*, vol. ii.; P. J. Varin, *La Vérité sur les Arnaulds* (2 vols., 1847).

Arnauld, MARIE ANGÉLIQUE, proper name *Jacqueline Marie*, sister of preceding: b. in Paris, Sept. 8, 1591; became through influence abbess of Port Royal when only eleven years of age, and was of course inefficient, but from 1608, when she was converted, she discharged her duties in the most exemplary manner, and won great fame. She resigned in 1626, was superior of another community of nuns, but returned in 1636 and became prioress under her sister, who had succeeded her as abbess. D. in the convent of Port Royal, Paris, Aug. 6, 1661. See her life by Miss Frances Martin, London, 1873.

Arnauld d'Andilly, ROBERT: French writer; b. in Paris in 1589; a brother of Antoine Arnauld (1612-94), and the father of Angélique (de Saint-Jean). He was appointed intendant of the army in 1634, and retired to the monastery of Port Royal about 1643. He produced a translation of Josephus's *History* (1669), and wrote autobiographical memoirs (1734), besides two volumes of lives of saints, called *Vies des Saints Pères du Désert*. D. in Paris, Sept. 27, 1674. His son Simon was Marquis de Pomponne, and his brother Henry, b. in Paris, 1597, was a devout and zealous Jansenist; became Bishop of Angers, 1649; d. there June 8, 1692.

Arnault, aar-nō', VINCENT ANTOINE: French poet and dramatist; b. in Paris, Jan. 1, 1766. He produced a tragedy, *Marius at Minturnæ* (1791), which was warmly applauded, and other tragedies, entitled *Lucretia* (Lucrèce, 1792) and *Germanicus* (1816). He was appointed in 1808 secretary-general to the university. He was admitted in 1829 into the French Academy, of which he was chosen perpetual secretary in 1833. Among his works is *Souvenirs of a Sexagenarian* (4 vols., 1833). D. at Goderville, near Havre, Sept. 16, 1834.

Arnd, or Arndt, arnt, JOHANN, D. D.: German Lutheran divine; b. at Ballenstedt, Dec. 27, 1555. He became pastor in his native place, 1583, at Quedlinburg in 1590, at Brunswick in 1596, and at Eisleben, 1605. In 1611 he became general superintendent of Lüneberg. He published a very popular work on *True Christianity*, which was translated into many

languages. An English translation by Rev. A. W. Boehm, chaplain at the Court of St. James, was published in 1712, and thoroughly revised, with extended introduction, including sketch of Arnd's life, by C. F. Schaeffer, D. D., Philadelphia, 1868. D. at Celle, May 11, 1621.

Arndt, ERNST MORITZ: German patriot and popular political writer; b. at Schoritz, in the island of Rügen, Dec. 26, 1769. He traveled extensively in Europe after he left college, and was appointed Professor of History at Greifswald in 1806. He published a *History of Serfdom in Pomerania and Rügen*, and animated the Germans to resistance against Napoleon in his *Spirit of the Times* (*Geist der Zeit*, 1807). He also promoted the patriotic cause by many eloquent and spirited poems and prose-writings. His celebrated national song, *What is the German's Fatherland?* (*Was ist des Deutschen Vaterland?*), is, perhaps, the most popular of all the patriotic songs of Germany. He married in 1817 a daughter of the celebrated Schleiermacher. In 1818 he was appointed Professor of History at the University of Bonn. He was suspended in 1819 on account of his liberal opinions, but was restored to his chair in 1840. He was a member of the national assembly which met at Frankfort in 1848, but he seceded with the constitutional party in 1849. Among his works is *Souvenirs of my Outward Life* (*Erinnerungen aus dem äussern Leben*, 1840). D. at Bonn, Jan. 29, 1860. His statue at Bonn was unveiled July 29, 1865. See his biography by D. Schenkel (1866; 2d ed. 1869); W. Baur (Zurich, 1861; 5th ed. Hamburg, 1882). See Schenkel, *E. M. Arndt: eine Biographie* (1866).

Arue, THOMAS AUGUSTINE, Mns. Doc.: English musician; b. in London, Mar. 12, 1710. He was a skillful performer on the violin. He set to music Addison's *Rosamond* in 1731, and gained a high reputation by the music which he composed for Milton's *Comus* (1738). This formed an era in the history of English music. The national air *Rule Britannia* was his composition. Among his chief productions were *Artaxerxes*, an opera (1762), and *Eliza*, an opera. D. in London, Mar. 5, 1778.

Ar'nee, or Ar'na (*Bos arnee*): a large animal of the family

Arnee.

Bovidae; a native of India, nearly allied to the ox and bison. It is larger than an ox, and the horns are very long.

Arneth, ALFRED: See the Appendix.

Arn'hem, or Arn'heim (anc. *Arenacum*): a fortified town of Holland, capital of the province of Gelderland, on the right bank of the Rhine, 57 miles by rail S. E. of Amsterdam (see map of Holland, ref. 6-H). It is very ancient, well built, has a governor's palace, and a famous church containing the tombs of the Dukes of Gelderland; also manufactures of paper, cotton, and wool. Sir Philip Sidney died at Arnheim in 1586. It was taken in 1795 by the French, who were driven out by the Prussians in 1813. Pop. (1891) 50,194.

Arn'heim, or Arnim, JOHANN GEORG, von: German general and diplomatist; b. at Boitzenburg, in Brandenburg, in 1581. He gained the rank of field-marshal in 1628, and entered the service of Saxony in 1630. He commanded a wing of the army of Gustavus Adolphus at Leipzig in 1631, and was opposed to Wallenstein in 1633. In May, 1634, he

defeated the imperialists at Liegnitz. D. at Dresden, Apr. 18, 1641.

Ar'nica [a Mod. Latin term of unknown origin]: a plant of Switzerland and Germany, of which the flowers and root are used in medicine, generally in the form of the tincture or fluid extract. It contains an active principle, arnicin, and two peculiar volatile oils and various resins. The preparations from the flowers are said to be stronger than those made from the root. The use of arnica in medicine is very limited, and it possesses far less activity for good than is generally thought. It is used externally for bruises and sprains as a lotion, and internally as stimulant in typhoid and other low fevers. It has also been used in Germany for the treatment of such severe nervous troubles as paralysis, but is of no value in such cases. When it does good in the treatment of bruises a large part of the gain is through the effect of the alcohol which the tincture contains. The dose of the tincture of arnica flowers is ten to forty drops.

Arnim: See ARNHEIM, JOHANN GEORG, VON.

Arnim, ELISABETH OF BETTINA, VON: German authoress; b. at Frankfort-on-the-Main, Apr. 4, 1785; was a sister of Clemens Brentano. She had a very sensitive spirit and ardent imagination. In her youth she cherished a passionate admiration and platonic affection for Goethe, with whom she corresponded. She was married in 1811 to Ludwig Joachim von Arnim. Among her works are *The Correspondence of Goethe with a Child* (3 vols., 1835), which she translated into English, and *Die Gûnderode* (2 vols., 1840), which are commended as graceful and fascinating. D. in Berlin, Jan. 20, 1859.

Arnim, HARRY KARL KURT EDUARD, Count von: b. at Moitzelfitz, in Pomerania, Oct. 3, 1824. As envoy to Rome in 1864 he was noted for his attitude toward the Ecumenical Council, and was prominent in 1871 in the negotiations with the French resulting in the Treaty of Frankfort; was ambassador to Paris in 1872, and to Constantinople in 1874, but was dismissed from the service by Bismarck, who dreaded his influence with Emperor William. He had a controversy with Prince Bismarck, and was afterward prosecuted for stealing state documents from the German embassy at Paris. After he removed beyond the jurisdiction of the German courts he was sentenced to five years of penal servitude for treason and insults to the chancellor and the foreign office. D. at Nice, May 19, 1881.

Arnim, LUDWIG JOACHIM, VON (generally called ACHIM VON ARNIM): popular and fantastic German poet, distinguished for his originality; b. in Berlin, Jan. 26, 1781. He devoted some years to the study of the physical sciences, and published a *Theory of Electricity* (1799). He was one of the founders of the romantic school of German literature. In conjunction with Clemens Brentano, whose sister, Bettina, he married, he published a collection of popular songs entitled *The Boy's Wonder-horn* (3 vols., 1806). Among his works, which exhibit a rich imagination, are *The Poverty and Riches, Guilt and Repentance of the Countess of Dolores*, a novel (1810); *Angelica the Genoese and Cosmus the Rope-dancer*; and *The Crown Guardians* (1817). D. at Weipersdorf, near Dahme, 14 miles S. of Berlin, Jan. 21, 1831. See Diel's *Clemens Brentano* (1877); J. B. Heinrich's *Clemens Brentano* (1878).

Ar'no: celebrated river of Italy, which rises at Mt. Falterona in the Apennines, and falls into the sea 7 miles below Pisa, which city, like Florence, is intersected by this stream. Its valley (Val d'Arno) is one of the most beautiful regions in Italy. The banks of the river are partially dyked on account of the floods which sometimes occur, and ordinarily small vessels can ascend to Florence, but since the opening of the railway traffic it is not much navigated. Its length is 140 miles; basin, 3,300 sq. miles.

Arno'bins, AFER: Christian apologist; b. of pagan parentage; became a Professor of Rhetoric at Sicca, in Numidia, having among his pupils Lactantius. About 303 was converted, and wrote some time between then and 313 his *Disputationes adversus Gentes* (or *adversus Nationes*), in seven books (Eng. trans. *The Seven Books of Arnobius against the Heathen* [New York, Christian Literature Co., vol. vi., 1888]), of which the first two defend Christianity and the remainder expose the absurdities of paganism. It shows, however, an imperfect acquaintance with Christianity, and has its principal value as presenting the arguments which were then powerful in the conversion of educated heathens.

The best edition of the original Latin is by A. Reifferscheid (Vienna, 1875).
Revised by S. M. JACKSON.

Arnold, BENEDICT: general and traitor; b. at Norwich, Conn., Jan. 14, 1741. In his boyhood he was noted for his audacity and unruly disposition. He enlisted in the army, but soon deserted. He was employed in an apothecary's at Norwich till 1762, when he moved to New Haven and set up in the drug and bookselling business for himself. He acquired property, and became a general and the owner of several small vessels employed in trade with the West Indies. In this business he failed, and incurred a suspicion of fraudulent dealing. He obtained a commission as colonel in the service of Massachusetts soon after the war broke out, in April, 1775. In the autumn of that year he commanded a force of about 1,000 men sent to capture Quebec, and in the long march through the pathless forests of Maine proved himself well fitted for such a service. Having reached the St. Lawrence river, he effected a junction with Gen. Montgomery, who had the chief command. They attacked Quebec in Dec., 1775, but failed to take it, and Arnold was severely wounded. He was raised to the rank of brigadier-general for his service in this campaign. He commanded a small flotilla which encountered a superior force on Lake Champlain, Oct. 11, 1776, and displayed there such unflinching courage as well as skill that he gained much applause, although he was not victorious. He was deeply mortified by the action of Congress, which neglected him, while it gave the rank of major-general to five of his juniors in rank. In 1777 he was appointed a major-general, but as he remained below the other five he was still discontented. He took part in the battle of Bemis Heights, Sept. 19, 1777, where he was involved in a quarrel with Gen. Gates. At the battle of Stillwater, Oct. 7, he entered the field without permission from Gates, rushed into the hottest part of the action, rode about issuing orders in every direction, and acted like a madman. He received on that day a severe wound, which disabled him for some months, and Congress at last accorded him full rank. In June, 1778, he was appointed to the command of Philadelphia, where he lived in an extravagant style and ran into debt. His first wife, Margaret, daughter of Samuel Mansfield, whom he married Feb. 22, 1767, died June 19, 1775; while in Philadelphia he married Margaret, daughter of Edward Shippen (afterward chief justice of Pennsylvania). He made many enemies, who trumped up charges against him, from most of which he was cleared by a court martial, which, however, ordered him (Jan. 26, 1780) for some trifling offenses to be reprimanded by the general-in-chief. Washington turned the reprimand into a eulogy, as he believed that Arnold had been persecuted. Shortly after this Arnold committed his great crime for which he had made long preparation. He solicited and obtained (in July, 1780) command of West Point, the most important fortress in the U. S., which he offered to betray into the possession of Sir Henry Clinton. The agent chosen by the British general to conduct the negotiations with Arnold was Major John André. (See ANDRÉ, JOHN.) Arnold and André had an interview on Sept. 21, and made the final arrangements for the surrender of West Point, but in consequence of the capture of André, Sept. 23, 1780, the plot was detected and Arnold escaped in the British sloop *Vulture*, Sept. 25. He received about £6,300 from the British Government as a reward for his treachery. Having joined the British army and issued an address to the American people in vindication of his course, he obtained command of an expedition against Virginia, which sailed from New York in Dec., 1780, passed up the James river, and burned and pillaged a considerable amount of property. In the autumn of 1781 the troops under his command burned New London, Conn. He went to England about the end of the war, and passed many years in that country, where he was generally despised. He died in London, June 14, 1801. See his life by Sparks, *Library of American Biography*, vol. iii., and by I. N. Arnold (Chicago, 1880).
Revised by S. M. JACKSON.

Arnold, Sir EDWIN: journalist and poet; b. at Rochester, England, June 10, 1832; graduated at Oxford 1854, and was subsequently appointed principal of the Government Sanskrit College at Poona, in the Bombay Presidency, and fellow of the University of Bombay, which positions he resigned in 1861 and joined the editorial staff of the London *Daily Telegraph*. His epic *The Light of Asia* (1879) has run through many editions. He has also published *Hitopadesa*, the *Indian Song of Songs*, and other translations;

History of the Administration of India under the late Marquis of Dalhousie (1862-64); *India Revisited* (1886); *The Light of the World* (1891); and many other works, translations from the Sanskrit and the Persian, or otherwise relating to Eastern poetry and religion. An edition of his poetical writings was published in 1888 in 8 vols. He was made Knight Commander of the Indian Empire by Queen Victoria in 1888. In 1889 he visited the U. S. and lectured, and in the autumn he went to Japan. Just before this visit his wife, a daughter of W. H. CHANNING (q. v.), of Boston, died, and he dedicated a volume of poems, *In my Lady's Praise* (1889), to her. One of the poems was a curious *Casket of Gems*, in which an acrostic was made by selecting gems, the initials of whose names spelled out his wife's name in full. From Japan he wrote letters to the *London Daily Telegraph* which were published in book form; namely, *Seas and Lands* (London, 1891) and *Japonica* (N. Y., 1891). The same year he renewed his visit to the U. S. on a reading-tour. His *Azuma, or a Japanese Wife* (1892), is a drama of the East, and *Potiphar's Wife and other Poems* (1892) a collection of verse.

Arnold, FREDERICK: author and divine; b. at Cheltenham, England, in 1833; educated at Christ Church College, Oxford. Author of *Public Life of Lord Macaulay* (1862); *The Path on Earth to the Gate of Heaven* (1865); *History of Greece* (1861); *Christ Church Days* (1867); *Turning Points in Life* (2 vols., 1864); *Memorials of Oxford and Cambridge* (1874); *Our Bishops and Deans* (2 vols., 1875); *Three-cornered Essays* (1886); *Robertson of Brighton* (1887); *Clerical and Literary Reminiscences* (2 vols., 1890), etc.

WILLIAM S. PERRY.

Arnold, FRIEDRICH: Professor of Anatomy and Physiology in the University of Heidelberg; b. Jan. 8, 1803, at Edenkoben, near Landau; M. D., University of Heidelberg, 1825; assistant professor in medical faculty of Heidelberg 1834; professor and director of the Anatomical Institute, University of Zurich, 1835; Professor of Anatomy and Physiology, University of Freiburg, 1840-45, University of Tübingen 1845-52, and University of Heidelberg 1852-73, retiring from his professorship in 1873. Among his numerous important professional works are *Der Kopftheil des vegetativen Nervensystems beim Menschen in anatomischer und physiologischer Hinsicht*; *Lehrbuch der Physiologie des Menschen*; *Ueber die Athmungsgrösse der Menschen*, etc.

Arnold, GEORGE B., Mus. Doc.: musician; b. at Petworth, England, 1832; appointed organist of Winchester cathedral 1865; has composed much church music and several oratorios. His first oratorio, *Ahab*, was produced in London, at Exeter Hall, in April, 1864. *Sennacherib* was composed for the Gloucester meeting of the Three Choirs Festival in 1883. *The Song of the Redeemed* was composed for St. James' church choir, New York, and first brought out there April 12, 1891.

D. E. HERVEY.

Arnold, GEORGE: poet; b. in New York, June 24, 1834; lived at Alton, Ill., till 1849, and afterward at Strawberry Farms, Monmouth co., N. J. He enlisted in the Union army during the civil war, and his humorous war correspondence, *McArone Papers*, appeared mainly in *Vanity Fair* in 1860-65. *Drift: a Seashore Idyl*, and *Poems, Grave and Gay*, were published posthumously in 1866, with a memoir by William Winter. D. at Strawberry Farms, N. J., Nov. 3, 1865.

HENRY A. BEERS.

Arnold, GOTTFRIED: b. at Annaberg, Saxony, Sept. 5, 1666; d. at Perleberg, Prussia, May 30, 1714; became court preacher at Allstedt 1700; preacher at Werben 1705, then at Perleberg 1707, and published (1699-1700) his *Impartial History of the Church* (2 vols.; best ed. Schaffhausen, 1740-42, 3 vols.), written on the principle that no individual or sect shall be condemned by history because he was condemned by the Church of his time—a principle to which not only the Roman Catholics but also the Lutherans were strongly opposed. See his life by F. Dibelius, Berlin, 1873.

Arnold, JOHANN GEORG DANIEL: writer and jurist; b. in Strassburg, Feb. 18, 1780; became Professor of Roman Law in that city (1811). He published a work on Roman law (1812), and wrote in the Alsatian dialect a comedy of *Whitmonday*, which was praised by Goethe. D. in Strassburg, Feb. 18, 1829.

Arnold, JONATHAN: b. at Providence, R. I., Dec. 14, 1741; as a member of the Colonial Assembly brought forward in 1776 a bill repealing the oath of allegiance to Great Britain; was a surgeon in the Revolution, and a member of

Congress (1782-84). He was long a judge of the Orange County court, Vermont. D. Feb. 2, 1798.

Arnold, JURY: See the Appendix.

Arnold, LAUREN BRIGGS: agriculturist and dairyman; author of *American Dairying*; b. at Fairfield, N. Y., Aug. 13, 1814; d. at Rochester, Mar. 7, 1888. He was a prominent investigator of the processes of cheese-making, and was a frequent lecturer upon the subject in the U. S. and Canada. He was also lecturer upon dairy-husbandry in Cornell University in his later years.

Arnold, LEMUEL HASTINGS (son of Jonathan): b. at St. Johnsbury, Vt., Jan. 29, 1792; graduated at Dartmouth in 1811; became a lawyer and manufacturer in Rhode Island; was Governor of that State 1831-33, member of Congress 1845-47. D. at Kingston, R. I., June 27, 1852.

Arnold, LEWIS G.: general; b. in New Jersey, Dec., 1815; graduated at West Point in 1837; served gallantly in Mexico, and in 1862 became a brigadier-general of U. S. volunteers. Stricken with paralysis in that year while on duty, he was placed on the retired list in 1864. D. in South Boston, Sept. 22, 1871.

Arnold, MATTHEW: English poet, critic, and "apostle of culture"; eldest son of Thomas Arnold, of Rugby; b. at Laleham, Middlesex, Dec. 24, 1822; educated at Rugby; studied in Balliol College, Oxford; graduated in honors 1844; elected fellow of Oriel College (as his father had been) 1845; became private secretary to Lord Lansdowne in 1847; a lay inspector of schools in 1851; and was Professor of Poetry at Oxford (1857-87). The collected edition of his poems appeared in 1869, and was reprinted in 1877, 1881, and 1885. His prose-writings comprise *Essays in Criticism* (1865; second series in 1888); *On the Study of Celtic Literature* (1868); *Culture and Anarchy* (1869); *St. Paul and Protestantism* (1870); *Literature and Dogma* (1873); *Last Essays on Church and Religion* (1877); *Mixed Essays* (1879); *Irish Essays and Others* (1882). His educational writings, which have a high value, include *Report on Education in France, Germany, and Holland* (1861); *A French Eton or Middle-class Education and the State* (1864); *Schools and Universities of the Continent* (1868); and *Higher Schools and Universities in Germany* (1874). In June, 1882, he delivered the annual Bede lecture at Cambridge, on the subject *Literature and Science*, and in the winter of 1883-84 he made a lecturing tour through the U. S. See his *Discourses in America* (1885). He received the honorary degree of Doctor of Laws from Edinburgh 1869, Oxford 1870, and Cambridge 1883. He exerted a remarkable influence upon the young men in the universities and colleges of the English-speaking world by means of his essays, which are fresh in matter, peculiar in style (having the trick of repeating a phrase in many successive pages, yet so cleverly as not to produce weariness), and very independent in thought. He enriched the conversation of liberally educated persons by numerous expressive phrases, such as "sweetness and light" (borrowed from Swift); "conduct is three-fourths of life"; "The Eternal not ourselves which makes for righteousness," etc. He was skeptical and critical, discontented and unsettled, but his influence was on the whole good. His poems did not enjoy the popularity of his essays. He might have excelled in translating Greek had he chosen to do so, as he was a superior scholar and master of English in prose and verse. D. in Liverpool, England, Apr. 15, 1888.

Revised by S. M. JACKSON.

Arnold of Brescia: See ARNALDO.

Arnold, PELEG: b. at Smithfield, R. I., 1752; was a delegate to Congress from Rhode Island 1787-89, and afterward was long chief justice of the Supreme Court of Rhode Island. D. at Smithfield, R. I., Feb. 13, 1820.

Arnold, Gen. RICHARD (son of Lemuel H.): b. at Providence, R. I., Apr. 12, 1828, and graduated at West Point in 1850. He entered the artillery, and in 1862 became a brigadier-general of U. S. volunteers, serving chiefly in the Gulf States. In 1866 he was breveted major-general U. S. A. D. on Governor's island, New York harbor, Nov. 8., 1882.

Arnold, SAMUEL, Mns. Doc. (Oxford, 1773): an English musician; b. in London, Aug. 10, 1740. He became composer to the Covent Garden theater about 1762. His opera, *Maid of the Mill* (1765), was very popular; also *Rosamond*, (1767). He was appointed organist to the king in 1783, and composed four volumes of *Cathedral Music*. D. in London, Oct. 22, 1802.

Arnold, SAMUEL GREENE: b. at Providence, R. I., Apr. 12, 1821; graduated at Brown University in 1841, and at Cambridge Law School in 1845. He was several times Lieutenant-Governor of Rhode Island, served for a few weeks as a volunteer in the late civil war, and became U. S. Senator in 1863. He published a *History of Rhode Island* (7 vols., 1859-60), and numerous addresses, reviews, and articles for periodicals. D. at Providence, R. I., Feb. 13, 1880.

Arnold, THOMAS, D. D.: English teacher and historian; b. at Cowes, in the Isle of Wight, June 13, 1795. He entered the University of Oxford in 1811; graduated in 1814, and became a fellow of Oriel College in 1815. He gained the chancellor's prize for Latin and English essays in 1815 and 1817. He removed to Laleham, near Staines, in 1819, and married Mary, a daughter of Rev. John Penrose, in 1820. In 1828 he was ordained a priest, and became head-master of Rugby School, which he conducted with eminent wisdom and decided success, fulfilling the prophecy that he would regenerate public-school education in England. He did better than merely turn out clever scholars. He cultivated among the students a sense of duty and a high moral and religious tone. He set an example of Christian manliness which induced many followers, for to him religion was the dominant force, the very life. He was a Whig or Liberal in politics, and a strenuous opponent of the High Church and new school of theology represented by Pusey. In 1832 he purchased Fox How, a small estate between Rydal and Ambleside, where he afterward spent his vacations. He contributed to the *Quarterly Review* and *Edinburgh Review*, published a good edition of Thucydides (1830-35), and five volumes of sermons (1828-42). His capital work is a *History of Rome* (3 vols., 1838-42), which he did not live to finish. It terminates near the end of the second Punic war. In 1828 he became B. D. and D. D. at Oxford. He was appointed Regius Professor of Modern History at Oxford in 1841, and delivered there an introductory course of lectures which were published in 1842. He died at Rugby, of angina pectoris, June 12, 1842, leaving three sons, Matthew, Thomas, and William D., and a name of priceless value. See his life by Dean Stanley (2 vols., 1844, many editions and reprints), and the novel of Thomas Hughes, *Tom Brown at Rugby*; also Zinzow's *Thomas Arnold* (1869).
Revised by S. M. JACKSON.

Arnold, THOMAS KERCHEVER: English clergyman; b. at Stamford, 1800; educated at Cambridge, became fellow of Trinity College 1821; rector of Lyndon, Rutlandshire, where he died, Mar. 9, 1853. He published a number of popular text-books for schools, among which are manuals for the Greek, Latin, French, and German languages.

Arnolfo di Cambio: sculptor and architect; b. at Colle, 1232; d. at Florence, 1310. He was a master of that beautiful combination of building and sculpture peculiar to mediæval Italy. The rich west front of the Cathedral of Orvieto and a rich tomb in the same city, the tomb of Pope Honorius III. in Santa Maria Maggiore and that of Pope Bonifacio VIII. in St. Peter's, both at Rome, and other important works in Central Italy, are either wholly or in great part of his design. But his most important work was done in Florence, where there still remain for our admiration the Bargello (now the National Museum), the Church of Orsanmichele with its very elaborate shrine, the Church of Santa Croce, the marble exterior of the baptistery, the beginning and general design of the public palace (Palazzo Vecchio), and the great cathedral from almost its commencement up to the roof of the nave.
RUSSELL STURGIS.

Ar'not, WILLIAM: b. at Seone, Perthshire, Scotland, Nov. 6, 1808; educated at the University of Glasgow; ordained as a minister of the Established Church in 1839; subsequently joined the Free Church movement (1843), and was one of its ablest champions. In 1863 he removed to Edinburgh. He was a delegate to the meeting of the Evangelical Alliance in 1873 at New York. He declined the degree of D. D. from the universities of Glasgow and New York city. His best-known books are *Laws from Heaven for Life on Earth*; *Illustrations of the Book of Proverbs* (2 vols., 1857-58); and *The Parables of our Lord* (1865). See his autobiography and memoir (London, 1877). D. in Edinburgh, June 3, 1875.

Arnott, NEIL, M. D. (Aberdeen, 1814), F. R. S. (1838): b. at Arbroath, near Montrose, Scotland, 1788; was educated at Aberdeen, and in medicine in London; became a surgeon in the East India Company's service; settled in London in 1811 as a physician; published *Elements of Physics*

(1827); *Essay on Warming and Ventilating* (1832); a *Survey of Human Progress* (1861), etc. He was distinguished as an inventor, especially of a smokeless grate, known as "Arnott's stove," and as a benefactor of institutions of learning. D. in London, March 22, 1874.

Arnotto: See ANNOTTO.

Arnould, or Arnoult, aar-noo', SOPHIE: a popular French actress; b. in Paris, Feb. 14, 1744. She was very successful as an opera-singer, and was distinguished for her wit and conversational powers. Her society was sought by such men as D'Alembert and Diderot, and her beauty was praised by several eminent poets. D. in Paris, 1803. See her biography by Lamotte-Langon (2 vols., Paris, 1837), and by E. and J. de Goncourt (1857), and her *bon mots* in *Arnoldiana* (1813).

Arnprior: on Canadian Pacific Ry., Renfrew co., Ontario, Canada (for location of county, see map of Ontario, ref. 1-G); situated on Chats Lake, at the confluence of the Madawaska and Ottawa rivers, 52 miles W. of Ottawa; has saw-mills, woolen-mills, and marble-works. There are iron mines in the vicinity. Pop. (1881) 2,147; (1891) 3,341.

Arns'berg, or A'rensberg: a town of Prussia, in Westphalia; situated on the river Ruhr; 46 miles S. S. E. of Münster (see map of the German Empire, ref. 4-D). It contains several churches and a gymnasium; also manufactures of broadcloth, linen, etc. In the Middle Ages it was a seat of the Vehmic court. Pop. 6,733.

Arn'stadt: an old town of Germany; in Schwarzburg-Sondershausen; on the river Gera, 10 miles S. of Erfurt, with which it is connected by a railway (see map of the German Empire, ref. 5-E). It is one of the most ancient Thuringian towns. Here are manufactures of gloves, pottery, etc. In the vicinity are copper mines and saline springs used for bathing. Pop. 11,287.

Arnswalde, aarns'vaal-de: a town in the Prussian province of Brandenburg, 66 miles N. E. of Frankfort-on-the-Oder; has chemical manufactures, iron-foundries, and spinning-works. It is on the railroad from Stettin to Posen (see map of the German Empire, ref. 3-H). Pop. about 7,500.

Ar'nulf (in Lat. *Arnulphus*): Emperor of Germany; son of Carloman of Bavaria. The latter was a grandson of Charlemagne. Arnulf, b. about 850, was elected King of Germany in 887 A. D., invaded Italy about 894, and captured Rome in 896. He was crowned as emperor by the pope at Rome. He died at Regensburg, Dec. 8, 899, and was succeeded by his son, Louis IV. See Gagern, *Arnulfi Imperatoris Vita* (1837).

Aroids [from Lat. *arum* = Gr. *ἄρον*, a plant-name + Gr. *εἶδος*, form]: the *Araceæ*; a family of herbaceous monocotyledons, bearing small flowers upon a fleshy spike (spadix) which is commonly inclosed in a spathe. About 900 species are known, distributed mainly in warm climates.

CHARLES E. BESSEY.

A'rolsen: a town of Germany; capital and residence of the Prince of Waldeck; on the Aar, 23 miles N. N. W. of Cassel (see map of the German Empire, ref. 4-E). It has manufactures of woolen cloth. Here is a fine castle of the Prince of Waldeck, with a library of 30,000 volumes. Pop. (1890) 2,620.

Aro'ma [Lat. = Gr. *ἄρωμα*, spice, sweet herbs]: the principle in plants or other substances which constitutes their fragrance; the peculiar odor of aromatic plants, such as nutmeg, cloves, vanilla, and lavender. It is extremely subtle, and seems to be almost imponderable, as these substances diffuse their odors for a long time without sensible diminution of weight. The aroma of plants is imparted to fixed oils by maceration.

Aromatari, GIUSEPPE, degli (jyū-sep-pe dayl'-yēē ā-rō-mā-taa'reē): learned physician and naturalist; b. at Assisi, Italy, about 1586; practiced medicine with great success at Venice about fifty years. His fame reached England, and he received and declined invitations from James II., from the pope, and others. His principal work is *De Generatione Plantarum ex Seminibus*, a treatise on the reproduction of plants, showing the analogy between their seeds and the eggs of animals. D. in 1660.

Aromatic Hydrocarbons: See HYDROCARBONS.

Aromat'ies [Lat. *aromat'icus*, deriv. of *arō'ma*, a spice]: spicy plants or drugs; substances which emit aroma or agreeable perfumes, and are generally characterized by a

warm, pungent taste, as cloves, cinnamon, ginger. They often contain essential or volatile oils or resins. The term aromatic is also applied to several animal substances, as ambergris, musk, and castor. See AROMA.

Aromatic Vin'egar: a compound or mixture of ordinary vinegar with aromatic essential oils, and a powerful perfume. As it is very volatile, and is an excitant when snuffed in the nostrils, it is used as a remedy for fainting and nervous debility. It is often prepared by combining crystallizable acetic acid with the oils of cloves, lavender, rosemary, and *Acorus calamus*.

Aroo: See ARU.

Aroos'took: a river of the U. S.; rises in Piscataquis co., Me., flows northeastward through Aroostook County into New Brunswick, and enters the St. John's river. Length about 120 miles.

Arpád: the national hero of Hungary and the chief of the Magyars, who in 889 A. D. migrated from Galicia, and conquered the Slavonic people of Croatia and Transylvania. He is called the founder of the kingdom of Hungary. D. in 907 A. D. The dynasty of Arpád terminated in Andrew III., in 1301.

Ar'pe, PETER FRIEDRICH: b. at Kiel in Holstein in 1682; was Professor of Law (1717-22) at Kiel, and a learned jurisconsult and writer. He wrote *Themis Cimbrica* (1737), describing the institutions and manners of the Cimbric and other tribes. D. about 1745.

Arpeggio, ar-pej'ō [Ital., connected with *arpeggia're*, play on the *arpa*, or harp]: in music, a chord of which the notes are given in succession; or the sounding the notes of a chord in quick succession, so as to imitate the harp.

Arpent: a French land-measure nearly equivalent to an English acre. The French now measure land by the *hectare* instead of the *arpent*, which is obsolete.

Arpi'no (anc. *Arpi'num*): a town of Italy; province of Caserta; pleasantly situated on high ground, 5 miles S. of Sora (see map of Italy, ref. 6-E). It is surrounded by very beautiful scenery, has a royal college, several churches and convents; also manufactures of woolen cloth, paper, etc. Here is a cyclopean wall and other remains of Arpinum, which was founded by the Volsci, and became a Roman *municipium* about 188 B. C. It is celebrated as the native place of Caius Marius and of Cicero. Variegated and white marbles are quarried in the vicinity. Pop. 11,629.

Arraca'cha [native name]: an umbelliferous South American plant (*Arracacha esculenta*). It grows in Colombia, Jamaica, and other tropical regions, and is cultivated for its roots, which are large and sweet, and are eaten after being boiled or roasted. The taste is described as between that of a parsnip and a sweet chestnut. This plant was recommended as a substitute for the potato, and attempts were made to cultivate it in England, but that climate was found to be unfavorable.

Ar'rack', or **Rack**: an alcoholic liquor distilled from fermented rice; a common intoxicating drink in the East Indies and other Oriental countries. Also a strong drink obtained from the fermented sap of the palm-tree, and often called palm-wine or toddy. Among the species of palms which yield this drink are the cocoanut-palm and the date-palm. When new it has an oily and disagreeable taste, which is improved by age.

Arragon: See ARAGON.

Ar'rah: a town of British India; in the presidency of Bengal, 25 miles W. of Dinapoor (see map of N. India, ref. 6-G). The British here gained a victory over the mutinous Sepoys in 1857. Arrah was the scene of several exciting incidents of that mutiny. Pop. (1891) 42,998.

Ar'ran: an island of Scotland, in the Frith of Clyde, county of Bute, 13 miles W. of Ayrshire, and 4 miles E. of Cantyre (see map of Scotland, ref. 13-E). It is about 20 miles long, 12 miles wide, and has an area of 165 sq. miles. The surface is mountainous, the granite peaks of the northern part being remarkably grand. Goatfell, the highest peak, is 2,860 feet above the level of the sea. Here is a cavern in which Robert Bruce once hid himself. The geology of Arran, it is said, presents a greater succession of strata than any other equal portion of the British isles. The southeastern half consists of Devonian sandstone, trap-rock, and carboniferous strata. The northwestern half exhibits a central granite nucleus, bordered by mica-slate

on one side, and by lower Silurian rocks on the other sides. Pop. about 6,000.

Arran, SOUTH ISLES OF: three small islands lying across the entrance to Galway Bay, about 4 miles off the west coast of Ireland, and 27 miles S. W. of the city of Galway (see map of Ireland, ref. 10-B). They are named Inishmore, Inismain, and Inishere (or Innishere). Area, 18 sq. miles. They once contained twenty churches and monasteries, and St. Kenanach church, built in the seventh century, is still standing. Here are also remains of a cyclopean fort of unhewn stone, supposed to have been built in the first century, and described as among the most magnificent barbaric monuments of Europe. The old shrines and relics scattered through the islands attract many visitors.

Arrangement: the adaptation of a piece of music to an instrument different from that for which it was originally composed, as when orchestral compositions are adapted to the piano, or when a piece originally written for an instrument or instruments is adapted for a voice or voices.

Arras (anc. *Nemetacum*, afterward *Atreb'ates*): a fortified city of France, capital of the department of Pas-de-Calais, on the river Scarpe and on the Railway du Nord, 30 miles N. E. of Amiens, and 100 miles N. N. E. of Paris (see map of France, ref. 2-F). It was formerly the capital of Artois, and was the seat of a bishop as early as 390 A. D. It was fortified by Vauban, and ranks as a fortified town of the third class. The citadel is separated from the town by an esplanade, but it is inclosed within the same wall. Arras is well built, partly on a declivity and partly on flat ground, and is adorned by fine public buildings, among which are a cathedral, a town-hall, and a theater. It has a museum, a school of design, and a public library of about 36,000 volumes. Here are manufactures of hosiery, lace, woolen and cotton goods, etc. In the Middle Ages it was so famous for its tapestry that this article was commonly called *arras* by the English. It was the birthplace of Robespierre. The grain-market of Arras is said to be the most important in the N. of France. Pop. (1896) 26,144.

Arras'tre: a mill used in Spain and the Spanish colonies for grinding gold and silver ores. It is a circular basin of granite or other hard rock, in the center of which a vertical wooden shaft revolves, with four horizontal arms, to which large flat stones are attached by chains. The ore is broken into small fragments before it enters the arrastre. The revolution of the shaft is produced by two mules. See SILVER.

Ar'rawak Ind'ians: a race or collection of tribes in Guiana, remarkable for the euphony of their language and their mild and friendly disposition toward the whites. They were formerly very numerous and powerful. They have been much benefited by the labors of Moravian missionaries.

Ar'rebo, ANDERS CHRISTENSEN: Danish poet; b. at Årøskjøbing, Jan. 2, 1587; d. at Vordingborg, Mar. 12, 1637. His chief work is the *Hexæmeron*, on the creation of the world, an imitation of the *Divine Week* of Du Bartas. His main importance, however, is as the introducer of Renaissance influences into Danish poetry. G. L. KITTEDGE.

Arrest' [from Old Fr. *arest*, deriv. of *arester*, stop, check, ultimately from Lat. *ad*, to + *restare*, stay back]: the apprehension or seizure of a person by lawful authority, usually by the command or direction of some court or officer of justice. It may take place either in civil or criminal cases.

(1) *In Civil Cases*.—In this instance it may be either on *mesne* or final process. The object of the first is to make it certain that the defendant will answer the order of the court. He may either remain in custody or give bail, according to the rules of practice, as security for his appearance. On final process the arrest is in the nature of an execution. The defendant is to be kept in confinement, either in jail or within prescribed limits, until the judgment is satisfied, or until he is discharged by order of the court. In the early common law an arrest was allowed almost as a matter of course, imprisonment for debt being the regular practice. This rule is now greatly modified, and by a statute in Great Britain and in a number of the United States an arrest can only be had in special cases and upon a judge's order. The facts necessary to be shown as a basis for the order are presented on affidavit. There are certain persons privileged from arrest by rules of general prevalence, such as members of legislatures, or witnesses while attending the sessions of the legislatures or courts, and while

going to and returning from the same. The arrest in such cases is irregular, and the party arrested may be discharged on motion. This privilege is secured to members of Congress by the U. S. Constitution. An original arrest can not be made on Sunday, nor is it lawful to break into a house for this purpose, owing to the legal rule that "a man's house is his castle." This rule does not apply where the defendant has been rescued, and the officer is proceeding regularly to retake him. The common law permits an arrest by night as well as by day. This rule is sometimes affected by statute.

(2) *In Criminal Cases.*—The power to arrest in this class of cases is much less restricted. None are privileged (except ambassadors and their servants), outer doors may be broken open, Sunday is not regarded, and a warrant is not in all cases essential. Such an arrest is made either under a warrant, or by an officer without a warrant, or by a private person without a warrant. A warrant is granted by a magistrate on information in writing and supported by oath, and is executed by the person to whom it is addressed, usually a sheriff or constable. An arrest may be made without a warrant by a peace officer, such as a sheriff or constable, when a felony or breach of the peace is committed in his presence, or where a felony has been committed, or he has reasonable ground to suspect that it has been, though not in his presence, and he has also reasonable ground to suspect the party arrested. The right of a private person to make an arrest without a warrant is much more restricted. He must be prepared to show that a felony has been *actually* committed, as well as reasonable grounds of suspicion that the party arrested was the wrong-doer. A private person is bound to arrest for a felony committed in his presence. In making an arrest necessary force may be used, and in case of felony even life may be taken where arrest is enjoined. An arrest can only properly be made within the jurisdiction of the court. When a person charged with crime escapes from one State to another, his return may be demanded under the laws of Congress. Should he escape to a foreign country, he may in certain cases be retaken under an extradition treaty with that country. See EXTRADITION.

The word "arrest" is also used in law in connection with judgment. This means that judgment is not to be entered, although a verdict has been given, on account of some reason appearing upon the record, as where the allegations in the pleadings are not a sufficient basis for an action.

T. W. DWIGHT.

Arrhidaeus, PHILIP: a son of Philip II. of Macedon by a dancing-girl, Philinna of Larissa; accompanied his half-brother, Alexander the Great, in his campaigns in Asia, and was always kindly treated by him, but never held any civil or military command. He was imbecile, and it was said that he had become so from a potion administered to him while a boy by Olympias, his father's wife and Alexander's mother. He was present at Babylon when Alexander died, and was immediately proclaimed king by the army, though the son of Alexander by Roxana, born shortly after, was associated with him. He now married Eurydice, a granddaughter of Philip II., a daughter of Cynane, his own and Alexander's half-sister. Eurydice was, like her mother, a woman of thoroughly masculine education, of many masculine talents, and of an inordinate ambition. She wished to get rid of Roxana and her son, of Olympias, and of Alexander's generals; and after the death of Antipater (in 319) she collected an army and marched against Polysperchon. But in Polysperchon's army was Olympias, and the Macedonian soldiers declared that they would never fight against Alexander's mother. Eurydice was deserted, captured in her flight, and confined, together with her husband, in a narrow dungeon, whither Olympias sent to her a sword, a rope, and a cup of hemlock. She accepted the presents, made Arrhidaeus drink the hemlock, and then hanged herself (317 B. C.).

Ar'rian (Gr. Ἀρριανός; Lat. *Arria'nus Fla'vius*): Greek historian; b. at Nicomedia, in Bithynia, about 100 A. D.; was a pupil and friend of Epictetus. He was a Stoic in philosophy. From 131–137 A. D. he was governor of Cappadocia under Hadrian. He is said to have served in the army against the Goths and Alani. He spent the closing years of his life in Athens, and died before 180 A. D. In his life as in his writings he took Xenophon as his model, and Epictetus was to him what Socrates was to Xenophon. As Xenophon wrote the *Memoirs of Socrates*, so he composed

the *Discourses of Epictetus* (Διατριβαί Ἐπικτήτου), in eight books, of which four are extant, and edited his master's *Enchiridion* (Ἐγχειρίδιον), a manual of Stoic morals, which still enjoys great popularity. His principal historical work is the *Expedition of Alexander* (Ἀνάβασις Ἀλεξάνδρου), in seven books, title and number both being in imitation of Xenophon's *Anabasis*. The work is based on Ptolemy and Arrian's *Anabasis*. The work is based on Ptolemy and Arrian's *Anabasis*, and commends itself to the student of history by its simplicity and sobriety. The book on *India* (Ἰνδική), a geographical appendix to the *Anabasis*, is written in the Ionic dialect. An official report to Hadrian is preserved under the title *Περίπλους πόντου Εὐξείνου*, a narrative of a coasting voyage around the Euxine. A treatise *On Tactics* (Τακτική) and a slight tract *On Hunting* (Κυνηγετικός) have also come down to us under his name, with fragments of various historical works. In his language Arrian tries to revive the elegance of the classical period, but his speech betrays him, and his labored simplicity is lacking in charm. Ed. by Dübner and Müller (1846). Minor writings by Hercher in the Teubner Library. Annotated ed. of *Anabasis* by Krüger (1835–48), by Sintenis (1863), by Abicht (1879). For the philosophical works, see Schweighäuser, *Epicteteæ philosophicæ monumenta* (1799); for the geographical remains, Müller, *Geographi Græci minores*, i. pp. 257–402.

B. L. GILDERSLEEVE.

Arriaza, ā-rēe-aa'tha, JUAN BAUTISTA: Spanish poet, sometimes called ARRIAZA Y SUPERVIELA; b. at Madrid in 1770. He passed some years in London as secretary of legation, and published in 1803 *Emilia*, a poem on the influence of the fine arts. Having returned to Spain in 1807, he took an active part in politics, and wrote in support of absolute monarchy. He obtained an important position in the department of foreign affairs. In 1810 he produced *Poesias Patrioticas*. D. in Madrid, 1837.

Arrière Ban: See BAN.

Arri'ghi di Casanova, JEAN TOUSSAINT: Duke of Padua; a Corsican general; b. at Corte, Mar. 8, 1778. He entered the French army in early youth, and served with distinction at Marengo, Austerlitz, and Friedland, and was raised to the rank of general of division on the field of Esslingen, in 1809. He lived in exile from 1815 to 1820; was elected to the French Legislative Assembly in 1849. D. in Paris, Mar. 22, 1853. See his biography by A. Du Casse (2 vols., Paris, 1866).

Arro'ba: a Spanish weight and measure; used also in Brazil and the Spanish colonies. There are ten kinds of *arroba* for weight, ranging between $21\frac{8}{100}$ lb. avoirdupois and $32\frac{5}{100}$ lb. avoirdupois. Only two of the number are as great as 28 lb. There are eleven kinds of *arroba* for liquid measure, ranging from $2\frac{7}{100}$ gal. to $9\frac{9}{100}$ gal. The *arroba* for Spain generally is (or was, as it is abolished) $4\frac{2}{100}$ gal.

Arrondissement, ā-roii-dees'mon [Fr., a district or circuit]: a principal civil division of the departments of France. Each department is divided into arrondissements, each arrondissement into cantons, and each canton into communes. See FRANCE.

Arroo: See ARU.

Ar'rowhead: an aquatic plant of the genus *Sagittaria* and family *Alismaceæ*, natives of both cold and tropical climates. They have unisexual flowers, with many stamens and many carpels, which are compressed and one-seeded. The *Sagittaria sagittifolia*, a native of Europe, is a beautiful plant with arrow-shaped leaves, which rise above the surface of the water. The *Sagittaria variabilis* of the U. S. is very similar to it. The *Sagittaria sinensis* (Chinese arrowhead) is cultivated in China in ponds and ditches for the sake of its nutritious corns, which abound in starch.

Arrow-headed Characters: See CUNEIFORM INSCRIPTIONS.

Ar'rowroot: the starch or fecula from the root of the *Maranta arundinacea* and other species of *Maranta*. It is much esteemed as an easily digestible diet for infants and invalids. Large quantities of it are imported into the U. S. and Europe from Bermuda and Jamaica, where it is cultivated. It is also raised in Georgia and Florida. The roots, or rather rhizomes, yield about 25 per cent. of this starch, which is in the form of a light, opaque, white powder. It is often adulterated with potato-starch and other substances. The name arrowroot is said to refer to the use of the fresh roots as an application to wounds inflicted by poisoned arrows; and the expressed juice has been recommended as an

antidote to poisons, and a cure for the stings and bites of venomous insects and reptiles. Some think that the name

Arrowroot.

cloth or hair to separate the fibers, and the starch is allowed to settle. Albumen and salts are held in solution, while the starch settles down as an insoluble powder, which is finally dried in the sun. According to Benzon, the fresh rhizomes contain—

Starch.....	26.00
Cellular fibers.....	6.00
Albumen.....	1.58
Gummy substances.....	0.60
Volatile oil.....	0.07
Chloride of calcium.....	0.25
Water.....	65.50
Total.....	100.00

The prepared arrowroot is almost pure starch. It has a peculiar firm feel between the fingers, and when rubbed produces a peculiar crackling sound, like that of dry snow in very cold weather. Like starch from other sources, it is insoluble in cold water, but forms on boiling a gelatinous solution.

The purity of arrowroot is best determined by microscopic examination, as, while the starch granules of different plants (see STARCH) are almost identical in chemical composition and properties, they are often very peculiar in size, form, and structure. The granules of the genuine *Maranta* arrowroot are of a regular ovoid form, of nearly equal size, and smooth on their surface; while the granules of potato-starch, one of the most common adulterants, are irregularly ovoid, very variable in size, from $\frac{2}{1000}$ to $\frac{3}{100}$ of an inch in diameter, and streaked and furrowed on their surface. The fecula of many other plants is used either as a substitute or an adulterant for the true arrowroot. *Zamia integrifolia* yields an arrowroot in the West Indies and the neighborhood of St. Augustine, Fla. *Arum vulgare* (wake-robin) yields Portland arrowroot in the isle of Portland. *Curcuma angustifolia* yields East Indian arrowroot. *Jatropha Manihot*, the cassava or tapioca-plant, yields Brazilian arrowroot. *Tacca oceanica* yields Tahiti arrowroot. *Alstromeria pallida* yields Taleahuana arrowroot. The potato yields, by careful preparation, the English arrowroot. Starch similar to arrowroot is also prepared in the West Indies from the roots of *Dioscorea sativa* or yam, of *Colocasia esculenta*, and from the fruit of *Artocarpus incisa* or breadfruit-tree.

For use, arrowroot should be rubbed to a paste with a little cold water, and while this is stirred a considerable quantity of boiling water should be added. It may be sweetened with sugar and flavored with lemon-juice or with wines and spices. For infants it may be prepared with milk. A tablespoonful is sufficient for a pint of water or milk.

C. F. CHANDLER.

Arrowsmith, AARON: an English geographer; b. at Winston, Durham, July 14, 1750; became distinguished as a publisher of excellent maps, over 100 in number. D. in

London, April 23, 1823.—His son AARON, and his nephew JOHN, were also noted for the excellence of their maps.

Arrowsmith, JOHN, D. D.: b. at Gateshead, near Newcastle-on-Tyne, England, Mar. 29, 1602. He was educated at Cambridge, and was one of the ablest Puritan divines of his time; became member of Westminster Assembly 1643, D. D. and Regius Professor of Divinity at Cambridge, and master of St. Catharine's Hall, all in 1644; vice-chancellor 1647, and master of Trinity College from 1653 till his death in Feb., 1659. Wrote *Tactica Sacra* (1657); *Armilla Catechetica*, in English (1659), etc.

Arsaces I. (in Gr. Ἀρσάκης): the founder of the Arsacidae and of the kingdom of Parthia; lived about 250 B. C. His origin and history are involved in much obscurity. He is said to have been the chief of a nomadic tribe of Seythians or Baetrians. All his successors assumed the name of Arsaces.

Arsaces III.: King of Armenia; was a son of Tiridates III., whom he succeeded about 340 A. D. He waged war against Sapor, King of Persia, and formed an alliance with Julian the Apostate about 360. The defeat and death of Julian are ascribed to the treachery of Arsaces, who deserted him in the campaign of 363 A. D.

Arsaces VI., or Mithridates I.: King of Parthia; enlarged his dominions by the conquest of Bactria, and extended his conquests to the Indus. He defeated Demetrius Nicator of Syria. After a reign of twenty-five years or more, he died about 135 B. C.

Arsacidae: a dynasty of Parthian kings which was founded by Arsaces in 256 B. C., and continued to reign until 226 A. D. The last king of this dynasty was Artabanus IV. (Arsaces XXIX.).

Arsenal [through Italian and French, from Arab. *dār agginā'ah*, literally, house of construction]: a storehouse or magazine of arms and military stores, or a manufactory of arms, equipments, etc.

The arsenals of ancient castles and strongholds were located in their keeps, and served as repositories of arms, etc.

The TOWER OF LONDON (*q. v.*) remains as a type of this class, and contains a collection of antique arms, armor, etc. Corresponding collections exist at Vienna, Delft, Berlin, Paris, and Madrid.

Great modern arsenals are located at Cherbourg, Brest, and Toulon, France, with lesser ones at the centers of military districts. Similar repositories of arms, supplies, etc., usually known as "dépôts," are established in each of the military districts of Germany, Russia, Austria, and the other European states, at which are collected everything necessary for the immediate mobilization of the troops of the district.

In Great Britain there is the great arsenal of Woolwich, which has given employment to more than 10,000 men at one time, and at which immense quantities of all kinds of warlike material are manufactured and stored (see WOOLWICH). Besides this arsenal there are the great dockyards of Chatham, Sheerness, Portsmouth, Plymouth, Pembroke, etc.

In the U. S., at the beginning of the Revolution, neither arsenals nor armories existed; but in 1776 the manufacture of powder was commenced in Virginia, and in 1777 brass cannon were cast in Philadelphia. An arsenal was established at Carlisle, Pa., and a foundry and laboratory were, on the recommendation of Gen. Washington, established at Springfield, Mass., which was the origin of the present National armory. Supplies were furnished Gen. Schuyler from here in July, 1777, and before 1787 the manufacture of small arms had commenced. The arsenal at Harper's Ferry was commenced in 1795. These two arsenals furnished small arms and supplies during the war of 1812, and the former is now the principal manufacturing arsenal of the U. S. The arsenal at Harper's Ferry continued in use until the civil war, when it was destroyed, and has not since been rebuilt. See HARPER'S FERRY.

In 1838 the Ordnance Department was placed in charge of the arsenals and armories. Under its direction grew up the system of making arms by machinery with such accuracy and adherence to established patterns that all the parts of similar arms are interchangeable. This system has given great facility in repair of arms in the field, and is now universally adopted.

At the beginning of the civil war there were twenty-three arsenals and armories in the U. S., nine of which, besides

the Springfield armory, were converted into arsenals of construction. The Springfield armory became capable of turning out 1,000 rifles a day, and a large number of private armories manufactured an equal number under the direction and inspection of ordnance officers. These arms were so made that the corresponding parts could be interchanged with those of the Springfield.

Recently the number of arsenals has been still further reduced, and of those which remain the greater number are used only as dépôts and for repairs.

Small arms are manufactured at Springfield, ammunition at Frankford, and the Rock Island arsenal is designed for extensive manufactures when needed. The arsenal at Watervliet, N. Y., has been equipped as a gun foundry for the manufacture of modern high-powered cannon, etc.

The following is a list of arsenals, armories, and dépôts now occupied:

Allegheny arsenal, Pittsburg, Pa.; Augusta arsenal, Augusta, Ga.; Benicia arsenal, Benicia, Cal.; Columbia arsenal, Columbia, Tenn.; Fort Monroe arsenal, Fort Monroe, Va.; Fort Snelling ordnance dépôt, St. Paul, Minn.; Frankford arsenal, Philadelphia, Pa.; Indianapolis arsenal, Indianapolis, Ind.; Kennebec arsenal, Augusta, Me.; National armory, Springfield, Mass.; New York arsenal, Governor's island, New York city; Omaha ordnance dépôt, Omaha, Neb.; Rock Island arsenal, Rock Island, Ill.; St. Louis powder dépôt, Jefferson Barracks, Mo.; San Antonio arsenal, San Antonio, Tex.; U. S. powder dépôt, Dover, N. J.; Vancouver barracks ordnance dépôt, Vancouver Barracks, Wash.; Watertown arsenal, Watertown, Mass.; Watervliet arsenal, Watervliet, N. Y.

Ar'senic, as an adj. pronounced *ar-sen'-ik* [from Gr. *ἀρσενικόν*, deriv. of *ἀρσην*, masculine; said to be so named from its strength as a poison]; chem. symbol, *As*; atomic weight, 75; the common name of arsenious acid or white oxide of arsenic, a virulent poison. (See ARSENIOUS OXIDE.) The name arsenic is limited in scientific language to the metal. Arsenic is found native to a limited extent, but occurs usually in combination with metals or with sulphur, or both. The most important arsenical minerals are those in which arsenic is combined with iron, cobalt, and nickel, as, for example, *mispickel*, or *arsenical pyrites*, FeAsS ; *cobalt glance*, CoAsS ; *nickel glance*, NiAsS ; *arsenolite* or *arsenite*, As_2O_3 , etc. Arsenic also occurs in small quantities in many other minerals, specially in antimony ores, iron pyrites, etc., hematite iron ores, the soil, mineral waters, etc. Arsenic is, in fact, one of the most widely diffused elements in nature.

Owing to its occurrence in antimony ores and iron pyrites, it is liable to find its way into the various preparations of antimony, into sulphuric acid, and the various chemical products of which this acid is the basis, as sodic sulphate and carbonate, hydrochloric acid, superphosphates, etc. In the chemical examination of the bodies of persons supposed to have been poisoned the greatest care is necessary to procure reagents entirely free from arsenic.

Metallic arsenic is prepared by sublimation: (1) from arsenical pyrites; (2) from a mixture of arsenious acid and charcoal.

Arsenic is a brittle metal, of a steel-gray color. On the fresh fracture it exhibits a bright metallic luster, which soon tarnishes. Its specific gravity varies from 5.62 to 5.96. Its atomic weight is 75. It crystallizes in rhombohedra. It volatilizes at a dull red heat without previous fusion, with a peculiar odor, described as resembling that of garlic. When heated in the open air it burns with a bluish flame.

(For the detection of arsenic see ARSENIOUS OXIDE.) With oxygen, arsenic forms two important compounds—arsenious oxide, As_2O_3 , and arsenic oxide, As_2O_5 , which give rise to arsenious acid, HAsO_2 , and arsenic acid, H_3AsO_4 . With sulphur, arsenic forms three important compounds—realgar, AsS , orpiment, As_2S_3 , and As_2S_5 . Arsenic combines with metals in the same manner as sulphur and phosphorus, which it resembles, especially the latter, in many respects. Its compound with hydrogen, arsine, AsH_3 , is analogous to ammonia, NH_3 .

Metallic arsenic is rarely used in the arts. Lead containing a small proportion of arsenic is used for the manufacture of shot, and iron containing a little arsenic is very fluid when melted, and better adapted for fine castings for which strength is not essential.

Revised by IRA REMSEN.

Arse'nious Oxide (or **Anhydride**): As_2O_3 ; the substance commonly called *arsenic* or *white arsenic*. It is also frequently spoken of as *arsenious acid*.

Occurrence.—It is found native, as the mineral arsenolite, in silky, crystalline crusts on ores of silver, lead, nickel, antimony, etc., in the Hartz Mountains and other localities.

Preparation.—At Reichenstein, in Silesia, arsenious oxide is prepared by roasting arsenical pyrites (*mispickel*), FeAsS , in a muffle furnace. At Ribas, in Catalonia, *mispickel* is roasted in reverberatory furnaces without muffles, the crude product being subsequently purified as at Reichenstein. At Andreasberg, in the Hartz, native arsenic is roasted for the silver it contains, the arsenious oxide being obtained as an incidental product. Much arsenious oxide is produced in the roasting of tin and cobalt ores at Altenberg, in Saxony, and of tin ores in Cornwall.

Arsenious oxide usually appears as a very heavy, white, gritty, crystalline powder. It has no decided taste. At 218°C . it volatilizes to a heavy, colorless, odorless vapor, which condenses to octahedral crystals on cool surfaces. When heated with charcoal it is reduced to metallic arsenic. In its common octahedral form it is soluble in about 30 parts of cold or 10 parts of boiling water. When thrown into water, a portion floats like wheat flour, while the portion which sinks rolls itself into little round pellets, dry within. It is nearly insoluble in alcohol, absolutely insoluble in ether. It is soluble in hot dilute acids to a greater extent than in water, but it mostly separates on cooling. It dissolves readily in alkalies, forming *arsenites*.

Effect of Arsenious Oxide on the Animal Economy.—Arsenious oxide when taken into the stomach is soon absorbed into the blood, and circulates with that fluid, exhibiting power over certain diseases, especially intermittent fever and skin diseases, as psoriasis, lepra, eczema, etc. It is also classed among the tonics, and is given for nervous disorders, especially those which are periodic. Among the remedies for chorea (St. Vitus's dance) it holds a prominent place.

The quantity necessary to destroy life varies considerably. Under circumstances favorable for its operation the fatal dose for an adult is from 2 to 3 grains. Death from a poisonous dose of arsenic may occur in a few hours, or after the lapse of many days. Arsenic has been used as a slow poison, the symptoms being attributed to inflammation of the bowels from natural causes. In most cases its detection is easy. Arsenic is used by anatomists as an antiseptic; but is dangerous, as it is apt to get into cuts on the hands and cause disagreeable symptoms. In some countries, especially in Styria, arsenic is taken by the inhabitants to increase their endurance. When used habitually it can be taken in comparatively large doses. Cases are recorded by good authorities in which 6 grains and more have been taken at a time.

The most effective chemical antidote for arsenic is ferric hydroxide, prepared by the rapid precipitation of a solution of a per-salt of iron (as the persulphate or trichloride) by an alkali (as ammonia). The mixture of ferric hydroxide with magnesia, obtained by precipitating the iron solution with an excess of calcined magnesia, is still more efficacious. In case of an overdose or of intentional poisoning the following treatment is recommended: Evacuate the stomach by the stomach-pump, using lime-water; administer large draughts of tepid sugar and water, magnesia and water, or lime-water; avoid the use of alkalies, but administer charcoal and ferric hydroxide. If the fatal symptoms be averted, let the patient for a long time subsist wholly on farinaceous food, milk, and demulcents.

It is an easy matter for the chemist to detect arsenic, the method most commonly used being that known as *Marsh's test*. This consists in pouring a little of the solution of the suspected substance into a vessel containing pure zinc, water, and sulphuric acid, and from which hydrogen gas is being given off. This gas acts upon the compound of arsenic, forming the compound arsine, AsH_3 , which is a gas, and is therefore given off mixed with the hydrogen. When set fire to, this mixture burns with a peculiar livid flame, which deposits a black spot on a piece of white porcelain introduced into it. So also, if the gases are passed through a tube, and the tube heated, metallic arsenic is deposited in the tube in front of the part heated. Antimony acts much like arsenic, but it is not difficult for the chemist to distinguish between them.

Arsenites.—Arsenious acid forms with bases a series of salts, which are not very stable and have been but little studied. "Fowler's Solution" is a solution of equal weights of arsenious oxide and potassic bicarbonate, boiled with water and flavored with spirits of lavender. It contains 64 grains of arsenious oxide in 1 pint. The sheep-dipping

mixtures commonly employed are composed of arsenious acid, soda, sulphur, and soap, which, when used, are dissolved in a large quantity of water, and thus constitute essentially dilute solutions of arsenite of soda. Arsenite of copper, or Scheele's green, is a pigment largely used as a pretty and cheap green paint. The same substance is extensively employed in the manufacture of green paper-hangings for the walls of rooms; and recent inquiries would lead to the belief that rooms covered with paper coated with this green arsenite of copper are detrimental to health, from the readiness with which minute particles of the poisonous pigment are detached from the walls by the slightest friction, are diffused through the room, and ultimately pass into the animal system. It is also said that arsine, H_3As , a very poisonous gas, is generated in damp weather. Another green pigment is named Schweinfurth's green: it contains arsenious acid, oxide of copper, and acetic acid, and is a double arsenite and acetate of copper.

Revised by IRA REMSEN.

Arsin'oë: daughter of Ptolemy I., King of Egypt; b. about 316 B. C. About 300 B. C. she was married to Lysimachus, King of Thrace. She instigated Lysimachus to put to death his son Agathocles (born before her marriage), in order to promote the succession of her own son. By this crime Lysimachus was involved in war with Seleucus, King of Syria, and was killed in 281 B. C. Her sons having been murdered by Ptolemy Ceraurus, she fled to Egypt, and became the wife of her brother, Ptolemy Philadelphus.

Arsinoë: an Egyptian princess; daughter of Ptolemy Auletes, and sister of the famous Cleopatra. Caesar, having conquered Egypt (48 B. C.), took her as a captive to Rome, but soon released her. She was assassinated by Mark Antony in 41 B. C.

Arsinoë: an ancient city of Egypt; capital of a nome; situated near Lake Mœris, about 50 miles S. S. W. of Cairo. It was originally called Crocodilopolis (the city of crocodiles) because it had a temple devoted to the worship of those reptiles. Ptolemy Philadelphus gave it the name of Arsinoë in honor of his queen. The site is now occupied by the town of Medinet-el-Fainm.—Arsinoë was the name of another city of Egypt, situated at the N. W. extremity of the Red Sea, near the modern Suez. It was an important emporium, connected with the Nile by a canal.

Ar'sis and **The'sis**: two Greek words (*ἄρσις, θέσις*) signifying raising up and setting down. This musical term denotes the rising and falling of the foot in beating time. It is also applied to the elevation and depression of the voice, and to the accentuation of syllables in the scansion of poetry, *thesis* being the stress of voice given to the strongly accented syllables, and *arsis* being the withdrawal of stress in the other syllables.

BENJ. IDE WHEELER.

Ar'son [from Lat. *arde're, ar'sum*, burn]: the willful and malicious burning of the house of another. There must be an actual burning—an unexecuted attempt to fire a house does not constitute the offense. If the act be negligent instead of willful, the crime is not committed, and the wrong-doer is only liable to a civil action. The English law on this subject has been modified in this country. Arson is in some instances divided into degrees, and cases included in it which were not offenses at common law. It is made a crime by statute law to set fire to one's own house with intent to injure another—as, for example, to defraud insurers. The punishment of arson is severe, and in some of its degrees capital.

Art [through Fr., from Lat. *ars, artem*]: (1) the systematic application of knowledge in producing a desired result. (2) A systematic collection of principles and rules for attaining a desired end. Under this last head the arts are divided scientifically into (1) those which are intended to produce material results, termed the useful arts (those useful arts in which the effects are produced entirely or mostly by machinery or by mechanical contrivances are termed **MECHANIC ARTS**, *q. v.*); and (2) those intended to produce æsthetic results, termed the **FINE ARTS** (*q. v.*). The application of æsthetic principles, or the laws of taste to works which are intended to produce a religious effect, is termed religious art; the application of the laws of taste to works of a material nature is termed industrial art. (See **FINE ARTS**.) The word *art* is often used as a collective term for any or all of the fine arts (as the "study of art," a "patron of art"): as relating to the fine arts are also used various derivatives and compounds of the word art (as "artist," "ar-

tistic," "art-museum"). For formative arts, arts of design, etc., see **FINE ARTS**.

The term "liberal arts" (*artes liberales*) was applied by the Romans to the higher studies, which only freemen could pursue. They were summed up in the following verse:

Lingua, Tropus, Ratio, Numerus, Tonus, Angulus, Astra.

The term "servile arts" (*artes serviles*) they applied to trades practiced only by slaves, and summed up as:

Rus, Nemus, Arma, Faber, Vulnere, Lana, Rates.

In modern times, the term "liberal arts" is applied to the collection of studies in philosophy, science, art, and history which compose the academic and collegiate (ante-professional) course of study; hence to graduate in the arts. bachelor of arts (A. B.), master of arts (A. M.).

G. F. COMFORT.

Art, Psychology and Philosophy of: See the Appendix.

Ar'ta: a nomarchy or province of Thessaly, Greece. It is the extreme northwestern province, adjoining Albania, along the river Arta, and forming part of the northern coast of the Gulf of Arta. Capital, Arta (anc. *Ambracia*). Area, 395 sq. miles. Pop. (1889) 32,090. See **AMBRACIA**.

Arta, Gulf of (the ancient *Si'nus Ambrac'ius*): a gulf of the Ionian Sea, in the N. W. of Greece; lies between Acarnania and Albania, and is nearly landlocked. It is about 25 miles long and about 10 miles wide. The naval battle of Actium was fought near this gulf.

Artaba'nus (in Gr. *Ἀρτάβανος*), written also **Ardavan** and **Ardoan**: King of Parthia, and the last of the dynasty of the Arsacidæ. He began to reign about 216 A. D., and waged war against the Roman Emperor Macrinus. He was defeated and taken prisoner by the Persians under Ardshir, who put him to death in 226 A. D.

Artaba'zus (in Gr. *Ἀρτάβαζος*): Persian general; a favorite of Xerxes; commanded a large division of the army which invaded Greece in 480 B. C. He took part in the battle of Platea (479 B. C.), after which he retreated with his division by forced marches to Byzantium, and thence crossed into Asia.

Artabazus: Persian general and satrap; revolted against Artaxerxes III. in 356 B. C. Having been defeated in battle, he took refuge at the court of Philip of Macedon. He was pardoned, returned to Persia, and fought for Darius at Arbela. He was satrap of Bactria under Alexander after 330 B. C.

Artapher'nes (in Gr. *Ἀρταφέρνης*): Persian satrap and a half-brother of King Darius Hystaspis. He was appointed satrap of the western part of Asia Minor in 506 B. C. He used his power to restore Hippias, who had been expelled from Athens. About 498 B. C. he subdued the Ionians, who had revolted against the King of Persia.

Artaphernes: general; son of the preceding; was associated with Datis in the command of the Persian army which invaded Greece in 490 B. C., and was defeated at Marathon. He also served in the army of Xerxes in Greece in 480.

Artaud, *āar-tō'*, **NICOLAS LOUIS**: French writer; noted as a Greek scholar; b. in Paris, Dec. 6, 1794. He became inspector of the Academy of Paris soon after the revolution of 1830. He translated the dramas of Sophocles (3 vols., 1827); the comedies of Aristophanes (6 vols., 1830); and the tragedies of Euripides (1832). He obtained the office of inspector-general. D. in Paris, Nov. 9, 1861.

Artaxerx'es I., **LONGIMANUS** (Gr. *Ἀρταξέρξης Μακρόχειρ*; Pers. *Ardsheer Darāzdāst*): a King of Persia; son of Xerxes I., whom he succeeded in 465 B. C. He was called Longimanus ("long-handed") because his right hand was longer than his left. The Egyptians revolted against him about 460, but they were reduced to subjection about 455 B. C. In 449 the Persians were defeated by the Athenian forces of Cimon, near Salamis, in Cyprus. Artaxerxes died in 425 B. C., and left the throne to his son, Xerxes II.

Artaxerxes II. (surnamed **MNEMON**, because he had a good memory): the eldest son of Darius II. of Persia. He became king in 405 B. C. His younger brother, Cyrus, who was Governor of Asia Minor, revolted and raised a large army, in which were 10,000 Greeks. The king, commanding in person, defeated the army of Cyrus at Cunaxa in 401. Cyrus was killed in this action, which was followed by the famous retreat of the Ten Thousand. (See **TEN THOUSAND, RETREAT OF**.) Agesilaus, the Spartan, invaded the dominions of Artaxerxes, and gained several victories, but this

war was ended by the peace of Antalcidas (387 B. C.). He put to death Darius, his eldest son, for a conspiracy. He died in 362 B. C., aged about ninety-four, and was succeeded by his son, Artaxerxes III. See Plutarch, *Life of Artaxerxes*; Diodorus Siculus; Thirlwall, *History of Greece*.

Artaxerxes III. (or Ochus): King of Persia; a son of the preceding; began to reign in 361 B. C., and disgraced himself by his cruelty and sensuality. Among the important events of his reign was the subjugation of Egypt, which he effected about 350 B. C. D. in 338 B. C. It is supposed that he was poisoned by his eunuch, Bagoas.

Arte'di, PETER: Swedish naturalist; b. at Anund, Feb. 22, 1705; educated at Upsal, where he formed an intimate friendship with Linnæus. They co-operated on the principle of a division of labor in the field of natural history, and Artedi chose the department of ichthyology, in addition to physiology and mineralogy, which they both cultivated. He visited England in 1734. Soon after his return he was drowned in a canal at Amsterdam, Sept. 27, 1735. He left a Latin work on fishes, which Linnæus published in 1738, and which is highly commended. See Linnæus, *Life of Artedi*, prefix to the work mentioned above.

Artemido'rus (Gr. Ἀρτεμίδωρος): a famous interpreter of dreams; lived under Hadrian. His *Dream-book* (Ὀνειροκριτικά) was edited by Hercher (Leipzig, 1864); Ger. trans. by Krauss (Vienna, 1881).

Ar'temis (Gr. Ἄρτεμις): a Greek goddess corresponding to the Roman DIANA (*q. v.*).

Artemis'ia (Gr. Ἀρτεμισία): a martial Queen of Halicarnassus; a tributary or ally of Xerxes I., King of Persia. She commanded in person her fleet, which fought for Xerxes against the Greeks, and she displayed skill and courage at the battle of Salamis (480 B. C.). According to tradition, the gods compelled her to jump from the Leucadian rock, the famous *lover's leap*, into the sea, wherein she was drowned, because she put out the eyes of a youth who did not return her affection.

Artemisia: an Oriental princess celebrated for her conjugal affection and her grief for the loss of her husband, Mausolus, Prince of Caria, who died in 352 B. C. She erected to his memory at Halicarnassus a magnificent mausoleum (so called in honor of Mausolus), which was considered one of the seven wonders of the world. Remains of it still exist. According to tradition, she mingled his ashes with her wine and died of grief. See J. C. Avenarius, *Dissertatio de Artemisia et Mausoleo* (1714).

Artemisia: a genus of plants of the family *Compositæ*; comprises numerous species of herbs and shrubs, natives of the temperate regions of Asia and Europe. They generally have an aromatic odor, and a warm or acrid and bitter taste. The *Artemisia absinthium* (or wormwood) grows wild in Great Britain and the U. S., is perennial, and has bipinnatifid leaves. Containing a bitter principle and an essential oil, both very strong, it is used in medicine as an anthelmintic or vermifuge. Among the other species which have medicinal properties are the *Artemisia santonica* (Tartarian wormwood or southern-wood), a native of Tartary; *Artemisia indica* (Indian wormwood), which grows on the Himalaya Mountains; *Artemisia arborescens* (tree wormwood), which is a native of the Levant; and *Artemisia vulgaris* (mugwort), which is a native of Great Britain. The dried flower-buds of several species of *Artemisia* are sold under the name of wormseed. On the Western plains and the dry table-lands of the Rocky Mountains several species are known as "sage-brush," the largest of which is *A. tridentata*. See WORMWOOD.

Artemus Ward: See BROWNE, CHARLES FARRAR.

Ar'tery [Lat. *artēria*, from Gr. ἀρτηρία; probably connected with ἀρτέειν, hang]: any one of the vessels which convey the blood passing from the heart to the various parts of the body. With the exception of the pulmonary, arteries derive their blood, which has been oxygenated in the lungs, from the left side of the heart. The pulmonary arteries, however, carry venous blood from the right heart to the lungs. The arterial walls consist of three coats—an inner, lined with endothelial cells; a middle, principally muscular

and elastic tissue coat; and an outer fibrous tunic. It will thus be seen that the arteries are not rigid, like metal tubes, but capable of distension and contraction. This power is most important in the maintenance of proper circulation, and when it is disordered by rigidity or excessive elasticity untoward results are occasioned. The former happens in old people and in younger persons who have been subjected to a life of exposure and hard work or addicted to the excessive use of alcohol; the latter in many debilitating affections, particularly fevers in which general as well as arterial relaxation occurs. The condition of the arteries therefore is most important to the physician in indicating general bodily affections, and also in warranting the suspicion of various diseases which follow as a result of the arterial disease and failing circulation. This test is of all the more value because the arteries are in several places, particularly at the wrist, accessible to careful examination. (See PULSE.)

Arteries are liable to various other diseased conditions, such as inflammation and aneurism. In wounds of arteries bright-red blood issues in spurts, whereas dark blood flows from injured veins and in continuous stream. The arteries are usually deep-seated, the veins near the surface.

WILLIAM PEPPER.

Artesian Wells: drill-holes sunk into the earth, usually to depths of several hundred feet, through which water from pervious strata rises to the surface. Compared with their depth, the diameter of these holes is very small, being in general from 3 to 6 inches, though sometimes as small as an inch. In the U. S. the tendency is to apply the epithet "artesian" to any deep-drilled well, even though the water obtained is brought to the surface by pumps. The name is

FIG. 1.—Ideal section illustrating the chief requisite conditions of artesian wells. A, a porous stratum; B and C, impervious beds below and above A, acting as confining strata; F, the height of the water-level in the porous bed A, or, in other words, the height of the reservoir or fountain-head; D and E, flowing wells springing from the porous water-filled bed, A. (According to T. C. Chamberlin.)

derived from Artois (ancient *Artesium*) in France, where such wells have long been used, but wells of this character were probably in use in other countries at earlier dates, as they are mentioned by ancient writers.

The principal conditions upon which artesian flows depend are the existence of pervious strata, such as sandstone, inclined at a gentle angle to the horizontal, and inclosed between less pervious layers, as, for example, shales or clays. Also the higher edge of a pervious bed thus conditioned must receive an abundant supply of water either directly from rainfall or from the drainage of the adjacent country, and there must be little or no escape at lower levels. When this bed is full of water, and the water is not in motion, the pressure at the lowest part of the bed is equivalent to that exerted by a column of water of the height to which complete saturation extends. If, however, there is a small outlet and the water moves toward this, the pressure at the lowest point of the saturated rock will be reduced, and will be less and less, according as the place of escape is made larger or is lower down. When water thus under pressure finds for itself a natural outlet a spring is formed, but when the bed is tapped artificially by a drill-hole, and the water rises to the surface, an artesian well is the result. In all cases the water has come from higher ground by working its way gradually down through the minute interstices or crevices in the inclined rock, and, pressed by the other particles behind, rises through the easiest outlet.

Occurrence of Artesian Water.—In many places where the surface of the ground slopes so gently that to the eye the country appears to be nearly level, and the underlying rocks dip at the rate of only a few feet to the mile, the difference in elevation between the top of the well and the catchment or drainage-area from which the water comes may not be apparent. In such localities the discharge of the water seems to be at variance with the laws of gravity, but in all instances the necessary difference in elevation can be found by examination of topographic maps, or, in absence of these, by leveling. In order, therefore, to investigate the possibilities as to the occurrence of artesian water it is essential to have at hand a map showing the elevation of all parts of the country under examination, and to acquire by thorough observation all available facts concerning its geologic

structure. By this means the probability of success in experimental tests of this character can be determined.

By far the greater number of artesian flows come from stratified porous rocks, and especially from those but partially consolidated. In rare instances water in large quantities is found in close-textured crystalline or slaty rocks where these are greatly fissured or traversed by numerous

obstructions caused by sand it discharged in 1889 only about one-third as much. A third well at Paris has been completed to a depth of 2,360 feet, the temperature of the water obtained being 94° F.

Probably the deepest bore-hole in the world is at Schladebach, near Köttschau, on the railway between Corbetha and Leipzig, undertaken by the Prussian Government in search for coal. The apparatus used was a diamond drill, and the total depth reached is 5,740 feet. There are several other wells in Germany over 4,000 feet deep. In the U. S. deep wells have been put down mainly in the search for petroleum, and, not being

successful, have been continued for exploration purposes to depths of nearly 5,000 feet. One drill-hole at Wheeling, W. Va., driven to a depth of 4,500 feet, did not encounter water below 1,600 feet. In nearly all civilized countries artesian wells of 1,000 feet and upward are to be found, and their frequency is such that little comment is necessary. In Southern Algeria and out upon the desert of Sahara flowing wells have become of great importance, since they make possible the development of agriculture at oases formed by their presence, and also furnish water at points along routes of trade and military roads. The few thousand acres brought under cultivation by these wells have become important centers in the vast desert areas.

Throughout the U. S. artesian wells are numerous, being found on the Atlantic coast, in the valley of the Mississippi, along the Gulf of Mexico, in the northern plains region, in valleys among the Rocky Mountains, and those near and along the Pacific coast. They furnish in the aggregate a large amount of water for municipal and domestic supply, for cattle, and to some extent for cultivating the soil. In Western New York and Pennsylvania, Ohio, Indiana, West Virginia, Kentucky and Tennessee are probably over 50,000 wells of from 1,000 to 2,000 feet in depth, drilled for the purpose of obtaining petroleum or the inflammable gas which usually accompanies this fluid. From many of these wells

FIG. 2.—Section illustrating the thinning out of a porous water-bearing bed, A, inclosed between impermeable beds, B and C, thus furnishing the necessary conditions for an artesian fountain, D. (According to T. C. Chamberlin.)

jointing-planes. The chief structural conditions of stratified rocks giving rise to flowing wells are found, as shown in the figures, first, when the water-bearing layers between inclosing strata, and extending unchanged over wide areas, have been gently curved into the form of a basin, or, second, when a pervious bed, gently dipping, thins out or becomes relatively close-grained or water-tight.

How Located.—The location of artesian wells has been in the past left largely to chance, experimental holes being drilled at points where water was desired, but with little or no reference to the structure of the rocks. A notion has prevailed that if a well were drilled deep enough water would ultimately be obtained. Experience has at last taught the folly of spending large sums of money without some definite information concerning the probability of reaching a rock of porous nature which presents the conditions requisite for supplying water, for without such knowledge the chances of success are small. There are regions, however, in which, in the absence of specific knowledge of the underlying strata, as obtained by the usual methods of geological inquiry, it is necessary to sink a deep well as a test, but these are comparatively rare.

With the acquisition of knowledge concerning the geologic structure of a region and the completion of maps showing the elevation of the surface, it becomes possible to outline areas in which artesian success may be anticipated, and to mark off the localities where it is useless to bore. There will then remain doubtful areas of considerable size where local conditions decide success or failure. The necessity of bringing together all available information and plotting it upon maps, in order to forbid useless expenditure or to teach caution, should not need argument. With increase of depth beyond a few hundred feet the chances of encountering porous strata filled with fresh waters become less and less, from the fact that the rocks are less apt to be pervious at great depths, and the waters are more likely to be heavily charged with saline matter, since the temperature is higher and they have presumably been longer exposed to soluble minerals.

As a general rule, it may be said that artesian waters are more impregnated with mineral salts than surface waters, notable exceptions being in cases in which rain-water falls upon sandy soil, and passes at once into an open stratum of quartzose sandstone free from impurities, from which it is soon brought again to the surface. If petroleum or gas is present in the rocks, this, under suitable conditions, will be forced to the surface, water following only when the lighter fluids have been displaced. The manner of sinking a bore for artesian water varies with the depth and with the nature and inclination of the rocks to be penetrated. The methods by which deep wells are bored or drilled are described in the article WELL-DRILLING (*q. v.*).

Noted Wells.—Among the most noted of deep flowing wells is the Grenelle well at Paris. This city is situated in the lowest portion of a rock basin, so that the strata slope toward it. The well was begun in 1833 under the auspices of the Government and completed in 1841, having reached a depth of 1,795 feet. At first it yielded over 700,000 gal. a day, but in 1852 the tube, originally 6.7 inches in diameter, was crushed by the pressure of the surrounding beds of clay, and was replaced by a new tube 4 inches in diameter, the supply then being 200,000 gal. per day. On the completion of a neighboring well at Passy in 1861 the discharge sank over 10 per cent. At the summit of the delivery pipe, 125 feet above ground, the daily yield was in 1889 a little over 70,000 gal. The water is excellent, but must be cooled for drinking purposes, since the temperature is 82° F., or about 32° above the mean annual temperature of Paris. The well at Passy at first yielded 4,400,000 gal. per day, but owing to

FIG. 3.—Geological section from Chartres to Verdun through the Paris basin. Horizontal scale, 90 miles to the inch; vertical scale, 1,500 feet to the inch.

salt water would flow if not prevented by suitable devices, and in nearly every respect as to structure, method of drilling, and other circumstances, these may be classed as artesian wells. See PETROLEUM.

In nearly every large city of the U. S. deep wells have been drilled to obtain water for industrial purposes, and in many instances with success. In New York good water has been found at moderate depths in large quantities, although the structure was apparently unfavorable. At Chicago, St. Louis, New Orleans, Charleston, S. C., Denver, and many other localities are notable wells. The water of some of these is clear, pure, and suitable for all general purposes. In other cases it is somewhat or quite saline, there being every degree of impurity to the strongest brine. Many waters, notably those from deep wells in Indiana, are characterized by sulphurated hydrogen, rendering them disagreeable to the taste, but not necessarily worthless for manufacturing purposes. On low lands along the coast, for instance, that of New Jersey, or in the lower Mississippi valley, where the surface water is not suitable for drinking, the flowing wells have proved of incalculable benefit, enabling on the one hand a large population to remain safely at the summer

resorts, and on the other permitting the utilization of rich agricultural lands without great risk to health from impure water.

In the western half of the U. S., where the rainfall is insufficient for the needs of agriculture, artesian wells have proved of great value, since they furnish in many localities a perennial supply in quantities sufficient for household use, and occasionally for the cultivation of small areas. There were in June, 1890, as shown by the census, over 8,000 artesian wells upon the farms of the western half of the country. Of these, nearly 4,000 were employed in irrigation, watering about 52,000 acres. Of these over 2,000 were in the State of California, irrigating over 38,000 acres. The average depth of these flowing wells was 210 feet, average cost \$245, and average discharge over 54 gal. per minute, or about 78,000 gal. per day. Comparatively few have been put down for irrigation alone, the greater number being drilled primarily for the purpose of obtaining drinking-water; but since the amount consumed in this way is small, a large surplus is available for other uses. The temperature of the water from these comparatively shallow artesian wells is usually low, from 40° to 50° F., varying slightly throughout the year. From the deeper wells, 1,000 feet or more, the water is warmer, and thus is of more value for irrigation if not impregnated with earthy salts.

Most of the artesian wells show a gradual decrease in the amount of water discharged, this resulting either from the well being gradually filled with fine sand or from increasing leakage into pervious strata. Sometimes, however, the diminished flow is due to a gradual exhaustion of the basin or rocks containing the water, due to the fact that the discharge from the wells nearly equals the amount entering from the catchment area or gathering grounds. Artesian areas in California, Colorado, Utah, and other localities have been so completely developed, and so many outlets provided, that the wells on the higher grounds have ceased to flow, or discharged only after heavy rains. As settlement advances it seems probable that all artesian areas will gradually approach this condition unless protected by efficient legislation. Already in many States laws against the wasting of artesian waters have been enacted, and the attempt has been made to compel owners of wells to stop the flow at times when water is not needed. By this means draining of the saturated beds can be in part prevented, and the wells will be less apt to interfere with each other. F. H. NEWELL.

Ar'teveld' (or **Artevelde**), JACOB, van: Flemish demagogue; b. at Ghent, 1285; became a rich brewer, and by his talents and eloquence acquired much influence and popularity. The people of Ghent, who had revolted against the Count of Flanders, chose Arteveld as their commander. He banished a number of Flemish nobles and knights, and adopted a despotic and arbitrary policy. As an ally of Edward III. of England, he waged war against France. Having formed a design to give the sovereignty of Flanders to the English Black Prince, he provoked a revolt of the Flemings, who killed him in Ghent, July 9, 1345. See Froissart, *Chronicles*; biographies by J. de Winter, *J. van Artevelde* (1846); J. Hutton (London, 1882); and W. J. Ashley (London, 1883).

Arteveld, PHILIP, van: a son of the preceding; b. at Ghent in 1340. He was also a popular favorite, but passed many years of his mature life as a private citizen. When Ghent was besieged by the Count of Flanders in 1381, and reduced to a desperate condition, Arteveld was appointed to the chief command. May 3, 1382, he defeated the count, and then assumed the title of regent. Charles VI. of France intervened in favor of the Count of Flanders with an army, and Arteveld was defeated and killed at Roosenbeeke, Nov. 27, 1382. See Froissart, *Chronicles*.

Arthri'tis [Gr. ἀρθρίτις, deriv. of ἄρθρον, joint]: literally, inflammation of a joint; a term inclusive of gout and rheumatism, though properly applicable to inflammations of the joints of whatever character.

Arthro'dia [Gr. ἀρθρωδία, from ἀρθρώδης, well-jointed; ἄρθρον, joint + εἶδος, form]: a connection of bones, in which the head of one is received into a very superficial cavity in another, so as to admit of motion in almost all directions, as in the joint between the humerus and the scapula.

Arthrop'oda [from Gr. ἄρθρον, a joint + πούς, ποδός, foot]: one of the great divisions or branches of the animal kingdom, formerly included by Cuvier in his *Articulata*. They are characterized by having the bilaterally symmetrical

body made up of a series of essentially similar joints or segments, each of which may bear a pair of jointed feet, whence the name of the group. The mouth is near the anterior end, upon the lower surface; the intestine terminates below, near the posterior end. The heart is dorsal and propels the blood forward. The nervous system consists of a "brain" above and in front of the mouth, and a series of secondary nerve centers on the lower surface behind the mouth, there being a pair of these centers in each segment. These centers or ganglia are connected together by two longitudinal nerve cords, which also connect them with the brain, one cord going on either side of the throat, so that the alimentary canal may be described as passing through the nervous system. From the brain nerves go to the eyes and other sense organs of the head; from the other centers to the appendages and muscles of the corresponding segments. The outer wall of the body is usually hardened by a peculiar chemical substance known as chitine, and the external jointing which is so evident is produced by a thinning of this integument to form a hinge, allowing one part to move upon another. As this external crust can not increase in size, provision is made for the growth of the animal by periodical castings of the skin. The appendages show much variation in size and function. Thus some may become supporters of sense organs, some are modified to form jaws to chew the food, some are for walking, some for breathing, while not infrequently they disappear in the adult from more or fewer of the segments on which they occurred in the young. The Arthropods reproduce exclusively by eggs, but both *Crustacea* and *Hexapoda* afford numerous instances of PARTHENOGENESIS (*q. v.*).

Three great divisions of *Arthropoda* are recognized: (1) The *Crustacea*, breathing by gills; (2) the *Arachnida*, breathing by gills, lungs, or air-tubes (trachea); and (3) the *Antennata* or true insects, breathing by air-tubes and provided with antennæ. The species are very numerous, there being about 10,000 *Crustacea*, 2,000 *Arachnida*, and 500,000 true insects. Yet in all the similarities of structure are plainly marked. J. S. KINGSLEY.

Ar'thur, Ar'tur, or Ar'tus: a semi-fabulous British hero and King of the Britons; supposed to have flourished about 500 or 550 A. D., after the Romans evacuated the island. He is celebrated as the hero of the romances of the Round Table, and his exploits were favorite themes of mediæval romancers. According to the usual form of the story, he defeated the Saxon invaders in several engagements, but was finally killed in a battle against his rebellious nephew Modred. See ROMANCES. Revised by G. L. KITTEDGE.

Arthur, ALFRED: See the Appendix.

Arthur, CHESTER ALAN: twenty-first President of the U. S.; b. at Fairfield, in Franklin co., Vt., Oct. 5, 1830; graduated at Union College, New York, in 1848; studied law in Vermont, supporting himself by teaching, then came to New York city in 1853, and was that year admitted to the bar; was delegate to the first Republican State convention at Saratoga (1856). Before the civil war he was judge-advocate of the second brigade of New York State militia, and afterward engineer-in-chief on staff of Gov. Morgan, of New York. In 1861 he was inspector-general of New York, and subsequently quartermaster-general of New York until the expiration of Gov. Morgan's term of office. He was collector of the port of New York under President Grant from 1871 to July 12, 1878, and was chairman of the Republican State committee of New York. He was nominated for Vice-President of the U. S. by the Republican convention at Chicago, Ill., June 8, 1880, and elected Nov. 2, 1880. Upon the death of President Garfield, Sept. 19, 1881, he became the twenty-first President of the U. S. His accession was viewed with considerable apprehension by the independent men of all parties because of his affiliations with mere politicians; but he quickly showed his appreciation of the duties and responsibilities of his office, threw off his former unworthy associates, chose an excellent cabinet, and gave the country a clean and able administration. D. in New York city, Nov. 18, 1886. Revised by C. K. ADAMS.

Arthur, JOSEPH CHARLES, D. Sc.: botanist; b. in Lowville, N. Y., Jan. 11, 1850; educated in Iowa Agricultural College, the Johns Hopkins, Harvard, and Cornell universities; botanist to New York Agricultural Experiment Station 1884-87; Professor of Vegetable Physiology and Pathology in Purdue University 1887 to present. He has written many papers on plant-diseases, notably *History and*

Biology of Pear-blight (1886). He is one of the editors of the *Botanical Gazette*, and in conjunction with Dr. Coulter and Dr. Barnes published a *Handbook of Plant Dissection* (1886).

