THE JOURNAL

OF THE

Society of Chemical Industry.

VOL. XXIII.—1904.

LONDON:
EYRE AND SPOTTISWOODE, HIS MAJESTY'S PRINTERS.
EAST HARDING STREET, FLEET STREET, E.C.

The Society of Chemical Industry.

LIST OF PAPERS READ BEFORE SECTIONS OF THE SOCIETY DURING THE YEAR 1904.

N.B.—The words within ( ) indicate the Journal in which the Paper appears and the Section before which it was read.

PAGE

Archbutt, L. Note on the Determination of the Iodine Value by Iodo-Bromide. (31 Mar., Nottingham) 306

Baker, J. L. A Resumé of the Report, Minutes of Evidence, and Appendices of the Royal Commission on Arsenical Poisoning. (29 Feb., London) 159

and Dick, W. D. The Possibility of Malt becoming Contaminated with Arsenic when Sulphur is Employed during Kilning. (29 Feb., London) 174

Baskerville, C., and Foust, T. B. Rare-Earth Mordants. (15 Feb., New York) 104

Berry, W. G. Identification of Gutta-Percha and Allied Gums by Means of their Resins. (31 May, New York) 529

Biggs, J. W. H. *See* Clowes, F. 358

Carpenter, R. Forbes, and Linder, S. E. Studies on the Claus Reaction. Part II. (15 June, Liverpool) 577

Chikashige, M., and Matsumoto, H. The Defects of Uncarburetted Water-Gas as Fuel for Laboratory Use. (30 Jan., London) 50

Cloud, T. C. Determination of Minute Quantities of Arsenic in Copper Ores and Metallurgical Products. (31 May, London) 524

Determination of Minute Quantities of Bismuth in Copper and Copper Ores. (31 May, London) 523

Clowes, F. Number of Bacteria in the Water of the North Sea, and the Effect of Sea and River Water and of Biological Treatment on the Number of Bacteria present in Sewage. (15 April, Nottingham) 359

and Biggs, J. W. H. The Solubility of Atmospheric Oxygen in Sea-Water and in Water of Different Degrees of Salinity. (15 April, Nottingham) 358

Cobb, J. W. Coal-Ash. (15 Jan., Yorkshire) 11

Coblentz, V. Modern Synthetic Medicinal Products. Part II. (15 Feb., New York) 93

Collins, S. H. The Composition of Milk in the North of England. Part II. (15 Jan., Newcastle) 3

Davies, S. H. Note on the Relative Efficiency of Heat-Insulating Media. II. Steam-Pipe Coverings. (16 May, Yorkshire) 478

and McLellan, B. G. The Amount of Cocoa Butter contained in the Cocoa Bean. (16 May, Yorkshire) 480

Davies, Ll. J. *See* Rowland, J. S.

De Mosenthal, H. Observations on Cotton and Nitrated Cotton. (31 March, London) 292

Dibdin, W. J. The Treatment of Sewage by Bacteria. (31 March, Yorkshire) 312

Dick, W. D. *See* Baker, J. L.

Divers, E. Raschig's Theory of the Lead-Chamber Process. (31 Dec., London) 1178

Divers, E. Theory of the Action of Metals upon Nitric Acid. (31 Dec., London) 1182

Dufton, A. *See* Gardner, W. M.

Dunn, J. T. The Fusion of Refractory Materials. (15 Dec., Newcastle) 1132

Ewan, T. The Estimation of Cyanates. (15 March, Scottish) 244

Ford, J. S. Lintner's Soluble Starch and the Estimation of "Diastatic Power." (30 April, Scottish) 414

Foust, T. B. *See* Baskerville, C.

Gardner, W. M., and Dufton, A. The "Dalite" Lamp for Colour-Matching. (15 June, Yorkshire) 598

and North, B. Stability of Standard Solutions of Potassium Permanganate and Ammonium Oxalate. (15 June, Yorkshire) 599

Garry, H. Stanley, and Watson, H. J. Notes on Petroleum Spirit or Benzene. (15 July, Nottingham) 701

Gemmell, G. H. The Chemical and Mechanical Testing of Portland Cement. (31 March, Scottish) 306

Gray, A. *See* Mills, E. J.

Gray, T. High-Temperature Measurements (with Demonstration of Pyrometer). (31 Dec., Scottish) 1192

and Robertson, J. G. A Comparison of Different Types of Calorimeter. (15 July, Scottish) 704

Griffen, M. L. The Making and Settling of Bleaching Powder Solutions. (29 Feb., New York) 174

Grosvenor, W. M., jun. Analysis of Commercial Acetate of Lime. (31 May, New York) 530

Guttmann, O. The Oldest Document in the History of Gunpowder. (15 June, London) 591

Hackford, J. E. *See* Trotman, S. R.