Arthur, TIMOTHY SHAY: novelist; b. near Newburgh, N. Y., in 1809. He removed to Philadelphia, Pa., 1841, and there founded *Arthur's Home Magazine* in 1852. He published some fifty stories, which have proved popular as domestic and Sunday-school books—*Ten Nights in a Bar-room*, *Tales of Married Life*, *Woman's Trials*, *Fireside Angel*, *Tom Blinn's Temperance Society*, etc. D. in Philadelphia, Mar. 6, 1885. H. A. B.

Arthur, WILLIAM: b. at Kells, Ireland, in 1819; educated at Hoxton College, and went to India in 1839 as a Wesleyan missionary, where he was engaged for some two years. He resided in France 1846–48. He became secretary to the Wesleyan Missionary Society 1851; became honorary secretary 1868, and was president of the Methodist College at Belfast, Ireland, 1868–71. Among his works are *A Mission to the Mysore* (London, 1847); *The Successful Merchant* (sketches of the life of Mr. Samuel Budgett, 1852); *The Tongue of Fire, or True Power of Christianity* (1856; 40th ed. 1885, many reprints); *The Pope, the Kings, and the Peoples* (1877, 2 vols); *The Difference between Moral and Physical Law* (1883); and *Religion without God and God without Religion* (1885–87, 2 parts).

Arthur, WILLIAM PATRICK ALBERT: prince of the United Kingdom, Duke of Connaught and Strathearn and Earl of Sussex, Duke of Saxony, Prince of Coburg and Gotha, son of Queen Victoria of England; was b. in Buckingham Palace, London, May 1, 1850, and married Mar. 13, 1879, to Princess Margaret Louise of Prussia, third daughter of Prince Frederick Charles, and grandniece of the Emperor William I.

Arthur's Seat: a rocky hill which rises in the environs of Edinburgh to the height of 822 feet above the level of the sea, and commands a prospect of great extent and superlative beauty. It is supposed to derive its name from King Arthur. It is formed of several varieties of trap-rock upheaved through the carboniferous strata, and presents on the southern and western sides perpendicular precipices.

Ar'tichoke [viâ Ital. *articiocco*, and Span. *alcarchofa*, from Arab. *al-kharshûf*]: a perennial herbaceous plant (*Cynara Scolymus*) of the natural order *Compositæ*; is nearly allied to the thistle. It is a native of the Mediterranean region, and is cultivated for food. The genus is distinguished by the bracts of the involuere being fleshy at the base, and emarginate with a hard point. The part which is eaten is the succulent flower-head, gathered before the flowers expand, and boiled or made into a salad. The Jerusalem artichoke (*Helianthus tuberosus*) is an entirely different plant, a native of North America, which is sometimes cultivated for its potato-like tubers.

Ar'ticle [Lat. *articulus*, little joint; deriv. of *artus*, joint. In grammar, a formal translation of Gr. *ἄρθρον*]: a word used in various senses, usually denoting a distinct part of a systematic work. It may signify a single clause in a contract, treaty, or other written document, a particular, separate charge or item in an account, or a point of faith. In grammar it is a part of speech, usually the shortest and simplest of all; in mercantile language, a particular commodity; in journalism, the principal editorials are called *leading articles*.

Articles: in law, various kinds of instruments drawn up under distinct heads or divisions. Instances of the use of the word are a libel in admiralty, where the libellant (or plaintiff) is said to "articulately propound"; "articles of agreement," "articles of impeachment," "articles of partnership," or of peace or of war. "Articles of Confederation" is a phrase employed to designate the compact made between the original thirteen States of the U. S., forming a general government before the present Constitution, and which, having gone into effect Mar. 1, 1781, continued in force until the first Wednesday of Mar., 1789.

Articles of Faith: the particular points of doctrine which together make up the sum of Christian belief. The various churches of Christendom, not being agreed upon all these points, have for the most part set forth their own expositions of belief; and it is to these creeds, symbols, or confessions that the term Articles is most commonly applied. The Articles of the English Church, which are not, strictly speaking, Articles of Faith, or a creed, but "Articles of Religion," though formerly forty-two in number, are now re-

duced to thirty-nine. (See THIRTY-NINE ARTICLES.) In the Episcopal Church in the U. S. Article XXI. *Of the Authority of General Councils* is omitted, "because it is partly of a local and civil nature, and is provided for, as to the remaining parts of it, in other Articles." In the Standard American Prayer-book of 1892 the Articles appear with a separate title-page, indicating that they are not to be regarded as a part of the Prayer-book. The Methodist Episcopal Church in the U. S. has reduced these Articles in its *Book of Discipline* to twenty-five. Revised by W. S. PERRY.

Articles of War: an act of Congress approved Apr. 10, 1806, to establish rules for the government of the U. S. army. Separate articles (those now in force, approved in 1864, to supersede the old articles of 1802) establish rules for the government of the navy. Also the code of military law embodied in the Mutiny Act annually passed in the British Parliament. For the enforcement of such Articles of War power is given to the crown to establish courts martial to try and punish offenses according to the Articles themselves. Another annual Mutiny Act embodies "Articles of War for the Marine Forces," which relates exclusively to the royal marine forces *while employed on shore*. The navy is not controlled by any annual Mutiny Act, but the Articles of War relating to it are contained in an old act of Parliament, the 22d Geo. II. c. 33.

Articles, The Six: were set forth by King Henry VIII. and accepted by Parliament in 1539. They asserted the doctrine of transubstantiation, condemned the marriage of priests, enjoined the continued observance of vows of chastity, and sanctioned private masses and auricular confession. These articles were imposed on the people solely by the king and Parliament without any authority of the convocation of the clergy. They were repealed by 1 Edward VI., cap. 12, sections 1 and 3.

Articula'ta [neuter plur. of Lat. *articulatus*, jointed]: the *articulated animals*; one of the four primary or grand divisions of the animal kingdom according to the system of Cuvier. The group has now been dismembered, the species included in it being usually distributed into the two primary groups or sub-kingdoms of Arthropods and Vermes.

Articulation: (in speech) see ELOCUTION; (in anatomy) see JOINT.

Artific'ial Butter: See BUTTER.

Artificial Horizon: a horizontal mirror, usually the surface of a basin of mercury, used to determine the altitude of a star or other object when the sensible horizon is ill defined.

Artificial Limbs: See LIMBS, ARTIFICIAL.

Artificial Stone: See CEMENT and ARTIFICIAL STONE, under STONE.

Arti'gas, José: a South American general; b. at Montevideo, Uruguay, in 1755; became in early life a leader of the gauchos, a class of outlaws. In 1811 he entered the service of the Junta of Buenos Ayres, for which he fought against the Spaniards or royalists. He defeated the latter in several battles, and became in 1814 master of Uruguay. He attempted to conquer Buenos Ayres, but was finally defeated in 1820. D. in Paraguay, 1851.

Artil'ery [Old Fr. *artillerie*, deriv. of *artillier*, fortify; deriv. of Late Lat. *artícula*, dimin. of *ars*, art]: in early times, all kinds of missile employed in warfare, and the machines by which they were propelled.

The artillery engines in use by the ancients were chiefly the ballista and catapult, for throwing stones and heavy darts, and the battering-ram, for effecting breaches or demolishing walls. These engines were rude, bulky, heavy, clumsily constructed, and required many men and much time and labor for their transportation, placing in position, and manœuvring; but for the period and purpose they were doubtless of great power and sufficiently destructive. The effective range of the ballista and catapult did not exceed 100 or 150 paces, but at this distance they were capable of discharging missiles of 300 lb. weight. In the Middle Ages the cross-bow came into military use, and gradually supplanted the catapult. It is probable that an engine of similar construction took the place of the ballista. These engines were constructed of tough, fibrous wood, and in some instances of steel. By their introduction greater portability and some increase of range were obtained.

Since the introduction of gunpowder the term "artillery" is understood to denote all firearms other than those used as

hand-weapons. It therefore includes all guns, howitzers, mortars, and machine-guns, and excludes muskets, rifles, and pistols. It is synonymous with *ordnance*, and is generally used in a plural sense; when in the singular, it is usual to say *a piece of artillery*. Carriages upon which pieces are mounted or transported, together with the ammunition, implements, equipments, etc., employed in the service of pieces, are called *artillery material*, and are always mentioned with the prefix "artillery" or its equivalent. Troops employed in artillery service are called *artillery troops*. In speaking of artillery, the term "cannon" is frequently used, signifying always the piece, and nothing more. See **ORDNANCE**.

Previous to 1846 all cannon were made with smooth cylindrical bores; their sizes were then designated by the weight of their solid shot, in pounds, or by the diameter of the bore, expressed in inches or centimeters. This latter method is now used for all rifled cannon, except in England, where the size is often, but very imperfectly, expressed by the weight of the piece in tons or hundredweights.

The birth of artillery, as we to-day understand it, dates from the introduction of gunpowder into Europe. The earliest record of the construction of cannon is about the middle of the fourteenth century, but contemporaneous mention is obscure, and refers to cannon more as curiosities than as engines of war. The first well-authenticated use of cannon in battle was by Edward III. of England in the battle of Cressy, A. D. 1346. Even on this occasion it would appear that their effect upon the French was due more to astonishment than to any inherent power of the novelty itself. From this date, however, the construction and use of cannon increased with great rapidity. At the very first they were of small caliber, throwing stone or leaden balls of only 3 or 4 lb. weight, but before the close of the century they were capable of throwing stone projectiles of 40 or 50 lb. for field-guns, and of 200 lb. for siege or fortification guns. In fact, their excessive size and weight not only seriously interfered with but actually prevented their general use. The earliest cannon were constructed of iron bars joined together longitudinally and strengthened by exterior hoops of iron. Wood wound with rope, and sometimes with wire, was also used upon the exterior to strengthen them. One of the most interesting of ancient *monster* cannon still extant is the "Mons Meg," made in 1486 at Mons, Brittany, and now in the castle of Edinburgh. An inscription on the carriage

FIG. 1.—"Mons" Meg.

states that it was employed at the siege of Norham Castle, in 1513. It burst in 1682 in firing a salute. It is made of iron bars hooped together, and its bore is 20 inches in diameter. Another superb specimen of early cannon—of much later date than the preceding—is the "Tsar Cannon" (or "King of Cannon"), in the arsenal of the Kremlin, Moscow. It was made early in the seventeenth century under the Emperor Theodore. It is of bronze, with a caliber of about 30 inches. The carriage upon which it stands is merely an ornamental support. Cast without trunnions, it

FIG. 2.—The Tsar cannon.

was probably laid in permanent position for firing. Still more curious are the famous Turkish guns defending the

Dardanelles. The diameter of the shot is 36 inches; length of gun, 15 feet. These pieces likewise were without trunnions, and also without means for lateral motion. It was impossible, therefore, to train them upon moving objects; consequently, after being loaded they awaited the arrival of the hostile vessel at the spot where the shot would strike before being fired. So recently as 1807 these clumsy weapons were brought into requisition against the British fleet under Admiral Duckworth in its passage up the Dardanelles. Gustavus Adolphus introduced the so-called "leather" cannon, consisting of a thin metal tube strengthened with bands and cords and inclosed in a tightly-fitting cover of boiled and varnished leather.

In the very infancy of cannon-construction the breech-loading principle suggested itself, and was made use of in a crude manner; but the low state of the mechanic arts forbade the exact mechanism necessary to perfect the idea. About the middle of the fifteenth century cannon began to be cast in iron, and toward the latter portion in various alloys. A. D. 1477, Louis XI. of France caused many cast-iron cannon to be fabricated for use against the cities of Picardy and of Flanders. About this period the projectiles for large cannon, which had hitherto been of stone, were made of cast iron; but to some extent stone balls continued in use for a number of years afterward. Shells were also introduced at this time, and we have a record of their use by Charles VIII. of France at the siege of Naples, A. D. 1494. Brass cannon were first cast in England by John Owen, 1535, and a few years later in Scotland by order of James IV. During the last half of the sixteenth century mortars for throwing shells were introduced in Germany, and in the first half of the seventeenth century in France. Mortars were at first discharged by igniting the shell before it was introduced, and then igniting the charge in the mortar. The great danger of such a practice caused its abandonment, but not until it had been followed for half a century. Toward the latter part of the seventeenth century a short cannon, a howitzer (German *Haubitze*), was introduced for the purpose of using large shells by direct fire. In 1799 there was introduced a short cannon of large relative caliber called a *carronade*, named from the Carron iron-works, where it was first cast. No long guns for firing hollow projectiles at long range by direct fire were known until 1812, when Col. Bomford, of the U. S. Ordnance Department, invented a gun for that purpose, which he improved in 1814 and called a *columbiad*. Some years afterward this invention was introduced into France by Gen. Paixhans, and was generally called in Europe by his name. In 1841 a gun of this character, but of somewhat different model, and called a *seacoast howitzer*, was introduced into the U. S. service, and three years later these were followed by columbiads of altered model, increased weight, and greater power.

After a long series of experiments for the purpose of determining the best form and distribution of metal in guns, Admiral (then Lieut.) Dahlgren, U. S. navy, produced in 1856 the gun bearing his name. These pieces are of cast iron, cast solid and cooled from the exterior; they are of great thickness at the breech and as far forward as the trunnions, and from thence to the muzzle rapidly diminishing in thickness, so that their external configuration is not unlike that of a champagne bottle. They are adapted exclusively for hollow projectiles, and are chiefly of 9-inch and 11-inch caliber. Previous to the introduction of rifled cannon they were considered a most serviceable gun.

For several years previous to 1860, Gen. (then Capt.) Rodman, U. S. army, was engaged upon investigations for the improvement of gunpowder and for the better casting of heavy ordnance. In that year he produced the gun now bearing his name. These guns are of cast iron, and his invention was the process by which heavy ordnance is cast hollow and cooled from the inside by means of a stream of cold water flowing through a hollow core occupying the place of the bore of the gun, the exterior being, in the meanwhile, kept from rapid cooling by fires around the gun in the casting-pit. Rodman guns are further distinguished by great thickness of metal at the breech, by graceful curves of their exterior lines, and by the absence of all exterior ornamentation, sharp angles, or edges, and of the cascabel and swell of the muzzle, and by having the trunnions at the center of gravity, thus doing away with preponderance and greatly facilitating the service of the gun. With the exception of the "siege" 4.5-inch rifle, all the Rodman pattern are smooth-bore guns, having calibers of 8, 10, and 15 inches respectively. A couple, for experimental purposes, were

cast having a caliber of 20 inches. All Rodman guns are adapted to the use of solid as well as hollow projectiles. The 15-inch gun (Fig. 3) weighs 25 tons, the solid shot 450 lb. and the charge is 100 lb. of mammoth powder. The piece

FIG. 3.—15-inch Rodman gun.

is mounted on an iron carriage provided with two pneumatic buffers for checking recoil. At the time of the adoption of the Rodman 15-inch gun it was the most powerful piece of artillery in existence. In its employment against iron-clad vessels its shots were intended to have a racking effect, in contradistinction to the punching effect of rifle projectiles. By many it is still considered a serviceable gun, capable of great execution against the powerful armor of modern ships. Improvements are now in progress whereby a more powerful charge can be used and a still greater efficiency secured. All nations are now, however, replacing their smooth-bore guns with rifles, as rapidly as possible.

Soon after the rifle-principle had been applied to small arms, experiments commenced to be made with a view to applying it to cannon; and in 1846 cast-iron rifled pieces, loaded at the breech, were invented by Col. Cavalli, of the Sardinian service, and Baron Wahrendorf, of Sweden, for the purpose of firing elongated projectiles. After two or three years of successive improvements, this invention proved the practicability of applying the rifle-principle to cannon and demonstrated the great advantages to be derived from such application. From that period up to the present time the minds of military inventors and constructors have been actively alive to the subject of rifled ordnance. A great variety of guns have been produced, and long and exhaustive experiments made to determine the best form and construction of piece, number and twist of grooves, character of breech-mechanism, and form of projectile. Each year has added its improvements, and enormous strides have been made during the last twenty-five years in gun-construction, and in that of carriages and projectiles and the manufacture of steel and of gunpowder. More is due, probably, to the improvements made in the two last named than to any other cause.

The history of modern artillery may be divided into three epochs—the first, the introduction of rifled cannon in the Italian campaign of 1859, which showed the advantages of the new weapons; the second, their general adoption by all European powers, and their employment in the campaigns of 1866 and of 1870-71; the third, the introduction of the present armaments by the different European powers after the Franco-German war, which showed the necessity for improved and more powerful guns. The increased power, accuracy, and range of the modern rifle-musket called for a corresponding improvement in field-artillery, while the progress made in armor-plating for ships of war demanded that heavy ordnance should be constructed with power sufficient to pierce their armor. Passing over the various stages of improvement—which, to a great degree, was that of experiment—the following is the present status of gun-construction among the principal nations of Europe.

First, as regards *Field-artillery*. Commencing with the German guns, as the pioneers along the path of progress, these are made of crucible steel of low carbon hooped around the breech with a jacket of the same material. The breech-closing apparatus is that known as the “round-wedge breech-block”—i. e. a cylindro-prismatic wedge tightened in the breech of the gun by means of an interrupted screw acting perpendicularly to the axis of the piece. The breech-block is perpendicular to the axis of the bore, and works horizontally in a mortise cut through the breech of the piece immediately in rear of the cartridge-chamber. The breech-block being withdrawn, the projectile and cartridge are inserted from the rear; the block is shoved in and tightened by means of the screw just mentioned. The piece is fired

in the ordinary way, by friction-primers. The gas-check is composed of a ring of soft steel abutting against the steel plate in the surface of the wedge. The ring is fitted into a recess cut into the rear of the cartridge-chamber; and when the gun is discharged, the ring, being instantaneously expanded, and at the same time pressed rearward with tremendous force, hermetically closes the tube of the piece and prevents all escape of gas. A single ring endures a vast amount of firing and seldom has to be renewed. The gun just described is known throughout the world as the “Krupp gun.” (A general idea of the field-piece is given in Fig. 4.)

FIG. 4.—Field-piece.

The most important detail in the construction of a breech-loading gun is an efficient and durable gas-check; and this was the great desideratum until Broadwell, of the U. S., invented the ring just mentioned, and which is known by his name. There being no demand for his invention in the U. S., he patented it in Great Britain, and soon after it was adopted by Krupp, the great gun-manufacturer, of Essen in Germany.

The Russian guns and the Italian 3.43-inch gun are of similar construction, and they, as well as the German guns, are supplied to the various governments by Krupp. Their breech-loading mechanism, as well as that of the Italian 2.95-inch, is similar to that employed in the German guns. The French guns are also of steel, and are strengthened around the breech by six mild-steel rings, which, as in Great Britain, are put on hot. The Italian 2.95-inch gun is of bronze; the Austrian guns are made of the so-called steel bronze, composed of an alloy of 92 parts copper and 8 tin. The guns are chill-cast in iron molds, and the bore is hardened and compressed by forcing coned steel mandrels through it with tremendous pressure. By this means the material is brought into such a state that from the inside of the bore to the external surface of the gun the metal is brought into the most favorable condition for resisting the explosive force of the powder-charge. The breech-action of the Austrian field-piece is similar to that of the German guns, except that the breech-block has not a round back; but the edges of the rear surface are chamfered off.

The breech-closing mechanism of the French guns presents several peculiarities. It consists of a solid interrupted screw. The surface of the thread of both the male and the female screws being divided into six equal parts, the threads of the alternate parts are removed, so that one-sixth of a turn disengages the thread and allows the breech-screw to be removed. The axis of the screw is coincident with the axis of the bore, and the screw has a diameter greater than that of the bore, so that the square face of the screw abuts against and closes the cartridge-chamber. The screw, having been turned until the threads are disengaged, is withdrawn by hand and swung to one side upon hinges, after the manner of a door. The charge is then inserted, the screw swung back, shoved in, and secured by giving it a slight turn, thereby engaging the threads. This method of closing the breech is known as the “Reffye,” or French, system. The interrupted-screw principle was a U. S. invention, patented in 1853 by J. P. Schenkel and A. S. Savoni. Six guns upon this plan were cast at Boston for the British Government in 1855. The gas-check of the French gun consists of two parts—viz., a steel mushroom-shaped plate, the long stalk of which projects through the breech-screw and is allowed a certain amount of play backward and forward, and an elastic gas-check, composed of a thick cake of a mixture of asbestos and mutton-fat wrapped in canvas and secured by tin cups and brass rings. This gas-check is strung on the stalk of the mushroom, rests between the posterior surface of the latter and the anterior face of the breech-screw, and serves by its elasticity to close the breech

when the charge is fired. The guns are vented through the stalk of the mushroom. The German and Russian guns and the Italian 3.45-inch are vented through the breech-piece, and the vent is so arranged that the charge can not be ignited till the former is screwed home. The Austrian guns and the Italian 2.95-inch are vented through the metal of the gun.

The British were among the first to adopt a breech-loading field-gun, but after a time dropped it and returned to the muzzle-loader. This was in consequence of the undue importance attached to their East Indian service, where it was feared the breech-mechanism, if out of order, could not be repaired. The breech-loading system which they adopted was that of Sir William Armstrong. The body of the piece was made by welding together several wrought-iron tubes at their ends; these tubes are formed by twisting square bars of iron around a mandrel and welding the edges together, after the manner of a fowling-piece. The part of the gun in rear of the trunnions was strengthened by two additional tubes. The breech was closed with a block slipped by hand into a vertical mortise in the breech of the piece, directly behind the cartridge-chamber, and was held in its place by a breech-screw abutting against it from behind. The axis of this screw was coincident with that of the bore of the gun, and was bored out so as to constitute a prolongation of the bore. The vent was through the breech-block, which worked with a vertical action instead of horizontally, as in the Krupp system. The British have returned to breech-loaders, using, as before, the Armstrong system, but employing steel instead of iron. The breech-fermeture is a modification of the French Reffye mechanism.

With regard to rifling, a diversity of practices obtain concerning the number and the depth of the grooves. But with the adoption of breech-loaders and an increasing twist the number of grooves has been increased, their depth and width diminished, and the projectiles are generally made to take the rifling by the use of copper rings. All use elongated projectiles, solid shot, shell, and case-shot, or shrapnel. The muzzle-velocities of guns of the different services vary from about 1,300 to 2,000 feet for field-guns. The weight of piece also varies, but averages 800 lb. for light guns, and 1,100 lb. for the heavier class of field-pieces.

The carriages and limbers of most modern guns are of steel, or of a combination of steel and wood, and the ammunition-chests open to the rear like a cupboard instead of chest fashion.

The field-guns and carriages are driven by pole-draught, except in the British service, where shafts are used. All the wheels have naves after the pattern known in the U. S. as the "Archibald wheel." Fifty-five inches is the average diameter of the wheels, and the average track is 60 inches. The weight of a piece on its carriage, fully equipped, with ammunition-chests filled, varies from 4,784 lb. for the Russian heavy gun to 2,744 lb. for the light Italian piece; the average, however, is about 3,600 for light guns and 4,500 for heavy. The light Italian gun is drawn by four horses, all other nations use six, except for the English heavy piece, where eight are used. All caissons have six horses, except for that of the light Italian piece, for which four are used. The Austrians and the Italians have, when on a war footing, eight pieces to a battery, and so likewise do the Russians, except for their horse-batteries, in which six are used. All other nations have six pieces to a battery.

The Armstrong breech-loader, now introduced into the British service, consists of a steel tube with a wrought-iron jacket. Its breech is closed somewhat after the French plan—viz., by an interrupted screw. The gas-check is a shallow steel cup attached to the face of the breech-screw.

Previous to the civil war the field-artillery of the U. S., in common with that of other nations, was smooth-bore 6 and 12 pounder guns and 12-pounder howitzers, all of bronze, mounted on wooden carriages of excellent pattern. At the outbreak of the civil war rifled muzzle-loading pieces were introduced. Mr. Parrott, of the West Point foundry, introduced a 10 and a 20 pounder—3-inch and 3.67-inch respectively. These guns had a cast-iron body, of the usual form and dimensions of guns, strengthened by shrinking a band of wrought iron over that portion of the piece surrounding the charge. The grooves had an increasing twist. The projectiles were solid shot, shell, and case-shot, all of a pattern devised by the inventor of the gun. A malleable cup or ring attached to the bottom of the projectile, and expanding by the effect of discharge, caused the projectile

to take the grooves. The smaller of these two guns proved to be an excellent weapon, and did good service; the larger gun, from some occult cause, was a failure. At the same period another rifled gun was introduced by the U. S. Ordnance Department. This piece had a bore of 3 inches and was of wrought iron, constructed by wrapping boiler-plate around an iron bar, so as to form a cylindrical mass, which, being brought to a welding heat, was passed through rollers, so as to unite it solidly; the trunnions were afterward welded on and the piece bored, rifled, and turned to its proper size and shape. The method originated at the Phoenixville iron-works, Pennsylvania. This gun fired solid shot, shell, and case, and both it and the Parrott used canister for close quarters. A variety of patterns of projectiles were used, but that which proved most serviceable was the Schenkel, which consisted of a cast-iron body with a *papier-maché* sabot surrounding the rear part of it. The force of discharge swaged this sabot into the grooves and caused the projectile to rotate. This also proved a most excellent gun, and was extensively used during the war. The carriage for both this and the Parrott 10-pounder was that of the old smooth-bore 6-pounder. In addition to these two rifles a bronze smooth-bore 12-pounder of the Napoleon pattern was also much used, and did good service.

A 4.5-inch rifle-gun (known in the U. S. classification as a siege-piece) was to some extent used as a heavy field-piece, and, although somewhat cumbersome for bad roads, proved a useful weapon. Its use in this manner corresponded to that of the heavy field-batteries of European armies. It is of cast iron, and in exterior form is of the Rodman model.

A limited number of steel breech-loading guns of 3.2-inch caliber, with an interrupted screw fermeture, have been made, and are now used for field-guns. A 3.6-inch gun of similar construction is in process of manufacture, with which it is proposed to arm the mounted batteries, using the 3.2 for the horse-batteries. The carriages are of steel and iron, except the wheels, which are of wood, with the Archibald nave. These are the approved models of field-guns of to-day.

Certain patterns of machine-guns were taken into the field during the civil war, but were little used. One of these—called, in derision, the "coffee-mill"—had a hopper, in which the cartridges were dropped, and from which they were fired through a single barrel by means of a hand-crank. Another pattern of machine-gun was an improved form of the vibaudequin, or organ-gun, of the fifteenth century, known during the war as the "Requa rifle-battery." This piece received favorable notice at the siege of Charleston in 1863. It consisted of twenty-five barrels arranged side by side in a horizontal plane and secured by an iron frame, a sliding-bar in the rear worked by two levers forcing the cartridges into the chambers. The Gatling gun was adopted just too late to be used in this war, and the French mitrailleuse saw its first service in the Franco-German war of 1870-71.

The GATLING GUN (*q. v.*) is a machine-gun, invented by R. J. Gatling, of Indiana, in 1861. The first gun was made by him in 1862; in the following year he caused it to be brought to the notice of the French Artillery Committee. This was before the invention of the French, or the Montigny, mitrailleuse, and may therefore be considered the first practical military machine-gun. The perfection to which it has been brought in all its mechanical appliances has caused it to be introduced into the military service of most nations, and it has proved the forerunner of the Gardiner, the Lowell, and the Hotchkiss—all invented in the U. S.; as the Requa battery has of the Nordenfeldt, of Swedish invention.

In the civil war the armies of the Confederate States used rifled cannon (obtained chiefly from Great Britain) of the Armstrong, Whitworth, and Blakely patterns. The Whitworth field-piece is forged solid from low steel; the larger guns are built up with coils or hoops forced on by hydraulic pressure. The cross-section of the Whitworth bore is a hexagon with rounded corners, and the twist is very rapid. The projectiles are quite long, those intended for armor-punching being made of hardened iron or steel, with very thick flat heads, to prevent glancing. The projectiles are manufactured hexagonal, of the form and dimensions of the bore, and are thus made to take a rotary motion when fired. This gun had an extraordinary range and great accuracy, being in these respects far ahead of other guns of its date, and approximating closely to the most modern forms. The Blakely gun is also a built-up gun, combining in its con-

struction the principles of initial tension and varying elasticity, the object being to bring the strength of all the metal of the piece into simultaneous play to resist the explosion of the powder-charge. The inner tube is of low steel, and the rings, also of steel, are of varying quality. The piece is rifled with one-sided grooves and fired with projectiles having an expanding base-ring. The Confederates also used a rifle known as the "Brooke gun," made after the plan of Capt. Brooke of the Confederate service. It somewhat resembles the Parrott in shape and construction; the rifling is similar to that of the Blakely. See RIFLING OF ORDNANCE.

Rifled guns have entirely superseded smooth-bores for field-service, and breech-loaders have taken the place of muzzle-loaders. This class of artillery has now stood the test of three great wars—viz., the Austro-Prussian, the Franco-German, and the Russo-Turkish; to which may be added the recent Anglo-Egyptian and many other minor struggles. It is estimated that four-fifths of all breech-loading field-pieces in existence are upon the Krupp plan. The French, for obvious reasons, were compelled to adopt another system, and the British adhere to the Armstrong, somewhat modified. Armstrong has produced a 2.5-inch gun, and Krupp one a trifle larger, intended for use in mountain-warfare; it is constructed in two parts screwed together. By this means the piece is divided into two lengths convenient for mule-packing. When the parts are screwed together—which can be done with great facility and quickness—a gun is obtained far surpassing in power anything that can be obtained from a mountain-gun of ordinary construction, limited, as it must be, in weight to the mode of transportation on mule-back. The Armstrong gun, just mentioned, has been used with considerable effect in Afghanistan.

The tendency of modern warfare has been to give greater value to a more powerful field-artillery. Infantry-fire has become so terrible, and its range has been so much prolonged, as to make necessary a like increase of the power of field-artillery fire. To this end inventive energy has been directed toward the production of guns of much larger caliber, but of such improved pattern, both of piece and of carriage, as to secure the desired end without increasing the weight to be drawn by the teams or impeding the mobility of batteries on the field.

In the early stages of artillery the *personnel* of it consisted of mechanics and laborers hired for the handling of the pieces and the management of the trains. These persons served a regular apprenticeship and had a guild of their own; when war broke out the different monarchs hired as many as they required or could get. Their pay was considerably greater than that of an enlisted soldier. Guns were hauled to the field on cumbersome carriages and placed in position as best they could be; here they remained stationary, and, in case of disaster, nearly always fell into the hands of the enemy. At this period there were no tactical manœuvres. A step in advance of this system consisted in attaching one or more pieces to each regiment of infantry, from which men were detailed to serve the guns. During the Thirty Years war the cannoneers, with regularly appointed officers, became recognized in Germany as a component part of the army. For a long period, however, after this, artillery-drivers were hired as before. The horses were strung out in single file, and the drivers walked by their side. A great variety of calibers existed, producing infinite confusion in ammunition and equipments. In the early part of the seventeenth century Maurice and Henry Frederick of Nassau made many improvements, among which was a reduction in the number of calibers, restricting them to 6, 12, and 24 pounders for field-service. The dimensions of these pieces were fixed, while handles and cascabels, shaped for the attachment of ropes, facilitated mechanical manœuvres. The gun-carriages, which had limbers, and the ammunition-wagons were similarly reduced to four varieties, and their dimensions made so uniform that wheels and other parts were interchangeable. About the same time Gustavus Adolphus, perceiving the advantage that would result from field-guns capable of quick motion and rapid fire, introduced light pieces made of thin copper wrapped with rope and leather; these, not proving durable, were replaced by iron 4-pounders weighing 650 lb. and drawn by a single pair of horses. Rapidity of fire was attained by the use of cartridges, the slow process of inserting the powder with a ladle being thus got rid of. Two of these guns were

attached to each regiment of infantry. Gustavus did much, also, toward developing the tactical powers of the arm by massing the heavy guns in strong batteries on the wings and center, and doing away with the old fashion of stringing them along the line at regular intervals. As guns have improved in range and power this principle of massing them has proved more and more advantageous, and has led to the abandonment of attaching batteries to small subdivisions of an army. In France, toward the end of this century, artillery material was modified and improved, much attention being paid to the character of the gun-metal, to the form of the chamber, and to the proper length and weight of the piece. The calibers for field-service were restricted to 4, 8, 12, and 16 pounders, which calibers were retained until the change to rifles. Gun-carriages were also changed for the better and provided with limbers, while trains of wagons or carts were organized for carrying ammunition; some of the carriages were made of wrought iron. Louis XIV. was the first sovereign to create a special artillery-force; he raised, in 1671, a regiment for artillery-duty, and in 1690 founded the first artillery-school. To his age belong also the important inventions of the elevating-screw, the prolonge, and the priming-tube filled with powder, the old method being to work powder into the vent from a horn.

During the first part of the eighteenth century artillery was generally recognized as an arm, had its regularly incorporated troops, and in consequence made very marked progress. Field-artillery performed an important part in the campaigns of Marlborough. In 1747 the French began to fire howitzers in siege-operations without first igniting the shell, it having been found that the flash from the charge would light the fuse if there was no tamping. The gun-carriages and ammunition-wagons were still of various patterns, each arsenal having its own way of constructing them; the axletrees were of wood and the limbers very low, with horses attached in single file. After the Seven Years war field-guns began to be assigned permanently to brigades in batteries of five to ten guns. In Prussia, Frederick the Great introduced short, light regimental guns of 3, 6, and 12 pound caliber; his example was followed by Austria and other countries. He also established howitzer-batteries. Frederick at first looked upon artillery with disfavor, and permitted it to run into a state of great confusion with reference to the models for each caliber. After Rossbach, where it did excellent service, he seems to have got over his prejudice, and we are indebted to him for the first horse-artillery, in 1759. It consisted of a battery of ten light 6-pounders, and, though long in a very inefficient condition, and destroyed at Kunersdorf and again at Maxen, was always reorganized. The Seven Years war opened the eyes of the Austrians to the importance of the artillery arm, which was carefully reorganized and improved under the direction of Prince Liechtenstein, who was created chief of artillery, with rank and authority commensurate with the importance of his position; this gave their artillery an immense advantage and assured its constant superiority to that of most of the contemporary powers. The Russians always attached great importance to their artillery. When they entered Germany in 1758 they had 425 guns to 104,000 men; three light howitzers were attached as horse-artillery to each dragoon regiment. Artillery in that century consisted of guns attached in pairs to each infantry battalion, of guns of position organized into large batteries, and of siege-guns. The number of guns was usually four or five to a thousand men. The regimental guns advanced with the battalions, unlimbered at musket range, and thence were moved forward by hand. The position-guns were posted at the most favorable points along the line, and generally remained stationary throughout the battle. The bronze cannon of this age were elaborately ornamented with carvings and with the ciphers and crests of arms of the reigning monarchs, the early custom of giving a special name to each piece being retained.

Such was the condition of artillery when Gribeauval appeared upon the stage. This celebrated Frenchman, having served in the Austrian artillery under Prince Liechtenstein during the Seven Years war, returned to France with a thorough knowledge of all the improvements suggested by the experience of that struggle, and was intrusted in 1765 with the reorganization of the French artillery, then in a very poor condition. He began by creating a distinct material for each service, field, siege, and seacoast. His field-guns were 4, 6, and 8 pounders. By reducing windage and improving the powder he was enabled greatly to reduce the length and weight of field-guns. To these were added a 6-inch howitzer, still re-

taining a small charge, though proportionately larger than that before used. These pieces were without ornaments, and were cast solid and then bored out, which made their dimensions much more exact than the old hollow-cast cannon; the trunnions were strengthened by rimbases, and copper vent-pieces enabled the guns to be rebushed. The horses were hitched in double file, which greatly facilitated the movements of the carriage, and the draught was made easier by iron axletrees, higher limbers, and traveling trunnion-beds. Fixed ammunition, elevating-screws, and tangent-scales, together with bricoles and prolonges, facilitated the service and increased the mobility of the piece. Stronger carriages were made for the lighter guns, and uniformity was established in all new constructions by requiring the arsenals to make every part of the carriages, limbers, and caissons after certain fixed dimensions, so that parts could be interchangeable and spare material carried into the field exactly corresponding to those in use. An equipment was thus obtained which could be moved and repaired with a facility hitherto unknown. These reforms were so excellent as to secure the permanency of many of them as the basis of the system of the present day.

Gribeauval's reforms did not stop at the material, the *personnel* of the French artillery being completely reorganized in 1765 through his efforts. Two guns were still assigned to each infantry battalion, which were served by detachments from a company of artillery attached to each brigade of four regiments. The rest of the artillery was organized into two or three reserves, each reserve consisting of divisions of eight pieces, to each of which was assigned a company of artillery. Here we have the creation of the artillery unit—the company organization, afterward merged into that of the battery with its horses and drivers, for the first time inseparably joined to its munitions and guns.

The French introduced horse-artillery in 1792 and cut down their batteries to six pieces, eight being found too unwieldy. In 1799 they entirely abandoned battalion-guns, as impairing the mobility of the infantry, one or two batteries attached to divisions taking their places. An artillery-train or corps of drivers, composed of enlisted men, was organized in 1800 and distributed among the French batteries; they had previously depended upon civilian drivers hired with their teams by contractors, the result being that drivers, horses, and harness were always in bad condition. The use of artillery in mass dates from the French camp at Boulogne in 1805, where this important tactical improvement was conceived and taught. The great value of it was made manifest in the battles subsequently fought by Napoleon. In 1827 the French replaced the two flasks which formed the trail of the Gribeauval system by a single piece, called the "stock," which permitted the carriage to turn in a smaller circle than before. The mode of connecting the limber with the gun-carriage was simplified by employing a hook-shaped pintle to the axletree instead of an upright bolt; this greatly facilitated the manœuvres of limbering and unlimbering, and admitted of an ammunition-chest being placed on the limber, the wheels of which were made interchangeable with those of the gun-carriage. A caisson provided with chests for the transportation of ammunition, constructed upon the general principles of the limber and gun-carriage, admitted of such mobility as to allow it to accompany its piece in all manœuvres. These improvements were soon adopted by all European nations, and in 1832 were introduced into the U. S. service and were the carriages used during the civil war. Within the last twenty years iron and steel have gradually replaced wood in the construction of field-carriages in most European services, and are now used in the U. S.

The systems of field and siege artillery in the U. S. were chiefly derived from those of France. After the war of 1812 with Great Britain the artillery arm was almost entirely neglected; no field-batteries were kept up, and the heaviest gun mounted on the seacoast in 1820 was a 24-pounder. The four regiments of artillery, though mostly garrisoning the forts of the Atlantic coast, performed little other than infantry duty; artillery as a science was not thought of, and as an art was scarcely at all practiced.

The British artillery, about the beginning of the French Revolution, had been greatly neglected, and was behind that of other nations. There was no reserve artillery, each regiment having two guns, whose horses and drivers were hired. As late as 1799 there were only two 6-pounders to a brigade of infantry; each piece was drawn by three horses tandem, the driver on foot with a long wagoner's whip.

Horse-artillery was, however, introduced in 1793, and a drivers' corps established the following year. In 1802 the battalion-guns were abandoned, and were replaced by field-brigades of mounted batteries and troop, or horse, batteries. The detachment of drivers with a field-brigade was an independent organization under its own lieutenant, who had no authority over the cannoneers and took rank after all the artillery officers proper. The drivers' corps was abolished in 1822, and men were enlisted for the Royal Artillery both as cannoneers and as drivers. The troop, or horse, artillery, however, continued to have drivers especially enlisted for that purpose, and to this faulty system the other batteries reverted after the Crimean war.

The proportion which field-artillery should bear to other troops in campaign depends upon the nature of the country and of the projected campaign, and the character of the troops comprising the army. In a wooded and broken country less artillery can be advantageously employed than in an open country with good communications, and more is required when the field of operations is limited than where long and rapid marches, made more for purposes of invasion than for fighting, are intended. More also is required when the army is composed of raw and inexperienced troops than when of well-instructed veterans. In the Crimean war the proportion of artillery was a fraction less than three guns per 1,000 infantry; in the Italian campaign of France and Sardinia against Austria, the proportion was between three and four pieces per 1,000; in the Seven Weeks war, the proportion was about the same; in the Franco-German war, the proportion was three guns per 1,000; and in the Russo-Turkish war it was a little greater. During the civil war in the U. S. the proportion was at first a little over three pieces for 1,000 infantry, but as the latter became more veteranized this was reduced to about two pieces. Much of this reduction, however, was due to the superior organization given toward the close of the war to the artillery, as hereafter mentioned. The proportion of artillery serving with cavalry is generally a fraction less than that for infantry. Improvements in small-arms have had a tendency to increase the value of artillery-fire, and nations that have had most recent experience are increasing the proportion of their field-guns.

In the U. S. the field-artillery of the army consists at present of ten mounted batteries, two to each regiment of artillery. The other ten batteries of each regiment are armed and equipped as infantry, and serve mostly in forts and garrisons on the seaboard.

During the war of 1812 with Great Britain, field-batteries were created by mounting foot-batteries from the artillery regiments. At the close of the war all these batteries reverted to the status of foot "companies," and none were mounted until 1836, when Capt. Ringgold succeeded in having his company organized into a field-battery. This was soon followed by three others—one from each of the regiments of artillery. The pieces for each battery were four 6-pounder bronze guns and two 12-pounder howitzers. The carriages and equipments were of the best-known pattern, and, under selected officers, these batteries soon acquired an astonishing degree of efficiency. One field-battery for each regiment was then the legal number. During the war with Mexico (1846–48) an additional field-battery to each regiment was authorized. These were all mounted during that war, but at the close of it were dismounted, and remained so until a short time before the outbreak of the civil war. When that war broke out (1861), a regiment of *light* artillery was added to the regular establishment, and a vast number of volunteer batteries were called into existence. During the Mexican war the field-batteries were attached, as a rule, to infantry divisions. There were no corps organizations during the war.

During the first year of the civil war a division of infantry of about 5,000 men was the highest organization, and to each division (in the Army of the Potomac, where the organization of all arms was the most complete) were attached three field-batteries, one of regulars and two of volunteers. By thus mingling the instructed batteries with those freshly raised, the latter acquired a knowledge of their duties with marvelous rapidity, and in the battles that ensued the field-artillery proved itself the strong point of reliance for the other arms. For a couple of years after the formation of army-corps during that struggle, the assignment of batteries to divisions continued. It was soon perceived, however, that this arrangement was faulty in the extreme. The batteries, by being attached to an arm of a

different nature, were badly provided for, and soon ran down in material. Their services were confined to the operations of the particular division to which they were attached, and frequently, from the nature of the ground or other causes, their full effectiveness was impaired or entirely misdirected, whereas if they had not been thus trammelled they could have been more advantageously used in other parts of the field. To a great degree it prevented the massing of artillery and the crushing effect of concentrated fire, and a large division of reserve batteries had therefore to be maintained for this purpose, and also for affording a recuperating place for the deteriorated divisional batteries. Toward the close of the war the divisional batteries of each corps were united and formed an artillery brigade, which was a distinct command, under a field-officer of suitable rank. Each of these brigades had its own staff and supply organization, and was thus enabled to maintain the batteries in the highest state of efficiency. This organization admitted of the most effective use of artillery on the field of battle, and consequently the proportion of artillery, which before had been three guns to a thousand infantry, was considerably reduced and reserves almost entirely dispensed with. The horse-artillery portion of the field-artillery was organized upon the same principle. These batteries operated, of course, with the cavalry, opened and maintained the actions for them in regular fields of battle, accompanied that body even on those rapid, and sometimes remote, "cavalry raids" upon the communications of the enemy which constituted so extraordinary a feature of that war. The services of this body of artillery could not possibly be excelled in brilliancy and *élan*.

During peace the mounted batteries of each regiment constitute a school for the purpose of diffusing throughout the regiment instruction in field-artillery service. The captains are changed when desirable, and the lieutenants after a tour of two years. In the event of war, all the batteries of a regiment can be mounted at the shortest notice and supplied with instructed officers.

The personal arms of an artilleryman of the field-batteries consist of a saber and a revolver for the officers and the non-commissioned officers, and a saber only for the drivers and the cannoners. During the civil war it was found that the saber was an encumbrance worse than useless, and it was therefore dispensed with in the field. The artilleryman of batteries not mounted is armed and equipped as an infantry soldier. The facings of the uniform for artillery are scarlet, otherwise the dress is the same as that for other troops. The pay of mounted batteries is the same as for cavalry; for all others it is the same as for infantry.

The *Drill Regulations* for field-artillery were originally adopted in 1844 from the French, and, although since revised a number of times, are essentially the same now, but, together with those for heavy guns and foot-batteries, have recently been modernized and simplified.

Heavy Artillery.—In 1862 Capt. Palliser introduced into England a method of converting smooth-bore cast-iron guns into rifles. This he did by inserting a tube of wrought iron or steel into the bore of the piece and rifling the tube. The rifled piece thus formed has a less caliber than the original gun, and in order to secure the requisite thickness of tube the original bore of the piece is reamed out to a greater diameter. The tube consists of two parts, called the A and B tubes. The former extends the entire length of the bore, and contains the rifling; the latter, or B, tube is shorter, envelops the rear part of the long tube, and is shrunk upon the latter, which is cut away for that purpose. The two tubes thus united have the same exterior diameter from end to end, and are made to fit accurately the bore of the cast-iron casing. The bottom of the tube is closed by a steel or iron cup-shaped plug screwed into the A tube. The tube is secured from slipping forward by a muzzle-collar screwed into the face of the piece, and from turning by a steel pin tapped through the casing into the tube. Formerly the tubes were inserted from the muzzle, but more recently the gun has been bored through the breech and the tube or tubes inserted from that end and closed by a screw breech-plug. This system of conversion worked so favorably in England that soon after its adoption there it was taken up in the U. S., with a view to utilizing the large stock on hand of smooth-bores. A number of 10-inch smooth-bores were converted into 8-inch muzzle-loading rifles, which, for their length, were very efficient guns, and which are still retained in service.

At the commencement of the civil war (1861), Mr. R. P.

Parrott, proprietor of the West Point foundry, New York, produced his system of guns. These guns are of cast iron, of about the usual dimensions, strengthened by a band or ring of coiled wrought iron shrunk over that portion of the breech surrounding the charge. The bodies of the larger Parrott guns are cast hollow, on the Rodman plan. Parrott guns consist of 300, 200, 100, 30, 20, and 10 pounders, the diameters of the bores being respectively 10, 8, 6, 4, 4.2, 3.67, and 3 inches, and weights of projectile 200, 150, 86, 28, 19, and 10 lb. A large number of these guns were used during the civil war, on both sea and land, and the amount of work done by them was very great. They were, in fact, the first rifles used in any country for bombardments and the breaching of masonry. The Lancaster gun at Sebastopol was scarcely an exception to this. Large numbers of Parrott guns were employed in the siege of Charleston (1863). These pieces successfully bombarded the city at a distance of 7,000 yards, and demolished the walls of Fort Sumter at distances varying from 3,500 up to 4,300 yards.

In the hasty preparation for hostilities consequent upon the outbreak of the civil war a number of old-pattern 24, 32, and 42 pounders were rifled, but proved of little service. At the siege of Fort Pulaski, Ga., in 1862, five of these, together with five 4.2-inch Parrotts, effected a breach in the heavy masonry of that fort in a few hours, firing from a distance of 1,650 yards. The Parrott guns, although in many instances showing wonderful endurance, are, nevertheless, liable to burst; especially was this the case with those supplied to the navy. This fact has caused them to be omitted from the system of artillery established for the U. S. service. There are, however, many of them still mounted in works.

In the matter of modern heavy guns it may be said that all civilized nations which attempt to keep their armaments up to a modern standard have adopted high-power steel breech-loading guns, and are replacing their older guns with them as rapidly as possible. There still remain in service, however, in nearly all nations a greater or less number of the older patterns, which are still efficient against all but the most heavily armored ships, and will probably be retained for a number of years in important places, and then be transferred for further use to those of less importance. Among these are the large muzzle-loading, smooth-bore, and converted rifled guns of the U. S., Turkey, and a few other nations; the muzzle-loading Armstrong guns of England, Italy, and Turkey; and the cast-iron, steel-hooped rifles of Italy and France.

Germany was the pioneer in the manufacture of steel cannon, and with the magnificent works of Krupp at Essen still leads the world in capacity for their manufacture. Krupp, besides supplying Germany, has furnished large numbers of guns to other governments. The calibers made at these works vary from light mountain-guns to the 120-ton gun of 15.75 inches. The standard calibers of Germany are 15.75, 13.97, 12, 9.45, and 5.87 inches.

Italy purchases her most powerful guns from Germany and England; she has mounted a number of 100-ton 17-inch Armstrong muzzle-loaders, and has purchased from Krupp a 119-ton, 40 cm. (= 15.75-inch) rifle capable of piercing 24 inches of steel at a mile. Great Britain has her Royal gun-foundry at Woolwich and Armstrong's and Whitworth's establishments to draw upon. She has 110-ton, 16.25-inch Armstrong guns mounted on some of her ships, and lesser calibers down to 4 inches, including certain wire-wound guns of 6 inches and 9.2 inches which have passed successful tests, but which have not yet been placed in service. Her modern rifles have the interrupted screw ferreture.

France has developed in a wonderful degree her gun-producing capacity, and at the factory of the Société des Forges et Chantiers de la Méditerranée, of which M. Canet is the director and originator of the system used, is turning out a large number of guns remarkable for their finish, beauty of manufacture, high initial velocity, and accuracy of fire. The calibers made range from 3.6 inches up to 16.8 inches, and the lengths of bore between 20 and 50 calibers. Besides the large number furnished to the French Government, this factory has also sold heavy guns in greater or less numbers to Greece, Spain, Portugal, Chili, and Japan.

The muzzle velocities obtained with the Canet guns vary between 1,605 feet per second for the 20 caliber up to 2,624 for the 50 caliber guns. A velocity of 2,661 feet per second has been obtained with a 36 caliber gun in actual trials.

Messrs. Schneider & Co., of the Creusot works, also man-

ufacture guns giving corresponding velocities; they guarantee with 6-inch 40 caliber guns 2,674, and with 9.6 and 12 inch 40 calibers 2,625, feet per second.

The U. S., although late in entering into the manufacture of modern steel rifles, has now (1893) made a fair beginning, and has established gun factories at Washington under the navy, and at Watervliet, N. Y., under the army. Both have made high-power rifles up to 12 inches caliber, which compare favorably with any made abroad.

The Bethlehem iron-works at Bethlehem, Pa., have built an extensive plant for the manufacture of iron, steel, and guns, and are now engaged in making both for the use of the Government.

The failure of several of the largest guns, and the difficulty of handling such large weights, together with the greatly increased power of the smaller guns, have led many of the best informed artillerists to think that no advantage results from the use of guns of more than 12 or 13 inches caliber; and this opinion seems to be rapidly gaining ground, although able men still advocate the use of 16-inch guns on land, even if they are not to be carried on ships.

The unceasing changes in calibers, lengths, and details of construction of heavy guns make it useless to try to give the detailed armament of any nation. It will not be attempted. Information upon these points may be obtained from the annual reports of the bureaus of intelligence of the War and Navy departments, and from the *Almanach de Gotha*.

The siege of Paris by the Germans in 1871, and the bombardment of Alexandria by the British in 1882, are instances of the work of which rifled ordnance is capable.

Following closely upon the introduction of rifled guns was that of rifled howitzers and mortars, and the results obtained were no less wonderful than for guns. So far as now known, the mortar was the first form in which artillery of a large size was used. At first they were employed to throw stone balls at great angles of elevation, which produced effect merely by their crushing force. Cast-iron shells were invented about 1480, and first used by the Turks at the siege of Rhodes. Since their first introduction as engines of war mortars have had various forms, chiefly as to shape and dimensions of the powder-chamber. Until 1861 all mortars had their trunnions cast upon the breech, and the elevation was given by means of a wooden quoin under the muzzle; since the above date all mortars made for the U. S. service, excepting the small cohorn, have been cast with their trunnions at the center of gravity, thus greatly facilitating their service. Mortars of very large caliber have from time to time been fabricated, but the largest is that now at Woolwich, England, constructed in 1857 by Mr. Mallet. It is

made in six sections (so as to be transported), which are fitted gas-tight and bound together by six staves; the breech is a solid forging set in a cast-iron base. This mortar has fired shells weighing 2,481 lb., containing a bursting-charge of 480 lb., to a distance of 2 miles. A small mortar (called the "cohorn," after its inventor), of such lightness as to be readily carried by a couple of men, has proved of great service in the field and in siege operations. A similar mortar has been devised for mountain-service, arranged so as to have the piece carried by one mule, while another carries the bed. Smooth-bore mortars have inherent defects as to accuracy of fire; it was to overcome these, and also to secure greater range for curved fire, that rifled mortars were devised (Fig. 5). Armstrong in 1864 constructed one—a

muzzle-loader—of 6.4-inch caliber which gave such good results that other nations were encouraged to take up the subject. Breech-loading methods were soon introduced, and rifled mortars upon this plan are now everywhere taking the

FIG. 5.—9-inch Krupp rifled mortar.

place of the old style smooth-bore muzzle-loaders. The calibers used are approximately 6, 8, 10, and 11 inches, and the lighter are in some instances mounted on carriages for field service (Fig. 6). For seacoast defense the U. S. is now building a large number of 12-inch rifled mortars which fire elongated projectiles, and are effective for ranges varying from 1 mile to 6 miles, and some up to 8 miles. There is every indication that they will be used for firing high explosives.

Wrought iron, and in some instances steel, have entirely superseded wood in the construction of carriages for heavy

FIG. 6.—6-inch Krupp rifled mortar.

ordnance. Various plans for checking recoil have been invented, but that most generally adopted is what is known as the "hydraulic buffer," but which in reality works with oil, glycerin, or some other non-freezing or corroding fluid,

FIG. 7.—16-inch (71 tons) Krupp gun, mounted on coast-carriage.

- | | | |
|---|---|--|
| A, 40-centimeter (15.75 in.) gun; length, 32 ft. 10 in. | F and G, Tangent and trunnion sights. | N, Hand-wheel for elevation, with train of wheels working on toothed elevating-arc O. |
| B, Breech-closer, showing (C) end of driving-screw. | H, Carriage, wrought iron. | P, Graduated disk, showing quadrant elevation, being set by reverse (inner) edge of elevating arc. |
| D, D, Studs for hooking on shot-guide. | I, Loading-platform. | Q, Q, Q, Handles for working traversing-gear. |
| E, E, Rings for rammer-pulley blocks. | J, Crane, pivoting vertically on pillar hinged horizontally at K with counterspring on arm L, beneath the carriage. | |
| | M, Chilled iron projectile. | |

contained in a cylinder similar to that of a steam-engine. A piston attached to the moving part of the carriage works back and forth in the cylinder, and is so arranged that the

rate of flow of the liquid from its front to its rear may be regulated. When the piece is fired, the sudden jar of recoil is taken up by the action of the fluid, and the top-carriage glides back with an easy motion. Pneumatic buffers upon the same principle are used in the U. S. for the 15-inch gun.

Fig. 7 is given to illustrate the necessary complications introduced into the construction of gun-carriages of heavy guns when worked by hand.

Various plans have been proposed of late years to secure a practicable disappearing gun-carriage—i. e. a carriage so constructed that the piece can be raised to a height sufficient to fire over a parapet, and then lowered so as to be loaded in a secure position behind the parapet. The Moncrieff "counterpoise gun-carriage," designed to effect this object, having given satisfactory results upon trial with short muzzle-loading guns, was extensively adopted by the English. In the U. S., Major King, of the Engineers, invented a "depressing-carriage" which upon trial also gave good results. This carriage consists of a chassis with an inclination to the rear of about 30 degrees. The top-carriage is attached to a counterpoise by a band composed of wire ropes. The counterpoise is a heavy mass of metal descending into a well in front of the chassis. When the piece is fired from the usual position the top-carriage slides back and downward, where it is caught by a brake and held until the piece is reloaded. A slight movement of the lever of the brake releases the top-carriage, and the gun ascends to the firing position. The great length of modern guns has rendered necessary the use of disappearing carriages and platforms worked by steam or hydraulic power. A number of these are still in the experimental stage, not having stood the test of war service, although introduced to a limited degree in seacoast works. Disappearing-carriages are intended to protect the piece and carriage as well as the cannoneers. The accuracy of modern artillery-fire increases the danger to the guns with which a work is armed, and the disabling of a piece is of greater moment now than formerly, when works were garnished with a great number of pieces, but of such small size as to be readily replaced when injured.

The artillery troops of the regular army of the U. S. consist of five regiments, each composed of 1 colonel, 1 lieutenant-colonel, 3 majors, 1 adjutant, 1 quartermaster, 1 sergeant-major, 1 quartermaster-sergeant, 2 principal musicians, and 12 batteries. Each battery consists of 1 captain, 2 first lieutenants, 2 second lieutenants, and 150 enlisted men (sergeants, corporals, artificers, musicians, and privates). In time of peace the President is authorized to reduce the battery organization to 1 captain, 1 first lieutenant, 1 second lieutenant, and 60 privates; practically, this number is but about 35. The law requires that one battery in each regiment shall be "mounted"—i. e. equipped with guns, horses, etc.—and gives the President discretion to mount as many of the others as the exigency of the public service may seem to him to demand. When not thus mounted the remaining batteries of artillery serve as heavy or garrison artillery, principally in the seacoast fortifications. See EXPLOSIVES, GUNPOWDER, ORDNANCE, PROJECTILES, MACHINE AND RAPID-FIRE GUNS, RIFLING OF ORDNANCE, etc.

JOHN C. TIDBALL.

Artillery, Schools of: Special schools for instruction in artillery have for many years been organized and maintained by the various nations of the civilized world as a component part of their military establishment. As early as A. D. 1515 such a school was organized by the Venetians. A few years later Charles V. established a school of artillery in Spain and another in Sicily. Toward the end of the next century (1679) a school of application for artillery was founded at Douai by Louis XIV. The engineers had a school at Mézières. Both of these schools passed through many vicissitudes and removals until 1802, when the two were combined at Metz, and continued there until that place passed into the hands of the Germans. After the close of the Franco-German war this school was reopened at Fontainebleau, where it now is. An artillery school was organized in Saxony at about the same date as that at Metz, and some years afterward similar schools were established by other states of Germany. The Artillery and Engineering School in Berlin is a technical school, and has a course of two years. In Sweden, Austria, and Russia artillery schools were in existence before the close of the seventeenth century. About the middle of the eighteenth century the artillery school at Woolwich was established in Great Britain.

In some nations the school is a joint one for artillerists and engineers, but this is exceptional, the general rule being to keep the instruction of these two scientific corps separate and distinct. In the U. S. an artillery school for practice was established at Fort Monroe, Virginia, in 1824, and it continued in existence for about six years, and as a practical school solely, when the exigencies of the military service (due chiefly to Indian wars) caused its discontinuance. In May, 1858, a school for practical and theoretical instruction was organized at the same place. This school languished after the first year and a half of its existence, and was finally brought to an end in 1861 by the great civil war. In Nov., 1867, an artillery school for theoretical as well as practical instruction was again established at Fort Monroe, and has since continued uninterruptedly up to the present date—1893. This school was organized under the command of Brevet Maj.-Gen. Barry, who remained at the head of it until 1877, when he was succeeded by Gen. Getty, 1877-83; Gen. Tidball, 1883-89; and Col. R. T. Frank, 1889.

The organization of the U. S. Artillery School, adopted in 1867, contemplates a course of studies and practical training not limited to what is necessary for merely expert artillerists, but one which aims to qualify officers for any duty they may be called upon to perform, or for any position, however high in rank or command, to which they may aspire in service. Such an advance is demanded by the progress made in the methods of warfare during the last twenty years, particularly as regards artillery, wherein improvement has been from almost primitive rudeness to the requirements of an exact science, combining with it many cognate branches heretofore considered of but little importance to a military man. With reference to the U. S. Military Academy, the artillery school is a post-graduate institution.

The *personnel* of the school consists of the commandant (both of the post and school), the directors of instruction, instructors and assistant instructors, and such other officers and troops as may be assigned to it for duty or instruction. The commandant, the two other field-officers of artillery on duty with it—who shall be directors of instruction—and the commanding officer of the Fort Monroe arsenal constitute the staff of the school. The adjutant of the post is *ex-officio* secretary of the staff and custodian of all records. The troops usually at the school are five foot-batteries of artillery (one from each regiment) and such officers and enlisted men as may be ordered to the school for instruction. The batteries are permanently assigned, and are called "instruction batteries." The officers for instruction are lieutenants, four to each battery, attached thereto for a tour of two years, commencing Sept. 1 of each alternate year. Prior to 1875 the course of instruction was for one year only. Experience proved this to be too short a period in which to accomplish all that was desired. The additional time allows of much more thorough and extended instruction.

In addition to the drawback arising, as just mentioned, from want of time, the school was greatly crippled during the first years of its existence for want of proper facilities for instruction. Aside from a few old and worn-out instruments obtained from the Engineer Bureau, there was nothing in that line. Text-books even were limited in number, and supplied from small sums received from time to time from the contingent fund of the War Department. In 1878 a small appropriation was granted by Congress. This has been continued annually since that time. By a judicious management of these appropriations the school facilities have been increased, until now they may be considered upon a very respectable footing. In the meanwhile other improvements were made, adding greatly to the convenience and comfort of the post and school. Among these may be mentioned new barracks for the soldiers, additional quarters for officers, and buildings for library, school-rooms, laboratories, etc.

The course of instruction is divided into six departments, as follows, viz.:

1. Engineering. Embracing land and topographical surveying and reconnoissance, field-works, permanent fortification, and siege-works.
- Steam and mechanical engineering. To include an elementary course on the steam-engine, mechanism, hydraulic power, and machinery.
2. Artillery. To include exterior and interior ballistics, the employment of artillery, artillery material, munitions, armor, etc.
3. Electricity and submarine mining. Consisting of a course of instruction upon theoretical and practical electric-

ity, and the theory and practical construction and use of submarine mines.

4. Chemistry and high explosives. Including lectures, laboratory work, and experimental work upon the different branches.

5. Military science. Including minor tactics, logistics, battle tactics, strategy, and military geography.

6. Practical military exercises. Including practical use of all classes of field, siege, garrison, and seacoast guns, howitzers and mortars, and machine-guns.

These departments are supplemented by instruction in photography, telegraphy, cordage, etc.

Students who pass successfully through the entire course of instruction are awarded a certificate of proficiency, and special reports are made in all cases of failure.

The military policy of the U. S. demands, above that of most other nations, that her means for military instruction should be of the most efficient nature. Unlike the states of Europe, she is not required to stand constantly in an offensive and defensive attitude toward contiguous neighbors. Her wars of magnitude are comparatively rare; those educated in the school of experience by one war pass beyond the period of active service before another occurs, and fresh armies have to be raised from the civil population and compelled to learn the practice of war under the most adverse circumstances. Particularly is this the case with artillery instruction, which, from the very nature of artillery service and material, can not, like that of other arms, be disseminated among the people by either the militia or the volunteer system. In consequence of the smallness of the regular army, the only means of securing efficient preparation for the use of artillery in war lie in providing for a corps of thoroughly trained artillery officers; consequently, the necessity of maintaining an artillery school of theory and practical application. See MILITARY ACADEMIES.

JOHN C. TIDBALL.

Artiodac'tyl [from Gr. *ἄρτιος*, complete, even + *δάκτυλος*, finger, toe]: a member of that division or sub-order of ungulates or hoofed mammals in which the number of toes is even, either two or four in all the existing forms. The axis of the foot passes between the third and fourth toes, which are equal in size and have their hoofs flattened on the inner side. In the perissodactyls the axis passes down the center of the third digit, and the number of toes is odd in all existing forms save the tapir. The artiodactyls contain two principal groups—the *Pecora* or ruminants, in which the stomach is compound, and the *Suina* or allies of the hog and hippopotamus, in which it is simple. D. S. JORDAN.

Artocarpa'ceæ [from Gr. *ἄρτος*, bread + *καρπός*, fruit]: a natural order of exogenous plants, of which the *Artocarpus incisa*, or breadfruit, is the type; it is regarded by some botanists as a sub-order of *Urticaceæ*. This order comprises more than fifty species, nearly all natives of tropical countries. See JACK-TREE.

Artois, aar-twaw' (anc. *Atreba'tes*): a former province of France, bordering on Flanders, in the department of Pas-de-Calais (see map of France, ref. 2-F). The capital of Artois was Arras. Artesian wells were named from Artois (in Latin, *Arte'sia*). Charles X. of France before his accession was Count of Artois.

Artotype: See PHOTOGRAPHY.

Arts, BACHELOR OF and MASTER OF: See DEGREES.

A'ru: a group of islands situated between lat. 5° 20' and 6° 55' S., and between lon. 134° 10' and 134° 45' E.; S. of New Guinea, nominally in the Dutch government of the Moluccas. There are five principal islands and many small ones. Total area about 3,000 sq. miles (see map of East Indies, ref. 8-K). The largest island is 70 miles long and 20 miles wide. Some of the natives have adopted Christianity. Here is a town called Dobbo, into which British goods are imported annually to the amount of about \$15,000. The exports are pearls, trepang, and birds of paradise. Pop. of islands, 7,750.

Arn'ba: an island of the Dutch West Indies; W. of Curaçoa and 20 miles N. of Cape St. Roman; peninsula of Paraguana (see map of West Indies, ref. 9-H). The capital is Oranjestad, with a fort named Zoutman (lat. 12° 28' N., lon. 70° 11' W.). Area, 69 sq. miles. Pop. (1891) 7,743.

A'rum [Lat. *a'rum*, Gr. *ἄρον*, wake-robin]: a genus of dicotyledonous herbaceous plants of the family *Araceæ*. This genus has a convolute spathe, the spadix naked at the point. In some of its species a stench like that of carrion is pro-

duced during flowering, and in some a remarkable degree of heat.

Arum Family: See AROIDS.

Ar'undel, THOMAS: Archbishop of Canterbury; b. at Arundel, 1353; became Bishop of Ely at the age of twenty-one; was at different times Lord High Chancellor of England (1386-89; 1391-96; 1399; 1407; 1412); Archbishop of York, 1388; Archbishop of Canterbury, 1396; was banished for complicity in the insurrection against Richard II., 1397; returned with Henry of Lancaster (Henry IV.), 1399, and took possession of his see; persecuted the Lollards and followers of Wiclif. D. at Canterbury, Feb. 19, 1413.

Arundel, THOMAS HOWARD: Earl of Arundel and Surrey; art collector; b. in London, 1592; made a famous collection of ancient sculptures bearing the name of the *Arundel Marbles*, which was presented to the University of Oxford in 1667. The principal portion of it is the *Parian Chronicle*, originally chronological tables of Greek history, from 1582-264 B. C. (interpreted by Boeckh in *Corpus Inscript.*, vol. ii.). D. in Padua, 1646. The Arundel Society, London, is named after him.

Arns'pices, or **Harus'pices** [Lat., literally entrail examiners, from *haru-*; cf. *hira*, entrails; Gr. *χορδή*]: Roman soothsayers, who foretold future events from the inspection of the entrails of the victims offered at the altars of the gods.

Aruwimi, aar-roo-wee'mee: a tributary of the Congo, rising to the N. W. of Albert Nyanza. Its general course is westward, and it empties into the Congo at the village or station of Aruwimi, or Basoko, in lat. 2° 40' N., after a course of about 600 miles. It receives various names in its course, as the Luhali, Novelli, Ituri. The name of the river is sometimes applied to the district of the Congo Free State through which it flows.

Ar'vad: ancient city of Phœnicia, on small island near mouth of the river Eleutherus; said to have been founded by the Sidonians and noted for the seafaring skill of the inhabitants.

Arval Brethren (in Lat. *Fratres Arvales*): a very ancient college of priests, at Rome, twelve in number, chosen by co-optation for life, from the highest families, and under the empire, including the emperors. They celebrated a yearly festival for three days in the latter half of May, offering sacrifices for the fertility of the fields. To their cult there are but few allusions in literature, but the minute details of their ceremonial are contained in a series of inscriptional records dating from 14-241 A. D., which have been found from time to time in the grove of the Dea Dia, 5 miles from Rome on the Via Campana. These were published under the title *Acta fratrum Arvalium*, by G. Henzen (Berlin, 1874). Since then other fragments have been discovered. See also *Birt* under Dea Dia in Roscher's *Lexikon der Griechischen und Römischen Mythologie* (columns, 966-975). M. WARREN.

Arvic'ola [from Lat. *arvum*, field + *-cola*, inhabitant]: a genus of small animals of the order *Rodentia*, allied to the rat and mouse. They are distinguished by the prismatic form and fangless structure of the molar teeth. The *Arvicola agrestis* (field campagnol) and the *Arvicola riparia* (bank campagnol) are natives of England. There are over twenty species, called field-mice, in the U. S.

Arvieux, LAURENT CHEVALIER, d': French traveler and Orientalist; b. at Marseilles in 1635. He negotiated a treaty with the Dey of Tunis in 1668, and was consul at Aleppo from 1679 to 1686. He wrote a *Treatise on the Manners and Customs of the Arabs* (1717). From his papers Labat compiled *Memoirs of Chevalier d'Arvieux, Containing his Travels in Asia* (6 vols., 1735). His works are commended by Niebuhr. D. in 1702.

Arivaipa: See ATHAPASCAN INDIANS.

Ar'widsson, ADOLF IWAR: b. at Padasjoki, Finland, Aug. 7, 1791; studied at the University of Åbo, and was appointed docent in history there in 1817. A periodical which he founded in 1821 was suppressed in the same year by the Russian Government, and in 1822 he was exiled. He went to Stockholm, where he was made director of the royal library. D. at Wiborg, Finland, June 21, 1858. He published, among other works, *Svenska Fornsänger* (3 vols., 1834-42); *Stockholm förr och nu* (1837-40); and a translation of the Icelandic *Saga of Frithjof* (*Frithjofs Saga*).

Revised by G. L. KITTEDGE.

Arx: in Roman archæology, a stronghold within, or closely connected with a city. The term is applied to the citadels of the towns of Italy, and those where the Roman civilization prevailed; thus we speak of the arx of Tusculum. The term is nearly equivalent to *acropolis* in a Greek city. The arx of Rome was one of the two high points of the capitoline hill, the other being the capitolium; it is not entirely certain which of the two was the arx, but it is generally thought to be where the Church of S. Maria in Ara Cœli, or, shorter, the Ara Cœli, stands.

RUSSELL STURGIS.

Ar'yan (also spelled *Arian*): a term which the stricter usage among modern philologists limits in application to the Indo-Iranians and the Indo-Iranian speech-family, i. e. the family whose chief ancient representatives are the Sanskrit and Zend. It represents a name which this people applied to itself in distinction to the darker-skinned peoples about it, and of which the Sanskrit form was *āria-* or *ārya-*. The etymology of the word is uncertain, as is usually the case with proper names, but it may perhaps signify "the band of the loyal." Many philologists, and especially anthropologists, have used the term in a broader sense to denote the whole family which is by others called the Indo-European or Indo-Germanic. Such is particularly the case in England, where, however, of late the term Indo-European has been gaining ground. Indo-Germanic is commonly used in Germany, Indo-European in France and the U. S. See **INDO-EUROPEANS** and **LANGUAGE**. BENJ. IDE WHEELER.

Ar'zachel: Jewish astronomer; b. in Spain, and lived about 1050–1100. He ascertained the obliquity of the ecliptic, and prepared astronomical tables, called *Toledo Tables*.

As (gen. **As'sis**): a Roman weight; also called **Libra**; nearly equal to the modern pound. It was divided into twelve uncia, "ounces," and was equal to 10 oz. 18 dwts. 13½ grs. Troy. *As* was also the name of a brass Roman coin which originally weighed a pound, but in consequence of the increase of the value of metal, compared with that of food and other commodities, it was gradually reduced to half an ounce. During the second Punic war the value of the *as* was about two farthings, but its weight and prices in Rome were so variable that its value can not be accurately fixed. See **SESTERTIUS**.

Asa'ba: the capital of the Niger territories in West Africa, and the seat of the government of the Royal Niger Company—a company controlling the greater part of the Niger basin. Asaba is on the Niger, 150 miles from the coast and 75 above the delta, in lat. 6° 20' N., lon. 7° E. (see map of Africa, ref. 5-C). Here resides the chief justice of the supreme court, and here are also the central prison, the civil and military hospitals, and other public buildings.

A'sa Du'eis (i. e. sweet asa): a drug highly prized by the ancients as an antispasmodic and diuretic. It was worth its weight in gold, and was obtained from a plant of the genus *Thapsia*, a native of Barbary and Southern Europe.

Asafœtida: See **ASSAFŒTIDA**.

Asagra'a [named in honor of Asa Gray, the botanist]: a Mexican plant which has bulbous stems, linear, grass-like leaves, and spikes of whitish flowers. The *Asagraea officinalis*, which is said to be the only species of this genus, produces the cebadilla-seeds from which the poison veratrine is prepared.

Asan'der (in Gr. Ἀσανδρος): Macedonian general; brother of Parmenio; appointed governor of Lydia by Alexander the Great in 334 B. C. After the death of that king he was satrap of Caria, an ally of Ptolemy, and an enemy of Antigonus, against whom he waged war about 314 B. C.

As'aph, Saint: cathedral city in the northwest of Flintshire, Wales (see map of England, ref. 8-E). The cathedral, one of the smallest in Great Britain, was built in 1284 on the site of a wooden structure founded before 596. Pop. (1891) 14,000.

Asarabac'ca: See **ASARUM**.

As'arum (Gr. ἄσαρον): a genus of herbaceous plants of the family *Aristolochiaceæ*; is distinguished by kidney-shaped leaves, twelve-horned stamens, distinct from each other and from the style, and by a bell-shaped, three-lobed perianth. *Asarum europeum* is a native of Europe. The roots and leaves are stimulant, purgative, and emetic, and contain a bitter principle or crystalline substance called *asarin*. *A. canadense*, a native of North America, called wild ginger, is

a stimulant and diaphoretic. Two other species grow in the Atlantic States. Also called *Asarabacca*.

As'ben, called also **A'ir**: a kingdom of the Southern Sahara, bordering on the Sudan, of considerable but ill-defined area, now within the French sphere of influence. It is in the Niger drainage-basin, but its rivers are usually dry. It is on a great caravan route from the north to Sokoto. It includes a large tract of desert, and some fertile land which produces dates. The climate is hot and dry. Capital, Agades, with a population of about 7,000.

Asbes'tos, or **Asbestos** [Gr. ἄσβεστος, unquenchable; ἀ-, not + σβεννύναι, quench. Originally applied by the Greeks to unslaked quicklime; Pliny, to whom the present perverse use of the term is due, probably applied it in the sense of "inconsumable"]; a fibrous mineral composed of fine, flexible, and easily separable filaments of a silky luster. It is a variety of actinolite and tremolite, and consists chiefly of silica, magnesia, and lime, or pyroxene. The fibers of a very silky variety of asbestos are called amianthus. Asbestos may be woven into cloth which is incombustible, and if soiled may be cleansed by fire. The ancients wrapped the bodies of the dead in such cloth, in order that when they were burned on the funeral pyre their ashes might be kept separate. It was also used for the wicks of the lamps in the temples. Mountain-cork and mountain-leather are varieties of asbestos. It is now employed as a material for roofing, boiler-felting, night-lamp wicks, steam-packing, and paper-stock. Asbestos is abundant in Canada, Corsica, Savoy, the Valtelline, and the Tyrol. Seventy-one tons were mined and marketed in the U. S. in 1890.

Asbjörn'sen, aās-byörn'sen, PETER CHRISTEN: b. in Christiania, Norway, Jan. 15, 1812; studied botany and zoölogy; visited Asia Minor and Egypt in 1849–50; spent two years at the academy of Tharand, Saxony, 1856–58, and on his return was appointed inspector-general of the forests of Norway. Besides a number of popular books on natural history and essays on forest culture, he published *Norske Folke-Eventyr* (1842–43) in connection with Jorgen Moe; an additional collection of the same in 1871 (2d ed. 1876); and *Norske Huldreeventyr og Folkesagn* (1845–48; 3d ed. 1870). D. in Christiania, Jan. 6, 1885.

Revised by G. L. KITTEDGE.

As'boline [from Gr. ἄσβολος, soot]: a nitrogenous substance found in soot.

As'both, ALEXANDER SANDOR: Hungarian officer; b. at Keszthely, Hungary, Dec. 18, 1811; fought under Kossuth in the revolution of 1848, and in 1851 removed to the U. S. He entered the Union army on the breaking out of the war in 1861, distinguished himself in various engagements, and was made a major-general in 1865. He was minister to the Argentine Republic in 1866, and died at Buenos Ayres, Jan. 21, 1868.

As'bury, FRANCIS: Methodist bishop; b. at Handsworth, Staffordshire, England, Aug. 20, 1745, of Methodist parents; was converted at the age of thirteen; became a local preacher at sixteen; an itinerant under Wesley at twenty-two; removed to America in 1771 as missionary; in 1772 became Wesley's "general assistant" in America. In 1784 he was elected bishop of the new Methodist Episcopal Church, and was consecrated by Bishop Coke. His labors and success in establishing his Church (chiefly in fields where churches were almost unknown) are among the most remarkable of which history bears record. D. at Spottsylvania, Va., Mar. 31, 1816. See *Asbury's Journals* (New York, 1852), and life by W. P. Strickland (1858).

Asbury Park: a noted summer resort on Atlantic coast of Monmouth co., N. J. (for location, see map of New Jersey, ref. 4-E); about 5 miles S. of Long Branch; has seven churches, a fine opera-house, electric street-railway, artesian water-works, and complete sewer-system. Pop. (1880) 1,640; (1890) 3,815; (1900) 4,148. EDITOR OF "JOURNAL."

As'calon (in Gr. Ἀσκάλων), called *Ash'kelon* in the Bible: one of the five capital cities of the Philistines, a former seaport of Palestine, 10 miles N. of Gaza, 12 S. by W. of Ashdod or Azotus, and 42 W. S. W. of Jerusalem. It was a place of much importance; the seat of the Philistine licentious Astarte worship; its temple was plundered by the Seythians, B. C. 625. Herod the Great was born there. It was taken by the crusaders, A. D. 1099; partially destroyed by the Saracens, but rebuilt by Richard Cœur de Lion. Its first fall came when its small and insecure harbor was filled with

stones by the Sultan Bibars, A. D. 1270. It is now a small village called *Asculan*, and has extensive ruins.

Revised by S. M. JACKSON.

As'caris (Gr. *ἀσκαρίς*): a genus of intestinal parasites, of which the most common is the roundworm, *Ascaris lumbricoides*, found in the intestines of man. Children frequently have them, principally in the small intestines. The body of this worm is round, elastic, with a smooth surface, of a reddish or yellowish color; it tapers especially toward the anterior extremity, which commences abruptly by three tubercles which surround the mouth. The body is transversely furrowed with numerous fine lines, and marked also with four lines from head to tail. In the female there is usually a constriction of the body at the distance of about one-third of its length from the mouth. Sometimes, especially in young and weakly children, their accumulation may cause serious reflex disturbances; even convulsions may be thus produced. There are no symptoms (apart from the passage of the worms from the bowels) invariably connected with their presence. Itching of the nose, capricious appetite, swelling of the abdomen, and grinding the teeth when asleep may all occur, but they may also be produced by other causes. *Oxyuris vermicularis*, the small white threadworm or seatworm, was formerly classed as an *Ascaris*, but is better called *Oxyuris*. Its length is from two-twelfths to five-twelfths of an inch, the female being larger than the male. The head is blunt, widening on each side; the body tapers (at least in the female) to a point. Seatworms, by the itching they produce, often distress children very much; they are less frequently met with in adults. For *treatment* of worms, see ANTHELMINTICS. As a common name *Ascarides* is the plural of *Ascaris*. Revised by WILLIAM PEPPER.

Ascawa'na Lake: a beautiful sheet of water, 2 miles long and 1 mile wide, in Putnam valley township, Putnam co., N. Y. It is a place of summer resort.

Ascension: an island in the Atlantic Ocean, 750 miles N. W. of St. Helena; belongs to Great Britain (see map of World, ref. 6-I). It has an area of 35 sq. miles. It is volcanic and mountainous, one peak rising to the height of 2,870 feet. It has a fort in lat. 7° 55' 55" S. and lon. 14° 25' 5" W. Turtles, vegetables, and birds' eggs are procured here. It was discovered in 1501 by the Portuguese on Ascension Day, but was uninhabited till Oct. 15, 1815, when the English took possession of it, and established a military station there after the arrival of Napoleon Bonaparte at St. Helena. It is used as a coaling, victualing, and store dépôt for British ships on the west coast of Africa. Chief town, Georgetown, a British naval station. The island is a sanatorium for the Europeans of West Africa. Pop. about 360.

Ascension [from Lat. *ascensio*, an ascent]: in astronomy, see RIGHT ASCENSION.

Ascension Day, or **Holy Thursday**: one of the great religious festivals of the Roman Catholic and Anglican Churches, held on the fortieth day after Easter, to commemorate the ascension of Christ into heaven. Ascension Day has been observed at least since 68 A. D., and perhaps earlier. St. Augustine speaks of it as universally observed in the Church, and contends that it must have been instituted either by the apostles themselves or the bishops immediately succeeding them. This feast concludes the cycle of festivals of our Lord, and is marked out in the English and American Prayer-books, by the proper preface provided for it in the communion office, as one of the great festivals to be observed with the administration of the Eucharist daily during the octave.

Asect'icism [from Gr. *ἀσκητής*, hermit, one who disciplines himself; deriv. of *ἀσκειν*, practice, discipline]: a voluntary retirement from the world and the practice of acts tending to mortify the body; so called from the rigid discipline to which the devotee subjects himself, the object of the ascetic being to advance the spiritual interest of himself or others. Asecticism was practiced among Jewish and pagan nations long before the time of Christ, especially in India. The Essenes in Judæa and the Therapeutæ in Egypt were bodies of Jewish asectics. At the present day asecticism is most prevalent among Brahmaus, Buddhists, and Christians of the Armenian, Coptic, Greek, and Roman Catholic Churches. Early in the second century zealous members of the Christian Church devoted themselves to lives of poverty, celibacy, and abstinence from all sensual gratification. Some of these remained among men, others dwelt apart as hermits. The union of numbers of hermits

into one body was first made by Pachomius, 340 A. D. This was the virtual origin of MONASTICISM (*q. v.*).

Ascet'ies: those who practice ASCETICISM (*q. v.*).

Asch: a town of Austria; in Bohemia; 100 miles W. of Prague (see map of Austria-Hungary, ref. 3-C). It has factories of linen, calico, paper, hosiery, and leather goods, and many dyeing establishments and breweries. Pop. 15,557.

Aschaffenburg: a town of Bavaria; in the circle of Lower Franconia; on the right bank of the Main, 24 miles by rail E. S. E. of Frankfort (see map of the German Empire, ref. 6-D.) It has a royal castle, a Gothic church, a library of about 22,000 volumes, a hospital, a gymnasium; also manufactures of woolen goods, paper, straw goods, etc. It belonged to the Elector of Mentz for many centuries, and was ceded to Bavaria in 1814. A victory of the Prussians over the Austrians was gained here July 14, 1866. Pop. (1890) 13,275.

As'cham, ROGER: English scholar and writer; b. at Kirby Wiske, near Northallerton, in Yorkshire, in 1515. He graduated at St. John's College, Cambridge, in 1534, became a fellow, and distinguished himself as a classical scholar. In 1544 he published a work in defense of archery, entitled *Toxophilus*, which is remarkable as a specimen of pure English style. He was appointed in 1548 tutor to the Princess Elizabeth, whom he instructed in Greek and Latin, but he resigned that position in 1550. Soon after this event he was sent as secretary of embassy to the court of the Emperor Charles V., and passed three years in Germany. Although he was a Protestant, he was appointed Latin secretary to Queen Mary in 1553, and after her death (in 1558) he was retained at court in the double capacity of secretary and tutor to Queen Elizabeth, who again took lessons in Greek and Latin. He remained at her court until his death in London, Dec. 30, 1568, having by his prudence or good fortune passed through very perilous times without persecution or dishonorable temporizing. His chief work, *The Schole-Master* (1570), contains excellent advice on the subject of teaching Latin. His complete works were edited by J. A. Giles (London, 1864-65, 3 vols.). See Dr. Johnson's *Life of R. Ascham*, prefixed to his works (1767); E. Grant, *De Vita Rogeri Ascham* (1576) is the original source, but the best life is in German by A. Katterfeld (Strassburg, 1876).

Asch'bach, JOSEPH: German historian; b. at Höchst, near Frankfort-on-the-Main, April 29, 1801. He became Professor of History at Bonn 1842, and in 1853 at Vienna. He was ennobled 1870, retired 1872. D. in Vienna, April 25, 1882. His most important works are a *History of the Emperor Sigismund* (4 vols., 1838-45); *Allgemeines Kirchenlexicon* (4 vols., 1846-50); and *Roswitha und Conrad Celtes* (1867). He also wrote a *History of the Visigoths* (1827); a *History of the Omeyyades in Spain* (2 vols., 1829-30); and a *History of Vienna University* (3 vols., 1865-88).

Asch'ersle'ben: a town of Prussia; province of Saxony; on the river Eine; 18 miles W. S. W. of Magdeburg (see map of German Empire, ref. 4-F). It has about seven churches, one synagogue, and a gymnasium, and is surrounded by a strong wall. Here are manufactures of flannel, frieze, linens, pottery, and brandy. Pop. (1890) 22,893.

As'cians, or **As'cii** [from Gr. *ἄσκιος*, shadowless; *ἄ-*, not + *σκιά*, shadow]: the people of the torrid zone, who twice in the year have the sun perpendicularly above their heads, and hence are without shadow.

Ascid'ia, or **Ascid'ians** [from Gr. *ἀσκίδιον*, dimin. of *ἀσκός*, leathern bottle]: a sub-class of animals belonging to the class *Tunicata*. The words ascidian and tunicate have often been used as synonyms. They are flask-shaped, attached by one end, and inclosed in a gelatinous or leathery tunic, and have the mouth and the anal orifice usually close together. This external tunic was formerly regarded as corresponding to the mantle of the mollusks, with which the tunicates were associated. The greater part of the cavity of the mantle is occupied by the branchial sac, which has numerous slit-like perforations, and serves at once as pharyngeal cavity and as respiratory organ. They have no eyes or other organs of special sense, but they have hearts and a circulation of blood, with a remarkable peculiarity that its direction is sometimes reversed. In their mature state they are fixed by the base to some solid substance, as a rock or seaweed, but the young, resembling tadpoles in form, swim by means of a vibratile tail, which disappears when they

settle. These young forms are in many respects fish-like, a fact which has led naturalists to the conclusion that the group of tunicates are degenerate descendants from a fish-like type. The majority of the group are solitary or simple forms, but some of them live in colonies formed by budding, the members of which are connected by a stem, though each has its own heart, respiratory apparatus, and digestive organs. In other kinds, called compound ascidians, the tunicates of many are united into a mass, and they form systems like zoöphytes. The individuals in these systems have always sprung by gemmation from one, and both the solitary and compound ascidians propagate by eggs. "In the dim obscurity of the past," says Darwin, "we can see that the early progenitor of all the *Vertebrata* must have been an aquatic animal provided with branchiae, with the two sexes united in the same individual, and with the most important organs of the body (such as the brain and heart) imperfectly developed. This animal seems to have been more like the larvæ of our existing marine ascidians than any other known form." *Descent of Man* (vol. ii., p. 372). See TUNICATA.

Revised by DAVID S. JORDAN.

Ascidi'um [for etymology, see ASCIDIA]: in botany, a hollow, pitcher-shaped body which occurs on the leaves of certain plants, as *Nepenthes* and *Sarracenia*. It usually contains water, and is sometimes furnished with reflexed hairs, which prevent the escape of insects that fall into it. (See NEPENTHES.) In zoölogy, a genus of tunicates belonging to the *Ascidia*.

Ascit'es [from Gr. ἀσκίτης (sc. νόσος, disease), a kind of dropsy; from ἀσκός, leathern bottle]: dropsy of the abdominal cavity is most frequently an indication of portal obstruction caused by "cirrhosis" or other disease of the liver, which hinders the return of venous blood to the heart and causes pressure in the veins, leading to transudation of serum into the peritoneal (abdominal) cavity, whence the name. In other cases it is a symptom of general dropsy; or it may result from cancer or tubercle of the peritoneum; or, in children especially, it may appear as a temporary and quite inexplicable phenomenon, without serious danger or distress. Ascites must be regarded in almost all cases as a very grave symptom of disease, yet there are not a few cases where the immediate danger passes away, and the patient becomes for the time comfortable; but such results are temporary and unfrequent. The treatment is governed by the cause, but is largely palliative. Diuretics may be useful, but hydragogue cathartics are much more effective in relieving the symptom. Tapping may be practiced where the dropsy very seriously distends the abdomen.

Revised by WILLIAM PEPPER.

Asclepiada'ceæ: See MILKWEED FAMILY.

Asclepi'adæ [Gr. Ἀσκληπιάδαι]: among the ancient Greeks, those who were reputed to be the descendants of Æsculapius, the god of medicine; afterward those who were trained in his temples (Asclepiions) in the science and art of healing. Aristotle, though not a physician, was one of the family of the Asclepiadæ. Young men designed for the medical vocation, if sons of physicians, began their studies before their twentieth year; others, after a preparatory education lasting from the seventeenth to the twentieth year; in both, the special medical training probably did not end before their twenty-fifth year. Much secrecy and exclusiveness were observed in their initiation; and after the first ordeal of preparation had been passed, at the commencement of the ceremonies of illumination, the HIPPOCRATIC OATH (*q. v.*) was administered to the candidate. At the close of the period of training came the ceremony of coronation, by which the young Asclepiadæ were fully introduced into the profession of medicine. See Watson, *Medical Profession in Ancient Times* (New York, 1856).

Asclepiade'an Verse [from its inventor, *Asclepiades*]: a logædic measure (see LOGÆDIC) made up of trochees and irrational dactyls. In Horace the first foot is always a spondee. The Lesser Asclepiadean runs thus:

Ma'ece | na's ata | vi's || e'dite | re'g i | bu's. *Od. i. i. 1.*

The Greater Asclepiadean thus:

Tu' ne | quae'sie | ri's || se'ire ne | fa's || que'm mihi | qu'em ti | bi'.
Od. i., xi. 1.

See Schmidt's *Rhythmic and Metric*, transl. by White (pp. 97-99).

Asclepi'ades [in Gr. Ἀσκληπιάδης]: celebrated Greek physician; b. at Prusa, in Bithynia; flourished about 100 B. C.

He practiced at Rome, where he founded a school, and was very popular with the Romans on account of his pleasant and simple remedies. His maxim was that a physician ought to cure his patients safely, speedily, and agreeably. He relied much on diet, bathing, and exercise or gestation. He wrote several works, of which only small fragments are extant. See C. G. Gumpert, *Asclepiadis Bithyni Fragmenta* (Weimar, 1798); G. F. Bianchini, *La Medicina d'Asclepiade* (Venice, 1769); A. G. M. Raynaud, *De Asclepiade medico ac philosopho* (Paris, 1862).

Ascle'pias [named, on account of its medicinal virtues, from Ἀσκληπιός, the Greek name of Æsculapius, the god of medicine]: a genus of perennial herbaceous plants, the type of the family *Asclepiadaceæ*, mostly natives of the U. S. The corolla is wheel-shaped and reflexed, the crown or coronet is fleshy, and each of its hooded appendages has an incurved horn. The *Asclepias cornuti* (or *A. syriaca*) (milkweed or silkweed) is an American plant, abounding in an acrid milky juice, which contains caoutchouc. The seed-vessels are filled with a silky down, which is sometimes used for stuffing pillows. The fiber of the stem is said to be valuable for ropes. The *Asclepias tuberosa*, sometimes called pleurisy-root or butterfly-weed, has handsome flowers. Its root is used as an expectorant and diaphoretic. Many other species of *Asclepias* grow in the U. S.

As'coli. GRAZIADIO ISAIA: the most eminent linguistic student Italy has produced in the nineteenth century; b. at Göritz, of Jewish parents, July 16, 1829; became Professor of Comparative Philology in the Accademia Scientifico-letteraria of Milan in 1860; made senator in 1889. He is one of the small group of eminent scholars in Europe and America (e. g. Bopp, Brugmann, Whitney) who have given to the study of language its rigidly scientific character. His investigations have extended to very widely diverse fields, and everywhere have led to brilliant results. In his *Studj orientali e linguistici* (1854), and his *Fonologia comparata del sanscrito, del greco e del latino* (1870), as well as in his *Saggi indiani*, published in the *Archivio glottologico italiano*, he has shown himself a master of the larger science of comparative Indo-Germanic philology. His brilliant studies in Romance philology (Wallach, Roumanian, Rhaeto-Romansch, and especially in the dialects of Italy) have given a firm basis to important divisions of this science. His *Saggi ladini* (also first published in the *Archivio*), in which these studies are summed up, must long remain essential for the study of the origins of the Italian and more closely allied Romance tongues. His Celtic researches also have been most fruitful; and he has touched upon the Semitic languages. He was the founder in 1873 of the *Archivio glottologico italiano*, a review which has continued to be the organ of the best Italian students of language. See his *Studj Critici* (Torino, 1877), German trans. by Merzdorf, *Kritische Studien zur Sprachwissenschaft* (1878); also, *Vorlesungen über die vergleichende Lautlehre des Sanskrit, des Griechischen und des Lateinischen* (trans. by Bazzigher and Schweizer-Sidler), 1872. A. R. MARSH.

Ascoli di Satria'no: an episcopal city of Italy, in the province of Foggia; 25 miles by rail S. E. of Foggia, on the eastern slope of the Apennines (see map of Italy, ref. 6-G). Near it, Pyrrhus, in 279 B. C., won a great victory over the Romans, and in 1246 A. D. an imperial army crushed the Apulian insurgents led by Cardinal Rainer. Pop. about 10,000.

Ascoli-Piceno, aas'kō-lēē pee-chay'nō: a province of the Marches, Central Italy; bounded N. by Macerata, E. by the Adriatic Sea, S. by Teramo, and W. by Perugia. Area, 808 sq. miles. The province consists chiefly of mountain-ridges running parallel to each other, the portion on the coast being of superior beauty. Chief town, Ascoli-Piceno. Pop. (1879) 210,610; (1890) 214,927.

Ascoli-Piceno (anc. *Asculum Picenum*): an old episcopal city of Central Italy; province of the same name, situated on a hill and on the river Tronto, 53 miles S. of Ancona (see map of Italy, ref. 5-E). It commands a fine view of the Apennines, a few miles distant. It is well built, and has a cathedral, a museum, a theater, a library, and many private palaces. It was annexed to the Papal States in 1426. A battle was fought here between Tancred of Sicily and the Emperor Henry VI. of Germany, in which the latter was defeated (1190). Pop. 23, 847.

Ascomyce'tes [literally sac-fungi; from Gr. ἀσκός, bag + μύκης, -ητος, mushroom]: a class of (mostly) parasitic plants

much degraded from general red seaweed type. They produce enlarged end-cells which divide internally into spores. These spore-sacs are known as *asci* (sing. *ascus*), and the spores as *ascospores*. The class may be divided into seven orders: viz., (1) simple sac-fungi (*Perisporiaceæ*); (2) subterranean sac-fungi (*Tuberoideæ*); (3) black-fungi (*Pyrenomycetæ*); (4) lichens (*Lichenes*); (5) eup-fungi (*Discomycetæ*); (6) rusts (*Uredineæ*); (7) smuts (*Ustilagineæ*). These include many families, not a few of which are composed of very harmful parasites. With the sac-fungi are commonly associated three orders of "imperfect fungi," viz., *Sphaeropsidæ*, *Melanconieæ*, and *Hyphomycetæ*. Although the details of the structure of these latter are not fully known, it is probable that they are sac-fungi. Of the sac-fungi proper about 13,000 species are known, and of the "imperfect fungi" about 8,000.

CHARLES E. BESSEY.

Asco'nus Pedia'nus, QUINTUS: Roman critic and commentator; b. probably at Padua, and lived from about 3-88 A. D. He taught at Rome, and wrote a reply to the critics of Vergil. Among his works were valuable commentaries on Cicero's *Orations*. Poggio Bracciolini found in 1416 at St. Gall commentaries on these orations—*In Verrem*, *In Divinationem*, *Pro Cornelio*, *In Toga Candida*, *In Pisonem*, *Pro Scauro*, and *Pro Milone*. The first two of these are no longer considered genuine by scholars. (Best edition of genuine commentaries by Kiessling and Schoell, Berlin, 1875.) He wrote a *Life of Sallust*, which is not extant. M. W.

Ascut'ney Moun'tain: an isolated mass of granite in Windsor co., Vt., 3,165 feet above the level of the sea (see map of Vermont, ref. 8-C). Its summit affords an extensive and beautiful view of the valley of the Connecticut river.

Asel'li, GASPARO: an Italian anatomist and physician; b. at Cremona about 1580. He became Professor of Anatomy at Pavia, and acquired distinction by the important discovery of the lacteal vessels in 1622. He wrote on this subject a treatise entitled *De Lactibus sive Lacteis Venis* (published in 1627, a year after his death).

Asexual Generation: See ALTERNATION OF GENERATIONS.

Asfeld, CLAUDE FRANÇOIS BIDAL, Marquis, d': an able French general; b. in 1667. He served with distinction in Spain, and commanded the French cavalry at Almanza in 1707. He was second in command under Villars in Italy in 1733, was commander-in-chief in Germany in 1734, and became a marshal of France in that year. D. Mar. 7, 1743.

Asgard: the heavenly residence of the Scandinavian gods. See SCANDINAVIAN MYTHOLOGY.

Asgill, Sir CHARLES: British general; b. in 1762. He served against the U. S., and having been captured at Yorktown was selected by lot from the prisoners to be hung in retaliation for the death of an American officer, but he was saved by the intercession of the French court. D. in 1823.

Ash: an important tree of the genus *Fraxinus* and family *Oleaceæ*, distinguished by imperfect flowers, sometimes destitute of corolla, and leaves unequally pinnate. The fruit (*samara*) is winged. The genus *Fraxinus* comprises about thirty species, mostly natives of Europe and North America, and valuable for timber, for fuel, and shade trees. The *Fraxinus excelsior*, the common ash of England, is a beautiful ornamental tree, and the timber is much esteemed by carpenters, joiners, coachmakers, and wheelwrights. It grows to the height of 100 feet or more. Cultivation has produced several varieties of it, among which is the weeping-ash, the branches of which droop nearly to the ground. The *Fraxinus ornus*, or flowering ash, a native of Southern Europe, has more perfect flowers than the other species. A saccharine substance called manna is obtained from it by making incisions in the bark, and sometimes exudes spontaneously. Among the noblest trees of the genus is the *Fraxinus americana*, or white ash, which is abundant in the Northern and Middle U. S. Its leaflets are petiolate, ovate, or lance-oblong, entire, acuminate, and in autumn are changed to a dark brown or purple tint. The timber is tough, and valuable for the same purposes as the *Fraxinus excelsior*. In the forests of the U. S. occur also *F. viridis* (green ash), *F. pubescens* (red ash), *F. quadrangulata* (blue ash), and others. The black ash (*F. sambucifolia*) has a tough wood separable into thin layers, and is used in basket-making. The mountain-ash, conspicuous for its clusters of red berries, is a species of *Pyrus*, having no affinity with the genus *Fraxinus*.

Revised by CHARLES E. BESSEY.

Ashan'tee: an extensive kingdom of Western Africa, Upper Guinea, nominally tributary to the British Gold Coast colony; is between lat. 5° and 9° 30' N., and between lon. 0° 55' E. and 4° 7' W. It lies inland from the coast between the Volta and Comoe rivers. Area about 40,000 sq. miles. Population estimated at from 1,000,000 to 3,000,000. It is generally mountainous, well watered and fertile, and covered with dense forests, which are almost impenetrable. The staple products are maize, rice, sugar, yams, tobacco, cocoanuts, gums, and dyewoods. Gold is said to be abundant here, and the chief articles of export are gold-dust, palm oil, and slaves. The people are warlike and fierce, and human sacrifices are common. They have some skill in the manufacture of sword-blades, cotton cloths, and golden ornaments. The government is a despotism. Capital, Coomassie (or Kumassi). The British, who have a fort on the coast at Cape Coast Castle, were involved in a war with the Ashantees, which began in 1807, and continued until 1825. The Dutch also had a colony on the coast until 1871, when they ceded it to the British.

In 1873 a war arose between the Ashantees and the British, because the British refused to pay the annual tribute to the King of Ashantee which the Dutch had formerly paid him. The Ashantees first attacked the Fantis, living under British protection, entirely defeated them, and subsequently succeeded in driving all the natives friendly to the British into the two forts, Elmina and Cape Coast Castle. The British troops under Sir Garnet Wolseley then invaded Ashantee, pushed forward directly toward Coomassie, and after some fighting took it and burned it. The King of Ashantee agreed to pay an indemnity to the British, and the war ceased. Trouble having again arisen in 1895, another expedition, under Sir Francis Scott, was sent. Coomassie was taken, a protectorate declared, and the king carried to Cape Town as a hostage, Jan., 1896.

Ash'burton, ALEXANDER BARING, Lord: an English diplomatist; b. in London, Oct. 27, 1774; was a son of Sir Francis Baring, an eminent merchant. He was employed in his youth in mercantile affairs in the U. S., and married a daughter of Senator William Bingham of Pennsylvania (1798). In 1810 he became the head of the firm of Baring Brothers & Co. of London. He represented Taunton (1806-26), Callington (1826-31), Thetford (1831-32), North Essex (1833-35), in Parliament, in which he acted with the Liberal party until 1831, when he became a supporter of Sir Robert Peel and a moderate Conservative. He was created Baron Ashburton in 1835. In 1842 he was sent as a special ambassador to the U. S. to settle a dispute which had long been pending in relation to the northeastern boundary. He was selected for this mission because he was acquainted with the American people and institutions, and was inclined to a pacific policy. Lord Ashburton and Mr. Webster negotiated this important treaty, which was signed at Washington in Aug., 1842, and was called the Ashburton Treaty. For this service Parliament accorded him a complimentary vote of thanks. D. at Longleat, May 13, 1848, and was succeeded by his son, William Bingham Baring.

Ashby, TURNER: a Confederate general; b. at Rose Hill, Fauquier co., Va., 1824. He was appointed a brigadier-general in 1862, and was greatly distinguished as a cavalry commander. During Banks's pursuit of Jackson in the Shenandoah valley, Gen. Ashby was in command of cavalry covering the rear of Jackson's army, and in an engagement near Harrisonburg, June 5, 1862, he was shot through the body and killed. His loss was severely felt by the Confederates, he being one of their ablest and bravest cavalry leaders.

Ashby-de-la-Zouche, -zooch': a market-town of England, in Leicestershire; 20 miles by rail N. W. of Leicester (see map of England, ref. 9-H). It has a ruined castle in which Mary Queen of Scots was once confined, and an ancient church in which was the burial-place of the Hastings family. Here are iron smelting-works and manufactures of hats and hosiery. Coal mines and salt-springs occur in the vicinity. Pop. 8,500.

Ash'dod, or **Azo'tus** (modern *Asdood* or *Esdūd*): an ancient city of the Philistines, in Palestine, about 3 miles from the Mediterranean and 12 miles N. E. of Ascalon (see map of Palestine, ref. 10-B). It was an important city and stronghold of the Philistines, who, after defeating the people of Israel in the time of Samuel, captured their ark and carried it to the temple of Dagon in Ashdod. It was dismantled by Uzziah, besieged by Psammetichus, and destroyed by the

Maccabees. It is called *Azotus* in the New Testament (Acts viii. 40). Near its site is a village of mud-houses called *Asdood* or *Esdûd*, on the sea 21 miles S. of Jaffa.

Ashe, JOHN: a general and patriot of the Revolution; b. at Grovelly, Brunswick co., N. C., in 1720: he took an active part in the political movements which preceded the Revolution, and served as a brigadier-general during the war. D., a prisoner of war, in Sampson co., N. C., Oct. 24, 1781.

Ash'e, or Ashi: Jewish rabbi of Sora, in Babylonia (353-427 A. D.). He was eminent for his learning and genius, and was the founder of the Babylonian *Talmud*. Devoting his life to the organization of the vast mass of commentary (Gemara) on the *Mishna*, he laid the foundation on which his successors built.

Revised by C. H. Toy.

Ash'er: a tribe of ancient Israelites, descended from Asher, eighth son of Jacob by the handmaid Zilpah. They were assigned a portion of land in the N. W. of Palestine, but never entirely dispossessed the Canaanites and Phœnicians who dwelt there. The tribe furnished but one noteworthy person, the prophetess Anna, who lived during the infancy of Christ (Luke ii. 36-38). The territorial boundaries and the history of this tribe are very obscure.

Ashe'ra: a Phœnician idol or image, most probably representing the goddess Ashtoreth. The image was always of wood, and is frequently mentioned in the Old Testament.

Ash'es: the solid or earthy residuum left after the combustion of wood, coal, or other organic substances. The most important ingredient of the ashes of land-plants is potash, or a salt of potash with a portion of lime and silica. The potash is extracted from ashes by a process called lixiviation—leaching. By dissolving the salt contained in the ashes the water is converted into lye, which is afterward evaporated by boiling. The insoluble part of the ashes remaining after lixiviation is called leached ashes, which is composed of carbonate of lime, phosphate of lime, oxide of iron, etc. The ashes of marine plants, and those that grow near the sea, contain soda instead of potash, with a small portion of iodine. The soda is also separated from the insoluble mass by lixiviation. Wood-ashes are extensively used in the manufacture of soap, and are useful as manure. The salts obtained from them by lixiviation are called potash and pearlash, which latter is a carbonate of potassa. Bone ashes consist mostly of phosphate of lime, which is a valuable manure. See AGRICULTURAL CHEMISTRY, POTASSIUM, and SODA-ASH.

Asheville: city; capital of Buncombe co., N. C.: between the French Broad and the Swannanoa rivers; on the Southern Railway; 142 miles W. by S. of Salisbury (for location, see map of North Carolina, ref. 5-E). It is in a tobacco-growing region, at an elevation of 2,389 feet above sea-level, and is widely known as a summer and winter health resort. It contains 24 churches, 4 public-school buildings, 8 other educational institutions, 2 libraries, 2 national and 2 State banks, 15 hotels, 2 daily and 4 weekly newspapers, 5 tobacco warehouses, and flour, cotton, and wood-working mills. Pop. (1880) 2,616; (1890) 10,235; (1900) 14,694.

Ash'hurst, JOHN, JR., A. M., M. D.: surgeon; b. in Philadelphia, Pa., Aug. 23, 1839; M. D., University of Pennsylvania, 1860; acting assistant surgeon, U. S. army, 1862-65; surgeon to the Episcopal Hospital, Philadelphia, 1863-80; appointed Professor of Clinical Surgery, University of Pennsylvania, 1877; vice-president surgical section, International Medical Congress, 1876; author of *Injuries of the Spine* (1867); *Principles and Practice of Surgery* (5th ed. 1889); editor *International Encyclopædia of Surgery* (6 vols., rev. ed. 1888).

Ash'land: railroad junction; Boyd co., Ky. (for location of county, see map of Kentucky, ref. 2-K); on the Ohio river, 13 miles below Catlettsburg. It has large blast-pig-iron furnaces, complete rolling-mill, and a Bessemer-steel plant, and manufactures steel nails, fire-brick, and furniture extensively. Iron ore, pig iron, and bituminous and cannel coal are shipped from this point. Pop. (1880) 3,280; (1890) 4,195; (1900) 6,800.

EDITOR OF "NEWS."

Ashland: town; Cass co., Ill. (for location of county, see map of Illinois, ref. 6-C); on Chi. and Alt. and Ohio and Miss. R. Rs.; 21 miles from Springfield; is an important shipping-point for grain and other agricultural products. Pop. (1880) 609; (1890) 1,045; (1900) 1,201.

Ashland: town; Middlesex co., Mass. (for location, see map of Massachusetts, ref. 2-H); 24 miles S. W. of Boston. The chief business is the manufacture of boots and shoes,

boxes and thread. Pop. of township (1880) 2,394; (1890) 2,532; (1900) 1,525.

EDITOR OF "ADVERTISER."

Ashland: village; Saunders co., Neb. (for location of county, see map of Nebraska, ref. 7-K); on B. and M. Riv. R. R. and on Salt Creek, about 3 miles from its entrance into the Platte river; 24 miles N. E. of Lincoln. It is surrounded by a rich farming district, which contains superior magnesian limestone. Pop. (1880) 978; (1890) 1,601; (1900) 1,477.

Ashland: town; on New York, Pennsylvania and Ohio R. R.; county seat of Ashland co., O. (for location of county, see map of Ohio, ref. 3-G); 65 miles S. W. of Cleveland, and 85 miles N. N. E. of Columbus; has ten churches, elegant public schools, and Ashland University. There are several manufactures, and a railway north and south is under construction. Has one daily, one semi-weekly, and two weekly papers. Pop. (1880) 3,004; (1890) 3,566; (1900) 4,087.

EDITOR OF "GAZETTE."

Ashland: town and health-resort; on railroad, Jackson co., Or. (for location of county, see map of Oregon, ref. 7-C); the largest town in Southern Oregon; situated in a fruit region. It has a high school, water-power, a woolen factory, planing-mills, quartz mines and mills, abundance of pure mountain water, etc. There are numerous mineral springs here and in the vicinity. Pop. (1880) 842; (1890) 1,784; (1900) 2,634.

EDITOR OF "TIDINGS."

Ashland: borough in the Mahanoy valley; in the center of the anthracite coal-fields of Schuylkill co., Pa. (for location of county, see map of Pennsylvania, ref. 5-H); on Phil. and Reading and Le. Val. and Pa. R. Rs.; 13 miles from Pottsville, the county-seat. It has large machine-shops, foundries, factories, etc., and extensive mining industries. Pop. (1880) 6,052; (1890) 7,346; (1900) 6,438.

PROPRIETOR OF "EVENING TELEGRAM."

Ashland: on railroad, Hanover co., Va. (for location, see map of Virginia, ref. 6-H); 17 miles N. of Richmond. In May, 1864, Gen. Sheridan, in the course of a raid, destroyed a dépôt here. It is the seat of Randolph-Macon College. Pop. (1880) 764; (1890) 948; (1900) 1,147.

Ashland: city on Chequamegon Bay, Lake Superior; 181 miles from St. Paul, 410 miles from Chicago; capital of Ashland co., Wis. (for location of county, see map of Wisconsin, ref. 2-C). Ashland is the fifth port on the Great Lakes in tonnage of vessels entered and cleared; is terminus of four railroads (Northern Pacific, Wis. Cent., Ch., St. P., Min. and O., and Mil., Lake Sh. and W.); has several churches, public and parochial schools, a business college, and Federal buildings. It is the center of vast lumber, iron, and brown-stone industries. Its ore docks are immense; capacity, 100,000 tons. Ashland has two very large charcoal blast-furnaces, used in manufacture of pig iron. In 1892 175,000,000 feet of lumber were produced here, and 2,300,000 tons of ore were shipped. The real growth of Ashland dates from the development, in 1885, of iron mines in the Gogebic range, 40 miles S. E. Pop. (1890) 9,956; (1900) 13,074.

EDITOR OF "NEWS."

Ash'lar: originally a large block of stone with squared sides, smoothly cut and dressed on its beds and joints. But the word is now more generally used as an adjective applied to cut stonework, or to a number of dressed stones laid in place. See MASONRY.

Ash-leaved Maple: See BOX-ELDER.

Ash'ley: a small river of South Carolina; rises in Colleton County, and flowing southeastward, unites with the Cooper river at Charleston.

Ashley: village; Washington co., Ill. (for location of county, see map of Illinois, ref. 9-E); on Ill. Cent. and L. and N. R. Rs.; 62 miles from St. Louis; in a farming and fruit-growing district. Pop. (1890) 1,035; (1900) 953.

Ashley: borough; Luzerne co., Pa. (for location of county, see map of Pennsylvania, ref. 3-11); on Cent. R. R. of N. J.; 3 miles from Wilkesbarre; is in a coal-mining district, and has manufactories of machinery. Pop. (1880) 2,799; (1890) 3,192; (1900) 4,046.

Ashley, LORD: See SHAFTESBURY.

Ashmead-Bartlett, Sir ELLIS, M. P.: English statesman; b. at Brooklyn, N. Y., 1849; educated at Oxford University; was called to the bar 1877; entered Parliament 1880; held the position of Civil Lord of the Admiralty in Lord Salisbury's administration; has been a frequent speaker in the

House and on public platforms, and is noted for his antipathy to Russia. His brother is married to Baroness Burdett-Coutts.
C. H. T.

Ash'mole, ELIAS, F. R. S.: b. at Lichfield, England, May 23, 1617; was educated at Oxford, and served as gentleman of ordnance under King Charles I. in the civil wars. In 1646 he turned his attention to the study of judicial astrology and Rosierucianism, and Oct. 16 of that year became one of the earliest English Freemasons. He was Windsor Herald 1660-75. In 1659 the younger Tradescant gave him his collection of curiosities, which Ashmole presented in 1682 to Oxford University. It was the basis of the present Ashmolean Museum. He wrote *Theatrum Chemicum Britannicum, containing severall poetecall pieces of our famous English philosophers, who have written the hermetique mysteries in their owne ancient language* (1652); *The Way to Bliss* (1658); *History of the Order of the Garter* (1672); *Antiquities of Berkshire* (3 vols. folio, 1719); and a whimsical *Diary* (1717). D. in London, May 18, 1692.

Revised by HENRY A. BEERS.

Ash'muu, JEHUDI: a promoter of colonization in Liberia; b. at Champlain, N. Y., in April, 1794; graduated at University of Vermont, 1816; became professor in Bangor Theological Seminary, later entered the Episcopalian Church; went to Liberia in 1822 as an agent of the Colonization Society, and rendered important services. D. in New Haven, Conn., Aug. 25, 1828. See his *Life* by R. R. Gurley (2d ed. 1839).

Ashmuunen: See HERMOPOLIS MAGNA.

Ashoka: See ASOKA.

Ashtabu'la: important railroad center, Ashtabula co., O. (for location of county, see map of Ohio, ref. 1-J); 55 miles E. of Cleveland, and the principal town between that city and Erie. It has extensive railroad connections with the coal-mining regions of Ohio and Pennsylvania and the great manufacturing districts of Pittsburg and the Mahoning valley. It has a splendid harbor, and receives the largest amount of iron ore of any port in the U. S., and in the amount of ore shipped it is surpassed by few on the lakes. The town has electric light, water-works, electric street railroad, fine public buildings, and is becoming an important manufacturing center. Pop. (1870) 1,999; (1880) 4,445; (1890) 8,338; (1900) 12,949. EDITOR OF "NEWS."

Ash'taroth: See ASHTORETH.

Ash'ton-in-Ma'kerfield: a town of England, in South Lancashire (see map of England, ref. 7-F). The inhabitants are mostly employed in cotton-factories and in collieries. Pop. (1891) 13,379.

Ashton-under-Lyne: a town of England; in the S. E. part of Lancashire; on the Tame; 6½ miles by rail E. S. E. of Manchester (see map of England, ref. 7-G). It is a great seat of the cotton manufacture, and is remarkable for the rapidity of its growth. It returns one member to Parliament. It has a church built in the time of Henry V., a theater, a mechanics' institute, etc. Many of the inhabitants are employed in calico-printing, bleaching, dyeing, and the manufacture of machines. Pop. (1881) 37,040; (1891) 40,494.

Ash'toreth, or (in plural form) **Ash'taroth**: a Syrian goddess, worshiped by the ancient Israelites and other nations of Western Asia. She was called the Queen of Heaven, and appears to have been a personification of the moon. The Greek and Latin name for her is Ashera, translated "grove" in the Authorized Version of the Bible; it should be rendered "statue." Her worship existed in the days of Abraham and is incidentally mentioned in all parts of the Old Testament. She is commonly identified with ASTARTE (*q. v.*). Her chief temples were at Tyre and Sidon.

Revised by S. M. JACKSON.

Ashur: See ASSHUR.

Ashville (North Carolina): See ASHEVILLE.

Ash-Wednesday (in Lat. *Di'es Cin'erum*; literally, day of ashes): the first day in Lent, also known as *Caput Jejunii*, the head or beginning of the fast; called *Ash Wednesday* because in ancient times it was the custom for penitents to appear in the church covered with sackcloth and ashes. In the English Prayer-book the "Commination" service is used on Ash-Wednesday as a provisional substitute for the "godly discipline" to which, of old, offenders were subjected to on this day. Portions of this service were incorporated into the Ash-Wednesday office in the American

Book of Common Prayer in 1789; and "A Penitential Office for Ash-Wednesday" has been appended to the "Special Prayers and Thanksgivings" in the Standard of 1892.

W. S. PERRY.

Asia, ā'shi-a: the largest continent on the globe; has been commonly supposed to be the oldest habitat of the human race. It comprises nearly one-third of the land-surface of the earth, having about 17,000,000 sq. miles and about 900,000,000 inhabitants, or nearly two-thirds of the entire population of the earth. Asia is bounded N. by the Arctic Ocean, touching the 78th parallel N. latitude; on the E. by the Pacific, S. by the Indian Ocean, S. W. by the Red Sea, lying between it and Africa, and W. by Europe and the Mediterranean, Black, and Caspian Seas. The coast-line exceeds 33,000 miles, and is indented by great bays and gulfs, forming the great peninsulas of Asia Minor, Arabia, India, Siam, Annam, Korea, and Kamtchatka. Connected with Africa by the narrow Isthmus of Suez, this has been penetrated by the Suez Canal, uniting the Red Sea with the Mediterranean. On the N. E. the narrow Bering Strait separates it from the continent of America.

Mountains, Rivers, etc.—The mountains of Asia surpass in height those of all other parts of the globe, the loftiest summit being Mt. Everest, in the Himalayas, 29,002 feet, while the mean height of the range (running in Southern Asia between India and Tibet) is 18,000 feet. The long chain of Altai Mountains stretches 3,000 miles across Northern Asia; the Ural Mountains divide Asia from Europe. The mountains of the Caucasus are 10,000 to 18,000 feet high; Mt. Ararat, in Armenia, is 17,212 feet; the Taurus Mountains in Asia Minor, the Kamtchatka range in Northeastern Asia, and many other heights, diversify the whole face of the country. Immense plains or steppes (the plain of Siberia being larger than all Europe) lie between the mountain-ranges. The table-land of Tibet (over 16,000 feet high), of Afghanistan and adjacent countries, of Persia (2,000 to 6,000 feet), of Hindustan, etc., represents other great natural features of Asia. Asia has great rivers flowing hundreds of miles through fertile regions, the Indus, Ganges, Euphrates, Tigris, Hwang-Ho, Amúr, Obi, Yenisei, and Yang-tse-kiang being the chief. Lakes abound, and the great Caspian Sea and Aral Lake are the principal inland bodies of water. Geologists find evidence of great structural changes, indicating the very recent formation of large portions of Asia. Vast areas of dry land were once covered by water. No active volcanoes exist in the interior, but several are found on the east coast. Traces of glacial action abound on the Himalayas.

Climate, Soil, and Productions.—The extremes of heat and cold are found in Northern and Southern Asia, the mean temperature of Upper Siberia being near zero, and the highest mean temperature of India about 82°, with continuous heat, at some seasons, much nearer 100°. A large part of Asia lies in the temperate zone, and has a mild climate. The bleak regions of Northern Asia have a sterile soil, with very little rainfall, the earth being frozen constantly to a depth of 300 feet. The hotter regions near the Indian Ocean and China Sea are subject to violent cyclones or typhoons, and the heated air blown over Southern Asia by the S. W. monsoon brings watery vapor and heavy falls of summer rain. The annual rainfall varies from 5 to 100 inches. The great diversities of climate, water-distribution, and soil yield a corresponding variety of natural productions. In forestry, while vast regions of territory have been wholly stripped of trees, pines, birches, and willows abound in the N., balsams, palms, acacias, banyans, breadfruit, magnolia, cedars, etc., in Southern and Central Asia. Medicinal plants, dyewoods, and spices grow in profusion. China and Japan are the great cultivators of the tea-plant and the camellia. Rice is of Asiatic origin, and in the cooler regions wheat, oats, barley, rye, buckwheat, maize, and millet are grown. Bananas, plantains, yams, sugar-cane, pepper, tobacco, indigo, cotton, hemp, flax, and that baneful plant the opium poppy, are largely cultivated. The orange, lemon, olive, peach, fig, mulberry, vine, etc., all are natives of Asia. Among the animals are the ox, buffalo, sheep, goat, horse, camel, elephant, yak, reindeer, dog, ape, bear, fox, lion, tiger, leopard, boar, rhinoceros, etc. Among birds are the eagle, vulture, raven, owl, heron, swan, goose, duck, flamingo, albatross, pigeon, nightingale, bird of paradise, parrot, ostrich, etc. The cobra and other serpents infest the tropical regions. Fish are abundant in the inland and ocean waters.

Insect life is rampant in the warmer regions, and the locust in innumerable swarms often devastates wide areas. The great fertile districts, cultivated by native industry, sustain the enormous population and yield surplus productions for export, roughly estimated at \$450,000,000 per annum. Gold is found in Siberia and Japan; silver, in China, Asiatic Russia, Annam, etc.; mercury, tin, lead, copper, and iron, in Japan, Siberia, India, Persia, and Turkey; coal is mined in China, Japan, and Siberia; and salt is abundant. Asia is also rich in precious stones.

Civilization, Religion, etc.—Asiatic civilization, although differing widely from that of Europe and America, has its own peculiar development. Oriental culture reaches to a certain point, after which civilization is stationary instead of obeying the law of progress as in the Western nations. In Western Asia are the seats not only of Hebrew civilization, but of those great Oriental monarchies of the Babylonians, Assyrians, and Persians, among whom architecture, road-building, and the useful and decorative arts were carried to a high degree of perfection. In India, likewise, are the magnificent remains of an architecture far superior to anything erected by the modern Hindus. In the northern half of Asia the people live almost wholly by hunting or by keeping flocks in the great grazing regions. They are of a low order of intelligence, but in Siberia are peaceful tribes. The great Tartar race, embracing the Mongols, Manchus, and Turks, are divided into Buddhists and Mohammedans, and are gradually losing their nomadic and predatory habits, becoming more assimilated to Chinese civilization. The Chinese and Japanese are very little migratory, but are a settled people of traders and cultivators of the soil. In China Buddhism and Taoism prevail, but nearly everybody is also a follower of Confucius. The Japanese are mostly Buddhists, but some are followers of Shintō. Brahmanism is the religion of India, but in certain regions the Mohammedans are in the majority, while W. of India Asia is almost wholly Mohammedan, except some small districts of Syria and Asia Minor, where there is a population of Christians. The Greek Church has many adherents in Russian Asia, while the Armenians and Nestorians are numerous in Turkey and Persia. Vague estimates place the adherents of the native religions of Asia at 600,000,000, the Mohammedans at 90,000,000, the Christians at 12,000,000 (4,000,000 Roman Catholics, 7,000,000 Greek Church, and 1,000,000 Protestants, etc.), and the Jews at 350,000. Of savages, properly speaking, Asia holds few, and those in the remote hyperborean regions or in the southern archipelago.

Population, Language, etc.—The inhabitants of Asia are of the Mongolian, Aryan, and Semitic races, and their ancestry runs far back beyond recorded history. The Mongols include the whole of Eastern and Southeastern Asia—viz., the Chinese, Japanese, Tartars, Siamese, Turcomans, Kamtchatkans, Malays, etc. The languages used by this great division are very various, including the Arabic alphabet employed by all the Turkish varieties, the monosyllabic language of the Indo-Chinese, the rude dialects of the Arctic regions, and the Singhalese, Tamil, and Carnatic in Southern Asia. The Aryan race embraces the people of Afghanistan, Baluchistan, Persia, and Northern India. These use the Indo-European languages—viz., Sanskrit, Persian, and Armenian. The third great group includes the Syrian, Hebrew, and Arabian races, speaking the Semitic tongues. Among these various races and languages, between thirty and forty distinct nations are distributed.

History.—The oldest historical records are of Asiatic origin, and, however obscure, will be studied with increasing interest as time goes on. About 600 B. C. the union of the kingdoms of Babylonia, Assyria, Persia, and Media took place under Cyrus the Persian, whose dominion reached from the Mediterranean to the Indus. About 500 B. C. begin the remarkable records of the Vedic theology in India. The Persian monarchy was destroyed by Alexander about 330 B. C., soon after which his Asiatic empire was dissolved. The Roman invasions of Asia about the beginning of the Christian era, with the conflicts continued for centuries between them and the Persians, made no advance beyond Armenia. Christianity was born in Syria, spread rapidly over Asia Minor and the whole Roman empire, becoming the only religion of Europe, but producing no similar effects in Asia. Mohammedanism, with its spirit of conquest, made great advances and acquired a permanent foothold. The annals of Asia abound in records of tyranny and cruelty perpetrated by the Mohammedans, who have unquestionably obstructed its progress in civilization, and the predatory

warfare of the Tartar tribes of the Mongolian race fills many of the bloodiest pages of Asiatic history. The dynasties of India and China have been prolific in wars and rebellions, but the people, with their fixed customs and their productive soil, have remained and multiplied where their ancestors flourished thousands of years ago. A prodigious change was effected in Asia by the modern influx of British and Russian settlement. The British East India Company founded its powerful empire in the East upon its mastery of the great avenues of trade and shipping, and through the dominant and aggressive character of the British race Great Britain has become firmly established as the paramount power in India. At the same time she has competed with Russia in extending the outposts of European civilization farther and farther into Central Asia, and they now stand face to face on the confines of Afghanistan and the Pamirs. France is firmly planted in Southeastern Asia, and is contributing her share to the material and intellectual advancement of the Far East. A progressive spirit has taken a firm hold in Japan, and she has become a great power in the East. Korea is no longer a "hermit" nation; and even China under the influence of foreign contact has waked up and is assimilating European ideas and methods. The old-time exclusiveness is disappearing; the telegraph ramifies the land, and railways are beginning to stretch out over the provinces and bring them nearer to each other.

The following table gives the chief political divisions of Asia, together with their areas and population, according to the best authorities:

COUNTRIES.	Sq. miles.	Population.
Afghanistan.....	257,000	5,000,000
Annam.....	106,250	5,000,000
Arabia.....	1,230,000	5,000,000
Baluchistan.....	130,000	500,000
Bokhara.....	92,254	2,500,000
Cambodia.....	32,370	1,500,000
Caucasia.....	91,346	5,011,555
Ceylon.....	25,364	3,008,466
China proper.....	1,322,841	383,182,793
Dependencies.....	2,881,560	27,180,000
Cochin China.....	23,000	1,991,500
Cyprus.....	3,584	209,300
Hongkong.....	29	221,441
India—British, including Burma.....	965,000	221,173,000
French.....	205	282,900
Portuguese.....	1,080	561,400
Feudatory states.....	598,000	66,081,000
Japan, including Formosa.....	161,640	43,718,000
Kafiristan.....	5,000	200,000
Khiva.....	22,320	700,000
Korea.....	92,000	14,000,000
Persia.....	640,000	10,000,000
Russia in Central Asia.....	1,639,780	29,467,900
Siberia.....	4,925,000	6,000,000
Samos.....	289	43,901
Siam.....	200,000	5,000,000
Straits Settlements and dependencies.....	36,130	930,870
Tonquin.....	34,740	9,000,000
Turkey in Asia.....	686,370	22,500,000
Totals.....	16,203,152	869,964,026
Borneo.....	283,400	1,734,000
Java.....	50,848	23,064,086
Philippine islands.....	114,326	7,000,000
Sumatra.....	162,608	2,972,383
Totals.....	611,182	34,770,469
Totals for Asia.....	16,814,334	904,734,495

AINSWORTH R. SPOFFORD. Revised by R. LILLEY.

Asia Minor: the ancient name of a peninsula forming the western extremity of Asia, now called ANATOLIA (*q. v.*). It was bounded N. by the Euxine (*Pon'tus Euxi'nus*) and Propontis, S. by the Mediterranean, and W. by the Ægean Sea (*Æge'um Ma're*). The principal divisions were Bithynia, Cappadocia, Cilicia, Galatia, Ionia, Lyaonia, Lydia, Lycia, Mysia, Pamphylia, Phrygia, Pontus, and Paphlagonia, which will be noticed separately. The Mt. Taurus range extends through the southern part, and Anti-Taurus through the northern. The principal rivers are the Halys (Kizil-Irmak), which rises in the eastern part and enters the Euxine; the Sangarius (Sakareeyah), which also flows into the Euxine; and the Meander, which enters the Ægean Sea. Here flourished many famous and powerful kingdoms of antiquity, and here many conquerors in successive generations contended for supremacy. "We are now," says Malte-Brun, "to tread upon a soil rich in interesting and splendid recollections, with an existing population completely debased by ignorance and slavery. The glory of twenty different nations which

100 110 F 120 130 140 150 160 C 170 180 H 190 I Bering Str. J

F 90 Greenwich 110 H 120 I 130 J

once flourished in Western Asia has been extinguished: flocks wander over the tombs of Achilles and Hector; and the thrones of Mithridates and Antiochus have disappeared, as well as the palaces of Priam and Cræsus." Recently, however, much has been done to determine the boundaries and geographical characteristics of the nations which once flourished on this now desolate peninsula. In 1886, 1887, and 1888 Prof. W. M. Ramsay made extensive and careful explorations, and first determined in modern times the location of many of the ancient cities. He was able also to establish with considerable confidence the remarkable system of roads by means of which the country was traversed by the Romans. Scarcely less important was the work of Prof. J. R. S. Sterrett, carried on between 1882 and 1885, when by means of a systematic study of inscriptions he was able to make many determinations of great geographical value. See *The Historical Geography of Asia Minor*, by Prof. W. M. Ramsay (London, 1890); *The Wolfe Expedition to Asia Minor*, by J. R. S. Sterrett (Boston, 1888).

Revised by C. K. ADAMS.

Asiarchs: "certain chiefs of Asia" (Acts xix. 31), were wealthy citizens who had been chosen by the cities of that part of the province of Asia of which Ephesus was the metropolis under the Romans to preside at and indeed to pay for the public games, and watch that the customary rules and regulations were not infringed upon. The office was held only one year, and only by one man at a time, but the title was probably given to those who had held it, which accounts for Luke's plural. It was considered a high honor.

Revised by S. M. JACKSON.

Asiatic Societies: societies formed for the promotion of the knowledge of the language, literature, and history of the Asiatic nations. The first society of this kind was established by the Dutch at Batavia in 1780. The next was the Royal Asiatic Society of Bengal, founded at Calcutta by Sir W. Jones in 1784. Among those of more recent date are the Société Asiatique, founded at Paris in 1822; the Royal Asiatic Society of Great Britain and Ireland, 1823; the Asiatic Society of Ceylon, 1845; the German Oriental Society in 1845; the North China branch of the Royal Asiatic Society, established in 1847; the American Oriental Society in 1842; the Japan branch of the Royal Asiatic Society in 1872; and the Italian Asiatic Society, established in 1887.

Asina'rii [deriv. of Lat. *a'sinus*, ass]: a nickname originally given to the Jews because they were said to worship an ass, but afterward also applied to the Christians, against whom the same accusation was made. The story is told us by Tertullian (*Apology*, 16; *Ad Nat.*, 1, 14), and has been most curiously illustrated by a drawing scratched in mockery on the walls of the pedagogium in the palace of Cæsar in Rome some time in the second century, and representing some Christian convert worshipping a man with an ass's head hanging on a cross. Underneath in Greek is written "Alexamenos is worshipping God." The drawing was discovered in 1856 on a wall under the western angle of the Palatine, and is now preserved in the library of the Collegio Romano.

Asinins: See POLLIO.

Ask: in Scandinavian mythology, the first man created by Odin, Honer, and Loder from an ash-tree. See SCANDINAVIAN MYTHOLOGY.

As'kalon, or Ashkelon: See ASCALON.

Askelon: See ASCALON.

As'kew, ANNE; b. at Stallingborough, near Grimsby, Lincolnshire, 1521; a gentlewoman of high distinction in the reign of Henry VIII., and an intimate court-friend of his queen, Catharine Parr. She was the daughter of Sir William Askew, of Kelsey, Lincolnshire; married to Thomas Kyme, and bore him two children. In March, 1545, she was imprisoned and examined in London by Christopher Dare and Sir Martin Bowes, Lord Mayor of London, and subsequently by Bonner, on the charge of denying transubstantiation. She was released on bail, and on June 13 acquitted. The next year she was arrested for heresy, and some time in June, 1546, in the Tower, she was tortured by the rack, Wriothesley, the lord chancellor, and Sir Richard Rich inflicting this inhumanity with their own hands. Finally, being unable to walk to Smithfield, she was carried there in a chair, and her body chained to the stake, at which she was burnt on the 16th of July, 1546.

Revised by S. M. JACKSON.

Ask'ja: the largest volcano of Iceland; situated in 65° N. lat. and 16° 45' W. lon. The crater has an area of 23 sq. miles, circumference of 17 miles, and depth of 700 feet. The height of the mountain is 4,633 feet. The surface of the crater is covered with lava floods and a hot-water lake, while volumes of steam issue from numerous vents. A great eruption occurred in 1875.

C. H. T.

As'mai', or Asmayi: b. about 741; d. about 830; the preceptor of Harun-al-Raschid, and the most celebrated representative of Arab scholarship not only at that court, but in that century. The most widely known of his many productions are his synchronous history of Persia and Arabia before Islam (which Rawlinson has characterized as "perhaps the most valuable and authentic historic volumes in the whole range of Arabian literature") and his romance of *Antar*, the "Iliad" of the desert. But besides these he wrote a great number of other works, poetical and scientific, and founded a literary school which has produced many renowned pupils, such as Thâlab, Ibn-el-Anberi, Sukkari, and others.

Revised by J. R. JEWETT.

Asmode'us, or Asmo'doi: a demon, who, according to the Apocryphal book of Tobit, killed the seven husbands of Sara upon the wedding-nights, until Tobias, under the direction of Raphael, married Sara and drove away the demon by burning in the bride's chamber the heart and liver of a fish he had caught in the Tigris. When the demon smelled the fumes, "he fled into the uttermost parts of Egypt and the angel bound him." In the *Talmud* he is called the prince of demons, and a Talmudic tale tells us how he once drove Solomon out of his kingdom, though at length Solomon got the ascendancy over him and compelled him to work for him in building the temple, which he did without noise by means of Sharnis, a mysterious stone. The name is the Persian *Aeshma-dæva* (see Spiegel, *Eranische Alterthümer*), and the figure of the demon is in general Persian. C. H. TOY.

As'monæ'ans, or Asmoneans: the proper designation of the family of Jewish princes better known as the Maccabees. The name was derived, according to Josephus (*Antiq.* xii. 6), from a certain Asmonæus who lived about 300 B. C., but who otherwise is unknown to history, which makes the derivation somewhat doubtful. His great-grandson, Mattathias, was a distinguished patriot and leader of a revolt against the King of Syria. He had several sons, who ruled over Judea and were called MACCABEES (*q. v.*).

As'nyk, ADAM: Polish poet and patriot; b. at Kalish, Sept. 11, 1838; studied at Warsaw, then in Paris and Heidelberg. He took part in the insurrection of 1863 in Poland, and was forced to spend some years in exile in Germany. He had lived in Cracow since 1872. He published *Poezye* (3 vols., 1872-80); several historical tragedies, *Walka Stroumictew* (1869); *Cola Rienzi* (1873); *Kiejstut* (1878); and a comedy, *Przyjaciele Hioba* (The Friends of Job), in 1879. D. Aug. 2, 1897.

A. R. MARSH.

Aso'ka, Aço'ka, or Asho'ka (with the by-name *Piyadassi*): an ancient King of Maghada, in India; was a grandson of Chandragupta (or Sandracottus). He reigned about 250 B. C., was converted to Buddhism, and erected a great number of monasteries. His dominion extended over the greater part of Hindustan. See É. Senart, *Les inscriptions de Piyadasi* (Paris, 1881-86, 2 vols.); and *Notes d'épigraphie indienne* (1888).

Asp, or Asp'pie (Lat. *as'pis*; Gr. *ἀσπίς*): a species of venomous serpent mentioned by ancient writers. Some of these describe its bite as inevitably fatal, and as producing speedy death without pain. Modern naturalists identify it with the *Naja haje*, a species of hooded viper which is found in Egypt, and is from 3 to 5 feet in length. When it is irritated it dilates its neck. The figure of the *Naja haje* occurs on the sculptured monuments of the ancient Egyptians. The jugglers of modern Egypt cause it to dance to their music, and throw it into a cataleptic state. The name of asp is also applied to the *Viperas as'pis*, common in many parts of Europe. It is much dreaded on account of its bite.

Aspar'agus [from Gr. *ἀσπάραγος*, or *ἀσπάρραγος*]: a genus of plants of the family *Liliaceæ*, natives of Southern Europe and Africa. Its species are partly shrubs and partly herbaceous. They have a six-parted perianth, six stamens, one style, and the fruit is a berry. The most important species is *Asparagus officinalis*, the common asparagus of gardens, which is a native of Europe, and is generally cultivated in Europe and the U. S. It was used as food by the ancient Romans. It grows to the height of about 4 feet, and thrives

best in a rich and deep soil. This plant is raised from the seed, and should not be used until about three years have elapsed after the planting of the seed. The perennial roots continue for many years to send up every spring a crop of tender shoots, which, after having attained the height of a few inches, are cut a little below the surface of the ground. A peculiar principle called *asparagine*, $C_4H_6N_2O_3$, is obtained from these shoots, and also from the root of the marsh-mallow.

Aspa'sia (in Gr. Ἀσπασία): a celebrated woman of ancient Greece, remarkable for her genius, beauty, and political influence; b. at Miletus, in Asia Minor, about 470 B. C. She became in her youth a resident of Athens and the leader of the *hetairai*. Her house was a celebrated resort for the most eminent Athenians, including Socrates, who professed to be her disciple. Pericles was another of her admirers, and in order to live with her (445) he divorced his wife. Having been accused of impiety and inducing free women to become *hetairai* by Hermippus, a comic poet (432), she was defended by Pericles and acquitted. She had a high reputation for talent, and a report obtained currency that she composed part of the great funeral oration which Pericles pronounced over the Athenians who fell in battle about 430. After the death of Pericles, 429, she lived with Lysicles. There is extant an antique bust inscribed with the name of Aspasias. See the works on the age of Pericles by E. Filleul (Paris, 1873, 2 vols.), and A. Schmidt (2 vols., June, 1877-79). Revised by S. M. JACKSON.

Aspasias the Younger: an Ionian woman whose original name was MILTO. She became the favorite mistress of Cyrus the Younger, who changed her name to Aspasias. She was distinguished for beauty and intellect. She was taken captive by King Artaxerxes at the battle in which Cyrus was killed, 401 B. C., and was consecrated by him as a priestess of Anaitis.

As'pect: look, appearance, countenance. In astrology the position of one planet with respect to another. Aspect is defined by Kepler as "the angle formed by the rays proceeding from two planets and meeting at the earth." The ancients reckoned five aspects—namely, conjunction, indicated by the symbol \cup ; opposition, by \otimes ; trine, by Δ ; quartile, by \square ; and sextile, by \times . Planets in conjunction have the same longitude; in opposition the difference of their longitude is 180° .

As'pen, or **Tremulous Poplar** (*Populus tremula*): a tree of the natural family *Salicaceae*; a native of Europe and Western Asia. It is remarkable for the mobility of its leaves, which, having long petioles laterally compressed, are caused to flutter by the gentlest breath of air. The name aspen is also applied to the *Populus tremuloides* and *grandidentata*, natives of the U. S., resembling the European aspen in the proverbial quivering of their leaves.

Aspen: city; on the Colo. Midland and Denver and Rio Grande R. Rs.; capital of Pitkin co., Col. (for location of county, see map of Colorado, ref. 3-C); has an altitude of 7,700 feet and is in a beautiful mountain-locked valley. The city has several churches, excellent public schools, etc. Its principal business is mining, and some of the most famous lead and silver mines of the State are here. The production of silver is at the rate of \$10,000,000 per annum. Pop. (1885) 3,874; (1890) 5,108; (1900) 3,303.

EDITOR OF "TIMES."

Aspergillum: a genus of tubicular bivalve mollusks, characterized by the soldering of both valves to the inner surface of the calcareous sheath. The shell has the form of an elongated cone, the larger end of which expands into a disk, which is pierced by many small tubular holes. Hence it derives its popular name of "watering-pot." The animals of this genus are borers, which live in sand. They are chiefly found in the Indian and South Pacific Oceans. Others have been found fossil in Europe.

As'pern, or **Gross Aspern**: a village of Austria; on the left bank of the Danube, 5 miles E. N. E. of Vienna (see map of Austria-Hungary, ref. 5-F). Aspern, with the adjacent village of Essling, was the scene of a great battle between Napoleon and the Austrian Archduke Charles after the French army had taken Vienna. The French crossed the river by a bridge which they constructed at the island of Lobau, and began the attack on May 21, 1809. After half of the French had crossed the river, the Austrians assumed the offensive. Both of the villages were taken and retaken, and the day closed without a decisive result. The

fight was renewed on the 22d, when Napoleon retreated to the right bank of the river, having lost about 7,000 killed and 30,000 wounded and prisoners. The Austrians lost about 20,500 killed and wounded.

Asphalt [from Gr. ἄσφαλτος, a loan-word]: a general name for the solid forms of bitumen. Asphalt is widely distributed in nature and exhibits several very distinct varieties. Generally asphalt is distinguished from coal by being soluble in bisulphide of carbon and benzole. It occurs disseminated through many crystalline rocks, often deprived of its volatile matter and resembling anthracite. See ASPHALTIC COAL. It occurs often in veins that have evidently been injected into fissures in a plastic condition: albertite and grahamite are examples. On the coast of California, near Santa Barbara, veins of asphaltic sand occur; also in the island of Cuba and in Albania and various localities in France. At Seyssel, in the department of Ain, and Val de Travers, in the canton of Neuchâtel, in the Rocky Mountains and in Texas, veins of limestone impregnated with asphalt occur. French authors have given these latter forms the name of *asphalte*. Asphalt also occurs in beds, where it has resulted from the oxidation of mineral tar, or primarily of petroleum. Such deposits, of small extent, are frequently met in Southern California. In the N. E. states of Mexico deposits of this character of enormous extent occur. The most noted are found in Tamaulipas, on both sides of the river Thamesi; in Vera Cruz, a small mountain near the village of Moloasan, 1,200 feet high, is largely composed of asphalt, which is called by the Indians *chapatote*. On the island of Trinidad and near San Timolis, Venezuela, lakes of asphalt occur. They are each about 3 miles in circumference, and are supposed to float on water. While the surface of the Trinidad lake is sufficiently hard to admit of teams being driven over it, the whole mass is in constant motion around several vortices. Trunks of trees arise and after a time disappear again.

The lake is situated in the crater of an extinct volcano, and the supply is partly renewed (estimated 20,000 tons a year) by a flow from a subterranean source. It has an area of 114 acres, and its depth has been ascertained by boring to be 18 feet near the sides and 135 feet in the middle. During 1881-99, 1,375,415 tons of asphalt were removed. It is dug up with pick and shovel, and conveyed to the shore in carts, where it is lightered to vessels off-shore. On the voyage it becomes compacted into a solid mass that has to be again broken up with the pick. When unloaded it is heated in tanks over a slow fire, and the roots of vegetation with which it is contaminated are removed, and the hot pitch strained through a sort of colander into barrels.

In the mountains that border the eastern coast of the Adriatic Sea and the island of Ragusa, asphalt has accumulated in a great variety of forms and on an immense scale. Asphalt is also of frequent occurrence in the neighborhood of the Dead Sea, where it frequently rises to the surface of the water and floats or is cast ashore by the waves. Asphalt from this source has been an article of local commerce from the most remote antiquity. The asphalt of commerce is obtained from Trinidad, Cuba, Dalmatia, and Syria, and asphaltic limestone from Seyssel and Val de Travers. Other localities furnish local supplies of more or less value.

Pure asphaltum has a specific gravity of 1.2 to 1.3, and hardness 2.5 to 3. It is a dry solid with a conchoidal fracture and glossy, black surface. Some varieties are brownish black in color, with a more or less splintery fracture. These are earthy and impure; when rubbed it has a peculiar odor. It is usually easily melted, is very inflammable, and burns with a yellow, sooty flame, leaving but little or no residue. It is sparingly soluble in alcohol, the fixed and essential oils and ether, and readily soluble in benzole and bisulphide of carbon. With benzole it forms a solution of an intense black color which is used in the arts under the name of black varnish. Asphalt is very brittle at low temperatures, but when warmed it may be sufficiently hard to readily break by a sudden blow, and at the same time yield to the tread. When subjected to destructive distillation it is resolved into a distillate of oils of varying density, and a tarry residue that becomes solid when cold, and is called asphaltum.

The uses of asphalt are:

1. Varnish.
2. Insulation.
3. Water-proofing.
4. Cement.
5. Roofing and paving.

Varnish prepared with asphalt is known as *black varnish*, and is used principally upon iron structures. It is prepared by dissolving Syrian or other of the purer asphalts in benzole or liquids containing benzole. A black enamel is obtained on iron by applying the varnish to the hot iron, by which the volatile ingredients of the varnish are expelled and the surface left smooth as if polished.

Asphalt enters into many mastics and cements that are used by many different methods of application, chiefly for underground purposes of insulation. Asphalt is one of the most tenaciously adhesive substances in nature. This is proved by the persistence with which for unknown centuries the alabaster slabs of Nineveh and Babylon have been held in their places by the asphalt that was used to retain them. In modern times it is used to make constructions water-proof. Foundations of brick or stone are saturated with asphalt dissolved in some more fluid form of bitumen and then laid in asphaltic mortar or cement. This makes a water-proof foundation of the most durable character. For cement asphalt is mixed with petroleum residue to render it more plastic, and the whole tempered with one-seventh its weight of sharp sand. Cement of this character was used with great success in the construction of the arch over the water main at High Bridge in New York city.

It was also used in the construction of the La Salle Street tunnel in Chicago, where its superiority was fully demonstrated, this tunnel being free from water, while those finished with hydraulic cement are never free from more or less infiltration. This cement is also used in the construction of foundations where vibration is for any reason to be avoided.

Enormous quantities of Trinidad asphalt enter the composition of roofing materials at the present time. Felt made for the purpose is saturated with a mixture of asphalt, coal-tar, pitch, and petroleum residue, or still bottoms. The felt is then laid together and rolled of two or three thicknesses, in such manner that *two or three ply* felt is obtained. In this compound felt the two or three layers are so completely cemented together that the whole appears as if it was one piece of felt. When laid the felt is held in place by nails driven through tin disks, and the whole completely covered with the cement used in preparing the felt. While this is still soft the whole is covered with sharp sand or screened gravel. This makes a roof that is tight and durable, and is being extensively used, especially for large structures.

Artificial bituminous mastics, made largely of Trinidad asphalt, for use in pavement have been made by artificially incorporating fine sand or pulverized limestone with natural asphalt, and are used in vast quantities. No method of mixture, however, has ever produced a combination equal to those found in nature.

The natural asphaltic sands of La Goleta on the coast of California contain 50 per cent. of sand, so fine and so uniformly distributed as to give the appearance of a pure asphalt. Others found in France, Spain, Mexico, and the Northwest Territory contain from 10 to 18 per cent. only of bitumen. They are locally valuable as a material for roadways.

The bituminous limestones, called asphaltic rock, found at Seyssel and at Val de Travers are the most valuable deposits of asphalt known. Quite recently deposits of very similar character have been observed in Texas, but they have not yet been developed. That from Seyssel consists of 80 per cent. limestone and 10 per cent. bitumen. The Val de Travers rock is richer, containing 20 per cent. bitumen. The stone is massive, of irregular fracture, and of a liver-brown color. Though easily scratched with the fingernail, it is difficult to break with a hammer.

The bituminous mastics are generally made by mixing these bituminous limestones in powder with the mineral tar extracted from the *molasse* or bituminous sandstone of the same locality. Seven to 8 per cent. of mineral tar is required for the Seyssel mastic, and $4\frac{1}{2}$ to 5 per cent. for that of Val de Travers. The rock is first broken into fragments of 3 inches in size and then poured through toothed rollers, and afterward heated to 500° F. in a cylinder in which a helix revolves, the pieces being fed in at one end. The mastic is then put on to a concrete bed, hot and rolled. For transportation it is prepared by heating the mastic in kettles with 8 per cent. of Trinidad asphalt at 280° for five hours, when it is run into molds. When used, these bricks are again broken and heated with more Trinidad asphalt and sand for ten hours at 300° F., when it is

spread hot, rubbed, and rolled. Five million sq. yards of surface have been put down in Paris, with a length of 1,000 miles. It has also met with great favor in all the larger cities of the U. S. During the ten years previous to 1899 the U. S. produced 657,957 tons of asphaltum and imported 2,906,140 tons. See BITUMEN.

Asphaltic Coal: certain coal-like substances which are found filling irregular cavities and fissures, generally of the older rocks. They have been often classed as coals, but differ in composition and geological position from all true coals. They are not stratified, but fill fissures into which they have evidently flowed when in a fluid or plastic state. They are, in fact, ancient asphalts, which have become more compact and drier—i. e. containing less oil and gas—in the lapse of ages. These asphaltic coals are found in carboniferous rocks in New Brunswick and West Virginia, and in Devonian strata in Ohio and Kentucky.

Revised by G. K. GILBERT.

Asphodel: an herbaceous plant of the genus *Asphodelus* and family *Liliaceæ*, nearly related to the asparagus and onion. The asphodels are natives of Barbary, Sicily, Greece, and other parts of the Levant. Several species are cultivated in gardens for the beauty of their flowers, as the *Asphodelus luteus* (yellow asphodel). *A. ramosus* is said to be the flower which Homer describes as growing in the meadows of Elysium. It is now abundant in Apulia. The ancients imagined that the manes of their friends fed on its roots, and they planted it near their tombs.

Revised by CHARLES E. BESSEY.

Asphyx'ia [Gr. from *a-*, not + *σφύξις*, pulse; *σφύζειν*, throb]: originally cessation of the motion of the heart; but the word has now come to signify disturbance and finally arrest of breathing by suffocation or strangulation. It occurs in drowning, by water excluding air from the lungs; in hanging or choking, by the compression of the windpipe, preventing the entrance of air; in the presence of certain gases, as chlorine or pure carbonic acid, by spasmodic closure of the glottis or entrance to the windpipe. It has been proved by careful observations that after death by asphyxia the left cavities of the heart are empty, and the right distended with blood. This is owing to the fact that venous blood, not renewed by exposure to the oxygen of the air, will not circulate through the lungs, thus being forced to accumulate in the right or venous side of the heart. The mode of treatment of asphyxia must depend on its cause. (See DROWNING.) In partial strangulation, abstraction of blood in moderate amount may unload the heart and promote the movement of the blood, after the cause of obstruction has been removed. For asphyxia from irrespirable gases the first necessity is a supply of pure air. When the heart has almost or quite ceased to beat for a few moments, life is sometimes restored by artificial RESPIRATION (*q. v.*), or by application of galvanic electricity to the chest.

Revised by WILLIAM PEPPER.

Aspic: See ASP.

Aspid'ium: a genus of ferns (shield-ferns), whose fruit-dots are covered with round or kidney-shaped shields (*indusia*). There are about 500 species widely distributed throughout the world.

C. E. B.

Aspidich'thys [from Gr. *dorís*, -*idos*, shield + *ιχθύς*, a fish]: a genus of fossil fishes, described by Dr. Newberry, from the Devonian rocks of Ohio; allied to *Pterichthys*, but very much larger. The middle dorsal plate of the carapace is a foot wide and a foot and a half long, more than an inch thick at the center, and its external surface is studded with smooth enamel tubercles as large as split peas.

Aspinwall [named for WILLIAM H. ASPINWALL (*q. v.*); called **Colon** by the natives]: seaport in the republic of Colombia; on the north side of the Isthmus of Panama, and on Navy Bay, 48 miles by rail from Panama, and on the Caribbean Sea; lat. 9° 21' N., lon. 79° 54' W. (see map of North America, ref. 11-H). Aspinwall was founded in 1852 by the Panama R. R. Company, and is the northern terminus of the Panama R. R., which was opened in 1855. It has a good harbor, which is deep enough for large ships, and has several large hotels. It was formerly a great thoroughfare for the travel between California and the Atlantic States. Steamers ply frequently between this place and New York, which is about 2,000 miles distant. A ship-canal between Aspinwall and Panama, the latter on the Pacific Ocean, was attempted, but failed because of the enormous cost. Pop. 1,800, but fluctuating. See PANAMA and SHIP-CANALS.

Aspinwall, WILLIAM, M. D.: b. at Brookline, Mass., May 23, 1743; graduated at Harvard in 1764, and subsequently took his medical degree in Philadelphia; became a surgeon in the Revolutionary army, and after the war was a prominent Jeffersonian politician in Massachusetts. He practiced medicine with great success at Brookline, and was distinguished for the practice of "inoculation" and his early adoption of vaccination. D. at Brookline, Mass., Apr. 16, 1823.

Aspinwall, WILLIAM H.: b. in the city of New York, Dec. 16, 1807; was trained as a clerk in the house of G. G. & S. Howland; became a partner in 1832; formed the firm of Howland & Aspinwall in 1837; retired from the firm in 1850. D. in New York, Jan. 18, 1875. He was the chief promoter of the construction of the Panama R. R., the northern terminus of which is named after him, and acquired a fortune in the Pacific trade, being a large owner of the Pacific Mail Steamship Company.

Aspirate [from Lat. *aspiratus*, partic. of *aspira're*, breathe upon]: in pronunciation, a breath-sound or a consonant accompanied by a breath-sound. In the stricter use of modern philology, the term is applied to those explosives (stops) which end in a breathing, really due to an audible escape of breath after a forcible breaking of the closure; such are the Sanskrit aspirates *kh, gh, ph, bh*, etc., the Greek aspirates *θ, φ, χ* (as pronounced in fifth and fourth centuries B. C.), and even the modern German and English *k, t, p*, initially before an accented vowel. In popular use the term is often made to include the fricative sounds, as German *ch*, or even the sound of *h*, *spiritus asper*, which is, in general, no more than a collective representation for a variety of whispered vowels, the particular vowel character in each case being determined by the following vowel; thus compare *hā, hē*, in which *h* represents two different sounds.

BENJ. IDE WHEELER.

Aspirator [Mod. quasi-Lat. format. from Lat. *aspira're*, breathe upon]: an apparatus used by chemists to draw air or other gases through bottles or other vessels. It is a tight vessel filled with water, having a tube with a stopcock connected with the upper end, and another tube with a stopcock connected with the lower end. The former tube is attached to the vessel through which the gas is to be drawn; the stopcocks are both opened, and the weight of the water issuing from the lower tube acts as a suction, and draws in the gas.

Aspis, or Clupea: an ancient and important fortified city of the Carthaginians, on the Mediterranean, about 50 miles E. of Carthage; founded about 310 B. C. It was the place where Regulus landed in the first Punic war, and was a distinguished episcopal see from 411 to 646 A. D. It was the last spot on which the African Christians made a stand against the Saracens. Remarkable ruins are to be seen there.

Asplenium: a genus of ferns (the spleenworts) whose elongated fruit-dots are covered with a membrane (*indusium*) attached its full length at one side. About 350 species are known, many of which are grown in greenhouses.

C. E. B.

Aspromonte: a mountain at the southwestern extremity of Italy; 6,300 feet high; 16 miles E. N. E. of Reggio (see map of Italy, ref. 9-G). Here Garibaldi and the greater part of his army were taken prisoners in Aug., 1862.

Aspropotamo (i. e. white river): the ancient *Achelous*; the largest river in the kingdom of Greece. It rises in Albania, flows in a S. S. W. direction, and after a course of about 100 miles enters the Mediterranean (or Ionian) Sea, nearly 15 miles W. of Missolonghi.

Asquith, HERBERT HENRY: English public man; b. at Morley, England, Sept. 12, 1852; scholar and afterward fellow of Balliol College, Oxford; B. A., 1874; called to the bar at Lincoln's Inn, 1876; queen's counsel, Feb., 1890; elected member of Parliament for East Fife, July, 1886, and again in 1892; Secretary for Home Affairs in Mr. Gladstone's Cabinet, 1892; ecclesiastical commissioner, 1892-95.

Ass, or Don'key: a quadruped of the genus *Asinus* and family *Equidae*. It is characterized by long ears, a black cross over the shoulder, and short hairs on the upper part of the tail. It is remarkable for its patience, stolidity, and power of endurance, and has been the domesticated drudge of man from time immemorial. The ass is probably a native of Central Asia, as it is now found wild in that region.

Vast numbers of the wild ass (which the Romans called *onager*) roam over the great Asiatic deserts and steppes, feeding on saline herbage. They also inhabit Persia, Asia Minor, and Syria. An interesting notice of this animal is given in the thirty-ninth chapter of Job. The wild ass is a high-spirited animal of extraordinary speed, and is one of the principal objects of the chase in Persia, where its flesh is highly esteemed as food. There appears to be some doubt whether the domesticated ass is descended from this wild animal, so much superior in speed and other qualities. In Oriental countries the custom of riding on the back of the tame ass is very common; and the Old Testament informs us that it was thus used by patriarchs and kings in the earliest times. The asses which are raised in Syria and other parts of the East are a better breed than those of Europe. The animal is not much employed in the U. S., except for the propagation of mules, which are the hybrid progeny of the ass and mare. Being very sure-footed and able to live on scanty fare, the ass is well adapted for service as a beast of burden in rocky and mountainous regions. Its milk is recommended as a diet for dyspeptic and consumptive patients. The proverbial stupidity of the ass seems rather due to its patience and endurance than to any particular want of intelligence.

Assab': a bay, a territory, and a town on the African shore of the southern part of the Red Sea. The bay is about 40 miles N. W. of the Bab-el-Mandeb, opening northward. It is about 16 miles long by 5 broad, and is full of islands. The territory is an ill-defined region on the coast near the bay, in what is called the Danakil country, now the Italian colony of Eritrea. The town, near the mouth of the bay, is an Italian station. Pop., with the district immediately around it, 6,800.

M. W. H.

Assafœtida, or Asafœtida [from Lat. *asa* (loan from Pers. *azā*, mastic) + *foetidus*, stinking]: a gum-resin or the concrete juice of the root of *Nartherx assafœtida* (the *Ferula assafœtida* of Linnaeus). It is a native of Persia and Afghanistan, has a peculiar and disagreeable odor, and is extensively used in medicine as an antispasmodic. It is considered an efficacious remedy for hysteria, nervous diseases, and spasmodic pectoral affections. In many parts of Asia it is used as a condiment.

Assal': a salt lake of Eastern Africa; 25 miles S. W. of Tajura, and about 760 feet below the level of the sea. It is 8 miles long and 4 miles wide, and has an area of 20 sq. miles. The shores are covered with crusts of salt about a foot thick. Large quantities of salt are carried hence by caravans to Abyssinia.

Assam': a province of British India, bordering on China, and forming part of the valley of the Brahmaputra. It is included between lat. 25° 45' and 28° 15' N., and between lon. 90° 35' and 96° 50' E. Area, 49,004 sq. miles. It is well watered by numerous rivers, and has a fertile soil, but a large part of it is swampy and subject to inundation. The staple products of the soil are rice, tea, cotton, opium, and mustard. Gold, silver, and precious stones are found here, and coal, petroleum, and iron are abundant. The rainy season lasts about six months, from April to October, during which time the whole country is inundated. The large and dense forests of Assam are infested by great numbers of elephants, tigers, leopards, rhinoceroses, buffaloes, etc. Assam was ceded to the British by Burma in 1826. The religion of the Assamese is Brahmanism. Pop. (1901) 6,122,201.

M. W. H.

Assas'sin [viâ Fr. from Arab. *hashshāshīn* (plur.), hashish-eaters]: one who attacks and kills by treachery or surprise a person who is unprepared for defense. The word was originally the name of a fanatical sect or order, the disciples, it is said, of Alo-ed-Deen (Aloaddin), commonly called Sheikh-el-Jebel, or the "Old Man of the Mountains." The founder of the order is said to have been Hassan-ben-Sabah, who flourished in Persia about 1080 A. D. They were called Assassins from their immoderate use of hashish, an intoxicating drug obtained from Indian hemp. The order consisted of several degrees, the lowest of which were *Fedavis* or *Fedais* (i. e. the devoted), who were not initiated into the secret doctrines and mysteries, but with blind obedience executed the bloody orders of the prince or Old Man of the Mountains.

Assault' [through Old Fr. from Lat. *adsili're, assili're*, to leap upon; *ad*, upon + *sali're, saltum*, leap]: in military language, a sudden and vigorous attack on a fortified post or camp, or an effort to carry by open force a breach which has

been made in a fortress. In the regular routine of sieges (as they *were* formalized, for recent changes in the art of fortification and in the character of firearms have rendered the old rules somewhat inapplicable) the "assault" is one of the last scenes of the drama called a "siege." In the regular siege the assault (if, instead of gaining the breach by covered "approaches," it is decided to resort to it) is delivered after the outworks are captured, and one or more "breaches" formed (by "breaching batteries") in the body of the place. It is usually performed by picked troops or volunteers (sometimes called a "forlorn hope"), who, at a concerted signal (upon which the besiegers' artillery ceases to fire), issue from the contiguous parallels or places of arms, descend into the ditch, and advance rapidly and without much order, but without firing, upon the breach. "Firing parties" are stationed in neighboring parallels to keep down the fire of the besieged, and "supports" are close at hand to follow up the assaulting party, if successful in effecting an entrance.

Under Louis XIV. commandants of besieged places were forbidden to capitulate before receiving *three* assaults. Under Napoleon it was declared dishonorable and punishable with death to capitulate before receiving at least one assault. According to Vauban and the "schools," the open assault is a "useless massacre," which, if successful, results only in the demoralization of the troops, the sacking of the place, and the destruction of resources valuable to the besiegers. Nevertheless, it is sometimes compulsory, as in the case of the assault of Constantine (1837) by the French, with a loss of 500 out of 1,750. In Spain the British army delivered terrible assaults, as those at Badajoz (1812) and St. Sebastian (1813); the loss at the former (which failed, the place being entered by *escalade*) cost 3,700 men, and the latter (successful) 2,000, killed and wounded. The bloody assault by which the siege of Sebastopol was terminated Sept. 8, 1855, was necessitated by the fact that the "approaches" could be pushed forward no farther. This so-called siege differed from an ordinary siege in this, that "the difficulty was to conquer the Russian army upon a ground prepared beforehand, quite as much as to surmount the material obstacle presented by the fortifications" (*Niel*). The allied loss in this assault (killed and wounded) was nearly 10,000; that of the Russians, 11,700 men; thus terminating a siege of eleven months' duration, and which cost the besiegers 150,000 and the Russians 84,000 men.

Assault and Bat'tery: an assault is an offer or attempt to inflict corporal injury upon another, accompanied by circumstances which indicate an intent, coupled with a present ability, to do actual violence. If violence be actually inflicted, the act amounts to a battery; but the offer or attempt to do violence is alone sufficient to constitute an assault. It is not necessary that an actual intention to do violence exist; it is enough that there be a sufficiently indicated intent, so that it would appear to a reasonable mind that the apparent purpose was the true one. Moreover, if threats or offers of violence be made, but there is an apparent present inability to carry them into effect, there is no assault committed. Thus one might vehemently threaten actual violence; but if an impassable barrier, as a ditch or wall, intervened between him and the person menaced, the act would not be an assault. A battery is really the consummation of an assault, and therefore requires that the offer or attempt to do violence be carried into effect by the actual use of violence. An assault and battery is sometimes justifiable, as when it is committed in the reasonable defense of one's person or his real or personal property. And in exercising this right of defense the person threatened is justified in acting upon reasonable appearances, but in no case should the force used be greater than is properly adequate to repel the assault or avert or prevent the injury apprehended. An assault and battery is also sometimes justifiable when committed in the cause of rightful discipline, as where a father or schoolmaster inflicts moderate punishment upon a child, or the master of a vessel upon a seaman; but in these cases also there must be no excess of violence. An assault and battery is both a civil and a criminal wrong, and there may be a civil action for damages by the person injured, and also a criminal prosecution instituted. In criminal law there are also recognized certain forms of aggravated assault which receive severer punishments than common assault, as an assault with intent to kill, with intent to commit rape, etc.

GEORGE CHASE.

Assay', or **Assay'ing** [O. Fr. *asayer*; Ital. *assaggiare* < Late Lat **exagiā're*, deriv. of *exā'gium*, weighing, testing]:

the process of ascertaining the proportion of gold or silver in an alloy, or of pure metal in a metallic ore. Silver plate and manufactured articles of gold and silver generally contain an alloy of copper or other metal. (See ALLOY.) In Great Britain each article before it is sold is assayed at Goldsmiths' Hall, so as to determine the proportion of precious metal in its composition. The process of assaying gold and silver depends on the principle that those metals can not be converted into oxides by union with the oxygen of the air, while the baser metals with which they are alloyed can be oxidized if raised to a high temperature. The apparatus employed in this process consists of a *cupel*, a small shallow vessel made of bone-ash, and a *muffle*. The latter is made of fire-clay, is about 8 inches long, 3 or 4 inches in diameter, and is shaped like a railway tunnel (that is, having a flat bottom and an arched top); it is open at one end and closed at the other, and has several apertures in its sides for air to pass through. Weighed fragments of mixed silver and lead are placed on cupels, which, introduced into a muffle, are exposed to the heat of a furnace until the metals are melted. The oxygen of the air unites with the lead, forming an oxide, which is partly volatilized and partly absorbed by the porous cupel. At the end of this process of *cupellation* there remains a globule of pure silver, which by its diminished weight shows how much alloy was contained in the sample. During the assay of silver by the foregoing process, called the *dry method*, a small loss of silver occurs. For this reason the *humid* process has been adopted in the mints of France, of the U. S., and of other nations. This method consists in dissolving the compound or impure silver in nitric acid of density 1.25, and adding a solution of common salt (NaCl), which causes the precipitation of the chloride of silver (AgCl) in white flocculi. The solution of salt is made of a definite strength, and is poured out of a graduated vessel until all precipitation of pure silver ceases. The assay of gold ores or impure gold is performed in a manner similar to that of silver. If gold alloyed with copper is to be assayed, some silver must be added to the alloy. The alloy of the three metals, gold, silver, and copper, may be assayed by cupellation, by which the copper is oxidized and the gold and silver remain combined. These may be separated by a process called *parting*, which, however, is only practicable when the alloy contains three parts of silver to one of gold. The parting or quartation consists in acting on the alloy by hot nitric acid, which dissolves the silver, forming the soluble nitrate of silver, and leaves the gold in a solid and separate state. As no ore of gold or artificial alloy contains so much silver as three to one, it is necessary to incorporate an additional quantity of silver with it. This is done by wrapping the proper quantities of gold and silver in lead-foil and heating them on a cupel. The metallic button which is the result of this cupellation is hammered on an anvil, and rolled into a thin plate or ribbon, which is coiled up and called a *cornet*. This is exposed in a glass vessel to the action of nitric acid, which, dissolving the silver, leaves a brown, spongy mass of gold. It is then heated in a crucible, annealed, and weighed. As jewelry and other articles can not be assayed either by the dry or humid method without injuring their form, their purity is ascertained by the use of the *touchstone*, with which a streak is drawn on the surface of the gold. Black basalt is one of the minerals used as a touchstone.

As'saye: a village of S. India, in the Nizam's Dominions, 24 miles N. of Jaulna (see map of S. India, ref. 3-D). It was the scene of the Duke of Wellington's first great victory. On Sept. 23, 1803, with a force of 2,000 British and 2,500 natives, he utterly defeated the Mahrattas, numbering from 30,000 to 50,000 men, partly officered by the French. Wellington, then Gen. Wellesley, captured 98 cannon, and lost 1,560 killed and wounded.

Asselyn, or **Asselijn**, *ās'sel-līn*, JAN (OR HANS): landscape and animal painter; b. at Antwerp in 1610; studied painting, first in his native city under Isiah Vandervelde, then in Rome, where Bamboccio and Claude Lorraine became his models; settled subsequently in Amsterdam, and died there in 1660. He painted battle-pieces, animals, and landscapes, and his views of the neighborhood of Rome are much appreciated.

Asseman'ni, GIUSEPPE SIMONE: Bishop of Tyre *in partibus*; a learned Maronite; b. at Tripoli, in Syria, in 1687. He was sent in 1715 by the pope to Syria and Egypt to collect manuscripts, and was keeper of the Vatican Library (1738-68). He published a valuable work on Syrian litera-

ture, entitled *Bibliotheca Orientalis Clementino-Vaticana* (4 vols., 1719-28). D. in Rome, Jan. 14, 1768.—His nephew, STEFANO EVODIO, an Orientalist, born at Tripoli in 1707, was educated at Rome. He was Archbishop of Apamea in *partibus*. He succeeded his uncle, Giuseppe Simone, as keeper of the Vatican Library, in 1768. He published several catalogues of Oriental manuscripts. D. in Rome, Nov. 24, 1782.

A. R. MARSH.

Assem'bley: in politics, a convention or body of men associated for civil or legislative business, and possessing more or less political power. In some States of the U. S. the legislature is collectively called the *General Assembly*, and was formerly also called the *General Court*, and had certain judicial powers which are now mostly taken away; in some of the States the lower branch of the legislature is called the *Assembly*, and the other house is called the *Senate*. At the beginning of the French Revolution the members of the *Tiers État* (Third Estate), who had been chosen to represent the common people in the States-General, assumed (Jan. 17, 1789) the title of *Assemblée Nationale*, and, having been joined by the more liberal members of the nobility and clergy, proceeded to frame a new constitution. The court denied their authority, and made a not very vigorous effort to dissolve the Assembly, but failed, and finally yielded to the popular current. This body, which was termed the Constituent Assembly, formed a constitution which was accepted by the king, and, having ordered the election of a legislative assembly, dissolved itself Sept. 30, 1791. The Legislative Assembly, from which all members of the Constituent Assembly were expressly excluded, met Oct., 1791, and continued to undermine or defy the royal authority, which was abolished Aug. 10, 1792. Having convoked a *National Convention*, the Assembly closed its labors and existence Sept. 21, 1792. The formation of the second French republic (Feb., 1848) was followed by the election of a National Assembly, which met in May of that year, and, having formed a constitution, transferred its power to the Legislative Assembly. This body was dissolved or abolished by the *coup d'état* of Dec. 2, 1851. The third republic was proclaimed Sept. 4, 1870, but, on account of the presence of German armies in France, the election of deputies was postponed until the armistice, which began just after the capture of Paris, Jan. 30, 1871. The National Assembly met at Bordeaux in February, and elected Adolphe Thiers as *chef du pouvoir exécutif* (chief of the executive power).

Revised by F. STURGES ALLEN.

Assembly, General: See GENERAL ASSEMBLY.

Assembly, Unlawful: See RIOT.

Assessments (political): See CIVIL SERVICE REFORM.

Asses'sor [from Lat. *assessor*, one who sits beside, assistant, judge; *ad*, to + *sede're*, sit]: in Great Britain, a person, usually a lawyer or jurist, who is appointed to advise the judge; the legal adviser of a magistrate in determining police and similar cases. In several inferior courts assessors are appointed by statute. The burgesses of every borough are required to elect annually two assessors, who assist the mayor in revising the burgess lists and in presiding at the municipal elections. An assessor is also a person elected by the people, as in the U. S., or appointed to assess or appraise all taxable property, in order that the owner of the same may pay a tax proportioned to its value. This valuation or appraisal is called assessment. The assessed value is usually less than the real, or less than the price for which it could be purchased.

As'seteagne Island: an island off the east coast of Northampton co., Va., to which it belongs (for location of county, see map of Virginia, ref. 6-J); has a brick lighthouse 129 feet high, standing 2 miles from the S. W. extremity of the island and showing a fixed light of the first order, 150 feet above the sea, in lat. 37° 54' 37" N., lon. 75° 21' 04" W.

As'sets [O. Fr. *asez*, enough < vulg. Lat. *ad satis*, to sufficiency]: in law, denotes the property in the possession of an heir or under control of an executor, administrator, or trustee, applicable to the payment of debts and charges against the estate which they represent. It is mainly applied to the case of heirs, executors, and administrators. Assets are either real or personal. Real estate is assets in the hands of an heir; personal property, in like manner, in those of an executor or administrator. If the real estate is devised to an executor, he takes it as trustee. Assets are also distinguished into legal and equitable, the first being under the

control of a court of law, and the second administered by a court of equity; and the two courts are not governed by the same rules. In the U. S. this last distinction is, by reason of statute law, of little consequence, as all the estate of a deceased person becomes a fund for the liquidation of his debts, according to a prescribed statutory order. The distinction between real and personal assets is still of importance, as it is a general rule that real estate is not to be taken for the payment of debts until the personal property is exhausted. A testator may by a sufficiently clear direction in his will avoid the effect of this rule, and make his real estate the primary fund for the payment of his debts.

Assh'ur, or Ash'ur: an ancient and populous city; capital of Assyria; on the Tigris, 40 miles below Calah, and 60 miles S. of Nineveh. Its site is marked by extensive ruins at Kileh-Sherghat. Here is a large square mound or platform, 2½ miles in circumference, about 100 feet above the level of the plain, and composed in part of sun-dried bricks. Cuneiform inscriptions of great interest have been found here.—A son of Shem was also called ASSHUR, from whom the name of the city was derived.

Asshurbanipal (i. e. Asshur creates a son): the greatest of the Kings of Assyria; ruled at Nineveh 668-626 B. C. The literary remains from his library and the treasures of art from his palace have been brought in large numbers to the British Museum. See ASSYRIA (*History*). D. G. LYON.

Assien'to (or preferably **Asiento**): a word applied to treaties which the Government of Spain made with several foreign nations for the purpose of supplying her colonies with Negro slaves. The first of the assientos was made with the Flemings, in the reign of the Emperor Charles V. The Genoese obtained the contract in 1580. The privilege was transferred to the Portuguese in 1696, and to the French in 1701. The British acquired it by the treaty of Utrecht, 1713, but resigned or sold it to Spain about 1750, since which no such contract has been made.

Assign, or Assignee: See ASSIGNMENT.

Assignat, äs'-ig-nät (in Fr. ää'sëen'yaa'): one of the notes forming the paper currency issued by the French Government in 1790, and at subsequent periods of the revolutionary régime. It was based on the security of the national domains, which consisted of the confiscated estates of the Church and wealthy *émigrés*. The total amount of assignats issued was 45,578,000,000 francs. The public credit having been ruined by the reign of terror and anarchy, the value of the assignats declined lower and lower. In June, 1793, one franc in silver was worth three francs in paper. The Government, in order to check their depreciation, passed a law to fix the maximum prices of commodities, the effect of which law was very injurious to trade. In Mar., 1796, one franc in gold was equivalent to 300 francs in paper. In July of that year the assignats were recalled, and replaced by the *mandats*.

Assign'ment [from Lat. *assigna're*, appoint]: in law, the act of making over to another one's estate or interest. The person making the assignment is an *assignor*; the recipient is an *assignee* or *assign*. The word is mainly used in reference to transfers of leases, incorporeal rights, such as copyrights and patents, and rights of action. Such transfers are to some extent by statute law required to be in writing. It is a rule of *common law* that a thing in action is not assignable, though this doctrine is not followed in a court of *equity*, an assignment being regarded in that court as in the nature of a declaration of trust, so that the assignor becomes a trustee for the assignee. There are some exceptions to this rule, as in the case of mere personal causes of action and cases where public policy intervenes. Such an assignee simply takes the rights of his assignor, and holds subject to any defenses which the debtor could urge against his creditor. There is a class of things in action not subject to this infirmity, such as bills of exchange, promissory notes, checks upon banks, and public securities payable to order or bearer. He who purchases these in good faith and before maturity, for a valuable consideration, may shut out for the most part the defenses which might have been urged against the payee. Such paper is termed negotiable. In this way the distinction between that which is negotiable and that which is assignable becomes of great practical consequence. It is a frequent practice on taking an assignment of a claim to obtain a statement from the debtor that he has no defense to it. He would then be precluded from setting up any that he might have on the doctrine of estoppel.

The word "assignment" is also used to indicate the act of setting apart dower for a widow in the real estate of her husband. It is also employed in case of bankruptcy or insolvency, to indicate the act of transfer of a failing debtor's property to a person called an assignee, who is substantially a trustee for the benefit of the creditors. A failing debtor by the laws of some States is permitted to make a voluntary and even preferential transfer to an assignee acting in the same general manner, though such laws are substantially superseded for the time being when there is a U. S. bankrupt law in operation.

T. W. DWIGHT.

Assimilation (in plants): the change or series of changes made upon the carbon-dioxide (carbonic acid gas) and water in green cells, resulting in the production of a hydrocarbon food-stuff (usually starch). We can not yet give an exact account of the successive steps in assimilation. The principal facts, however, are as follows: Carbon-dioxide contains carbon (C) and oxygen (O) in the proportion of one atom of the former to two of the latter (CO₂). Water contains hydrogen (H) two atoms and oxygen (O) one atom (H₂O). These are taken in by the green cells, and eventually starch is produced, whether directly or indirectly is not now certainly determined. Some oxygen is liberated during assimilation, indicating a breaking up of one or both of the constituents. It can readily be seen that six molecules of carbon-dioxide and five of water afford the necessary elements in the proper quantities for the formation of a molecule of starch. Thus:

One molecule of starch = C₆H₁₀O₅ + 12 atoms of O set free.

It is not to be supposed that the process is as simple as this; on the contrary, it is probably quite complex, this statement serving merely as a summary of the results. Assimilation takes place in cells which contain chlorophyll, the green substance of plants, and only in the light. Parts of plants destitute of chlorophyll are destitute of the power of assimilation, nor can green cells assimilate in darkness.

CHARLES E. BESSEY.

Assiniboia, ăăs-sin'i-boi'-a (named from *Assiniboine*): a district of the Northwest Territories and a future province of the Dominion of Canada. It is rectangular in form and has Saskatchewan district on the N., Manitoba on the E., North Dakota and Montana on the S., and Alberta on the W. It is a part of the great plains E. of the Rocky Mountains, but has many hills and coteaus. The most celebrated of the latter is a low ridge called the Missouri Coteau, extending from about the center of the district southeastward far into North Dakota. The country is well-watered, and has many small lakes. About a third of it is drained by the Saskatchewan river, which empties into the north end of Lake Winnipeg; about a half drains through the Qu'appelle and Souris rivers into the Assiniboine, and so into the south end of the same lake; the remainder consists in part of small independent basins, and in part drains into the Missouri river. Area, 95,000 sq. miles; pop. (1885) 22,083, but rapidly increasing. Of the population, 4,492 were Indians and 1,017 half-breeds; 5,853 were engaged in agriculture. There were 160,000 acres under cultivation, and the live stock included 8,000 horses, 20,000 cattle, 9,000 sheep, and 17,000 swine. Wheat (1,000,000 bushels in 1885), barley, oats, pease, and potatoes are raised; and there is a considerable production of peltry, including 13,000 muskrat skins, 3,000 mink, and 900 beaver. The Canadian Pacific Railway passes nearly centrally through the district. Capital, Regina, which is also the capital for the Northwest Territories generally. The climate of Assiniboia is rather severe, but the winter temperature is frequently tempered by chinooks. It is subject to severe blizzards, and the most of the severe winter storms and cold waves of the Northern States come from Assiniboia.

MARK W. HARRINGTON.

Assisi, ăăs-see'scē: a town of Italy; province of Perugia; built on a steep hill, 13 miles S. E. of Perugia (see map of Italy, ref. 5-B). It is surrounded by a wall flanked with towers, and has a cathedral built in the eleventh century and many monasteries. It is the native place of St. Francis, and has remarkable paintings by Cimabue and Giotto, and a large and beautiful Gothic structure, Convento Sacro, with fine paintings. Among the remains of the ancient Assisium is a beautiful portico of the temple of Minerva. Pop. about 6,000.

Assis'tance, Writ of: in Great Britain, a writ issued by the court of chancery to the sheriff directing him to put a

party in whose favor a decree has been rendered in possession of land to which the decree has declared him to be entitled; also, in the U. S., a writ issued by the colonial courts to aid the crown officers in enforcing the acts of trade.

Revised by F. STURGES ALLEN.

Assiut, ăăs'scē-ōōt', **Assioot**, or **Siut** (anc. *Lycopolis*): a district and a city of Upper Egypt. The district is a very fertile one. Area, 840 sq. miles; pop. (1882) 562,137. The city is the capital of Upper Egypt; is near the Nile, in lat. 27° 11' N.; the terminus of the railroad on the left bank of the river, and 228 miles S. of Cairo. It is the finest city in Egypt, except Cairo, and has fine mosques and bazaars, a palace, baths, and a cotton-factory. It is the seat of a flourishing American mission. It is the chief resort of the caravans from the Sudan, and was until recently a center for the slave-trade. It is also an important military station, and has a large manufactory of pipe-bowls. Traces of the ancient civilization are abundant in and about it, including the ruins of a Roman amphitheater. The view of the Nile valley from the tops of the adjacent Lybian hills is said to be the finest in Egypt. The population is said to be industrious and reliable. Pop. 31,575.

M. W. H.

Assize [O. Fr. *asise*, a sitting, assessment; past partic. of vb. from Lat. *assidere*, sit down to]: an ancient English court; also, formerly, a writ to recover the possession of a freehold. The word is now used in the plural to denote the stated sittings of the judges of the superior courts in England in the various counties, by virtue of several commissions, to try civil and criminal cases.

Revised by F. STURGES ALLEN.

Associate Presbytery: 1. The organization formed by Ebenezer Erskine and others, who seceded from the Church of Scotland in 1733. In 1745, having grown to forty-five congregations, it was reconstituted under the name of the *Associate Synod*. In 1747 it was torn into two bodies, commonly known as Burgher and Antiburgher, each of which claimed the name Associate Synod, though from 1778 the Antiburghers are called the *General Associate Synod*. 2. In 1799 the "Old-light" Burghers, having separated themselves from the "New-light" majority, called themselves at first the *Associate Presbytery*, but from 1805 the *Associate Synod*, or *Original Burgher Synod*. *Constitutional Associate Presbytery* is the name taken by the Old-light Antiburghers, when they separated from the New-light majority, in 1804.

Through many schisms and reunions these bodies are now represented in various existing Presbyterian Churches, particularly those that are known as "United," or "Reformed," or "Secession," or "Seceder," as well as in the Associate Church of North America, the Associate Reformed Synod of New York, the Associate Reformed Synod of the South, and the Associate Synod of North America. For statistics of these Churches, and for their history, with the history of the various "Associate" movements, see the article PRESBYTERIAN CHURCH; also UNITED PRESBYTERIAN CHURCH, UNITED SECESSION CHURCH, UNITED ORIGINAL SECEDERS, SCOTLAND, CHURCH OF, and FREE CHURCH OF SCOTLAND, etc.

W. J. BEECHER.

Associated Presbyteries: the presbyteries of Morris County, Westchester, Northern, and Saratoga (in New York State), organized from 1780 to 1807. So far as their associated character is concerned, they were soon absorbed in other bodies. See PRESBYTERIAN CHURCH.