Hardwick, W. Roscoe. The Manufacture of Sulphuric Acid from Arsenical Pyrites. (15 Mar., Liverpool) 218

Harvey, T. F. The Determination of the Iodine Absorption of Oil of Turpentine. (30 April, Nottingham) 413

Hopwood, A. The Ignition of Clays in Kiln Cases. (15 June, Manchester) 592

Howard, B. F. Rapid Estimation of Mercury by Means of Hypophosphorous Acid. (29 Feb., London) 151

Hudson, O. F. The Glazing of Certain Kinds of Silicious Pig-Iron, and its Cause. (15 June, Nottingham) 595

Huebner, J., and Pope, W. J. The Lustre, the Tinctorial Properties, and the Structural Alterations which result from Treating Cotton with Mercerising and other Liquids. (30 April, Manchester) 404

PAGE

Hutton, R. S., and Petavel, J. E. Preparation and Compression of Pure Gases for Experimental Work. (15 Feb., Manchester) 87

Hyde, F. S. Graphitic Acid or Oxide. (31 Mar., New York) 300

Ingle, H. The Examination of Linoleum and the Composition of Cork. (31 Dec., Scottish)... 1137
  The "Iodine Value" of Unsaturated Organic Compounds. (30 April, Scottish) 422

Inglis, J. K. H. The Loss of Nitre in the Chamber Process. (30 June, London) 643

Jackson, D. D. An Apparatus for the Direct Determination of the Specific Gravity of Cement. (15 June, New York) 593

Jaffe, A. *See* Richardson, F. W.

Kilmer, F. B. The Preparation of Cotton Fibre for Surgical Purposes. (31 Oct., New York)... 967

Leighton, A. E. *See* Macnab, W.

Le Sueur, E. A. Note on the Fractional Condensation of Air, with a View to the Commercial Production of Oxygen. (15 April, Canadian) 350

Linder, S. E. *See* Carpenter, R. Forbes.

McGill, A. The Improvement of Boiler-Feed Water. (15 April, Canadian) 351
  The Improvement of Boiler-Feed Water. (31 May, Canadian) 516

McKee, G. W. On the Decomposition of Benzene at High Temperatures. (30 April, Canadian) 403

McLellan, B. G. *See* Davies, S. H.

Macnab, W., and Leighton, A. E. The Products and Relative Temperature of Combustion of some Smokeless Powders. (31 Mar., London) 298

Mackey, W. McD. Coal Washing. (30 April, Yorkshire) 431

Mardick, J. R. Present Methods of Tannin Analysis and their Influence on the Manufacture of Leather. (31 Dec., New York) 1187

Marshall, A. Acetone; its Manufacture and Purification. (30 June, London) 645
  The Determination of Moisture in Nitroglycerin Explosives. (29 Feb., London) 154

Matsumoto, H. *See* Chikashige, M.

Matthews, J. Merritt. Artificial Silk. (29 Feb., New York) 176

Mills, E. J., and Gray, A. Testing Colloids. (31 May, London) 526

Moore, R. W. Analyses of Jalap. (30 April, New York) 412
  Chemistry in Customs Administration. (15 Nov., New York) 1017

Moulton, J. Fletcher. The Trend of Invention in Chemical Industry. (30 Nov., London) ... 1063

North, B. *See* Gardner, W. M.

Parker, J. Gordon, and Payne, F. E. Munro. A New Method for the Analysis of Tannin and Tanning Materials and the Identification of Admixtures in Tanning Extracts and Liquors. (30 June, London) 648, 1074

Payne, F. E. Munro. *See* Parker, J. Gordon.

Petavel, J. E. *See* Hutton, R. S.

Pope, W. J. *See* Huebner, J. 404

Procter, H. R. Some Recent Methods of Technical Water Analysis. (15 Jan., Yorkshire) 8
  The University and Technology. (30 Nov., Yorkshire) 1074

Richardson, F. W., and Jaffe, A. Estimation of Cane-Sugar, Lactose, &c., in Milk, &c. (31 March, Yorkshire) 309

Robertson, J. G. *See* Gray, T.