Associated Press: an association of newspapers in the U. S. for the collection of news. Its principal center was at New York, but there were subordinate centers, as at Cincinnati, Chicago, and Washington, to which items of news were transmitted, to be there condensed and distributed to the various journals. The association either sold the news it collected to other similar associations in different parts of the country or in Europe, or exchanged with them. In 1892 it was absorbed by *The United Press*, an association organized in 1882 for similar purposes.

Associate Synod: See ASSOCIATE PRESBYTERY.

Association of Ideas (otherwise called **Mental Association**, or simply **Association**, **Suggestion**, **Connection of Ideas**, **Train of Thought**, **Succession of Thoughts**, etc.): a principle or law in mental philosophy exercising an important influence upon the operations of the mind. "When a traveler visits the ruins of Athens or of Rome, the plain of Pharsalia or of Marathon, the sight of these places awakens the memory of the men and of the deeds which have made

them glorious." The names of the great recall their achievements. A portrait revives similar memories, and calls up emotions which might have seemed dormant forever.

It may be a sound,
A tone of music, summer's eve, or spring,
A flower, the wind, the ocean, which shall wound,
Striking the electric chain.—Byron.

These facts rest upon the reciprocal power of thought to evoke thought. Under this power arises what is called the association of *ideas*, but its law is the law of intellectual gravitation—its sphere is the universe of mind. It is wider than "ideas," and extends to all our mental modifications. Our cognitions, emotions, and active powers, all come under the law of association. Our feelings, our willings, and our efforts are as completely held in groups by internal bonds as our ideas are.

Association may connect ideas by a simple link or by a multitude of links. The idea of the civil war of England prompts the question, "What is the value of a Roman denarius?" There are no two thoughts so remote as to have no link. The laws of association have been variously enumerated. Some of the most obvious and important are:

1. Simultaneity and succession, synchronism and chronology. Thus Cæsar and Pompey, Luther and Leo, Charles I. and Charles II.; Aristotle back to Plato, Descartes on to Spinoza.

2. Contiguity and remoteness between ourselves and the things, or between the things themselves: New York and Brooklyn, ourselves and our antipodes. We think of Mercury as nearest the sun, and that suggests Neptune as the farthest off.

3. Resemblance and contrast to the eye in works of art, which recall the original to the mind: metaphor; punning rests on the association of sounds that resemble with things that differ. Night recalls day, sickness recalls health.

4. The logical relations involve association of ideas, though not all association of ideas is logical: cause and effect, workmen and work, father and child, the universe and God, object and means, analogy, premise and conclusion, part and whole. The relations of physical, mechanical, and cosmical order are of the same kind, and hence association is the mother of invention and discovery.

5. The association of the verbal sign with the thing signified, which is the essence of language and the necessary preliminary to reasoning. Two or more of these causes may co-operate in particular cases, or the thing may in one aspect give rise to one association, in another aspect to another. Aristotle reduces the principle of association to three parts: Proximity in time and contiguity in place as one; resemblance, contrast. Hume says: "There appear to be only three principles of connection among ideas—namely, resemblance, contiguity in time or place, and cause or effect. A picture naturally leads our thoughts to the original (resemblance); the mention of one apartment introduces an inquiry concerning the others (contiguity); we think of a wound and the pain which follows it (cause and effect)." Augustine reduces the principle to one: What is once together is afterward together. Hobbes says: "The cause of the coherence or consequence of one conception to another is their first coherence or consequence at that time when they are produced by sense." Cardaillae (1830) in substance repeats Hobbes when he says that simultaneity is the common condition of all the other connections: nothing can be linked now that has not been linked before. Hamilton in the same way reduces the laws to two, simultaneity and affinity; and these two laws, he asserts, are only modifications of one law, redintegration, or totality: "Those thoughts suggest each other which had previously constituted parts of the same entire or total act of cognition." This is ending where Augustine began. Hamilton maintains that a third thought may be associated with a first through a second which "does not rise into consciousness," "suggestions passing through one or more ideas which do not themselves rise into consciousness." This false theory in metaphysics he illustrates by an example drawn from a false theory in physics—to wit, that billiard-balls in a row, intermediate between the first one, which is struck, and the last one, which flies off, remain motionless. Hamilton's whole position and argument are marked by the crudity and self-contradiction which often mar his lectures. The true theory in such cases is that the acts of consciousness are too rapid to mark themselves deeply and distinctly enough in memory to be carried on by it to the end of the process. Reflection usually with very little difficulty ar-

ticulates all the parts. When Hamilton reflectively associated Ben Lomond with the Prussian system of education, he simply did slowly what he had done before rapidly. The human mind is subtler than light, far beyond the degree in which light is subtler than lead. Consciousness is the essential condition of an idea. Memory, as objectively separated in time from consciousness, is not essential to it. Both can be born together, and both die together. A precedence in the order of thought must not be confounded with a precedence objectively in time. Alexander Bain reduces the primary attributes of intellect to three, of which the third is retentiveness, the facts connected with which may, with few exceptions, "be comprehended under the principle called the law of contiguity or contiguous adhesion. The principle of contiguity has been described under various names—as Hamilton's law of 'redintegration,' the 'association of ideas.' The principle may be stated thus: Actions, sensations, and states of feeling, occurring together or in close succession, tend to grow together or cohere in such a way that when any one of them is afterward presented to the mind the others are apt to be brought up in idea." Bain further discusses agreement, law of similarity, compound association, constructive association.

Not all ideas once integrant are necessarily redintegrated. The strength of the impression which they originally made, their duration in fellowship, the time which has elapsed since we had them, the cogency of their connection, are all determining forces. But in advance of all this the tendencies of the law of association in the particular individual are determined by the native constitution of his mind and by the circumstances of his whole training, mental and moral. These tendencies carried out make the poet or the mathematician, the sensualist or the sage. An illegitimate association of ideas may mar a whole life, may work out crime and ruin. One and the same thing may be to two persons a deadly or a reviving savor. The same flag calls forth the fiercest assaults and the most vigorous defense. The same strain of music awakens joy, sadness, hope, or despair. The poem of Wordsworth on the *Power of Sound* is but an exquisite painting of one class of illustrations of the power of association. There are national tendencies under this law as well as individual. Governments and societies are built for ages on the ideas associated with a single central idea embodied in a word. It is the association of ideas which makes the mightiest and holiest bond of our life—the tie of the home, the native land, the Christian communion. It makes the heart of the Swiss sicken and die for the little rocky mountain-nook which is associated with the *Ranz des Vaches*. The principle of the association of ideas is therefore not only of profound interest in psychology, but has great importance in morals. Like every power of man, it comes under the law of moral responsibility. Association is in certain respects involuntary, and habit can in any case carry it beyond the proper control of the will. But the will can largely determine what shall be the original links of association, and bear an important part in determining whether we shall follow up or repress a particular class of associated ideas. The association of a profane or ludicrous idea with a sacred name or fact may make that name or fact through a whole lifetime the means of recalling blasphemy or mockery.

The attempts to account for the association of ideas are of course affected by the general features of the different systems. The effort to give them in whole or in part an organic mechanical relation has been made by Descartes, Hartley, Bonnet, and a number of later writers, who relate them to brain-fiber and the nerve. Locke says: "They seem to be but traces of motion in the animal spirit." Kant (*Anthropologie*) truly says: "It is in vain to look for a physiologic solution of them." This wonderful power of the human mind is part of the perfection which it owes to the Great Being who is its author. The thinker who makes ideas and their associations physical things is as extravagant as the idealist who converts the solid earth into a mere relation between the mind that thinks of itself and the mind itself thus thought of. The materialist and the absolute idealist are the antipodes of the one world of extravagance in thought. The later psychologists, Herbart, Benecke, and others, have made clearer the twofold character in the association of ideas: First, where the associated elements are homogeneous, and produce what Herbart calls perfect fusion; second, where the elements are heterogeneous, and result in complication or imperfect fusion. This distinction is regarded as of great value for the entire soul-life, but es-

pecially with reference to the points at which the approaches of soul to the physiological processes are closest.

A well-regulated association of ideas on our own part and a delicate perception of what is likely to be the association in the minds of others with particular words or things are essential to the charm of conversation and of social intercourse. Without both of these a good and intelligent man may be a bore and a nuisance. One of the characteristic differences between logic and wit is that logic keeps the association of ideas under the control of reason, while wit uses it for combinations which triumph over reason and carry it away a delighted captive. The active imagination is the result of this force of the association of ideas. The imagination no more creates its own primary elements than the painter creates the matter of his colors or his canvas. The imagination selects and combines what the law of association furnishes. Its most daring so-called "creations" are capable of an easy analysis, which shows that they are shaped under this law. The memory is largely dependent upon association. (See MEMORY and MNEMOTECHNICS.) Various uses have been made of the principle of association in philosophy. Hume employs it to explain the idea of causality; Reid and others to account for the force of habit. But though the association of ideas can become the subject of culture, it is, as we have seen, primary and innate.

The association of ideas has been observed by thinkers from an early period. Aristotle speaks of it in his *Treatise of Reminiscence* very briefly, but in a manner worthy of his wonderful acuteness. It is to Locke, however, in the latest edition of his *Human Understanding*, we owe the first discussion of the subject with a fullness at all commensurate with its importance; and no system worthy of the name, since Locke, has failed to devote a large space to it.

Associations for Advancement of Science: See AMERICAN ASSOCIATION FOR ADVANCEMENT OF SCIENCE and BRITISH ASSOCIATION FOR ADVANCEMENT OF SCIENCE.

As'sonance: in prosody, the repetition of the same accented vowel with different consonants, as *hat* and *man*, *late* and *shape*. "The rule of assonance requires the repetition of the same vowels in the assonant words, from the last accented vowel inclusive" (*Marsh*). This may extend to several syllables. This substitute for rhyme is common in Spanish poetry, and also in old French poetry.

C. H. T.

As'sos, or **Assus** (in Gr. Ἄσσοσ): an ancient city and seaport of Asia Minor, in the territory of Mysia; was situated on the north shore of the Gulf of Adramyttium, between Cape Lectum and Andros, about 7 miles from the opposite coast of the island of Lesbos or Mitylene. It occupied a commanding position and was connected with the sea by a long, steep ascent; was well protected by walls, and was still visited by shipping in the time of the apostle Paul. The surrounding country was famous for its wheat. Assos was singularly a Greek city, and contains many interesting ruins, including those of a theater, citadel, temples, etc. The Street of Tombs is one of its most remarkable features. The earliest work done by the Archaeological Institute of America was a thorough exploration of the site of Assos, in 1881-83; the first volume of a full report upon this was published by the Institute in 1882.

Revised by RUSSELL STURGIS.

Assouan, ās-swān' (anc. *Sye'ne*): a town of Upper Egypt, on the right bank of the Nile, near the border of Nubia, 115 miles S. of Thebes; lat. 24° 5' N., lon. 33° E. (see map of Africa, ref. 3-F). It is 2½ miles below the First Cataract, and is remarkable for its picturesque situation and ancient monuments. Here are quarries of syenite, a variety of granite which derives its name from Syene. From these quarries came the red obelisks that adorned various temples of Egypt. Here are also ruins of a large Saracen or Arabian town, among which are found many Cufic inscriptions. Here, according to some authorities, the poet Juvenal died in exile about 125 A. D., but this is not now generally believed. Pop. 4,000.

Assump'sit [Lat., he has taken upon himself, perf. act. 3d sing. of *adsu'mere*]: a contract not under seal, either written or oral, express or implied, as distinguished from a *covenant*, or written contract under seal; also, a common-law action to obtain damages for the violation of such an agreement. It is usually divided into common or *indebitatus assumpsit*, brought in general upon an implied prom-

ise; and special assumpsit, which is founded on an express promise. This action is now generally superseded by statute.

Revised by F. STURGES ALLEN.

Assump'tion: village; on Ill. Central R. R., Christian co., Ill. (for location of county, see map of Illinois, ref. 7-E); 23 miles S. of Decatur. It has flouring-mills. Pop. (1880) 706; (1890) 1,076; (1900) 1,702.

Assumption of the Vir'gin: a festival of the Greek and Roman Churches in commemoration of the resurrection and miraculous ascent of the Virgin Mary to heaven. It is held on August 15. Protestant Christians unanimously reject the tradition of these events.

Assumption of Moses: a pseudepigraphical or apocryphal book containing a pretended account of the death of Moses and of the assumption of his soul to heaven. Some suppose that St. Jude alludes, in his reference to the contest between the archangel Michael and the devil, to the statements made in this book; but it is not certain that it existed in apostolic times.

Asswan: See ASSOUAN.

Assye: See ASSAYE.

Assy'ria (in Gr. Ἀσσυρία, L. *Assyria*): the ancient Semitic kingdom of Asshur, whose great capitals were Asshur, Nineveh, and Calah, on the Tigris river. Assyria proper was a small region about these capitals. It was settled by colonists from Babylonia, according to the statement of Genesis x. 8-12, which is supported by many considerations drawn from the native literature and from a study of the native religion, art, and institutions. Assyria was bounded N. by what is now Armenia, E. by Media, S. by Babylonia, with an indeterminate line on the W. At times the boundaries were greatly enlarged by conquest, and included Babylonia, portions of Elam, Palestine, Egypt, parts of Arabia, and Asia Minor; in a word, most of Asia west and south of Assyria proper. This period of enlargement falls particularly in the eighth and seventh centuries B. C. Assyria proper has no mountains, though it has several ranges of hills. Its chief streams besides the Tigris are the Upper Zab and the Lower Zab, both of which enter the Tigris on the E. The natural fertility of the soil was aided by irrigation. During the long, dry summer season the heat becomes intense.

History.—Our sources of information regarding Assyrian history are chiefly the native literature preserved in the cuneiform inscriptions, and the remains of art and industry dug from the ruins. These sources are now so abundant as to supersede very largely what has been written on the subject by classic authors. Many of the great kings have left a double record of their lives, one in the bas-reliefs with which they lined their palace walls, and one on books of stone and clay. Some of the kings felt an interest in past history, and have given us valuable epitomes. The royal annals frequently make references to past events, stating the number of years which have intervened. Sennacherib, 705-681 B. C., fixes for us the date of Tiglathpileser I. at about 1120-1100 B. C. A long inscription of Tiglathpileser I. mentions restoring a temple at the capital, Asshur, which had been built 701 years previously by Shamshi-Raman, son of Ishmi-Dagan. This carries the erection of the temple back to about 1820 B. C., the oldest Assyrian date yet recovered. Shamshi-Raman and his father are called *Isshak*, a word which is believed to mean priest-prince. It seems likely, therefore, that in their day Assyria had not yet grown into a kingdom. In the sixteenth century B. C. royalty is well established, and we have letters written from this time to the Pharaohs. Assyria now begins a series of quarrels with Babylonia, which, with interruptions, continued till Nineveh was destroyed. The Assyrians were more warlike than the Babylonians, and were more often the successful contestants. In the eighth and seventh centuries Babylon was at times tributary to Assyria. The first Assyrian king from whom we have long records is Tiglathpileser I. One of these, an octagonal clay prism, of which four copies were dug from the ruins of Asshur, contains 809 lines of writing, recording the wars, hunts, and buildings of the king. Assurnazirpal (884-860) carried his conquests to the shores of the Mediterranean. From his palace at Calah many of the finest bas-reliefs were excavated by Mr. A. H. Layard, and are now in the British Museum. These bas-reliefs, as well as the inscriptions on them, were often duplicates. Several of these were sent to America, and copies are now in the Boston Museum of Fine Arts, the Mercantile Library of St. Louis, the libraries of Yale University, the University of Pennsylvania,

and in several other libraries and institutions of learning. His son Shalmaneser II. (860-824) was the first Assyrian king, so far as we yet know, to come into relations with Israel. He defeated a great coalition led by Damascus, one of the allies being Ahab, who furnished 2,000 chariots and 10,000 soldiers. Jehu likewise paid tribute to Shalmaneser. The successors of Shalmaneser continued these western campaigns. Tiglathpileser III. (745-727), the first Assyrian king mentioned by the Hebrews (2 Kings xv. 29), and now proved to be identical with Pul (2 Kings xv. 19), carried a portion of northern Israel into captivity. With him begins the period of Assyria's greatest glory. The last dynasty was founded by Sargon (722-705), and includes some of the greatest names in the history—Sennacherib (705-681); Esarhaddon (681-668); and Assurbanipal (668-626). Under this dynasty the kingdom reached its greatest territorial enlargement. Sargon put an end to the kingdom of Israel (722). The discovery of the palace of Sargon at Khorsabad, a few miles N. E. of the ruins of Nineveh, by P. E. Botta, in 1843, was the beginning of the era of exploration. In the Louvre are some fine winged bulls and bas-reliefs from this palace. The Berlin Museum contains an inscribed monument of Sargon, found on Cyprus, set up there at the time when this island submitted to Assyria.

Sennacherib has left a vivid account of his campaign in Palestine in 701 (cf. Isa. xxxvi. and xxxvii). He destroyed Babylon, but his son rebuilt it eleven years later. Esarhaddon names the western kings who were subject to him, and among them we find Manasseh of Judah. He made three campaigns to Egypt, and died on the road during the third. By his will Assurbanipal succeeded him in Assyria, and another son, Shamash-shum-ukin, in Babylon, with a certain degree of inferiority to Assurbanipal. After twenty years the two brothers became involved in a disastrous war, which resulted in the death of Shamash-shum-ukin, but which struck a serious blow at Assyrian greatness and hastened its decay.

Assurbanipal, the most illustrious Assyrian ruler, gathered in his palace at Nineveh a library of clay books, and was a great patron of letters. He seems to be the Osnappar of Ezra iv. 10. Under the name of Sardanapalus his true character has been much distorted by classic tradition. Little is known of his successors or of the destruction of the Assyrian power in 606 B. C.

The best history of Assyria is C. P. Tiele's *Babylonisch-Assyrische Geschichte* (1 vol. in two parts: Gotha, part i. 1886; part ii. 1888). George Rawlinson's *Five Great Monarchies* is still serviceable, though greatly in need of revision. Franz Kanlen's *Assyrien und Babylonien* is very useful, and gives a full bibliography, though, like the *Five Great Monarchies*, not the work of a specialist. See, further, George Smith's *History of Babylonia* (1 vol.); George Smith's *History of Assyria*; A. H. Sayce's *Ancient Empires of the East*; E. Meyer's *Geschichte des Alterthums* (vol. i., Stuttgart, 1884); F. Hommel's *Geschichte Babyloniens und Assyriens* (Berlin, 1885-87); Justi's *Geschichte des Alten Persiens* (Berlin, 1878); Perrot and Chipiez's *History of Art in Chaldaea and Assyria*, from the French (2 vols., London, 1884); A. H. Sayce's *Assyria, its Princes, Priests, and People* (1 vol., London); E. A. W. Budge's *Babylonian Life and History* (London); E. Schrader's *Cuneiform Inscriptions and the Old Testament*, from the German (2 vols., London, 1885, 1888); *Records of the Past* (new series, edited by A. H. Sayce, 6 vols., 1888-92); G. Maspero's *Life in Ancient Egypt and Assyria* (New York, 1892).

Social Organization.—The social organization of the ancient Assyrians and Babylonians was complex and highly developed, as we can clearly see in the numerous records of social transactions. Our information is fuller regarding Babylon, but the constitution of society was perhaps not very different in Assyria. While the monarchy was hereditary, the insurrections, revolutions, and dynastic changes of which we read show that the subjects often made their own wishes felt. Real estate was owned by the people, who bought and sold it at will. Slavery was an old institution. Captives of war were at times enslaved, and the children of slaves inherited the condition of their parents. While the king and perhaps also the wealthy had many wives, the rule among the common people was monogamy. Women might hold property and engage in all forms of commercial transactions. Lawsuits, in the later Babylonian times at least, were decided by a board of judges, apparently without the intervention of lawyers. Fraudulent claims were punished by fines as well as by loss of the suit. The

great complexity of the social organization must have divided the society into numerous castes and guilds. The good order, the industrial activity, the prosperity are clear from the commercial records, and are likewise attested by the fact that most of the Jews, on the fall of Babylon in 538 B. C., preferred residence there to returning to Palestine. See G. Maspero's *Life in Ancient Egypt and Assyria* (1 vol., New York, 1892); Budge's *Babylonian Life and History*; Tiele's *Babylonisch-Assyrische Geschichte*.

Religion.—Like the Semites in general, the Assyrians and Babylonians were a very religious people. All their wars were carried on in the name of the gods, and in important commercial transactions the gods were invoked to punish violators of agreements; restoration and adornment of the temples were specially meritorious works. The great gods were largely the striking objects and moods of nature—as the heavens, Ann; the sun, Shamash; the moon, Sin; the weather, Raman. There was no supreme deity, but there was in Assyria a special national god called Asshur. The national god at Babylon bore the name Marduk. The most striking difference between the pantheons of Assyria and Babylonia is that Asshur has no place in the latter, while Marduk has place in the former, though not the first place. A notable fact is the disposition to group the gods in triads. The first of these consists of Ann, god of the heavens; Bel, god of the earth; and Ea, god of the abyss—corresponding to the cosmogonic notions of the people. A second triad comprised Sin, the moon-god; Shamash, the sun-god; and Raman, the weather-god. As god of the abyss, Ea had control of the sea and of canals, and was likewise the god of wisdom. Shamash, as the seer of all things, was the great judge of things in heaven and on earth. Raman was in charge of the rains, which he used to reward the good or to deluge the wicked. Among the other great deities were Ishtar, who appeared both as war-goddess and as goddess of love, and whose worship, under the name of Ashtoreth and Astarte, spread far to the W. of Assyria; Nergal, the god of the chase; Adar, the god of war; and Nabu, the inventor of writing and god of literature. There were also other gods of great consequence, as the fire-god, the pestilence-god, the messenger-god, etc. The gods are represented by symbols and by human and animal forms. A favorite symbol was the numeral. Thus Sin, the moon, was 30, for the thirty days of the month; Ishtar was 15; Marduk 11. At other times the moon was represented by his disk; the sun by an image of that orb; the weather-god by the lightning. The great sun-god of Sippar is represented by a sun-disk and also by a human figure. Sometimes the gods are represented by combinations of elements, as of a man, ox, lion, and eagle, in the giant figures carved from stone acting as guardians of palaces and temples. The winged globe, within which a human bust appears, is another favorite symbol. The human-shaped statues were at times overlaid with gold, adorned with jewels, and dressed in gorgeous attire. After the great gods came the demons and spirits, which, if hostile, were a source of constant dread, and to ward off or exorcise which there existed an elaborate system of magic. Sometimes these spirits even attacked the greater gods, producing solar and lunar eclipses, or joining the dragon Tiamat in resisting the work of creation. Disease was due to them, and hence medicine and magic were closely allied. The gods were believed to reveal themselves to men by oracles, and in dreams and visions. The oracle of Ishtar at Arbela was one of the most famous. Ishtar appears to a seer by night, and encourages the Assyrian army to cross a swollen river. Marduk and Sin reveal themselves to Nabonidus, and communicate instructions regarding the restoration of a temple. Men approached these gods by prayer and by sacrifice. Many of the psalms are prayers for the divine favor. The royal prayers are for victory, peace, numerous offspring, and firm throne. But some of the later Babylonian royal prayers also ask the gods to implant in the heart a reverence of the deity, so that no sin may be committed against him. The temples were numerous. Among the oldest and most famous was the temple of Shamash at Sippar, built nearly 4000 years B. C. The people whom Sargon transported from Sippar to Samaria, being sun-worshippers, burned their children in the fire (2 Kings xvii. 31). A second famous temple was that of Nabu at Borsippa, represented now by the ruins called Birs Nimrud. Most grand and magnificent of all was the temple of Marduk at Babylon, whose superiority is due to the political supremacy attained by Babylon under Hammurabi about 2300 B. C. This is the temple on which Nebuchadnezzar lavished so much wealth, and which Herodotus describes in

detail. While the great temples were sacred to individual gods, they were provided with numerous shrines in which other gods were also worshiped. The same city might have several temples, each with many shrines. One tablet records for us the list of temples in the city Asshur, and the many gods who had shrines therein. The temples consisted of chambers and courts with houses for the priests, places for altars and sacrifices, depositories for records and other valuables. A tower of solid masonry, with an external ascent by an inclined plane, was also an attachment to the temple, and there may at times have been a shrine on the top of this tower. The sacrifices were oxen, sheep, birds, wine, oil, and the fruits of the earth. They were offered daily, as well as at special times. The priests in whose charge was the elaborate religious system must have been a very influential portion of the community. The vitality of the system is seen in its power to survive the greatest political changes. Both Persian and Greek kings of Babylon record restorations of the ancient temples in language similar to that used by their great Semitic predecessors.

The most elaborate study of the religion is by A. H. Sayce in the *Hibbert Lectures for 1887*. See also the account in C. P. Tiele's *Babylonisch-Assyrische Geschichte*, and in other works mentioned higher up under the sub-heading *History*.

Assyrian Art: The Assyrians were artists of no mean ability, as is witnessed by the thousands of sculptured slabs of alabaster and limestone exhumed by Layard, Botta, Place, and other explorers. These slabs, about 8 feet high, formed

FIG. 1.—Bas-relief. Assyrian court officials.

a wainscoting for the crude brick walls of the royal palaces, and represent, in low relief, scenes of war and the chase, and mythological subjects. While far inferior to the best Greek reliefs, they surpass the Egyptian in fidelity to nature, especially in their representations of animal life. More striking even than the reliefs are the "portal guardians"—winged and human-headed bulls and lions of great size and terrible aspect—flanking the city gateways and palace entrances. All Assyrian sculpture is subordinate to the architecture, in which art the Assyrians achieved colossal works in spite of the scarcity of stone and timber and the lack of fuel, which compelled them to use their abundant clay-deposits in the form of crude brick, and to employ the more

FIG. 2.—Remains of Propylæa at Khorsabad.

costly burned brick only for facings and decorations. Buildings in several stories being impracticable with such poor materials, they raised enormous clay-mounds, carefully drained by vaulted sewers; faced them with hard brick or stone, and built upon them palaces of vast extent, elaborately planned with courts, halls, and chambers, separated by crude-brick walls from 10 to 30 feet thick. The lack of good timber, and the generally admitted fact that the Assyrians did not employ the column except in minor structures, restricted the spans of the halls and rooms to 25 feet or less,

except in a few cases, where it would appear that barrel-vaults were used, built of crude or burned brick. The interior chambers must have been poorly lighted, a fact of less

FIG. 3.—Winged bull with a human head, from Nimrod; now in the British Museum.

consequence in a hot climate than in one like ours. The walls were wainscoted with the alabaster reliefs already referred to; above these they were either plastered and painted, or adorned with enameled tiles in sumptuous symbolic or conventional patterns in blue, green, red, yellow, and black. In these decorative details, largely imitated from Egyptian motives, the Assyrians showed great taste, as well as in the arts of weaving, embroidery, and bronze-working.

FIG. 4.—Plan of the palace of Sargon at Khorsabad.

The temples followed Chaldæan models, and consisted of small shrines or observatories surmounting terraced pyramids with exterior ramps, the whole faced with enameled brick in divers colors. For Assyrian art, etc., see Perrot and Chipiez, *History of Art in Chaldea and Assyria* (tr. Armstrong, 1884); V. Place, *Ninive et l'Assyrie*; also the works of Layard and Botta. Fergusson's conclusions regarding Assyrian architecture (*Palaces of Nineveh and Persepolis Restored*) have not found general acceptance.

A. D. F. HAMLIN.

Assyrian Explorations: the explorations carried on in the site of the ancient Assyria. The great period of exploration begins with the appointment in 1842 of P. E. Botta as French consul at Mosul. Botta began by digging in the ruins of Nineveh just across the Tigris from Mosul, but without much result. Learning that at a modern village named Khorsabad, a few miles north of Nineveh, stones of ancient buildings might be dug from the earth, he investigated the spot, and soon came upon what proved to be the palace of Sargon. This was fully excavated by himself in 1843 and

1844, and his consular successor, Victor Place, whose excavations extended from 1851 to 1855. Botta published his results in five magnificent folios, entitled *Le Monument de Ninive* (Paris, 1847-50), and Place published his in two folios, entitled *Nineveh et l'Assyrie* (Paris, 1867-70). Botta's great success at Khorsabad led Austen Henry Layard to take up the work at Nineveh, Calah, and other ruined cities of Assyria and Babylonia, and Mr. Layard's good fortune enriched the British Museum with vast treasures of Assyrian art and literature. In his *Nineveh and its Remains* and *Nineveh and Babylon* are the accounts of his excavations carried on in 1845-47, and in his second expedition beginning in 1849. In Babylonia W. K. Loftus led two exploring parties in 1849 and in 1853, while J. E. Taylor was at the same time digging in the ruins of Mugheir, commonly identified with Ur of the Chaldees. Two expeditions by George Smith, of the British Museum, resulting from his discovery in 1872 of a deluge story on the tablets, greatly enriched the museum treasures (cf. his *Assyrian Discoveries*). Mr. Hormuzd Rassam, who took part with Mr. Layard in exploring Nineveh, made repeated visits to the East for the British Museum, and met with great success, notably at Nineveh, at Balawat and at Abu-Habba. In 1877 the French consul, E. de Sarzec, began excavating the ruins of Telloh, about midway between Babylon and the Persian Gulf, and made the discovery of the remarkable statues in the round which are now one of the ornaments of the Louvre. With the aid of Prof. León Heusey he has published the story and representations of the art objects in *Découvertes en Chaldée*. In the winter of 1884-85 there was an American party to Babylonia, led by Dr. William Hayes Ward, the expenses being met by Miss Catherine Wolfe. Some hundreds of tablets, seals, and other objects, acquired by purchase, now in the Metropolitan Museum of New York, are the result. The Germans have in recent years sent an expedition to Babylon, whose most interesting feature was the excavation of an ancient Babylonian burial-mound, which shows that cremation was extensively employed. The discovery at el-Amarna, in Egypt, in 1887, of several hundred clay tablets in cuneiform script and in the Assyrian language, many of which were written in Phœnicia and Palestine, has revealed to us the fact that this script and language were used for international purposes in the sixteenth century B. C. In 1889-92 extensive diggings were carried on at Niffer, S. E. of Babylon, by Prof. John P. Peters, of Philadelphia. Many interesting objects were found, including a great mass of clay tablets and fragments, some thousands of which are now deposited in the library of the University of Pennsylvania.

D. G. LYON.

Assyrian Language: the language of the ancient Semitic people who lived in the valleys of the Tigris and Euphrates rivers. (See SEMITIC LANGUAGES.) The oldest specimens of this language date from about 4000 B. C., and the latest from about the beginning of our era. The most ancient and most recent are from Babylonia, this country antedating Assyria as a power, and continuing after the fall of Assyria (606 B. C.). The name Assyrian has gained general currency, though Babylonian might be better, especially in view of the fact that the Assyrian people were originally a colony from Babylonia. The dialectical differences are few, the most important being the Babylonian tendency to a softer pronunciation of the mutes, *b* for *p*, *g* for *k*, *tau* for *teth*.

The Assyrian belongs to what is known as the northern branch of the Semitic stock of languages, being thus more closely related to the Aramaic and Hebrew than to Arabic, the chief member of the southern branch. It had originally all the sounds found in Hebrew, but has suffered great phonetic degradation. This is particularly true of the gutturals and the so-called quiescents (*waw* and *yōd*).

In its grammar the Assyrian has the general characteristics of the Semitic languages, but there are certain features peculiar to it, or which belong to it along with one or two others. There is no article; in the noun three case-forms exist, represented by final *u*, *i*, *a*; the verb has four primary stems (simple stem, as *sapānu*, to overwhelm; intensive stem, as *suppunu*, to overwhelm much; causative stem, as *shuspunu*, to cause to overwhelm; and reflexive, passive stem, as *naspunu*, to be overwhelmed), and four secondary, made by insertion of the syllable *ta* in the primary stems. From the simple and the reflexive stems two tertiary stems are formed by insertion of the syllable *tan*. Each verb stem has a perfect and an imperfect form. The perfect, commonly called permansive, indicates condition or state, and is usually passive in signification. Of the imperfect there are two forms,

the shorter being the usual form in narrating past events, while the longer is used for repeated and future actions. In vocabulary and syntax the Assyrian language is strikingly like the Hebrew, and the chief difficulty in acquiring it comes from the complexity of the written character. The recovery of the language kept pace with the decipherment of the inscriptions, the chief workers being Henry Rawlinson, Edward Hincks, and Jules Oppert. Grammars have been published by Jules Oppert, Joachim Mécant, A. H. Sayce, and Friedrich Delitzsch. The last named, both English and German, 1889, is the most recent and the best. The Assyrian dictionary of Edwin Norris (1868-72) omits the verbs and extends only into the letter N. Friedrich Delitzsch has begun in German a lexicon on the scale of a thesaurus. For beginners several chrestomathies have been prepared, among which those of Friedrich Delitzsch and of Abel and Winckler deserve special mention. The *Assyrian Manual* published by the writer of this article makes it possible for a student to acquire the language without learning the signs. The growth of interest in the Assyrian language during the past decade has been remarkable, especially in Germany and the U. S., and there are now many institutions in both countries where the subject is taught.

D. G. LYON.

Assyrian Literature: Assyrian writings may be grouped as historical, social-commercial, scientific, religious, and poetical. The historical writings are preserved on clay and stone, and are found in the ruins of palaces and temples, especially at the four corners of the great edifices. The finest record of Assurbanipal was found by Hormuzd Rassam in the ruins of Nineveh, walled in by solid masonry. Some of the royal records are arranged chronologically. Others follow a geographical or an oratorical order. Closely related to the historical are such state documents as royal proclamations, reports from generals, petitions to the king, and oracular responses. Under social-commercial are included the inscribed boundary stones and the great mass of small clay tablets, already found by scores of thousands, recording loans, sales, partnerships, lawsuits, marriages, wills, adoption of children, etc. These are found especially in the ruins of temples. They are commonly known as "contract-tablets," and many of them are stamped with the seals of the contracting parties. Of peculiar interest are those called "case-tablets," on account of the outer covering of clay completely concealing the inner document, and duplicating its record. The object was the better protection of the inner record against violence or fraud. In case of dispute it was always possible to break the covering in order to read the original on the inner tablet. By scientific must be understood the astronomical reports, computations of eclipses, lists of squares and cubes, grammatical and lexico-geographical compilations, and other lists showing the beginning of interest in botany, zoölogy, geography, geology, etc. The religious documents include lists of the gods, of the temples and sacrifices, of omens and portents, of magical formulæ, etc. Here belong also the hymns and psalms. These last are poetic in form, and they make with the epic and the mythological writings what might be called literature in the narrower sense of the word. The poetical writings come for the most part from the library of Assurbanipal, but they are copies from older Babylonian originals. The hymns and psalms sing the praises of the great gods, as Shamash, the sun-god; Sin, the moon-god; Raman, the weather-god; Marduk, the national god of Babylon, etc. Some of these productions indicate genuine poetic feeling and religious fervor. This is particularly true of the so-called penitential psalms, which frequently remind the reader, both in tone and in expression, of the biblical psalms. A most remarkable literary fragment is the account of the descent of Ishtar, goddess of love, to the Assyrian Sheol. This region, presided over by a goddess, is located in the subterranean waters, and is surrounded by seven walls. The inmates live in gloom, have clay for food and feathers for clothing. The seven gates are guarded by a watchman, who strips the goddess of ornament and apparel before he grants her entrance. Once within the innermost gate there is no exit for her except by intervention of other gods in her behalf. The creation of the world is represented by a series of tablets, of which considerable fragments have been recovered. Beginning with a condition of chaos, the first tablet relates how by the commingling of the waters of the abyss (personified as a male called *Apsu* and as a female called *Tiamat* = *Tehōm*, "abyss," Gen. i. 2), the gods were

generated. After a break in the story, we find *Tiamat* as a dragon engaged in a fierce contest with the gods, by one of whom she is finally slain. Then follows the creation of the constellations, the moon, sun, animals, and doubtless, last of all, man, though the close of the story has not yet been found. The war of the dragon with Marduk, who slew her, is a favorite theme in the art, especially on the seals. The most considerable literary work yet found is the epic commonly known, after its hero, as the *Izdubar* epic. It is written on twelve tablets, containing in all some 3,600 lines of writing. Fragments of several copies have been found, and some of the tablets have been almost entirely restored. The discovery of a portion of this epic among the clay books in the British Museum by George Smith in 1872 gave a new interest to Assyriology, because there is related on the eleventh tablet a deluge story which is strikingly similar to the one recorded in Genesis. The epic is believed to have taken shape in Babylonia prior to 2000 B. C. The scene is laid at Erech, at a time when this ancient city is oppressed by a foreign tyrant. *Izdubar*, the hero, residing at Erech, has a dream which none can interpret until he induces *Eabani* to come into the city. *Eabani* is a composite creature, partly man and partly bull, famous for wisdom, whose home has been in the mountains. He interprets the dream, and the two become fast friends. They succeed in ridding Erech of the oppressor. Hereupon, *Ishtar*, goddess of love, attracted by his prowess, woos *Izdubar*, but is rejected. At her request, *Ann*, her father, the god of the heavens, sends down a monster bull to gore the two friends, but after a fierce struggle they dispatch this creature. This struggle is a favorite theme with the ancient artists. The gods then smite *Eabani* and *Izdubar* with disease. The former dies in agony, and the latter travels over the world, across its deserts and mountains, in search of healing. At last he arrives at the gates of death and finds them barred and guarded. After much parleying he gains admission, and is rowed by a boatman to the blessed isles at the mouth of the rivers, where he finds a deified man who gives him the secret by which he may be healed, but before doing so he relates to *Izdubar* the deluge story already mentioned. After this *Izdubar* is healed by following the instructions given, and then returns to Erech to lament the dead friend *Eabani*. Sir Henry Rawlinson first pointed out the astronomical character of this poem, which seems to represent the annual passage of the sun through the heavenly constellations. The twelve tablets correspond to the twelve zodiacal signs and to the twelve months of the Babylonian year. The *Izdubar* story has been supposed to be connected with the stories regarding *Hercules*, *Nimrod*, and *Samson*. Indeed, the poem is by some scholars called the *Nimrod* epic. The exact pronunciation of the cuneiform signs by which the name *Iz-du-bar* is written has not yet been made out. Quite recently Mr. T. G. Pinches, of the British Museum, has expressed the opinion that the hero ought to be called *Gilgames*. Fragments of fables have likewise been found among the Assyrian writings, in which the eagle, the fox, the serpent, the horse, and the ox are the speakers. That the poetic literature of Babylonia was once extensive is proved by some fragments in the British Museum giving a list of the ancient works, with the names of their reputed composers. Some of these works have doubtless perished completely. Others still await the spade of the explorer. For what has already been recovered we are indebted mainly to the farsightedness of *Assurbanipal*, who caused copies to be made for his own library at Nineveh.

Great collections of inscriptions in the original script have been edited by Sir H. C. Rawlinson, P. E. Botta, J. N. Strassmaier, and Hugo Winckler. Collections of translations from the monuments are found in George Smith's *Chaldean Account of Genesis*; *Records of the Past*, edited by A. H. Sayce; A. H. Sayce's *Hibbert Lectures for 1887*; *Keilinschriftliche Bibliothek*, edited by E. Schrader (Berlin, 1889-90). Accounts of the literature are given in A. H. Sayce's *Babylonian Literature*, and in George Smith's book just mentioned. A well-digested bibliography of modern works on Assyriology is given in Friedrich Delitzsch's *Assyrian Grammar* (Berlin, 1889), and also (in chronological arrangement) in F. Kaulen's *Assyrien und Babylonien*; Carl Bezold's *Kurzgefasster Überblick über die Babylonisch-Assyrische Literatur* (Leipzig, 1886) can be used only by students of the original. The journals whose interest is mainly or largely the study of the Assyrian language and literature are the *Proceedings of the Society of Biblical Archaeology* (London); the *Zeitschrift für Assyriologie*

(Leipzig); the *Beiträge für Assyriologie* (Leipzig); and the *Babylonian and Oriental Record* (London). D. G. LYON.

Ast, GEORG ANTON FRIEDRICH: German philologist and critic; b. at Gotha, Dec. 29, 1778; appointed Professor of Classical Literature at Landshut in 1805, and obtained the same chair in the University of Munich in 1826. He wrote, besides other works, a *Manual of Aesthetics* (1805); *Introduction to Philology* (1808); and *The Life and Writings of Plato* (1816). He also published a good edition of the works of Plato, with a Latin version and a commentary (11 vols., 1810-32). D. in Munich, Oct. 31, 1841.

Ast'acus [Lat., lobster, from Gr. ἀστράκος]: a genus of crustaceans, including the crayfishes of Europe and the Pacific States of the U. S. Those of the Eastern U. S. belong to another genus, *Cambarus*. See CRAWFISH.

Astar'te [the Greek and the Phœnician form of *Ash-tareth*]: a goddess worshiped by the Phœnicians, Syrians, and Carthaginians, and the original of the Greek *Aphrodite* (*Venus*). The common view is that as *Baal* was the sun-god, so *Astarte* was the moon-goddess, or goddess of the heavens. She is variously represented, but more usually with four wings (the two uppermost of which are intended to symbolize the horns of the moon), wearing a pointed cap, and holding a dove in her hand, as shown in the accompanying illustration, taken from an image of *Astarte* found in Etruria. The Syrians built to her a famous temple at Hierapolis. Her chief temples, besides that at Hierapolis, were at Tyre and Sidon. The Assyrian goddess called *Ishtar* or *Istar* is identified with *Astarte*. But, according to another view, *Astarte* is the virgin goddess of death and war, who, unlike *Ashera* (*q. v.*), lays the strictest chastity and continence upon her priests and priestesses.

Astarte.

Revised by S. M. JACKSON.

Astarte: a genus of bivalve mollusks; the type of the family *Cyprinidae*, nearly related to the *Veneridae*. Fossils of some 200 extinct species are widely distributed over the world. Some of them are found in the lias formation. Fifteen or twenty species of *Astarte* now exist in the deep sea in various parts of the world.

Astat'ic [from Gr. ἀστατος, unstable; ἀ-, not + στήναι, stand]: applied to the magnetic needle when it is withdrawn from the action of the earth's magnetism, and has no longer a *static* position of equilibrium under the influence of this force; also to the galvanometer of which such needles form an essential part. A needle becomes *astatic* when the axis about which it is movable is placed parallel to the lines of force of the magnetic field in which it lies, because it can not receive any motion from the force, and will rest in any position. The term is generally applied to a pair of needles, which are rendered neutral as regards the earth's magnetism by placing them parallel to one another, the north-seeking pole of the one in opposition to that of the other.

E. L. NICHOLS.

As'ter [from Gr. ἀστήρ, star]: a genus of plants of the family *Compositæ* (which Lindley proposed to call *Asteraceæ*). This genus comprises a great number of species, generally herbaceous, mostly natives of the U. S. Many of them are cultivated in the gardens of Europe for the beauty of the flowers, which bloom from July to November. The ray-florets, which are never of the same color as the disk, are purple, blue, violet, white, etc. Among the remarkable American species are *Aster novæ-angliæ*, *Aster puniceus*, *Aster cyanus*, and *Aster spectabilis*. The China aster (*Aster chinensis*; *Callistephus chinensis*) is a favorite garden-flower in England and the U. S. Many varieties are cultivated, and present a great diversity of colors. They prefer a rich soil, and bloom until the end of autumn.

CHARLES E. BESSEY.

Aster, ERNST LUDWIG, von; b. at Dresden, Oct. 5, 1778; received a military education, and served first in the Saxon, then in the Russian, and finally (after 1815) in the Prussian service. In 1810, while still in the Saxon army, he attracted the attention of Napoleon by a plan for the fortification of Torgau, and while in the Prussian service he undertook the fortification of Coblenz and Ehrenbreitstein; was made inspector-general of all the Prussian fortresses and general of infantry in 1842. D. at Berlin, Feb. 10, 1855. His *Nachgelassene Schriften* were published at Berlin (5 vols., 1856-61).—His brother, KARL HEINRICH VON ASTER, b. at Dresden, Feb. 4, 1782; d. there Dec. 23, 1855; colonel in the Saxon army; wrote several valuable military works, of which the most noted are *Lehre vom Festungskriege* (2 vols., 1812; often reprinted and translated into other languages), and *Die Gefechte und Schlachten bei Leipzig* (2 vols., 1852-53).

Asteracanthus [from Gr. ἀστήρ, star + ἄκανθα, spine]: a genus of fossil sharks, of which only the dorsal defensive spines are known. These are found in the Mesozoic rocks of England, and were named by Agassiz from the stellate tubercles with which they are ornamented.

Asteria: See SAPPHIRE.

Asteroid [from Gr. ἀστεροειδής, star-like; ἀστήρ, star + εἶδος, form]: one of the small planets which revolve around the sun, between the orbits of Mars and Jupiter. The name was first used by Sir William Herschel, but is not universally recognized by astronomers, "small planets" being sometimes preferred. As far back as the time of Kepler it was noticed that a wide gap existed between the orbits of Mars and Jupiter, in which an additional planet might be so placed that the distances of all the planets would then follow a uniform law. (See BODE'S LAW.) It was therefore surmised that a planet yet to be discovered might actually revolve in this region. After the discovery of the planet Uranus this conviction became so strong that an association of astronomers was organized to search for the supposed missing member of the solar system. The zodiac was divided among twenty-four observers, each of whom was to search through one hour. But just as the search was commencing the discovery was made by an astronomer who did not belong to the association at all. Piazzi, at Palermo, was at work on his great *Catalogue of Stars*, and, on the first day of the nineteenth century, his attention was attracted by an apparent change of place in one of the stars he had observed. In a few days more it proved to be the planet required to fill the gap. When the orbit was computed it was found that the new planet travels at a mean distance of 2.767 from the sun, the earth's distance being unity, while the predicted distance, from Bode's Law, was 2.8. The approach to the expected distance was so near that the law seemed to be confirmed, and the planet to be the one member necessary to complete the solar system. Piazzi gave it the name *Ceres*.

But while astronomers were congratulating themselves on this new proof of law and harmony within the solar system, a fresh discovery threatened to throw all into disorder again. On Mar. 28, 1802, while examining a part of the constellation Virgo, Olbers, a physician and astronomer of Bremen, noticed a small star which he was sure had not previously been visible. In two hours he found that it must be a new planet. In the course of a month an approximate orbit was found for it, and its mean distance was found to be nearly the same as that of *Ceres*. Thus there were two planets where only one had been wanted to complete the system. Olbers was led to expect that others would be found, and, a search being instituted for the purpose, a third was discovered on Sept. 1, 1804, and a fourth on Mar. 29, 1807.

The discovery of four planets where apparently only one belonged, and the fact that these planets were excessively small, much smaller, in fact, than Mercury itself, suggested to Olbers the idea that these four bodies were the fragments of a single original planet which had been destroyed through some internal explosion, or, perhaps, by coming into contact with some heedless comet. This idea has since become celebrated under the name of "Olbers's hypothesis." The author of the hypothesis himself suggested that, if true, there were probably many other fragments, but that the orbits of all these fragments must pass through a common point, namely, the point where the explosion occurred. This, however, would not be true unless the cataclysm was of comparatively recent occurrence. Owing to the secular variations to which all orbits in the solar system are subject, the orbits of these planets would change their form

and position in such a way that, after a few thousands of years, the common point of intersection would no longer be recognizable. Thus, so long as only four bodies were known, it was impossible to find any decisive test for or against the hypothesis. It therefore remained for many years a mere subject of speculation, the general current of the best opinion being against it.

Thirty-eight years passed after the discovery of *Vesta* before another of the supposed fragments was found. But in 1845 the astronomical world was interested by the discovery of a fifth, and two years later a sixth was added. Ambitious observers then began to search for new ones with greater system and zeal than before, with the result that not a year has since passed without adding one or more to the list, the approximate average rate of discovery since 1850 being about ten per year. The number now known (1900) is about 450.

The number of these bodies is now so great that it is almost impossible to keep the run of their motions. In fact, two or three are as good as lost, but will doubtless be rediscovered at no distant time. Apparently all that can be done with them is to discover them, get an approximate orbit, and let them go again, bearing, metaphorically speaking, the initials of the astronomer that found them. Formerly they were found only by careful and systematic search with the telescope, and by the exercise of a great amount of skill derived from long practice; but the introduction of photography into astronomical research has placed in the hands of astronomers a much more simple and effective method. Planets show themselves on the photographic plate in a very curious way. To the eye they are indistinguishable from the stars, and can be detected as planets only by their motion. In taking a photograph of the stars the plate has to be exposed for a considerable period, perhaps half an hour or an hour, and to be so moved by clockwork that the image of the star shall constantly be formed on the same point of the plate. Since a planet will move among the stars, it follows that if a planet is also making its impression on the plate the motion will cause the planet to be represented by a straight line instead of by a point, as in the case of a star. In the space even of half an hour a planet moves over such a distance as to make an appreciable line. Thus all the planets that happen to be in the field of the plate will be detected.

Eros, discovered by Wolf, Feb. 17, 1899, by the photographic method, is the most important astronomical discovery of modern times. Two thirds of its orbit lies between the orbits of the earth and Mars, instead of between those of Mars and Jupiter. It approaches the earth nearer than any other known heavenly body excepting the moon, and its parallax at such times amounts to almost 1', hence its great value in determining the earth's distance from the sun. It makes this near approach once in thirty-one years, and was in this position three years previous to its discovery. Fortunately, it was quite near in Dec., 1900, and careful and valuable observations were made. *Eros's* diameter is about 17 miles, and at its nearest approach it is just visible to the naked eye.

The bodies forming this group are distinguished from the larger planets by a number of characteristics.

1. Their very small size. They are so small that, unless with some of the recent great telescopes of the world, they appear to the eye simply as points of light, and so admit of no measurement. Judging from the amount of light which they reflect, the largest may be 300 or 400 miles in diameter, the smallest perhaps 10 or 20. The whole mass of them, known and unknown, is so small that it has not yet been detected by its attraction upon the planet Mars, as it would be if equal to a single large planet.

2. The orbits are generally much more eccentric than those of the larger planets, one, *Polyhymnia*, having so large an eccentricity that its greatest distance from the sun is double its least distance. Hence the brightness, as seen from the earth, varies in a yet greater degree; many are scarcely visible when at their greatest distance from the sun, unless with the most powerful telescopes.

3. The inclinations of their orbits are also in the general average much greater than in the case of the larger planets. Many exceed ten degrees, and one, *Pallas*, is nearly thirty-five degrees.

This great eccentricity and inclination, and the small size of the planets, are about what might be expected if Olbers's hypothesis were true; nevertheless, at the present time the general consensus of opinion is against it. In fact, when the secular variations of the orbits are computed, it is found

that if they were subjected only to the action of the larger planets the orbits never could have intersected in a single point. Still this is not absolutely conclusive, because, if at any time two of the planets had passed very close together, they might possibly have so influenced each other as to make a considerable change in their orbits. This kind of action does not admit of being calculated or foreseen. But the idea now is that the original ring of matter out of which these bodies were formed, instead of collecting into a single planet, as in the case of the larger ones, separated itself into these minute fragments, owing to the absence of any one center of condensation sufficient to draw the entire ring into its neighborhood.

S. NEWCOMB.

Asteroid'ea [from Gr. *ἀστήρ*, star + *εἶδος*, form]: a class of the division *Echinodermata*, including the starfishes. It is characterized by the star shape, with five or more angles, and by the fact that its ambulacral feet are confined to the ventral surface. Two orders, *Stellerida* or *Asteridea*, the starfishes, and *Ophiuridea*, the brittle stars, are usually recognized. See STARFISH.

D. S. J.

Asterol'epis [from Gr. *ἀστήρ*, star + *λεπίς*, scale, in allusion to the marks on the dermal plates of the head]: a genus of fossil ganoid fishes, described by the famous geologist, Hugh Miller, from the Scotch old red sandstone. Some are believed to have been 20 feet long.

Asthma, *ἄσθμα* [Gr. *ἄσθμα*, panting, from *ἀῆναι*, breathe hard]: in a general sense, any disease characterized by difficulty of breathing, occurring in paroxysms; thus spasm of the glottis is sometimes called "thymic asthma"; autumnal catarrh is known as "hay asthma"; the dyspnoea (difficult breathing) of Bright's disease has been, with questionable propriety, called "uræmic asthma"; and similar symptoms arising from heart or lung disease have also been mistaken for true asthma, which, however, may be associated with these various diseases. True asthma, according to Niemeyer, includes only those cases where the point of the irritation producing the attack is either at the origin of the vagus nerve or in some remote part of its course. This does not exclude cases of reflex asthma, such, for example, as may occur in uterine disease. Others state that irritability and hyperæmia of the bronchial mucous membrane are essential elements of the disease; and the readiness with which powdered ipecacuanha, the exhalations from feathers, etc., will excite paroxysms, would appear to confirm this view. It is rare to find structural changes of any organ in cases of simple asthma. The trained diagnostician alone can discriminate between asthma and dyspnoea from other chest diseases. True or nervous asthma consists in a paroxysmal spasm of longer or shorter duration, attacking the muscular elements of the bronchial tubes, diminishing temporarily their caliber, and thereby obstructing respiration. The peculiar wheezing and whistling sounds produced by the breathing of asthmatic persons are due to the air passing through narrow air-tubes. While true asthma may thus occur without any disease of the lungs, it very commonly leads to diseases by its repeated occurrence. Of such distension of the tissue by excessive air, a disease called emphysema is most common; and from the fact that the elasticity of the lungs is greatly impaired by this distension the subsequent paroxysms of asthma are all the more severe. Notwithstanding the great distress which may accompany the attack of asthma, the immediate danger is not great. The smoking of salt-peter paper or of stramonium leaves, the administration of opiates, coffee, belladonna, conium, cannabis, chloral, vapor of chloroform, etc., may or may not relieve the paroxysm. Iodide of potassium benefits many cases, permanently or temporarily. Quinia, Fowler's solution, iron, and other tonics are often useful. A nutritious diet, with careful regulation of the bowels, is important. The compressed air-bath is recommended as affording great relief during the paroxysm.

Revised by WILLIAM PEPPER.

As'ti (anc. *As'ta Pompe'ia*): a city of Italy, in the province of Alessandria; situated on the river Tanaro, and on the Turin and Genoa Railway, 36 miles by rail E. S. E. of Turin (see map of Italy, ref. 2-A). It is a bishop's see, has a fine Gothic cathedral, a royal college, a theological seminary, a printing-office, established in 1479, and many elegant mansions. Here are several manufactories of silk stuffs. This is the native place of the poet Alfieri. Asta Pompeia was a town of great antiquity. In the Middle Ages it was the capital of a republic, which existed from 1098 to 1155. Its light white and sparkling wine is in very great demand. Pop. about 34,000.

Astié, *ἄσ'τῆ-αῖ'*, JEAN FRÉDÉRIC: b. at Nerac, department of Lot-et-Garonne, France, Sept. 21, 1822; was a pastor in New York 1848-53, became Professor of Philosophy at Lausanne 1856, and wrote, besides various theological works, *Le Réveil religieux des États-Unis* (Lausanne, 1857), *Histoire de la République des États-Unis* (2 vols., Paris, 1865), *Théologie allemande contemporaine* (1874), *L'Orthodoxie et le Liberalisme* (1880), and *La Crise théologique et ecclésiastique* (1881). D. at Lausanne, May 20, 1892.

Astig'matism [from Gr. *ἀ-*, not + *στίγμα*, a point, i. e. focus]: a peculiar defect in the eye which consists in its refracting the rays of light differently in different planes. The defect may be detected by looking at a small pinhole in a card held up against any bright object, and moved to different distances from the eye. To an ordinary eye the image of the hole remains circular at all distances, but to an eye having the peculiar defect in question the image of the hole, as the card is moved away from the eye, becomes elongated, and at a certain distance passes into a straight line. This imperfection may be corrected by means of a cylindrical or spherico-cylindrical lens. Revised by WILLIAM PEPPER.

Astolphus, or **Astul'phus** (in Fr. *Astolphe*; in Germ. *Ais'tulf*): King of the Lombards; obtained the throne in 749 or 750 A. D. Having seized Ravenna about 752, he threatened Rome. The pope then applied for help to Pepin, King of the Franks, who defeated Astolphus in 754, and forced him to cede Ravenna and the Pentapolis to the pope. This is said to have been the origin of the temporal power of the popes. D. in 756 A. D.

Aston Manor: a suburb of Birmingham, England. Pop. (1881) 53,842; (1891) 68,639.

As'tor, JOHN JACOB: b. at Waldorf, near Heidelberg, in Germany, July 17, 1763; emigrated to the U. S. in 1783, and invested his capital in furs, which he took to London and sold with much profit. He next settled at New York, and engaged extensively in the fur-trade. He exported furs to Europe in his own vessels, which returned with cargoes of foreign commodities, and thus rapidly amassed a fortune. In 1811 he founded Astoria on the western coast of North America, near the mouth of the Columbia, as a dépôt for the fur-trade, for the promotion of which he sent two expeditions to the Pacific Ocean. He was remarkable for his sagacity and diligence in business. He purchased in New York a large amount of real estate, the value of which increased enormously. At his death (in New York city, Mar. 29, 1848) his fortune was estimated at \$20,000,000. He left \$400,000 to found a public library in New York. See ASTOR LIBRARY.

Astor, WILLIAM WALDORF: public man and author; b. in New York, Mar. 31, 1848; only son of John Jacob Astor, and great-grandson of John Jacob Astor, founder of the family; was graduated at Columbia Law School, admitted to the bar 1874; member of New York Assembly 1877, of the New York Senate 1879; U. S. minister to Italy 1882-85; author of *Valentino* and *Sforza*. Removed to London in 1890, and in 1899 was naturalized as a British subject.

Asto'ria: town; Fulton co., Ill. (for location of county, see map of Illinois, ref. 5-C); on C. B. & Q. R. R., 119 miles from Rock Island; surrounded by fine coal-fields, and much coal is mined. Pop. (1880) 1,280; (1890) 1,357; (1900) 1,684.

Astoria: city and port of entry; capital of Clatsop co., Ore. (for location of county, see map of Oregon, ref. 1-B); in the extreme northwestern part of the State; on the south bank of the Columbia river, 15 miles from its mouth. It is the headquarters of the salmon and fishery business of the Northwest; 24 of the 38 canneries of the Columbia river are here, yearly packing \$3,000,000 worth of salmon. The city is the general dépôt for coast and river steamers, has large lumber-trade, water-works, gas-works, electric light, electric street railway, telephone system, district telegraph messenger service, extensive summer travel, fine public schools, free mail-delivery, iron-works, machine-shops, etc. Pop. (1870) 639; (1880) 2,803; (1890) 6,184; (1900) 8,381.

PROPRIETOR OF "ASTORIAN."

Astor Library: a library of New York city, founded by John Jacob Astor (d. 1848), who bequeathed \$400,000 for that purpose. His will directed that the government of the library should be vested in eleven trustees, including the mayor of New York and the chancellor of the State. The library, erected on Lafayette Place, was opened in 1853. William Backhouse Astor (d. Nov. 24, 1875), eldest son of

the founder, added \$200,000 to his father's bequest, besides building an addition on adjoining property which he gave. John Jacob Astor (d. Feb. 22, 1890), grandson of the founder, bequeathed \$450,000 for this library, and in his lifetime presented it three lots on which he erected an addition, and added to the central building. It now has 260,651 volumes. In 1896 it was consolidated with the Lenox and the Tilden Libraries as the New York Public Library.

As'trabad': a town in the northern part of Persia, capital of a province of its own name. It is on a small river which enters the southeastern part of the Caspian Sea, from which it is about 20 miles distant (see map of Persia, ref. 2-H). The situation is not healthful in summer, but is rendered attractive by extensive gardens. The greater part of the town is in ruins. Here are some manufactures of silk and cotton stuffs. Pop. 15,000; of province, 80,000.

Astrachan: See ASTRACHAN.

Astræ'a (in Gr. Ἀστραία): goddess of justice, a personage of classic mythology; was said to be a daughter of Jupiter and Themis. At the termination of the Golden Age, when violence began to prevail in the world, she ascended to heaven, being the last of the goddesses to leave the earth.—ASTRÆA is also the name of an asteroid discovered by Hencke in 1845. Its mean distance from the sun is 2.577 times that of the earth. It completes a revolution in 1,511 days.

Astræa: a genus of coral animals of the order *Madreporaria*. They live in the sea, and form calcareous skeletons (star-corals), which are characterized by sessile, star-shaped, lamellate cells, crowded on the upper surface. The polyps are often an inch in diameter. They form large, hemispherical masses of coral.

Astræa viridis.

Astrag'alus [Lat., from Gr. ἀστράγαλος, vertebra, ball of the ankle-joint]: in anatomy, the first or uppermost bone of the tarsus, which forms with the leg-bones the hinge of the ankle-joint. Its lower surface rests on the os calcis, or heel-bone.

Astragalus: a genus of herbaceous and shrubby plants of the family *Leguminosæ*. The leaves are pinnate, with an odd leaflet, and the pod is two-celled. It comprises numerous species, mostly natives of the temperate and cold parts of the eastern hemisphere. Several species of *Astragalus* growing in Persia and Asia Minor yield gum-tragacanth. The *Astragalus bæticus* is cultivated in Hungary and Germany for its seeds, which are used as a substitute for coffee. Numerous species of *Astragalus* are found in the U. S., especially westward.

Astrakhan': a government in the southeastern part of European Russia, bounded N. by Samara, E. by Orenburg and the Caspian Sea, S. by Caucasia, and W. by the country of the Don Cossacks and Saratov (see map of Russia, ref. 10-G). It is intersected by the Volga, which divides it into two nearly equal parts. Area, 91,327 sq. miles. The surface is nearly level, and the soil mostly sterile and saline. A large part of it is occupied by salt marshes and saline lakes. The fisheries of the Volga in this government are very valuable, many sturgeon being caught in it. Pop. (1897) 1,002,316, of whom 220,000 are Kirghiz Tartars and 139,000 Kalmucks.

Astrakhan, or Astrachan: a city of Russia, capital of the above government; is situated on an island of the river Volga, 40 miles from its entrance into the Caspian Sea (see map of Russia, ref. 10-G). It has crooked and dirty streets, and houses mostly built of wood. It contains a cathedral, about 35 churches, 15 mosques, an archiepiscopal palace, a botanic garden, an Indian temple, and a gymnasium. Immense quantities of fish are exported hence. The other articles of export are leather, fur, linen, and woolen goods. This place is the seat of Greek and Armenian archbishoprics. It has an extensive trade, and manufactures of silk and cotton. Steamboats ply between this place and the ports of the Caspian Sea. Pop. (1897) 113,075.

As'tralite: a variety of glass resembling aventurine, containing crystals of a cuprous compound, which exhibits a dichroitic iridescence of dark red and greenish blue. It is made by fusing and cooling slowly a mixture of 80 parts of silica, 120 of litharge, 72 of carbonate of soda, 18 of borax glass, 24 of scale oxide of copper, and 1 of scale oxide of iron.

As'tral Spir'its: spirits supposed by the ancient Persians and other Orientals to animate the stars. This opinion or superstition was adopted by some of the Greeks and Jews. The demonologists of the Middle Ages conceived them as fallen angels or souls of departed men.

Astrin'gent [from pres. partic. of Lat. *astrin'gere*, draw together; *ad*, to + *strin'gere*, bind]: an agent which produces a persistent contraction in organic tissues, and thus checks discharges from the body, such as excessive purging or diarrhœa and hæmorrhages. Astringents are of two classes, vegetable and mineral. Of the former, tannic and gallic acids are the prevailing active principles, and these may be obtained and used in the pure state. The most common vegetable astringents are galls, oak-bark, logwood, blackberry root, rhatany, catechu, and kino. Of mineral astringents, the most important are acetate of lead, sulphate and chloride of iron, nitrate of silver, alum, carbonate of lime, and the mineral acids, sulphuric, nitric, and hydrochloric.

Astroca'ryum [from Gr. ἄστρον, star + κάρυον, nut]: a genus of palms; comprises about sixteen known species, natives of tropical America, and remarkable for the sharp spines with which the stem and almost every part are armed. They have pinnated leaves. The murumuru palm (*Astrocaryum murumuru*), a small tree about 10 feet high, grows on the Amazon and bears a fruit about an inch long, which is esculent and highly esteemed. Another edible fruit is produced by the tucuma palm (*Astrocaryum tucuma*), which grows near the Amazon to the height of 30 to 40 feet. The *Astrocaryum vulgare*, called tucum palm, is more lofty than the tree last noticed. It is cultivated by the natives, who obtain from the epidermis of its unopened leaves a fine and strong fiber of which they make cordage, nets, etc.

Revised by CHARLES E. BESSEY.

As'trolabe [from Gr. ἀστρολάβον, star-taking; ἄστρον, star + λαβεῖν, take]: a name given by the Greeks to a circular instrument used to make astronomical observations, which is now superseded by better instruments. The ancient astrolabe consisted of two or more circles having a common center, and so inclined to each other as to enable the astronomer to observe in the planes of different circles of the sphere at the same time.

Astrol'ogy [Gr. ἀστρολογία, star-doctrine; ἄστρον, star + λέγειν, discuss]: originally, astronomy; later, a spurious science which professed to explain the events of human life by the influence of the stars or planets. Astrology, which is a very ancient form of superstition, may be defined as the study of horoscopes and an attempt to predict the fortunes of men by the positions and aspects of the stars. Judicial astrology is supposed to have originated in Chaldæa. The Jews, after their captivity in Babylon, were much addicted to it, and the same delusion has prevailed among all the nations of Europe. In ancient Rome, during the empire, astrologers were a numerous and influential class. In the Middle Ages astronomy proper was chiefly studied as subsidiary to astrology, which was considered as the more important of the two sciences. The relation between astrology and astronomy was like that between alchemy and chemistry. The Copernican system contributed greatly to bring astrology into discredit. The fundamental conception of astrology seems to have been drawn from the actual influence of the sun upon the earth in affecting health, fertility, and temperature. Connected with these facts was the worship of the heavenly bodies as divinities. The notion of Aristotle, set forth in the twelfth book of the *Metaphysics*, that the heavenly bodies were "ensouled," and that each moved in its orbit by a conscious volition, gave currency to similar ideas among the students of the Peripatetic system. The power of these heavenly beings was supposed to flow out from their dwelling-places, and affect beings on the earth for good or evil. Astrological predictions are founded on the relative positions and aspects of the sun, moon, and planets at the moment of birth, and on certain arbitrary influences supposed to belong to each of these bodies. To facilitate the determination of the aspects,

the whole heaven, visible and invisible, is divided into twelve equal parts by the horizon, the meridian, and four other circles passing through the north and south points of the horizon and the points of the equator (or prime vertical), which are at the distance of thirty and sixty degrees from the meridian. These equal spaces are called the twelve houses of the heavens, and the circles by which they are circumscribed are called circles of position. The circles of position are supposed to remain fixed, so that a celestial body is carried through each of the twelve houses in the course of a day by the diurnal rotation. The first house is contained between the eastern horizon and the next circle of position going to the eastward. The beginning of the first house, or the point of the ecliptic just rising, is called the horoscope. The first house is the house of life; the second, of riches; the third, of brothers; the fourth, of parents; the fifth, of children; the sixth, of health; the seventh, of marriage; the eighth, of death; the ninth, of religion; the tenth, of dignities; the eleventh, of friends; and the twelfth, of enemies. Each of the houses has one of the heavenly bodies as its peculiar lord. They have different powers, the first being the most powerful. The next object is to consider the aspects or configurations of the influential bodies. The ancients reckoned five aspects. (See ASPECT.) The quartile and opposition were considered malignant or adverse, the trine and sextile as benignant or propitious, and the conjunction was an indifferent aspect. The influences ascribed to the planets were as arbitrary as those ascribed to the aspects. Saturn, being at the greatest distance from the sun, was supposed to be of a cold nature; Jupiter, Venus, and the Moon, temperate and benignant; Saturn and Mars were the most dangerous. The influence of the sun and Mercury varied according to circumstances. See Zadkiel's *Handbook to Astrology* and LILLY, WILLIAM.

Astronomy [from Gr. *ἀστρονομία*, classification of stars, *ἀστρονόμος*, astronomer; *ἄστρον*, star + *νέμειν*, arrange]: the science which treats of the constitution, motion, and appearance of the heavenly bodies, and the art or practice of utilizing their known positions for determining positions on the surface of the earth.

Under the term heavenly bodies is included every visible mass of matter outside the atmosphere of the earth. Since these masses of matter, known as planets, stars, comets, etc., are, in most cases, immensely larger than the earth itself, it follows that, so far as mere extent is concerned, the field of astronomical science is immensely greater than that of all other sciences combined. The earth is but a speck in the order of creation, and every other science besides astronomy is concerned with what is going on upon this little speck of matter. In the present article we can do nothing more than give a general idea of the development and present condition of the science, referring to subdivisions for all details.

Astronomy is the oldest of the sciences, and the development of the ideas on which modern astronomy rests is co-extensive with the history of civilization. The names of the constellations antedate all authentic history; and the earliest thinkers devoted to the heavenly bodies an amount of careful study which, had it been applied to mundane things, would, we may suppose, have enabled them to anticipate many of the conclusions of modern science. The development of the ideas of the constitution of the universe has been so natural and orderly that no treatment of astronomy is complete without explaining it.

There is no doubt that the first conception which ignorant men formed of the earth was that of a vast, extended plain. But it needed very little observation to show that this supposed plain was an illusion, and that we really live on the surface of a globe. Ptolemy himself, about the time of the Christian era, gave the proofs that the earth is a sphere as fully and clearly as they are given in our modern geographies; in fact, we have no authentic record of a time when men did not know that the earth was a globe.

The earliest astronomical system was that in which this globe was supposed to be at rest in the center of the universe, all the heavenly bodies revolving around it in the space of twenty-four hours. The theory which assigned the earth to this position in the universe is known as the Ptolemaic or geocentric system. (See PTOLEMAIC SYSTEM.) It remained the accepted system until the time of Copernicus, whose hypothesis or discovery that the sun is the actual center of the planetary motions, and that the earth revolves on its own axis, introduces the second great era in the progress

of astronomy. To this era belong not only Copernicus, but Kepler, Tycho Brahe, and Galileo. The Copernican system had to be established, and the laws of the motion of the planets discovered, before further progress was possible. The third era was introduced by Sir Isaac Newton, through the discovery of gravitation. The Newtonian system did not supersede that of Copernicus, but only generalized and explained it by referring the celestial motions to known mechanical laws. The heavenly bodies were no longer mysterious creations, revolving in ellipses owing to some inscrutable law impressed upon them by their Creator; but they were simply masses of matter, flying through space with perfect freedom, each gravitating toward all the others, and toward the sun. The motion in ellipses, which had been demonstrated by Kepler from observation, was shown to be the result of gravitation toward the sun.

The acceptance of the Copernican and Newtonian systems and the discoveries made with the telescope have completely revolutionized our ideas of the universe and the place of the earth in it. So long as the latter was considered as the center, all the rest of creation was supposed to be within a comparatively short distance of it. Surrounding the earth were a succession of spheres, and outside of all the empyrean, the realm of fire, the abode of the gods. But the new system of astronomy, and the discoveries, observations, and measurements made possible by the telescope, extended the universe, step by step, into the domains of infinity itself. The earth became merely one of a number of bodies circulating around the sun, some larger and some smaller than itself. The fixed stars became not merely points of light, but suns, each with its possible retinue of inhabited planets. As observations were made upon these stars to determine their distance by their annual parallax, they retreated farther and farther toward infinity. Copernicus probably supposed them not very far outside the solar system. Kepler supposed that they were arranged near the surface of an immense sphere. As the arts of measurement improved, it was found that even the whole orbit of the earth, a stretch of 186,000,000 miles, must form a very small angle as seen from the nearest of the stars: To determine this angle became one of the great problems of astronomy; yet it eluded all measurement generation after generation. The first quarter of the nineteenth century was past when the illustrious Bessel found, by the aid of a new instrument, that there was one star which was only 600,000 times the distance of the earth from the sun. This distance has since been diminished a little, and another star in the southern hemisphere has been found to be distant only about 270,000 times the radius of the earth's orbit. A score of others have been found within a distance of 2,000,000 or 3,000,000 of these radii; but the great mass of the stars still lies without this range, and all we can say of their distances is that they are immeasurably great, even with the refined instruments of modern astronomy. See STARS.

The stars forming, as it were, the basis of creation, the centers of possible planetary systems, we reach the question of their number and extent. About 5,000 are usually visible to the naked eye, but very keen observers can detect as many as 8,000. The number visible is greatly increased when a small telescope is used, and continues to increase with the power of the instrument, rising, in the case of the most powerful telescopes, to perhaps 50,000,000, or many thousands for every one visible to the naked eye. But even then there is no evidence that the smallest stars are seen, but every reason to believe that greater instruments would show millions more in every direction.

Besides these millions of scattered stars, great clusters exist, in which powerful telescopes show a whole firmament of stars in a spot scarcely large enough to be visible to the naked eye.

As to the extent of the universe, and the scale on which it is constructed, we can do little more than set an inferior limit to the magnitude of creation. Beyond this limit we can not tell how extensive it may be. We may, however, conclude, with considerable probability, that most of the stars visible to the naked eye lie at distances which light would traverse in between fifty and three hundred years. In other words, if we conceive of two spheres described around our sun, the smaller with a radius over which light would pass in fifty years (in round numbers, three hundred millions of millions of miles), and another with a radius four times as great, it is probable that we should find a few score of the brighter stars within the inner sphere, and the great mass of the fainter ones visible to the naked eye, be-

tween the two spheres. If we suppose that the smaller telescopic stars have a general average of about the same intrinsic brilliancy as the brighter ones, we may conclude that they are placed at distances which light would traverse in from five to fifty thousand years. Of what is beyond we know nothing as yet.

Of the form and boundaries of this agglomeration of stars which forms the visible universe nothing certain is known, but it is certain that there is a great tendency to aggregation near the plane of the Milky Way. The latter is well known to consist of vast aggregations of telescopic stars too small to be separately visible to the naked eye. This fact was first clearly shown by Herschel, and led him to his celebrated theory that all the visible stars form a comparatively thin stratum, near the center of which our sun is placed. That the densest portions of the universe are spread out into such a stratum or plate there can be no doubt, but of the limits of the thinner portions, composed of stars scattered outside of this stratum, nothing positive can be asserted.

Nothing indicating either growth or decay has been actually observed in the stellar universe. There is no established instance either of a known star disappearing from the heavens, or of a really new one coming into view. The supposed cases of the latter kind are now found to be due to extraordinary variability; a small star, perhaps invisible to the naked eye, suddenly bursting forth into brilliancy, and after a time subsiding to its former magnitude. Several instances of this kind are on record, the last as late as 1866, when a star of the second or third magnitude suddenly appeared in the Northern Crown. An examination of Argelander's great star-catalogue showed that it was formerly a telescopic star of the ninth magnitude. After a few weeks it gradually returned to this magnitude, and has not since shown any kind of disturbance.

The stars are found to be moving among themselves in a way that must ultimately lead to an entire change of their distribution, and perhaps to their entire separation. The velocity of motion is usually from 20 to 50 miles per second, but in one instance it probably exceeds 200 miles per second. So far as observation can show, the rule is that each star moves forward independently in a straight line with a uniform velocity. From the few estimates of the masses of the stars which have been made, there is no reason to believe that their motions can be appreciably affected by their mutual gravitation, unless after the lapse of thousands of ages, or when two chance to pass near each other. The combined attraction of all the stars visible with the most powerful telescope, supposing their masses to be correctly judged by those of the stars which have been weighed, would never stop, and would hardly turn aside, the star Arcturus in its course of 60 or 80 miles per second, nor Groombridge 1830 in its headlong course of 200 miles per second. There is, in fact, no certain evidence that the stellar universe is held together by any bond of attraction whatever, as our solar system is. Mädler's view that Aleyone is the central sun of the universe is a piece of groundless speculation which has never received the assent of astronomers qualified to judge it. The stellar motions take place in every possible direction, and without regard to any known law, except that very frequently stars in the same region of space move nearly in the same direction.

Besides stars, we have nebulae as component parts of the telescopic universe. They are cloud-like patches of light scattered all over the heavens, but less numerous in the Milky Way than at a distance from it. Two of them, situated in the northern hemisphere, the great nebulae of Orion and of Andromeda, are clearly visible to the naked eye. Before the discovery of spectral analysis it was not possible to draw the line between nebulae and clusters of stars, because large numbers of objects which look like nebulae through small telescopes are found, with large ones, to be clusters of stars, and every increase in the power of the instrument was found to change objects from the former to the latter class. It was therefore doubtful whether all nebulae were not really clusters of stars too small or too distant to be resolved with the telescope. But, as soon as the spectroscope was turned upon such of these objects as could give a visible spectrum, it was found that many of them were not solid bodies at all, but masses of incandescent gas, generally hydrogen or nitrogen. To this class belongs the nebula of Orion, which is therefore a true nebula. On the other hand, the nebula of Andromeda gives a continuous spectrum, showing that the luminous matter is in a solid or

liquid state, and probably consists of an agglomeration of stars, though no telescope has yet resolved it.

We have no data whatever for forming a judgment of the distance of the nebulae, as we have in the case of the fixed stars. A favorite theory is that the forty or fifty millions of stars separately visible through the largest telescopes, the greater number of which, as we have said, are spread out in a thin, widely extended stratum, form a system to which our sun belongs, and that many of the resolvable nebulae are similar systems situated far outside of our own. In favor of this view is to be said that our Milky Way, viewed from a point 500 times the distance of the most remote star in it, would have the appearance of a nebula, and would give a continuous spectrum, although no telescope we possess would resolve it. It is therefore possible that many of the more distant resolvable nebulae may be such systems. But the greater number of visible clusters can not compare with our Milky Way in the number of their stars, as they only comprise a few hundreds or thousands. We can really draw no line of demarkation between the agglomerations of stars within our own system and the most distant cluster, the whole range from one extreme to the other being filled with known objects. We must therefore regard the views in question as forming a very grand but yet unproven hypothesis.

Our description of the stellar universe may be summed up by saying that it is composed of an unknown host of stars, certainly more than 50,000,000, mostly scattered in irregular aggregations forming the Milky Way, while many are aggregated in yet closer clusters, some of which are situated within the Milky Way and some without it, and of a number of enormous masses of incandescent gases situated at unknown distances. Our sun is simply one of these 50,000,000 of stars, without, so far as we know, any mark to distinguish him among his fellows. He is probably rather smaller than the average: removed to 1,000,000 times his present distance, which is probably the average distance of the stars of the first magnitude, he would shine only as a star of the third or fourth magnitude. He is, indeed, accompanied by a number of non-luminous planets, while, with one possible exception, no such companions are seen to the stars; but this does not disprove their existence, because every planet of our system would disappear from view in our most powerful telescopes at a distance far less than that of the nearest star.

The physical constitution of the sun and stars is a subject which has greatly occupied investigators in recent times, without leading them to an entirely certain and definite conclusion. The theory of Wilson and Herschel that the sun is a dark, cool body, surrounded by a stratum of luminous clouds floating in an atmosphere, has been one of the best known, but it is completely disproved by the modern discoveries of the conservation of force and the equivalence of heat and force. The enormous volumes of heat sent off by the sun can be supplied only by a continuous expenditure of force, and any theory which accounts for the solar light and heat must show whence that force comes. We know that our sun has been radiating light and heat in quantities as great as at present for thousands, or even millions, of years, while the sun of Herschel would cool off very quickly, and then cease to give either light or heat. In one respect, however, the theory in question is now universally agreed to: the "photosphere"—that is, the shining surface of the solar sphere—is composed of cloud-like matter, apparently floating in some kind of fluid, the whole being at an extremely high temperature. The spots are known to be dark depressions in the photosphere, as to the cause of which investigators are not yet agreed. Of the interior of this enormous globe we can see nothing, but there is good reason for holding that it is mostly formed of materials similar to those which compose the crust of the earth, heated to so high a temperature as to be completely vaporized and reduced to a state of *dissociation*, or one in which chemical union of different elements is no longer possible. At the same time the pressure to which this vaporous interior is subjected by the weight of its outer layers is so great that it is compressed into the smallest possible space, so that the mean density of the sun is not much greater than that of water.

On the outside, this mass is continually cooling off by radiation, and hence condensing to the solid or liquid state. The matter thus condensed forms the photosphere, which seems to be in a state of continual change.

Immediately above the photosphere lies a comparatively

shallow, but extremely complex, incandescent atmosphere, the absorption of which causes the dark lines in the solar spectrum. This atmosphere consists of hydrogen gas, mixed with the vapors of many of the metals, especially magnesium, calcium, sodium, and iron; the metallic vapors, except that of magnesium, mostly lying so near the base that they are not visible, even with a spectroscope, except just at the beginning and end of a total eclipse. This atmosphere shines with a red light, and was frequently seen during total eclipses of the sun, but its existence and nature were first clearly brought to light by Mr. J. N. Lockyer's spectroscope. This gentleman termed it the chromosphere. It is agitated by storms of fire, the fury of which exceeds anything ever pictured by the wildest imagination of the poet, the velocity of the wind sometimes rising to 100 miles per second, and masses of fiery vapor many times the size of our earth shooting up to the height of 20,000, 50,000, or even 80,000 miles. These masses constitute the red "protuberances" always visible during total eclipses of the sun, the nature of which was a complete mystery until the spectroscope was turned upon them by Janssen in India during the great eclipse of 1868. They are now the subjects of daily observation by spectroscopists.

Outside the chromosphere lies an appendage the nature of which is still involved in mystery, as it can be studied only during the rare moments afforded by total eclipses of the sun. It is seen in the glow of light which then surrounds the whole sun, extending to a height greater than the semi-diameter of that body, and is known as the solar corona. Its spectrum consists principally of a single green line, not identified with that of any terrestrial substance, but Janssen also recognized some of the lines of hydrogen during the eclipse of Dec., 1871. See SPECTRUM.

One of the most difficult questions respecting the sun is, Whence come the floods of heat which he is continually radiating into space? Why did he not cool off hundreds of thousands of years ago? Why does he not now grow cooler from year to year? Only in recent years have serious attempts been made to answer these questions, because only then was it recognized that heat was a form of force which could not be expended without being continually renewed. The theory now most generally received is that of *contraction*. It is supposed that as the sun cools off he contracts in volume; and it is found by calculation that a very small contraction will develop an enormous amount of heat in a mass so immense as that of the sun, so long as it does not condense to the solid or liquid state. Thus the supply of heat may be kept up for a million of years to come, but it must give out some time, unless renewed from some unseen source, and our system will then be involved in darkness and death.

By the motion of the spots it is found that the sun rotates on his axis in about twenty-five days, this being the period at the equator. But as we approach the poles the rate becomes slower and the period longer, approaching twenty-six days at a distance of 45°. Beyond this point very few spots are to be seen, and the law of rotation is not completely known. The liquid or gaseous or cloud-like character of the sun's surface is conclusively proved by the variation in the rate of rotation. See SUN.

The sun is accompanied by a retinue of eight major planets, of which our earth is one, and by a large group of minor planets, often called asteroids. (See ASTEROID.) The major planets may themselves be divided into two groups of four each, the four inner and smaller ones being Mercury, Venus, the Earth, and Mars, and the four outer and larger ones being Jupiter, Saturn, Uranus, and Neptune. The smallest of the outer group (Uranus) has more than ten times the mass of the largest of the inner group (the Earth), and is more than fifty times its size. Between the two groups is a wide gap in which the minor planets are found. The sun with its planets and their satellites form a connected group called the *Solar System*. For a description of this system and of the bodies which compose it, see ASTEROID, MOON, PLANET, SOLAR SYSTEM, and the names of the eight major planets mentioned above.

Besides the planets quite a number of comets are known to be members of the solar system, and a great number of others are suspected to be such, even though their time of revolution is so great that they have never been recorded as seen but once. The general rule is that a comet comes into view suddenly and unexpectedly, falling nearly toward the sun as if dropped from an infinite distance. It whirls around the sun in a parabolic orbit, and flies off into space

nearly in the direction from which it came. If astronomers have an opportunity of observing it carefully for several months, they can tell whether it is or is not flying so fast that the attraction of the sun will never bring it back again. It is thus definitely ascertained that the great comet of 1858 will return, in consequence of the sun's attraction, in about 1,950 years, probably between the years 3800 and 3820, after flying off into space to the distance of 15,000,000,000 miles.

The physical constitution of comets is still one of the enigmas of astronomy. Large comets are generally found to consist of three distinct formations: (1) a small bright, but ill-defined nucleus; (2) a round mass of hazy, nebulous, or foggy matter surrounding this nucleus, and indeed seeming to rise from it; and (3) a tail of extremely rare matter, but of enormous length, extending off from the comet in a direction opposed to the sun, growing wider and fainter as it extends, until it gradually becomes invisible. But the smaller telescopic comets often exhibit neither nucleus nor tail, but consist only of an irregular, ill-defined, nebulous mass, perhaps brighter at one point. As the comet approaches the sun the tail develops enormously, and frequently shows itself when none was visible at a distance. It is now generally considered that the tail of a comet is not a permanent appendage, but a stream of finely divided matter continually driven off from the comet into space by some repulsive force residing in the sun, the nature of which is not yet understood. It may be compared to the steam rising from a boiling pot, or to smoke from a chimney. If this view be correct—and it can hardly be disputed—all the comets are continually evaporating into space, and must in time be entirely dissipated. See COMET.

This theory of the constant dissipation of comets has recently received a striking confirmation in the ascertained coincidence of meteor-streams with the orbits of comets, and in the disappearance of Biela's comet from the heavens. It has long been known that we have either a meteoric shower or an unusual number of meteors every year on the nights of Aug. 9 and Nov. 14, and they are now found to be produced by the earth's atmosphere meeting a swarm of very minute particles which move in the respective orbits of two comets. The particles are supposed to be the fragments or dust of the comets which have become separated in the course of ages. See METEORS.

The sun, being seven hundred times as heavy as all the planets, keeps them moving in orbits around him by his own gravitation, while the motion of each planet is affected with small irregularities caused by the attraction of all the others. By this theory the courses of all the planets, and of the moon and many of the satellites, are predicted with an astonishing degree of accuracy. The first thing which gravitation settles is the motion of the earth itself on its axis. The daily revolution around its axis seems to take place with perfect regularity, but the axis itself is subject to several very slow motions, which make its direction decidedly different in the course of ages. These motions can not well be described without a globe, but as the whole earth and the instruments with which observations are made partake of them, they change all observed positions of the heavenly bodies, and these changes must be carefully allowed for in all calculations. See PRECESSION OF THE EQUINOXES.

The Copernican system and the theory of gravitation have reduced theoretical astronomy almost to branches of pure mathematics—mechanics, geometry, and trigonometry. The system is quite simple in its original conceptions, but very complex when we descend to minute details. A number of imaginary planes are conceived of as passing through the earth or sun, and extending out into infinity in every direction. The positions of the heavenly bodies are defined by their distances from these planes, and the angles which the line drawn from the sun or the earth to the body makes with different lines drawn in the planes. The most common mode of defining position is by giving three data: (1) the distance of the heavenly body from some point, either the center of the earth or the center of the sun, in a straight line; (2) the angle which this straight line makes with one of the planes in question; (3) a perpendicular being dropped from the body on the plane, the angle which the line to the point of intersection makes with some fixed line in the plane. When the distances are reckoned from the earth, it is usual to take the plane of the equator as that of reference; when from the sun, the ecliptic is usually selected. Both these planes are constantly changing their position in consequence of the attraction of the moon and planets on the earth, and this change has always to be calculated and

allowed for. This operation makes the subject a very intricate one, which can be fully developed only in works devoted especially to the subject.

The various branches of astronomical research may be included under three great classes. We have, first, a branch which is a direct continuation of the studies of the ancient and mediæval astronomers, namely, that which is concerned with the positions and motions of the heavenly bodies. Astronomers who pursue this branch prepare catalogues of stars, accurately determine their positions in the heavens by the aid of instruments of measurement, study the motions of planets, compute orbits of comets, measure the satellites of the planets, and investigate the laws of motion in the planetary system. Work of this kind frequently requires the co-operation of many men, and is therefore that principally pursued in the great national observatories. It is, perhaps, the least interesting branch of astronomy, since it is concerned with development and not with discovery. Yet to men with mathematical tastes it offers a splendid field for their ingenuity. Probably no achievement of the human intellect compares with that of discovering the laws of motion of the planets by the aid of gravitation, through countless ages past and to come.

Directly connected with this is the application of practical astronomy to the determination of positions on the earth. Every navigator who finds the longitude and latitude of his ship by observations of the sun with a sextant is an astronomer in this sense. This branch is principally pursued in the great national surveys, such as the Coast and Geodetic Survey in the U. S. It is intimately associated with GEODESY (*q. v.*). It is a branch of astronomy only in the sense that its work has to be done by observing the heavenly bodies, and that astronomical instruments and methods have to be used.

The usefulness of practical astronomy, and the perfection it has attained, may be judged from this consideration: take an astronomer blindfolded to any part of the globe, give him the instruments we have mentioned, a chronometer regulated to Greenwich or Washington time, and the necessary tables, and if the weather be clear, so that he can see the stars, he can in the course of twenty-four hours tell where he is in latitude and longitude within a hundred yards.

Another branch is known under various names, as physical astronomy, astrophysics, cosmical physics, etc. Probably the term astrophysics will supersede all others, because it is concerned with the physical constitution of the heavenly bodies. Photography has in recent times come to its aid, and proved a most powerful method of research. The great progress made in scientific photography has made it possible to obtain an impression on a photographic plate of objects which are quite invisible to the naked eye, or even in the telescope, and has led to the discovery of new nebulae in this way.

But the great instrument of research in this line has been the spectroscope. The chemical constitution of the stars is now being investigated, and their motions to and from the earth have been subject to measurement. The most wonderful discovery in this line is that of Vogel, that the variations of light in the star Algol, which have been observed for a century or more, are due to the revolution of a dark body around it, partially eclipsing it during each revolution, as it passes between the earth and the star. The body itself, and the whole mechanism of its motion, is absolutely invisible, star and planet forming but a point which the most powerful telescope can not distinguish. Yet the attraction of the invisible planet upon the star, wholly intangible in any other way, is measured in the spectral lines by a minute change in the wave-length of the light which the star emits. Modern science has in no direction gone farther than in this. See ALGOL.

S. NEWCOMB.

Astruc. aăs'truk'. JEAN: French mediæval writer; the son of a Huguenot pastor; b. at Sauve, in Languedoc, Mar. 19, 1684. He was educated at Montpellier, became M. D. 1703; appointed Professor of Anatomy at Toulouse in 1710, and of Medicine at Montpellier in 1716. Having removed to Paris in 1728, he became consulting physician to the king, and in 1731 Professor of Medicine at the Royal College. He had a high reputation as a professor. He published, besides other medical works, *De Morbis Venereis* (On Venereal Diseases, 1736). His medical researches led him to study those passages in the Pentateuch which treat of diseases. While so doing he lighted upon the discovery which has immortalized him: viz., he noticed that in some passages of Genesis in Hebrew God is called Elohim and in others Jehovah,

whence he inferred that the passages so distinguished belonged to two different documents from which Moses had compiled his book. This was the virtual start to the fruitful Pentateuch criticism, and the germ of the documentary hypothesis of Eichhorn. He issued his book anonymously under the title *Conjectures sur les mémoires originaux dont il paroît que Moïse s'est servi pour composer le livre de la Genèse* (Brussels, 1753). (There is a copy of the rare volume in the library of Union Theological Seminary, New York city.) Besides the two principal documents, the so-called Elohist and Jehovist, he distinguished nine or ten others on the basis of repetitions and alleged inconsistencies. He did not, however, dispute that Moses was the compiler of Genesis, nor that he was the author of the rest of the Pentateuch. D. in Paris, May 5, 1766. See A. C. Lorry, *Vie d'Astruc*, in his edition of Astruc's *Mémoires pour servir à l'histoire de la Faculté de Médecine de Montpellier* (Paris, 1767).

Revised by S. M. JACKSON.

Astulphus: See ASTOLPHUS.

Astu'ria: a former kingdom in the N. of Spain: bounded N. by the Bay of Biscay, and S. by the Cantabrian Mountains. The Asturians made a long and brave resistance to the Goths and Vandals who invaded Spain about 500 A. D., but were finally subdued. Asturia was the only part of Spain that was not conquered by the Moors. See ASTURIAS.

Asturias: an ancient division of Spain, now the province of Oviedo; area of 4,091 sq. miles. It is bounded N. by the Bay of Biscay, E. by Santander, S. by Leon, and W. by Galicia (see map of Spain, ref. 12-D). The surface is mountainous, and abounds in wild and picturesque scenery. Along the southern border extends a chain of mountains, the summit of which, called Peña de Peñaranda, is about 11,000 feet high. It has extensive forests of oak, chestnut, beech, and fir. Among the mineral resources are copper, iron, lead, cobalt, antimony, marble, coal, and zinc. The eldest sons of the Kings of Spain formerly took the title of Prince of Asturias. Pop. (1887) 595,420. The chief town is Oviedo. See ASTURIA.

Asty'ages (in Gr. 'Αστυάγης): King of Media; a son of Cyaxares I.; reigned from 593 to 569 B. C. He had a daughter, Mandane, who was married to Cambyses, a noble Persian, and bore a son who was Cyrus the Great. He was succeeded by Cyaxares II., the last King of Media (569-536 B. C.).

Asuncion. aă-soon'-sē-ōn' (i. e. assumption): a city of South America, the capital of Paraguay; situated on the left (east) bank of the river Paragnay, 645 miles N. of Buenos Ayres; lat. 25° 16' 29" S., lon. 57° 42' 42" W. (see map of South America, ref. 7-E). It was founded by the Spaniards in 1536. It has a cathedral, five churches, a government palace, a college, a public library, etc. Hides, tobacco, timber, and *yerba maté* (or Paraguay tea) are shipped here by the river. The houses are mostly built of brick, one story high. Pop. of commune (1886) 24,838.

Asylum [Lat. *asylum*, from Gr. ἄσυλον, refuge; ἄσυλος, inviolable; ἀ-, not + σύλη, σύλον, right of seizure]: a sanctuary and place of refuge and security for criminals and others; any place of retreat and security. In ancient Greece the temples, altars, and sacred places were appointed as asylums for criminals and persecuted persons, and it was considered a sacrilege to kill or remove by force those who had taken refuge in them. They were, however, sometimes surrounded and watched until they died of starvation. Among the ancient-Jews cities of refuge were appointed for the benefit of persons who had accidentally committed manslaughter. Romulus is said to have attracted men from other states to Rome by offering an asylum to criminals, debtors, or outlaws. Asylums became so numerous under the Roman empire that they were considered nuisances by honest people, and were nearly all abolished by Tiberius. In the reign of Constantine the Great all Christian churches were asylums. The privilege was afterward extended to convents, and was much abused by criminals in the Middle Ages. Several popes, in order to prevent this abuse, excluded murderers and some other classes of offenders from the privilege of sanctuary, which was abolished in England by acts passed in 1534 and 1697. In modern usage the term asylum is applied to charitable institutions for the relief of the blind, insane, orphans, etc.

Asylum, in international law: The jurisdiction of a state covers only its own territory. When one of its subjects takes refuge within another state he becomes amenable to the laws of that state. The right of asylum then is that exercise of the right of sovereignty which forbids one gov-

ernment to apply its laws to its own or its enemy's subjects when within the jurisdiction of another government. It may be used to protect individuals, ships with their crews, or armed bodies. It may apply within the territory of a state, upon its ships on the high seas, in certain cases even in its embassies in foreign parts. Where the refugee is a common criminal, the country of his refuge, not wishing crime to go unpunished, yet undesirous of assuming this burden itself, will probably surrender him. This is solely under treaty regulation, however. Extradition is thus a limitation of the right of asylum. (See EXTRADITION.) But the surrender of political offenders is not customary, since their crime is not against society, and no sympathy with their punishment can be presumed. If such offenders escape to foreign men-of-war in port, or to foreign ships on the high seas, the right of asylum holds good. In most countries if they seek refuge in foreign embassies the right would be denied them. In Oriental countries and in the states of South America, however, it has been frequently exercised. An instance of this was seen in Chili after the overthrow of Bahnaceda, when a number of his adherents were protected in the U. S. legation. The U. S. Government has consistently discouraged such protection as a settled policy, though granting it in some such instances. Where armed troops are driven by superior force into neutral territory the right of asylum is granted them, but they are not at liberty to use this refuge as a vantage ground for making war. The practice is to disarm and intern them in the interior of the neutral country until the close of the war. A man-of-war may take refuge from superior force within the waters of a neutral, but subject to whatever conditions it chooses to lay down.

THEODORE S. WOOLSEY.

Atabalipa : See ATAHUALLPA.

Atacama, aã-taã-kaa'ma : a territory of Chili ; bounded N. by the province of Tarapaca, E. by the Argentine Republic and Bolivia, S. by the province of Coquimbo, and W. by the Pacific Ocean. Area, 43,180 sq. miles, including former province of Atacama, Bolivia. The country is for the most part mountainous and sterile, and produces only along the banks of a few rivers some vegetables and a few fruits. It contains, however, rich copper mines. The climate is dry and warm : most of the springs contain salt water. Capital, Copiapo. Pop. (1891) 67,205.

Atac'amite : an ore of copper, abundant in the desert of Atacama (whence its name), and occurring also as a crust on the lavas of Vesuvius and Etua. It may be defined as a hydrated oxychloride of copper, or a combination of protoxide of copper with chloride of copper. It is a rich ore, containing 55 or 60 per cent. of copper. The natural varieties of atacamite are crystallized, massive, and pulverulent or granular. The primary form of its crystals is a rhombic prism. The greenish incrustation which is formed on antique bronze weapons, utensils, etc., and which is called *æruo nobilis*, is composed of this salt.

Atahuall'pa, or **Ataba'lipa** : the last inea of Peru ; a son of Huayna Capac, who died in 1529. By his will the latter divided his dominions between his two sons, Huascar and Atahuallpa, who obtained the kingdom of Quito. These brothers reigned in peace about five years, after which Huascar sent an envoy to Atahuallpa, and required him to render homage for the kingdom of Quito. That inea, who was ambitious and warlike, refused to pay homage, and, having invaded Peru with an army, defeated Huascar and took him prisoner in 1532. He spared the life of Huascar, but deprived him of his throne and liberty. In the same year Peru was invaded by Pizarro and a small army of Spaniards. The inea, with an unarmed retinue, approached the camp of Pizarro in Nov., 1532, for a friendly interview, during which a Spanish priest informed the inea that the pope had given Peru to the King of Spain. As he rejected with indignation the authority of the pope, the treacherous Spaniards seized him and massacred his attendants. The captive inea offered to ransom himself by a quantity of gold which would fill the room in which he was confined as high as he could reach. The Spaniards accepted the gold, but refused him liberty. Pizarro accused Atahuallpa of plotting against him, and ordered him to be tried by a court martial, which condemned him to be burned alive. After he had consented to be baptized his sentence was commuted to strangulation, and he was executed Aug. 29, 1533. See Prescott, *Conquest of Peru*, vol. i.

Atalan'ta (in Gr. Ἀταλάντη) : the name of two mythical personages who figure in ancient Greek legends—(1) the most

swift-footed of mortals, and renowned for personal beauty. Having many suitors, she offered to marry any man who should defeat her in a foot-race, with the condition that if he lost he must be put to death. He was to be unarmed, but she was to carry a spear. Hippomenes, who had received from Aphrodite three golden apples, became the successful competitor by dropping them one by one before Atalanta, who could not resist the temptation to stop and pick them up. Having forgotten, in his joy, to thank the goddess as he should, the latter took revenge in singular fashion. She so inflamed him that he embraced his bride within the shrine of Cybele, who thereupon in punishment changed the pair into lions. (2) Another Atalanta was a renowned huntress, like Artemis. She wounded the Calydonian boar ; took part in the Argonautic expedition ; and wrestled successfully with Peleos at the funeral games of Pelias. She won the patient, long unrequited love of Meilanion, and finally yielded to his quiet persistency and married the hero, to whom she bore Parthenopaios. See W. Immerwahr, *De Atalanta* (Berlin, 1885).

Revised by S. M. JACKSON.

Ataman : See ATTAMAN.

Atamas'co Lily (*Zephyranthes atamasco*) : an amaryllis-like ornamental bulbous plant, with white or flesh-colored flowers, native of the Southern U. S., but cultivated for upward of 250 years.

C. E. B.

At'aulf, **Adaulf**, or **Adolf** (in Lat. *Ataul'phus*) : King of the Visigoths, and a brother-in-law of Alarie I., whom he succeeded in 411 A. D. He had aided Alarie in the capture of Rome in 410, and had captured Placidia, a sister of the Emperor Honorius, whom he married. In 412 he retired from Italy into Gaul, where he defeated Jovinus, took Bordeaux (*Burdigala*), and conquered Aquitania. He was assassinated by one of his own officers in 415 A. D.

At'avism [Fr. *atavisme*, from Lat. *atavus*, ancestor] : 1. In natural history atavism is the reappearance in animals or plants of traits belonging to their remote progenitors which their immediate parents did not present. *Reversion* is a term nearly synonymous, used (by Darwin and others) to indicate not only the occasional or individual appearance of such remotely descended traits, but the actual returning to them of a variety or species. Domesticated breeds of animals allowed to run wild become, after a time, nearly (seldom exactly) like their wild ancestors. This is a familiar fact with horses, cattle, hogs, and pigeons. The wild horses on the great North American prairies and on the pampas of South America, though all derived from those imported to the Western continent by Europeans, are nearly of one size, shape, and color ; and the same is true of the wild herds of cattle of the South American pampas and llanos. Domestic hogs running wild assume, in a few generations, a moderate size, slender figure, and (in some places at least) a nearly black color, with head and tusks approaching those of the wild boar of Europe. Darwin mentions the fact that in all the breeds of domestic pigeons there appear occasionally birds of a slaty-blue color, with bars and other marks characteristic of the ancestral rock-pigeon (*Columba livia*). He also considers the occasional appearance of stripes upon a horse or mule as indicating ancestral identity between the now distinct species of the equine genus. 2. In human pathology atavism is a reversion (similar to the above) to morbid traits existing in ancestors, but not in immediate parents. This may be briefly illustrated by an example (from *Lectures on Practice of Medicine*, by Sir T. Watson) : A deaf-mute man married a woman whose hearing was perfect, and had two children by her—one a deaf-mute son, who died childless ; the other, a *hearing* daughter, who married a *hearing* man, and gave birth to two *deaf-mute* daughters and a *hearing* son. This son married a woman also with good hearing, and had by her a deaf-mute son. One of the daughters married a deaf-mute and bore a hearing son. Gout, consumption, insanity, and other diseases sometimes thus disappear for one, two, or more generations in a family, and yet return in a manner evidently due to hereditary (though interrupted or latent) transmission.

Revised by WILLIAM PEPPER.

Ataxia, **LOCOMOTOR** : See TABES DORSALIS.

Atba'ra (*Astab'oras*) : a river of Northeastern Africa ; rises in Abyssinia, near Lake Dembea (or Tsana), and flows north-westward. After receiving several tributaries from the mountains, it traverses the desert of Southern Nubia, and enters the Nile in lat. 17° 37' N., and about 25 miles S. of Berber. It is the last tributary that the Nile receives, and is one of the principal causes of the inundation of Egypt. Its

length is estimated at 550 miles. In the dry season, October to June, it contains no water except standing pools. Crocodiles and hippopotami abound in this river, on the borders of which are great numbers of elephants, rhinoceroses, giraffes, lions, etc.

Atchafalaya Bay'on: an outlet in Louisiana of the Red river, from whence it issues near the mouth of the latter at the northern extremity of Point Coupée parish. It flows nearly southward through Chetimaches Lake, and enters Atchafalaya Bay, a part of the Gulf of Mexico. The whole length is estimated at 225 miles. It is navigable for steamers. At the entrance to the bay is Southwest Reef, with an iron lighthouse 50 feet high.

Atchison: city and important railroad center; capital of Atchison co., Kan. (for location of county, see map of Kansas, ref. 4-J); beautifully situated on the west bank of the Missouri river, at the extreme western point of the "Great Bend." It is one of the principal commercial cities in the State and has fine public-school buildings, one of which cost \$50,000, academies, and St. Benedict's, Midland, and St. Louis colleges; 10 churches; has fine paved streets (vitrified brick); 3 newspapers, and the largest output of flour of any city in Kansas. Pop. (1870) 7,054; (1880) 15,105; (1890) 13,963; (1900) 15,722. EDITOR OF "PATRIOT."

A'te (in Gr. Ἄτη): in classic mythology, a goddess supposed to avenge crimes, and also to stir up mischief. According to Homer, she was a daughter of Jupiter, who, for her mischief-making character, banished her from Olympus.

A'teles [Gr. ἀτελής, imperfect; ἀ-, not + τέλος, completion]: a genus of South American monkeys, characterized by the absence of a rudimentary condition of the thumb of the anterior hands. They have long, prehensile tails. The genus comprises the marimonda (*Ateles beelzebub*), which is very numerous on the Orinoco, besides a dozen other species.

Atella'næ Fa'bulæ [from *Atella*, a small Oscan town in Campania, south of Capua]: rude farces, largely improvisatory, performed originally in the Oscan vernacular, with certain stock characters. Afterward they were brought to Rome, and acted by Roman youth of good family, wearing masks. Still later (about 89 B. C.) they received a literary development at the hands of Pomponius and Novius. The ordinary masks or characters were four in number: Mæcus, the simpleton; Buceus, the loquacious glutton and boaster; Pappus, the old man constantly outwitted; Dossennus, the cunning parasite. See fragments in O. Ribbeck's *Comicorum Romanorum Fragmenta* (pp. 225-76). M. WARREN.

A Tem'po (literally, in time): a musical term used to denote that after some short relaxation in the time the performer must return "to the [proper] time," or original degree of movement.

A Tempo Gius'to (in the correct time): in music, a direction to the performer to keep the rhythm true and correct without retarding or accelerating the time.

Ateuchus: See SCARABÆUS.

Athabasc'a: a river and lake of the Northwest Territories of British North America. The lake is about lat. 59° N., and between lon. 106° and 112° W. It extends E. and W. about 230 miles, and has an average width of 20 miles. The river rises in the Rocky Mountains, flows northeastward, and enters the lake near its western extremity. The water of this lake is discharged through Great Slave river, eventually into the Mackenzie river.

Athabasca (from Athabasca Lake): a district of the Northwest Territories, Canada, and a future province of the dominion. It is nearly square in form, with Alberta on the S. and British Columbia on the W.; on the N. and E. are the still undistricted Northwest Territories. The northern boundary is a parallel not far from that of 60° N., and the eastern one is for the most part formed by Athabasca and Great Slave rivers. It is south of Great Slave Lake, and Athabasca Lake is on the eastern border; Peace river crosses the district diagonally; Little Slave Lake is in the southern part of the district. The surface is made up of wooded plains broken by low mountain-ranges. The population is mostly Indian, including the Strongbow and Beaver nations. The agricultural possibilities of the district are greater than the geographical situation would indicate. Wheat, barley, and potatoes can be raised in favorable situations in all parts of the district, and occasional chinook winds give warm weather for a few days, even in midwinter. Peltry is the chief product of the country at present, and the old Hudson's Bay Com-

pany's posts are numerous. There is quite a settlement at Dunvegan, in the southwestern angle on the Peace river. The area of Athabasca is 104,500 sq. miles. M. W. H.

Athali'ah: a Queen of Judah; a daughter of Ahab, King of Israel, and Jezebel. She was married to Jehoram, King of Judah, whom she survived, and became a notorious idolater. After the death of her son Ahaziah, about 884 B. C., she usurped the royal power and murdered all the males of the royal family except Joash. In 878 B. C. she was killed by the partisans of Joash. Her story is the subject of one of Racine's most celebrated tragedies. See 2 Kings viii. and xi.

Athana'sian Creed (in Lat. *Sym'bolum Athanasia'nium*): so called because it was mistakenly supposed to have been written by Athanasius (d. 373). It did not appear in Greek till the eleventh or twelfth century, and was then evidently a translation. In the West it was commented upon by Venantius Fortunatus in 570. And it contains extracts from Augustine's *Trinity* (415 A. D.), and from the *Commonitorium* of Vincentius Lirinensis (434 A. D.); so that it was probably written not far from 450 A. D., and apparently in Gaul.

The Athanasian Creed is the sharpest and most rigid of the three catholic symbols. It sometimes takes as its title the words *Quicumque vult*, with which in its Latin version it commences. The entire passage of which those words are a part is in English as follows: "Whosoever will be saved, before all things it is necessary that he hold the catholic faith; which faith except every one do keep whole and undefiled, without doubt he shall perish everlastingly." Then follows a minute and precise exposition of the Trinity, and an equally exact statement of the doctrine of the incarnation; after which this clause occurs: "This is the catholic faith; which except a man believe faithfully he can not be saved." The common inference would be that unless a man held the doctrine precisely as it is taught in the creed he can not be saved. On account of these "damnatory clauses," as they are sometimes called, many Christians, while substantially accepting the doctrines of the creed, disapprove of its being used in the churches. Though still retained in the church-service in England, and its use appointed for certain festivals, it is omitted from the American Book of Common Prayer, although its retention was ardently desired by Seabury, the first American bishop.

Revised by WILLIAM STEVENS PERRY.

Athana'sius (in Gr. Ἀθανάσιος), SAINT: a celebrated Greek Father of the Church; b. at Alexandria about 296 A. D. His education was directed by Alexander, Archbishop of Alexandria, with whom he lived as a son with a father. Alexander ordained him a deacon in 319, and was accompanied by him to the general Council of Nice (325), in which Athanasius distinguished himself by his eloquence, learning, and zeal against Arianism. In 326 or 328 he was elected Archbishop of Alexandria by the clergy and the people to succeed Alexander. The beginning of his episcopate was signalized by the organization of the Church in Abyssinia, through Frumentius, whom he consecrated as its first bishop (329). But to his dying day he was in trouble from the Meletians, the schismatics who supported Meletius, Bishop of Lycopolis, in his insubordination to the Archbishop of Alexandria, and especially from the Arians, whose doctrines he opposed so determinedly. His enemies contrived to gain the ear of Constantine, whom they convinced that Arius had really altered his views. So the emperor ordered Athanasius to restore him to communion. But he refused (331). Then he was summoned to appear at a council held in Casarea (334) to answer to certain alleged offenses, but he would not attend it. The next year he was by Constantine summoned to appear at the Council of Tyre (probably June 6) to answer several charges, and was there deposed. The Emperor Constantine banished him to Treves, but the Emperor Constantius, on the death of Constantine, restored him (338) to his see, and he was received with great rejoicing. Yet in 340 Athanasius deemed it advantageous to lay his case before the Bishop of Rome. In his absence he was deposed by a council held at Antioch (341). He recovered his office in 346. The Arians prevailed in the Council of Arles (353) and in that of Milan, which, under the influence of the Emperor Constantius, condemned Athanasius in 355. He was again driven out of Alexandria (356), and took refuge in the solitudes of Upper Egypt, where he passed six years, and wrote several doctrinal works. Shortly after the accession of Julian the Apostate he returned to Alexandria (Feb. 22, 362), under the general order that all bishops exiled by his predecessor should be allowed to return to their

homes. But the pagans easily persuaded Julian to banish Athanasius on the ground that he was destroying their religion, and so for a fourth time he was an exile (362). The next year he was restored by Jovinian. In 365 he was once more exiled by the Arian Emperor Valens, but after a few months (366) he was allowed to return, and continued in peaceable possession of his office until his death, May 2, 373. Athanasius was the most eminent and influential leader of the orthodox party (who were sometimes called Athanasians), and was distinguished by his fortitude under persecution, self-sacrifice, steadiness of purpose, versatility, resourcefulness, width of ready sympathy, and other virtues which endeared him to his people and qualified him to be a pillar of the militant Church in stormy and perilous times. He left numerous polemical and religious works, written in Greek in a simple, nervous, and perspicuous style. The most complete edition, unhappily inaccurately printed, is Migne's, in his *Patrologia Græca* (vols. xxv.-xxviii.). J. E. Thilo edited his select dogmatic works (*Athan. Opp. dogm. selecta*, Leipzig, 1853), and W. Bright his *Orations against the Arians* (his chief work; London, 1873; 2d ed. 1883); and his *Historical Writings* (Oxford, 1881). His principal works, including his writings against the Arians, his *Life of Antony* (founder of monasticism, a disputed work), and his *Festal Letters*, have been translated and edited by Archibald Robertson, with admirable introductions, general and special (New York, Christian Literature Co., 1892), who has written a sufficiently full life of Athanasius for the general reader. See also the *Life*, popular yet scholarly, by H. R. Reynolds (London, Religious Tract Soc., 1889).

SAMUEL MACAULEY JACKSON.

Athapascan Indians: the whole stock or family of North American Indians, formerly called Tinnah, extending from Alaska and British North America to Mexico; also a single tribe, the Athapascan Indians proper, dwelling around Athabasca Lake and along Slave river. The name is derived from Lake Athabasca in British North America, and signifies, according to Lacombe, "place of hay and reeds." In literature it once referred specifically to the Northern Tinnah, Chippeweyans or Montagnais, in Alaska and British North America W. of Hudson's Bay and N. of Churchill river.

Habitat.—As defined by Gallatin the area occupied by the Athapascan Indian family is included in a line drawn from the mouth of the Churchill or Mississippi river to its source; thence along the ridge which separates the north branch of the Saskatchewan from those of the Athapascans to the Rocky Mountains; and thence northwardly till within 100 miles of the Pacific Ocean, in lat. 52° 30'. The only tribe within the above area excepted by Gallatin as of probably a different stock was that of the Quarrelers, Kutchin or Loucheux, living at the mouth of Mackenzie river. This tribe, however, has since been ascertained to be Athapascan. The Athapascan Indians thus occupied almost the whole of British Columbia and Alaska, and were, with the exception of the Eskimo, by whom they were cut off on nearly all sides from the ocean, the most northern family in North America. Since Gallatin's time the history of this family has been further elucidated by the discovery on the part of Hale and Turner that isolated branches of the stock have become established in Oregon, California, and along the southern border of the U. S. The boundaries of the Athapascan Indian family, as now understood, are best given under three primary groups—*Northern*, *Pacific*, and *Southern*.

(1) The *Northern Group* includes all the Athapascan tribes of British North America and Alaska. In the former region the Athapascans occupy most of the western interior, being bounded on the N. by the Arctic Eskimo, who inhabit a narrow strip of coast; on the E. by the Eskimo of Hudson's Bay as far S. as Churchill river, S. of which river the country is occupied by Algonquian tribes. On the S. the Athapascan tribes extended to the main ridge between the Athabasca and Saskatchewan rivers, where they met Algonquian tribes; W. of this area they were bounded on the S. by the Salishan tribes, the limits of whose territory on Fraser river and its tributaries appear on Tolmie and Dawson's map of 1884. On the W., in British Columbia, the Athapascan tribes nowhere reach the coast, being cut off by the Wakashan, Salishan, and Chimmesyan families. The interior of Alaska is chiefly occupied by tribes of this family. Eskimo tribes have encroached somewhat upon the interior along the Yukon, Kuskokwim, Kowak, and Noatak

rivers, reaching on the Yukon to somewhat below Shageluk island, and on the Kuskokwim nearly or quite to Kolnakoff Redoubt. Upon the two latter they reach quite to their heads. A few Kutchin tribes are, or have been, N. of the Porcupine and Yukon rivers, but until recently it has not been known that they extended N. beyond the Yukon and Romanzoff Mountains. The region to the N. of those mountains is occupied by Athapascan tribes. Only in two places in Alaska do the Athapascan tribes reach the coast—the K'naia-khotana (Kenai), on Cook's Inlet, and the Ah-tena, of Copper river.

(2) The *Pacific Group*.—Unlike the tribes of the Northern group, most of those in the Pacific group have removed from their prairie habitats since the advent of the white race. The Pacific group embraces the following: Kwalliioqua, formerly on Willpah river, Washington, near the Lower Chinook; Owilapsh, formerly between Shoalwater Bay and the heads of the Chehalis river, Washington, the territory of these two tribes being practically continuous; Tlatskanai, formerly on a small stream on the northwest side of Wapato island. Gibbs was informed by an old Indian that this tribe "formerly owned the prairies on the Tsihalis at the mouth of the Skukumchuck, but, on the failure of game, left the country, crossed the Columbia river, and occupied the mountains to the south"—a statement of too uncertain character to be depended upon; the Athapascan tribes now on the Grande Ronde and Siletz reservations, Oregon, whose villages on and near the coast extended from Coquille river southward to the California line, including, among others, the Upper Coquille, Sixes, Euchre creek, Joshua, Tutu tûnnë, and other "Rogue river Indians" or "Tou-tou-ten bands," Chasta Costa, Galice creek, Naltûnne tûnnë, and Cheteo villages; the Athapascan villages formerly on Smith river and tributaries, California; those villages extending southward from Smith river along the California coast to the mouth of Klamath river; the Hupa villages or clans formerly on Lower Trinity river, California; the Kenesti or Wailakki who live along the western slope of the Shasta Mountains, from North Eel river (above Round valley) to Hay Fork; along Eel and Mad rivers, extending down the latter about to Low Gap; also on Dobbins and Larrabee creeks; and Saiaz, who formerly occupied the tongue of land jutting down between Eel river and Van Dusen's Fork.

(3) The *Southern Group*.—This group, which is the best known, includes the Navajo, Apache, and Lipan.

Navajo.—Ten Kate says that the term Navajo has been erroneously attributed to the Spanish *navaja*, a pocket-knife, instead of to *navajo*, a tank or pond formed by heavy rains. Bancroft states that "Navajo is said to mean *grand semaille* or great sowing."

Habitat and Population.—The Navajo, since first known, have occupied the country on and S. of the San Juan river in Northern New Mexico and Arizona, and extending into Colorado and Utah. They were surrounded on all sides by the cognate Apache, except on the N., where they meet Shoshonean tribes. In 1630 they were mentioned as "Apaches de Navajo" by Benavides in his letter to Philip IV. The first known reference to them by the single name Navajo is found in Blaeu, *Atlas*, xii. p. 62, 1667. The Spanish missionaries among them were killed in 1680. Schermerhorn (in *Massachusetts Historical Collection*, 2d ser., p. 29, 1812) mentions them as the "Namakan, an erratic people, N. W. of Santa Fé, and estimated at 2,000 warriors and 6,500 souls." The Navajo made their first treaty with the U. S. Nov. 22, 1846. At that time they were in the main range of the Cordilleras on Colorado river, 200 miles W. of Santa Fé. Bent gave their population in 1846 as 1,000 families and 7,000 souls. Backus, in Schoolcraft, gave their habitat in 1853 as W. of Santa Fé, extending from near the Rio Grande on the E. to the Colorado on the W., and from the land of the Utes on the N. to that of the Apaches on the S. Eaton, in Schoolcraft, said that the Navajo moved down into the country near the Sierra of Cibolletta (San Mateo Mountain), but were so severely treated by the Comanche and others that they abandoned that country and removed to their present abode. The population of the Navajo in 1891 was 16,102.

Sociology.—Matthews says that among the Navajo descent is in the female line, and that, although the names of the Navajo clans are not now totemic, the legend to which he refers in an article on the Navajo social organization seems to indicate that some of them once were of that character. On the other hand, among the Athapascan tribes

found by Dorsey in 1884 on the Siletz reservation, Oregon, descent is reckoned in the male line. A list of the Navajo clans is given by Matthews. In the tradition recorded by him it is said that the present Jiearilla Apache are supposed to be descended from part of the Navajo. The same tradition tells of bands of Apache, Ute, and Zuñi who joined the Navajo, and among the present clans are several which are supposed to have sprung from the captive Mexicans and refugees from alien tribes.

Apaches.—According to Corbusier, *Apache* is a term of the Yuma linguistic family, applied to southwestern tribes which differ in origin, race, and language. Its real meaning is "hostile man." To prevent confusion the term is confined to tribes of the warlike Athapascan stock. The first recorded use of the term is that of Oñate in 1598.

Habitat.—Joutel, in 1687, referred to the Apache as Chancres or Chanzes, placing them in Texas W. or N. W. of Louisiana and the Maligne river. Margry gives a list (A. D. 1700) which speaks of the Canessy territory, 35 or 40 leagues from the Naouadiches tribe. It is spoken of as lying about 145 or 150 leagues W. of the mouth of the Mississippi river, a longitude corresponding to that of the Choumans or Quivira. Jefferys, in 1763, placed the Canney in Louisiana between 95° and 100° W. of London, and between 35° and 37° N. latitude. Gatschet now identifies these people, the Cancees, Cancy, etc., with the Lipan and other Athapascan Apache, who are called *kantsi*, or "deceivers," by the Caddo. José Cortez, writing in 1799, defines the boundaries of the Lipan and Apache as extending N. and S. from 29° N. to 36° N., and E. and W. from 99° W. to 114° W.; in other words, from Central Texas nearly to the Colorado river in Arizona, where they met tribes of the Tuman stock. He located the Lipan in the eastern part of the above territory, extending in Texas from the Comanche country (above Red river) S. to the Rio Grande (Cortez in *Pac. R. R. Rept.*, iii. pt. 3, pp. 118, 119, 1856). In more recent times the Apache, as well as the Lipan, have gradually moved southward into Mexico, where they extend as far as the province of Durango.

Lipan.—According to Bandelier, the original name of this people is said to have been "Ipa-nde," of which "Lipan" is a corruption.

Habitat and Population.—According to Margry, the Lipan were first mentioned in 1699 as allies of the Comanche, and as probably living in Texas. The Apaches and Lipan were in the cañons of San Saba and on the Rio Colorado of Texas in 1792, at which time the Tonkawe and Towakarehu (the latter a Caddoan tribe, often called Towocconie or Tawakoni) intended making war on the Lipan. Cortez, in 1799, stated that the Lipan habitat was bounded on the W. by that of the Llanero Apache, on the N. by the Comanche territory, on the E. by the Mexican province of Coahuila, on the S. by the left bank of the Rio Grande, and on the right by the military posts of Coahuila—which would make the Lipan habitat about coterminous with that part of Texas between the Pecos river and the province of Chihuahua. In 1805 the tribe was divided into three bands of 300, 350, and 100 men, respectively. In 1816 the Lipan numbered 800, and ranged from the Rio Grande to the interior of Texas. Whipple spoke of the Lipan as a tribe which ranged over the country from Tucumeari creek, along the Canadian river, and occasionally to the Rio Pecos. In 1884 the Lipan were chiefly in Old Mexico, near the Rio Grande, some being in the Santa Rosa Mountains. In 1886 there were 90 Tonkawe and Lipan on the Ponca, Pawnee, and Otoe reservation, in the Indian Territory, but the number of the Lipan alone was not stated. A Mexican document of 1828 distinguishes between the Lipanes del Sur (Southern Lipan) and the Lipanes Llaneros (Prairie Lipan) or Lipanes del Norte (Northern Lipan). Orozco y Berra divides the Lipan into three parts: Lipajenne or Lipanes (in Coahuila), Lipanes de Arriba, and Lipanes de Abajo. He places them in the provinces of Nuevo Leon, Coahuila, and Tamaulipas, in Old Mexico.

Language and Customs.—The relationship of the various tribes of Athapascan Indians to one another is clearly shown by a comparison of their languages, social organization, and mythology. In many cases there are words in the languages of the Northern group which differ only in one or two sounds from their equivalents in the languages of the Pacific group. This is applicable in some degree to the Southern group as compared with the Pacific. These languages are highly consonantal, and they exceed the Siouan languages in the use of classifiers, duals, pronouns, and conjugations. The

tribes of the Northern group subsist chiefly by hunting and fishing, and on this account they are compelled to wander over a larger territory than that which is traversed by their kindred of the Pacific group, who are the most sedentary of the Athapascan Indians. With the exceptions of the Hupa and some of the "Rogue river tribes," those of the Pacific group have not been very warlike. In this respect the tribes of the Southern group stand pre-eminent.

PRINCIPAL TRIBES.

A. Northern group:

Ah-tena.	Nagailer (Chin).
Kaiyuh-khotana.	Sarsi.
Kealtana.	Slave.
K'naia-khotana (Kenai).	Sluacus-tinneh.
Koyukukhotana.	Takulli (Carriers).
Kutchin (Loucheux).	Tahl-tan (1).
Montagnais.	Unakhotana.
Montagnards.	

B. Pacific group:

Átaäkút.	Naltúnne túnñé.
Chasta Costa.	Owilapsh.
Chetco.	Qwinctúnnetún (Pistol river).
Dakube tēde (on Applegate creek).	Saiaz.
Euchre creek.	Taltúctún tūde (on Galice creek, Oregon).
Hupá.	Tcémé (Joshuas).
Kalts'erea túnñé.	Tcētlēstcan túnñé.
Kenesti (Wailakki).	Terwar.
Kwalhioqua.	Tlatskanai (Claxtar).
Kwatami.	Tolowa.
Micikqwútme túnñé (or Upper Coquille).	Tutu túnñé (Tou-tou-ten, Lototen).
Mikono túnñé.	

C. Southern group:

Arivaipa.	Mescalero.
Chiricahua.	Minbreño.
Coyotero.	Mogollon.
Faraone.	Na-isha.
Gileño.	Navajo.
Jicarilla.	Pinal Coyotero (Tonto).
Lipan.	Tchikún (Pinaleno).
Llanero.	Tchishi (Hot Springs Apache).

Population.—The present number of Athapascan Indians is about 33,000, of whom about 8,595, constituting the Northern group, are in Alaska and British America, according to Dall, Dawson, and the *Canadian Indian Report* for 1888. About 895, comprising the Pacific group, are in Washington, Oregon, and California. About 23,409, belonging to the Southern group, are in Arizona, New Mexico, Colorado, Indian Territory, and Oklahoma. Besides these are the Lipan and some refugee Apache, who are in Mexico. These have not been included in the above enumeration, as there are no means of ascertaining their number.

A'theism [Fr. *athéisme*, from Gr. *ἄθεος*, without god; *ἀ-*, not + *θεός*, god]: the denial of the existence of God, or the doctrine that there is no God. Atheism may be either speculative or practical; the former consists in denying the existence of God; the latter in living as if there were no God. Speculative atheism is, strictly speaking, impossible, for the denial of the Divine existence necessarily affirms it. For if one deny God's being, his denial is worthless unless it rests upon some reason; but this reason must be absolute, or it can be no sufficient warrant for his denial, and this will only be to adduce absolute reason to declare that the Absolute Reason can not be, which is the very absurdity of all absurdities. To suppose the existence of some nature of things whose chain of invincible necessity stretches above and around the Deity is to suppose what, if it have any meaning, must itself be invested with the being and the attributes of the Godhead. Strictly speaking, the belief in a God would seem to imply a belief in his personality—that is, in his existence as a *conscious* being. But, according to its modern acceptance, atheism is understood to deny not merely the existence of a personal Deity, but also the presence in the universe (apart from *individual* intelligences) of any Principle of intelligence, beauty, or goodness. (See PANTHEISM.) Perhaps the most remarkable phase of systematic atheism is that which is set forth in the writings of Epicurus and his followers; for although that philosopher nominally acknowledged the existence of gods, he doubtless did so (as Cicero suggests) merely to avoid the popular odium which by a denial of their existence he was certain to incur. In his system of philosophy there is no all-pervading Intelligence, as in that of Anaxagoras—no principle of order, no law except the law of chance. All possible forms of existence have been tried in the fortuitous concourse of the primitive atoms, and those beings only which had at last attained, by repeated accidental trials, a certain regularity and completeness of parts possessed any permanent existence. Among many of the ancient nations in very early times to deny the gods was much the same as to deny all religious and moral obligations; hence the name "atheist" became a term of the greatest reproach; at length those who had political ends to serve came to use it, not very unfrequently, as a convenient method of exciting popular odium against an opponent; and it has been repeatedly applied to worthy and virtuous men, both in ancient and modern times. See the articles GOD and AGNOSTICISM.

Atheling [O. E. *ætheling*, belonging to a noble family; *æthel*, noble family; cf. Germ. *Adel*]: a title of honor among the Anglo-Saxons, applied first to the descendants of the first nobles, then to princes of the royal house, and finally (ninth and tenth centuries) only to sons and brothers of the reigning king.

Ath'elstan, or **Æthelstan**: an able Anglo-Saxon King of England; b. about 895 A. D.; the natural son of Edward the Elder, and a grandson of Alfred the Great. He began to reign in 925, and was the first actual sovereign of all England. On the death of Sihtric, King of Northumbria, Athelstan annexed that country. A league was formed against him by the Welsh, Scots, and Picts, whom he defeated in a great battle at Brunanburh, 937 A. D. He reigned over nearly all the island, except Scotland and Wales. He promoted learning and civilization, and was reputed one of the wisest of the Anglo-Saxon kings. He died without issue Oct. 27, 940, and was succeeded by his brother Edmund. See Freeman, *Norman Conquest*, vol. i.; Hume, *History of England*.

Athe'na (in Gr. *Ἀθηνῆ* or *Ἀθηνᾶ*), sometimes called *Pallas Athena*: the goddess of wisdom, and one of the principal divinities of the Greek mythology. According to an ancient legend she was the daughter of Jupiter, from whose head she issued in full armor. She was the favorite national di-

vinity of the Athenians, whose capital was named in her honor. She presided over the sciences, inventions, arts of peace, laws, etc., and was supposed to have invented every kind of art or work proper to women. *Athena* corresponds to the Roman MINERVA (*q. v.*).

Athenæ'um: in classical archaeology, a school founded by the Roman Emperor Hadrian at Rome for the cultivation of Greek learning. In modern time a term used somewhat loosely for literary institutions, such as support libraries, conduct courses of lectures, and the like.

Athenæ'us (in Gr. *Ἀθήναιος*): Greek man of letters and antiquary; b. at Naucratis, in Egypt; otherwise unknown except by his great work, which must have been composed after the death of Commodus (192 A. D.), who is ridiculed in it. The title of this work, *Δειπνοσοφισταί*, means *Banquet of the Learned* or *Professorial Dinner*, but the table-talk is a mere excuse; the literary faculty of Athenæus is naught, and his account of the imaginary banquet given by a noble Roman to a number of eminent men is nothing but an unwieldy vehicle for a rich fund of anecdotes, criticisms, and extracts from the works of about 700 poets and historians, most of whom would be practically unknown to us but for the learned compiler. Athenæus is simply invaluable as a repertory of literary, social, and domestic gossip, and our vision of whole ranges of antique life is due to him. Commentary by Casaubon (1597) and Schweighäuser (1801-07). Most recent critical ed. by Kaibel (3 vols., 1887-90). English translation in Bohn's Classical Library.

Revised by B. L. GILDERSLEEVE.

Athena'goras (in Gr. *Ἀθηναγόρας*) of **Athens**: a Greek philosopher and Christian writer; flourished about 170 A. D. We have by him an elaborate treatise *On the Resurrection of the Dead*; also an *Apology* (or rather *Legation*) addressed to Marcus Aurelius and Commodus about 177 A. D. Athenagoras has some pretensions to style. Edited by Otto (Jena, 1857). Am. ed. by W. B. Owen, New York, 1876 (in the Douglas series of Christian Greek and Latin writers). Translated by B. P. Pratten in the Ante-Nicene Christian Library (1867); ed. Coxe, New York, Christian Literature Co., vol. ii.

Ath'ens (*Ancient*): a celebrated Hellenic city (called in Gr. *Ἀθῆναι*, in Lat. *Athēnæ*) and republic, distinguished for unrivaled achievements in art and literature, and immortal in the records of Greek statesmanship and military glory. No state, ancient or modern, has produced in proportion to its size so many statesmen, orators, authors, and artists of the first order, or has had so lasting an influence on the civilization and culture of posterity.

Topography.—Athens is situated about 4 miles N. E. of the Saronic Gulf, in the portion of the Attic peninsula known as the plain (*πεδιάς*); lat. 37° 58' N., lon. 23° 44' E. The plain forms a grand natural theater, inclosed by mountains on every side except the south, where it opens seaward. It is bounded N. by Mt. Parnes, N. E. by Mt. Pentelics, S. E. by Mt. Hymettus, and W. by Mt. Ægaleos. About a mile north-east of the city rises Mt. Lycabettus, an isolated peak (height, 900 feet), which is a striking and prominent feature in the landscape. Within the city walls were four lower hills, composed of the same hard gray limestone; namely, the Acropolis, with the Areopagus (Mars Hill) west of it, and the Museum southwest. The Acropolis, or citadel, an isolated rocky eminence about 1,000 feet long and 450 wide (measured on its flat top), is near the center of the space inclosed by the walls of Themistocles. It rises abruptly 300 feet from the plain. The outline of its walls follows the brow of the cliff, and roughly resembles the outline of a human eye. It is inaccessible on all sides except the west, where the ascent, however, is very steep. From the citadel nearly the whole of the Saronic Gulf is visible, with Salamis, Ægina, and other islands; also the coast of the Peloponnesus, and the once hostile fortress of ACRO-CORINTHUS (*q. v.*).

Athens stands on a bed of limestone, but thinly covered, even in the depressions of the plain, with a light and rather sterile soil. The olive and the vine, however, flourish wherever they have sufficient irrigation; the orange and fig, which thrive in Laconia, do not ripen in Attica; and the palm, as at Rome, figures only as a garden exotic. The climate of Athens is delightful, and its air is proverbial for its singular purity and transparency. This feature is beautifully touched upon in one of the choral odes of Euripides's *Medea*. Byron's lines on an Athenian sunset, in the third canto of *The Corsair*, are equally impassioned. On account of "the violet hue which Hymettus assumes in the evening sky, in contrast to the glowing furnace of Lycabettus and

the rosy pyramid of Pentelicus" (Stanley). Athens was saluted by poets as violet-crowned (*ἰοστέφανοι*). The plain of Athens is watered by the Cephissus, the course of which is fairly hidden in a continuous olive-grove, and by its tributary rivulet Ilissus, which is quite waterless in summer. The Piræus was a rocky peninsula near the mouth of the Cephissus, with three well-protected harbors, to which Themistocles transferred the naval station of Athens from the sandy roadstead of Phalærum. The harbors were protected by a fortified city and a citadel built on the eminence called Munychia. The walls of Athens in its most prosperous period inclosed not only the city proper, but also a long and narrow suburb which extended from the city (*τὸ ἄστυ*) to the Piræus. A third long wall extended to the beach at Phalærum, some miles east of Munychia.

conical sister height of Mt. Lycabettus. Homer in the *Iliad* mentions Athens, with the house of Erechtheus and a temple of Athena. This allusion, once credited to Attic interpolators, was brilliantly confirmed by the discovery on the citadel, in the excavations of 1886 and 1888, of the foundations of a royal palace of the Mycenaean type (see MYCENÆ), and also of a very early temple built of Acropolis stone. Theseus, the national hero of Attica, is said to have united the twelve independent townships (*dēmi*) of the peninsula into one political body, with Athens for its capital. The historic kings of Athens were descendants of Peloponnesian princes, who traced their ancestry back to the Achaean Nestor. The last was Codrus, who, in the Dorian invasion of 1068 B. C., sacrificed himself for Athens, in compliance with an oracle which foretold success to the side whose king should be slain. The aristocracy made the heroism of Codrus a pretext for abolishing the royal prerogative. The Neleidae thereupon emigrated to Miletus, where they maintained a royal or princely rank for many years. The youngest son of Codrus, Medon, had been elected *archon*. The government became an oligarchy, or aristocratic republic. Until the close of the eighth century (714 B. C.) only Neleidae were eligible to the office of archon; but the archon's term had been reduced (752 B. C.) from life (*ἄρχων ἰσόβιος*) to ten years. In 683 the civil, religious, military, and judicial authority of the archon was divided among nine archons. (See ARCHON.) The second of the nine exercised the priestly functions of royalty, with which he retained the kingly costume and name (*ἄρχων βασιλεύς*). His wife acted the part of queen (*βασιλισσα*). It was the archon-king, also, who presided over

FIG. 1.—Plan of ancient Athens.

History.—The inhabitants of Attica asserted themselves to be aborigines, "sons of the soil." The historian Thucydides, who adopts this view, considers that before the development of maritime commerce the soil of Attica was too poor to tempt immigration or conquest. But the Athenians acknowledged the ties that bound them to the Ionians of the Peloponnesian peninsula and of Asia Minor. The relation of the Attic dialect to the Ionic branch of the Greek language is well known. Legendary traditions imply an ancestral worship of the tribal gods Apollo and Poseidon (Neptune). And the localization in Attica of the giant-stories which symbolize struggles between natives and immigrants (as in Canaan and Cornwall) indicates the subjugation of an earlier stock by Hellenic conquerors. The discrepancies of tradition are reconciled by assuming a gradual acquiescence of the Pelasgian or Protohellenic inhabitants of Attica in the rule of an Ionian aristocracy, which probably entered the peninsula from the north by way of Eubœa and Marathon. According to legend, Athens was founded by Cecrops, and was first called Cecropia or Cranaë. The name was changed later to *Athênæ* owing to the prominence acquired by the worship of Athena (Minerva), or, mythically speaking, in virtue of that goddess's triumph over Poseidon in a contest for the position of chief divine patron of Attica. It is more probable that the storm-goddess Pallas was surnamed the *Athenian* (*Ἀθηναία* or *Ἀθηνᾶ*, contr. *Ἀθηνᾶ*) from the seat of her most fervid worship. In this case the name of the city might well be derived from *ἄθ*, signifying point or peak. Before its artificial flattening the citadel rock rose some 100 feet higher than at present, so as to resemble the

the venerable court of the Areopagus, which dealt with all offenses regarded as sacrilegious, including bloodshed. The constitution of Athens at this period was based on the Ionic division of the people into four tribes (*φυλαί*). The names of the tribes were derived from the four sons of Ion (*Γελέωντες*, *Ὀπλητες*, *Αἰγικορέις*, *Ἀργάδεις*), but their signification implies an original division by the occupations of landholders, warriors, herders, and laborers. The proverbially severe legislation of Draco (archon 621 B. C.) brought no relief from the oppressive rule of the landlord class. Villeinage and serfdom for debt became crying evils. Political and class feeling crystallized into the sectional parties of the Plain (*πεδῖεις*, conservatives), the Hills (*διάκριοι*, radicals), and the Shore (*πάραλοι*, moderates). Solon, a descendant of Codrus, whom his birth and record made acceptable to all parties (archon 594 B. C.), undertook to remove the causes for dissension. Serfdom for debt was abolished, mortgages were largely canceled, the value of the silver drachma, the unit of currency, was reduced 27 per cent. The citizens were reclassified on a property basis, by the amount of their real estate, or their ability to pay taxes proportionate to an annual yield of 500, 300, 150 Attic bush. (*πεντακοσιομέδιμνοι*, *ἰππεῖς*, *ξενγίται*). Citizens of these classes were eligible to the Council (*βουλή*) of 400, and to most offices; but the archons and judges of the Areopagus could be of the first class only. The Areopagus, to which the auditorship of all public offices was assigned, became a powerful instrument on the conservative side. A fourth class of *θῆτες* paid no taxes, and was not eligible to offices, but rendered military service and sat in the popular Assembly

(ἐκκλησία). The ordinary courts were controlled by popular juries selected from a body of 6,000 jurymen. Solon also drew up a code of Attic law. His constitution, but not his legislation, was overthrown by the usurpation of Pisistratus (560 B. C.), a leader of the Hill faction, who managed, although twice ejected, to recover and transmit his dictatorship (τυραννία) to his sons, Hippias and Hipparchus (527 B. C.). The period of the Pisistratidæ was one of great public prosperity and excellent government. They paid great attention to public roads, which were even embellished with statuary; organized the Panathenaic athletic festival after the model of the Olympic games; caused the Homeric lays to be collected, critically edited, and regularly recited; and began the largest temple in Greece proper, that of Zeus Olympius, which remained unfinished for 700 years. The liberation of Athens from this mild despotism was popularly dated from the murder of Hipparchus by Harmodius and Aristogiton in 514 B. C. Hippias was unseated only in 510, when he retired to Sigœum on the Hellespont, a place which he held as a fief from Persia. He is credited with a large share in instigating Persia to make war on Athens. Herodotus tells with characteristic dry humor that a tooth the aged Hippias sneezed out in the course of the Persian landing at Marathon was the only one of his bones that found the coveted resting-place in Attic soil. The Solonian constitution was re-established in principle, but greatly expanded by Cleisthenes, an aristocratic leader of the Attic democracy (509 B. C.). The four classes were retained, but large numbers of

FIG. 2.—Restored view of Acropolis.

aliens and freedmen were enrolled as citizens in ten new tribes, which Cleisthenes substituted for the old-time four. The ten tribes were named after ancient Attic heroes (Κεκροπίς, Αἰγυίης, Αἰαντίς, etc.). Each was equally represented in the Council of 500; and, by a more curious than happy device, each batch of fifty senators from one tribe constituted an executive committee (πρυτάνεις) for one-tenth of the year, when it presided in parliament, dealt with embassies, etc., until relieved. Ten townships (δῆμι), not adjacent, appear to have been assigned to each tribe; later there were 174 in all. A Spartan attempt to overthrow this democratic constitution, with the assistance of Chalcis (Eubœa), resulted immediately only in the annexation of the Chalcidian territory to Attica as an Athenian colony, but was the prelude of the later protracted struggle between Athens and Sparta. In 499 Athens lent her aid to the revolt of the Ionian cities from Persia. The ancient Lydian capital, Sardes, was sacked and fired by the Athenian auxiliaries. After the defeat of the Ionian fleet, and the collapse of the confederacy with the fall of Miletus, the richest of the Ionian cities, Darius determined to subjugate Greece, and to punish the Athenians in an especial manner. The Persians sailed through the Ægean Sea, confirming their supremacy over the Greek islands, destroyed Eretria, and effected a landing at Marathon. Here the Athenian troops under Miltiades defeated the Persians signally (490 B. C.). The repulse of the Orientals on this occasion is commonly accounted one of the most momentous events in the history of the world. No further attempt against Greece was made for ten years. In the meantime, under the inspiration of Themistocles, Athens gave all her attention to the equipment of a strong

fleet. The army of Xerxes entered Greece by way of the Hellespont and the Thracian coast, forcing the pass of Thermopylæ after a memorable seven days' defense by a band of some 6,000 Greeks under King Leonidas of Sparta, who was finally surrounded and slain with all but two of his 300 Laedaemonians. The Athenians promptly evacuated Athens, removing their women and children to neighboring islands. Athens was occupied and destroyed by the Persian army, but a Greek fleet of 280 triremes utterly defeated and routed the Persian navy of 1,000 vessels in the Straits of Salamis (480 B. C.), into which the simulated treason of Themistocles, the Athenian commander, had entrapped Xerxes. An army of 300,000, remaining in Greece under Mardonius, was defeated at Plataeæ, in Bœotia, in the following year. This event was followed by the rapid development of the maritime power of Athens. Themistocles fortified the city and the Piræus, and the navy was so strengthened that Athens soon became the head of an important island confederacy, and ventured on daring expeditions against other Greek states and the maritime dependencies of Persia as far as Cyprus and Egypt. The Athenians also began to rebuild their capital, and to erect those masterpieces of architecture which have excited the admiration of succeeding ages. The able administration of Cimon, son of Miltiades, was excelled in brilliancy by that of Pericles, whose power became nearly absolute in 444 B. C., after his conquest of Eubœa, the negotiation of a thirty years' truce with Sparta, which relinquished the hegemony or leadership of the Greeks by land, the death of Cimon, and the banishment of Thucydides, the head of the aristocratic party. The citizens of the fourth class had been made eligible to public offices a generation before, and Pericles had himself broken the power of the Areopagus. The name of Pericles is almost a synonym for the most brilliant achievements of Athens in politics, literature, and art. During his long and able administration Æschylus, Sophocles, and Euripides trod the Attic stage, while Phidias in sculpture and Ictinus and Mnesicles in architecture were converting Athens and its Acropolis into a perfect museum of Greek art at its prime. In 431 Sparta, at the instigation of Corinth and other Dorian allies, but chiefly moved by her apprehension of further expansion on the part of Athens, resolved on war with the Athenian republic. This struggle was called the Peloponnesian war. It continued with little interruption for twenty-seven years, and resulted disastrously for the Athenians. The year 404 finds Athens with her walls dismantled, her navy surrendered to Sparta, and an irresponsible oligarchy of thirty reactionary politicians in possession of the government, under the protection of the Spartan Admiral Lysander. The darkest incidents of the war were the outbreak of the plague at Athens in the second year of the war, to which Pericles succumbed, and the capture and massacre of the whole fleet and army with which the Athenians had undertaken to conquer Syracuse, in the eighteenth (413 B. C.). Nearly all the principal Athenian commanders came to an ill end, being slain in battle, executed by the enemy or by their fellow-citizens, or exiled (Thucydides, Kleon, Demosthenes, Nicias, Lamachus, Alcibiades, and six of the last's successors). The Athenian democracy was re-established by the exploit of Thrasybulus, who expelled the Thirty Tyrants in 403. Strangely enough, the heyday of Attic comedy (Cratinus, Eupolis, Aristophanes) coincides with the Peloponnesian war. The same may be said of the philosophic teaching of Socrates, whose execution for irreverence to the gods and corruption of the young occurred in 399 B. C. The following period of military and political decline continues to be marked by the intellectual, literary, and artistic supremacy of Athens. It is illustrated by the genius of Plato, the orator Demosthenes, and the sculptor Praxiteles. The grandest eloquence of Demosthenes was called forth in his determined opposition to Philip of Macedon (the Philipics, delivered 351 to 341 B. C.), and after the victory of Philip over the alliance of Thebes and Athens at Chæronea, in his fulminant defense of his policy, in the oration *On the Crown*, delivered 330 B. C. Athens did not entirely succumb to Macedonia until the year after Alexander the Great's death in Babylon (322 B. C.), when Antipater garrisoned Munychia, abrogated the constitution, banished more than half the citizens, levied a war indemnity, and procured the death sentence of Demosthenes, who escaped execution by taking poison in the island of Calauria. Athens was unable to make itself more than temporarily independent of Macedonia (287 to 262 B. C.) after this. The beginning of her subjection is signalized by the comedies of Menander, in

literature, and she continued to be the chief home of culture and the fine arts in Greece proper. On the subjugation of Macedonia by Rome, Athens allowed herself to be incorporated in the Roman "sphere of influence" without serious resistance, which would have been futile after the fall of the Achaean league and of Corinth in 146 B. C., when Greece became a Roman province under the name of Achaia.

Athens enjoyed much municipal prosperity under Rome. Its monuments survived Sulla's occupation of the city (86 B. C.) in tolerable perfection. The Athenian schools of eloquence and philosophy attracted great numbers of students from Rome and all parts of the civilized world. Here Cicero, Vergil, and Horace received part of their education. The Emperor Hadrian favored Athens greatly. The completion of the temple of Zeus, and many other architectural improvements, dated from his reign. There exists a description of the city written shortly after (174 A. D.) by Pausanias of Magnesia in Asia Minor. The last calamities to overtake Athens were its occupation by the Goths under Alaric, A. D. 396, and the closing of its schools of philosophy, as strongholds of paganism, by the Christian Emperor Justinian, A. D. 529. This edict definitely extinguished the importance and renown of ancient Athens.

The population of Athens at the time of its greatest prosperity, just before the Peloponnesian war, was estimated by Leake at 192,000, including the Piræus. It is doubtful whether, even with slaves and aliens, the total population of Attica ever reached 500,000.

Monuments and Antiquities.—The walls of Athens were 60 stadia (6 miles) in circumference; their line can still be made out. The oldest extant vestiges of the city are on the rocky eminences within the walls, and serve to distinguish between the four chief divisions of the city, viz.: the town proper, on the Muses hill, the citadel, occupied by the royal residence and later reserved for sacred buildings, the court and assembly grounds on Areopagus and Pnyx, and the market-place in the depression between the hills. A northwest quarter was called the Ceramieus, on the way toward Eleusis, near the burial-ground; a southwest quarter bore the name of Melite; Diomeia extended northeast in the direction of Lycabettus; Limnæ was near the bed of the Ilissus, southeast. Much controversy has raged about the identification of two terraced esplanades, of which the lower has the form of a great semicircle with a stepped cube of rock at the central point, with the place of assembly of the Athenian people, or Pnyx. Ernst Curtius, the historian, contends that it was a Pelasgian sanctuary and altar dedicated to Zeus; but the former view is now again prevalent among scholars. On a narrow lane of the old town to the south of the Pnyx is a row of seven seats cut in the rock, supposed to mark the site of an early judicial court. Of the court on the Areopagus, on the other hand, nothing is left but a platform on the top of the rock or boulder which bears this name, and a flight of sixteen steps ascending to it. Some vestiges of the hexastyle Doric temple of Zeus, begun by Pisistratus, were brought to light by Penrose in his recent excavation of the foundations of the Corinthian Olympiæum finished by Hadrian. The Panathenaic stadium, or race-course, lies across the Ilissus back of this temple, again denuded of the marble seats with which it was furnished by the orator Herodes Atticus, a contemporary of Hadrian. For any other remains as old as the sixth century B. C. it is necessary to discriminate among the tombstones of the Ceramieus, or to examine the lower strata of the accumulations within the walls of the Acropolis. This work has lately been done with great thoroughness by the Greek Archaeological Society. It has been shown (1) that the earliest structures on the citadel date from the royal period; (2) that several ring-walls of early date preceded the outer one which is still extant and visible; (3) that ambitious attempts to embellish the old temple and sanctuary of Athena with colonnades and sculptures had already been made in the time of Pisistratus; (4) that the Athenians of the fifth century renovated the citadel, after the Persian invasion, with great disregard for the monuments of art partly destroyed by the enemy. Thus some twenty marble statues, some of them by artists of the highest repute at the beginning of the fifth century, were found built up in a terrace to the west of the Erechtheum, and are now among the choicest treasures of the Acropolis Museum. The majority appear to be dedicatory offerings to Athena of her own image, clad not in the usual martial array, but in the raiment of peace, befitting the patroness of artisans and artists (*Ἀθηνᾶ Ἐργάνη*). They are remarkable not only for the altogether new light

they have cast on the condition of sculpture in Athens about 540 to 480 B. C., but also for an unusually fine preservation of the ornamental coloring with which the Greeks habitually enlivened their works of sculpture. The Acropolis acquired an entirely new physiognomy under Cimon and Pericles. A small Ionic temple of Athena Victory, of Pentelie marble, to the right of the western ascent to the citadel, has been wrongly ascribed to the time of Cimon. Its small frieze bears a representation of combats between Greeks and Persians. The masterpiece of Periclean architecture was the grand gateway which Mnesicles designed

FIG. 3.—Ruins of the Parthenon.

to stretch entirely across the citadel rock just behind this, the Propylæa, left unfinished in 432 B. C. It consisted of a wall pierced by five unequal doorways, with two Doric hexastyle fronts, and an interior vestibule of the Ionic order. The central portion was flanked by smaller porticos of the Doric order, of which the northern served as a picture gallery. Passing through the Propylæa, still tolerably preserved, we ascend to the Parthenon, or temple of Athena Parthenos, regarded as the most perfect specimen of architecture ever executed. It was designed by Callicrates and Ictinus, was built in the Doric order of white Pentelie marble, and was dedicated in 438 B. C. It consisted of a walled cella, surrounded by a peristyle of 46 columns, which are over 6 feet in diameter and 34 feet high. The dimensions of the temple were 228 feet long, 101 feet wide, and 66 feet high to the top of the pediment. The Parthenon was adorned with exquisite sculpture, of which some parts are preserved. (See PARTHENON.) Within stood the statue of the virgin goddess Athena, by Phidias, of ivory and gold, fully armed and holding a figure of Victory, 6 feet high, on her extended right hand. The Erechtheum was a beautiful Ionic temple to Athena, standing north of the Parthenon, with two elegant porticos, still in fair preservation. It was completed in 393 B. C. The exact date of the Theseum, a handsome Doric temple in the lower town, is not known. The exterior is in excellent preservation, including a portion of the decorative sculptures. Other structures cluster about the Acropolis. The oldest is the theater of Dionysus, at the east end of the southern slope, forming a great semicircle of seats rising to the foot of the citadel cliff, around what was originally a circular space for the dramatic and choral performances, much built over in Macedonian and Imperial times with the high stages that had then come into fashion. Here the plays which reflect such literary glory on Athens, the tragedies and the comedies already touched upon, were given. Above the theater are two columns and vestiges of another monument commemorating dramatic victories. To the W. is a terrace once occupied by the sanctuary of Æsculapius. Further on a second theater, the Odeum, erected by Herodes Atticus in the age of the Antonines. Across the valley, on the Muses hill, rises the monument of Antiochus Philopappus, a titular prince of Comnagene, who had resided in Athens under the Roman régime. Burial within the city gates was illegal. The cemetery of the Ceramieus, in which many funeral monuments and relics of the Hellenic period have been brought to light, was out of bounds. Public buildings of a more municipal character are distributed north of the Acropolis. The most ex-

quisite is one long known as the "Lantern of Demosthenes," really the commemoration of a dramatic victory by one Lysicrates, in the form of a circular Corinthian temple, surmounted by a bronze tripod. It bears the date of 334 B. C. Other structures belong to the Macedonian and Roman periods. Such are the clock or dial-tower of Andronicus (Tower of the Winds), an octagonal pavilion adorned with the figures in bas-relief of eight wind-gods (164 B. C.), and the great Stoa, or court-house, of Attalus of Pergamum, in which St. Paul addressed the Athenian Areopagus; and for the Roman period a market-gate built under Augustus, a great portico similar to the imperial fora in Rome itself, erected by Hadrian, and the same emperor's arch, which marks the boundary between old Greek Athens and its eastern suburb of Roman or quasi-Roman country-houses. Of the temple of Zeus Olympius, which a Roman architect completed in the Corinthian order, a cluster of sixteen huge marble columns remains in one corner of the vast temple area, resembling the bunch of men left standing on a chess-board when the game is done (Wordsworth). The remains of a wall encircling only the central portion of the city, and abutting against the east and west extremities of the citadel, with the hasty repair of the citadel walls and gates by Diocletian, are witnesses of the last decline of the city which had once come near establishing its empire over the whole Mediterranean.

Athens (*Medieval and Modern*): the first European city of importance in which the new doctrines of Christianity were preached by St. Paul, and espoused by Dionysius, a member of the Areopagus, afterward canonized as St. Dionysius Areopagita. The Parthenon and other temples were early (sixth century) converted into Christian churches, and the see became an archbishopric in 857. Great deference was paid to the name of Athens under the Eastern emperors, even to formally acknowledging the city's autonomy. In 1019 Basil II. celebrated a feast of victory in the Parthenon. But in 1040 the Normans, under Harold Haardrada, captured the Piræus. Northmen cruising homeward from Byzantine service had before this covered an antique lion at this port with runic inscriptions. This lion, which afterward gave the name of Porto Leone to the Piræus, is now in front of the naval arsenal at Venice. The Latin conquest of Constantinople in 1204 resulted in the investiture of a French family, the De la Roche, with the newly created duchy of Athens. In 1312 the duchy became a dependency of Naples. In 1394 Rainerio Acciaiuoli of Corinth, a Florentine adventurer, ejected the Catalan garrison and made himself independent duke. In 1456 the Turks, after a hard siege, wrested Athens from his second successor. The siege and capture of Athens by the Venetian general Morosini was disastrous to its monuments, above all to the Parthenon, which, being at the time the Turkish powder-magazine, was wrecked by a shell skillfully dropped on it by a Hessian gunner. Morosini himself shattered some of its best sculptures in an attempt to remove them for transportation to Venice. The Turks soon recovered the stronghold and city, and flaunted the crescent banner from the minaret they had planted on the Parthenon, while the town sank deeper and deeper in utter insignificance and degradation. Rare visits by foreign explorers, like Stuart and Revett and Lord Byron, are the best part of its history, until within three months of the outbreak of the Greek revolution in the Peloponnesus the Greeks made themselves masters of the Acropolis (June 21, 1822), mainly by famine. The year 1826 saw a sharper struggle of the Greek garrison against the assaults of Kioutagi Pasha. The forced entrance of 650 Philhellenes, under Fabvier, with fresh ammunition, was a dramatic episode of this siege, but could not prevent the surrender of the Acropolis on June 5, 1827. This signaled the virtual collapse of the Greek war of independence, had it not been for the foreign intervention which followed. Athens was not evacuated by the Turks until the entry of the Bavarian troops with King Otho (1833). In 1835 it became the capital of the new kingdom of Hellas. The city was laid out anew, not very regularly, with broad boulevards, and a fair number of handsome public buildings, more or less classical in design. The royal palace and park, between Lycabettus and Hadrian's arch (1843), and the university

(1837) and cathedral (1855), are the most conspicuous landmarks of Othonian Athens. A collegiate institute for girls (Arsakeion), a school of arts, the National Museum, the Academy of Sciences, Parliament building, theater, and exposition building have been added since. The French, German, American, and British archaeological schools, and the embassies, are centers of the considerable foreign colony in Athens. The boulevards are well lined with attractive private residences and club-houses or hotels, and the town itself has quite lost its old-time Oriental character, except perhaps in the quarter toward the north foot of the Acropolis. The sites of ancient monuments are protected from encroachment and guarded. The city has macadamized streets, street-car service, and three railway stations. It lacks serious industries or commerce, in which particular it may be compared to Washington, D. C. The Piræus boasts a stock exchange and a governmental naval school. It is feebly fortified. Population of Athens in 1889, 107,251; Piræus, 34,327. See Bäder's *Greece*, pp. 33–90; Κωνσταντινίδης, *Ἱστορία τῶν Ἀθηνῶν* (1876); Gregorovius, *Geschichte der Stadt Athen*; Curtius, *Stadtgeschichte* (1891).

ALFRED EMERSON.

Athens: on railroad; capital of Limestone co., Ala. (for location of county, see map of Alabama, ref. 1–C); 27 miles W. N. W. from Huntsville. On Sept. 23, 1864, the Confederate general Forrest, with a large body of cavalry, invested the town, held by Col. Campbell of the 110th U. S. Colored Troops and 600 men, and demanded its surrender, which was finally made just as re-enforcements were on their way. The place was again occupied by U. S. forces, and again attacked by the Confederate general Buford Oct. 2–3, 1864, but this time the place was firmly held by Col. Slade, of the Seventy-third Indiana, and Buford repulsed. Pop. (1870) 887; (1880) 1,011; (1890) 940; (1900) 1,010.

Athens: city; railroad junction and capital of Clarke co., Ga. (for location of county, see map of Georgia, ref. 2–H); on Oconee river. It is the seat of the University of Georgia, the State College of Agriculture, the Luey Cobb Institute, several other schools of a high grade, and a number of common schools. It has cotton-mills and other manufactures, electric lights, sewers, a paid fire-department, water-works, and good streets. Pop. (1880) 6,099; (1890) 8,639; (1900) 10,245.

MANAGING EDITOR OF "BANNER."

Athens: village (founded in 1780); on W. S. R. R.; in Greene co., N. Y. (for location of county, see map of New York, ref. 6–J); situated on the west shore of Hudson river, opposite the city of Hudson. It has 7 churches, 2 grammar schools, 2 shipyards, limestone quarries, and manufactories of bricks, ice-tools, and glue. Pop. (1880) 2,106; (1890) 2,024; (1900) 2,171.

EDITOR OF "NEWS."

Athens: capital of Athens co., O. (for location of county, see map of Ohio, ref. 7–G); on four railroads (the Col., Hock. V. and Tol., the Tol. and Ohio Central, the Kanawha and Mich., and the Baltimore and Ohio Southwestern), and on the Hockhocking river, 41 miles W. S. W. of Marietta. Here are the Ohio University, founded in 1804, and the Southeastern Ohio asylum for the insane. Pop. (1880) 2,457; (1890) 2,620; (1900) 3,066.

EDITOR OF "HERALD."

Athens: on railroad, Bradford co., Pa. (for location of county, see map of Pennsylvania, ref. 2–G); embraces the junction of the North Branch of the Susquehanna with the Chemung (once called Tioga) river. Athens was early known as "Tioga," or "Tioga Point," and was the most important trading-post in the region. The borough is 15 miles N. of Towanda, the county-seat, and 4 miles S. from Waverly. Athens has the oldest academy in the section. Pop. (1870) 965; (1880) 1,592; (1890) 3,274; (1900) 3,749.

Athens: on railroad; capital of McMinn co., Tenn. (for location of county, see map of Tennessee, ref. 7–I); 55 miles S. W. of Knoxville. It is the seat of Grant Memorial University (formerly the East Tennessee Wesleyan University), Pop. (1870) 974; (1880) 1,100; (1890) 2,224; (1900) 1,849.

Athens: town on railroad; capital of Henderson co., Tex. (for location of county, see map of Texas, ref. 3–J); situated in a cotton-raising district, 75 miles from Dallas. The clay industry is the only business carried on, brick, tile, and pottery being manufactured here. Pop. (1870) 545; (1880) 368; (1890) 1,035; (1900) not returned separately.

EDITOR OF "REVIEW."

Atheri'na: a genus of fishes of the family *Atherinidae*, related to the mullets. They have a broad silvery band

along each flank. The genus comprises many species which abound in both America and in Europe. Those of the U. S. coast are called "silversides" and "smelt" and "Pesce Rey." They are good food-fish when not too small.

Atherosperma'ceæ [from *Atherosperma*, one of the genera]: a natural order of incomplete aromatic exogenous shrubs found in New Holland and South America, remarkable for having their flowers in a cup-shaped involucre, and the peculiar anthers of *Lauraceæ*.

Ath'erton, JOSHUA: b. at Harvard, Mass., June 20, 1737; graduated at Harvard University 1762; practiced law, became register of probate of Hillsborough co., N. H., and removed in 1773 to Amherst, N. H.; was for a time a loyalist, but took the oath of allegiance to the U. S., and was admitted to practice in the superior court in 1779; became a member of the convention to adopt the Federal Constitution; was afterward elected to New Hampshire House of Representatives and Senate, and was made attorney-general of the State in 1783. D. at Amherst, N. H., Apr. 3, 1809.

Ath'lete, plur. **Athletes**, or **Athletæ** [from Gr. ἀθλητής, deriv. of ἄθλον, prize in a contest]: among the ancient Greeks, a person who contended for a prize in public games as a wrestler, pugilist, or runner; a man who competed for honor or awards in contests of physical strength or agility.

Athletics: See SPORTS, ROWING, etc.

Athlone (*Athluhan*, i. e. ford of the moon): a market-town of Ireland, on both sides of the river Shannon, about 67 miles W. of Dublin (see map of Ireland, ref. 9-F); is chiefly in the county of Westmeath and partly in Roscommon. It is on the railway from Dublin to Galway, and about 2 miles S. of Lough Rea. Athlone Castle, built in the reign of King John, has been converted into an important military position. Pop. 6,755.

Ath'ol: town (incorporated in 1762); Worcester co., Mass. (for location of county, see map of Massachusetts, ref. 3-F); situated 26 miles from the city of Worcester, at the junction of Hoosac Tunnel R. R. and B. and A. R. R. It has 24 public schools (including a high school), 8 churches, and other public buildings. Silks, woolens, lumber, woodenware, castings, shoes, and many other goods are manufactured. Pop. (1870) 3,517; (1880) 4,307; (1885) 4,758; (1890) 6,319; (1895) 7,364; (1900) 7,061.

EDITOR OF "WORCESTER WEST CHRONICLE."

Ath'ole, DUKES OF, and Marquesses of Tullibardine (1703), and of Athole (1676); Earls of Tullibardine (1606), of Athole (1629), and of Strathtay and Strathardle (1703); Viscounts of Balquhider (1676), of Glenalmond and Glenlyon (1703); Barons Murray (1604); Barons Balquhider (1606); Barons Balvenie and Gask (1676, in Scotland); Barons Strange of Knoeklyn (1628, in England); Barons Percy (1722, in Great Britain); Barons Murray of Stanley (1786, in Great Britain); Earls Strange (1785, in Great Britain); Lords Glenlyon (1821, in the United Kingdom).—JOHN JAMES HUGH HENRY STEWART-MURRAY, the seventh duke, was born Aug. 6, 1840, and succeeded his father in 1864.

Athor, **Aythor**, **Het-her**, or **Hathor**: an Egyptian goddess, the daughter of Ra, supposed to correspond to the Aphrodite of the Greeks. The cow was regarded as her symbol.

A'thos, **Mount** [called *Hagion Oros* by the modern Greeks, and *Monte Santo* by the Italians, both names signifying holy mountain]: a celebrated mountain of Greece, at the extremity of the peninsula of Chalcidice, 80 miles S. E. of Salonica. It rises abruptly to the height of 6,350 feet above the sea, and is cut in various directions by deep ravines, which, covered with old luxuriant forests, present the most striking natural scenery. With the mainland it is connected only by the narrow isthmus through which in olden times Xerxes dug a canal to avoid the dangerous navigation around the promontory. In the Middle Ages Mt. Athos was occupied by numerous monasteries and was a celebrated seat of learning. The origin of some of those monasteries is by legend dated back to the time of Constantine. In the eleventh century they numbered 180, and exercised a decisive influence not only on the ecclesiastical and literary, but also on the political, affairs of the Byzantine empire. In the fourteenth century the deadness began. Nevertheless, here were preserved the remains of famous libraries which furnished to scholars many valuable Greek manuscripts. In 1892 there were twenty monasteries containing 6,000 monks.

See A. A. Neyrat, *L'Athos* (Paris, 1880); Athelstan Riley, *Athos, or the Mountain of the Monks* (London, 1887).

At'kins, JOHN D. C.: b. in Henry co., Tenn., June 4, 1825; was educated at the University of East Tennessee, and graduated there in 1846; was elected to the lower branch of the Legislature in 1849 and 1851, and to the State Senate in 1855; was a presidential elector on the Buchanan ticket in 1856, and a member of Congress from Tennessee from 1857-1861; then resigned and espoused the cause of the Confederates, serving in the field part of the time, as well as in the public councils. He was a member of the Confederate Congress at the time of the general surrender in 1865; was again returned to the Federal Congress 1872-74, and was re-elected to the 45th, 46th, and 47th Congresses. He was U. S. Commissioner of Indian affairs 1885-88.

Atkinson, EDWARD, Ph. D., LL. D.: economist; b. at Brookline, Mass., Feb. 10, 1827; educated in private schools and at Dartmouth College; has become widely known through the numerous articles on economic subjects which he has contributed to current literature, covering the topics of banking, competition, cooking, tariff laws, mechanic arts, and insurance. He organized a fire-insurance company on new principles, and invented an improved cooking-stove, called the "Aladdin Cooker." Among his longer works are *The Distribution of Products* (New York, 1885); *The Industrial Progress of the Nation* (1889); *The Science of Nutrition* (1892). C. H. THURBER.

Atkinson, JOHN: See the Appendix.

Atkinson, THOMAS, D. D., LL. D. (*Cantab.*): third Bishop of North Carolina; b. in Dinwiddie co., Va., Aug. 6, 1807; was graduated at Yale 1825; practiced law for nine years; was ordained deacon 1836 and priest 1837, and served in Norfolk and Lynehburg, Va., and Baltimore, Md.; was consecrated 1853 at Wilmington, N. C. Published sermons, charges, and polemic pamphlets. D. Jan. 4, 1881.

Atlan'ta: capital of Georgia and of Fulton co. (for location, see map of Georgia, ref. 3-G); situated 1,100 feet above the sea, on a high ridge dividing the Gulf and Atlantic slopes. It is the largest city in the State and the chief railroad center of the South. By rail it is 171 miles from Augusta and 95 from Macon.

State Capitol, Atlanta, Ga.

In 1845 the Georgia and the Western and Atlantic R. Rs. were completed to this point. Besides these roads, the Central, Richmond and Danville, Atlanta and West Point, Atlanta and Florida, Georgia Pacific, East Tennessee, Virginia and Georgia, Marietta and North Georgia, and the Georgia, Carolina and Northern, all center here. Atlanta has 132 miles of street-railway lines. The city has no water-transportation, the Chattahoochee river being 7 miles distant.

There are 24 public schools (separate schools for white and colored children), with 230 teachers, and a total attendance of 10,399. There are located here the State Technological School, several colored universities and seminaries of high standing, medical colleges, and a law school. There are 82 churches (70 for white people and 12 for colored people), 2 hospitals, an orphans' home, and a Young Men's Library Association, now merged into the Public Library, the gift of Andrew Carnegie.

Business Interests.—Atlanta has been a port of delivery for many years. The wholesale houses number 217; banks, 20 (with a capital and surplus of \$4,532,500); loan and build-

ing associations, 24; manufactories, 700, with a capital of \$18,000,000, and employing 16,000 hands. There are in operation 3 large cotton-factories, 9 furniture-factories, 25 foundries, machine-shops, and agricultural implement works, 4 cottonseed-oil mills, 7 fertilizer-factories, 1 glass-factory, and 4 ice-factories. There are 23 newspapers—3 dailies, the *Constitution* (morning paper), and the *Journal* and the *Daily News* (afternoon papers). The taxable wealth is \$54,480,228, and within the past ten years \$10,000,000 have been invested in buildings.

The first house was built in 1836. The place was called Terminus until 1843, when its name was changed to Marthasville, and it was incorporated as a town. In 1847 it was incorporated as the city of Atlanta. The population was then about 2,500. Atlanta has sometimes been called the "Gate City." According to the U. S. census the population was (1870) 21,789; (1880) 37,409; (1890) 65,533; (1900) 89,872.

At the beginning of the war period the city was growing rapidly, with a population of 15,000. The Confederates made it a manufacturing center and a *dépôt* of supplies. The siege, beginning with the battle of July 21, 1864, found it a city of 30,000 inhabitants. Sherman's bombardment lasted forty days, and many citizens were killed by the shells. The Federals captured the place Sept. 2, and held it until the middle of November, when they destroyed it and started on their "march to the sea." (See SHERMAN, WILLIAM TECUMSEH.) The city was burned with the exception of about a dozen buildings in the center and 450 dwellings. After the surrender the rebuilding of the city was very rapid. The new Capitol and the Equitable building cost \$1,000,000 each. A very successful Cotton States' Exposition was held here Sept. 18–Dec. 31, 1895. The attendance on some occasions exceeded 100,000.

The health record of Atlanta is very satisfactory. The mortality report for the decade shows a death-rate of 19 in 1,000 in the general population, but of only 12 in 1,000 whites. The climate is mild and equable, the mercury rarely rising to 95° in summer or falling below 12° in winter.

Atlanta has 225 miles of streets, many of them paved with Belgian block. The buildings are of brick, granite, and marble, and are of a very substantial character. Within a radius of 15 miles are numerous popular suburbs. Fort McPherson, the army-post, is about 4 miles distant, and steam and electric lines connect it with the city. For many miles around the enterprise of many market-gardeners and progressive farmers has developed the country, and made it resemble the more thickly settled portions of the Northeastern and Middle States. A new Federal prison has just been completed at a cost of \$1,500,000.

WALLACE P. REED.

Atlanta: city and railroad junction, Logan co., Ill. (for location of county, see map of Illinois, ref. 6–E); 39 miles N. N. E. from Springfield. Atlanta is the trading-point for a highly productive grain and stock growing district. It has one of the largest and best school-buildings in Central Illinois. Pop. (1880) 1,368; (1890) 1,178; (1900) 1,270.

EDITOR OF "ARGUS."

Atlanta: town; Cass co., Tex. (for location of county, see map of Texas, ref. 2–K); on Texas and Pac. R. R., 28 miles from Jefferson, in a lumbering district. It is a shipping-point for cotton. Pop. (1880) 396; (1890) 1,764; (1900) 1,301.

Atlant'ic: city; capital of Cass co., Ia. (for location, see map of Iowa, ref. 6–E); on the East Nishnabotone river; 79 miles W. by S. from Des Moines. Has numerous manufacturing interests, including starch-works, pork-packing, soap-factory, canning-factory, and two machine-shops; a water-works plant valued at \$100,000, and fine electric-light and gas plants. Atlantic has four large ward schools, and a fine high-school building. Pop. (1880) 3,662; (1890) 4,351; (1900) 5,046.

EDITOR OF "TELEGRAPH."

Atlantic Cable: See CABLE (ELECTRIC).

Atlantic City: railroad center and fashionable watering-place, Atlantic co., N. J. (for location of county, see map of New Jersey, ref. 7–C); on the Atlantic Ocean, 60 miles S. E. of Philadelphia. Pop. (1880) 5,477; (1890) 13,055; (1900) 27,838. The summer population at times exceeds 100,000. Forty express trains run daily to and from Philadelphia. Numerous hotels and boarding-houses are open both winter and summer, with modern facilities for sea-water bathing. The town is lighted by electricity, and has electric street-cars. A plank-walk extending 4 miles along the ocean-front is a special feature. Boating and fishing facilities are unexcelled.

The public schools employ forty-six teachers, and are first class. There are good churches of several leading denominations.

EDITOR OF "DAILY UNION."

Atlantic Ocean: that part of the aqueous envelope of the earth which separates America from Europe and Africa. Where it adjoins other oceans its boundaries are indefinite, and geographers have arbitrarily assigned them various positions. Good usage separates it from the Arctic Ocean at the north by lines from Northern Labrador to Greenland and from Greenland to Iceland and Southern Norway; and separates it from the Southern Ocean by a line joining the southern extremities of America and Africa. In common parlance the term includes open bays, such as the Bay of Biscay and the Gulf of Guinea, but does not include the Gulf of St. Lawrence, the Gulf of Mexico, the Caribbean Sea, the Mediterranean and Black Seas, and the North and Baltic Seas, all of which are landlocked dependencies. With the addition of these dependencies the Atlantic has an extent of 30,000,000 sq. miles, nearly one-fourth the water area of the globe; without them its area is about 27,000,000 sq. miles, and its mean depth 2,220 fathoms. The length of the Atlantic from north to south is 7,500 miles, and its average width 3,600 miles. Midway it is constricted to about 1,800 miles by the approach of the eastern angle of South America to the prominence of the African coast north of the Gulf of Guinea. The great lobes thus separated are nearly equal in area and depth, and are called the North Atlantic and South Atlantic Oceans.

Topography of Bed.—With small exception the continental coasts of the Atlantic are margined by broad shoals, deep water beginning somewhat abruptly at a distance of several hundred miles. These shoals, sometimes called the continental shelves, are broadest on the American side. Their greatest development at the north is called the Banks of Newfoundland. Between the continental shelves the bottom exhibits a diversity of configuration comparable with the greater features of a continental area. In the northern part of the North Atlantic, from Great Britain to Labrador, the bottom lies at moderate depth, and has been called the Telegraphic plateau. An irregular plateau extends thence southward to the Azores, and then southwestward, and afterward northwestward to Bermuda, traversing the middle of the ocean. A great trough, from 2,000 to 3,000 fathoms deep, lies east of it, and extends to the coast of Brazil, where it is joined by another great trough, margining North America from Newfoundland to Florida and thence skirting the West Indies. The deepest sounding of the Atlantic, 4,561 fathoms, was obtained a few miles N. of Porto Rico island. The South Atlantic is traversed midway from N. to S. by a submerged plateau, from which spring St. Paul, Ascension, and Tristan de Cunha islands. A broad trough, 2,500 to 3,000 fathoms deep, follows the African coast, and a less regular trough the coast of South America.

Circulation.—The easterly trade-winds of the inter-tropical region drive the surface water of the ocean westward, the westerly winds of middle latitudes drive the water eastward, and there results in each oceanic lobe a great circular movement. In the North Atlantic the circulation is from left to right; in the South Atlantic from right to left. By the configuration of the bottom the rate of movement is locally accelerated, and currents are produced to which individual names are given. Of this class are the Guiana current, the GULF STREAM (*q. v.*), the North African current, the Brazil current, and the South African current. The Greenland current follows the east coast of Greenland southward; the Labrador current also moves southward; the Arctic current, formed by their combination, follows the east coast of the U. S., and finally disappears under the Gulf Stream. The Guinea current, an eddy or back-water current of the equatorial current, follows the Guinea coast eastward. Near the middle of each oceanic lobe is a great tract without definite or continuous current. In the North Atlantic it is characterized by the abundance of floating seaweed, and is called the Sargasso Sea. See also OCEAN.

Atlantic Telegraph: See TELEGRAPH.

Atlant'ides (in Gr. Ἀτλαντίδες): in classic mythology, the daughters of Atlas. They were also called Hesperides, Pleiades, and Hyades. See HESPERIDES.

Atlant'is: a large island which, according to an ancient tradition that was credited by the Greek geographers, was

situated in the Atlantic Ocean W. of Africa, just over against the Pillars of Hercules. In reality, this was a great continent, larger in extent than Libya and Asia put together, and yet it was only the passage to another continent, for which the Mediterranean was nothing but a simple harbor. One of the earliest writers who mentions Atlantis is Plato, who, in his dialogue *Timæus*, states that an Egyptian priest gave Solon a description of it. Plato gives a beautiful picture of this island, to which he adds a fabulous history. Nine thousand years before the time of Plato, Atlantis was (so the legend ran) populous and powerful, and conquered the western part of Europe and Africa. At one time its whole power was arrayed against the nations bordering on the Mediterranean, and every nation gave way for the tremendous force of the invaders, except alone the Athenians. Though abandoned by all, the Athenians fought bravely and were victorious. The gods finally came to the rescue of the earth. An earthquake afterward caused the whole island to sink in the ocean. This is the explanation of the shallows which are found in that part of the Atlantic Ocean. See Rudbeek, *Atlantica* (4 vols., 1675-98); Bailly, *Lettres sur l'Atlan de Platon*; Carli, *Lettres Américaines*; Donnelly, *Atlantis: The Antediluvian World*.

At'las (in Gr. Ἄτλας): a mythical personage, said to be a son of Japetus and Clymene, and a brother of Prometheus. He was represented by the ancient Greek legends as a leader of the Titans in the war against Jupiter, for which offense he was condemned to support the vault of heaven on his head or shoulders. According to some writers who have rationalized the myth, he was a king who acquired great skill in astronomy.

Atlas: in anatomy, the first cervical vertebra; the piece of the vertebral column nearest to the skull. It forms, with the occipital bone, the joint on which the head moves in bowing. It turns on the pivot of the second cervical vertebra, the "axis," when we look from side to side.

Atlas [so called because some early collections of maps had prefixed a picture of Atlas upholding the sphere]: a volume containing a collection of maps, usually including more or less descriptive letterpress. The name was probably first applied as the proper title of such a book by Gerard Mercator (1512-94) to his *Atlas*, published in the year of his death. Among the best atlases are the works of Stieler (in German, French, Swedish, Finnish, Italian, etc.), of Menke, Spruner, Berghaus, Sydow, Andrees, and others, illustrating not only geography proper, but history, ethnography, geology, astronomy, botany, and other sciences; the works of A. K. Johnston, Black, Bartholomew, Stanford, and numerous others in Great Britain; and of Colton, Morse, Bradley, Johnson, Rand, McNally & Co., and D. Appleton & Co., and many others in the U. S.

Atlas Mountains: a mountain-system of Africa; mostly in Morocco and Algeria; extends from Cape Gher on the Atlantic to Cape Bon on the Mediterranean. It is a congeries of mountains, sometimes isolated and sometimes connected, with many irregular branches. The system is divided into the Greater and the Lesser Atlas, the latter of which is nearer to the Mediterranean. The highest point of the system is in Morocco, and is estimated at 13,000 feet above the sea. Mt. Mitsin rises to 11,400 feet. Numerous metals are found in these mountains.

Atmometer [from Gr. ἀτμός, vapor + μέτρον, measure]: a hollow ball of porous earthenware joined with a graduated glass tube, used for measuring amount of evaporation. The ball and tube being filled with water and exposed to the free action of the air, the extent to which the water transudes through the porous material and is removed by evaporation is measured on the tube. The instrument was invented by Sir John Leslie.

Atmosphere [from Gr. ἀτμός, vapor + σφαῖρα, sphere]: the envelope of æriform fluid which surrounds and rests upon the earth, and in which we live, move, and have our being, or any similar envelope surrounding a heavenly body.

In chemical composition the atmosphere surrounding the earth is a mixture of oxygen and nitrogen, in the proportion, by measure, of 21 parts oxygen and 79 parts nitrogen. It also contains about 4 parts in 10,000 of carbonic acid, and usually some impurities, which vary from place to place, arising from local causes. Among these are ammonia and sulphuretted hydrogen. To ordinary observation it seems so light as to be almost immaterial, as is evinced by the phrase "as light as air"; yet 12 cubic feet weigh a pound,

and a single large room therefore contains more than an ordinary man could lift. The weight of the whole mass is such that it presses on every square inch of the earth's surface with a weight which averages 14.7 lb. The entire mass of the whole atmosphere may be found by multiplying this quantity by the number of square inches on the whole surface of the earth; the result is that the entire weight, in tons, would require sixteen digits for its expression. In round numbers we might say that it is five thousand millions of millions of tons. This mass is such that the combustion of all the coal which has been mined in a century, or is likely to be mined for centuries to come, would not appreciably increase the quantity of carbonic acid in the air.

To the ordinary vision air is invisible, and therefore does not reflect light. But the light of the blue sky can be nothing but light reflected from the great mass of atmosphere above our heads; and the glow of the evening twilight can also arise from nothing but reflected sunlight. But dust and other impurities may play an important part in the reflection of light.

The height to which the atmosphere extends has not been definitely fixed. The phenomena of twilight show that it certainly does not reflect the light of the sun at a height greater than 45 miles; perhaps not even at a height so great as this. But observations on meteors show that it really extends to a height of at least 100 miles, and indeed, at that height, is sufficiently dense to cause the rapid combustion of a meteor passing through it. Observations on the aurora lead at least to a suspicion that this phenomenon sometimes takes place at a height of three, four, or five hundred miles. We can hardly suppose it to occur in an absolute vacuum; though it would be unsafe to infer from this that the medium in which it occurs is an extension of the atmosphere proper.

For fuller details of the physical properties of air, see ACOUSTICS, BAROMETER, and PNEUMATICS; also CLIMATE, CYCLONE, METEOROLOGY, STORM, WINDS, etc. S. NEWCOMB.

Atmospheric Electricity: See LIGHTNING.

Atoll, or **Atoln**: a low, circular reef of coral, inclosing a lagoon, which in many instances communicates with the ocean by a narrow inlet, or by more than one. See CORAL ISLANDS.

Atom [from Gr. ἄτομος, indivisible; ἀ-, not + -τομος (τέμνειν), cut]: a minute, indivisible particle of matter. According to one theory of speculative philosophy, matter is infinitely divisible. On the other hand, chemists maintain that all matter consists of particles which do not suffer decomposition, whatever chemical influences the matter may be subjected to. They believe that all the atoms of each element have the same weight and form, but the atoms of different elements have unequal weights. This conception is based upon a very thorough study of an immense number of chemical phenomena, which can be satisfactorily interpreted only by its aid. It has nothing to do with the old metaphysical discussion as to the question whether matter is or is not infinitely divisible—a question which it is hardly profitable to discuss in the present state of our knowledge. See ATOMIC WEIGHTS, CHEMISTRY, MOLECULES, and STEREO-CHEMISTRY.

Revised by IRA REMSEN.

Atomicity: See CHEMISTRY.

Atomic Theory: See CHEMISTRY.