Rowland, J. S., and Ll. J. Davies. Method for the Determination of Phosphorus in Iron Ores. (31 Dec., London) 1186

Sadtler, S. S. A Method for the Determination of Certain Aldehydes and Ketones in Essential Oils. (31 March, New York) 303

Schaak, M. F. Methods for the Rapid Estimation of Boric Acid. (15 July, New York) 699

Sharwood, W. J. On the Cupellation of Platinum Alloys containing Silver or Gold and Silver. (30 April, New York) 412

Sisson, G. Notes on the Production and Use of Liquefied Carbon Dioxide. (15 March, Newcastle) 242

Smith, R. Greig. The Bacterial Origin of the Vegetable Gums. (15 Feb., Sydney, N.S.W.) ... 105
  The Bacterial Origin of the Vegetable Gums. Part II. (31 Oct., Sydney) 972

Smith, Watson. Action of Certain Solutions upon Aluminium and Zinc. (16 May, London) 475

Sodeau, W. H. Notes on some Temperature Regulators. (15 Dec., Newcastle) 1134

Stillwell, A. G. Acetic Acid in Acetate of Lime. (31 Mar., New York) 305

Stocks, H. B. Destructive Bacteria in Manufacturing Operations. (31 Mar., Liverpool) 298

Tatlock, R. R., and Thomson, R. T. The Analysis of Waters, and their Changes in Composition when employed in Steam-Raising. (30 Apr., Scottish) 428

Thomason, W. The Preparation of Lead Glazes of Low Solubility, and some Points to be Observed in the Process. (16 May, London) 470
  The Volatilisation of Lead Oxide from Lead Glazes into the Atmosphere of a China Glost Saggar, and its Effect upon the Leadless Glaze Ware in the same Saggar. (16 May, London) 469

Thomson, R. T. *See* Tatlock, R. R.

Trotman, S. R. The Electrolytic Estimation of Arsenic. (29 Feb., Nottingham) 177
  The Mineral Constituents of Sumac. (15 Dec., Nottingham) 1137
  and Hackford, J. E. An Electrical Heater for Laboratories. (15 Dec., Nottingham) 1137
  and Hackford, J. E. The Differentiation of the Different Forms of Nitrogen in Glue. 30 Nov., Nottingham) 1072
  See Wood, J. T.

Tyrer, T. Incandescent Alcohol Lamps. (31 May, London) 528
  The Need of Duty-Free Alcohol for Industrial Purposes. Part II. (15 Mar., London) ... 221

Watson, H. J. Glue and Glue Testing. (31 Dec., Nottingham 1189
  See Garry, H. Stanley.

Webster, C. S. Stanford. Luminescope for Comparing Substances under the Influence of Radium Rays. (31 Dec., London) 1185

Wood, J. T., and Trotman, S. R. Note on Collin. (30 Nov., Nottingham) 1071

Worstall, R. A. The Iodine Absorption of Spirits of Turpentine. (31 Mar., New York) 302

Journal of the Society of Chemical Industry

INDEX OF VOL. XXIII.—1904.

INDEX OF AUTHORS' NAMES.

N.B.—In this Index (P) indicates that the matter referred to is an abstract of a Patent.
The titles of new books are given in quotation marks.

A

PAGE

Aagaard, A. Leather; Waterproof Dressing for —— (P)..... 830

Abady, J. *See* Simmance 456

Abel, T. *See* Badische Anilin und Soda Fabr. 438

Abelmann, T. Varnish; Manufacture of Quick-drying —— (P) 830

Abelous, J. E. Oxido-reducing Enzyme in Plants 766

and Aloy, J. Oxido-reducing Enzyme in Plants.......... 275

Abelspies, J. F. C. Ores; Concentrators for —— (P)......... 1222

Abendroth, H. A. Ammonia-Water Apparatus (P) 978

Abraham, H. *See* Standard Paint Co. 1217, 1217

Abraham, K. Sugar; Analysis of ——...................... 340

Abt, A. Wool; Mordanting —— with Aluminium Sulphate, &c. 58

Accumulatoren-fabrik Aktienges. Metals; Electrolytic Extraction of —— (P) 718

Ach, F. *See* Boehringer und Soehne 503, 503

Acheson, E. G. Carbon Articles; Manufacture of —— (P) ... 192

Acree, S. F. α-Naphthylmagnesiumbromide; Preparation of —— 318

Actiengesellschaft für Anilinfabrikation. Arylated 1.8-Naphthylaminesulphonic Acids; Preparation of —— (P) .. 1210

Cyanines for Photographic Purposes (P) 999

Dyeing Hair, Feathers, and Furs (P)..................... 982

Dyeing Mixed Silk and Cotton Goods (P) 17

Dyestuff; Red Lake from Azo —— (P) 984

Dyestuffs; Green Sulphurised —— (P)..................... 486

Dyestuffs; Mono-azo —— (P) 657

Dyestuffs; Mono-azo Mordant-dyeing —— (P) 319

Dyestuffs; Polyazo —— (P) 57

Dyestuffs; Red Monazo —— (P) 367

Dyestuffs; Sulphide —— (P).............................. 783

Dyestuffs; Sulphide Yellow —— (P) 16

Dyestuffs; Sulphur —— derived from Indophenol (P) ... 319

Dyestuffs; Yellow Sulphide —— (P)...................... 898

Dyestuffs; Yellow Sulphurised —— (P)............... 16, 656

Film for the Pigment Photographic Process (P).......... 727

Lakes from Sulphide Dyestuffs (P) 873

Photographic Flash-light Powder (P)..................... 836

Actienges. für Chem. Ind. Nutritive Substance, from Blood (P) 499

Decolorised Albuminous Substances; Manufacture of —— (P).................................. 201

Adam, J. M. Separating Apparatus: Centrifugal —— (P) ... 316

Adams, A. A., and Springborn, E. Sewage, &c.; Purification of —— (P).................................. 947

Adams, M. J. *See* Adams, S. H. 676

Adams, S. H. Tanks; Apparatus for Emptying Liquid Sewage —— (P) 676

Adams, W. H., jun. *See* Hubbard.......................... 22

Addicks, L. Copper; Economic Balance in Electrolytic Refining of —— 667

Addicks, W. R. Water-Gas; Manufacture of Carburetted —— (P) 602

Adiassewich, A. Shale Oil, &c.; Desulphurising —— (P)..... 247

Adnet, C. E. *See* Cambier.................................. 500

See Tixier 489

Adolph, G. Alkali Chlorides; Electrolysis of —— by the "Bell" Process 786

Adrot, G. Briquettes of Coal and Peat (P) 653

Advance Furnace Co. Furnace; Electric —— (P) 192, 192

Ahrendts, C. Stones, Artificial, or Bricks; Manufacture of —— (P) 490

Ahrens, F. B., and Gorkow, R. Coal-Tar Bases............... 654

Aiken, R. H. Copper Ores; Smelting of —— (P).............. 66

Akers-Douglas, A. Order on Explosives in Coal Mines .. 205, 1044

Aktiebolaget Separator. Separating Apparatus; Centrifugal —— (P).................................. 895

Aktieselskabet Venezuela Asfalt Komp. Asphalt; Manufacture of Artificial —— (P) 318

Aldrich, N. W., and Ryan, J. F. Rubber; Extracting —— without Solvents (P) 448

Aldrich, T. B. Halogen Tertiary Butyl Alcohol; Manufacture of —— (P)................................ 726, 726

Alexander, J. S. L., and Shiels, A. Annealing Metals, and Apparatus therefor (P) 1150

Alexander, P. India-Rubber; Oxygenated Compounds in —— 943

India-Rubber; Weber's Method for Direct Determination of —— 765

Alexandroff. *See* Zelinsky 75

Alexandrow, A. *See* Rudakow.................................. 674

Alilaire, E. L. Skins; Tanning of —— (P).................. 1227

Alix, J., and Bay, J. Coal Analysis: Frequent Cause of Error in —— 800

Allen, A. H., and Tankard, A. R. Boric Acid in Cider, &c.; Determination of —— 883

Allen, B., jun. Tanning Drum (P) 495

Tanning Wheel (P).................................. 495

Allen, C. M. *See* Bagga'ey.............................. 869, 869

Allen, F. E. Drying Apparatus (P)........................... 858

Allen, T. S. Steel: "Ageing" of Sheet —— 754

Allgem. Elektro-Metallurgische Ges. *See* Savelsberg.......... 753

Alliot, H. Fermentation in the Distillery 333

and Gimel, G. Fermentations; Action of Oxidising Agents on Purity of ——.................................. 498

and Gimel, G. Molasses; Use of Oxidising Agents in Fermentation of Sulphited.................................. 946

Alliott, J. B., and Scott-Moncrieff, W. D. Sewage, &c.; Apparatus for Distributing —— 1108

Allis-Chalmers Co. Electric Furnace (P) 1223

Allison, J. J. C. Coke; Manufacture of —— (P) 977

Alliston O. F. Hydrosulphite N F: Employment of —— in Calico Printing.................................. 487