Atom'ic Weights, or **Chem'ical Equiv'alents**: the proportions by weight in which chemical elements unite. One element must be selected as the starting-point of the series, and an arbitrary value affixed to it, and thereafter all the other elements can have their values awarded to them according to the proportional amounts in which they combine. It can be demonstrated that a given amount of one element is equivalent to, and serves the same purpose in combining with, a second element as a greater or less amount of a third substance. Hydrogen is taken as 1, and all the other elements are represented by a quantity which is the minimum amount in which they unite with 1 of hydrogen. For a table of the atomic weights, see CHEMISTRY.

Atomiza'tion: in practical medicine, the very minute subdivision of liquids for inhalation or application to the throat. It was first introduced in France by Sales-Girons. It is effected by forcing a fine jet of liquid against either a solid body or a strong current of air, so as to convert it into diffused spray. Bergson, for instance, applied to this use the tubes used as *odorators* to spread perfumed liquids through the air. Two glass tubes with minute orifices are fixed at right angles to each other, so that the end of the

upright tube is near and opposite to the center of the orifice of the horizontal tube. The upright tube being placed in the liquid to be atomized, air is forcibly blown through the horizontal one. The current of air passing over the outlet of the upright tube rarefies the air in the latter, causing a rise of the liquid through it, and its very minute subdivision (atomization, nebulization, pulverization) as it escapes. Siegle has applied steam-power, generated by the heat of a spirit-lamp, to the propulsion of vapor for atomization. Richardson's *hand-ball* spray-producer is a simpler apparatus, constructed essentially upon the same principle. One of its uses is, by the rapid evaporation of ether or rhigolene, to produce a great degree of cold for local *anæsthesia* (i. e. to annul sensibility in a part for a surgical operation).

Atonement: I. THE WORD.—The *English* word is derived from "at-one-ment," and its earlier signification was "reconciliation." At present it is universally used in the sense of "satisfaction for an offense," "expiation." In the authorized *English* version of the Bible the word occurs only once in the New Testament (Rom. v. 11), and there represents *καταλλαγή*, "reconciliation." In the Old Testament it occurs frequently, translating *כָּפַר*, to "cover with sacrificial blood," and hence to "expiate," to "appease," to "purge away." The biblical equivalent of the word in the Old Testament is *כָּפַר*, "expiation." In the New Testament: (1) As it respects God, *ἱλάσκεσθαι*, to "propitiate" (1 John ii. 2 and iv. 10); (2) as it respects sin, to "expiate" (Heb. ii. 11); (3) as it respects the sinner, *ἀγοράζειν*, to "redeem" (by blood, Rev. v. 9), and *λυτροῦν*, to "ransom by substitution" (1 Pet. i. 18; 1 Tim. ii. 6).

II. THE DOCTRINE. 1. *Patristic*.—The biblical view above presented has always prevailed in the Church as the basis of religious experience. It was, however, but imperfectly discriminated as a logical conception by the early teachers. From an exaggerated conception of the independence and power of the kingdom of Satan, many of the Fathers, as Irenæus, Origen, and even Augustine and Jerome, etc., founded on such texts as Col. ii. 15 and Heb. ii. 14 the notion that Christ by his sufferings rendered satisfaction to Satan, who had acquired rights of conquest over the human race.

2. *The Anselmic*.—The doctrine which was from the beginning the living principle of the devotional writings of all Church teachers and of all liturgies and hymns, and which since his time has been taught in the authorized creeds of all sections of the Church, was first systematically unfolded by Anselm, Archbishop of Canterbury (1093–1109), in his tract, *Contra Deum Homo*. He teaches that the essential moral perfection of the divine nature, which is immutable, necessarily demands the punishment of sin—that sin is an intrinsic and infinite evil. The law is consequently unrelaxable, and the penalty must be executed upon the sinner unless a substitute (1) personally free of all legal demands and (2) of sufficient dignity is willing to be punished in his stead. This condition is answered only by a Person at once divine and human—i. e. a divine Person who has assumed a human nature. Christ made atonement for the sins of men by vicariously suffering the legal penalty of death to which they were condemned, and thus expiated the guilt of sin and propitiated the justice of God.

(1) This was in substance taught from the beginning. Athanasius (d. 373), *Contra Arianos*, i. 60, etc.: "Laden with guilt, the world was condemned of law, but the Logos assumed the condemnation, and suffering in the flesh gave salvation to all." Augustine (d. 430), *De Pec. Mer.*, i. 56; Gregory the Great (d. 604), *Mor. in Job*, 17: 46.

(2) The same doctrine is taught in the standards of the Roman and the orthodox Greek Churches, *Conc. Trent.*, sess. 6, e. 7: "Jesus Christ, who when we were enemies merited justification for us by his most sacred passion on the tree, and satisfied God the Father for us." *Cat. Rom.*, ii. 5, 63; *Orthodox Conf. of Apos. East. Church*, by Petrus Mogilas (A. D. 1642); Winer, p. 85.

(3) The same doctrine is taught in the confessions, liturgies, and hymns of every branch of the Lutheran and Reformed churches: *Formula Concordiæ* (Lutheran); Hase, *Libri Symbolici*, p. 684; *Heidelberg Cat.*, Ques. 60; *Second Helvetic Conf.*, ch. 15; *Gallie Conf.*, art. 18; *Belgic Conf.*, art. 22; *Westminster Conf.*, ch. 8, § 5; *Liturgy and Articles of the Church of England*, art. 28, art. 31: "The offering of Christ, once made, is that perfect redemption, propitiation, and satisfaction for all the sins of the whole world both original and actual."

3. Abelard (d. 1142) first systematically developed what has since been known as the "moral influence theory of the atonement." He regards the love of God as the sole principle determining him in his provision of redemption for sinners. All that God's nature or will requires of a sinner as prerequisite to forgiveness and happiness is repentance and reformation. As rebellious men are obstinately indisposed to this repentance, and are afraid to trust his favor, God by his alliance with human nature in Christ, and by his surrender of him to death, makes such an exhibition of his love for man as awakens man's love for and trust in him, and so disposes man to repentance. This view is essentially the doctrine of the Socinians of the fifteenth century (*Racovian Cat.*) and of modern Unitarians, and of such Trinitarians as Maurice, Jowett, and Bushnell.

4. The "governmental theory of the atonement" was first propounded by Hugo Grotius (d. 1645) in his work against the Socinians, *Defensio Fidei Catholice de Satisfactione Christi*. He taught that the moral law under which men are held, including precept and penalty, is a positive product of the divine will. The right of waiving or relaxing its demands is therefore an element of God's prerogative as moral sovereign. But since this gratuitous remission of the penalty in case of some sinners would weaken the motives restraining the subjects of the divine government in general from disobedience, by affording an example of impunity, the benevolence of God requires that he should make such an example of suffering in Christ as will indubitably exhibit his determination not to allow sin to pass in any case without signal marks of his displeasure. This doctrine has never been accepted by any historical Church as an adequate rationale of the atonement, nor has it been embodied in any creed, but it has been frequently adopted by several schools of theologians—e. g. the supernaturalists of the last age in Germany, as Stäudlin, Flatt, and Storr, and in America Jonathan Edwards, Jr., Smalley, Maxey, Dwight, Emmons, and Park.

5. The "mystical theory," which, existing in various forms, may be generally stated thus: That the reconciliation effected by Christ is brought about by the mysterious union of God and man accomplished by the incarnation, and not by his sacrificial death. This was held by the Platonizing Fathers, by followers of Scotus Erigena during the Middle Ages, by Oslander and Schwenkfeld at the Reformation, and by the school of Schleiermaeher among modern German theologians. See Prof. Edwards A. Park's *Atonement*; Dr. Shedd's *Hist. of Christ. Doctrine*; Ritschl's *Hist. of Doc. of Reconcil.*; Schaff's *Hist. Chr. Ch.*; Watson's *Institutes*; Winer's *Comp. of Docs. of Christendom*; Outram, *De Sac.*; Hase, *Libri Symbol.*; Niemeyer, *Collec. Conf.*; the recent works on the Atonement by Thomas J. Crawford (Edinburgh, 1871; 2d ed. 1874) and R. W. Dale (London, 1875; 9th ed. 1883).

A. A. HODGE.

Atonement: A statement of the ROMAN CATHOLIC DOCTRINE. 1. Sin is an offense against God; it deprives the soul of the friendship of God, makes it the slave of the devil, and is deserving of punishment. (*Council of Trent*, session vi. e. 1; also Colossians i. 13; ib. ii. 14.) 2. All men sinned in Adam. (Romans v. 12.) 3. In strict justice, God could have refused forever to pardon fallen man. In his mercy, he could have pardoned sin by a mere act of his free will without any satisfaction from man, but directly on man's simple repentance and purpose of amendment. The contrary opinion limits the free will and the infinite mercy and power of God. Yet the ordinary condition for the remission of sin is that the sinner should make reparation for the sin. God may be content with an incomplete reparation, or he may demand a complete, rigorous reparation equal to the offense. This is what God demanded. 4. Such reparation could be given only by a man, for man had sinned. At the same time it could be given only by God; for, the offense being infinite, only an infinite person could repair it. Hence no one but a person at once God and man, the God-man Jesus Christ, could give adequate satisfaction for sin. Hence, too, the incarnation of Christ was necessary only hypothetically. 5. The Son of God became man to satisfy for us, and instead of us. He is the natural mediator between God and man. By his incarnation he is our great High Priest. 6. As priest he could satisfy the justice of God for us by any expiatory act of his life. But he chose to do so by the most perfect act, by the sacrifice of his life on the cross. 7. By his sacrifice Jesus Christ has redeemed the whole human race, and freed man from the slavery of the

devil. Christ's sacrifice was offered to God the Father. "Jesus Christ, when we were enemies, merited justification for us by his most sacred passion on the cross, and satisfied God the Father for us." (*Roman Catechism.*) 8. The fruit of Christ's sacrifice is applied to each of us by sacraments, sacrifices, good works, etc. 9. The satisfaction of Christ was free, as all grace is free. It was vicarious. It was infinitely meritorious—i. e. of unlimited inherent dignity and value. It was superabundant—i. e. sufficient for the salvation of all men. It was universal—i. e. offered for all men. 10. From what is said above it follows: (1) That the atonement does not consist merely in the effect produced on the hearts of men by the doctrines, character, example, life of Christ; nor (2) merely in the hypostatic union of the two natures, the human and the divine, in one person; nor (3) merely in the fact that Christ taught the truth and sealed his teaching with his blood; nor (4) merely that he manifested by his death his self-sacrificing love; nor (5) merely that he died a martyr. It is something more. These opinions, held by some outside the Church, entirely omit what is essential to the atonement, i. e. the fact that Christ as Priest offered himself as victim to satisfy the justice of God the Father for the sins of the world. See H. N. Oxenham, *Doctrine of the Atonement* (London, 1865, 1869, and 1881).

JOHN J. KEANE.

Atra'to: a river of South America; in republic of Colombia; rises near the Cordillera, flows northward through Cauca, and after a course of about 280 miles (185 navigable) enters the Gulf of Darien by several mouths. It traverses a region rich in gold. In 1857 the Government of the U. S. sent an expedition to explore a route for a ship-canal from the Atrato to the Pacific. In 1870-72 the explorations under Capt. Selfridge, U. S. navy, were resumed, and all the routes between Panama and the Atrato examined, with results far from realizing the hopes entertained of a favorable route.

A'treus (in Gr. Ἀτρεΰς): an ancient and celebrated King of Mycenæ; was called a son of Pelops. He was the father of the famous *Atridae*—i. e. Agamemnon and Menelaus. The story of Atreus and his family was embellished by the ancient fabulists and tragic poets with many wild legends, involving horrible crimes and calamities.

Atri'des (in Gr. Ἀτρεΐδης), plural **Atridae** (in Gr. Ἀτρεΐδαι): a patronymic from *Atreus*; signifies a son or descendant of Atreus. The name in the singular is more usually applied to Agamemnon, but the plural is used to designate the two brothers, Agamemnon and Menelaus.

A'trium [Lat., a court, a hall]: in Roman architecture, an entrance-hall or central apartment, which was the principal part of a private house. In this room the family lived and took their meals. Here stood the Lares and Penates, and here the female servants were employed in weaving and other labors. The atrium was also used as a waiting-room for clients and other visitors. In ecclesiastical architecture the term denotes an open space before a church, forming part of the narthex or ante-temple.

Atrophy [from Gr. ἀ-, not + τρέφειν, nourish, feed]: wasting or decrease in size of parts of the body. This occurs normally at advanced age; also in the uterus after pregnancy, and in the thymus gland in early life. Atrophy is to be distinguished from *hypoplasia*, a condition in which full development has never been reached.

At'ropine, or **Atro'pia**: a peculiar alkaline principle obtained from the *Atropa belladonna*; is very poisonous. It exists in all parts of the plant. A very minute portion of it has the power to dilate the pupil of the eye. Atropine is composed of carbon, 70.98; oxygen, 16.36; hydrogen, 7.83; and nitrogen, 4.83.

Attacapan Indians: a numerous family of North American Indians who inhabited the district of Louisiana, still popularly styled the "Old Attacapa country" or "Tuckapa country," which included the parishes of Louisiana between the Red, Sabine, and Vermilion rivers and the Gulf of Mexico; also some adjoining counties of Texas. Very little beyond fragments of its language is now known of the family, but it is evident that the language is distinct from all others, except possibly the Chitimachan. The knowledge of it possessed by Gallatin was derived from a vocabulary and some scanty information furnished in 1805. More was obtained in 1885 by the Bureau of Ethnology from a few survivors in Calcasieu Parish, La. The Coco and Hiyeketi are the only tribes of this linguistic family the names of

which are identified. The Attacapa were mentioned by Pénicaut in his account of the exploration ordered by M. de Bienville in 1703. The name Attacapa is derived from a Choctaw word meaning "man-eater," and is merely a term of obloquy devised by enemies and never adopted by the family itself; but they have never appeared historically under any other except the two tribal names mentioned above. In the early colonial period the name was also applied to several Texan tribes accused of anthropophagy, with rather more evidence than can be produced against other North American Indians, but which is by no means conclusive. See INDIANS OF NORTH AMERICA.

GARRICK MALLERY.

Attach'ment [from Old Fr. *attachement* < *a-* (L. *ad-*) to + a verb from the same root as E. *tack*, a nail]: the apprehension of a person or seizure of a thing by virtue of a writ or order issued by a court or judge under authority of law. The word is sometimes used to denote the process itself. In respect to property, the term is usually applied to seizure on *mesne* process. Attachment was originally one of the common-law means of obtaining an appearance in an action by the defendant. In some of the States a plaintiff can at the commencement of any action to recover money attach the property of the defendant as a security for the payment of the judgment expected to be recovered; and in case of recovery the property is to be applied in satisfaction of the judgment. But the more usual rule is that there can be no seizure of property, except in specified cases, till the rights of the parties have been settled by judgment of the court. The exceptions are chiefly in cases where the defendant is a non-resident or a fraudulent debtor, or is attempting to conceal or remove his property for the purpose of defrauding or delaying his creditors. An attachment is said to be foreign where a creditor attaches property in the hands of a third person belonging to his debtor, or a debt due from a third person to such debtor. The name is said to arise from the fact that the proceeding is often resorted to for the purpose of collecting a debt against a non-resident. In some of the Eastern States this proceeding is called "trustee-process"; in other States it is generally known as "garnishment," meaning a warning. Foreign attachment was derived from local customs in London and other cities, and formed no part of the general law of England.

Attachment is issued against the officers of the court for any misconduct or neglect of duty, and against any person who has been guilty of contempt of court. The object of the attachment is to bring the guilty party actually before the court. He has then an opportunity to show cause why he should not be found guilty, or, in legal language, to "purge himself of the contempt." If he can not do this he is subject to such punishment as the law permits and the court may award.

T. W. DWIGHT.

Attain'der [subst. use of O. Fr. *ataindre*, touch, accuse < Lat. *attingere*, touch. The meaning "stain" is due to false association with Fr. *tindre* < Lat. *tingere*, dye]: in law, the extinction of civil rights as the consequence of a judicial sentence of death for a capital crime. From this moment the criminal was deemed to be legally dead, incapable of bringing an action, except to reverse the attainder, or of appearing in court as a witness. Its two most important consequences are forfeiture and corruption of blood. The effect of forfeiture upon the offender's land was such that it related back to the time of the commission of the offense, and avoided intermediate sales, even to purchasers in good faith. The consequence of corruption of blood was that the person attainted was incapable of inheriting himself or of transmitting an estate by inheritance to another. Thus if a grandfather owned land, and a son were attainted, his descendant could not inherit from the grandfather, even though the son were dead when the land passed from the grandfather. This harsh rule is now modified in England by statute. Forfeiture, except in cases of treason and murder, does not extend in the case of estates of land beyond the natural life of the offender. By the U. S. Constitution no attainder of treason shall work corruption of blood or forfeiture, except during the life of the person attainted. In case of rebellion the U. S. might regard the rebels either as belligerents or traitors. In the former aspect of the case they would not be bound by the restriction just referred to, but might, under the rules of public law applicable to a state of war, confiscate their property. If, however, they were treated as subjects and as guilty of treason, the restriction of the Constitution would become operative.

Attakapas, at-tuk'a-paw: a large and fertile district in the southern part of Louisiana, comprising, according to old maps, several parishes. It produces large quantities of sugar and molasses. Though often used in conversation, the name has no legal existence.

Atta'lea: a genus of palm-trees including about twenty species, native of tropical South America and the West Indies. The leaves are pinnate with a much-compressed principal rachis and drooping pinnules. The pistil of the flowers is tricarpellary, and the fruit, a smooth berry or drupe, generally contains three edible seeds. Some species are of much economic interest—e. g. *A. funifera*, the Piassabe or Coquilla palm of Brazil, which yields fiber and "Coquilla nuts," and *A. cohune*, the Cohune palm of Honduras, whose seeds yield a valuable oil. See PALM FAMILY. C. E. B.

Attal'la: town; Etowah co., Ala. (for location of county, see map of Alabama, ref. 2-D); on L. and N., E. T. Va. and G., and Queen and Crescent R. Rs.; at southern extremity of Lookout Mountain, 56 miles from Birmingham; has excellent public schools for white and colored children, 5 churches (3 white and 2 colored), water-works, electric lights, charcoal-furnace, and several iron and steel works. In the surrounding region, which is favorable to agriculture, are fine iron-ore deposits. Attalla has a large cotton-trade, and in the shipment of iron is the second place in the State. Pop. (1880) 351; (1890) 1,254; (1900) 1,692.

EDITOR OF "HERALD."

Attalus I.: King of Pergamus; b. 269 B. C. He succeeded his cousin, Eumenes I., in 241 B. C., defeated the Gauls who had occupied Galatia, and became an ally of the Romans in a war against Philip of Macedon. He was reputed a wise ruler and able general. D. in 197.

Attalus II., surnamed PHILADELPHUS: b. 210 B. C.; was the second son of Attalus I. He succeeded his brother, Eumenes II., in 159 B. C., was a constant ally of the Romans, and patronized arts and sciences. D. in 138.

Attaman, or **Het'man**: the title of the chiefs of the Cossacks, formerly elected by the people. (See COSSACKS.) After the revolt of Mazeppa the office was suppressed by the Czar of Russia until 1750. Catherine II. abolished the office among the Cossacks of the Ukraine; among those of the Don it still exists, but its prerogatives have been greatly reduced. The heir-apparent of the Russian crown is principal attaman of the Cossacks.

Attar of Ro'ses [from Pers. *atar*, loan-word from Arab. *itr*, perfume]: the oil or essence of *Rosa centifolia* and its varieties, *Rosa damascena* and *Rosa moschata*. It is prepared by distillation of the petals in Persia, India, and other Eastern countries, whence it is exported in small vials. It is very costly, and is often adulterated: 100,000 roses, from 10,000 bushes, are said to yield but 180 grains of attar. It is often called *otto* of roses. That of Adrianople is called the best. In 1887 25 acres were planted with roses near Leipzig, Germany, for the purpose of manufacturing the attar. In the first year about 4 lb. of the oil and 6,000 lb. of rose-water were obtained. From 1,000 lb. of rose-leaves 1 lb. of oil was obtained. IRA REMSEN.

Attention: See the Appendix.

Atterbom, PETER DANIEL AMADEUS: b. at Åsbo, in Southern Sweden, Jan. 19, 1790; studied (1805) at the University of Upsala languages and literature, history and philosophy; traveled in Germany and Italy 1817-19; was tutor to the Crown Prince Oscar 1819-21, and was appointed doцент in 1821 and professor in 1828 at the University of Upsala, where he died July 21, 1855. In 1807 he formed the literary association *Aurora*, and in 1810 he founded the critical periodical *Phosphoros*; and it was through these two institutions that the French or pseudo-classical taste which reigned in all Swedish literature and art received its first and its heaviest blows. The romantic ideas which started this whole movement were afterward developed by Atterbom in a long series of brilliant writings, poetical and historico-critical—*Lycksalighetens Ö* (2 vols., 1824-27); *Samlade Dikter* (2 vols., 1836-37); *Svenska siare och skaldar* (6 vols., 1841-55); and *Poesiens historia* (4 vols., 1862); but the form of the romantic school represented by Atterbom did not become the model of modern Swedish poetry.

Atterbury, FRANCIS: English prelate, writer, and politician; b. at Middleton-Keynes, in Buckinghamshire, Mar. 6, 1662. He entered Christ Church, Oxford, in 1680, took holy orders in 1687, and became lecturer in St. Bride's

church, London, in 1691. Having gained distinction as a pulpit orator, he was appointed a chaplain to the king. He was the author of a witty but superficial *Examination of Dr. Bentley's Dissertations on the Epistles of Phalaris*, which appeared under the name of Charles Boyle, his pupil, in 1698. He was a Jacobite in politics, and a zealous defender of High Church doctrines. He was appointed chaplain to Queen Anne in 1702, Dean of Carlisle in 1704, and Bishop of Rochester in 1713. His turbulent and imperious temper several times involved him in difficulties, and his hopes of promotion were blasted by the death of Queen Anne in 1714. He was a friend of Pope, Swift, and Bolingbroke. In Aug., 1722, he was committed to the Tower on a charge of treason as an accomplice in plots for the restoration of the Stuarts. He was convicted by the House of Lords in May, 1723, and was condemned to perpetual banishment. He became a resident of Paris, where he died Feb. 15, 1732. Four volumes of his sermons were published in 1740. His reputation as a writer is founded on his sermons and letters, which have great literary merits. See his *Epistolary Correspondence* (5 vols., London, 1783-90), edited by J. Nichols; *Memoirs and Correspondence*, compiled by F. Williams (2 vols., 1869).

Atterbury, WILLIAM WALLACE, D. D.: Presbyterian minister, distinguished as a leader in the Sabbath-reform movement; born of honorable Huguenot parentage at Newark, N. J., Aug. 4, 1823. At Yale he took the courses in arts and in theology, and a partial course in law. He was pastor to Presbyterian churches in Lausing, Mich., six years, and in Madison, Ind., twelve years. In 1869 he succeeded the Rev. Philip Schaff as secretary of the New York Sabbath Committee, and has since devoted himself to that work, traveling, preaching, lecturing, and writing for the press. His honorary degree was given him by the University of the City of New York in 1888. W. J. B.

Attfield, JOHN, M. A., Ph. D., F. R. S.: chemist and pharmacist; b. Aug. 28, 1835, in Hertfordshire, England; studied in the Pharmaceutical Society's School 1853-54, and was first prizeman in all subjects; Demonstrator of Chemistry at St. Bartholomew's Hospital 1854-62; appointed to the chair of Practical Chemistry in the Pharmaceutical Society's School 1862. He was dean till 1887, and senior professor till his retirement in 1896. His chief work is *A Manual of Chemistry, General, Medical, and Pharmaceutical*, of which seventeen large editions have been published. C. H. THURBER.

Attic [from Lat. *atticus*, pertaining to Attica; Gr. Ἀττικὸς]: pertaining to or characteristic of ancient Athens, or its people, language, literature, etc. In architecture an *attic base* is a form of base employed in the Ionic and sometimes in the Corinthian order, and consists of two toruses separated by a scotia, and resting upon a square plinth. An *attic story*, or, more briefly, an *attic*, is a subordinate story introduced into the uppermost frieze or immediately below the architrave, or added above the main cornice. It is of less height than the other stories, and usually has small, square, oval, or horizontally oblong windows. The attic is a feature of frequent occurrence in the Italian palaces, especially of Rome, Vicenza, and Venice. *Attic wit* and *Attic salt* signify a poignant and delicate wit specially characteristic of the Athenians. A. D. F. HAMLIN.

Attica [in Gr. Ἀττική]: a state of ancient Greece; bounded N. by Bœotia, E. by the Ægean Sea, S. W. by the Saronic Sinus, and W. by Megaris. It occupied a triangular peninsula, at the S. E. extremity of which is the promontory of Sunium. A range of hills called Mt. Cithæron extends along the northern border. The surface is diversified by limestone hills and plains, the soil of which is light and unproductive. About 10 miles N. E. of Athens rises Mt. Pentelicus, which has an altitude of 3,884 feet, and contains inexhaustible quarries of white marble of a superior quality. Among the prominent physical features of the country are Mt. Hymettus, about 3,500 feet high, and Mt. Laurium, whose silver mines have again attracted great attention. The principal streams are the Cephissus and Ilissus, which flow southwestward into the Saronic Gulf. The climate is dry and extremely pleasant. The chief productions are wheat, olives, figs, and grapes. Rich silver mines were worked at Laurium. Attica was very advantageously situated for commerce, and was at one time the greatest maritime power of the world. The people of Attica, who belonged to the Ionic division of the Hellenic race, planted colonies in various distant lands. The region which they colonized on the western coast of Asia Minor was called

Ionia. The capital of Attica was Athens (Athenæ), and the inhabitants of Attica were citizens of Athens, possessing the right to assemble in the capital, and take part in the legislative and judicial proceedings. The ancient population is estimated at 500,000, the majority of whom were slaves. Modern Attica is deficient in forest trees, and presents an arid and rather desolate aspect, except in spring. (For the history of Attica, see ATHENS.) ATTICA and BŒOTIA form a department of the modern kingdom of Greece, comprising Megaris and the islands of Egina and Salamis. It has an area of 2,472 sq. miles. The soil is less fertile than it was in ancient times, and is not well cultivated, but it still produces olives, grapes, and some wheat. Pop. (1889) 257,764.

Attica: city and railroad junction, Fountain co., Ind. (for location of county, see map of Indiana, ref. 6-B); on the Wabash R. R. and river; 21 miles W. S. W. of Lafayette; has various manufactures. Pop. (1890) 2,320; (1900) 3,005.

Attica: village and railroad junction; on Erie, N. Y. Central, and Buffalo, Attica and Arcade R. Rs.; Wyoming co., N. Y. (for location of county, see map of New York, ref. 5-D); 31 miles E. of Buffalo; is located in an agricultural district. Pop. (1880) 1,935; (1890) 1,994; (1900) 1,785.

Atticus: b. at Sebaste, Armenia; went to Constantinople; became a presbyter; was a leader in the conspiracy against Chrysostom, patriarch of Constantinople, and testified against him in the synod. Atticus was, after some months of intrigue, elected patriarch of Constantinople, Mar., 406, and held that office till his death, Oct. 10, 426. Pope Innocent I. refused at first to recognize him as patriarch. Atticus declined for a long time to put the name of Chrysostom on the diptychs of the Church.

Atticus, Titus Pomponius: an accomplished Roman of the equestrian order; b. in 109 B. C. During the war between Sulla and Marius he remained neutral, and passed many years (86-65) in Athens, to which city he rendered important services. He was an intimate friend of Cicero, whose letters to him are still extant. Having returned to Rome in 65 B. C., he declined to take part in political affairs, and distinguished himself by his moderation, generosity, and mediatorial spirit. He was on friendly terms with the leaders of both parties that divided the Romans. He wrote, beside other books, an epitome of Roman history called *Annalis*, but all his works are lost. His daughter was the wife of M. Vipsanius Agrippa, the eminent statesman. D. in 32 B. C. See Corn. Nepos, *Life of Atticus*; Hüllemann, *Diatribes in T. Pomponium Atticum* (1838); Boissier, *Cicero and his amis* (Paris, 1884).

Attila [Gr. Ἀττίλας; Ger. *Et'zel* or *At'zel*; Hung. *Ethele*]: a famous barbaric conqueror and King of the Huns; was a son of Mundzue (or Mundzuccus). He succeeded his uncle Ruas as King of the Huns in 434 A. D., his subjects being nomadic hordes who occupied Pannonia and Sarmatia. He extended his dominion by conquest over Germany and Scythia, and obtained the surname of THE SCOURGE OF GOD. The Vandals, Ostrogoths, and Gepidæ fought under his banner. In 447 he invaded the Roman empire of the East, and defeated the armies of Theodosius II., who obtained peace (448) by the payment of an annual tribute of 2,100 lb. of gold, after the Huns had devastated Thrace and Macedonia. Marcian, who succeeded Theodosius II. in 450 A. D., refused to pay tribute to Attila, saying, "I have gold for my friends and iron for my enemies." In 451 A. D. Attila invaded Gaul with an army estimated at 700,000 men, and besieged Orléans (*Aurelianum*), which was relieved by the approach of a Roman army commanded by Aëtius. Attila retired to Champagne, and awaited the enemy on the Catalaunian plain, near the site now occupied by Châlons-sur-Marne. Here he was defeated in a great battle by the combined armies of Aëtius and Theodoric, King of the Visigoths, in June, 451 A. D. It is stated that 250,000 men or more were killed in this battle. Attila then retired into Germany. In 452 he led an army into Northern Italy, which he ravaged, and threatened Rome. The Emperor Valentinian III., unable to defend his capital, invoked the mediation of Pope Leo I., who had an interview with Attila, and persuaded him to grant the Romans a truce. Attila retired from Italy, and died in Pannonia in 453 A. D., on the night after his marriage with Ildico. He was buried by night, and the prisoners who dug his grave were killed, in order that the place of his burial might be kept secret. He had two sons, named Ellac and Dengezie. He is described as short, somewhat misshapen, with broad shoulders, a large head, flat nose, and small, deepset and singularly

piercing eyes. See Jornandes, *De Rebus Geticis*; Amédée Thierry, *Histoire d'Attila et ses successeurs* (Paris, 1864; 6th ed. 1884).

Attius: See ACCIUS.

Attleborough: Bristol co., Mass. (for location of county, see map of Massachusetts, ref. 5-I); on Old Colony R. R., 12 miles from Providence, R. I., and 30 S. S. W. of Boston; has extensive manufactures of jewelry, calicoes, clocks, metal, buttons, braids, and straw bonnets. Pop. of township (1880) 11,111; (1890) 7,577; North Attleborough having been set off as a separate town subsequent to 1885, when Attleborough had a population of 13,175; (1900) 11,335.

Attorney [O. Fr. *atorné*, past partic. of *atourner*, assign, i. e. one assigned to a function]: one who acts for or on behalf of another. Attorneys are of two kinds—in fact and at law. An attorney in fact is an agent, though the term is commonly applied to one who is authorized to act for another by a writing called a power of attorney. An attorney at law is one who is authorized by law to act in the place of another in the management or conduct of law proceedings. In England the term is employed to denote a class of legal practitioners whose duties are preliminary to those of the barrister, who conducts the cause in court. An attorney is admitted there after a prescribed term of study, on passing an examination directed by the court. Barristers come to the bar through the action of voluntary societies of lawyers which have existed for several centuries. In the U. S. the same person is in general admitted both as counselor (answering to barrister) and attorney, and examined in the same manner and under the same authority as to his qualifications to perform both classes of duties. An attorney is an officer of the court, and liable to be punished for a breach of duty, and in aggravated cases to have his name stricken from the roll, and thus lose his right to practice. His duties to his client require the exercise of reasonable care. He is responsible for negligence or willful default whereby his client sustains loss; for example, for the disclosure by him of confidential communications. He is entitled to compensation, and has a lien upon his client's papers or securities in his possession, and upon any judgment obtained through his exertions.

Attorney-General: an officer in England whose duty it is to prosecute for the king in criminal matters, and to manage civil actions or proceedings where his revenue or other property is concerned, as well as to enforce public rights. The U. S. and the respective States have a public officer of the same name, with similar duties.

Attorney, Power of: See POWER OF ATTORNEY.

Attraction [Lat. *tractio*; *ad.* to + *tra'here*, draw]: the tendency of bodies to approach each other and unite; the force which brings bodies together and resists their separation. The principal kinds of attraction are—the attraction of gravitation (see GRAVITATION); capillary attraction; chemical attraction (see AFFINITY); the attraction of cohesion, which unites the particles of a body, and operates only between two portions of matter that are in contact; and magnetic attraction (see MAGNETISM). These attractions are divisible into two classes—1, those which act at sensible and measurable distances, as gravitation and magnetic attraction; and 2, those which extend only to extremely small or insensible distances, as chemical attraction and the attraction of cohesion.

Attraction of Mountains.—In 1774 Maskelyne made an experiment on the mountain Schehallion, in Perthshire, to ascertain the attraction of mountains. This and subsequent experiments have established the fact that mountains are capable of producing sensible deflections of the plumb-lines of astronomical instruments.

Attucks, CRISPUS: a mulatto or half-breed Indian who was the leader of the mob which attacked the British troops in Boston, Mar. 5, 1770. Attucks and a number of others were killed in this affray, which was called "the Boston Massacre." It was the outcome of several previous quarrels between the people and the soldiery, and served to incite revolutionary feeling among the people. A monument to him was dedicated in Boston, Nov. 14, 1888.

Attwood, GEORGE: See ATWOOD, GEORGE.

Atwater, LYMAN HOTCHKISS, D. D., LL. D.: b. at Hamden, Conn., Feb. 23, 1813; graduated at Yale in 1831; tutor and theological student at Yale (1833-35); pastor of First Congregational church in Fairfield, Conn. (1835-54); became in

1854 Professor of Mental and Moral Philosophy at Princeton, N. J. In 1869 the department of Economics and Politics was given to him, and from that time he was Professor of Logic, Metaphysics, Ethics, Economics, and Political Science. He was an editor of the *Princeton Review*, 1869-78. He published a *Manual of Elementary Logic* (Phila., 1867). D. at Princeton, Feb. 17, 1883.

Atwater, WILBUR OLIN: agriculturist; b. at Johnsburgh, N. Y., May 3, 1844; graduated as A. B. at Wesleyan University in 1865 and as Ph. D. at Yale in 1869; studied for two years in the universities of Leipzig and Berlin, and elsewhere in Germany; became Professor of Chemistry in East Tennessee University and in the Maine State College, and has occupied the like position in Wesleyan University since 1873. He was director of the first agricultural experiment station in the U. S., the work of which was done in 1875-77 in the chemical laboratory of Wesleyan University. When the experiment station enterprise was made national by the establishment of stations throughout the U. S. under act of Congress, and the office of experiment stations was organized in 1888 as a central bureau in connection with the U. S. Department of Agriculture, he was made the first director of the office, and is still associated with it. He is also director of the Storrs (Connecticut) Agricultural Experiment Station. His specialty is biological and agricultural chemistry. Of his publications, the articles in the *American Chemical Journal*; *Report of the United States Fish Commission*; *Annales de Chimie et de Physique*; *Comptes Rendus* of the French Academy of Sciences; *Zeitschrift für Biologie*; *Berichte der Deutschen Chemischen Gesellschaft*; and *Landwirthschaftliche Jahrbücher* have the most scientific interest. Those in the *Century Magazine* are doubtless better known to the general public than any others.

Atwill, EDWARD ROBERT, D. D.: first Bishop of West Missouri; b. at Red Hook, N. Y., Jan. 18, 1840; graduated at Columbia College 1862, and at the General Theological Seminary 1864; ordained deacon 1864, and priest 1865. He served in the dioceses of New York, Vermont, and Ohio, and was consecrated Oct. 14, 1890. He has published sermons and addresses, and a tract on confirmation. W. S. P.

Atwood, GEORGE, F. R. S.: English mathematician; b. in London in 1746. He was a fellow of Trinity College, Cambridge, where he lectured on natural philosophy. He published a *Treatise on the Rectilinear Motion and Rotation of Bodies* (1784); a *Dissertation on the Construction of Arches* (1801), and other works. D. at Westminster, July, 1807.

Atwood, ISAAC M.: See the Appendix.

Atwood's Machine: a machine invented by George Atwood to demonstrate the laws of uniformly accelerated motion, and illustrate the relations of time, space, and motion in the case of a body falling under the action of gravitation. This machine is so constructed, by means of pulleys and wheels that turn with the least possible friction, that a weight (or falling body) suspended from one of the pulleys descends much more slowly than a body falling in free space, yet increases in velocity in the same ratio as when falling in the air. See FALLING BODIES.

Aubanel, ô'bañ-nel', JOSEPH MARIE JEAN BAPTISTE THÉODORE: Provençal orator and poet; b. at Avignon, Mar. 26, 1829; one of the most active of the group of men who have aimed to restore the Provençal tongue to its old-time literary dignity. In 1854 he was one of the seven persons who founded the Society of *Felibrige*, whose object has been the purification and renewal of the degraded dialects of Provence and Catalonia; and in March, 1876, when Mistral reorganized the society as an academy, with three grand divisions of its activity (Provence, Languedoc, and Catalonia), Aubanel was chosen majoral, and syndic for Provence. Under his guidance were founded almost all the schools of Felibres now in existence. Meanwhile he was publishing from time to time poems in the new Provençal tongue: *La Miougrano entraduberto* (1860); *La Perlo, vers* (1880); *La Ventoux, vers* (1882); *Lou Castelas, vers* (1883). He has published also a drama, *Lou Pan dcu peccat* (1883). Aubanel has been called "the French Petrarch."

A. R. MARSH.

Aube, ôb: a river of France; rises in Haute-Marne, flows northwestward through the department of Aube, passing Clairvaux, Bar-sur-Aube, and Arcis, and after a course of 140 miles enters the Seine about 24 miles below Troyes.

Aube: a department in the northeast part of France; formed of the southern portion of the province of Champagne and a small part of Burgundy (see map of France, ref. 4-G). It is bounded N. by the department of Marne, E. by Haute-Marne, S. by Côte-d'Or and Yonne, and W. by Seine-et-Marne. Area, 2,317 sq. miles. It is intersected by the rivers Seine and Aube. The surface is nearly level; the soil is fertile, especially in the southeast part, which produces grain, wine, etc. It has manufactures of cotton and woolen stuffs, hosiery, glass, and leather. It is divided into five arrondissements. Capital, Troyes. Pop. (1896) 251,435.

Auber, ô'ber, DANIEL FRANÇOIS ESPRIT: French composer; b. at Caen, Jan. 29, 1782. He was a pupil of Cherubini, and produced in 1813 *Le Séjour Militaire*, an opera which was not successful, but his comic opera called *La Bergère Châtelaine* (1820) was warmly applauded. In 1821 he composed *Emma*, an opera which was much admired. His works are remarkable for grace, originality, and ingenious combinations. The opera of *La Muette de Portici*, or *Masaniello* (1828), is called his masterpiece. He was elected a member of the Institute in 1829. Among his most popular operas are *Fra Diavolo* (1830); *Le Domino Noir* (1837); *Haydée* (1847); and *Manon Lescaut* (1856). He was director of the Paris Conservatory of Music (1842-1870) and chapel-master under Louis Philippe and Napoleon III. D. in Paris, May 12, 1871. See FÉTIS, *Biographie Universelle des Musiciens*; L. de Loménie, *Galerie des Contemporains*.

Au'berlen, KARL AUGUST, D. D.: German orthodox theologian; b. at Fellbach, in Württemberg, Nov. 19, 1824; educated at Tübingen; became professor at Basel 1851. D. at Basel, May 2, 1864. He is known to English readers through his able work *The Divine Revelation, an Essay in Defense of the Truth*, translated and published in Edinburgh, 1867.

Aubert, ô-bâr', JEAN LOUIS, Abbé: French poet and fabulist; b. in Paris in 1731. He edited a journal called *Les Petites Affiches*, and published in 1756 a collection of fables which gained a European reputation. They were highly commended by Voltaire, who wrote to Aubert, "You have placed yourself beside La Fontaine." He became Professor of French Literature in the Collège Royal, Paris, in 1773. D. in 1814.

Aubert du Bayet, JEAN BAPTISTE ANNIBAL: French general; b. in Louisiana, Aug. 29, 1759. He fought for the U. S. under Rochambeau, and was chosen in 1791 a member of the French Legislative Assembly, in which he supported the same principles as La Fayette. He commanded at the siege of Mentz, which was taken by the Prussians in 1793, and was Minister of War for several months in 1795. D. at Constantinople, where he was ambassador, Dec. 17, 1797.

Aubervilliers, ô-ber-vec'yā: a town in France; department of the Seine; 4 miles N. of Paris, and one of its suburbs (see map of France, ref. 3-F). Pop. (1881) 19,437; (1886) 22,223; (1896) 27,332.

Aubigné, Merle, d': See D'AUBIGNÉ, JEAN HENRI MERLE.

Aubigné, THÉODORE AGRIPPA, d' (dô-been-yā'): French Protestant historian and soldier, distinguished for his wit, learning, and audacity; b. in Saintonge, France, Feb. 8, 1550. He studied at St. Maury, Geneva, under Beza, and at an early age joined the Huguenot army, then waging a civil war against the court. He afterward entered the service of Henry of Navarre, whose favor he enjoyed. He fought for Henry against the Catholic League, and distinguished himself at the battle of Coutras (1587). His chief work is a history of his own times, entitled *Histoire Universelle, 1550-1601* (3 vols., Maillé, 1616-20). He left autobiographic memoirs, *Sa vie à ses enfants* (1557-1618), published under the title *Histoire secrète de T. A. d'Aubigné* (Amsterdam, 1731) and as *Memoires* (Paris, 1854; 2d ed. 1889). His complete works appeared in Paris, 1873-77, 4 vols; the 5th vol. promised. D. at Geneva, Apr. 29, 1630. His son Constantine was the father of Madame de Maintenon. See his biography by A. V. Salis (Heidelberg, 1885), and by G. Guizot (Paris, 1890). Revised by S. M. JACKSON.

Aubin, ô-bañ': a French town; department of Aveyron; 20 miles N. E. of Villefranche, in a mining region, with furnaces, etc. (see map of France, ref. 8-F). It contains a church of the twelfth century with remarkable sculpture, and has considerable trade in sheep, iron goods, etc. Pop. about 10,000.

Aublet, ô-blā, ALBERT: contemporary genre, history and portrait painter of the French school; b. in Paris; pupil of

Gérôme; first-class medal, Paris Exposition, 1889; Legion of Honor, 1890. His first notable work was *The Wash-room of the Reserves in the Cherbourg Barracks*, Salon of 1879. His best historical work is the *Meeting of Henri III. and the Duc de Guise*, Salon of 1880. W. A. C.

Auburu: on railroad; Lee co., Ala. (for location of county, see map of Alabama, ref. 5-E); 60 miles E. N. E. of Montgomery. It is the seat of the Alabama Agricultural and Mechanical College. Pop. (1870) 1,018; (1880) 1,161; (1890) 1,440; (1900) 1,447.

Auburn: city; on C. P. R. R.; capital of Placer co., Cal. (for location of county, see map of California, ref. 6-D); 33 miles N. E. of Sacramento and 126 miles from San Francisco. Auburn has the Sierra Normal College and a grammar school. Its principal industries are mining, fruit-raising, and general farming. It was founded as the county-seat in 1851. There are near the town very rich quartz and gravel mines, and many quartz-mills. Pop. (1870) 800; (1880) 1,229; (1890) 1,595; (1900) 2,050.

EDITOR OF "PLACER ARGUS."

Auburn: town (founded in 1836); capital of De Kalb co., Ind. (for location of county, see map of Indiana, ref. 2-G); on B. and D. R. R., Detroit div. of Wabash R. R., and the Jackson branch of the Lake Shore R. R.; 22 miles N. of Fort Wayne, Ind.; has 2 schools, 8 churches, a court-house, and jail; manufactures of buggies, church furniture, road-building machines, stoves, windmills, cigars, etc.; and has 2 wells of natural gas in use, besides 2 electric-light plants. Pop. (1880) 1,542; (1890) 2,415; (1900) 3,396.

EDITOR OF "COURIER."

Auburn: city on railroad; capital of Androscoggin co., Me. (for location of county, see map of Maine, ref. 9-B); 34 miles from Portland; on the Androscoggin and Little Androscoggin rivers, which furnish extensive water-power. It has manufactures of cotton and shoes. The shoe-product has greatly increased in recent years, and employs about 4,000 hands. The city has excellent public schools, is lighted by electricity, is growing rapidly, and many new industries are being introduced. Pop. (1870) 6,169; (1880) 9,555; (1890) 11,250; (1900) 12,951.

EDITOR OF "GAZETTE."

Auburn: city of Nebraska; capital of Nemaha County (for location of county, see map of Nebraska, ref. 11-H); on the Little Nemaha river; 65 miles by rail S. of Omaha and 72 miles S. E. of Lincoln; on the Missouri Pacific and Burlington and Missouri R. Rs. Has 7 churches, 3 newspapers, a public library, and several factories. Pop. (1890) 1,537; (1900) 2,664.

PUBLISHER OF "GRANGER."

Auburn: city and important railroad center; capital of Cayuga co., N. Y. (for location of county, see map of New York, ref. 4-F); 174 miles W. of Albany, and on both sides of the outlet of Owasco Lake, 2½ miles distant, which supplies its manufactures with water-power and is also the reservoir for the Auburn Water-works Company (the Holly system). Many of the private houses display an elegant style of architecture, and are adorned with beautiful gardens. Auburn has twenty-two churches, and is the seat of a theological seminary under the direction of the Presbyterians, which has recently added large new buildings and is largely endowed. This city was long the home of the late Hon. William H. Seward. A fine bronze statue of him was unveiled here Nov. 15, 1888. Here is a State insane asylum and a large stone State prison, noted for its system of discipline. The convicts, numbering 1,285, manufacture pearl buttons, furniture, stove-hardware, horse-collars, etc.

The city has manufactures of wool, cotton, iron, threshing-machines, agricultural implements, etc. Here are also very large manufactures of reapers, mowers, and binders. The census of 1890 showed 209 manufacturing establishments, with a capital of \$10,382,611, employing 6,001 persons, to whom wages were paid during the year amounting to \$2,472,574; value of product, \$9,064,093. Pop. (1880) 21,924; (1890) 25,858; (1900) 30,345. EDITOR OF "ADVERTISER."

Au'burndale: a part of the city of Newton, Middlesex co., Mass. (for location of county, see map of Massachusetts, ref. 2-H); on Charles river and B. and A. R. R.; 10 miles W. of Boston. It has two churches, and is the seat of Lasell Seminary. Pop. (1895) 2,816; (1900) not given separately.

Auburudale: village; Lucas co., O. (for location of county, see map of Ohio, ref. 1-E); on Mich. Cent. and Lake Shore and Mich. So. R. R. (Wagon Works station); near the west side of Toledo; wagon manufacturing is a thriving industry. Pop. (1890) 1,609; now (1900) a part of Toledo.

Auburu Theological Seminary: an institution founded in 1818 by the Presbyterian Synod of Geneva, and incorporated in 1820 under the name "The Trustees of the Theological Seminary of Auburn in the State of New York." A board of trustees has immediate control, but the trustees and the professors are appointed by a board of commissioners, which also exercises general control and has a concurrent vote in all appropriations of funds. The commissioners are elected by certain presbyteries, at present eighteen in number, each presbytery electing three.

The seminary occupies a group of handsome stone buildings on a large campus in the city of Auburn, and has an invested endowment of about \$570,000. There are ten professors. The total number of students (1900) is not far from 1,500. The theological position of the seminary is that of a strict, though tolerant, orthodoxy. W. J. BEECHER.

Aubusson, PIERRE, d' (dō'bū-soi'): grand-master of the order of St. John of Jerusalem; born of a noble French family in 1423. At an early age he joined the order, the headquarters of which was at Rhodes. He distinguished himself by his energy and courage in fighting against pirates, and was employed on important missions to several courts. In 1458 he formed a league between the Kings of France and Hungary against the Sultan Mahomet II. He was elected grand-master of his order in 1476, and fortified Rhodes as an advanced post for the defense of Christendom against the victorious Turks. The great aim and idea of his life was the formation of a league of Christian princes against the infidels. In May, 1480, Mahomet II. commenced the siege of Rhodes with an army of about 100,000 men. The Turks were repulsed in several desperate assaults, in which Aubusson was severely wounded, and they were forced to abandon the enterprise in July, 1480. In 1489 he was appointed a cardinal. In 1501 he was chosen general-in-chief of the armies of the German Emperor, the King of France, and the pope, who had formed a league against the Turks. His success was hindered by the jealousy and discord of these allies. D. July 13, 1503. He is regarded as one of the ablest Christian statesmen and commanders of his time. See Dominique Bouhours, *Histoire de Pierre d'Aubusson* (Paris, 1676; 3d ed. La Haye, 1739; Eng. trans. London, 1679). Revised by S. M. JACKSON.

Aubusson, dō'bū-soi': a town of France; department of Creuse; on the river Creuse; 22 miles S. E. of Guéret (see map of France, ref. 6-F). It has a celebrated manufactory of carpets. Velvets and woolen stuffs are also made here, as well as tapestries. Pop. about 7,000.

Auch, ōsh (anc. *Augusta Ausco'rum* or *Elimberis*): an old town of France; capital of the department of Gers; on the river Gers; 43 miles by rail S. of Agen (see map of France, ref. 8-E). In the time of Cæsar it was the capital of the Ausci or Auscii. It has a beautiful Gothic cathedral, an archbishop's palace, a royal college, a public library, a museum of natural science, and a town-hall. Here are manufactures of linens, cotton stuffs, leather, etc. Armagnac brandy is exported from this town, which was once the capital of Armagnac. Pop. (1881) 14,186; (1896) 14,838.

Auche'nia [from Gr. *αὐχὴν*, neck; in allusion to the length of their necks]: a genus of South American animals of the order *Ruminantia* and family *Camelidae*. The genus comprises the alpaca and the llama, and other species, all of which inhabit the mountain-ranges of the Andes. They are nearly allied to the camel, which they resemble in general form and in the structure of the stomach. They differ from the camel in having no hump; also in dentition, and in the more cloven feet and movable toes. Some naturalists think that the alpaca is not a distinct species, but a variety of the llama. See ALPACA.

Auchinleck, awch'-in-lek': Ayrshire village, 15 miles E. of Ayr (see map of Scotland, ref. 13-F); seat of the Boswell family. Sir Alexander Boswell, son of Johnson's biographer, established here in 1815 the Auchinleck Press for the printing of MSS. and rare works.

Auchmuty, awk'mōō-te, SAMUEL, D. D.: Episcopal clergyman; b. at Boston, Jan. 16, 1722; was graduated at Harvard in 1742. He was ordained to the diaconate in 1747 by the Bishop of London, and was appointed missionary of the Society for the Propagation of the Gospel in Foreign Parts; acting as assistant, and as catechist to the Negroes of Trinity parish, New York. In 1764 he succeeded Rev. Dr. Barclay as rector of Trinity. In 1766 he received the degree of D. D. from the University of Oxford, which honor was re-

peated by King's (now Columbia) College the following year. He adhered to the royalist party in the Revolution. D. in New York, Mar. 4, 1777. Revised by W. S. PERRY.

Auchmuty, Sir SAMUEL: British general; a son of the preceding; b. in New York, June 22, 1756, and graduated at King's (now Columbia) College in 1775. He fought against the U. S. in 1776-78, served many years in India, and in 1806 obtained command of an army sent to South America. He took the fortified city of Montevideo from the Spaniards in 1807, and captured Java from the Dutch in 1811. D. in Dublin, Aug. 11, 1822.

Auck'land: a seaport-town; former capital of the British colony of New Zealand; situated on the northeast coast of the island of New Ulster or northern island of New Zealand; lat. 36° 50' S., lon. 174° 50' E. (see map of World, ref. 7-D). It has two fine harbors and considerable trade. It is connected by steamships with Sydney, Melbourne, Honolulu, and San Francisco. It is the see of an Anglican bishop, and has four banks, several newspapers, and many fine buildings. The mean temperature of the coldest month is about 50° F., and that of the warmest about 68°. Auekland was founded in 1840. Pop. (1891) 28,773; (1896) with suburbs, 41,758.

Auckland, GEORGE EDEN, Earl of: an English peer; b. at Eden Farm, Beckenham, Kent, Aug. 25, 1784; inherited the title of baron at the death of his father in 1814. He acted with the Whigs, became President of the Board of Trade in 1830, First Lord of the Admiralty in 1834, and Governor-General of India in 1835. He was created Earl of Auckland in 1839, and returned to England in 1841. He died without issue at the Grange, near Alresford, Hampshire, Jan. 1, 1849.

Auckland, WILLIAM EDEN, Lord: an English diplomatist and lawyer: was born in Windlestone Hall, Durham, Apr. 3, 1744. He was one of the three commissioners appointed in 1778 to negotiate with the revolutionists in the U. S. Having been sent as ambassador to France in 1785, he negotiated a commercial treaty with that nation. He published *Principles of Penal Law* (1772) and other works. In 1793 he received the title of baron. D. at Eden Farm, Beckenham, Kent, May 28, 1814. See his *Journals and Correspondence*, ed. by his son, 4 vols., London, 1860-62.

Auckland Islands: a group of islands of volcanic origin; discovered in 1806 by the British in the South Pacific, about 180 miles S. of New Zealand (see map of World, ref. 7-D). The largest island is about 30 miles long and 15 miles wide, and has two good harbors. This group is valuable as a whaling-station.

Auc'tion [Lat. *auctio*, increase, sale by increase of bids, from *auge're*, increase]: in law, the act of exposing property for sale by open competition to the highest bidder by a person called an auctioneer. Every bid is deemed to be an offer, which is accepted by the auctioneer when his hammer falls. On general principles of the law of contracts, the offer may be withdrawn by the bidder at any time before acceptance. The acceptance of a higher offer is the rejection of the lower one. Such a sale must be fairly conducted by both seller and buyer. The secret employment of "puffers" or fictitious bidders by the owner to unduly enhance the price is a fraud on the purchaser, who may avoid such a sale. The same rule applies to secret agreements between purchasers to stifle competition. Such sales frequently take place under conditions made known at the time of sale. These must be followed by the party to whom they are applicable. An auctioneer is to some extent an agent for both parties—as, for example, to sign on their behalf a written memorandum of sales, where that is required by law. The conduct of auctioneers is sometimes regulated by statute. In what is known as a *Dutch auction*, the auctioneer starts with a high price and comes down till he meets with a bidder.

Audæus, or **Audius** (in Syriae *U'do*): the founder of a religious sect called Audians; was a native of Mesopotamia. He was banished to Scythia in 338 A. D., and died about 370 A. D. He incurred the enmity of the clergy by censuring their luxuries and vices. The Audians are accused of professing anthropomorphism.

Aude, *ōd*: a maritime department in the S. of France: bounded N. by the departments of Tarn and Hérault, E. by the Mediterranean, S. by the Pyrénées-Orientales, W. by Ariège and Haute-Garonne, and has an area of 2,437 sq. miles. It was formerly part of the province of Languedoc. The surface is partly mountainous, being near the foot of the Pyrenees; the soil of the valleys is fertile and calcare-

ous. It is intersected by the river Aude and the canal of Languedoc (or Canal du Midi). Among the mineral resources of Aude are iron, coal, and marble. The staple productions are grain, olives, wine, and fruits. It has manufactures of silk and woollens, etc. Capital, Carcassonne. Pop. (1891) 317,372; (1896) 310,513.

Audebert, *ōd'bār'*, JEAN BAPTISTE: an eminent French artist and naturalist; b. at Rochefort in 1759. He first acquired distinction as a miniature-painter, and subsequently applied himself to natural history, the love of which became his ruling passion. He published in 1800 a *Natural History of Apes, Lemurs, and Galeopithecæ*, with sixty-two admirably colored plates, printed in oil-colors by a new method which he invented. He was the first to use gold-leaf in illustrating the plumage of birds. His splendidly illustrated *History of Humming-birds, Flycatchers, Jacamars, etc.*, appeared in 1802. He died in Paris, Dec. 5, 1800.

Audenarde, *ō'den-aard'*, or **Oudenarde**, *ow'den-aard'*: a town of Belgium; in East Flanders; on the Scheldt; 14 miles S. S. W. of Ghent. It has a fine Gothic town-hall (see map of Holland and Belgium, ref. 10-C). Pop. 5,000. Here Prince Eugène defeated the French army in July, 1708.

Audiffret-Pasquier, *ō'dēe-fray-pās'kēe-āy*, EDMÉ ARMAND GASTON, *Duc d'*: French politician; b. at Paris, Oct. 23, 1823; elected to the National Assembly, Feb. 8, 1871, where he soon acquired a strong position. He was the first person elected life senator by the Assembly. In 1876 he was elected president of the Senate, which office he held until Jan., 1879. Elected member of the French Academy in 1878. C. H. T.

Au'diphone [malconstructed of Lat. *audi're*, hear + *φωνή*, tone]: an instrument for the deaf; is shaped like a large fan, and made of a sheet of vulcanized rubber about $\frac{1}{2}$ of an inch thick, fastened to a handle of the same substance. This sheet is curved at the farther end, when used, by pulling a cord which is put through holes in the upper edge, and passes along the inner side of the sheet into a slot in the handle. The curve required is very small, but the more deaf the person using the instrument the tighter must the rubber be drawn. When in use the straight or lower end of the sheet is kept in contact with the upper jaw-teeth, and any sound striking against the rubber sheet is communicated to the nerve of the ear through the teeth and bones of the head, so that ordinary conversation can be heard. The same result is produced in the case of artificial teeth if well fitted.

Au'ditor [from Lat. *audi're*, hear]: a person whose duty it is to examine and pass upon the accounts of those who have been intrusted with money, or to examine a particular account and certify the result. Most public and private corporations have such officers. An auditor is appointed by courts in the course of some actions to examine and state accounts, and report them to the court for further proceedings. The U. S. Treasury has six auditors who have charge of the accounts of (1) the civil service, customs, judiciary, etc.; (2) Indian affairs, etc.; (3) quartermaster-general, etc.; (4) navy; (5) internal revenue, State Department, and Patent-Office; and (6) the Post-Office.

Au'ditory Nerve [*auditory* is from Lat. *audito'rius*, pertaining to hearing; *audi're*, hear]: the special nerve of hearing, sometimes called the *acoustic* nerve. It is the seventh nerve rising from the base of the brain, and lies in close association with the facial nerve, or the nerve supplying the muscles of the face. It originates in the nucleus lying on the floor of the fourth ventricle of the brain, and it makes its exit from the skull through the internal auditory meatus, where it enters into the petrous portion of the temporal bone, and is divided into fine filaments, supplying the vestibule and cochlea of the ear. See EAR and ACOUSTICS.

Audley, Sir JAMES: follower of the Black Prince, and one of the original knights of the order of the Garter; displayed such courage in the battle of Poitiers in 1356, in which he was wounded, that the Black Prince immediately retained him as his own knight, and later appointed him Governor of Aquitaine. D. at Fontenay-le-Comte in 1369.

Audley, THOMAS, LORD AUDLEY OF WALDEN: an English lawyer; b. in Essex in 1488. He became Speaker of the House of Commons in 1529, Keeper of the Great Seal in 1532, and Lord Chancellor of England in 1533. He presided at the trial of Sir Thomas More. According to some authorities, he disgraced himself by his subservience to the arbitrary

will of Henry VIII. D. in London, Apr. 30, 1544. See Lord Campbell, *Lives of the Lord Chancellors*.

Audouin, ô'doō-an', JEAN VICTOR: an eminent French naturalist and comparative anatomist; b. in Paris, Apr. 27, 1797. He was one of the founders of the *Annales des Sciences Naturelles*, first issued in 1824, and co-operated with Milne-Edwards in researches into the *Crustacea* and *Annelida*. He succeeded Latreille as Professor of Entomology at the Museum in 1833, and was chosen a member of the Institute in 1838. Among his works is a *History of the Insects which Infest the Vine* (1840-43). D. in Paris, Nov. 9, 1841.

Audran, ô'dran, EDMOND: opera-composer; b. at Lyons, France, Apr. 11, 1842; educated at the École Niedermeyer, Paris; in 1861 organist of St. Joseph church, Marseilles; composed overtures, marches, masses, and motets, but achieved his greatest fame as a composer of light operas, which are almost as well known in England and the U. S. as in France. His best as well as best-known works are *Olivette* (Paris, 1879; London, 1880); *The Mascot* (Paris, 1880; London, 1881); and *Gillette de Narbonne* (Paris, 1882; London, 1883). D. E. HERVEY.

Audran, GÉRARD: a French engraver of the first order; b. at Lyons, Aug. 2, 1640. He studied under Carlo Maratti at Rome for several years, and returned to Paris about 1670. Having been appointed engraver to the king, he engraved for him the masterpieces of Le Brun, *The Battles of Alexander*. Among his works are two cartoons of Raphael, representing the *Death of Ananias* and *Paul and Barnabas at Lystra*, and *Coriolanus*, after Poussin. D. in Paris, July 26, 1703. (See Strutt, *Dictionary of Engravers*.)—Others of the Audran family attained eminence as engravers: as Benoît (1661-1721); Claude père (1592-1677); Claude fils (1640-84); Germain (1631-1710); and Jean (1667-1756).

Audubon: railroad junction: capital of Audubon co., Ia. (see map of Iowa, ref. 5-E, for location of county); is in Le Roy township; a stock-raising and farming region. Pop. (1880) 792; (1885) 1,152; (1890) 1,310; (1900) 1,866.

Audubon, JOHN JAMES: naturalist; b. near New Orleans, La., May 4, 1780. He was the son of an opulent French naval officer who owned a plantation in the then French colony. In his childhood he became deeply interested in the study of birds and their habits. He was educated partly in Paris, whither he was sent about 1794, and he studied design under David, the eminent painter. He returned to the U. S. about 1798, and settled on a farm which his father gave him, on the Perkiomen creek, in Eastern Pennsylvania. Here he found time and opportunity for his favorite study. He married Lucy Bakewell in 1808, sold his farm, and became a merchant at Louisville, Ky. About 1810 he began to make extensive excursions through the primeval forests of the Southern and Southwestern States, in the exploration of which he passed many years. He made colored drawings of all the species of birds that he found. He resided with his wife and children for several years at Hendersonville, on the Ohio river. In 1824 he visited Philadelphia, where he met Charles Lucien Bonaparte, who encouraged him to publish a work on ornithology. Before this date he is said to have failed in trade and been reduced to poverty, and to have successively followed the occupation of portrait-painter and dancing-master. He went to England in 1826, and commenced in London the publication of his great work, for which he obtained a large number of subscribers at \$1,000 a copy. This admirable work was entitled *The Birds of America* (10 vols. folio, 1830-39), and was illustrated with 448 beautiful colored plates of 1,065 species of birds, of the natural size. The work is divided into five volumes of letterpress, and five of engravings designed by the author. This was pronounced by Cuvier "the most magnificent monument that art ever raised to ornithology." Audubon returned to America in 1829, and again explored the forests, lakes, and coasts from Canada to Florida to collect materials for another work. This was his *Ornithological Biography, or an Account of the Habits of the Birds of the United States, etc.* (Edinburgh, 5 vols., 1831-39). He revisited England in 1831, and returned home in 1839, after which he resided at Minniesland, now called "Audubon Park," on the Hudson river, now part of the city of New York. He published a cheaper edition of his *Birds of America* (7 vols. 8vo, 1844), and was associated with Dr. Bachman in the preparation of a work on *The Quadrupeds of North America*, with plates (6 vols., 1846-50), the drawings of

which were made by his sons, Victor Gifford and John Woodhouse Audubon. He died in New York city, Jan. 27, 1851. See *Life and Adventures of John J. Audubon*, edited, from materials supplied by his widow, by Robert Buchanan (New York, 1867-69).

Auenbrugger (ow'en-bröoch'-ger) von Au'enbrug', LEOPOLD (called AVENBRUGGER by the French): a German physician who introduced percussion of the chest as a means of diagnosis; b. at Gratz, in Styria, Nov. 19, 1722. He studied at Vienna, and practiced there. He announced his discovery in a work called *Inventum novum ex Percussione Thoracis Humani* (New Discovery by the Percussion of the Human Chest, 1761). D. in Vienna, May 17, 1809.

Auer, ow'er, ALOIS: b. in Wels, Austria, May 11, 1813; learned the printer's trade; occupied himself with the study of languages; 1841 appointed director of the state printing establishment in Vienna; discovered spontaneous impression, or nature-printing, in photography, and invented several presses. Author of *Discovery of Spontaneous Impression* (1854); *History of the Vienna State Printing Establishment* (1851); issued the Lord's Prayer in 603 languages in Roman type (1844); and the same in 200 languages with the national alphabets (1847). D. in Heitzing, near Vienna, July 10, 1869. C. H. T.

Auer, JOHN GOTTLIEB, D. D.: second missionary bishop of Cape Palmas and parts adjacent, on the west coast of Africa; b. at Neubulach, in Württemberg, Nov. 18, 1832. After studying several years at the mission school at Basel, Switzerland, he became (1858) a missionary at Akrapong, among the Akrapim Mountains, in Africa. In 1862 he connected himself with the American Episcopal mission at Cape Palmas, and was ordained deacon and priest on Apr. 20, 1862, by Bishop John Payne, whom he succeeded Apr. 17, 1873. D. at Cavalla, in Africa, Feb. 16, 1874.

W. S. PERRY.

Auerbach, ow'er-baach, BERTHOLD: German author; very popular during his lifetime; b. at Nordstetten in the Black Forest, Württemberg, Feb. 28, 1812. He was intended for the synagogue, and was educated at Carlsruhe, Tübingen, Heidelberg, and Munich universities, but at eighteen announced his intention of devoting himself to literature. His earliest work was *Judaism and Modern Literature*, but his merit was not recognized until he issued his *Village Tales of the Black Forest*. During the Franco-Prussian war he was correspondent for one of the Berlin papers. Among his novels are *Baarfüssle*, *Edelweiss*, *On the Heights*, *Joseph in the Snow*, and *Waldfried* (1874). *The Professor's Lady* is perhaps his most characteristic work. In all his writings the influence of Spinoza can be traced, whose works he translated into German. D. at Cannes, Feb. 8, 1882.

Auersperg, ow'ers-perkh, Prince ADOLPH WILHELM DANIEL: b. July 21, 1821; a son of Prince Wilhelm Auersperg and brother to Prince Carlos; entered the army very early, and was a major in Prince Eugene's dragoons when he left the military service in 1870. In 1867 he was elected a member of the Bohemian Diet, and in the same year was appointed president of the assembly on the resignation of Count Hartig. In 1868 he was elected a member for life of the upper chamber of the Austrian Reichstag, and in 1870 was made governor of Salzburg. Finally he succeeded Count Beust as president of the Austrian ministry, Nov. 25, 1871. Like his brother, who at an earlier date was president of the Cisleithan ministry, he represented the German interest in Austria, and supported the present organization of the empire, established by Benst, and comprising an Austrian division, in which the German element predominates, and a Hungarian, in which the Magyars rule. In 1879 he became president of the highest chamber of accounts. D. in his castle, Goldegg, near Vienna, Jan. 5, 1885.

Auersperg, ANTON ALEXANDER, Count von: a German poet whose *nom de plume* was ANASTASIUS GRÜN; b. at Laybach, April 11, 1806. He displayed much wit and humor in a poem called *Spaziergänge eines Wiener Poeten* (Promenades of a Poet of Vienna, 1831). Published a volume of poems (*Gedichte*, 1838), which must be considered the principal work of his life. An ardent promoter of liberal ideas in feudal Austria, he died at Graz, Sept. 12, 1876. Revised by JULIUS GOEBEL.

Auersperg, Prince CARLOS WILHELM: an Austrian statesman; b. May 1, 1814. In 1867-68 he was president of the

Cisleithan ministry. He was a member of the Reichstag, of which he was president, and of the Bohemian Diet, where he acted with the German party. D. in Prague, Jan. 4, 1890.

Auerstädt, ow'er-stet: a village of Prussian Saxony, 10 miles W. of Naumburg (see map of German Empire, ref. 5-F), noted as the scene of an important victory gained by the French general Davoust over the Prussians, commanded by the Duke of Brunswick, Oct. 14, 1806, which was also the date of the battle of Jena.

Au'fidus: the name of an ancient river in Italy, near the mouth of which was fought the great battle of Cannæ, 216 B. C. See OFANTO.

Aufrecht, ow'frect, THEODOR: Orientalist; b. at Leschnitz, Upper Silesia, Jan. 7, 1822; became Professor of Sanskrit at Edinburgh 1862, at Bonn 1875; retired to live at Heidelberg 1889. He published at Berlin, 1861-63, the *Hymns of the Rig-Veda* (see SANSKRIT LITERATURE), the first complete edition of this great monument (Max Müller's, begun in 1849, was finished in 1874). Besides many other important works, Aufrecht published a catalogue of the Sanskrit MSS. in the Bodleian Library (Oxford, 1864), and *Catalogus Catalogorum, an Alphabetical Register of Sanskrit Works and Authors* (Leipzig, 1891). C. R. LANMAN.

Au'geas (in Gr. *Αὔγέας* or *Αὐγέας*): a mythical King of Elis, who is said to have owned 3,000 oxen. One of the twelve labors imposed on Hercules by Eurystheus was to cleanse in one day the Augean stables, in which the dung of these oxen had accumulated for many years. Hercules turned the river Menios or Alpheus through the stables, and killed Augeas because he refused to pay his wages, which was one-third part of the herd.

Augereau, ô'zher-ô', PIERRE FRANÇOIS CHARLES (DUC DE CASTIGLIONE): a French marshal; b. in Paris, Nov. 11, 1757; became a fencing-master at Naples before the Revolution; enlisted as a private in the French army in 1792, and gained the rank of general of division in 1796. In 1796 he contributed to the victories of Lodi, Castiglione, and Arcola. He enforced the will of the majority of the Directory in the *coup d'état* of the 18th Fructidor of the year 5 (Sept. 4, 1797), and was chosen a member of the Council of Five Hundred in 1799. He became a marshal of France in 1804, Duke of Castiglione in 1805, served with distinction at Jena in 1806, and was wounded at Eylau in 1807. In 1813 he displayed intrepid courage at Leipzig. He transferred his allegiance to Louis XVIII. in 1814. D. in La Houssaye, June 12, 1816.

Au'gian Co'dex: a defective uncial manuscript of the Pauline Epistles; was found in the monastery of Augia Dives or Major, at Reichenau, Lake Constance, Switzerland; was purchased by Dr. Bentley in 1718, and is now in Trinity College, Cambridge. It is known as F in the list of uncials of the N. T., has the Latin Vulgate in parallel columns to the Greek, and dates from the ninth century. Scrivener issued a transcript of it, Cambridge, 1859. See F. H. A. Scrivener's *Introduction*, pp. 167-69; C. R. Gregory, *Prolegomena*, pp. 424-26.

Augier, ô'zheë-ay', GUILLAUME VICTOR ÉMILE: French dramatist; b. at Valence, Sept. 17, 1820; has contributed a great number of pieces to the modern French stage. His first success was *La Ciguë*, represented at the Odéon in 1844. In 1848 his play *L'Aventurière*, after the manner of the Romantic school, was acted with great success, and is still by many considered his masterpiece. In 1849 *Gabrielle* was not merely a great success upon the stage, but also obtained from the French Academy the Montyon prize because of its moral tendency. Other plays by Augier are *Le Gendre de M. Poirier*, written with M. J. Sandeau in 1855; *Maître Guérin* (1864); *Paul Forestier* (1868); *Jean de Thommeray* (1873); *Madame Caverlet* (1876); *Les Fourchambault* (1875). Augier became a member of the French Academy in 1857. He is the chief representative of the school of French dramatists which, succeeding the Romanticists, gave up the extravagances of these, though not striving for the complete realism of the moderns. Thus his dramas have generally a moral or political tendency. D. at Croissy, Oct. 25, 1889. A. R. MARSH.

Au'gite [from Gr. *ἀγίτης*, name of a stone; *ἀγλή*, luster]: a crystalline mineral sometimes called **Pyroxene**, is nearly allied to hornblende. It often occurs in volcanic rocks, is composed of silica, lime, and magnesia, and is usually of a greenish color. It crystallizes in six or eight sided prisms

variously modified, and is an essential component of basalt, dolerite, and augite porphyry.

Augs'burg (anc. *Augusta Vindelicorum*): an ancient and important city of Germany, in Bavaria; capital of the province of Swabia and Neuburg; is situated on the river Lech, at the mouth of the Wertach, 39 miles by rail W. N. W. of Munich; lat. 48° 21' 42" N., lon. 10° 54' 16" E. (see map of German Empire, ref. 7-E). Several railways extend from it toward the four cardinal points, and connect it with Munich, Nuremberg, etc. The Roman Emperor Augustus planted a colony here in 12 B. C. It became a free imperial city in 1276, after which it was an important commercial emporium. This city was also one of the chief centers of German art, and the native place of Holbein. It was also the native place of the Fugger family, at one time the richest family in Europe. Some decline in its prosperity occurred after 1500, but it still has an extensive trade and many large manufactories of cotton, silk, machinery, and paper. Augsburg is one of the principal money-markets of the Continent, and owes much of its importance to its banking business and operations in stocks. The *Allgemeine Zeitung*, issued in Augsburg, is one of the most celebrated and widely circulated journals of Germany. Pop. (1895) 80,798, one-third Protestant.

Augsburg Confession: the first Protestant Confession of Faith; presented to the Emperor Charles V. at the Diet of Augsburg, June 25, 1530. When the Elector John of Saxony was summoned to the Diet, he requested the Wittenberg theologians, Luther, Melancthon, Jonas, and Bugenhagen, to prepare a paper setting forth the complaints to be made concerning abuses in the Church. This was done by them with considerable haste in the memoranda known as the Torgau Articles, from the name of the place where the last notes were made. Portions of these memoranda were elaborated with great care. Other portions consist simply of disjointed words and phrases, intended to suggest the thought to the composer. These articles may be found in English in the *Book of Concord*, Jacobs, Philadelphia, 1883, vol. ii., pp. 75-98.

Luther having been left at Coburg, Melancthon accompanied the Elector of Saxony to Augsburg as his chief theological adviser. As they reached Augsburg on May 2, and the emperor delayed appearing until June 15, abundant time was given by Melancthon, in consultation with Jonas, Regius, Osiander, Brenz, and other theologians, and the princes and representatives of the states and free cities, to formulate the confession. A pamphlet of Dr. Eck having been found in circulation, charging the Lutherans with some of the gravest heresies that had ever appeared, and confounding their doctrines with those of the Reformed and Anabaptists, rendered it necessary for Melancthon to formulate an explicit and complete statement of the doctrines taught by the Lutherans. The Confession therefore consists of two parts. The Articles on Abuses, prepared on the basis of the Torgau Articles, constitute about two-thirds of the Confession. To this were prefaced twenty-one doctrinal articles. Of these the last two are based on the Torgau Articles, and the other articles principally upon the Marburg Articles, revised at Schwabach in Oct., 1529. These articles may also be found in English in the volume above mentioned, pp. 69-74. During the preparation of the Confession it was repeatedly submitted in rough drafts to Luther and approved by him, and discussed sentence by sentence before the princes and theologians. The introduction was written by the Saxon Chancellor Brück. It was read in German before the emperor, and given to him in both German and Latin. Both of the originals soon disappeared. As, during the preparation, numerous transcripts had been made, and unauthorized editions at once appeared, Melancthon prepared an edition in both German and Latin, which was printed even before the adjournment of the Diet, but not issued until the following year. Melancthon afterward undertook in editions published in 1540 and 1542 to make radical changes in the interests of Church union upon a less definite doctrinal basis. These editions are known as those of the *Variata*, in distinction from the *editio princeps* of 1531, known as *Invariata*. The latter alone has symbolic authority in the Lutheran Church, the former being only an interesting private document, and, with the exception of the parts intended to affect the terms of confessional obligations, an important exposition and defense of the original document. Dr. Schaff has given a correct estimate of it: "It best exhibits the prevail-

ing genius of the German Reformation, and will ever be cherished as one of the noblest monuments of faith from the pentecostal period of Protestantism." It formed the basis not only of ecclesiastical but also of political guarantees, the Reformed, until the Peace of Westphalia (1648), enjoying toleranee in Germany, according to the terms of the Peace of Augsburg (1555), only because of a certain degree of agreement with the Augsburg Confession. The efforts of Henry VIII. of England, from 1535 on, to enter the Smalcald League were met by the Lutheran princes with the presentation of the Augsburg Confession and its Apology for adoption as the necessary ecclesiastical preliminary for civil negotiations. This led to protracted conferences concerning the Augsburg Confession and discussions of its articles, in connection with which English theologians (Fox, Heth, and Barnes) were sent to Wittenberg, and Lutheran theologians (Myconius, etc.) were sent to England. The Thirty-nine Articles, and the various confessions framed after them, have their historical origin in these negotiations. (See Jacobs, *The Lutheran Movement in England*, Philadelphia, 1891.) The earliest translation of the Augsburg Confession into English was made by Richard Taverner, the translator of the Bible, in 1536; republished in Philadelphia, 1888. The most recent is the thorough revision, on the basis of Taverner, prepared for the Common Service for English-speaking Lutherans, and published first in the *Church Book of the General Council*, Philadelphia, 1891.

LITERATURE.—In English: Krauth, *Augsburg Confession, with Notes* (1868); *The Conservative Reformation and its Theology* (1871); *A Chronicle of the Augsburg Confession* (1878); Jacobs, *The Book of Concord, with Historical Introductions*, etc. (1882-83); Schaff, *Creeeds of Christendom*, vol. iii. (1877); B. M. Schmucker, *English Translations of the Augsburg Confession* (1887). In German: G. L. Plitt, *Einleitung in die Augustana* (1867); O. Zöckler, *Die Augsburgische Konfession als Symbolische Lehrgründe* (1870); A. W. Vilmar, *Die Augsburgische Konfession erklärt* (1870). Among the earlier commentators, Carpzov, *Isagoge in Libros Symbolicos*, will be found most satisfactory.

HENRY E. JACOBS.

Au'gur: among the ancient Romans, a soothsayer, a diviner, a person who professed to foretell events by the flight of birds or other omens. The augurs were supposed to be capable of interpreting the will of the gods, and divinely gifted with special qualifications for this service. Their office was considered as very important in the state, no public enterprise being undertaken unless they declared the omens favorable. Their divinations were called auguries or auspices, the latter of which terms, though properly applied to the inspection of the flight of birds, was extended by the Roman writers to other signs. In the earliest period of Roman history the number of augurs was only two, one from each of the tribes, Ramnes and Tities; in 300 B. C., when the Ogulnian law was passed, there were four, who must be patricians. The law rendered the plebeians eligible to the office of augur, and increased the number to nine. Sulla increased the number to fifteen; Julius Cæsar appointed a sixteenth, but after him the college remained at fifteen. The augurs held office for life, and had the power of filling vacancies that occurred in their college.

Revised by S. M. JACKSON.

Augur, CHRISTOPHER COLON: soldier; b. 1821 in New York; graduated at West Point in 1843; in infantry till Mar. 4, 1869, when he became brigadier-general U. S. army. He served chiefly at frontier posts 1843-61, in the military occupation of Texas 1845-46, in the war with Mexico 1846-48, engaged at Palo Alto, Resaca de la Palma, and as aide-de-camp to Brig.-Gens. Hopping and Cushing, scouting and on expeditions against Northern Pacific Indians 1855-56, engaged in several skirmishes, and as commandant of cadets at Military Academy 1861. In the civil war became, Aug. 9, 1862, major-general U. S. Vols., and served in the defenses of Washington 1861-62, in operations on Rappahannock and in the Shenandoah valley 1862, in command of a division in the Fifth Corps 1862, engaged at Cedar Mountain (severely wounded and brevet colonel), in Gen. Banks's expedition to New Orleans 1862; in command of the district of Baton Rouge 1863, in expedition to Port Hudson 1863 (brevet brigadier-general), engaged in action and siege of the place; in command of department of Washington 1863-66, of the Platte 1867-71, and of Texas from 1871. Brevet major-general Mar. 13, 1865, for gallant and meritorious services in the field. Retired July 10, 1885. D. Jan. 16, 1898.

Augur, HEZEKIAH: sculptor; b. at New Haven, Conn., Feb. 21, 1791; was also noted for mechanical ingenuity. He invented a carving-machine which is in general use, and as sculptor produced *Jephthah and his Daughter*. D. at New Haven, Jan. 10, 1858.

August [Lat. *Augustus*; in Fr. *août*]: the eighth month of the year, so named in honor of Augustus Cæsar. Before his time it was called *Sextilis*—that is, the sixth month, because the Roman year once began on the 1st of March. In the calendar of Julius Cæsar the first, third, fifth, seventh, ninth, and eleventh months consisted each of thirty-one days, and each of the other months of thirty, except February, which in common years had twenty-nine, and in leap-year thirty days. To gratify the vanity of Augustus, one day was taken from February and added to August.

Augusta: a seaport of Sicily. See AGOSTA.

Augusta: city and important railroad and commercial center; county-seat of Richmond co., Ga. (for location of county, see map of Georgia, ref. 3-J); the third city in size in the State; situated on the left bank of the Savannah river, 231 miles from its mouth, 120 N. N. W. of Savannah, and 136 N. W. of Charleston. It is at the head of steamboat navigation on the Savannah. Lat. 33° 28' N., lon. 81° 54' W. From its position it is actively engaged in the cotton-trade, receiving annually about 200,000 bales from a considerable portion of Georgia and South Carolina. Augusta also furnishes a good market for the general produce of its region. For many years it was the center of the wagon-traffic, sending out goods in all directions in the great lumbering wagons of that time, and receiving cotton and produce in return. After the railroads began to break up this trade the city declined for a time, but soon regained its trade, and is now enterprising and prosperous. The Augusta canal brings the waters of the Savannah river from above the city at such an elevation as to give a head of water-power of 33 feet.

Manufactures.—Augusta is one of the largest manufacturing centers of the South. The census of 1890 showed 417 manufactories; capital, \$7,075,996; average number of hands employed, 5,861; wages paid during the year, \$1,886,807; value of products, \$8,631,888. The city has now cotton-mills alone valued at nearly \$6,000,000, besides the Graniteville and Langley cotton-mills (across the river in South Carolina), which are practically a part of its manufacturing system. These cotton-factories employ 4,500 hands; pay \$1,000,000 in annual wages; operate 5,419 looms and 213,114 spindles, which spin annually 80,000 bales of cotton into 85,000,000 yards of cloth and 3,000,000 lb. of yarn, worth in the aggregate over \$6,000,000. These factory-buildings are very handsome, two of them being worth over \$1,000,000 each. Here are also extensive manufactures of fertilizers, flour, iron, lumber, ice, cotton-seed oil, tobacco, etc.

Education, etc.—Augusta has a medical school, the Medical College of Georgia, founded in 1830, a department of the State University at Athens. It has also an incorporated academy called the Richmond Academy, the Paine Institute, a private normal school, 3 high schools (one for colored pupils), and numerous grammar, intermediate, and primary schools. The city has 2 hospitals connected with the medical college, a Masonic hall, the Augusta Orphan Asylum, richly endowed, 2 Roman Catholic orphan asylums, a widows' home, and other charitable institutions.

Public Buildings and Monuments.—Among the principal are the city-hall, Odd Fellows' hall, the Masonic hall, Richmond Academy, the medical college, the opera-house, Independence and Confederate monuments, and several of the churches.

Streets, Avenues, etc.—These are spacious and elegant. The principal streets, Broad and Greene, have double rows of wide-spreading trees on each side of the commodious highways. Broad Street is paved with asphalt, and is 120 feet wide. The residences on lower Broad and Greene and other streets are tasteful and elegant. The streets cross each other at right angles. There is a well-regulated police force. The city cemetery, the Park, and the Augusta Exposition grounds near the city, are laid out in fine walks and drives, and are favorite places of resort. There is a horse-railroad from the city to Summerville, a beautiful suburb, which is one of the most noted resorts in the South for winter tourists and invalids. Water is supplied to the city from the Augusta canal, which has been enlarged and its power greatly increased. Augusta is lighted with electric lights. Pop. (1880) 21,891; (1890) 33,300 (a police census taken immediately afterward showed several thousand more); (1900) 39,441.

History.—Augusta was settled by English colonists under Oglethorpe, and laid out in 1735 under royal charter, and was named in honor of an English princess. It was again chartered in Jan., 1798, and incorporated as a city in Dec., 1817. It was for many years the most important inland town of the colony. It had acquired a considerable trade at the commencement of the Revolutionary war, but in the beginning of 1779 was captured by the British and loyalists, who held possession of it till the spring of 1781, when the British force there was commanded by a loyalist named Brown. On May 23, 1781, an American force under command of Gen. Henry Lee ("Light Horse Harry") laid siege to it, and on June 5 Brown surrendered. The Americans lost 51 killed and wounded; the British lost 52 killed, and 334, including the wounded, were taken prisoners. Augusta was the capital of Georgia for a number of years after the Revolutionary war. During the war of 1812 or the Indian wars it was not molested. In the civil war it was garrisoned by the Confederate troops, and twice threatened by Sherman—in his march to the sea, when he passed between it and Macon; and in his march through the Carolinas, when he made feints against both Augusta and Charleston—but it was not visited by a hostile force. PRESIDENT OF "THE CHRONICLE."

Augusta: town (founded in 1830); on C., B. and Q. R. R.; Hancock co., Ill. (for location of county, see map of Illinois, ref. 5-B); 37 miles N. E. of Quincy; has public schools and 3 churches. Its principal industries are stock-raising, farming, coal-mining, and flouring. Fine potter's clay and mineral paint are produced. Pop. (1880) 1,015; (1890) 1,077; (1900) 1,149. EDITOR OF "EAGLE."

Augusta: city; Butler co., Kan. (for location of county, see map of Kansas, ref. 7-H); 150 miles S. W. of Topeka, the State capital; is in a wheat-growing district. Pop. (1880) 922; (1890) 1,343; (1900) 1,197.

Augusta: city; Bracken co., Ky. (for location of county, see map of Kentucky, ref. 2-I); on railroad and on the Ohio river, 45 miles above Cincinnati; has 2 public schools, 2 private schools, a flouring-mill, a saw and planing mill, a harness-supply factory, 23 leaf-tobacco warehouses, and 2 newspapers. Pop. (1870) 960; (1880) 1,282; (1890) 1,447; (1900) 1,718. EDITOR OF "CHRONICLE."

Augusta: city; capital of the State of Maine, and seat of justice of Kennebec co. (for location of county, see map of Maine, ref. 9-C); on the Kennebec river, at the head of tidal navigation, 43 miles from its mouth, and 63 miles by railroad N. N. E. of Portland; lat. 44° 19' N., lon. 69° 50' W. The main division of the Maine Central R. R. passes through it.

State Capitol, Augusta, Me.

The chief part of the city is on the right (west) bank of the river, and many of the residences stand on ground which is much higher than the river. The State-house is a handsome granite structure, rebuilt and enlarged in 1890 at a cost of \$150,000. Among the public institutions are a hospital for the insane, a U. S. arsenal, and St. Catharine's school for young ladies. Augusta has abundant water-power, which is employed in manufactures of cotton-goods, paper, wood-pulp,

and lumber. The city has a free library and the Maine State Library. The National Military Asylum is outside the city limits. Nearly all the business portion of Augusta was consumed by fire in Sept., 1865. The city is growing rapidly, has fine water-works, electric light, electric street-railway, etc. A U. S. building, for post-office, pension office, U. S. court, etc., was erected in 1889 at a cost of \$191,000. Pop. (1870) 7,808; (1880) 8,665; (1890) 10,527; (1900) 11,683.

EDITOR OF "KENNEBEC JOURNAL."

Augusta: city; on C., St. P., M. and O. R. Rs.; Eau Claire co., Wis. (for location of county, see map of Wisconsin, ref. 4-C); 22 miles E. S. E. of Eau Claire; is situated in an agricultural and lumber region. Pop. (1880) 1,116; (1890) 1,187; (1900) 1,256.

Augustan Age: the reign of Augustus, first Emperor of Rome, under whom Roman literature reached its highest development. Ovid, Horace, Cicero, Vergil, and Catullus, are among the famous names of this period.

Augustana College and Theological Seminary: founded in Chicago in 1860; removed to Paxton, Ill., in 1863, and to Rock Island, Ill., in 1875. It is the educational center of the Lutheran Augustana Synod, and comprises six departments of instructions—theological, collegiate, preparatory, musical, commercial, and normal—with 27 professors and 575 students. It has a museum, and a library of 16,000 volumes and pamphlets. The seminary is designed to train young men for the Lutheran ministry. The collegiate instruction embraces the usual classical and scientific courses as well as post-graduate study. Presidents: L. P. Esbjoru, 1860; T. N. Hasselquist, 1863; O. Olsson, 1891-1900.

Augustan History: a collection of biographies of the Roman emperors, from Hadrian to Numerianus and Carinus, i. e. from 117-284, which in the MSS. bears the title *Vite diversorum principum et tyrannorum a divo Hadriano usque ad Numerianum a diversis compositæ*. While containing much valuable information, the biographies are uncritical, ill-arranged, with no sense of proportion, full of trivial anecdotes, and with no pretension to style or classical correctness. The work appears to have been compiled at the end of the third and the beginning of the fourth century by six writers, namely: Ælius Spartianus, Julius Capitolinus, Vuleacius Gallicanus, Trebellius Pollio, Ælius Lampridius, and Flavius Vopiscus. Of these writers no biographical details are known, and their very existence has recently been called in question by scholars who would brand the whole collection as the forgery of one individual, a view, however, which has been sufficiently refuted by E. Klebs in the *Rheinisches Museum* for 1892, vol. xlvii., pp. 1-52 and 515-549. Best edition by H. Peter (Leipzig, 1884). M. WARREN.

Augusti, JOHANN CHRISTIAN WILHELM: b. at Eschenberga, near Gotha, Germany, Oct. 27, 1772; studied at Jena, where he became a professor extraordinary in 1800, Professor of Oriental Literature in 1803, and Professor of Theology in 1807. In 1812 he became Professor of Theology at Breslau, and in 1819 at Bonn. In 1833 he became director of the Conservatory at Coblenz, where he died, Apr. 28, 1841. He was a man of great learning, an orthodox conservative Lutheran. His writings are valued as books of reference, though they are not without serious faults. His best-known works are *Denkwürdigkeiten aus der christlichen Archäologie* (12 vols., Leipzig, 1817-31); *Handbuch der christlichen Archäologie* (3 vols., 1836-37). He published various other works, historical and dogmatical.

Revised by S. M. JACKSON.