Aloy, J. *See* Abelous 275

See Frébault 1046

Alsop, J. N. Flour; Electrical Treatment of —— (P) 619

Gaseous Media; Generation of —— from Air (P)..... 611, 612

Aluminium Industrie Actienges. Steel: Deoxidising —— (P) 668

Alzugaray, J. B. de. Crucible Furnaces (P).................. 374

Iron, Steel, and their Alloys; Manufacture and Refinement of (P).................................. 118

Metals; Extraction of —— from Complex Ores (P) 24

  Tannate Mordant; Half Discharge for —— (Bourry) 748
Antinonnin (Potassium Orthodinitrocresol) as a Disinfectant in Brewing. (Will) 126
Antipyretics; Synthetic ——. (Coblentz) 96
Antipyrin: Dimethyl- and Diethylamido; Manufacture of ——. (P) Majert 85
Antipyrine; Application of —— in Analysis. (Reichard) 456
  Reaction for ——. (Bérenger) 207
  U.S. Customs Decision on ——. (T.R.) 571
Antirheumatics; Synthetic ——. (Coblentz) 100
Antiseptic Compound, and Manufacture of same. (P) (Endermann) 996
  Compounds, and Manufacture of same. (P) Lake. From Stearns und Co. 834
  Compounds; Solidification of ——. (P) Raetz 500
Antiseptics: Intestinal ——. (Coblentz) 99
  Synthetic ——. (Coblentz) 96
Apatite: Electrical Manufacture of Manure from. (P) Palmaer 124
Apiols, Dill- and Parsley: Constitution of ——. (Thoms) 797
Apomorphine Bromomethylate. *See under* Euporphrine.
Apopin, Shu-yu: Essential Oil of ——. *See under* Oils, Essential.
Apparatus and Machinery. (Class I.) 13, 39, 54, 79, 109, 139, 180, 211, 245, 276, 315, 342, 363, 434, 482, 537, 600, 652, 708, 743, 779, 814, 858, 894, 928, 975, 1020, 1078, 1139, 1201
  Philosophical and Scientific, for Colleges; U.S. Customs Decisions on ——. (T.R.) 389
l-Arabinose; Action of Lime on ——. (Kiliani and Koehler) 496
Archetypes; Transformation of Silver Bromide Negatives into ——. (P) Barricelli and Levi 130
Argentina; Customs Decision on Shale Oil. (T.R.) 40
  Denatured Alcohol Exempt from Internal Tax in ——. (T.R.) 509
  Trade of —— in 1903. (T.R.) 506
Argon; Presence of —— in Gases from Smoke Fissures in Guadeloupe. (Moissan) 564
Aristol; U.S. Customs Decision on ——. (T.R.) 345
Armour Plates and Projectiles; Manufacture of ——. (P) Fairholme and Fletcher 609
  Plates; Treatment of ——. (P) Engels 374, 986
Arnica Montana: Arnisterol, the Phytosterol of ——. (Klobb) 454
Arnisterol: the Phytosterol of Arnica Montana. (Klobb) 454
"Arrhenal" (Sodium Methyl Arsenate); Behaviour of —— in Marsh's Apparatus. (Vitali) 36
Arsenates; Preparation of ——. (Schairer) 115
Arsenic:
  American Trade in —— in 1903. (T.R.) 139
  in Copper Ores, &c.; Determination of Minute Quantities ——. (Cloud) 524
  Deposits in Spain; Development of —— 770
  Determination of —— Electrolytically. (Sand and Hackford) 761
  Determination of —— in Sulphuric and Hydrochloric Acids (Blattner and Brasseur) 338
  Electrolytic Estimation of ——. (Trotman) 177
  Electrolytic Methods for Detection and Determination of ——. (Thomson) 799
  Fumes; Arresting ——. (P) Baggaley 23
  and Iron; Soluble Compounds of ——. (P) Chem. Werke Hansa 383, 1043
Arsenic—*cont.*
  Mine in Virginia, U.S.A. (T.R.) 508
  in Nickel Speiss; Determination of ——. (Nissenson and Mittasch) 338
  Production of —— in 1903. (T.R.) 213, 1049
  in "Reduced Iron": Determination of ——. (Hill and Umney) 1046
  Reports and Recommendations on Tests for Detection of —— in Drugs. (Dunstan and Robinson) 999
  Separation of —— by Distillation. (Morgan) 762
Arsenic Pentachloride; Non-existence of ——. (Smith and Horn) 749
Arsenical Poisoning; Danger of —— in Autogenous Soldering. (Lunge) 1220
  Poisoning; Resumé of Royal Commission Report on ——. (Baker) 159
Arsenious Acid; Action of —— on Ferric Hydroxide. (Biltz) 1027
  Apparatus for Extraction of ——. (P) Biguet 1215
Arsenious Iodide; Determination of ——. (Duncan) 77
  Oxide; Briquettes of Solidified ——. (P) Souheur 253
Asbestos; Discovery of —— in Canada. (T.R.) 391
  Millboards, Slates, &c.; Manufacture of ——. (P) Ibbotson and Meldrum 936
  Production of the United States. (T.R.) 916
Asparagine; Determination of —— by the Sachsse-Schloesing-Longi Method. (Brown and Millar) 135
Asphalt, Artificial; Manufacture of ——:
    (P) Aktieselskabet Venezuela Asfalt Komp. 318
    (P) Rubitschung 65
    (P) Soriano 55
  Composition for Floors, &c. (P) Nusch. From Westdeutsche Thomasphosphat-Werke 750
  Mastic; U.S. Customs Decision on ——. (T.R.) 1050
  Mines in Colombia, South America. (T.R.) 278
  Occurrence of —— in Pedernales, Pesquero, and La Plata, Venezuela 112
  for Paving; Manufacture of ——. (P) Thompson 64
  Production of —— in the United States. (T.R.) 916
"Asphalts"; Examination of ——. (Donath and Margosches) 541
Asphalting Composition. (P) Preaubert and Thubé 1029
Asphaltum; Investigations on ——. (Lunge and Krepelka) 436
  Syrian ——, for Printing Plates, &c. (Fleck) 268
Aspidium Spinulosum; Fatty Oil of ——. *See under* Oils, Fatty.
Atropine; Reactions of ——. (Reichard) 1116
Attemporators for Distillery Fermentation Tuns. (Heinzelmann) 1230
Aucubin; Characteristics of ——. (Bourquelot and Hérissey) 558
Aurous Iodide; Preparation of ——. (Meyer) 1164
Australia; Customs Decision on Aceto-Salicylic Acid. (T.R.) 143
  Gold Production of ——. (T.R.) 1124
  Gold Production of —— in 1903. (T.R.) 508
  Imports by —— in 1903. (T.R.) 1048
  Queensland; Mineral Production of —— in 1903. (T.R.) 567
  South; Bowstring Hemp from —— 784
  South; Cotton from —— 784
  South; Hemp from —— 784
  South; Olive Oil Production of. (T.R.) 344
  South; Phosphate Deposits in ——. (T.R.) 80
  South; Wine Production of ——. (T.R.) 345
  Victoria: Mineral Production of ——. (T.R.) 1007
  Western; Goldfield at Murchison ——. (T.R.) 805
  Western; Mineral Output of ——. (T.R.) 770
Austria; Glass Manufacture in ——. (T.R.) 213
  Mercury Mines of Idria. (Genter) 65
  Olive Oil Production in ——. (T.R.) 41
Austria-Hungary; Chemical Trade of ——. (T.R.) 804
Autoclave: Copper ——. (P) Blasberg and Co. 246
Awards at St. Louis Exhibition 1014
Azo Dyestuffs. *See under* Dyestuffs.