Au'gustine (in Lat. *Aurelius Augustinus*), SAINT: the most eminent of the Latin Fathers of the Church; b. at Tagaste, in Numidia, Nov. 13, 353 A. D. He was a son of a pagan father and a Christian mother (Monica or Monnica), an excellent and devout woman, by whom he was instructed in religion. Educated at the best schools of Madaura and Carthage, he learned rhetoric, the Greek language, philosophy, etc. When, at the age of seventeen, he entered the great city of Carthage to complete his education, he was an eager, ambitious student and a youth of ardent passions, with a propensity to sensual pleasure. About the age of nineteen he embraced the doctrines of the Manichæans, and returned to Tagaste, where he taught rhetoric and grammar. He adhered to Manichæism about nine years, during part of which he lectured on rhetoric at Carthage. In the meantime his mother, by her prayers and exhortations, strove to convert him to Christianity, without success. He wrote at Car-

thage in his twenty-seventh year a treatise, *De Apto et Pulchro*, which is not extant. At length he perceived that the mystical phrases and futile speculations of the Manichæans were not capable of satisfying the wants of his spiritual nature. Much perplexed with doubts and unrest, he removed in 383 to Rome, and thence to Milan, where he was appointed Professor of Rhetoric in 384. He was deeply interested in the Platonic philosophy, and after he renounced Manichæism studied the Bible from a Platonic point of view. The sermons of St. Ambrose, then Bishop of Milan, made a deep impression on him, and after severe spiritual conflicts he became a Christian and was baptized on Easter Eve, 387. In 388 he went back to Tagaste, was ordained presbyter at Hippo in 391, associate bishop in 395, and bishop in 396. Among his earlier writings was a treatise against the Manichæans (*De Genesi contra Manichæos*), and *On True Religion (De Vera Religione)*. He published about 397 his *Confessions*, in thirteen books, a very interesting autobiography. He was a zealous opponent of Pelagianism, against which he wrote two treatises, entitled *On the Grace of Christ* and *On Original Sin*. Semi-Pelagianism was opposed by him, in 428, in two famous treatises on *Predestination* and on *Perseverance*. He also wrote vigorously against the Donatists. He finished about 426 a work, *De Civitate Dei* (On the City of God), which is regarded as the greatest monument of his genius and learning. One aim of this book was to vindicate the Christian faith against those pagans who asserted that the capture of Rome by Alaric and other calamities were consequences of the prevalence of the new religion. Near the end of his life he wrote the *Retractationes*, in which he reviewed carefully all his own works. Other important treatises are the *De Doctrina Christiana* and the *De Trinitate*. He left behind him also exegetical treatises, sermons, and letters in great number. The best edition of his works is that published by the Benedictines at Paris (11 tom. in 8 vols. fol., 1679-1700). He died at Hippo while that city was besieged by the Vandals, Aug. 28, 430. His character and writings exerted an immense and durable influence on the Church. "Of all the Fathers of the Latin Church," says Villemain, "St. Augustine manifested the most imagination in theology, the most eloquence, and even sensibility, in scholasticism." For learning his reputation is not so high. He was a poor Greek scholar, and knew nothing of Hebrew. See the biography in Latin by Possidius (the original source, written 432, in Benedictine edition), the Benedictine editors (in their edition very elaborate), and by G. Moringo (Antwerp, 1533); in French by L. S. Le N. de Tillemont (*Mémoires ecclésiastiques*, tom. xiii.) and J. J. F. Poujoulat (Paris, 1844, 3 vols.; 5th ed. 1866, 2 vols.); in German by F. A. G. Kloth (R. C.; Aachen, 1840, 2 vols.) and C. Bindemann (Protestant; Berlin, 1844-69, 3 vols.); in English by W. R. Clark (London, n. d.) and Philip Schaff (New York, 1886) —there is an English trans. of his chief works (Edinburgh, 1872-76, 15 vols.), ed. by Philip Schaff, reprinted and enlarged (New York, Christian Literature Company, 1886-88, 8 vols.).

Revised by S. M. JACKSON.

Augustine, or Austin, SAINT: the "apostle of England" and first Archbishop of Canterbury. He was a Benedictine monk, connected with a monastery in Rome, when he was sent by Pope Gregory I. to convert the Anglo-Saxons, in 596 A. D. He was received amicably by King Ethelbert, whose wife Bertha was already a Christian. He converted Ethelbert, and is said to have baptized 10,000 of his subjects. Augustine was consecrated archbishop at Arles in France by the Metropolitan of Arles, Vergilius. Seeking an interview with the British bishops who claimed a direct succession from the apostles' days, seven of these prelates met Augustine on the borders of Wessex, accompanied by the monks from the great monastery of Bangor and a large number of British priests. These bishops refused to admit the primacy of Augustine, and the results of the conference were far from being satisfactory to either party. The permanent results of the labors of Augustine were limited to the kingdom of Kent, where they began. D. at Canterbury, May 26, 607. See W. F. Hook's *Lives of the Archbishops of Canterbury*. W. S. PERRY.

Augustinian Monks: a monastic order of the Roman Catholic Church. This order was formerly divided into three classes, of which two still remain: 1. *Canons Regular*. —This class of ecclesiastics originated at Avignon in the year 1038, by authority of Bishop Benedict of Avignon. They were called Canons Regular because their ranks were

recruited from the lay and clerical canons who had not previously taken monastic vows. They assumed the name and rule of Augustine in 1139. They had 170 houses in England and 28 in Scotland. 2. The so-called *Hermits of St. Augustine*, one of the four great mendicant orders of the Church. This body incorrectly claims to have been founded by St. Augustine. Its true origin was in 1256, when Pope Alexander IV. compelled eight small bodies of Italian monks to unite in one order under the rule of St. Augustine, and exempted them from the jurisdiction of bishops. The Hermits of St. Augustine have now about 200 houses. They are much diminished in importance. *The Special Congregations* consisted of those Augustinians who desired a severer rule and better discipline than commonly prevailed in the order. Martin Luther was a member of the Special Congregation of Saxony. 3. *The Barefooted Augustinians* originated in 1582, by command of the King of Spain. They have a very severe rule. The number of monasteries in 1860 was about fifteen. This class is nearly or quite independent of the former.

Augustinian Nuns date themselves back to the company of nuns gathered at Hippo by Perpetua, the sister of Augustine. They are now of four classes: First, those under the guidance of Augustinian monks; secondly, those under the control of diocesan bishops; thirdly, barefooted nuns; fourthly, Augustines of the Interior of Mary. See Migne's *Dictionnaire des ordres Religieux*, tom. iv.; Dugdale, *Onomasticon*, vi. 37.

Augustulus, ROMULUS: the last Roman emperor of the West; a son of Orestes, a rich patrician. He obtained the title of emperor in 475 A. D., and was deposed by Odoacer in 476.

Augustus: a Latin word equivalent to the Gr. *Σεβαστός*, and signifying "majestic," "sacred," "venerable." It was a name or surname conferred on Caius Julius Cæsar Octavianus by the Roman Senate, 27 B. C.

Augustus (or August) I.: Elector of Saxony; a son of Henry the Pious; b. at Freiberg, July 31, 1526, and succeeded his brother Maurice in 1553. He was an intolerant promoter of Lutheranism, and persecuted the Calvinists, but was a liberal patron of learning, and under his administration the manufactures, agriculture, and commerce of the country were greatly promoted and improved; he also introduced some valuable reforms in jurisprudence. He was chiefly instrumental in negotiating the peace of Angsburg (1555). He died at Dresden, Feb. 12, 1586, and was succeeded by his son, Christian I.

Augustus II. of Saxony (and Augustus I. of Poland): b. at Dresden, May 12, 1670; was second son of John George III., Elector of Saxony, and Anna Sophia of Denmark. He possessed extraordinary physical strength, and was not deficient in mental faculties. He became Elector of Saxony on the death of his brother in 1694, and was elected King of Poland in 1697, having, for the sake of the crown, adopted the Roman Catholic religion. His competitor in this election was the French Prince of Conti. Augustus formed about 1700 an alliance with Peter the Great against Charles XII. of Sweden, by whom he was defeated in several battles. By a treaty signed in 1706 he renounced the crown of Poland, which Charles XII. gave to Stanislas Leszczynski. In consequence of the defeat of Charles XII. by the Russians in 1709, Augustus recovered the throne of Poland, and as an ally of Peter the Great waged war against Sweden for several years. Augustus was luxurious, licentious, and fond of splendor. He squandered the revenues of Saxony on his mistresses and on alchemists, whom he patronized. He had many illegitimate children, among whom was the famous Maurice of Saxony (Marshal Saxe). He died in Warsaw, Feb. 1, 1733, leaving the throne to his son Augustus. See Fassmann and Horn, *Friedrich August des Grossen Leben* (1734); Desroches de Parthenay, *Histoire de Pologne sous le Roi Auguste II.* (4 vols., 1734.)

Augustus III., FREDERICK: King of Poland: b. at Dresden, Oct. 7, 1696; was a son of the preceding. He was inferior in talents to his father. Having joined the Roman Catholic Church, he married, in 1719, Maria Josephine, a daughter of Joseph, Emperor of Austria. In 1733 he became Elector of Saxony, and was chosen King of Poland by a party of the Diet. Favored by the courts of Austria and Russia, he prevailed over his rival Stanislas. In 1742 he formed an alliance with the Empress Maria Theresa against Frederick the Great, who defeated the Saxons in 1745 and

captured Dresden. This war was ended in 1746, but Augustus was soon involved in the Seven Years war, which began in 1755, and his army was again defeated by the Prussians. He died in Dresden, Oct. 5, 1763, and his son, Frederick Christian, then became Elector of Saxony.

Augustus, WILLIAM: Prince of Prussia; a younger brother of Frederick the Great; b. at Berlin, Aug. 9, 1722. He distinguished himself at Hohen-Friedberg in 1745, became a general of infantry, and displayed skillful generalship at the battle of Lowositz in 1756. He died at Oranienburg, June 12, 1758, and left a son, who became King Frederick William II.

Augustus Cæsar, or simply **Augustus** (called in his youth **CAIUS OCTAVIUS**, and **CAIUS JULIUS CÆSAR OCTAVIANUS** after he became the heir of Cæsar the dictator): the first Roman emperor; b. at Velitræ, Sept. 23, 63 B. C. He was the son of Caius Octavius, a senator, and Attia, who was a niece of Julius Cæsar. His father having died 58 B. C., his mother was married to L. Marcus Philippus, who directed the education of young Octavius. At the age of sixteen he assumed the *toga virilis*, and was adopted as a son by Julius Cæsar, whom he attended in his expedition to Spain in 45 B. C. He became a pupil of Apollodorus of Pergamus, under whom he was pursuing his studies at Apollonia when Cæsar was killed, Mar. 15, 44 B. C. As he had been appointed the heir of the dictator, he hastened to Rome to claim his inheritance. Mark Antony, who then had the chief power in Rome, refused to deliver the property and papers of the late dictator. Octavius temporized, and in the turbulent and critical times that ensued exhibited the prudence and astuteness of a mature politician. He gained the favor of the Senate, which in Jan., 43 B. C., gave him the command of an army, which defeated that of Antony near Mutina (Módena). The adhesion of the army to his interest enabled him now to defy the authority of the Senate. He marched to Rome, was elected consul in Aug., 43, and formed a triumvirate with Antony and Lepidus against Brutus, Cassius, and the Senate. Antony and Octavius defeated Brutus and Cassius in the decisive battle of Philippi in 42 B. C., and, to confirm their power, proscribed and massacred thousands of their opponents in Italy. Augustus then obtained control of Italy by a new division of the provinces, but dissensions soon arose between him and Antony, who had command in Asia. An open rupture was, however, postponed, and Antony married Octavia, the sister of his great rival. About 38 B. C. the triumvirate was renewed for another period of five years, during which Octavius and Antony were virtually masters of the Roman world. Octavius defeated Sextus Pompey in battle in the year 36, and was chosen consul for the second time in 33. In the meantime, Antony, infatuated with Cleopatra, neglected his own interests, and by his ill-treatment of Octavia broke the only bond of union with his colleague. The contest for supreme power was decided by a great naval victory which Octavius gained at Actium in 31 B. C., after which he was the sole master of the Roman empire. He was subsequently chosen consul several times, and professed an intention to restore the republic, but he usurped absolute power, partly disguised under republican forms. In 27 B. C. the title of Augustus was conferred on him by the obsequious Senate, which retained the shadow of its former power. His favorite ministers and advisers were Agrippa, Mæcenas, and Asinius Pollio. He was thrice married; the names of his wives were Clodia, Scribonia, and Livia Drusilla. He had an only child, Julia. In 23 B. C. he accepted the *tribunitia potestas* (tribunitian power) for life. His reign was remarkably pacific and prosperous, and the Augustan Age was rendered the most brilliant in the Roman literature by the genius of Vergil and Horace, whom the emperor liberally patronized. He was a prudent and rather popular ruler, governing men with artful policy, and skillfully using their passions and talents to promote his own designs. The peace, order, and prosperity which his subjects enjoyed under his mild and modified tyranny reconciled them to the loss of their ancient liberty. He centralized the administration and enforced discipline in the armies. He adorned the city of Rome with public buildings, and made such improvement in that capital that it was said that he found it a city of brick and left it a city of marble. He was not happy in his domestic relations. His adopted sons, Caius and Lucius Cæsar, to whom he intended to leave the throne, died young. He was temperate in his diet and moderate and frugal in his style of living. He had studied oratory with some success, but on important occasions he would never speak with-

out careful preparation. He composed numerous works in prose and verse on various subjects. Having designated his stepson Tiberius as his successor, he died at Nola, Aug. 19, 14 A. D. See Suetonius, *Vita Augusti* (Life of Augustus); Nicolas Damascenus, *De Vita Augusti*; Tacitus, *Annales*; Beulé, *Auguste* (Paris, 1867; 3d ed. 1868); V. Gardthausen, *Augustus und seine Zeit* (Leipzig, 1891, *sqq.*, 4 vols.).

Revised by S. M. JACKSON.

Auk: the common name of several species of sea-fowl belonging to the family *Alcidae*. The auks are thickset, heavily built birds, with short wings and tail, and three-toed, webbed feet. They are found only in the colder por-

Great auk.

tions of the northern hemisphere, and many breed within the Arctic Circle, migrating southward in winter. They are strictly aquatic in their habits, visiting the shore only to breed: fly rapidly, though heavily, owing to the shortness of their wings, but are most expert swimmers and divers, using their wings as well as their feet when swimming under water. The most noted as well as the largest member of the family is the great auk or garefowl, *Alca impennis*, which has become extinct within the last fifty years. This bird was about the size of a goose; the head, neck, and upper parts were black, the under parts and a spot in front of the eye white. The wings were so small that the great auk was quite incapable of flight. It was a resident of the shores of Iceland and Newfoundland, but occurred in winter as far south as England and Virginia. At the time of the discovery of Newfoundland the great auk was found in immense numbers, and was largely used for food by the colonists and fishermen. At a later date the bird was killed for the sake of its feathers, and, as it bred only in a few localities and was helpless when on land, the species was soon extirpated. The ultimate cause of the extinction of the garefowl in Europe was the destruction of its most secure breeding place, a small islet off the southern coast of Iceland, by a volcanic eruption. The birds then moved to a more accessible spot, and were soon destroyed, the last specimens being taken for their skins. About 20 skeletons, 80 skins, and 70 eggs are known to be preserved in collections. Although by no means the rarest of birds, specimens of the great auk are very highly valued, an egg having been quite recently sold in London for £300, about \$1,500. The razor-billed auk, or razorbill, *Alca torda*, is a well-known species, common on both sides of the Atlantic, occurring at some localities in great numbers. Like the other members of the group, the razorbill lays a single, disproportionately large egg. It breeds on narrow shelves of rock, or under overhanging ledges, and its eggs, as well as those of the other species, are much sought after. Continued taking of the eggs has, in some localities, very perceptibly reduced the numbers of these birds. The term little auk is often applied to the dovekie, *Alle nigricans*, a small and abundant species found in great numbers on the eastern coast of Greenland as far north as lat. 82°. In winter it usually keeps well out at sea, unless driven inshore by gales. These two last-mentioned

species play an important part in the domestic economy of the Eskimo, supplying him with both food and clothing. See GUILLEMOT.
F. A. LUCAS.

Au'la Re'gia [Lat., king's hall or court]: a court established in England by William the Conqueror, and afterward regulated by Magna Charta.

Au'lic Council [*aulic* is from Lat. *aula*, court]: one of the two highest councils or courts of the former German empire, co-ordinate with the imperial chamber. The aulic council, which was organized in 1495, consisted of a president, vice-president, and eighteen councillors, six of whom were Protestants, whose unanimous votes could not be overruled by the Catholic majority. The members and officers of this council were appointed by the emperor, and had jurisdiction over all matters of feudality in which the emperor was directly concerned; all questions of appeal made by states from decisions in favor of the emperor in inferior courts; and Italian affairs in which the emperor was interested. After the dissolution of the German empire in 1806, the term aulic council was applied to the Emperor of Austria's council of state.

Au'lis: a town of ancient Greece, in Bœotia, on the Enripus. It had a temple of Artemis (Diana). According to the poetical legend, Agamemnon here assembled the Grecian fleet before the siege of Troy, and here he offered his daughter Iphigenia as a sacrifice. Aulis was in the territory of Tanagra, and is supposed to have been about 3 miles S. of Chaleis. Its present name is Vatchi.

Au'lus Gel'lius: a Latin author who lived during the reigns of the Antonines. Little is known of the events of his life. He resided much at Athens, where he composed his *Noctes Atticæ*, probably about 160 A. D. His book is a mass of curious information upon a great variety of subjects, and, though ill-arranged, is valuable to critics, from the light it throws upon many obscure points of ancient history and literature. The best edition is by M. Hertz (Berlin, 1883-85) and editio minor (1886). English trans., London, 1795; modern French trans., Paris, 1862, 2 vols.; German trans., Leipzig, 1875-76, 2 vols.

Aumale, ð-maal' (formerly **Albemarle**): a small town of France; department of Seine-Inférieure; 13 miles E. N. E. of Neufchâtel (see map of France, ref. 2-E). Pop. about 2,000. In the reign of Henry II. Aumale was erected into a duchy, and the title of Duke of Aumale was given to Claude, a brother of Francis, Duke of Guise.

Aumale, CLAUDE II., Duc d': French general; b. in 1526; was a brother of the famous Duke of Guise. He fought against the Huguenots at St. Denis (1567) and Montcontour (1569), and was one of the chief instigators of the massacre of St. Bartholomew (1572). He was killed during the siege of La Rochelle, Mar. 14, 1573.—His son, CHARLES DE LORRAINE, Duc d'Aumale, b. 1556, was an ardent partisan of the Catholic League. After the death of his cousin, Henry, Duke of Guise, 1588, Aumale and the Duke of Mayenne were the leaders of the League, and commanded the armies that fought against Henry IV. He had ill-success as a general. Having plotted treason with the King of Spain, he was condemned to death by Parliament in 1595, but escaped. D. at Brussels in 1631.

Aumale, HENRI EUGÈNE PHILIPPE LOUIS D'ORLÉANS, Duc d': the fourth son of Louis Philippe, King of the French; b. in Paris, Jan. 16, 1822. He entered the army in 1839, served several campaigns in Algeria, and was rapidly promoted. In May, 1843, having defeated Abd-el-Kader, whose camp and treasures became the spoil of the victors, he was raised to the rank of lieutenant-general. In Sept., 1847, he was appointed governor-general of Algeria, about three months after which Abd-el-Kader surrendered to him. On learning of the abdication of his father, he resigned his command, Mar., 1848, and went into exile, residing many years in England. He was chosen a member of the National Assembly in Feb., 1871, soon after which date that body annulled the decree or law which had excluded the Orleans princes from France. He was elected to the French Academy in the winter of 1871-72. He was banished in 1886, but the decree exiling him was revoked in 1889. In 1886 he gave his magnificent château at Chantilly to the Institute of France, with all its priceless contents, in trust for the French nation. In 1891 the University of Oxford conferred on him the honorary degree of doctor of laws. D. at Zucco, Sicily, May 6, 1897. Revised by S. M. JACKSON.

Aune [Fr. < O. Fr. *alne* < Late Lat. *alena*, loan-word from Teutonic; cf. Goth. *aleina*, Germ. *Elle*, Eng. *ell*, Lat. *ulna*, Gr. *ἄλμη*, elbow, forearm]: an old European cloth measure, having many values in different places, varying between 27 and 54 inches. The name survives only in Switzerland, where it signifies a measure equal to 4 feet in length, the foot being 30 cm. The Swiss aune is therefore about 47¼ inches long.

Au'ra [Lat., from Gr. *αἶρα*, breath]: a subtle vapor or exhalation.—*Aura electrica* (literally the electrical breeze), the sensation as of cold air experienced when electricity is received from a sharp point.—*Aura epileptica*, a peculiar sensation felt by epileptic patients as of a cold fluid ascending toward the head.—*Aura hysterica*, the sensation as of cold air ascending to the head, said to occur sometimes in hysteria.—*Aura seminalis* or *aura seminis*, the supposed vivifying principle of the *semen virile*, formerly believed to ascend through the Fallopian tubes, thereby impregnating the ovum in the ovarium.—*Aura vitalis*, a name for the principle of life.

Aurangzebe: See AURUNGZEBE.

Aurantia'ceæ [from Lat. *aurantium*, orange]: a family of dicotyledonous trees and shrubs, natives of the warm parts of Asia and Northern Africa. All parts of these plants contain a fragrant and volatile oil, which abounds especially in the leaves and in the rind of the fruit. The leaves are alternate, articulated with the petiole, and dotted or pellucid-punctate; the fruit is a kind of berry (*hesperidium*). The family comprises numerous species, some of which are remarkable for beauty and are highly prized for their fruits, as the orange, lemon, and citron. (See CITRUS.) The fruits of *Ægle marmelos*, *Cookia punctata*, *Glycosmis citrifolia*, and many others are also edible. The *Skimmia japonica*, a beautiful shrub of Japan, is more hardy than the other plants of this order, and flourishes in the open air in England. This family is commonly regarded as a sub-family of the *Rutaceæ*.
Revised by CHARLES E. BESSEY.

Aure'lian, or **Aurelia'nus**, CLAUDIUS LUCIUS VALERIUS DOMITIUS: a Roman emperor of humble origin; b. at Sirmium, in Pannonia, or, as some say, in Lower Dacia, Sept. 9, 214. He served with distinction in several campaigns, and raised himself by his merit to the highest rank in the army of Valerian. It is stated that he usually fought in the foremost rank. On the death of Claudius (270 A. D.), Aurelian was elected emperor by the army. Early in his reign the empire was invaded by the German tribe of Alemanni, whom he defeated. He abandoned Dacia to the Goths and Vandals, in order that the Danube might become the boundary of the empire. The most important and famous of his enterprises was an expedition against Zenobia, Queen of Palmyra, whose extensive dominions included Syria and Egypt. Having defeated her army in battle near Emesa, he captured Palmyra and its queen in 273 A. D., after which he received at Rome a triumph of extraordinary magnificence. He recovered Gaul from Tetricus, who had usurped royal power, and obtained the title of "Restorer of the empire." His memory is stained by the judicial murder of Longinus, the critic, and other acts of excessive severity. He was assassinated by his own officers between Byzantium and Heraclea in 275 A. D., and was succeeded by Tacitus. See Vopiscus, *Vita Aureliani*; Tillemont, *Histoire des Empereurs*; Gibbon, *Decline and Fall of the Roman Empire*, chap. xi.

Aurelius Antoninus, MARCUS: See ANTONINUS, MARCUS AURELIUS.

Aure'lius Victor, SEXTUS: a Roman historian who flourished about 360 A. D., under the Emperor Constantine and his successors. He was appointed prefect of Pannonia Secunda by Julian the Apostate about 360, and was prefect of Rome under Theodosius I. He wrote a series of biographies of the Roman emperors from Augustus to Constantine, entitled *De Caesaribus Historia*, which is extant and was first printed at Antwerp (8vo, 1579), with the commentary of Schottus; later ed. Schröter, Leipzig, 1829-31, 2 vols.; German trans. by Closs, Stuttgart, 1837. Two other works are falsely ascribed to him—namely, *The Lives of Illustrious Romans* and *Aurelii Victoris Epitome*.

Aurette de Paladines, CLAUDE MICHEL LOUIS, d' (dō-rel'-de-pal'-a-deen'): b. at Malzien, department of Lozère, France, Jan. 9, 1804; received a military education; served in Algeria 1841-48; distinguished himself and was made a general of division in the Crimean war, and was command-

er-in-chief of the ninth military division (Marseilles) at the outbreak of the Franco-German war. On Oct. 14 he was made commander-in-chief of the first army of the Loire. In the battle of Coulmiers (Nov. 9, 1870) he defeated Von der Thann, and compelled the Germans to retire from Orléans; but his attack on the left wing of the army of Prince Frederick Charles at Beaune-la-Rolande (Nov. 28) failed; on Dec. 2 he was defeated at Artenay by the Grand Duke of Mecklenburg, and on Dec. 3 and 4 was driven farther back by Prince Frederick Charles, who again occupied Orléans. Gambetta now instituted a committee of inquiry into the conduct of D'Aurelle, who immediately resigned his command, and afterward declined to accept any command under the Government. He sat in the National Assembly of Bordeaux, was one of the members associated with Thiers in the negotiations of peace, and was appointed commander first of the national guard in the department of Seine, afterward of the fourteenth military division (Bordeaux). In 1872 he published *La Première Armée de la Loire*. D. at Versailles, Dec. 17, 1877.

Aure'ola: See HALO.

Au'reus, or **Dena'rius Au'reus**: the standard and most ancient Roman gold coin, first struck in 217 B. C. The average weight of the aureus was about 121 grains—about the same as the Greek stater and the Persian daric.

Au'ricle [from Lat. *auri'cula*, dimin. of *auris*, ear]: the external portion of the ear. See EAR.

AURICLES OF THE HEART: those cavities of the heart which receive the blood returning from the veins, and convey it to the ventricles. The auricles are popularly called "deaf ears." See HEART.

Auric'ula (*Prim'ula auric'ula*): a plant of the family *Primulaceæ*, nearly related to the primrose, and much cultivated in flower-gardens. It is a native of the Alps and other mountains of Europe and Asia. It is prized for the beauty and fragrance of its flowers, which grow in the form of an umbel on a scape. The size and color of the flowers have been much improved by cultivation. Among the colors prevailing in the 1,200 or more cultivated varieties are red, pink, crimson, and mulberry. Some varieties present a single color, and others are variegated or are adorned with a green margin. The auricula blooms in April or May, and often has a second crop of flowers in autumn. It prefers a rich, light soil, and the finer varieties are usually cultivated in pots. The chief requisites of a good auricula are large flowers, which are nearly round, and have in the center a white or yellow eye which is distinct and round, its color not mixed with the ground color; and a long scape, strong enough to hold itself erect.

Auricula: a genus of *Auriculidæ*, a family of *Mollusca* of the class *Gasteropoda*. They have a spiral shell covered with a horny epidermis. The spire is obtuse or short, and the aperture elongated and narrow. They have respiratory organs adapted for breathing in air, and they frequent salt marshes or the vicinity of the sea. They are chiefly found in and near warm seas. Several species are fossil.

Auric'ular Confes'sion: private confession of sins to a priest. For certain offenses the early Church required confession. In the fifth century, owing to some scandals in public confession, Leo the Great (440-461) authorized the parish priest to receive confessions. By the twenty-first canon (*Omnia utriusque sexus fidelis*) of the Fourth Lateran Council, in 1215, under Innocent III., it is enjoined upon the faithful to confess their sins once a year, at least, to the parish priest, under pain of losing Christian burial. In the office for the Visitation of the Sick in the English Prayer-book the rubric directs that "the sick person be moved to make a special confession of his sins, if he feel his conscience troubled with any weighty matter. After which confession the priest shall absolve him (if he humbly and heartily desire it) after this sort," etc. This rubric and the absolution following it are not in the American Book of Common Prayer.

Revised by W. S. PERRY.

Au'rifaber, JOHANN [*Aurifaber* is a Lat. translation of Germ. GOLDSCHMIDT]: b. at Weimar or in the countship of Mansfeld, Saxony, in 1519; studied theology in Wittenberg 1537-40; tutor to the young count of Mansfeld 1540-44; became amanuensis to Luther in Wittenberg in 1545, and was with him when he died at Eisleben 1546; acted as army-chaplain during the Schmalkald war 1547; became court-chaplain at Weimar in 1551; deposed as a Flacianist 1561; fled to Eisleben; became minister at Erfurt in 1566,

where he died Nov. 18, 1575; edited the German writings of Luther (Eisleben, 1564-65, 2 vols.) and his *Epistolæ* (1556-65) and *Table Talk* (1566).

Auri'ga [in Lat., charioteer]: a northern constellation of the celestial sphere, sometimes called THE WAGONER. It contains Capella, a star of the first magnitude, which may be seen near the zenith in winter.

Aurigny: See ALDERNEY.

Aurillac, ô'-ree'yak' (anc. *Aureli'acum*): a town of France, capital of the department of Cantal; is pleasantly situated in a valley on the river Jourdanne, 272 miles S. of Paris (see map of France, ref. 7-F). It is well built and has wide and clean streets. The houses are covered with slate, which is quarried in the vicinity. Among its ancient and remarkable public buildings are the Church of Notre Dame, built in the thirteenth century, the castle of St. Stephen, and the college, which has a valuable library. Most of the town is of comparatively modern construction. It has manufactures of copper kettles, jewelry, paper, carpets, and woolens. Pop. (1896) 16,886.

Aurin: See ROSOLIC ACID.

Aurispa, GIOVANNI: (1370-1459); celebrated humanist and itinerant teacher (Venice, Bologna, Florence, Ferrara). He arrived in Venice from Constantinople in 1423, a memorable year for classical learning, for he brought with him 238 MSS., including the works of Plato, Lucian, Demosthenes, Dio Cassius, Arrian, Diodorus, Strabo, Æschylus, Sophocles, Apollonius Rhodius, Callimachus, Pindar, and many others, nearly all of these authors having been until then lost to Western Europe.

ALFRED GUDEMAN.

Aurochs, Germ. pron. ovr'oks [loan-word from Germ. *Aurochs* or *auerochs*, M. H. G. *urochse*, from Teut. **ūrus*, adopted into Lat. *ūrus*, wild ox + *ochse*: Eng. *ox*, etc.]: the common name for the European bison, *Bison bonassus*. Though once found in great numbers in many parts of Europe, it is now limited to the forests of Lithuania and the Caucasus. It bears many points of similarity to the American bison. It is a very powerful animal, being somewhat larger than an ordinary ox, and, though clumsy in appearance, can run rapidly for a short distance. The body of this animal exhales a strong odor, somewhat resembling musk. The aurochs is a good swimmer, and delights in dabbling in the water and rolling in the mud. Its food consists in a great part of lichens, of which it is especially fond. The Lithuanian herd has been preserved by imperial edict since 1820, and in 1860 numbered 1,700 individuals.

Aurochs.

Many were killed during the Polish uprising of 1863, and the official count of 1870 showed but 847. This number had dwindled to 600 in 1880, and is still on the decrease. The aurochs is protected by law in the Caucasus, as well as by the rough and unsettled nature of the country, and this locality will probably be the last stronghold of the once numerous bison.

The European bison furnishes a good example of the transposition of names. As the term penguin was originally given to the great auk, so the name *Aurochs* was given to the now extinct urus of Caesar's *Commentaries*, the *Bos urus* of scientific nomenclature, and a totally distinct animal from the bison. The name aurochs is, however, so firmly connected with the bison that it would be useless to attempt to make any change.

Revised by FREDERIC A. LUCAS.

Auro'ra: a Latin word signifying "morning," or the "goddess of morning," corresponding to the Greek *Ēos*. The poetical legend represents her as the daughter of Hyperion, the wife of the Titan Astræus, the mother of Hesperus, Boreas, Zephyrus, and Memnon. According to one mythical tradition, she loved Tithonus (a son of Laomedon), for whom she asked and obtained immortality, but forgot to ask perpetual youth. She lived with him at the end of the earth, on the banks of the Oceanus, and when he grew old she nursed him, until at last his voice disappeared and his body became dry and shriveled. She then transformed him into a cricket and locked him up in her chamber. After that time—the Greek mythology continues—she adopted the habit of carrying off young men distinguished for their

beauty, such as Orion, Cleitus, and others, until Father Zeus became angry and put a stop to that practice. She was sometimes represented as dressed in a saffron-colored robe, with a torch in her right hand.

Aurora: a luminous phenomenon common in certain regions surrounding the magnetic and geographical poles of the earth. In the northern hemisphere it is called the Aurora Borealis or Northern Lights, and in the southern hemisphere the Aurora Australis or Southern Lights. Nearly all our accurate knowledge of it is derived from studies of its manifestation in the northern hemisphere, because of the predominance of land areas there and of water areas in the southern hemisphere, but the same conditions seem to prevail in each. It is intimately associated with the electro-magnetic system of the earth, both as to its origin and visibility, although the causes and conditions of its intermittent manifestations are not yet fully understood. The most probable explanation, derived from recent investigations, is that the solar radiations possess electro-magnetic energy, which at the earth is distributed into two principal fields, one passing through the earth in a direction nearly parallel to the line joining the two magnetic poles, and the other nearly parallel to the plane of the ecliptic, the former acting by the law of magnetic induction, and the other by the law of magnetic refraction. The first field is peculiar to the polar regions, embracing the magnetic and the geographical poles, and the second is characteristic of the middle latitudes. Besides these fields there is the normal terrestrial magnetic field surrounding the earth, in which a freely suspended magnet comes to rest in definite positions according to the locality. There is an oval belt where these three fields come together, and overlapping each other produce an interference of vibrations which gives rise to the auroral luminosity. The light is apparently electrical, shooting out in long, thin streamers, which flash and quiver, though sometimes these become diffused and continuous over large spaces, here and there traversed by lines in certain directions, controlled by the magnetic fields. The special appearance at any time is the result of many complex conditions acting simultaneously, which depend upon the state of the atmosphere, especially the presence of aqueous vapor. The commonest optical effect is the long, low arch spanning the sky, of gray, green, purple, or red colors, sometimes brightening into the most magnificent display of evanescent tints, suffusing the whole heavens; there are also crisp, figured forms occurring in patches, which rapidly shift in position and give place to other weird and fanciful shapes; and finally, in the vanishing point of the terrestrial magnetic lines, the long streamers receding from the observer seem to unite in a glorious crown or halo called the *corona*. The geographical distribution of the auroras shows that there are certain well-marked lines of equal frequency, called *isochasmen*, which are closely related to the magnetic isoclinals and the meteorological isothermals, though not quite identical with them. The climatic conditions affect the relative frequency. If, for instance, the climate is dry and arid, or if it is excessively moist, the number of auroras seen will be a minimum, but a damp climate or the neighborhood of large bodies of water is favorable to a maximum number; low barometric pressures and their accompanying vapor conditions are also suitable to the appearance of auroras. The isochasmen extend downward over the ocean areas and contract along the edges of the northern continents. The belt of maximum frequency passes near Point Barrow, Hudson's Bay, Northern Russia and Siberia, the number soon falling off on each side, rapidly toward the pole and more slowly toward the equator. The maximum belt of frequency is observed to change its position in latitudes in several well-marked periods, depending upon the intensity of the solar energy. Thus, when the intensity increases, the polar field and the maximum belt spread out from the poles and embrace larger spaces on the earth. If the number of spots visible on the sun is taken as an indication of its electro-magnetic energy, then the frequency increases with the spots and the belt expands with them, this being seen obscurely in a 56-year period, but clearly in the 11-year period and in a period of about 27 days, that of the rotation of the sun on its axis. In the same way there is an annual period depending on the position of the sun relatively to the poles, having a maximum in March-April and September-October, and a minimum in December-January and June-July; also a diurnal period depending upon the local hour-angle of the sun, there being an increase in visibility from 6 p. m. to 11 p. m., a slow de-

crease from 11 p. m. to 2 a. m., and a rapid falling off from 2 a. m. till daylight, this law availing for the northern hemisphere. Many unsatisfactory attempts have been made to measure geometrically the heights of the aurora, but all the formulæ depend upon some assumption regarding its location in space, which really involves the result of the observation and computation. Hence we have heights of so great range as to make all such work untrustworthy, though it is generally thought that the aurora can occur anywhere within the limits of the atmosphere, from the surface of the earth to its final dissipation in space, according as the local state of it is favorable to the display. Each observer sees a ray or figure peculiarly his own, as is the case with the rainbow, and hence simultaneous observations from distant points are not capable of accurate combination. The spectrum of the aurora is likewise a very difficult thing to observe, because the faint, ever-shifting light can not be well retained in the focus of the instrument. But it is known that the auroral lines are quite the same as those occurring in the spectra of rarefied air and gases, such as oxygen in Geissler's tubes, and that it has some characteristic though inexact determined lines.

FRANK H. BIGELOW.

Aurora: town (incorporated in 1863); village of York co., Ontario, Dominion of Canada, on the Northern Division of the Grand Trunk Railway, 30 miles N. of Toronto (see map of Ontario, ref. 4-D). It has 5 churches, a high school, Mechanics' Institute with a large library, a bank, flour, saw, shingle, and planing mills, agricultural manufactories, a tannery, water-works, and electric lights. Pop. (1881) 1,540; (1891) 1,743.

EDITOR OF "BANNER."

Aurora: city and important railroad center; Kane co., Ill. (for location of county, see map of Illinois, ref. 2-F); on Fox river; 39 miles W. S. W. of Chicago. Besides the locomotive works and shops of the C., B. and Q. R. R., Aurora has many important manufacturing industries, including iron-works, wheel-scraper, buggy-top, sal-soda, silver-plated ware, road-carts, wood-working machinery, smelting, and other works and manufactures. The city owns its own water-works and electric-light plants, has fine electric street-railway, 5 banks, 25 churches, excellent schools, including Jenning's seminary, free public library, Y. M. C. A. building, etc. There are 5 daily, 1 semi-weekly, and 6 weekly newspapers. Pop. (1880) 11,873; (1890) 19,688; (1900) 24,147.

EDITOR OF "DAILY EXPRESS."

Aurora: Dearborn co., Ind. (for location of county, see map of Indiana, ref. 8-G); on Ohio and Miss. and Cl. Cin., Ch. and St. L. R. Rs., and the Ohio river; 25 miles W. by S. from Cincinnati, with which it is connected by steamboats. It has large barrel-factories and various manufactures, Ohio and Mississippi R. R. car-shops, an extensive grain and hay trade, and is engaged in milling, distilling, and coopering. Pop. (1880) 4,435; (1890) 3,929; (1900) 3,645.

Aurora: city; Lawrence co., Mo. (for location of county, see map of Missouri, ref. 7-E); on St. L. and San Fran. R. R.; 35 miles S. of Springfield, Mo.; is in a lead and zinc mining and a farming district. Pop. (1890) 3,482; (1900) 6,191.

Aurora: city (founded in 1872); capital of Hamilton co., Neb. (for location of county, see map of Nebraska, ref. 7-J); situated in an agricultural district, on the Wyoming branch of the B. and M. R. R.; 75 miles W. of Lincoln. It has 7 churches, 4 high schools, court-house, opera-house, large creamery, a foundry, machine-shops, water-works, and 3 newspapers. Pop. (1890) 1,862; (1900) 1,921.

EDITOR OF "REPUBLICAN."

Aurora: on railroad, Cayuga co., N. Y. (for location of county, see map of New York, ref. 4-F); is finely situated on the east side of Cayuga Lake, 25 miles N. W. of Ithaca. It is a place of summer resort, has many fine residences, some manufactures, and is the seat of Wells College for ladies and of Cayuga Lake Academy. Pop. (1870) 450; (1880) 444; (1890) 555; not returned separately in 1900.

Aurungabad (i. e. abode of Aurungzebe): a city of Hindustan; in the territory of the Nizam; 68 miles N. E. of Ahmadnagar, and 138 from Pu'na; lat. 19° 54' N., lon. 75° 33' E. (see map of S. India, ref. 3-D). It was a favorite residence of Aurungzebe. Among the monuments of its former grandeur are a ruined palace of Aurungzebe, and a mausoleum with domes of white marble erected by that monarch to the memory of his daughter. Many of the mosques and other public buildings are substantial, but signs of decay are visible. Pop. about 35,000.

Au'rungebe, or **Aurangzebe** (i. e. ornament of the throne), afterward called **Alum-geer**, or **Alamgir** (conqueror of the world); a famous Mogul Emperor of Hindustan; b. Oct. 22, 1618. He was a younger son of Shah Jehân, who ceased to reign in 1657. The elder sons, Dara and Shuja, then contended for the crown in battle, while Arungzebe affected indifference to temporal power, and craftily concealed his designs under the cloak of piety. Having procured the assassination of Dara and Shuja, he became master of the empire in 1658, and detained in prison his father until his death in 1666. As a bigoted Moslem he persecuted the Hindus and provoked the Mahrattas to revolt. He added Bejapoor and Golconda to his empire, and was one of the most powerful of the Mohammedan monarchs of India. His long reign was a period of outward and specious prosperity, but the empire was diseased at heart, and soon entered a state of decadence, which was partly the effect of his policy, duplicity, and intolerance. Conscious of the crimes by which he obtained power, he lacked confidence in his ministers, and is said to have lived in continual fear of treachery. D. Feb. 21, 1707. See Elphinstone, *History of India*; Bernier, *Voyages et Description de l'Empire Mogol*; J. Mill, *History of British India*.

Au Sa'ble (also called *Oscoda*): city and railroad junction, Iosco co., Mich. (for location of county, see map of Michigan, ref. 5-J); on Det., Bay City and Alpena R. R. and Au Sable and Northwestern R. R., and on Saginaw Bay, Lake Huron; 50 miles N. E. of Bay City. It has lumbering, salt-making, farming, and fishing industries. Pop. (1880) 1,328; (1890) 4,328; (1900) 1,116.

Auscul'tion [Lat. *auscul'tio*, listening; from *auscultare*, listen; cf. *auris*, ear, *auricula*, external ear]; the method of determining the condition of the heart and lungs by the sounds heard on applying the ear to the chest-walls, which was introduced by the celebrated French physician LAENNEC (*q. v.*) early in the nineteenth century. Some few observations had been made before his time, notably by Auenbrugger, of Vienna, who in 1761 introduced the art of PERCUSSION (*q. v.*), and by the French physician Piorry (*q. v.*), who invented the pleximeter, but it is to Laennec and particularly to his application of a hollow tube or STETHOSCOPE (*q. v.*) that we are indebted for the accuracy of auscultative processes. The diagnosis of pulmonary and cardiac diseases now rests very largely upon auscultation, and furthermore by this method much has been learned of the successive stages of various diseases, their progress, and the like.

Aus der Ohe, ADELE: See the Appendix.

Auso'nus, DECIMUS MAGNUS: an eminent Latin poet; b. at Burdigala (Bordeaux) about 310 A. D. He was liberally educated, practiced law in his early life, and gained distinction as a professor of rhetoric at Burdigala. In 364 A. D. he was appointed tutor to Gratian by the Emperor Valentinian. He held several high offices under the reign of Gratian, who raised him in 379 to the dignity of consul. He was a convert to Christianity, but better acquainted with the classical poets than with the Bible. He wrote epigrams, epistles, idyllia, etc., which were admired by his contemporaries, but display little genius, and are very faulty in style. His most happy performance is a description of the river Moselle in epic measure. D. about 394 A. D. See editions by K. Sehenkl (Berlin, 1883) and R. Peiper (Leipzig, 1886); of the Mosella alone by De Mirmont (Bordeaux, 1889). There is a German translation (Trier, 1885). M. WARREN.

Au'spices [from Lat. *auspicium*, for **avi-specium*, the observing of birds; *avis*, bird + *spec-*, observe]; among the ancient Romans, divinations founded on the flight of birds or other omens, by which the augurs or soothsayers professed that they could ascertain the will of the gods and predict events. (See AUGUR.) No important enterprise or business was undertaken without consulting the auspices. In performing this ceremony the augur with a wand marked out a portion of the sky for his observations, which portion, called a *templum*, was divided into right and left. If the birds appeared on the right hand, the omen was favorable; if they flew toward the left (*ad sinistram*), it was unfavorable. The chief magistrates also had the right to conduct this ceremony, and the commander of the army in time of war had the exclusive power of taking the auspices. If a victory was gained by his legate or lieutenant, it was said to be won under the auspices of the general-in-chief. Thus originated the common English phrase, "under the auspices" of some one. In such cases "auspices" signifies influence, patronage.

Aus'sig: an Austrian town; in Bohemia; on the Elbe; 46 miles W. N. W. from Prague (see map of Austria-Hungary, ref. 2-D); has coal mines in the vicinity, and manufactures of linen, gold, and silver work. Pop. (1880) 16,524; (1891) 24,083.

Aus'ten, JANE: authoress; b. at Steventon, in Hampshire, England, Dec. 16, 1775. She was educated by her father, who was rector of Steventon, and after his death she lived at Southampton and Chawton. Her first novel, *Sense and Sensibility*, appeared anonymously in 1811. She afterward produced *Pride and Prejudice* (1813), *Mansfield Park* (1814), *Emma* (1816); *Northanger Abbey* (1818), and *Persuasion* (1818); the first three were anonymous. These works represent with great fidelity the ordinary life of the middle classes of England. Many consider them the best novels ever written by a woman. D. at Winchester, July 18, 1817. See her memoir by her nephew, J. E. Austen Leigh; *The Story of Jane Austen's Life*, by O. F. Adams; and studies by Miss Thackery (*Book of Sibyls*), Mrs. Charles Malden (1889), and Goldwin Smith (1890).

Aus'terlitz: a small town in Moravia; on the Littawa; 12 miles E. S. E. of Brünn (see map of Austria-Hungary, ref. 4-F). It has a fine castle. Pop. about 3,000. It is celebrated as the scene of a great victory which Napoleon I. gained over the combined armies of Austria and Russia, commanded by their respective emperors, on Dec. 2, 1805. Napoleon had taken Vienna about Nov. 12, after which he fixed his headquarters at Brünn, where he had about 75,000 men. The armies of the allies, amounting to about 85,000, advanced in five columns to offer battle to the French, who occupied high ground partly covered by wooded eminences, morasses, and small lakes. The battle began about 7 A. M., when the allies attempted to turn the right wing of Napoleon, who attacked them in flank and at various points with great advantage. While a portion of the allied army was retreating across a frozen lake, the ice was broken by the French artillery, and nearly 2,000 men perished in the water. The allies lost about 30,000, killed, wounded, and prisoners, and the French about 12,000. Among the results of this victory was the treaty of Presburg, Dec., 1805.

Austin: city and railroad junction; capital of Mower co., Minn. (for location of county, see map of Minnesota, ref. 11-F); on Red Cedar river. Austin has a fine court-house, a beautiful opera-house, water-works, a board of trade, railroad shops, canning and preserving factory, pressed-brick works, flouring-mills, plow-factory, foundry, machine shops, creamery, marble-works, two newspapers, etc. Pop. (1880) 2,305; (1890) 3,901; (1900) 5,474.

H. O. BASFORD, PUBLISHER OF "REGISTER."

Austin: city on railroad; capital of Lander co., Nev. (for location of county, see map of Nevada, ref. 5-H); on the eastern slope of the Toyabe range of mountains. There are several quartz-mills and many rich silver mines here. Pop. (1870) 1,324; (1880) 1,679; (1890) 1,215; (1900) 702.

Austin: borough, Potter co., Pa. (for location of county, see map of Pennsylvania, ref. 2-E); on Sinnemahoning Valley R. R.; 13 miles from Coudersport, the county-seat. It is in a farming district, and was organized in 1888 from part of Portage township. Pop. (1890) 1,679; (1900) 2,300.

Austin: city and important railroad center; capital of Texas and of Travis County; in lat. 30° 16' 25" N., lon. 97°

State Capitol, Austin, Texas.

43° 58' W. (for location of county, see map of Texas, ref. 5-H); on the left bank of the Colorado river, which is a clear and beautiful stream, but is not navigable. Austin is

surrounded by fine scenery, and became the capital of the republic of Texas in 1839; was chosen capital of the State in 1850, and in 1872 was made the permanent capital by vote of the people. The Colorado river is here spanned by two fine bridges.

Austin was originally built on a beautiful plateau in the bend of the river, but now extends back from the original front about 2 miles and along the river about 2½ miles.

Streets and Avenues.—It is intersected by two central avenues 120 feet wide, extending from the Capitol grounds (about 10 acres, situated on Capitol Hill, a beautiful eminence near the center of the city proper) E., W., N., and S. to the original city limits, which are bounded E. and W. by avenues 200 feet wide. Most of the other streets are 80 feet wide, and none less than 60 feet. The principal streets are shaded, and the hills and valley studded with live-oaks and other forest trees.

Public Buildings.—The old Capitol, which was destroyed by fire, has been replaced by a magnificent stone edifice, for the cost of which 3,000,000 acres of State lands have been appropriated. The chief public buildings besides the Capitol are the temporary State-house, the post-office, general land-office, and graded-school building (all handsome and commodious stone edifices), the asylum for lunatics, mutes, and blind, and the Governor's mansion. The State University, a fine brick building, is on College Hill, in the northern part of the city. Pop. (1870) 4,428; (1880) 11,013; (1890) 15,700; (1900) 22,258. The dam, 1,200 feet long, 60 feet high, and 60 feet thick at base, across the Colorado river at a point 2 miles above the city, furnishing 14,500 horse-power for manufacturing purposes, etc., was carried away April 7, 1900, during a flood, and caused great losses to life and property.

EDITOR OF "STATESMAN."

Austin, ALFRED: English poet; b. at Headingley, near Leeds, England, May 30, 1835; educated at Stonyhurst College and St. Mary's College, Oscott, taking his degree at the University of London in 1853; called to the bar of the Inner Temple 1857, entering the law only out of deference to his parents, being himself determined from an early age to follow literature; went to Italy in 1861, on the death of his father; published *The Season, a Satire* (1861); *The Human Tragedy* (1862); *The Golden Age* (1871); *Interludes* (1872); *Rome or Death* (1873); *Madonna's Child* (1873); *The Tower of Babel* (1874); *Savonarola* (1881); *English Lyrics* (1890); in addition to three novels, several other volumes of poetry, and numerous political articles. Appointed POET LAUREATE (*q. v.*) Jan. 1, 1896.

Austin, COE FINCH: botanist; b. at Mount Hope, Orange co., N. Y., June 20, 1831; published *Musci Appalachiani* and *Hepaticæ Boreali-Americaneæ*, and described many species of mosses and liverworts. D. at Closter, N. J., Mar. 18, 1880.

Austin, JOHN: jurist; b. at Creting Mill, Suffolk, England, Mar. 3, 1790; called to the bar in London 1818; became the intimate friend of Jeremy Bentham, James Mill, and other influential persons; was Professor of Jurisprudence in the University of London 1826-32, but his public life was, on the whole, a failure. His fame rests on his *Province of Jurisprudence Determined* (London, 1832; 5th ed. 1885). D. at Weybridge, Surrey, Dec., 1859.

Austin, SAINT: See AUGUSTINE, SAINT.

Austin, SAMUEL, D. D.: Congregational minister; b. at New Haven, Conn., Oct. 7, 1760; graduated at Yale in 1783; became pastor at Fair Haven, Conn., 1786, and at Worcester, Mass., 1790; president of the University of Vermont 1815, resigned 1821. D. at Glastonbury, Conn., Dec. 4, 1830.

Austin, SARAH: English writer and accomplished translator; a member of the eminent Taylor family of Norwich; b. there in 1793. She was married in 1820 to John Austin, a barrister of London (*q. v.*). She wrote, besides other works, *Characteristics of Goethe* (from the German of Falk, 3 vols., 1833), which was very successful, and *Sketches of Germany from 1760 to 1814*. She produced a good translation from the German of Prince Pückler-Muskau's *Tour in England* (1832), and also one of Ranke's *History of the Popes* (3 vols., 1840), which was highly commended by Macaulay. D. at Weybridge, in Surrey, Aug. 8, 1867.

Austin, STEPHEN F.: b. about 1790; was a son of Moses Austin, a pioneer born at Durham, Conn. About 1821 he conducted a company of emigrants from New Orleans, and planted a colony where the city of Austin now stands. His

father emigrated to Texas about 1820, and obtained a land-grant and permission to plant a colony in that province; this grant was confirmed to the son in 1822 or 1823. Early in 1833 the Texan colonists formed a constitution, to obtain a ratification of which Austin and other delegates went to the city of Mexico. In consequence of the frequent revolutions and anarchy of Mexico, they did not obtain the admission of Texas into the confederacy. In 1835 Austin was chosen commander of the Texan army, and joined in the movement for the liberation of Texas. He went as a commissioner to the U. S. to obtain the recognition of Texas as an independent State. D. in Texas, Dec. 27, 1836. See Yoakum, *History of Texas*, 1856.

Austin, WILLIAM: lawyer and author; b. at Charlestown, Mass., Mar. 2, 1778; author of *Letters from London* (Boston, 1804); *An Essay on the Human Character of Jesus Christ*; *Peter Rugg, the Missing Man*, a legendary story published in the *New England Galaxy* (1824-26), etc. D. in Charlestown, Mass., June 27, 1841.

Austin, WILLIAM PIERCY, D. D., Oron., LL. D., Cantab.: Lord Bishop of Guiana and Primate of the West Indies; b. at Stone, Staffordshire, England, Nov. 7, 1807; consecrated Bishop of Guiana Aug. 24, 1842. D. Nov. 9, 1892.

Australasia (i. e. Southern Asia): the islands of the Southern Pacific, with Australia. It includes (1) Australia and Tasmania, area, 3,056,986 sq. miles, pop. 3,330,000; (2) New Guinea group, area, 313,000 sq. miles, pop. 837,000; (3) New Zealand group, area, 104,000 sq. miles, pop. 620,000; (4) Melanesia, including the Bismarek archipelago, Solomon islands, New Caledonia, Fiji, and others, area, 57,000 sq. miles, pop. 642,000. The total land area is about 3,531,000 sq. miles, and population 5,429,000, consisting in part of a brown Polynesian race, in part of black Papuans and Australians, in part European immigrants and some Malays. Great Britain claims all of (1) and (3), about one-third of (2), and about one-fifth of (4). The remainder are divided among the Germans, Dutch, and French, very little of the area being now without at least a nominal "protector." In 1899 a federation of British Australasian colonies was decided upon, to be called The Commonwealth of Australia.

Australia. aw-s-trā'li-a (formerly **New Holland**): the largest island on the globe; sometimes reckoned as a fifth continent; derives its name from its geographical location (*austrā'lis*, "southern"). Lying to the S. of Asia, between lat. 10° 39' and 39° 11' S., and 113° and 153¼° E. lon., its area is about 3,000,000 sq. miles. From E. to W. it is 2,500 miles, and from N. to S. 1,600 miles. The coast-line is indented by singularly few bays, except on the northern shore, which has the great Gulf of Carpentaria.

Geology and Physical Features.—The peculiar features of Australia suggest the probability of its having been at no remote period the bed of an ocean. In general it may be said to be dish-shaped, having a low-lying interior with comparatively elevated table-lands of sandstone formation at an average distance of about 30 miles from the coast, and with an altitude of from 1,000 to 3,000 feet. These table-lands are traversed in some places, principally in the east, by mountains, which are, however, of insignificant height, that of the highest summits being only about 7,000 feet above the sea-level. The principal mountains of the continent extend along its eastern side in a broken series from Cape York on the north to Wilson's Promontory on the south. Mt. Kosciusko, in the Warragong or Australian Alps of New South Wales, is the culminating point of the continent, and has an altitude of 7,308 feet. The geological formations are chiefly Palæozoic, Tertiary, and Secondary, broken by intrusions of granite, trap-rock, syenite, etc. Tertiary deposits are found in Victoria and on the west coast, while absent in Eastern Australia. Granite occurs largely along the coast and in the east drifts, and igneous rocks are found with fragments of palæozoic strata. In the interior occur great deposits of animal bones. In the district north of Spencer Gulf (called the "lake district of Australia") and elsewhere in the interior are numerous salt lakes, and some whose waters are fresh. Most of them vary in size with the season, becoming in the dry season shallow or nearly dried up. There are no active volcanoes, but numerous extinct ones are found in South Australia and in Victoria, the craters of many of which are now the basins of beautiful lakes. Australia's principal and only great river, the Murray, 1,100 miles long, is navigable in the interior, but its outlet where it empties into the Southern Ocean is a shallow lagoon. The Victoria, in the northwest, runs in a deep channel

AUSTRALIA

50 100 200 300 400

173 A 163 B 163 C 150 D Longitude West 153 from

through cliffs 300 feet high. Other rivers are the Glenelg, flowing through a fertile country and partially navigable, the Prince Regent, Brisbane, Richmond, Clarence, Hunter, Hawkesbury, Swan, Roper, Albert Murrumbidgee, and Darling. In periods of drought many of these streams dwindle into a chain of "water-holes." In Southeastern Australia, extending from the "lake district" on the W. to the mountains on the E., and from the coast far into the interior, is a vast region of grassy highlands covered with scattered heath, scrub, and thin forests of magnificent trees, and intersected by broad valleys. This immense district, which is drained by the Murray and its tributaries, has great areas of deep black soil of remarkable fertility. In ordinary seasons these tracts are covered with a luxuriant vegetation and furnish sustenance to great numbers of sheep, cattle, and horses. In a year of drought the grass and herbage, ordinarily so abundant, is dried up by the fierce heat, and the cattle and sheep die by the hundreds of thousands, and even the native animals perish of starvation. Extensive attempts are being made to insure a proper water-supply by the establishment of irrigation colonies. There are two of these (those of Mildura in Victoria and of Renmark in South Australia) on the banks of the river Murray, from which they derive the water for purposes of irrigation. There are about 500,000 acres in these colonies, on which the founders have spent about \$1,350,000 and the settlers \$500,000 more. The population numbers over 3,000, and is rapidly increasing. The seepage system of irrigation is employed, and the results obtained have proved highly satisfactory. In other places than these water for irrigation has been obtained from artesian wells, many of which have been bored. The flow from two wells alone is estimated to be about 5,000,000 gal. daily. The western half of the south coast of Australia is low and sandy, the west coast is skirted by detached mountain-ranges with intervening fertile valleys, and the northern coast is in many parts low and swampy. Of the great western interior, however, comparatively little is known, exploration being rendered almost impossible by the lack of water.

Climate.—In general the climate of Australia is warm and dry and very salubrious. Southern Australia gets little rain, while Victoria and New South Wales and parts of Queensland have from 32 to 44 inches annually. In the tropical regions there are but two seasons, the wet and the dry; but in the other portions of the continent the four seasons of the temperate zone are distinctly marked. Here the seasons of America and Europe are reversed, January and February being the hottest months of summer, and July the coldest of winter. Inland on the vast dry plains the heat rises to the height of 100° to 140° in the shade, while the coast-regions are quite temperate, with a mean annual temperature of 58° to 62°. Protracted droughts and violent floods characterize Australia, which has a marked poverty of permanent fresh-water reservoirs.

Soil and Productions.—The part of Australia lying in the tropical regions has forest products of great luxuriance, while the highlands, almost bare of trees, abound in pasture grass and herbaceous vegetation. The dry climate in the N. favors evergreen growth, while there is a marked absence of mosses and lichens. Of the eucalyptus, or gum-tree, 400 species are found, some being 150 to 200 feet high, with stately trunks. About 10,000 species of indigenous Australian plants are described, but none of the cereals and few of the esculent fruits or roots are natives of the soil. Cattle are abundantly raised by herdsmen. The marsupial animals predominate among the Australian mammals. There are found the kangaroo, opossum, flying squirrel, bear, wild dog, etc., but no ruminant beasts. The duck-billed platypus is peculiar to Australia, and forms a connecting link between quadrupeds and birds. Nothing similar to it exists in any other part of the world. The birds embrace near 700 species, among which are the white eagle, black swan, parrot, emu, lyre-bird, honey-eater, etc. Saurians or lizards are numerous. Food-fish abound, several species being peculiar to Australia. Gold was discovered in 1851 in Victoria and New South Wales, and later in Queensland. The annual value of gold exports was \$28,000,000 for the years 1888-90. Victoria alone has produced an aggregate of \$1,100,000,000 in gold. Large coal-fields exist, also profitable copper, iron, and lead mines. Wool is a great staple of Australia, sheep-farming being easy and profitable. Cotton, wheat, sugar, and tobacco are produced, and the grape flourishes. Aggregate exports reach nearly \$265,000,000 annually; total imports, \$301,000,000.

Weights and Measures.—The same as in Great Britain.

Inhabitants.—The aborigines of Australia, though similar to the Africans in thick lips, flat noses, etc., are lighter in color, being dusky brown, and have well-shaped limbs and straight or curly black hair. Their intelligence is of a low order; their knowledge of mechanic arts very slight. They build no permanent dwellings, but only hovels. The sole dress is a single garment, the skin being tattooed. Their hatchets are of stone, with spears and axes of hard wood, as is their peculiar weapon, the boomerang. The tribal relation exists and cannibalism is said to prevail among some tribes. They have no religion beyond believing in the god Buddai, a giant sleeping for ages, whom they expect some day to awake and eat up the world. The native Australians are computed at about 31,000. The rapidly increasing European population is almost wholly British, who have founded thriving settlements.

History.—Australia was first discovered by the Dutch and Spaniards in 1601 to 1606. Capt. Cook in 1770 explored the eastern coast, and took possession of the country for the British Government. In 1788 the first settlement of New South Wales began, Botany Bay following as a penal colony of Great Britain. Western Australia was set apart in 1829, Southern Australia in 1834, Victoria in 1851, and Queensland in 1859. Explorations of the almost unknown interior were conducted by Sturt in 1828-45; Leichhart (who never returned) in 1844; Stuart, 1858; Warburton, 1873; and Winnicke in 1883, proving that the unexplored interior is more fertile than previously believed.

Federation.—The union of the Australian colonies was proposed as early as 1850, and when the Dominion of Canada was established in 1867, the subject was again discussed. A Federal Council was established in 1883; but this was simply an advisory body. New South Wales refused to join in its deliberations from the first, and South Australia subsequently withdrew. The Russian scare, in 1890, gave fresh impetus to the movement, and a conference was held in Melbourne, followed by a convention in Sydney, in 1891, at which the first commonwealth bill was drafted. This bill was submitted to the local parliaments, but failed of adoption. After many conventions and compromises an agreement was reached, and a bill for the federation of the colonies was presented to the British Government in January, 1900. The bill was passed, with amendments, May 15, and the Earl of Hopetoun was appointed to be the first Governor-General of the Commonwealth of Australia, which dates from Jan. 1, 1901. The Constitution provides for a Federal Parliament consisting of a Governor-General, appointed by the sovereign, and a Senate and a House of Representatives, elected directly by the people. The judicial power is vested in the High Court of Australia, and in such minor federal courts as the Parliament may create. A uniform postal and telegraph service, government control of the railways, national defense, and a common tariff are provided for. The Constitution is modeled very closely on that of the United States.

Political Divisions.—Australia is divided as follows:

COLONIES.	Sq. miles.	Pop.
New South Wales, 1891.....	310,700	1,134,207
Queensland, 1891.....	668,497	393,718
South Australia, 1891.....	903,690	215,048
Victoria, 1891.....	87,884	1,140,411
Western Australia, 1891.....	1,060,000	49,782
Totals.....	3,030,771	3,033,166

Austra'sia: the eastern dominions of the Franks under the Merovingians; made a kingdom by Clovis, 511 A. D., comprising the present Lorraine, Belgium, and adjacent territory. It was merged in the empire of Charlemagne.

Aus'tria, Archduchy of: the nucleus around which the Austrian empire has grown. Area, 12,285 sq. miles. It is bounded N. by Bohemia and Moravia, E. by Hungary, S. by Styria, and W. by Bavaria. Pop. of Upper Austria in 1890, 785,831; of Lower Austria, 2,661,790. Both provinces are mountainous and abound in beautiful scenery. The Noric Alps extend along the southern boundary, and the northern parts of the archduchy are occupied by mountains called the Böhmerwald.

Austria-Hungary: an empire situated in the southeastern part of Europe between lon. 9° and 26° E., and lat. 42° and 51° N. It forms an irregular but compact region, surrounded on all sides by other countries, except where it bor-

ders the Adriatic. It is bounded W. and N. by the German empire, N. E. by Russia, E. and S. by the Danubian provinces and Turkey, S. W. by the Adriatic Sea, Switzerland, and Italy. Exclusive of Bosnia and Herzegovina, it has an area of 240,942 English sq. miles, ranking third in point of extent among the countries of Europe. Much of the territory is nearly as mountainous as Switzerland. The Alps extend over the southwestern portion, while the Carpathians, scarcely less in picturesqueness or importance, extend, in the form of a bow, along the northeastern portion for a distance of more than 600 miles. The valley of the Danube and its tributaries constitute a vast and fertile region of great importance. The Danube, with the exception of the Volga the largest river in Europe, has a course of about 820 miles within the country, and during nearly all of this distance is navigable for the largest vessels. The numerous tributaries of the Danube also form important waterways for commerce. Along the foot of the mountains there are numerous lakes and marshes. No other country in Europe contains so many or so valuable mineral springs. These are no less than 1,500 in number, the most celebrated of which are Karlsbad, Marienbad, Franzensbad, Teplitz, and Seidlitz. The climate, owing to the great differences of elevation, is extremely various. In the south grapes, Indian corn, and olives are among the most important products; while in the province of Dalmatia plants of a tropical nature flourish in the open air. In the middle zone the winters are colder and the summers hotter. The vine and maize are here cultivated only in favored situations, while wheat and oats are more generally grown. In the northern portion, embracing Bohemia, Moravia, Silesia, and Galicia, the winters are long and cold; grapes and maize are no longer grown, the principal crops being wheat, oats, rye, barley, hemp, and flax. In the Alps the rainfall sometimes reaches 60 inches; the average is from 20 to 24 inches; while on the plains of Hungary it is often as low as 16. The flora, owing to the great variety of soil and climate, is extremely various, ranging nearly all the way from the plants of the tropics to those of the arctic zone. It is estimated that the number of species is no less than 12,000. There are 90 species of mammals, 248 of birds, 377 of fishes, and more than 13,000 of insects.

Area, Population, and Religion.—The following table gives the area of the several provinces forming the empire, with the number of the inhabitants on Dec. 31, 1890:

PROVINCES OF THE EMPIRE, or CROWN-LANDS.	Sq. miles.	Pop. Dec. 31, 1890.
Lower Austria	7,654	2,661,799
Upper Austria	4,631	785,831
Salzburg	2,767	173,510
Styria	8,670	1,282,708
Carinthia	4,005	361,008
Carniola	3,856	498,958
Littoral	3,084	695,384
Tyrol	11,324	928,769
Bohemia	20,060	5,843,094
Moravia	8,583	2,276,870
Silesia	1,987	605,649
Galicia	30,307	6,607,816
Bukowina	4,035	646,591
Dalmatia	4,940	527,426
Hungary, including Transylvania	108,258	15,232,159
Croatia and Slavonia	16,773	2,200,977
Town of Fiume	8	30,337
Bosnia and Herzegovina	23,262	1,404,000
Totals	264,204	42,762,886

The population of Austria-Hungary is made up of a number of distinct races. Of these the Germans number only a little more than 9,000,000, while the Slavonians amount to as many as 17,400,000; the Magyars or Hungarians about 6,000,000; the Wallachians, 3,000,000; the Jews, 1,106,000; the Italians, 515,000. The Gipsies, Armenians, Bulgarians, Albanians, and Greeks make up the rest. About two-thirds of all the people profess the Roman Catholic religion. The Greek Catholics number about one-tenth of the entire population. Of Protestants there are about 375,000 in Austria proper, and 3,400,000 in Hungary. The statute of May 25, 1868, secures the substantial independence of the Church as regards the state, full liberty of faith and conscience, and the independent enjoyment of civil and political rights. Every religious body, legally recognized, has the right of ordinary public worship, the management of its own affairs, and the undisturbed possession of its own premises and endowments. In Hungary there is perfect religious equality, each religious denomination having the independent organization of its own affairs.

Products.—Agriculture is at the head of the industries of the country. Much attention is paid to the raising of cattle, but except in the Alpine regions the breeds are inferior. The country is distinguished, however, for the number and superiority of its horses. The finest and most beautiful horses are said to be found in Transylvania, while the largest and most powerful come from the vicinity of Salzburg. In the southern parts of the country horses are less numerous, and mules and asses very generally take their place. The productive land of Austria is estimated at 89.6 per cent., while that of Hungary is 84.4, making 86.9 per cent. for the whole country. This great percentage is owing largely to the systematic care of the forests, which occupy one-third of the productive area. The forests very generally belong to the state, and they are carefully managed by the boards known as the Administrators of Forests and Domains, the Direction of Forests and Domains, and the Ministry of Agriculture. It is estimated that the forests yield annually more than 27,000,000 cords of building-timber and firewood, much of which is exported. Of the standard crops the amounts produced are in the order of oats, rye, barley, and wheat. The crop of the sugar beet is in amount about two-thirds that of potatoes. In Hungary the products of wine and silk are large. Many of the Hungarian wines are of superior quality. The various mining industries of Austria-Hungary give employment to somewhat more than 150,000 persons. Coal is found in abundance. There is also a large supply of iron ore. Mines are successfully worked, producing silver, lead, zinc, and quicksilver. The exports of the country, valued in millions of florins, were in 1899: Grain, 69.6; timber, 85.3; sugar, 67; cattle and horses, 35.9; glassware, 11; coal, 36.3; wool, 8.8; gloves and shoes, 24.2; bed feathers, 9.2; fowls, 6.9; eggs, 39.9; beer, 6.9.

Education.—The educational organization of the country consists of: (1) Elementary schools; (2) gymnasia and Real schools; (3) colleges and universities; (4) technical schools; (5) schools for special subjects. In the elementary schools attendance is compulsory from the beginning of the seventh year to the end of the fourteenth. The subjects taught in these schools are prescribed, and embrace religion, reading, writing, language, arithmetic, elementary geometry, natural history, physics, geography, history, drawing, singing, gymnastics, and, for girls, domestic duties. The cost of maintaining the primary schools is defrayed in different ways by the local communities, in very few cases by the general Government. The gymnasia and Real schools are designed to give preparation for the universities and the technical schools respectively. The curriculum of the gymnasium extends over eight years; that of the Real schools over seven. They are maintained partly by the state, partly by the separate provinces, and partly, as in the case of the Church schools, by ecclesiastical foundations. In Austria proper there were in 1891 172 gymnasia and 78 Real schools; in Hungary, 158 gymnasia and 30 Real schools. In all the gymnasia there were in 1889 86,269 pupils, and in the Real schools 25,034. In the empire there are eleven universities, each having the four faculties—theology, law, medicine, and philosophy. In 1890–91 there were in all the universities 17,680 students, and 1,477 professors and instructors of subordinate grade. In the University of Vienna there are usually about 5,000 students. There are seven Government technical high schools, and no less than about 2,000 special technical training schools of lower grade for training in agriculture and all kinds of art, music, mining, commerce, and trade. Schools of this grade have about 150,000 pupils. There are 138 agricultural schools; 6 veterinary schools; 99 forestry schools; 9 art schools; 5 mining schools; 5 nautical schools; and 277 music schools. By the Trade Law of 1884 every commune, where there are 50 or more apprentices, is bound to provide a school for special technical instruction. Nearly 90 per cent. of the children of school age are in attendance at school.

Government.—The present Constitution of Austria-Hungary was adopted in 1867. It recognizes the existence of two states, united politically under one crown, but for local purposes quite independent. Those parts of the Government which are commonly associated with the prerogatives of monarchy are common to Austria and Hungary. These include (1) foreign affairs; (2) military and naval affairs; (3) finance; (4) defense; (5) coinage. The headship of the common monarchy is hereditary in the Habsburg-Lothringen dynasty, the official title being "Emperor of Austria, King of Bohemia, and King of Hungary." The monarch exercises legislative authority, with the "co-operation and consent of the representative bodies." These consist of the Imperial Par-

AUSTRIA-HUNGARY

Scale of Miles

liament (the Reichstag and the Reichsrath) and the provincial Parliaments. The two bodies of the Imperial Parliament, known as the Delegations, consist each of sixty delegates, twenty having been chosen from each of the Upper Houses of the Austrian and the Hungarian Parliaments, and forty from the Lower. The Austrian and Hungarian delegates legislate separately, communicating with each other in writing; but in case of disagreement, after three such interchanges, all come together and vote without discussion. The meetings are held annually and alternately at Vienna and Budapest. The ministry is responsible to the Delegations, and may be impeached. The departments of the united monarchy are the Ministry of Foreign Affairs, the Ministry of War, the Ministry of Finance. The Parliament of Austria, as well as that of Hungary, consists of an Upper and a Lower House. The Upper House in Austria is made up of the imperial princes (in 1900), 19 in number; of 67 nobles, possessing large estates; of 10 archbishops and 8 bishops; and of such men, distinguished in art or science, as may be appointed for life by the emperor. Of this class, the number in 1900 was 136. The Lower House consists of 425 members, elected, partly directly and partly indirectly, by vote of all citizens twenty-four years of age and possessing a small property. In this House 85 members represent the landed proprietors; 118 represent the towns; 21 the chambers of trade and commerce; 129 the rural population, and 72 are elected directly by the people. In Hungary the Upper House consists of all hereditary peers who pay a land tax of 3,000 florins or more; 40 dignitaries of the Catholic Church; 11 representatives of the Protestant confessions; 82 life peers appointed by the crown; and 17 state dignitaries, *ex officio*. The Lower House is composed, according to the law of 1889, of 453 members, elected for five years by all male citizens twenty years or more of age who pay a small annual tax. The army is founded on the principle of universal military service, beginning at the age of twenty-one and continuing three years for active service and seven years for the reserve. The annual contingent of recruits is about 103,100. The peace footing of the army in 1899 was 361,693; the war footing, 1,872,178. The navy in 1899 consisted of 115 ships, of which 25 were armor-clad.

History.—The empire took its rise from the margraviate founded on the south side of the Danube in the time of Charlemagne, and received its name *Ostreich* (eastern country) from its geographical relations with the rest of Germany. It continued under the rule of a margrave till 1156, when, the territory west of the Enns having been added, it was raised to a duchy. In the course of the next three hundred years it received further accessions of territory, and became an archduchy in 1453. The Habsburg dynasty, which still occupies the throne, was introduced in the thirteenth century. In 1283 Albert became sole ruler not only of Austria, but also of Styria and Carniola. From the accession of Albert to the Reformation the history of Austria was an exceedingly turbulent one; but from time to time considerable territorial additions were made. The Archduke Albert V., having married the daughter of the Emperor Sigismund, obtained the thrones of Bohemia and Hungary, and became emperor in the year 1438, as Albert II. It was his son Maximilian who, by marrying a daughter of Charles the Bold, acquired the Netherlands, and transferred the empire with these new acquisitions to Philip the Fair. Philip was married to Joanna, the daughter of the Spanish monarchs Ferdinand and Isabella, and their son, the celebrated Charles V., inherited not only Austria and the Netherlands, but also the vast possessions of Spain. The extent of these territories so strengthened the influence of the Austrian princes that they were able from that time on to secure for themselves the election to the imperial throne of Germany. In the Thirty Years' war Austria represented the interests of the Catholics. In the war of the Spanish Succession and the Seven Years' war the country also played leading parts. In opposition to the demands of Frederick the Great, the claims of Austria were upheld with great skill and power by Maria Theresa. When Napoleon I. came into power Austria took a conspicuous part, and was repeatedly defeated. When in 1806 Napoleon inflicted the fatal blow on the old German empire of creating the Confederation of the Rhine, and thus alienating from the empire about 16,000,000 of the people, the Emperor Francis renounced the imperial crown, and by that act practically dissolved the old empire. The events that resulted in the fall of Napoleon, however, did much to re-instate Austrian influence. In the new German empire there

was no emperor, but Austria became entitled to the presidency of the Diet, and in this way acquired a predominant influence. This continued until the war with Prussia in 1866, when Austria was overwhelmingly defeated at the battle of Königgrätz, and the Constitution of the empire was in consequence so remodeled as to give the dominant influence and authority to Prussia. Since 1866 Austria, though excluded from the German Confederation, has occupied an independent and influential position in the international affairs of Europe. Internal affairs have not been free from turbulence and difficulty. The revolution which swept over Europe in 1848 shook the Government of Austria to its foundations. After the downfall of Napoleon the conservative reaction under the powerful influence of Metternich swept everything before it. The revolution in Vienna followed immediately after that of Paris. Metternich was driven into exile. A long period of civil strife followed, in which Hungary took a leading part. The Austrian troops were repeatedly defeated by the Hungarians, and it was only when Russia joined Austria that the national cause became successful. It was not until Austria was defeated by Prussia in 1866, however, that the emperor consented to the adoption of a Constitution that would satisfy the demands of the people. In May, 1867, the new Constitution was adopted, and on June 8 the emperor and empress were crowned King and Queen of Hungary.

C. K. ADAMS.

Austrian Succession, WAR OF: See SUCCESSION WARS.

Autochthones [Gr. *αὐτόχθων*, of the land itself; *αὐτός*, self + *χθών*, earth]: literally those sprung from the land itself; hence the original inhabitants of a country. The Athenians claimed to be autochthones, and wore on their headdress an emblematic grasshopper, in reference to their origin. The same claim was made by many other peoples.

Au'to-de-Fé [Span., act of faith. The form with *-da-* is Portug.]: the name given in Spain and Portugal originally to the public announcement of the sentence passed by the Inquisition against heresy; later, the execution of that sentence by burning at the stake. High church days by preference were chosen for the deed. Multitudes of spectators assembled to witness the execution and the procession of monks and priests which formed a part of the ceremony. The first to take place was at Seville, under inquisitors appointed by Ferdinand V., Jan. 6, 1481; the last probably was in Mexico, 1815. In 1761 an auto-de-fé was held at Lisbon, at which upward of fifty persons perished. See INQUISITION.

Au'tograph [Gr. *αὐτόγραφον*, written by oneself; *αὐτός*, self + *γράφειν*, write]: a manuscript, usually a signature, written by the person himself; an original manuscript as distinguished from a copy. In modern times many persons devote much time to the collection of autographs, which are articles of trade. Some men study autographs as exponents of the character or temperament of the writers. See John G. Nichols, *Autographs of Royal, Noble, Learned, and Remarkable Personages Conspicuous in English History from the Reign of Richard II. to that of Charles II.* (1829); and *Isographie des Hommes Célèbres* (Paris, 3 vols., 1828-30).

Antol'yus (in Gr. *Ἀντόλυκος*): a Greek astronomer and mathematician; b. at Pitane, in Æolis; flourished about 325 B. C. He wrote a work on the revolving sphere, and another on the rising and setting of the fixed stars; both are extant (ed. R. Hoche, with Latin translation and commentary, Hamburg, 1877).

Automatograph: See RECORDING APPARATUS, PSYCHOLOGICAL, in the Appendix.

Autom'aton, plu. **Autom'ata** (Gr. *αὐτόματον*, neut. of adj., acting of itself): a piece of mechanism so constructed as to imitate the actions of an animal. This exercise of mechanical ingenuity is of very ancient origin. Dædalus was among the first who excelled in this art. Archytas of Tarentum, who lived about 400 B. C., is said to have made a dove that could fly. Among the most wonderful automata of modern times was the flute-player which Vaucanson exhibited in Paris in 1738. This had the form of a man, and performed with its fingers. He also produced an automaton duck which swam, dived, ate and digested barley (!), and quacked like a real duck. Kempelen constructed a famous automaton chess-player, the mechanism of which was very ingenious and complex. This automaton could beat the most of the players who tested its skill, but it was long suspected that a man was concealed in it—a Russian officer who had been

sentenced to death and escaped by this contrivance. It was afterward fully proved that the supposed skill of the automaton was due to the presence of a living man, who was concealed within the machine.

Automobile: See MOTOR CARRIAGES.

Autonomy [Gr. *αὐτονομία*, deriv. of *αὐτόνομος*, independent; *αὐτός*, self + *νόμος*, law]: the power or right of self-government; political independence. The term is used to designate the characteristic of the political condition of ancient Greece, in which nearly every city was a separate state, and the people were very tenacious of the independence and sovereignty of their respective cities. For this reason they could not form a large centralized republic.

Autoplasty [deriv. from Gr. *αὐτόπλαστος*, self-formed; *αὐτός*, self + *πλάσσειν*, shape]: an operation by which lesions are repaired by means of healthy parts being taken from the patient himself (usually from the immediate neighborhood of the lesion to be repaired), and made to supply the deficiency caused by wounds or disease. The operations for this purpose have different names, according to the parts affected, as *cheiloplastic* (the operation for the lips), *rhinoplastic* (for the nose), etc.

Autopsy: See POST-MORTEM EXAMINATION.

Autrefois Acquit, *ōtr'fwaa' āā'kee'* [Fr., formerly acquitted]: a plea by a person indicted that he has previously been tried for the same offense and acquitted.

Autrefois Convict, *ōtr'fwaa' kōn-vik'* [Fr., formerly convicted]: a plea by a defendant under the same circumstances as in the case of *autrefois acquit*, that he has previously been tried and convicted of the same offense. These pleas, if true, are a bar to the action by the rules of the common law. They are in this country established as constitutional rights, both by the U. S. Constitution and those of the respective States. The constitutional provision is that no person shall be subject for the same offense to be put twice in jeopardy of life or limb. This rule does not apply where a new trial is ordered for errors in a previous trial, nor where the judge in the course of a trial, in the exercise of a sound discretion, discharges the jury, so that there is no acquittal nor conviction. In each of these cases the accused may be tried again as often as the case arises. In a legal sense he has not been in jeopardy. The rule upon this point is the same in England under the common law as in the U. S. under constitutional provisions.

Autumn [Lat. *autum'nus*]: the season of the year which follows summer, sometimes, especially in the U. S., called *fall*, in reference to the fall of the leaves. In a vague and popular sense it comprises September, October, and November. In the language of astronomy it is the time which elapses between the autumnal equinox and the winter solstice. In the southern hemisphere, March, April, and May are the months of autumn. Autumn may be regarded as occupying the same relative position among the seasons of the year as evening among the periods of the day, and mature age among the stages of human life.

Autun, *ō'tūn* (anc. *Bibracte* and *Augustodunum*): a city of France; department of Saône-et-Loire; on the river Arroux; 26 miles by rail N. W. of Châlons-sur-Saône (see map of France, ref. 5-G). It is picturesquely situated at the foot of mountains, has a fine Gothic cathedral, a college, and library; also manufactures of cloth, paper, and carpets. It is the seat of a bishop. The ancient Bibracte was the chief city of the Ædui. Here are ruins of an amphitheater, temples, and other Roman antiquities. Autun was the scene of hostile operations between Garibaldi and the Germans in the winter of 1870-71. Pop. (1896) 15,543.

Auvergne, *ō-vār'n'* (anc. *Arverni* or *Alvernia*): a former province in the south central part of France; coincided nearly with present departments of Cantal and Puy-de-Dôme. It is a mountainous district of volcanic formation, presenting many conical and dome-like summits of extinct volcanoes. The soil in some parts is fertile, especially near the river Allier. Auvergne has produced many eminent men, among whom were Pascal, Turenne, Desaix, and La Fayette. The chief towns were Clermont and Aurillac.

Auvergne, LATOUR d': See LATOUR D'AUVERGNE.

Auvergne, Mountains of: a branch of the Cevennes, situated in the French departments of Cantal and Puy-de-Dôme. They separate the basins of the Allier, Cher, and Creuse from those of the Lot and Dordogne. The highest summits of these volcanic mountains are Mont d'Or, 6,188

feet high; Cantal, 6,093; and Puy-de-Dôme, 4,806 feet high. The last is a remarkable specimen of an extinct volcano. They are generally like truncated cones. The scenery of Auvergne is grand and picturesque.

Auwers, *ow'vers*, ARTHUR: astronomer; b. at Göttingen, Germany, Sept. 12, 1838; became assistant in the observatory at Königsberg 1859, at Gotha 1862; succeeded Encke as astronomer of the Royal Prussian Academy of Sciences in Berlin, 1866. While still a student he began to investigate the variable proper motions of Sirius and Procyon, fixing with great precision the motions of the unseen companions around them. As president of the Astronomische Gesellschaft, he took a leading part in the great co-operative work of constructing a catalogue of more than 100,000 stars. As secretary of the German Commission on the Transits of Venus, he was the leading executive officer in fitting out the expeditions for observing those phenomena in 1874 and 1882, and in the latter year he conducted the expedition to the Straits of Magellan to observe it. His most considerable works are the discussion of the German observations of the transit of Venus (4 vols. 4to) and the re-reduction of Bradley's *Observations*, of which two volumes have appeared and a third is in press. For this and other works he has received the gold medal of the Royal Astronomical Society, and foreign membership and the Watson medal from the National Academy of Sciences at Washington. S. NEWCOMB.

Auxanometer [Gr. *αὐξάνειν*, grow + *μέτρον*, measure]: an instrument for measuring the rate of growth of plants. In its simplest form it consists of a slender arm borne by a small wheel, which is moved by a cord attached at one end to the plant, and weighted at the other. By noting the movement of the arm over a graduated arc the rate of growth may be calculated. The arm sometimes is brought in contact with a revolving drum, on which it makes its record. CHARLES E. BESSEY.

Auxerre, *ō-zār'* (anc. *Autissiodorum*): a town of France; capital of the department of Yonne, on the left bank of the Yonne; 93 miles S. S. E. of Paris, with which it is connected by railway (see map of France, ref. 4-G). It has a fine Gothic cathedral, a college, a museum, and a public library of 25,000 volumes. Calico, serge, hosiery, and good wine are manufactured here. Pop. (1896) 18,576.

Auxonne, *ō-zon'*: a town of France; in the department of Côte-d'Or, on the Saône, here crossed by a bridge: 20 miles by rail S. E. of Dijon (see map of France, ref. 5-II). It has an arsenal, a barrack, and a magazine, with manufactures of woolen cloth and nails. Pop. (1896) 6,697.

Auzoux, *ō-zoo'*, THÉODORE LOUIS: b. at St. Aubin d'Ecroville, department of Eure, France, 1797; studied medicine in Paris; invented the so-called *anatomie classique*, a method of making permanent models of anatomical preparations in papier-mâché, and wrote *Mémoire sur le Choléra Morbus* (1832); *Leçons élémentaires d'Anatomie et de Physiologie* (1839); *Des Tares molles et Osseuses dans le Cheval* (1853); *Insuffisance des Chevaux forts et légers, du Cheval de Guerre et de Luxe* (1860). D. in Paris, May 7, 1880.

A'va: former capital of Burma; on the Irawadi river, lat. 21° 52' N., lon. 96° 1' E. (see map of S. India, ref. 2-I). In 1853 the capital was transferred to Mandalay, situated a few miles to the northeast. Ava is a fortified city, being surrounded by a wall (15½ ft. high and 10 feet thick) and a moat. There is also an upper or lesser town, with a higher wall (20 feet), containing a palace and Government buildings. The circumference of the city is 5½ miles, but the houses are very thinly scattered, and some quarters are entirely destitute of habitations. The dwellings are usually mere huts thatched with grass. The city is adorned with numerous temples with gilded spires, which give it an imposing appearance from a distance. One of these temples contains a sitting image of Gautama, in sandstone, 24 feet high, and several are large, beautiful, and celebrated. There are also several large monasteries. The city at one time contained 50,000 inhabitants or more. It is now much decayed, and there are few signs of industry. Pop. probably 8,000. Ava is the political center of a district with an area of 288 miles and a population of 354,200. In this are included the cities of Sagaing and Amarapura. M. W. H.

Ava, KINGDOM OF: See BURMA.

Avalokiteshvara: See KWAN-YIN.

A'va, or **Ka'va** (*Macro'piper methys'ticum*): a narcotic plant of the natural order *Piperaceæ*; is a native of many South Sea islands, the inhabitants of which intoxicate them-

selves with a fermented liquor prepared from its root (rhi-zome). It is a shrubby plant, with cordate, acuminate leaves, and was formerly classed with the genus *Piper*. The effect of this liquor is a stupefaction like that caused by opium, and is followed by copious perspiration. The liquor is prepared by maceration in water.

Av'alanche [Fr., from *avaler*, descend, verbalized phrase *à val* < Lat. *ad vallem*, to the valley]: a mass of snow or ice sliding or rolling down a steep slope. Usually a comparatively small amount of snow, starting near the top of a slope, dislodges other portions as it strikes them, so that the moving body grows in volume as it goes. The name avalanche is sometimes applied, rather figuratively, to sliding masses of rock. Avalanches abound on the steep upper slopes of all mountains reaching above the snow-line, and are important feeders of glaciers. They occur also between the snow-line and the upper limit of timber, and in many regions they fight for territory with the forests. The avalanche can not develop among trees, but once started on a bare surface above may overwhelm and destroy trees. Usually avalanche districts are uninhabited, but in Switzerland man encroaches on them, striving by the driving of stakes and planting of trees to prevent the snow from starting.

Ava'ri, or **A'vars**: a warlike tribe of Mongolians that entered the countries near the Don, the Caspian Sea, the Volga, and westward. Part of them remained near the Caucasus, and another part proceeded about 555 A. D. to Dacia. They served in the army of Justinian, and fought against the Gepidae. They in 568 obtained Pannonia. They oppressed the Slavi, and made inroads into Germany and Italy. In 769 they were defeated by Charlemagne, and nearly exterminated. They used to intrench themselves in circular walled camps, traces of which, called "Avarian rings," are still visible in Hungary. The Avars penetrated into Greece and established colonies in the Morea. Navarino derives its name from them. (See Thierry's *Attila*.) They appear to have amalgamated with the Bulgarians, or rather to have adopted the Bulgarian language, and their descendants are confounded with the Bulgarians, of whom numbers are found throughout Greece.

Avatār', or **Avatāra** [from Skr. *avatāra*-, descent, incarnation; *ava*, down + *tar*-, pass over]: in Hindu mythology signifies "descent," or "transformation," and is applied to incarnations of some of the principal deities, especially Brahma, Siva, and Vishnu. The avatars of Vishnu, which are particularly celebrated, are reckoned as follows: 1, Matsya, the "fish"; 2, Kūrma, the "tortoise"; 3, Varāha, the "boar"; 4, Narasiṅha, the "man-lion"; 5, Vāmana (or Wāmana), the "dwarf"; 6, Parashurāma; 7, Rāma Chandra, or Dasharatha Rāma; 8, Krishna; 9, Būddha; the tenth, yet to come, is called Kalki, the "horse."

Avat'cha, or **Avatch'ka**: a bay in the southeastern part of Kamtchatka. It has the best and most extensive harbor of the whole peninsula. The capital, Petropaulovski, is on this bay, and is strongly fortified. The same name is applied to a small town 20 miles S., and to a river on which it lies; also to one of three mountains near Petropaulovski.

A'vebury, **A'bury**, or **Abiry**: a small village of England, in Wiltshire, 25 miles N. of Salisbury (see map of England, ref. 12-H). It is the site of extensive remains of the prehistoric period in Europe, and is in the vicinity of several barrows and cromlechs of great antiquity. The principal relics, formerly ascribed to the Druids, consist of 100 large blocks of stone placed on end in a circle, inclosing a level area of about 470 yards in diameter, which was surrounded by a ditch and a high embankment. Some of the stones measure 20 feet high above the ground. Nearly a mile S. of this temple is a barrow or conical artificial mound called Silbury Hill, which is 170 feet high, and covers a space of 5 acres. This was undoubtedly constructed long before the Roman conquest of Britain, and the opinion of the later archæologists refers the whole group to times of very remote antiquity.

Avellane'da, GERTRUDE GOMES, de: Spanish poet; b. in the island of Cuba in 1816. She became a resident of Madrid about 1840, and published a volume of lyric poems in 1841. Soon after this date she produced several novels and successful tragedies entitled *Alfonso Munio* and *Egilona*. She was married in 1846 to Don Pedro Sabator, who died the same year. Among her works are *La Cruz*, a poem, and dramas called *The Glories of Spain* (1850) and *Sonambula*.

Avelli'no (anc. *Abellinum*): a fortified town of Italy; capital of province of same name; 25 miles E. of Naples; at the foot of Mt. Vergine (see map of Italy, ref. 6-F). It is the seat of a bishop, has a cathedral, a college, manufactures of paper, woolen goods, and macaroni, and an extensive trade in hazelnuts (*Nuces avellane*), chestnuts, and grain. It was much damaged by an earthquake in 1694. Pop. 23,753.

Avellino (formerly called **Principato Ulteriore**): a province of Campania, Italy; bounded N. by Benevento, E. by Foggia and Potenza, S. by Salerno, and W. by Caserta. Area, 1,410 sq. miles. The country is throughout mountainous. The soil everywhere is extremely fertile, and the harvests are therefore generally very large. The country is traversed by the Calore and the Ofanto. The chief products are cattle, sausages, linen, and leather. Pop. (1890) 408,675. Chief town, Avellino.