B

Bacteria; Agglutination of ——. (Bechhold) 730
  Beds; Apparatus for Use with ——. (P) Doulton and Pleace 1109
  Destroying —— by Boiling under Reduced Pressure. (Schut) 1040
  in Manufacturing Operations; Destructive ——. (Stocks) 288
  Treatment of Sewage by ——. (Dibdin) 312
Bacterial Infection in the Brewery; Detection of ——. (Falk, Hausmann, and Luff) 796
Bagdad Railway; Naphtha near the ——. (T.R.) 278
Balsam, White Peruvian; Constituents of ——. (Thoms and Biltz) 1111
Banana Fibre from Southern Rhodesia. (Bull) 980
Baobab Tree Fibre from Southern Rhodesia. (Bull) 981
Barbituric Acid; Transforming Iminobarbituric Acids into ——. (P) Maison E. Merck 1043
Barium; Determination of —— by Gasometric Method. (Riegler) 562
  Separation of Radium from ——. (Marckwald) 208
Barium Carbide; U.S. Customs Decision on ——. (T.R.) 391
  Chloride; Electrolysis of Pure ——. (Haber and Tolloczko) 1033

PAGE

Barium—*cont.*
Chromate; Use of —— in Determination of Sulphates and Chlorides. (Andrews) 1162
Hydrate; Manufacture of —— Electrolytically. (P) Harrison Bros. and Co. From Jahn 1223
Hydroxide; Electro-chemical Formation of ——. (P) Candau 606
Hydroxide; Manufacture of ——. (P) Harrison Bros. and Co. 371
Hydroxide; Manufacture of ——. (P) Joseph 1023
Manganate; Manufacture of a Special ——. (P) Tixier and others 489
Nitrate; Decomposition of —— by Heat. (Gottlieb) 545
Nitrite; Preparation of ——. (Witt and Ludwig) 61
Oxide; Manufacture of Porous ——. (P) Schulze 253
Oxide; Preparation of Porous ——. (P) Siemens Bros. and Co. 823
See also under Barytes.
Peroxide; U.S. Customs Decision on ——. (T.R.) 343
Platinocyanide; Preparation of ——. (Brochet and Petit) 1222
Sulphate; Behaviour of Colloidal Solutions towards ——. (Vanino and Hartl) 1117
Sulphate, Artificial; U.S. Customs Decision on ——. (T.R.) 343
Sulphate; Chlorine in Precipitated ——. (Hulett and Duschalk) 800
Sulphate of the Lezère District. (Guédras) 714
Sulphate, Production of ——. (P) Gilman 61
Sulphide; U.S. Customs Decision on ——. (T.R.) 461

Barley, Albuminoid Content of; Measuring —— by Pappenheim's Triacid Solution. (Lindner) 795
Conversion of Insoluble Protein in ——. (Nilson) 555
Corn: Absorption of Water by the —— during Steeping. (Bode) 554
Germination of ——. (Nilson) 379
Germinative Capacity of; Methods of and Apparatus for Testing ——:
(Schonfeld) 1105
(Wichmann) 1105
Judging Malting —— by Analysis. (Lintner) 31
Nitrogen Content of ——. (Prior) 673
Nitrogenous Substances Soluble in Water in —— 340
Relations between Percentage of Extract and Protein in ——. (Merz) 199
Research on —— 261
Roasting —— for Colouring Stout, &c. (P) Valentine 126
Starch in ——; Rapid Determination of ——. (Brown and Millar) 137
Tannin of ——. (Seyffert) 874
Tannin Constituents of ——. (Reichard) 498

Barleys; Germination and Kiln-Drying of ——. (Murphy) 497
Rich in Protein. (Wielding) 73

Barytes; Bleaching of —— and Recovery of Glauber Salt. (P) Gilman 983
U.S. Customs Decision on ——. (T.R.) 732
See also under Barium Oxide.

Basic Slag. *See* Slag.

Basil Oil, Essential. *See under* Oils, Essential.

Bath for Chrome Tanning. (P) Rosell 615

Baths for Electroplating. (Grésil) 904

Batteries; Various ——:
Electrical ——:
(P) Lord 717
(P) Kamperdyk 1222
(P) Noble and Anderson 611
(P) Portalier 445
Galvanic ——. (P) Fiedler and Gerard 403
High-voltage Galvanic ——. (P) De Gournay 940
Primary ——. (P) Edison Manufacturing Co. From Edison 870
Secondary ——:
(P) Betts 611
(P) Commelin and Viau 717
(P) Edison 24
(P) Fairweather. From Vesta Storage Battery Co. 1097
(P) Fennell and Perry 191
(P) Lyons and Broadwell 870
(P) Pescatore 1223
(P) Rosset 192
(T.R.) 41

Battery (Secondary) Gases; Rendering —— Non-explosive. (P) Edison Manufacturing Co. From Edison 870

Battery Cells, Plates, Elements, Solutions, &c.:
Anodes, Aluminium; Dimensions of Films on ——. (Mott) 792
Anodes, and Manufacture of same. (P) Blackman 717
Anodes, Copper and Aluminium; Behaviour of ——. (Fischer) 666
Cell; Carbon Primary ——. (Haber and Bruner) 940
Cell; Experiments with a New Primary ——. (Bousfield) 666
Cell; The Weston ——. (Barnes and Lucas) 665
Cells; Galvanic ——. (P) Ziegenberg 1223
Cells; Galvanic Dry ——. (P) Schauli and Löwenstein 257
Cells; Solid Daniel ——. (Haber and Tolloczko) 1033
Cells; Standard ——. (Wolff) 665
Cells, Standard; Preparation of Materials for ——. (Carhart and Hulett) 665
Diaphragm for Electrolytic Cells; New Form of ——. (Perkin) 869
Electrodes:
(P) Atkins 377
(P) Cornaro 377