A've Mari'a, or **Angel'ica Saluta'tio**: a form of prayer to the Virgin Mary (commencing Ave Maria, "Hail Mary"), which at first was simply the "annunciation" or salutation of the angel in Luke i. 28, and the words of Elizabeth (ib. 42), but grew by successive additions till it reached its present form in the time of Pius V. (1566-72). See ROSARY.

Ave'na [Lat., oats]: a genus of grasses containing forty species, mainly natives of the temperate regions of the Old World. The common oat (*A. sativa*) is a familiar example.

Avenger of Blood: In early ages, as now in barbarous countries, the infliction of the penalty for murder did not take place by the action of public authorities, but was left to the nearest male relative of the murdered person, whose duty was to pursue and slay the murderer. He was called the "avenger of blood" (in Hebrew *gōel*, which term, however, was of wider signification). The Mosaic law (Num. xxxv.) did not set aside this custom, but placed it under regulations, prohibiting the commutation of the penalty of death for money, and appointing six cities of refuge, three on either side of the Jordan, for the manslayer who was not a murderer, in which he might live till the death of the high priest under whom the deed was committed. He then was free to return home. A willful murderer was, however, to be given up to the avenger. The Koran sanctions the avenging of blood by the kinsman, but also sanctions the pecuniary commutation. The custom prevails among the Arabs at present, as well as in other rude nations.

Aventine Hill: See ROME.

Aventi'nus, JOHANNES: a German historian, whose proper name was Turnair or Thurnmaier; b. at Abensberg, in Bavaria, in 1466. He was invited to Munich in 1512, and appointed tutor to the sons of the Duke of Bavaria. His principal work is a *History of Bavaria* (*Annales Boiorum*, 1554), which was highly esteemed. The most complete edition is that published at Basel by Nicholas Ciser in 1580, in which the passages adverse to the Roman Catholics, which had been removed in the first edition, are restored. D. at Ratisbon, Jan. 9, 1534. A monument to him was unveiled at Abensberg in 1861. A complete edition of his works was issued by the Bavarian Academy of Sciences, Munich, 5 vols., 1880-84. See J. Ziegler, *Vita Aventini*.

Aven'turine: See QUARTZ.

Aventurine Glass, also called **Gold Flux** or **Gold Stone**: a variety of glass used as an ornamental stone by jewelers. The ground is of a rich yellowish-brown color, with innumerable golden scales. It may be made by fusing together 300 parts of powdered glass, 40 parts of copper filings, 80 parts of iron filings, and cooling slowly.

Avenue: village; Allegheny co., Pa. (for location of county, see map of Pennsylvania, ref. 5-B); in Harrison township; on Pa. R. R. and on Allegheny river; 22 miles N. E. of Allegheny. Pop. (1880) 415; (1890) 1,453; not returned separately in 1900.

Av'erage [from a Mediterr. maritime word appearing in Span. as *averia*, Ital. *avarria*, etc., meaning duty, impost; whence the meanings expense, distribution of expense among owners, mean]: a mean proportion; a medial sum or quantity intermediate between several unequal quantities. The relation of the average to the other quantities is such that the sum of the excesses of the greater above the average is equal to the sum of the defects of the less below it. The average of several quantities—for example 3, 7, 9, and 13—is obtained by adding them together and dividing the sum by the number of quantities. The sum 32, divided by 4, gives 8 as the average.

Average: a word used in maritime law in different senses when preceded by the words *general*, *particular*, or *petty*.

1. *General Average*.—This means the case where several interests connected together, as being engaged in a common adventure at sea, such as ship and cargo, are exposed to a marine peril, and one of these interests is voluntarily sacrificed, either in whole or in part, as the price of the safety of the residue of the property at risk; or expense is incurred for the same reason, and the amount of such sacrifice or expenditure is charged by law upon the respective interests in proportion to their value. The act of voluntarily casting away property under such circumstances is termed a "jettison." The elements of a general average case are said to be these: there must be a sacrifice of property, it must be voluntary, and must be successful. There is no general average allowed in cases of goods laden on deck, unless it is usual to place the goods there on a voyage such as the one in which this question arises. By the maritime law the master of the ship is intrusted with the power to order a jettison when the circumstances justify it. In the U. S. the law allows general average where a ship which would have foundered is voluntarily wrecked in such a manner as to save the cargo or a part of it. Expenditures of money in some instances justify a contribution of the nature of general average, as where they are incurred for the preservation of the ship or cargo from extraordinary perils, or where they are necessary for the completion of the adventure in which all the interests at risk are concerned; as, for example, for the prosecution of the voyage. The property upon which the contribution is assessed is the ship, cargo, and freights. The property lost contributes as well as that which is saved. The general principle is substantially this: as the whole property at risk is to the whole amount of the loss, so is each owner's particular interest to his share of the loss. This rule results in assessing a certain percentage of the loss on each owner, according to the value of his interest. The values are estimated by rule: the ship and appurtenances are valued as at the end of the voyage, and the cargo at its value at the time and place of discharge. An adjustment made at the end of a voyage at the port of arrival is deemed to be valid everywhere, according to a settled maritime rule. The special rules applicable to the cases in which general average is allowed are not precisely the same in England and in the U. S., and the subject branches out into much detail in the books of maritime law. Practically, it is closely connected with the business of marine insurance, as the insurance on ship, cargo, and freight may be made by different underwriters, and under the law of abandonment the rights to claim general average, as well as the burden of its assessment, may vest in and rest upon the respective insurers. 2. *Particular Average*.—This signifies damage happening to interest (ship, cargo, and freight) at risk at sea in consequence of pure accident. The loss in such a case rests upon the owner of the property injured or upon his insurer. 3. *Petty Average*.—This term refers to certain petty charges in port for pilotage, lights, towage, anchorage, and the like, which were formerly apportioned upon the owners of the ship and cargo. The modern practice is to include these charges in the freight.

T. W. DWIGHT.

A'verell, WILLIAM WOODS: soldier; b. at Cameron, Steuben co., N. Y., Nov. 5, 1832; graduated at West Point 1855; appointed lieutenant Mounted Riflemen; served on frontier and fighting Indians till 1859, when wounded. Served during the civil war; captain Third Cavalry U. S. A., July, 1862, and breveted major, lieutenant-colonel, colonel, brigadier-general, and major-general U. S. A. Resigned May, 1865. He was restored to his rank of captain Aug. 17, 1888, and was retired Aug. 31. D. in Bath, N. Y., Feb. 3, 1900.

Aver'nus [Lat., supposed to be from Gr. *Ἄορνός*; ἄ-, not + *ὄρνις*, a bird]: a famous lake [It. *Lago d'Averno*] of Italy, 10 miles W. of Naples. It occupies the crater of an extinct volcano, is about a mile in diameter and 170 feet deep. It was supposed that the name Avernus was given to it because the mephitic vapors killed the birds that flew over it. The ancients imagined that this lake was the entrance to the infernal regions. Agrippa, in the time of Augustus, opened a canal from Avernus to the sea, converting it into a harbor, but the canal was destroyed by an earthquake in 1538. It was specially dedicated to Proserpine, and an oracle was maintained here. This lake seems to have originally had no outlet. It is often visited by tourists.

Aver'roës, or **Averrhoes**, originally **Ibn-Roshd**: a celebrated Arabian philosopher and physician; b. at Cordova,

in Spain, 1126. He rose to great dignity in the Moorish kingdom, but late in life he was accused of heretical opinions, deprived of his office, and sent to live at a place near Cordova. Before his death, however, which occurred in Morocco, Dec. 12, 1198, he was restored to his patron's favor. He was a great admirer of Aristotle, on whom he wrote a celebrated commentary. In the Middle Ages he was called "The Commentator," and was said to have translated Aristotle into Arabic, which story was repeated over and over again, until in 1852 E. Renan proved it to be a fable; indeed, Averroës did not understand the Greek language.

Revised by J. R. JEWETT.

Aver'sa (anc. *Atella*): a town of Italy; province of Caserta; and in a beautiful plain 9 miles N. of Naples (see map of Italy, ref. 6-E). It is the seat of a bishop, is well built, has a cathedral, several convents, about ten churches, and a lunatic asylum. Pop. about 21,000.

A'very, WAIGHTSTILL: b. at Groton, Conn., May 3, 1745; graduated at Princeton in 1766; became in 1769 a lawyer in Mecklenburg co., N. C. He was an early and constant patriot in the Revolutionary war, being one of the signers of the Mecklenburg Declaration (1775), a member of the Hillsborough congress (1775), of the State congress (1776), first attorney-general of the State (1777), and was in 1779 a colonel of militia in active service. D. in Burke co., N. C., Mar. 15, 1821.

Averysboro: Harnett co., N. C. (for location, see map of North Carolina, ref. 3-G); on Cape Fear river, about 40 miles S. of Raleigh. During Gen. Sherman's Carolina campaign, while his army was marching toward Goldsboro, a strong force of Confederates under Gen. Hardee was entrenched in front of Averysboro (Mar. 16, 1865), to check Gen. Sherman and gain time for the concentration of forces at Smithfield under Gen. Johnston. After three or four hours' severe fighting the Confederates fell back to a second and stronger line. The attack being renewed along this line, fighting continued through the day, the Confederates being driven within their intrenchments; during the night, which was dark and stormy, their works were evacuated, and on the morning of the 17th it was found that the army of Gen. Hardee was retreating toward Smithfield. The Federal loss was about 600, killed and wounded; the Confederate loss was probably smaller, except in prisoners, of which many remained in Gen. Sherman's hands. This battle is known as the battle of Averysboro. Pop. of village (1880) 38; (1890) not separately returned.

A'ves [Lat. *a'vis*, a bird]: birds considered as a class, a group best distinguished by the presence of feathers. See BIRDS.

Avesta, or **Zend-Avesta**: the Zoroastrian Bible, forming with the Pahlavi books (see PAHLAVI) the ancient scriptures of the PARSIS (*q. v.*). In age, there is much of the Avesta that may date back a thousand years or more before Christ; but there are many portions several centuries later than this, while some parts may even belong to the beginning of the Christian era.

Avesta is a word of uncertain derivation; it has been supposed to signify "knowledge, the book of wisdom"; but more probably it means "the text," or "the law." The designation *Zend-Avesta*, often used for the book, should rather be *Avesta and Zend*, corresponding to the Pahlavi phrase *Avestāk va Zand* used of the scriptures. The latter word, *Zand* (Av. *azaiñti*), means "commentary, or explanation"; i. e. of the original *Avesta* or "text," and Parsi tradition so understands the terms.

For the discovery and first deciphering of the Avesta we are indebted to the young French scholar ANQUETIL DU PERRON (*q. v.*), who in 1754 went to the East and learned from the Parsi priests their sacred language. His translation (*Zend-Avesta, ouvrage de Zoroastre*, 3 vols., Paris, 1771) was so inaccurate, perhaps excusably, however, and often so fantastical that the question was raised, especially by Sir William Jones, whether Du Perron's work was not a forgery, or whether he had not, at least, been duped by the priests. Before many years, however, the authenticity of the Avesta and Anquetil's credit were happily vindicated, through the aid of Sanskrit, by such scholars as Burnouf (1825), Rask, and Bopp; and the scientific interpretation of the texts was carried on by men like Haug, Windischmann, Westergaard, Roth, and particularly Spiegel, and has been to-day by Bartholomae, Darmesteter, De Harlez, Hübschmann, Geiger, and especially Geldner.

Tradition has it that the Avesta was once far greater in extent than in its present form. We have mention in Pliny, for example, of 2,000,000 verses composed by ZOROASTER (*q. v.*); the semblance of truth is given to this statement also by Arabic authorities and by the Pahlavi works which tell of 21 Nasks, or books, of the original Avesta, inscribed in gold letters upon 12,000 cowhides, and deposited in the palace library at Persepolis. These books, it is claimed, were destroyed by the Greeks under Alexander the Great, when he allowed the library to be burned. It was this same victorious invasion of the great conqueror that broke the power of the Zoroastrian religion, which for centuries had been the ruling faith of Persia, including that of the Achaemenian kings, Cyrus, Darius, Xerxes, and their followers. The religion maintained a lingering existence, however, during the government of the Seleucidae and under the Parthian sway, until about the third and fourth centuries A. D., when it was restored to its former glory by the Sassanian dynasty, true Zoroastrian monarchs. It was at this time that the scattered portions of the Avesta were again gathered, as far as was possible, and edited, and the Avesta was made the canonical book of the state religion of Iran. The council, it seems, succeeded in collecting and restoring the fragments of about one-third of the original scriptures. The Mohammedan conquest in the seventh century, however, dealt a final fatal blow to the Zoroastrian creed. The fanatical followers of the Koran forced the worshipers of Mazda (see ORMAZD) to adopt the faith of the new prophet, or else they drove them into exile. Some of the fugitives fled to the mountains of Persia, where their descendants are still to be found, numbering only about 10,000; but most of them took refuge in India, especially in the neighborhood of Bombay, where as PARSIS (*q. v.*) they still form a thrifty, prosperous community of some 80,000 souls. It is these two scattered peoples that have preserved for us all they could rescue of their ancient sacred book.

What now remains of the Avesta would equal perhaps one-tenth of our Bible in extent. Like our own sacred text the extant portions of the Avesta are divided into several books. (1) The *Yasna* (Skt. *yajñá*), lit., "sacrifice," the chief liturgical work, and forming with the *Visperad* and *Vendidad*, below mentioned, a sort of Zoroastrian prayer-book. In the midst of the *Yasna* are inserted the five *Gāthās*, lit., "hymns, psalms," the sacred hymns, sayings, or sermons of Zoroaster himself. The *Gāthās* are the oldest part of the Avesta (see AVESTAN LANGUAGE), and in them we have before us the prophet speaking, much as does David in the psalms. (2) The *Visperad* (Av. *vispe ratavō*, "all the lords"), a collection of minor litanies, invocations, and offerings to the various divinities and spiritual heads of the faith. (3) The *Yashts* (Av. *yeshti*, "worship by praise"), some twenty-one longer hymns of praise and adoration of the ancient divinities and mythical heroes. (4) The Minor Texts, *Nyāishes*, *Gāhs*, *Sīrozahs*, *Afūngāns*, a collection forming a kind of manual of morning devotion. (5) The *Vendidad*, a species of Iranian Pentateuch, containing priestly injunctions and rules for rites and ceremonies, together with some legendary matter. (6) Under the head Avesta there belong also some fragments and glosses, such as those from the *Hādhoht Nask*, *Nirungistān*, *Aogema-daeca*, and the *Zand-Pahlavi Glossary*.

In style, much of the Avesta is easy and simple; the *Gāthās*, however, are extremely difficult. The keynote of their thought is the doctrine of the new kingdom, a better life, and the hereafter. They are written in verse resembling the Vedic meters. The rest of the Avesta is either composed in verse somewhat analogous to our familiar Hiawatha, or is written in prose. Meter is the sign of antiquity; prose, as a rule, is a mark of later age. There are exceptions, of course, like the prose "Yasna of the Seven Chapters" (Ys. 35-41), which is but little later than the *Gāthā* hymns. The metrical portions of the Avesta are not without poetic merit; most of the prose passages are young, without spirit, or even stupid. This distinction is easily recognized, and should be properly emphasized.

There is a fine edition of the text by Geldner, *Avesta, the Sacred Books of the Parsis* (Stuttgart, 1884, seq.); a complete dictionary was made by Justi, *Handbuch der Zend-sprache* (Leipzig, 1864). The best English translation that has appeared is by Darmesteter and Mills, *Zand-Avesta*, 3 vols., in the *Sacred Books of the East* (Oxford, 1880-87). There are several German and French grammars of the language; an English one is published in Boston (1892) by Ginn & Co. For a bibliography of the subject, consult the

names mentioned above. See also IRANIAN LANGUAGES, PAHLAVI, and ZOROASTER. A. V. WILLIAMS JACKSON.

Avestan, or Avesta Language: the ancient speech preserved in the AVESTA (*q. v.*), and the oldest member of the Iranian group of languages (see IRANIAN LANGUAGES), sometimes erroneously called *Zend*, which, however, really signifies "interpretation" or "commentary," and refers rather to the Pahlavi version of the Zoroastrian scriptures (see AVESTA). The term Old Bactrian for the language is now quite abandoned. Two dialects of Avestan are recognized: (1) the *Gāthā* dialect, the oldest form of the language as preserved in the *Gāthās*, or Psalms of Zoroaster (*q. v.*); (2) the Younger Avesta dialect, or the language of the rest of the texts. These dialects may, perhaps, be due also to a separation of place as well as to a difference of time.

The Avesta, as we now have it, is written in an alphabet of PAHLAVI (*q. v.*) origin; the writing runs from right to left, and the script is of much later date than the speech which it records. The language of the Avesta itself is most closely allied to Sanskrit (*q. v.*), though independent of it. By certain phonetic changes, each Sanskrit word may be transferred into its Avestan equivalent, and *vice versa*. Thus Av. *iməm þwām paovīm yānəm haoma jaidyemi*, "I ask of thee, O Haoma, this first boon," would answer to a possible Skt. *imām tvām pūrvyām yānām sōma gadyāmi*. Striking features of the Avestan phonology are: (1) the frequent use of epenthetic and anaptyctic vowels, e. g. Av. *dādmaidē*, "we give" = Skt. *dādmahē*; (2) a richness in its vowel-system; (3) the common occurrence of spirants (*þ, f*, etc.); and (4) the change of Skt. voiced aspirates (*gh, dh*, etc.) into stop sounds (*g, d*, etc.) which may develop into spirants. The Avestan inflectional system shows eight cases, three numbers, and, in the older texts, rich verbal forms quite parallel with the Vedic Sanskrit; in later passages, however, there is evidence of grammatical and syntactical decay.

Reference may be made to Justi's *Handbuch der Zend-sprache* (Leipzig, 1864); Spiegel's *Grammatik der Altiran. Sprachen* (Leipzig, 1882); Bartholomae's *Altiranische Dialekte* (Leipzig, 1883); Jackson's *Avesta Series* (Boston, 1892). A. V. WILLIAMS JACKSON.

Aveyron, ā-vāy-roŋ': a department in the south part of France; bounded N. by Cantal, E. by Lozère, Gard, and Hérault, S. by Tarn, and W. by Lot. Area, 3,376 sq. miles. It is intersected by the river Lot and the Tarn, and also drained by the river Aveyron. The surface is mountainous, and the chain of the Cévennes extends along the southeastern border of the department. Among its mineral resources are coal, copper, lead, zinc, and iron. The coal mines are very valuable. It has manufactures of cotton yarn, paper, woolen stuffs, carpets, and leather. It is divided into five arrondissements. Among the chief articles of export is Roquefort cheese. Pop. (1896) 389,464. Capital, Rodez.

Avezzana, ā-vet-zaa'na, GIUSEPPE: an Italian republican and patriot; b. at Chieri, in Piedmont, Feb. 19, 1789. He fought against Bustamente in Mexico in 1832, and became a merchant in the city of New York in 1834. Early in 1848 he returned to Italy to fight for the independence of his country, and was appointed commander of the national guard at Genoa. In Mar., 1849, he was chosen minister of war of the Roman republic and commander of the army. Rome was taken by the French in July of that year, and Avezzana escaped to the U. S. He joined Garibaldi in 1860, and fought with him; became delegate of the Italian House of Representatives 1867, and head of the Italia irredenta party in 1878. D. in Rome, Dec. 25, 1879.

Avianus, or Avianus, FLAVIUS (?): Latin fabulist, probably of the fourth or early fifth century A. D. (cf. O. Unrein, *de Av. vitae*, Jena, 1885), who threw into elegiac verse forty-two Æsopic fables. The work is dedicated to a certain Theodosius (perhaps Macrobius Theodosius). The author names as his forerunners Æsop, Socrates, Horace, Babrius, and Phædrus; but speaks as if his immediate source were a later collection of prose fables (*quas rudi latinitate compositas Elegis sum explicare conatus*). These were perhaps the fables of Titianus, spoken of by Ausonius (epist. 16). Avianus probably lived at Rome, and in the pagan circles there. His style is on the whole good, showing in some ways the same tendencies and ideals as that of Claudian. His version of the fables at once became popular, and as a school-book was much used and imitated during the early Middle Ages. Later the fables of Avianus were confused with those purporting to be by a certain *Romulus imperator* (tenth cen-

tury?), and thus came to be one of the sources of the extensive Æsopic literature of the later Middle Ages. In the eleventh century we have a prose version entitled *Novus Avianus* (ed. E. Grosse, Königsberg, 1868); in the twelfth century another version by Alexander Neckam (d. 1227). The French *Isopet-Avionnet* (Paris, fourteenth century) contains a French version.

BIBLIOGRAPHY.—*The Fables of Avianus*, ed. by Robinson Ellis (with extensive prolegg., etc.), Oxford, 1887; L. Hervieux, *Les Fabulistes latins depuis le siècle d'Auguste jusqu'à la fin du moyen âge* (2 vols., Paris, 1884); *Æsopus*—fables as first printed by W. Caxton, with those of Avian, Alfonso, and Poggio—by Joseph Jacobs (3 vols., London, 1889).

Avicenna, āv-vē-chen'na (the Latin form of *Ibn-Sina*): the most eminent of Arabian physicians; b. at Afshena, near Bokhara, about 980 A. D. He was well versed in mathematics, astronomy, philosophy, and other sciences. Before he was twenty years old he was reputed the most learned man of his time. He was employed as a physician by several Samanide sovereigns, and resided at Ispahān and Hamadān. He wrote in Arabic a large number of works on medicine and philosophy, the most important of which is his *System of Medicine* (Canon Medicinæ), which, translated into Latin by Gerardius Cremonensis (2 vols., 1595), was for five centuries a standard book of the highest authority in the schools of Europe. His writings exercised a powerful influence in spreading a knowledge of Aristotle's logic among his own countrymen, and subsequently among the Schoolmen. He died at Hamadān, June, 1037. See S. Klein, *Dissertatio de Avicenna Medico* (1846); Ibn-Khallikān, *Biographical Dictionary*, edited by De Slane (Paris, 1842); Freind, *History of Physic*.

Avicennia: a genus of plants of the family *Myoporaceæ*; consists of trees or shrubs resembling mangroves, and growing in salt swamps in tropical regions and in the southern hemisphere. The *Avicennia tomentosa*, the white mangrove of Brazil, has cordate, ovate leaves, downy on the lower side. Its bark is used for tanning. Its gum is used as food in New Zealand, and its seeds in India.

Avid'ius, CASSIUS: an able Roman general; b. in Syria; commanded for Marcus Aurelius an army which defeated the Parthians in 165 A. D. Having become Governor of Syria and commander of several legions, he revolted in 175 A. D., and took the title of emperor. He obtained possession of Egypt and part of Asia. He was killed by his own officers in 175 A. D.

Avie'nus, RUFIIUS FESTUS: a Latin poet of the latter half of the fourth century, distinguished for the vigor and correctness of his diction, as well as for a command of form remarkable in a period of decline. In subject-matter, however, he was not original. He translated into hexameters the *Phænomena* and *Prognostica* of Aratus (*q. v.*), and wrote in the same measure a *Description of the Earth*, following the *Periegesis* of Dionysios. Of his *Ora Maritima* in iambs only a fragment is extant, describing the coast of the Mediterranean, beginning with the Atlantic, as far as Marseilles. Best ed. by A. Holder (Innsbruck, 1887).

M. WARREN.

Avignon, āv-veen'yon (anc. *Ave'nio*): an ancient city of France; capital of the department of Vaucluse; situated on the left bank of the Rhône, 74 miles by rail N. N. W. of Marseilles (see map of France, ref. 8-II). It is the seat of an archbishop, and is surrounded by a rich country with delightful scenery. It contains a college, a public library of about 45,000 volumes, a museum of natural history, a botanical garden, a fine theater, a lunatic asylum, etc. Among the interesting and ancient public edifices are the mediæval walls, with battlements and flanking towers, the former palace of the popes, a vast irregular Gothic structure, originally a very strong fortress, now for a long time used as a barrack and prison, but recently restored, and now the episcopal residence; and the cathedral called Notre Dame des Dons, rebuilt by Charlemagne, and containing a richly sculptured chapel. Petrarch passed several years at Avignon and at Vaucluse (which is about 3 miles distant), where he first saw Laura. The manufacture of silk is the principal branch of industry in this city, which also has several paper-mills, iron-foundries, and manufactures of velvets and woolen stuffs. It has an active trade in wine, brandy, grain, etc. Avenio was the capital of the Cavares before the time

of Cæsar. It was taken by the Saracens in 730 A. D., and after many changes was purchased in 1348 by Pope Clement VI., and became the seat of the papal government. Seven successive popes resided at Avignon in the fourteenth century, during which it had about 100,000 inhabitants. The papal court was transferred to Rome in 1377, and Avignon was annexed to France in 1791. Pop. (1896) 45,107.

A'vila: a province in Spain; in Old Castile; bounded N. by Valladolid, E. by Segovia and Madrid, S. by Toledo and Caceres, and W. by Salamanca. Area, 2,981 sq. miles. The surface is mountainous, except the northern part. The chief article of export is merino wool. Pop. (1887) 193,093.

Avila (anc. *Ob'ila* or *Ab'ula*): an episcopal city of Spain; capital of province of same name; on the river Adaja; 71 miles by rail N. W. of Madrid (see map of Spain, ref. 15-E). It was once a rich and more populous city, having a flourishing university, founded about 1482 and abolished in 1807. It has a fine cathedral and convent. Pop. 9,136.

Avila y Zuñiga, LUIS, de (dā aa'vēc-laa-ēc-thoon-yee'-ga): Spanish historian and diplomatist; b. at Placencia, in Estremadura, about 1490. He enjoyed the favor of Charles V., who sent him as ambassador to Rome about 1558. He wrote in Spanish *Commentaries on the War of Charles V. in Germany in 1546 and 1547* (1548; last ed. Madrid, 1852; Ger. trans. Berlin, 1853). This work has considerable literary merit, but is not impartial. D. about 1552.

Aviler, āv-vēc-lay', AUGUSTIN CHARLES: b. at Paris in 1653; studied in Rome the profession of an architect, aided by a pension from the king. He was engaged for some time with Mansard in Paris, and afterward erected some fine buildings at various places, among them being the palace of the Archbishop of Toulouse. He wrote *Course of Architecture* (1691) and *Dictionary of all the Terms of Architecture, Civil and Hydraulic*. D. in 1700.

A'viles: a Spanish town at the mouth of the river of the same name; 15 miles W. N. W. of the city of Oviedo (see map of Spain, ref. 12-D); one of the most important trading-places in the province of Oviedo. Pop. (1887) 10,235.

A'vis, or **Aviz**: an order of knighthood in Portugal, instituted by King Alphonso I. in 1143 to promote the defeat of the Moors. The King of Portugal is grand master.

Avi'tus, ALCIMUS ECDICIUS, SAINT: Bishop of Vienne and Christian poet; b. of a senatorial family of Auvergne about 450 A. D.; succeeded his father (perhaps also his grandfather and great-grandfather) in the episcopacy about 490. He was a vigorous representative of Roman Catholicism among the Arian Burgundians, and endeavored to convert King Gundobad to orthodoxy. He seems also to have intrigued with the Franks after the conversion and baptism of Clovis (496)—an event which he celebrated in a letter full of adulation to Clovis himself (Ep. 46). He thus belonged to the party which for ecclesiastical reasons desired and helped on the subjection of Southern Gaul to the Franks.

Avitus is, however, chiefly known to the modern world as the author of a poem whose similarity in theme, and at times in treatment, to the *Paradise Lost* of Milton long since attracted attention. This poem was called by Avitus himself in a letter (Ep. 51) *De spiritalis historiae gestis*, and is in five books, to which St. Isidore of Seville (*De vir. illustr.*, Ch. xxiii) gives the following titles: I. *De origine mundi*; II. *De originali peccato*; III. *De sententia dei*; IV. *De diluvio mundi*; V. *De transitu maris rubri*. The poem is of course based upon Genesis and Exodus, and describes the Creation, the Fall of Man, the Flood, and the Captivity in Egypt. What is chiefly noteworthy about it, however, is that it is an heroic poem; i. e. deals with Bible history after the manner of the classic epic poets. For this reason Avitus has a place in a poetical tradition of great importance. To be sure, he was not the first to hit upon the sacred heroic. The Spaniard Juvencus had in his poem on the four gospels (*Evangeliorum libri IV.*, written 330 A. D.) told the life of Christ in this fashion: In the fourth or fifth century had been composed a long version in hexameters of the Pentateuch and the books of Joshua and Judges (attributed in some manuscripts to an unknown Cyprianus, but possibly in part due also to Juvencus); another of the Book of Jonah; still another (by a certain Victorinus) of the second Book of Maccabees. A Gallic lady, Proba by name, had undertaken to compose in mosaic fashion, with lines and phrases taken from the poems of Vergil, the history of the Fall and the Redemption (*Probae Cento Virgilianus*). In the century of Avitus himself and in Gaul there had been

made new poetical versions of Genesis; one, the *Metrum in Genesim*, by a certain Hilarius; another, the *Alethia seu Commentationum in Genesim libri III.* of Claudius Marius Victor, probably a professor of Marseilles. Sedulius also, in his *Paschale Carmen*, had found it necessary to preface his account of man's redemption by the story of his fall—the Paradise Regained by the Paradise Lost. In short, there had been established a new imaginative tradition before Avitus undertook to write his poem; and although his work is far the most poetical and powerful of those here mentioned, it is so largely because he made use freely and skillfully of what his predecessors had done.

Few literary traditions are more interesting than this to which Avitus made so important a contribution. It was destined to live on through the Dark and Middle Ages, and in the Renaissance to give rise to the great poems we all know about. We find it first in Anglo-Saxon England, where the poems attributed to CAEDMON (*q. v.*), from which again Milton has been charged with plagiarizing, show us the now epic material treated by a Germanic singer in the heroic manner peculiar to the north. A little later another Anglo-Saxon poem of great power, Cynwulf's *Christ*, though not directly based upon Latin epic originals, illustrates essentially the same tendencies. We know from Aldhelm, Bede, Aleuin, and others that no works were more widely known and read in England from the seventh to the ninth centuries than the poems of Juvenius, Sedulius, and Avitus; and we are justified in believing that, even in cases where direct borrowing has not been proved, the English poets were indirectly inspired by these examples. Nor were these the only poets to be attracted by the new material. In the ninth century we find it among the Germans on the Continent, giving rise to the Saxon *Hetiand* and the *Gospet-book* of the Frank Otfried. In the Middle Ages proper we find it in a double form. On the one hand, it gives us poetical versions of parts of the Bible in the vulgar tongues; on the other, the epic speeches, separated from the narrative, are thrown together in dialogue form, and we have the mysteries dealing with the Fall and the Redemption. After the Renaissance had renewed the interest of poets in the forms of classic art, we have great numbers of works in both these directions—the poetical version becoming the sacred heroic poem, the mystery becoming the sacred tragedy, without or with musical accompaniment (later the oratorio). There is not space to name all, or even a large part, of these works, but the following are worth mentioning, as having been spoken of now and again in connection with Milton: Antonio Cornozano's *Discorso in Versi della Creazione del Mondo sino alla Venuta di Gesù Cristo* (1472); DU BARTAS'S (*q. v.*) *La Semaine* (1579) and *La seconde Semaine* (1584); Hugo Grotius's Latin tragedy *Adamus Exul* (1601); Giovanni Soranzo's *Dell' Adamo* (1604); TASSO'S (*q. v.*) *Le sette giornate del Mondo Creato* (1607); Giovanni Battista Andreini's tragedy *Adamo* (1613); Alonzo de Azevedo's *Creación del Mundo* (1615); Phineas Fletcher's Latin poem *Locustæ* (1627); Andrew Ramsay's *Poemata sacra* (1633); Joost van den VONDEL'S (*q. v.*) tragedy *Lucifer* (1654). Before bringing the list to an end it is well to mention also a poem later than Milton's, but almost as famous in Germany as is the *Paradise Lost* in England, i. e. Klopstock's *Messias*, finished in 1773. Naturally, the poem of Avitus can not be said to have inspired directly all these numerous and diverse works. What can be said is that it belongs to the same tradition, and helped constitute that tradition.

Besides the *De spiritalis historię gestis*, we have from Avitus a poem, *De consolatoria castitatis lande*, addressed to his sister Fuscina; also fragments of controversial works in prose, and a considerable body of letters, which have great interest for students of the political and social condition of the fifth century. Avitus seems to have lived at least as late as 525, but we do not know the date of his death.

A. R. MARSH.

Avitus, MARCUS MÆCILIVS: a Roman emperor of the West; b. in Auvergne probably about 400 A. D.; was the father-in-law of Sidonius Apollinaris; fought under the banner of Aëtius; became prefect of Gaul in 439; and succeeded

Maximus as Emperor of the West in 455 A. D. He was deposed by Ricimer in 456. D. in 457 A. D.

Avoca, or **Ovo'ca**: a small river in Wicklow co., Ireland; enters the sea at Arklow. It runs through a very narrow and picturesque valley, inclosed between wooded banks from 300 to 500 feet high. The Vale of Avoca is the subject of one of Moore's songs.

Avoca (formerly *Pleasant Valley*): borough; Luzerne co., Pa. (for location of county, see map of Pennsylvania, ref. 3-1); on the Leh. Val., Del. and Hudson Canal Co. and Erie and Wyoming Val. R. Rs.; in a coal-mining region; 3 miles from Pittston. Pop. (1880) 1,913; (1890) 3,031; (1900) 3,487.

Avoca'do Pear, or **Alligator Pear** (*Per sea gratissima*): a fruit-tree of the family *Lauraceæ*; a native of the warm parts of America. It has leaves which resemble those of the laurel. The fruit is a drupe, like a pear in shape, and has a soft pulp of delicate flavor, which dissolves like butter in the mouth, and is called "vegetable butter." It is much esteemed in the West Indies, and grows in Southern Florida. In Mexico and Central America the fruit is often called *aguacate*.

Avocet: a web-footed bird of the genus *Recurvirostra*, having long legs and very long, slender bills. The avocets are easily distinguished from other wading birds by the upward curvature of the bill, which is like elastic whalebone, and is adapted to seeking in the mud for its food, which consists almost wholly of worms, insects, and little crustaceans. They are birds of powerful wing, and better adapted for flying and walking than swimming. The *Recurvirostra americana* abounds in the U. S. Another species, *Recurvirostra avocetta*, is common in Europe. The length of each species is about eighteen inches.

Avocet.

Avogadro, AMADEO, Count: physicist and chemist; b. in Turin, Aug. 9, 1776; studied jurisprudence at the Turin University; became Doctor of Laws in 1796, and then held a position under the Government until 1806, at which time he began his scientific work. In 1809 he became Professor of Physics at the gymnasium in Vercelli. In 1820 he was elected Professor of Mathematical Physics at the Turin University. He died in Turin, July 9, 1856, at the age of eighty years. He is known chiefly as the discoverer of the law governing the relations between the specific gravity and the molecular weight of substances in the gaseous state. This law, commonly called *Avogadro's law*, has been of the highest value in the development of CHEMISTRY (*q. v.*). I. R.

Avoid'ance: in English ecclesiastical law, the condition of a benefice void of an incumbent; a vacancy in a benefice.

Avoirdupois', or **Averdupois** [goods of weight; O. Fr. *avoir*, property; subst. use of verb *avoir*, have < Lat. *habere* + *de*, of + *pois*, weight < Lat. *pensum*]: the common system of weights by which we ascertain the weight of all commodities except medicines, gems, and precious metals. A pound avoirdupois contains 7,000 grains, the legal standard of which is such that a cubic inch of water weighs 252.458 grains. The pound is divided into 16 ounces, and an ounce into 16 drams. An ounce is equal to 437½ grains.

TABLE OF AVOIRDUPOIS.

27½ grains	= 1 dram,	dr.
16 drams	= 1 ounce,	oz.
16 ounces	= 1 pound,	lb.
28 pounds	= 1 quarter,	qr.
4 quarters	= 1 hundredweight,	cwt.
20 hundredweight	= 1 ton,	ton.

A cubic foot of water weighs 997.17 ounces avoirdupois.

Avo'la: a seaport-town of Sicily; province of Noto; 13 miles S. W. of Syracuse (see map of Italy, ref. 9-F); supposed to occupy the site of the ancient *Ibla* or *Hybta*, famous for honey. It has an active trade for grain, cattle, oil, and fruits. An earthquake in 1693 destroyed the ancient *Avola*. Pop. 13,182.

Avon: town; Norfolk co., Mass. (for location of county, see map of Massachusetts, ref. 3-1); on Old Colony R. R.; 17 miles S. of Boston, has boot and shoe manufactories. Pop. of township (1890) 1,384; (1900) 1,741.

Avon: village on the Erie and the Western N. Y. and Pa. R. Rs.; in Livingston co., N. Y. (for location of county, see map of New York, ref. 5-D); on the right bank of the Genesee river; 18 miles S. S. W. of Rochester. Avon is delightfully situated on a terrace 100 feet above the river. Here are sulphur springs, with several hotels, which are much frequented in summer by invalids. Pop. (1870) 900; (1880) 1,617; (1890) 1,653; (1900) 1,601.

Avon (river): There are several rivers bearing this name in England, Wales, Scotland, and France. The principal of them in English rivers are noticed below. Scotland has an Avon river which flows into the Clyde, another into the Forth, and a third into the Annan. France has two Avon rivers in the Loire system, and two connected with the Seine.

Avon, LOWER: a river of England; rises in Wiltshire; flows southward, then nearly northwestward, passes by Bath and Bristol, and enters the Bristol Channel after a course of about 80 miles. It is navigable for large vessels to Bristol, 7 miles. The valley of the Avon is very picturesque. Another river called Avon, or East Avon, rises in Wiltshire, flows southward, passes Salisbury, and enters the English Channel at Christ Church.

Avon, MIDDLE, or LITTLE: a river of England. Its whole course is in Gloucestershire, entering the Severn a little below the town of Berkeley.

Avon, UPPER: a river of England; rises near Naseby, in Northamptonshire; flows in a general S. W. direction through Warwickshire and Worcestershire, passing Rugby, Warwick, and Stratford, the birthplace of Shakspeare, and joins the Severn at Tewkesbury. It is about 100 miles long. Its tributaries are the Alne, Leame, Stour, and Swift.

Avondale: town; Jefferson co., Ala. (for location of county, see map of Alabama, ref. 3-D); on Queen and Crescent R. R.; 2 miles from Birmingham; in an agricultural and coal and iron mining district. Pop. (1890) 1,642; (1900) 3,060.

Avondale: village (now part of Cincinnati); Hamilton co., O. (for location of county, see map of Ohio, ref. 7-C); on Cin. and Northern R. R. Pop. (1880) 2,552; (1890) 4,473.

Avranches, aa-vraanish' (anc. *Abrin'cæ*): a town of France; department of the Manche; 32 miles S. W. of Saint-Lo (see map of France, ref. 3-C). It was an important Roman military station, and came into the possession of England at the Norman conquest. The Bretons captured the town in 1203. In the fourteenth century the English got possession of it, and held it until 1450. It was once a bishop's see, and its cathedral, destroyed in the time of the first French revolution, was the finest in Normandy. It is beautifully situated on a hill, and has a ruined cathedral, a college, and a convent. Here reside many English families, attracted by the beauty of the position and the cheapness of living. There is some trade in grain, cider, and salt; and has manufactures of candles, laee, nails, leather, parchment, etc. Pop. (1891) 7,785.

Avrillon, ää-vrëe'yon', JEAN BAPTISTE ELIAS: an eloquent Franciscan monk; b. at Paris in 1632; made profession Jan. 3, 1671, in the convent of the Minims (called *Bonshommes*) at Nigeon. He was a noted preacher 1676-1728, and left many devotional works, which are greatly esteemed in the Roman Church. Some of them have been translated by the Romanizing party of the Church of England. Among these are *Guide for Passing Advent Holyly* (London, 1844) and *Eucharistic Meditations* (1864). D. May 16, 1729.

Award [from the O. Fr. *awarder*, adjudge]: the result of an arbitration. (See ARBITRATION.) An award is governed by well-established rules, such as that it must conform to the agreement whereby the matters in dispute were submitted to arbitration; it must embrace them all; it must be final, as well as certain and reasonable. Where several matters are submitted, it is not necessary that each one should be specifically referred to in the award. If the arbitrators purport to dispose of the things submitted by a general result, it will be presumed, *prima facie*, that each subject was acted upon and embraced in their conclusion. The arbitrators in making an award are presumed to be guided by the rules of law which govern the questions involved in the subject-matter arbitrated upon. An award does not have the force of a judgment in a court of justice. If not performed, an action may be brought upon it. If a sum of money were directed to be paid, a debt would be created

which could be collected by action. Statutes sometimes allow a clause to be inserted in the submission that judgment in a court of justice may be entered upon the award. In such a case no action is necessary, and a judgment may be taken in accordance with the statute.

Awe, Loch: a lake of Scotland; in the county of Argyle; 8 miles N. W. of Inverary; extends 24 miles in a direction N. E. and S. W. Its average width is about a mile, but in some places it is 2½ miles wide. The adjacent scenery is very picturesque. The northeastern end is overshadowed by rugged mountains, one of which, Ben Cruachan, is 3,669 feet high. The water of this lake is discharged through the river Awe into Loch Etive. Loch Awe incloses many islands, and abounds in trout. Its scenes are favorites with artists and with tourists. On its islands are the ruins of several convents and castles.

Awn [M. Eng. *awene*; cf. O. N. *ögn*; O. H. G. *agana* > Mod. Germ. *Ahne*; Gr. *ἄχνη*, chaff]: a stiff and pointed bristle which occurs in the flowers of many grasses, forming the extremity of a glume or palet, as the beard of wheat and barley. The flowers of some grasses are awnless. The parts which are furnished with this organ are called *aristate*. The awn is a prolongation of the midrib of a glume or palet, or is a rigid, barren branch of inflorescence. Sometimes it is twisted, and liable to twist and untwist hygrometrically; sometimes it is serrate, as in barley.

Aw'yaw': See Oyo.

Axe: a tool used by carpenters and others for cutting wood; is of very ancient origin. Savage peoples of antiquity formed axes of stone, copper, bronze, etc. The axe of modern civilized nations is constructed of wrought iron, with a cutting edge of steel, which is welded to the iron when they are heated to a white heat. After it has been hammered and ground into the proper form, it is carefully tempered by heat and cold water.

Axe'stone: a mineral regarded as a variety of nephrite; is hard, tough, and more or less translucent. It occurs in primitive rocks in Saxony and New Zealand; the natives of the latter use it to make axes, hence the name.

Ax'holme Isle: a level and once marshy tract of England; in the northern part of Nottinghamshire; was drained in 1634 by a Dutchman named Vermuyden, and was for a long time inhabited by French and Dutch Protestant refugees. After much litigation between the colonists and the proprietors, the lands were divided in 1691, and about one-sixth was given to the former. It is now extremely fertile of all kinds of crops.

Ax'ia: a town of ancient Etruria, whose remains are identified with the sculptured tufaceous rocks at Castel d'Asso; 6 miles W. of Viterbo. Here are many chambers believed to be sepulchral. There are many Etruscan inscriptions. These remains were discovered in 1808. It is probable that Axia never was a large town, but it must once have been quite important.

Ax'inite [from Gr. *ἄξινη*, an axe]: an anhydrous silicate of alumina, lime, etc., with boracic acid; so named because it occurs crystallized in oblique rhomboidal prisms, so flat as to appear tabular and sharp like the edge of an axe. The crystals have a brilliant, glassy luster, and are translucent or sub-translucent.

Ax'iom [from Gr. *ἄξιωμα*, what commends itself, from *ἄξιος*, worthy]: in geometry, a proposition which admits of no demonstration, but is taken for granted as a self-evident truth; as, "The whole is greater than its part"; "Things which are equal to the same are equal to one another"; "Two straight lines can not inclose a space," etc. Every rational science requires such fundamental propositions and established principles, to which the assent of the student is demanded without proof as a basis for further argument. It is an axiom in logic that he who admits a principle admits its consequence.

Ax'is, plu. **Axes** [Lat., axle]: a straight line, real or imaginary, about which a body revolves is called the axis of rotation. Axis is an important term in astronomy, botany, crystallography, geometry, and mechanics. The axis of the earth or other planet is that diameter about which it revolves. In botany, the axis is the central part of a plant, around which various organs are arranged. The stem is called the ascending axis, and the root is the descending axis. The stem is an axis for the branches, the branch is an axis for the leaves, and the rachis is an axis of inflores-

cence. In geometry, the axis of any geometrical solid is the right line which passes through the center of all the corresponding parallel sections of it or the right line about which the parts of the figure are symmetrically disposed. Thus the axis of a cone is a right line drawn from the vertex to the center of the base. The axis of a curved line is formed by a right line dividing the curve into two symmetrical parts. A right line drawn through the foci of an ellipse is its transverse axis. The lines upon which the abscissas and ordinates of plane curves are measured are called co-ordinate axes, of which one is the axis of abscissas and the other the axis of ordinates. For determining points in space a third axis is used. In crystallography, each form of crystal, except the hexagonal prism and the rhombohedron, has three axes, one vertical and two lateral. In anatomy, the axis is the second cervical vertebra, which in man is the pivot on which the head turns. *Ax'is in Peritro'chio*, an old term for one of the five mechanical powers, commonly called the WHEEL AND AXLE. It consists of a wheel fixed immovably to an axle, so that both turn together around the axis of motion. *Axis of Elevation*, in geology, the line or direction in which rocks have been elevated by an internal force. This line generally governs the strike of the strata, or the direction of a horizontal line upon them, when removed from their natural or original position and inclined to the horizon.

Axis (*Axis aris*): a species of deer found in India and in many of the East Indian islands, sometimes called *chittra* by the natives. It resembles in size and color the European fallow-deer, but its horns are slender, pointed, and little branched. The female has no horns. It is easily domes-

Axis deer.

ticated, and is kept in parks in Europe. Other species, or marked varieties, are known. The horns are used for knife-handles.

Ax'le (in Lat. *ax'is*): a bar of iron or a wooden shaft which supports the body of a carriage or wagon, and is supported on two wheels, in the hubs or naves of which its ends are inserted. Also the part of machinery which forms the center of the revolving portion, or the immediate bearing of the revolution of a piece of machinery which revolves on its own center. Axles of railway cars, instead of revolving in the hubs of the wheels, are strongly keyed in them, and journals are turned on the portions outside the wheels. These journals pass through and revolve in boxes.

Ax'minster: a town of England; in the county of Devon, 16 miles E. of Exeter (see map of England, ref. 14-F). It has manufactures of woolen and cotton goods, etc. The Axminster carpets, whose manufacture was formerly the chief employment of the inhabitants, are excellent imitations of those of Persia and Turkey, but the so-called Axminster carpets are now made elsewhere. Pop. about 3,000.

Ax'olotl': a large larval salamander of the genus *Amblystoma* found in the lakes of Mexico and northward

Axolotl.

through the Rocky Mountains. It has bushy external gills, such as are permanent in the mud puppy (*Necturus*). It has, however, been shown to lose these gills, under some circumstances at least, when it develops into the common tiger salamander, *Amblystoma tigrinum*. It was, however, long regarded as a distinct animal, and known in science as *Siredon lichenoides*. It reaches a length of 8 or 10 inches. It is, however, claimed that the true axolotl of the Mexican lakes never leaves the larval state.

DAVID S. JORDAN.

Axoom: See AXUM.

Axtell, SAMUEL B.: jurist; b. Oct. 14, 1819; was educated at Oberlin and Western Reserve Colleges; elected a member of Congress in 1867 and again in 1869; in 1874 he was appointed Governor of Utah Territory, and afterward of New Mexico. In 1882 he was appointed chief justice of the Supreme Court of the latter Territory, resigning in 1885. D. in Morristown, N. J., Aug. 6, 1891. HENRY WADE ROGERS.

Ax'um, or Axoom (in Gr. *Ἀξούμη* or *Ἀξώμη*): ancient and decayed town of Abyssinia; the former capital of the Axumite empire; in the province of Tigre; 85 miles N. W. of Antalo (see map of Africa, ref. 4-G). Here is a Christian church, built about 1657, which is held in great veneration. Among the antiquities of Axum and the monuments of its former grandeur are several finely sculptured prostrate obelisks, and one granite monolith 60 feet high, which is still standing. The Axumite empire extended over Abyssinia and Yemen in Arabia. Through Adule, a port on the Red Sea, the people of ancient Axum carried on commerce with Arabia and India. Pop. 5,000.

Ayacu'cho: a department of Southern Peru; bounded N. by Junin, E. by Cuzco, S. by Arequipa, and W. by Huancavelica. Area, estimated at 24,213 sq. miles. It is drained by the Apurimac and its affluents. Gold and silver are found here, and in agricultural respects it is the richest part of Peru. Pop. 142,205.

Ayacucho: a town of Peru; in department of the same name; 25 miles E. N. E. of Huancavelica (see map of South America, ref. 5-B). Here the armies of Colombia and Peru completely defeated the Spaniards on Dec. 9, 1824. This victory, gained by Gen. Sucre, ended the Spanish dominion on the American continent, and was followed by the speedy surrender of all the Spanish soldiers in Peru. (See PERU and SUCRE.) Pop. 20,000.

Aye-Aye (*Chi'romys madagascariensis*): a very singular quadruped of Madagascar, belonging to the order of lemurs. It has a long, bushy tail, and is about as large as a hare. Each of its four extremities has an opposable thumb, and

the digits are armed with pointed nails, which it sometimes uses to pick kernels out of nuts. It sleeps during the day,

Aye-aye.

and is very active in the night, feeding on insects and fruits.

Ayer: an important railroad center, Middlesex co., Mass. (for location of county, see map of Massachusetts, ref. 2-H); 35 miles N. W. of Boston; formerly known as Groton Junction, and incorporated as a separate town in 1870. Pop. of township (1880) 1,881; (1890) 2,148; (1900) 2,446.

Ay'eshah, or **Aieshah**: the favorite wife of the prophet Mohammed; b. at Medina about 610 A. D.; was a daughter of Abu-Bekr, who afterward became caliph. In the twenty-fourth sura (or chapter) of the Koran, entitled "Light," Mohammed expressly vindicated her chastity, which had been questioned. After his death she took an active part in public affairs as an enemy of the Caliph Othman and his successor Ali, who defeated her in battle. D. in 677 A. D. See Irving, *Mahomet and his Successors*.

Aylesford, **EARLS OF** (1714, in the peerage of Great Britain), and **Barons of Guernsey** (1703, in the English peerage).—**CHARLES WIGHTWICK FINCH**, the eighth earl, was b. in 1851, and succeeded his father in 1885.

Aylmer: a lake in British North America; about 80 miles N. of Great Slave Lake. It is about 70 miles long and 40 miles wide. It lies on the margin of the forest area of Canada.

Aylmer: incorporated town, Elgin co., Ontario, Canada (for location, see map of Ontario, ref. 5-C); on the Air Line Div. of the G. T. Ry., 12 miles E. of St. Thomas. It is also connected with M. C. Ry., the dépôt being, however, 2½ miles N. It is surrounded by fine farming land. Aylmer has a large canning and fruit-evaporating industry, furniture-factory, pork-factory, hub and spoke factory, 2 organ-factories, 2 sash and door factories, 2 roller-mills, a foundry, water-works, electric-lights, 2 newspapers, etc.; has 5 churches, 5 public schools, a collegiate institute, and a mechanics' institute with a library of more than 4,000 vols. Pop. (1881) 1,540; (1891) 2,167. **EDITOR OF "EXPRESS."**

Aylmer: on Can. Pac. Ry. and Lake Deschenes, Ottawa co., Quebec, Canada (for location, see map of Ontario, ref. 2-H); has manufacturing and lumbering industries. A line of steamers for the Upper Ottawa navigation start from here. Pop. (1881) 1,762; (1891) 1,945.

Aylmer, or **Elmer**, **JOHN**: bishop of the Church of England; b. in Aylmer Hall, parish of Tivetshall St. Mary, in Norfolk, England, in 1521. He was educated at Cambridge, B. A. 1541; was tutor to Lady Jane Grey; became archdeacon of Stow 1553, but shortly after, for opposing transubstantiation, was deprived under Mary, and for safety fled to the Continent. On the accession of Elizabeth (1558) he returned to England; became archdeacon of Lincoln 1562, bishop of London 1576. He treated Roman Catholics and Puritans with severity on doctrinal grounds. He wrote in reply to John Knox's *Blast of the trumpet against the monstrous regiment of women*, a work entitled *An Harborowe for faithfull and trewe Subjects, against the late bloune Blaste, concerning the Government of Wemen* (Strassburg, 1559). D. in London, June 3, 1594. See Cooper, *Athenæ Cantabrigienses*, s. v. **S. M. JACKSON.**

Aylmer, **MATTHEW**, Lord: b. at Balrath, County Meath, Ireland, about 1643; became a rear-admiral in the British navy in 1693, having distinguished himself at the battle of La Hogue; vice-admiral 1694. He became in 1709 commander-in-chief of the fleet; was superseded in 1711, but restored in 1714. He was raised to the Irish peerage as Lord Aylmer, Baron of Balrath, in 1718. D. Aug. 18, 1720.

Aylmer, **MATTHEW WHITWORTH**, Lord: an English general; b. in 1775; succeeded to the peerage Oct. 22, 1785; entered the army as ensign in 1787; served at the siege of Copenhagen, also in Portugal in 1809, in the peninsular campaigns, and was made full general in 1825. He was Governor-General of Canada 1828-33. D. in London, Feb. 23, 1850.

Aymarás: See **BOLIVIA** and **INDIANS OF SOUTH AMERICA**.

Aymorés: an Indian tribe of Brazil. See **BOTOCUDOS**.

Ayr, âr: a river of Scotland; flows nearly westward through Ayrshire, and enters the sea at the town of Ayr; noted for stones used in sharpening cutlery. Length, 33 miles.

Ayr: a seaport; county town of Ayrshire, Scotland; at the mouth of the Ayr; 42½ miles S. S. W. of Glasgow. The river is here crossed by three bridges—the new bridge ("New Brig" of Burns, since twice rebuilt) for general traffic, the "Auld Brig," still open to foot-passengers, and a railway bridge. In 1873 Newton-on-Ayr and Wallacetown, on the north side of the river, were amalgamated. Ayr has an excellent academy, a public library (the gift of Andrew Carnegie), a handsome spire, a fine race-course, elegant suburbs, and a marine esplanade. With Campbeltown, Irvine, Inverary, and Oban, it sends a member to Parliament. It possesses a large carpet-factory and extensive docks. The chief export is coal. Pop. (1891) 24,791; (1901) 28,624.

Ayrer, **JACOB**: a German dramatist. He wrote numerous dramas in the style of Hans Sachs and partly after the model of English plays, from which he copied the character of the clown. D. at Nuremberg, Mar. 26, 1605. See his life by C. Schmitt (Marburg, 1851). **JULIUS GOEBEL.**

Ayres, **ârz**, **ROMEYN BECK**: soldier; b. at East Creek, Montgomery co., N. Y., Dec. 20, 1825; graduated at West Point 1847; promoted to colonel Second Artillery July 28, 1879, and Nov. 29, 1862, brigadier-general of U. S. Vols.; served in war with Mexico 1847-48, at various posts 1848-73, and on expedition to Yellow Medicine river 1857. In the civil war served in the Manassas campaign 1861, engaged at Blackburn's Ford and Bull Run as chief of artillery of division 1861-62, and of corps 1862-63, in Virginia Peninsula 1862, engaged at Yorktown, Williamsburg, New Bridge, Garnett's Farm, Gaines's Mill, Golden's Farm, and Glendale; in the Maryland campaign 1862, engaged at South Mountain and Antietam, in Rappahannock campaign 1862-63, engaged at Fredericksburg and Chancellorsville, in the Pennsylvania campaign, in command of a division 1863; engaged at Gettysburg (brevet major), in suppressing New York draft riots in 1863, Rapidan campaign 1863, engaged at Rappahannock Station and Mine Run, in Richmond campaign 1864-65, engaged at Wilderness (brevet lieutenant-colonel), Laurel Hill, Spotsylvania, Jericho Ford, Tolopotomy, Bethesda Church, Petersburg (wounded), Weldon Railroad (brevet colonel), Chapel House, Rowanty Creek, Dabney's Mill, Five Forks (brevet brigadier-general), and Appomattox Court-house; in command of a division in the district of Shenandoah 1865-66, and member of tactics board 1867-69. Brevet major-general U. S. army Mar. 13, 1865, for gallant and meritorious services in the field, and brevet major-general U. S. Vols. Aug. 1, 1864, for conspicuous gallantry in battles of Richmond campaign. D. at Fort Hamilton, New York, Dec. 4, 1888.

Ayr'shire: a maritime county of Scotland; bounded N. by Renfrew, E. by Lanark and Dumfries, S. by Kirkcudbright and Wigtown, and W. by the Frith of Clyde. Area, 1,149 sq. miles. The surface is generally undulating or hilly, and the southeastern part mountainous. It is drained by the Ayr, the Doon, the Lugar, and other small streams. The county is rich in minerals, especially coal, limestone, freestone, and iron. Silurian and Devonian strata occur here. The soil is generally fertile and well cultivated. Ayrshire is noted for its good dairies and superior breed of milch cows. It has important manufactures of cotton and wool. Pop. (1891) 224,222; (1901) 254,133. Capital, Ayr.

Ayr'ton, **WILLIAM EDWARD**, F. R. S.: physicist and writer on electro-technical subjects; b. in London, England, in 1847. Prof. Ayrton may almost be said to be the father of electro-technical education, since from 1873 to 1879, while professor at the Imperial College of Engineering, Japan, he organized and maintained courses of instruction in electrical engineering, a subject for which no practical provision had at that time been made in the technical schools of either Europe or America. Ayrton was educated at University College, London, where he received the degree of

B. A., with honors, in 1867. Like many of the older English electricians, he began his practical career in the Government telegraph service, in which he ultimately rose to the position of electrical superintendent. Since 1879 he has been Professor of Applied Physics at the City and Guilds of London Institute, the leading technical school in Great Britain. Prof. Ayrton has been at once a fertile writer on electrical subjects and a prolific inventor. The number of scientific papers from his pen is very large, nearly a hundred having appeared in the *Proceedings* and *Transactions* of the Royal Society, the Physical Society, the Society of Telegraph Engineers, etc. He is the author of the widely known text-book entitled *Practical Electricity*, and of a large number of papers in the *Proceedings* and *Transactions* of the Royal and other societies. In connection with Prof. Perry, he has been awarded some twenty-six patents in Great Britain, and several in the U. S., France, Germany, etc. He is a Fellow of the Royal Society, London, a vice-president of the Physical Society, and president (1892-93) of the Institution of Electrical Engineers. E. L. NICHOLS.

Aythor: See **ATHOR**.

Ay'ton, Sir ROBERT: Scotch poet and courtier; b. at the castle of Kinaldie, near St. Andrews, 1570, and was educated at St. Andrews. He was one of the first Scotchmen who wrote in English with elegance and purity; intimately acquainted with the eminent men of his time; and was in great favor at the courts of James I. and Charles I. D. in Whitehall Palace, Feb., 1637-38.

Ay'tonn, WILLIAM EDMONDSTOUNE: poet and essayist; b. in Edinburgh, June 21, 1813; and was educated in the university of that city. He studied law; was called to the bar in 1840; and married a daughter of Prof. John Wilson. He became Professor of Rhetoric in the University of Edinburgh in 1845. Under the assumed name of "Augustus Dunshunner" he contributed many articles to *Blackwood's Magazine*, and distinguished himself as a humorist as well as a poet. In 1848 he produced *The Lays of the Scottish Cavaliers, and other Poems*, which had great success (29th ed. 1883; n. e. 1891). Among his other works are a humorous tale called *How I became a Yeoman; Firmitian, a Spasmodic Tragedy* (1854); and *Bothwell*, a narrative poem (1856). D. at Blackhills, near Elgin, Scotland, Aug. 4, 1865. See his life by Theodore Martin (London, 1867).

Ayuntamien'to (literally, a joining or meeting): in Spain, a council or governing body of a town. These councils acquired much political influence and importance during the wars between the Moors and Spanish Christians. The Spanish kings granted to the towns municipal privileges and institutions which were similar to those of the ancient Romans, and promoted a spirit of liberty. The councils were elected by the vote of the citizens. These institutions were abolished under the Bourbon kings, and were restored in 1837. They were deprived of political power in 1844.

Azad'irine: a bitter principle found in an East Indian tree (*Melia Azadirach*), used to some extent as a substitute for quinine. This tree is called "Pride of China" in the U. S.

Azaïs' PIERRE HYACINTHE: b. at Sorèze, department of Tarn, France, Mar. 1, 1766; was educated in the Benedictine college of his native city, and became secretary to the Bishop of Oléron; was condemned to transportation on account of a bitter criticism of the excesses of the revolutionists, but escaped and lived for several years in retirement; went to Paris in 1806; Professor of History at the military school of St. Cyr, and afterward inspector of the public libraries of Avignon and Nancy; lost this position in 1815 because he wrote a defense of Napoleon; received a pension from the Government through the influence of Madame de Staël, and lived quietly in Paris, lecturing on philosophy in his garden, and publishing a great number of books. D. in Paris, Jan. 22, 1845. His two most characteristic works are *Le Système de Compensation* (1806) and *Le Système universel* (1812).

Aza'lea [from Gr. ἀζαλέος, dry; probably so called because it is usually found in dry situations]: a section of the genus *Rhododendron*, of the family *Ericaceæ*, still commonly regarded, especially by horticulturists, as a distinct genus. There are about 100 species or more, natives of North America, China, and other countries. Many of them are cultivated for their flowers, which are beautiful and fragrant. The *Azalea pontica*, a small shrub growing near

the Black Sea, has fragrant flowers covered with glutinous, hairy glands. The whole plant is narcotic and poisonous. Among the American species (which have deciduous leaves)

Azalea indica.

are the *Azalea nudiflora*, sometimes called honeysuckle, which is cultivated in English gardens, and the *Azalea viscosa*, which has glutinous and fragrant flowers. The *Azalea indica*, a native of India, is a favorite of florists, and is remarkable for its brilliant colors. The *Azalea calendulacea*, found in the Southern U. S., is said sometimes to clothe the mountains with a robe of living flame-color. Many hybrid azaleas are cultivated as flowering shrubs.

Aza'ni: an ancient and ruined city of Asia Minor, in Anatolia, on the Rhyndacus, which is here crossed by two Roman bridges, 73 miles S. S. W. of Brusa. Here are extensive remains, among which are an Ionic temple of Jupiter, with eighteen columns standing, and a theater 232 feet in diameter.

Aza'ra, Don FELIX, de: a Spanish naturalist; b. at Barbunales, in Aragon, May 18, 1746. He was a member of a commission sent in 1781 to South America to determine the boundary between the Spanish and Portuguese possessions, and he remained there twenty years. He prepared numerous maps of South America, and published in Spanish *Observations on the Quadrupeds, Reptiles, and Birds of Paraguay and La Plata* (5 vols., 1802). He also wrote *Travels in South America*, which were published in French (4 vols., 1809). These works are highly esteemed. D. in Aragon in 1811. See Walckenaer, *Notice sur F. Azara*, prefixed to his *Voyage dans l'Amérique Méridionale* (1809).

Azari'ah [Heb. אֲזַרְיָהּ, the Lord helps]: a name of frequent occurrence in the Old Testament: (1) Another name for Uzziah, the tenth King of Judah, who began to reign, according to Winer, 809 B. C. (2) One of Daniel's three friends, a noble of the tribe of Judah, carried captive to Babylon in 605 B. C., whose name was changed to Abednego. (3) The name of some twelve other persons mentioned in the Old Testament, most of whom were either priests or high priests.

Aze'glio, MASSIMO TAPPARELLI, Marquis d' (dat-zāl'yō): Italian statesman, author, and artist; b. at Turin, Oct. 24, 1798. He studied and worked as an artist in Rome, where he passed eight years (1821-29), and became a skillful landscape-painter. Having removed to Milan, he married a daughter of the celebrated author Manzoni. He published in 1833 an historical novel entitled *Ettore Fieramosco*, which was very popular. He stimulated the national spirit and patriotism of the Italians by another popular historical romance, *Niccolò de' Lapi* (1841). His political principles were liberal, but moderate. He wrote numerous political treatises, and fought against the Austrians at Vicenza in 1848. In May, 1849, he was appointed president of the council (prime minister) by King Victor Emmanuel. In this position he rendered important services to his country.

He was superseded by Cavour in 1852. D. at Milan, Jan. 15, 1866. See his life by Morozzo (Florence, 1884).

Azeve'do, MANOEL ANTONIO ALVARES, de: Brazilian poet; b. Sept. 12, 1831, at S. Paolo; d. Apr. 25, 1852. He was educated mainly in Rio de Janeiro, where his father was an eminent advocate. He himself had become a learned lawyer before his premature death. He is chiefly known, however, as the most passionate of Brazilian Romanticists. His poems are full of the revolt and despair of Victor Hugo, De Musset, Lamartine, and especially Byron. Aside from a few unimportant critical articles, his achievement is summed up in the edition of his poems published by his father: *Obras de M. A. Alvares de Azevedo, precedidas de um discurso biographico, etc.* (3 vols., 3d ed. Rio de Janeiro and Paris, 1862). A. R. MARSH.

Az'imuth [viâ Fr., from Arab. *as sumût*; *al*, the + *sumût*, way, points]: the angle made at the zenith by the meridian and the vertical circle in which a heavenly body is situated, or the angle measured along the horizon between the north or south point and the point where a circle passing through the zenith and the body cuts the horizon. In trigonometrical surveys on the surface of the earth the accurate determination of the azimuth of an object is very important. It is usually performed with a theodolite. Azimuth circles or vertical circles are great circles of a sphere, passing through the zenith and intersecting the horizon at right angles.

Azineourt: See AGINCOURT.

Azo-colors: an important class of dyestuffs that have come into prominence within the past few years. They belong to a group of compounds known as azo compounds, the simplest of which is azo-benzene. This is related to benzene as shown in the formulæ C_6H_6 , benzene, and $C_6H_5.N_2.C_6H_5$, azo-benzene. The azo-colors that were first manufactured are *aniline yellow*, $C_6H_5.N_2.C_6H_4.NH_2$; *chrysoïdine*, $C_6H_5.N_2.C_6H_3(NH_2)_2$; and *Bismarck brown*, $NH_2.C_6H_4.N_2.C_6H_3(NH_2)_2$.

In general terms whenever a diazo compound is brought together with a phenol or an amido compound, reaction takes place with the formation of a colored substance, and many of the products thus formed are valuable as dyes. The simplest diazo compound is diazo-benzene, the chloride of which is represented by the formula $C_6H_5.N_2Cl$. When diazo-benzene chloride acts upon the amido compound, aniline, $C_6H_5.NH_2$, aniline yellow is formed:

The simplest example of the products formed by the action of a diazo compound upon a phenol is the compound benzene-azo-phenol, $C_6H_5.N_2.C_6H_4.OH$, which is formed as shown in the equation below:

Among the most important azo-colors are the following: The *tropæolines*, *helianthin*, *acid yellow*, *anisol-red*, *benzopurpurin*, etc. Chrysoïdine was discovered almost at the same time by Caro and Witt independently, and its composition and constitution were established by Hofmann in 1877. The first dyestuffs formed by the action of diazo compounds on phenols were introduced by Witt in 1879 under the name of "tropæolines," and simultaneously by Poirrier, of St. Denis, under the name of "orange." These are all known in general as *acid azo-colors*. Of these an immense number have been patented, and a great many have come into use. *Secondary azo-colors* are those that contain two azo-groups, all of them being derivatives of the substance oxy-azo-azobenzene, $C_6H_5.N_2.C_6H_4.N_2.C_6H_4.OH$, which was discovered in 1879 by Caro and Schraube. "Bicbrich scarlet" and the "croceïn scarlets" belong to this class. The benzidine colors are also secondary azo-colors. The first of these brought into the market was "Congo red," which is formed by treating the tetrazo compound of benzidine with α -naphthylaminesulphonic acid:

Both acid and basic azo-colors dye silk and wool readily, but a mordant is necessary in order to make them take upon

cotton. The secondary azo-colors, however, have a decided affinity for cotton. This makes the benzidine colors especially valuable, as they can be dyed upon cotton directly from a soap-bath without the use of mordants. BENZOPURPURIN (*q. v.*) is the most extensively used of all the azo-colors. Those oxyazo compounds which are insoluble in water form unstable compounds when heated for some time in alcoholic or aqueous solution with potassium or sodium bisulphite. As these compounds are soluble in water, and are decomposed by steaming or by alkali, they can easily be deposited on the fiber.

IRA REMSEN.

Az'of, Azoph, or Azov, Sea of (the anc. *Pa'lus Mae'otis*, called by the Russians *More Asovskoe*): a large body of water situated in the southeastern part of Europe, between Russia and the Black Sea, with which it communicates by the Strait of Yenikale or Kertch (anc. *Cimmerian Bosphorus*). It extends from the Crimea to the mouth of the Don, about 200 miles, and is in some places 100 miles wide or more. Its area is estimated at 14,000 sq. miles. This sea, the water of which is nearly fresh, contains a great abundance of fish. A canal connects it with the Gulf of Perekop.

Azof, or Azov (anc. *Tan'ais*): a small town and fort of Russia; government of Ekaterinoslav; near the mouth of the river Don, 25 miles E. S. E. of Taganrog (see map of Russia, ref. 10-E). It has declined in population and importance. Its harbor is shallow. Azof was taken from the Turks by Peter the Great. It was settled by the Carians, and in ancient times had the name Tanais. After the taking of Constantinople by the Italians it passed into the hands of the Venetians, who held it until, in 1410, it was captured by the Tartars. The Christians were put to death by the captors, from whom came its present name. Pop. about 20,000.

Azores [Port. *Açores*, from *açor*, a hawk], or **Western Islands**: three groups of islands situated in the North Atlantic, about 500 miles W. of Portugal, to which they belong, and between lat. $36^{\circ} 55'$ and $39^{\circ} 44'$ N., and lon. $25^{\circ} 10'$ and $31^{\circ} 16'$ W. (see map of the World, ref. 4-I). The first group consists of Flores and Corvo. About 114 miles S. E. of this group is the central group of Terceira, St. George, Pico, Fayal, and Graciosa. St. Michael and St. Mary form the third group, which is nearly 70 miles S. E. of the central group. St. Michael, the largest of all, is 50 miles long, and varies in width from 5 to 12 miles, and has an area of 340 sq. miles. They are of volcanic formation, and have fertile soils, though the surface is mostly mountainous. The highest point is the Peak of Pico, which has an altitude of 7,613 feet. Volcanic disturbances of a terrible character have occurred at various times. Whole towns have disappeared in opening chasms, and in 1811 an island emerged suddenly from the deep, and later disappeared. The sugar-cane, coffee-plant, orange, and grapevine flourish here, but the soil is not well cultivated. The chief articles of export are wine, brandy, grain, and oranges. The inhabitants are very ignorant. The land is held by feudal tenure, and under such restrictions that the farmers never think of improving it, and simply gather the products which grow wild. It is owned in immense entailed estates. The people are extremely fond of music. They are not intemperate in their habits, are very clean in their dress, but are prone to the grossest superstition. The Azores have no good harbors. The Portuguese took possession of these islands in 1449. Area, 1,005 sq. miles. Pop. 269,401.

Az'otized Bodies (or **Principles**): substances which contain nitrogen (azote), and form part of the living structure of an animal or plant. Among them are albumen, fibrine, caseine, gelatine, and kreatine.

Azo'tus: the Greek name of *Ashdod*, an ancient city and stronghold of the Philistines, in Palestine, about 3 miles from the Mediterranean and 21 miles S. of Jaffa. See ASHDOD.

Azov, Sea of: See AZOF.

Azpeitia, äs-pā'yēe-tee'a: Spanish town in province of Guipúzcoa, 18 miles S. W. of San Sebastian (see map of Spain, ref. 12-G). In the convent of Loyola, a mile from the village, St. Ignatius of Loyola, founder of the Jesuits, was born, 1491. Pilgrims from all quarters flock to the great festival held here in his honor every year in July. Pop. about 6,000.

Az'tecs: a name of a Mexican nation which inhabited the table-land of Anahuac at the time of the Spanish con-

quest of Mexico. According to tradition, they came originally from Aztlan to Mexico, which was inhabited by the Toltecs before the migration of the Aztecs. It is supposed that the latter founded the city of Mexico (or Tenochtitlan) about 1325, some say as early as 1216, and became the most powerful and dominant people of Mexico or Anahuac. They made considerable progress in civilization and the useful arts, derived partly from the Toltecs. They were a warlike people, and conquered several neighboring tribes. "At the beginning of the sixteenth century," says Prescott, "the Aztec dominion reached across the continent from the Atlantic to the Pacific." The government was an elective monarchy, and the sovereign was selected from the brothers or nephews of the preceding king, so that the choice was always restricted to the same family. As they had never learned the art of alphabetical writing, their laws were exhibited to the public in hieroglyphical paintings or picture-writing. Their religion was a gross polytheism. They sacrificed human victims to their gods on a larger scale than other nations—i. e. about 20,000 annually. Astronomy was the science which they cultivated with most success. "We can not," says Prescott, "contemplate the astronomical science of the Mexicans without astonishment." They were acquainted with the cause of eclipses, and they recognized some of the most important constellations. They adjusted the times of their festivals by the movements of the planets, and fixed the true length of the tropical year with great precision. An immense dial, disinterred in 1790 in the great square of Mexico, has supplied us with interesting facts. The calendar engraved on it shows that they settled the hours of the day precisely; also the periods of the solstices and equinoxes, and the transit of the sun across the zenith. The Aztecs were diligent cultivators of the soil, and had acquired respectable proficiency in agriculture, but they had no horses, oxen, or other animals of draught. Their staple productions were maize and the agave or Mexican aloe, which supplied them with food, drink, and clothing. They were ignorant of the use of iron, but found a substitute in bronze, an alloy of copper and tin, of which they made weapons and tools. They also cast golden and silver vases of large size. In mimetic art they were much inferior to the Egyptians. The Spanish conquerors of Mexico destroyed nearly all the manuscripts which they found in the country, and it is not probable that the art of reading the picture-writing will ever be recovered. "The Aztec character," says Prescott, "was perfectly original and unique. It was made up of incongruities apparently irreconcilable. It blended into one the marked peculiarities of different nations, not only of the same phase of civilization, but as far removed from each other as the extremes of barbarism and refinement. It may find a fitting parallel in their own wonderful climate, capable of producing on a few square leagues of surface the boundless variety of vegetable forms which belong to the frozen regions of the north, the temperate zone of Europe, and the burning skies of Arabia and Hindustan." See Prescott, *Conquest of Mexico*, vol. i.

Revised by R. D. HITCHCOCK.

Aztec Antiquities: See CENTRAL AMERICAN ANTIQUITIES.

Azuay, ă-zoo-ay': a southern department of Ecuador; comprising the plateau of Cuenca and the mountains about it. It is fertile and rich in minerals, and largely devoted to the raising of cattle. Area, 11,300 sq. miles. Pop. 132,400.

Azu'ni, DOMENICO ALBERTO: an Italian writer known from his researches in maritime law; b. at Sassari, Aug. 3, 1749; was a judge in Genoa. He published *Droit Maritime de l'Europe* (Paris, 1805), and *Dizionario Universale ragionato della giurisprudenza mercantile*. D. at Cagliari, Jan. 23, 1827.

Azure [O. Fr. *azur*, from Pers. *lāzhwārd*, lapis-lazuli]: the fine blue color of the sky; also the blue pigment which is produced by melting a mixture of a salt of cobalt with quartz-sand and potash, and is used in coloring porcelain. In heraldry, azure is one of the colors employed in blazonry, and is represented in engraving by horizontal lines. It is

equivalent to the color of sapphire among precious stones. In painting, azure is a sky-colored blue, called ultramarine.

Azure-stone: See LAPIS-LAZULI.

Az'urine: a blue variety of the common red-eye or rudd

Azurine or blue roach.

(*Scardinius erythrophthalmus*), a minnow or chub found in the waters of England.

Az'urite: a deep blue carbonate of copper, differing slightly in composition from MALACHITE (*q. v.*), and often occurring with it as an ore of copper, and occasionally as an ornamental stone; but it is opaque, and not hard enough for jewelry. Arizona has yielded masses of deep violet-blue azurite, both pure and mingled with green malachite, that can be wrought into small articles of extreme beauty.

GEORGE F. KUNZ.

Az'ymites [from Gr. ἀζυμίτης, ἀζυμος, unleavened; ἀ-, not + ζύμη, leaven]: the opprobrious epithet applied by the Greek Church polemics to the Latins because the latter used unleavened bread in the celebration of the Holy Eucharist, while the Greek Church uses leavened bread. The Latins in reply called the Greeks "Fruentarians." "There is distinct evidence that unleavened bread was used in the Eucharist by the Latins, and by some Eastern sects in the seventh and eighth centuries, and there is probable evidence that it was used in the third. In the orthodox Eastern Church there can be no doubt that leavened bread has been used from a very early period indeed; if not from the very first, at any rate from the time when Judaizing sects insisted on using unleavened cakes, like those of the Passover, in the Lord's Supper" (Smith and Cheetham, *Dict. Christ. Antiq.*, sub "Elements" [i. 602]). The controversy upon the point was begun by the Greeks, but not until the eleventh century. It was fairly opened by Michael Caerularius, patriarch of Constantinople, 1043-59. The Greek and Latin Churches had long been on bad terms, but Caerularius brought matters to a crisis. The charge against the Latins on account of their use of unleavened bread is not stated by Photius in his famous *Encyclical Letter* (867), in which he goes over the points of difference between the two churches. This does not of course prove that it had not been made, but it does show that it was not considered by Photius very important. Caerularius raised it to prime importance. The argument of the Greek Church is that our Lord in instituting the Eucharist after the Passover-meal used true, nourishing bread as the sign of the new dispensation of joy and gladness; that of the Latin Church is that the Eucharist was instituted during the feast of the Passover, and therefore the only bread that our Lord could get for it was unleavened bread. The Greek position is stated in the *Orthodox Confession of the Eastern Church* (Q. 107), which specifies that the bread of the Eucharist shall be made from wheat, fermented and as far as possible pure. So also in the *Longer Catechism of the Eastern Church* (Q. 328) it is taught that the bread for the sacrament should be leavened pure wheaten bread. The Latins have made the use of such bread in the sacrament a grievous sin, but the Council of Florence (1439) decided that as transubstantiation took place just the same whether the bread was leavened or unleavened, the Greeks could not be anathematized for their practice in this respect.

SAMUEL MACAULEY JACKSON.

B

B: the second letter of the English alphabet, and of most others. It is a sonant consonant of the class known as labial mutes. It is cognate with the mutes *p* (surd) and *f*, and etymologically interchangeable with them and with the liquid *m* and the semi-vowels *w* and *v*. (See ALPHABET.) In ancient Rome *B* sometimes stood for 300, and \bar{B} for 3,000. The Greek β stood for 2, and β for 2,000. On old French coins *B* stands for Rouen; on Prussian, for Breslau. *B* in chemistry is the symbol of the element boron. As an abbreviation, *B.*, or *b.*, signifies "born," and sometimes "book."

B: in music, the seventh letter in the natural diatonic scale of either C major or minor. In this melodic connection it forms the "leading note" of the C scale, calling for the octave C to follow it. In the German language *B* corresponds to our B flat, the letter *H* being used for this, our B natural. *B.* is sometimes written as an abbreviation for the word *Basso*. D. B.

Baa'der, FRANZ XAVER, von: b. at Munich, Mar. 27, 1765; studied medicine at Ingolstadt and Vienna 1781-86; then natural science, especially mineralogy, at Freiberg, under Werner, 1788-92; visited England 1792-96, and held various positions in the Bavarian mining department from 1797 to 1820. In this period he wrote *Vom Wärmestoff* (Vienna, 1786); *Versuch einer Theorie der Sprengarbeit* (Freiberg, 1802); and *Anleitung zum Gebrauche der schwefelsäuren Soda oder des Glaubersalzes zur Glaserzeugung* (1815), for which he received a prize of 12,000 florins from the Austrian Government. Meanwhile he cultivated the study of philosophy and theology with great energy, became acquainted with all the leading men of the time and with their ideas, and finally brought himself to rest in the mysticism of Jakob Böhme. In 1826 he was made Professor of Philosophy and Speculative Theology at the University of Munich, and the deep enthusiasm and ingenious argumentation of his lectures and writings attracted great attention, though his ideas were mystical and the form in which he represented them aphoristical. His views tended to a reconstruction of the whole civilization on the basis of religion and of the Church, but in this new Church there should be no pope. In 1814 he presented a memorial to the sovereigns of Russia, Prussia, and Austria, in which he urged the necessity of bringing politics once more into close connection with religion, but in 1837, during the troubles at Cologne, he spoke with much sharpness against the pope. He died, however, a good Roman Catholic, May 23, 1841, at Munich. His philosophical writings have been published in a collected edition in 16 volumes by Franz Hoffmann (Leipzig, 1850-60), who also has given a general representation of his standpoint (Leipzig, 1857). Cf. Classen, on Baader, Stuttgart, 1886-87, 2 vols.

Ba'al, or **Bel** [Heb., lord]: an ancient North Semitic title of deity. Originally the *baal* seems to have been regarded as the owner and fructifier of the soil, and the name was given to any local deity. Every city and locality in Phœnicia had its *baal* (Baal of Tyre, etc.), and the same thing was probably true of Canaan (Baal-peor, etc., and see Judges vi. 26; ix. 4); hence the plural in O. T., "the baalim." Jehovah also had the title *baal* down to the time of the prophet Hosea (c. 750 B. C.); see Hos. ii., and the proper names (Ishbaal, etc.) compounded with this title. The worship of the Sidonian Baal was introduced into Israel by Jezebel (1 Kings xvi. 31), but the Canaanite Baals were there worshiped earlier. The title was in Phœnicia applied also to a celestial deity (Baal-shemem, "the Baal of the sky"). In the more developed Babylonian cultus the name (pronounced *Bel*, Latinized form *Belus*) was individualized and connected with the sun. In Carthage it appears in Hannibal, Hasdrubal, etc. See W. R. Smith, *Religion of the Semites*; Sayce, *Hibbert Lectures*. C. H. Toy.

Baal'bec, **Balbec**, or **Baalbek** [final *bek* derived, perhaps, from Arabic *bakka*, be thronged]: an ancient and magnificent city of Syria (called by the Greeks *Heliopolis*, i. e. city of the sun); situated in a valley or plain near the

foot of Anti-Libanus, about 42 miles N. W. of Damascus; lat. 34° 1' 30" N., lon. 36° 11' E., and about 3,800 feet above the level of the sea. Its origin and early history are not known. It was formerly one of the most populous and important cities of Syria, and contained many palaces and monuments. Antoninus Pius built here a grand temple, which subsequently became a Christian church. In 636, Baalbec fell into the hands of the Mohammedans, and in 748 was sacked by the Caliph of Damascus. The site is now occupied by a modern village of 2,000 inhabitants and extensive ruins of ancient temples, among which was the great temple of the sun. This was 324 feet long, and had a peristyle of fifty-four Corinthian columns, about 7 feet in diameter and 89 feet high, including capital and pedestal. Six of these columns are now standing. Some of the stones used in the walls or substructions of this temple are 64 feet long and 12 feet thick. The chief material of these temples was limestone or marble and granite. See Wood and Dawkins, *Ruins of Baalbec* (1757); Cassas, *Voyage Pittoresque de la Syrie* (1799); Volney, *Voyage en Syrie*; Robinson's *Later Biblical Researches* (1852, pp. 505-527); Bâdeker's *Palestine*, s. v.

Ba'badagh: a town of Bulgaria; on a tributary of the Danube, 93 miles N. E. of Silistria (see map of Turkey, ref. 2-E). It has considerable commerce with the coasts of the Black Sea, and has a Tartar high school. It was stormed by the Russians in 1771 and 1828, and was ineffectually besieged in 1854. Pop. about 10,000.

Babahoy'o: a town of Ecuador, in the province of Guayaquil; 20 miles N. E. of Guayaquil, on the Cabacol. The goods sent from Guayaquil into the interior go to this place, and are thence sent farther by mules. In consequence, there are large warehouses here. But Babahoyo is, in spite of this great trade, only a small, poorly built town.

Bab'bage, CHARLES, F. R. S. (1816): English mathematician; b. near Teignmouth, Devonshire, Dec. 26, 1792; graduated at Trinity College, Cambridge, in 1814. He early showed extraordinary genius for mathematics, and mechanical speculation and invention. His principal work is *On the Economy of Machinery and Manufactures* (London, 1832), which was translated into several languages. Among his other works is the *Ninth Bridgewater Treatise* (1837). But the public knows him best as the inventor of a calculating machine, which was never completed, although about £17,000 of the public money, and £6,000 of his own, was expended on it. He then spent his life upon the equally abortive analytical engine. His fellow-citizens knew him as the remorseless foe of organ-grinders. D. in London, Oct. 20, 1871.

Bab'bitt, ISAAC: b. at Taunton, Mass., July 26, 1799. He was a goldsmith, and made at his native town the first britannia ware produced in the U. S. In 1841 he received a gold medal for his valuable invention of the alloy which bears his name. Congress also gave him \$20,000. He afterward engaged extensively in the manufacture of this alloy, and also of soap. D. insane, May 26, 1862.

Babbitt Met'al: a soft alloy invented by Mr. Isaac Babbitt, of Boston, and used in lining boxes for axles and gudgeons, in order to diminish the friction and abrasion. These boxes are extensively used in the machinery of steamboats and locomotives. The alloy is prepared thus: to 4 lb. of melted copper add gradually 12 lb. of the best Banca tin, then 8 lb. of antimony, and finally 12 lb. more of tin.

Babeock, JAMES FRANCIS: See the Appendix.

Bab'cock, ORVILLE E.: soldier; b. in Franklin, Berkshire co., Vt., Dec. 25, 1835; graduated at the U. S. Military Academy July 6, 1861, and entered the army as second lieutenant of engineers; promoted to be first lieutenant Nov., 1861; captain 1863, major 1867, lieutenant-colonel 1884; upon graduating he was assigned to active duty as assistant engineer on the defenses of Washington, and subsequently on the staff of Gen. Banks on the Upper Potomac. In the Virginia peninsular campaign of 1862 he served with the engineer battalion at Yorktown and subsequent operations

of the campaign; in Jan., 1863, he was appointed lieutenant-colonel of volunteers, and served as assistant inspector-general of the Sixth Army Corps; as chief engineer and assistant inspector-general of the Ninth Corps; as chief engineer department of the Ohio; and in 1864 he became aide-de-camp to Gen. Grant, with whom he served in the battle of the Wilderness and in subsequent operations, terminating with the surrender of the Confederate armies in Virginia and North Carolina; in July, 1866, he was appointed colonel and A. D. C., and continued to serve as such to Gen. Grant until the latter was inaugurated President, when he was assigned to duty with the President, as his secretary. In 1871, in addition to his other duties, he was placed in charge of public buildings and grounds in the city of Washington, and also made engineer in charge of the Washington aqueduct, which duties he performed till 1877; also president of board of directors of Columbia Hospital for Women and Lying-in Asylum. Drowned in Mosquito Inlet, Fla., June 2, 1884.

Babcock, STEPHEN MOULTON, M. A., Ph. D.: agricultural chemist; b. at Babcock Hill, Oneida co., N. Y., Oct. 22, 1843; educated at Tufts College, Cornell University, and at Göttingen, Germany. Dr. Babcock has given special attention to the chemistry of milk and its products, is the inventor of the Babcock milk-tester, now much used by farmers for the determination of fat in milk, and is at present (1900) Professor of Agricultural Chemistry in the University of Wisconsin, having previously been connected with the chemical department of Cornell University. He was also chemist to the New York State Experiment Station. He is author of many articles upon the composition of milk and butter, and is joint author with Dr. G. C. Caldwell of *A Manual of Qualitative Chemical Analysis*. L. H. BAILEY.

Ba'bel, or **Ba'bil** [Heb. *bābel*, Babylon; perhaps from *bābili*, gate of the gods]: the Hebrew name of the city commonly called Babylon, which is the Greek form of the word Babel; it was also the name of the famous tower which the descendants of Noah began to build soon after the Deluge, on the plain of Shinar, but in consequence of the confusion of tongues they could not finish it. The projectors of the tower said, "Go to, now; let us build us a city, and a tower whose top may reach unto heaven, and let us make us a name, lest we be scattered abroad upon the face of the whole earth." (Genesis xi.) There is no evidence that the work was ever raised above the foundations, but several extravagant reports or traditions of its immense height have obtained currency. (See *The Chaldean Account of Genesis*, by George Smith, revised ed. by Sayce, 1880.) Sir Henry Rawlinson identifies it with the ruin now called Amrán, within the city of Babylon itself. But it is generally identified with Birs Nimrud in Borsippa, a suburb of Babylon. The ruin rises 154 feet above the level of the plain. Some persons have confounded the tower of Babel with the temple of Belus.

Bab-el-Man'deb [Arab., gate of mourning]: a strait which connects the Red Sea with the Gulf of Aden and the Indian Ocean. On the Arabian side of the strait is a cape called Bab-el-Mandeb. The strait is about 20 miles wide, and incloses the rocky island of Perim, on which is a British fort. The eastern channel is most frequented. It is 4 miles wide and 7 to 14 fathoms deep. The name was given to the strait because the navigation of the sea to which it is the entrance, owing to numerous small rocky islets, was, before the introduction of steamers, extremely dangerous.

Bá'ber, **Babur**, or **Babour**, MOHAMMED (surnamed ZAHÉER-ED-DEEN, i.e. protector of religion): a celebrated Emperor of India, and the first of the Great Moguls; b. Feb. 14, 1483. He was a descendant of Tamerlane (Timur-Leng). In 1494 he succeeded his father, who was King of Ferghána. The first part of his reign was disturbed by wars with neighboring powers, and he experienced great vicissitudes of fortune. He performed remarkable exploits in war, and extended his dominions by the conquest of Kandahar, Cabul, etc. He made an incursion into the Punjáb in 1505, and a second time in 1519. Having again crossed the Indus in 1524, he defeated Ibrahim, King of Delhi, on the plain of Paniput in 1526, and became master of India. He was an able ruler, and had a genius for poetry and music. He died Dec. 26, 1530, and was succeeded by his son Humayoon. See his autobiography (London, 1826), abridged in R. M. Caldecott's *Life of Báber, Emperor of Hindostan* (London, 1844); cf. Wheeler, *Short History of India* (1880).

Babenf, *baä'böf'*, FRANÇOIS NOEL: a French conspirator and Socialist, who assumed the name of CAIUS GRACCHUS; b. at Saint-Quentin in 1760. He founded in Paris, in 1794, *The Tribune of the People*, a journal in which he advocated equality and community of property. His disciples were called Babouvistes, and his system Babouvisme. He formed a conspiracy against the Directory, was arrested and tried in Paris, and, the sentence of death being pronounced upon him, he stabbed himself with a dagger, but not fatally, and was guillotined the next day, May 28, 1797.

Babi: the Malay word for "hog," is the name of several islands in the Pacific and Indian Oceans.

Bab'ington, ANTONY: English Catholic gentleman; b. at Dethick, Oct., 1561; entered into a conspiracy to free Mary Stuart and murder Queen Elizabeth. The plot being discovered, he was executed by hanging and quartering in London, Sept. 20, 1586, with a number of his companions. Queen Mary herself was executed largely on the evidence of a letter she was said to have written to Babington, approving of the plot to murder Elizabeth, although she strenuously denied having any knowledge of it.