PAGE

Battery—*cont.*
Electrodes; Carbon ——, for Primary Cells. (P) Mann 1097
Electrodes for Electrolysis. (P) Chem. Fabr. Griesheim 119
Electrodes for Secondary Batteries:
(P) Elektra Manufacturing Co. From Feldkamp 119
(P) Lennox and The Michigan Storage Battery Co. From Frank 377
(P) Meygret 119
(P) Pflüger Accumulatorenwerke Akt.-Ges. 377
(P) Roderbourg 376
(P) Sperry 1151
Exciting Compound for Batteries. (P) Marschall 257
Exciting Fluid for Batteries. (P) Primary Power Co. From Atwood 717
Plates; Protective Coating for Storage Battery ——. (P) Meygret 1223
Plates; Protective Sheath for Battery ——. (P) Meygret 445
Solutions for Use in Cells of Galvanic Batteries. (P) Wheatley. From the Atwood Electric Co. 377

Bauxite; Analysis of ——. (Faurel) 1114
in the Manufacture of Firebrick 64
Production of the United States. (T.R.) 1168
See also under Alumina.

Beer; Action of —— on Metals. (Seyffert) 796
Albuminoid Turbidity in ——. (Schonfeld) 332
Apparatus for Production of Non-Deposit ——. (P) Blaxter and others 832
Apparatus for Treating Fermentation-Gas from ——. (P) Wittemann Co. From Wittemann 832
Behaviour of —— towards Metals. (Brand) 1039
Brewing ——, and Apparatus therefor. (P) Southby 200
Carbon Dioxide in ——. (Langer) 555
Casks. *See under* Casks.
Causes of the "Head"-retaining Property of ——. (Mohr) 380
Causes and Prevention of Altered Flavour in ——. (Vogel) 1038
Condition, Viscosity, and "Head" Retention in ——. (Mohr) 756
Conditioning of —— by Bunging with Yeast. (Lindner) 6
Determination of Maximum Degree of Attenuation of ——. (Windisch) 263
Effects of Different Temperatures, &c., on Attenuation of ——. (Bleisch and Regensburger) 262
English Types of; Preparation of ——. (Seyffert) 907
Fermentation of Bottom-Fermented —— under Pressure. (P) Lapp 832
Filtering Material for; Purification of —— 199
Filtration of ——:
(Bauer and others) 876
(Ludwig) 499
Filtration and Albuminoid Turbidity of ——. (Windisch) 263
Filtration, and Permanence of "Head." (Windisch) 499
Filtration; Turbidities caused by ——. (Sellenscheidt) 333
"Head" Retention in ——. (Rossel) 674
"Head" Retention and Proteids in ——. (Schuler) 674
Incrustation: Action of Disinfectants on ——. (Tornell and Morell) 1230
Influence of Volume of Mashing Liquor on Quality of ——. (Jalowetz) 674
Influencing the Retention of "Head" in ——. (Bau) 756
"Lecithinated"; Production of ——. (P) Fournier 908
or Malt Extract; Nutritive ——. (P) Moberts 1107
from Malt with Short Acrospire. (Holzhauser) 795
Matabele ——. (Loir) 555
Metallic Turbidities in ——:
(Gabel) 555
(Schonfeld) 499
(Sellenscheidt) 555
Protective Coating for Vessels for containing ——. (P) Lapp 556
Recovered by Pressing Yeast. (Thausing) 674
Regulation of Final Attenuation of —— by the "Spring" Mashing Process:
(Kleinke) 198
(Windisch) 198
Resin Turbidity in ——. (Will) 126
Saké; Production of ——. (P) Jacquemin 32
Sarcina Infection of ——. (Claussen) 332, 876
Sarcina Sickness in ——. (Will and Braun) 757
Sulphur Dioxide in ——. (Graf) 898
Surface Influences in ——. (Emslander and Freundlich) 945
Treatment of —— and Apparatus therefor. (P) Monti 996
Turbidity of —— caused by Metallic Surfaces. (C.F.) 263
Turbidities in ——, caused by Tin. (Dinklage) 451
Wort; Continuous Purification of ——. (P) Hoffmann 32
See also Brewing.

Beers; Application of Hansen's Pure Yeast System for English Stock ——. (Claussen) 721
from Different Barleys; Comparison of ——. (Wahl) 945
English; Manufacture of ——. (P) Claussen 1230
Filtering ——, and Apparatus therefor. (P) Johnson and S. H. Johnson and Co., Ltd. 757
Pulp Boards for Filtration of —— 620
Top Fermentation; Chilling and Filtering of ——. (Van Laer) 722
See also Beverages *and* Brewing.

Beeswax, Artificial Colouring Matter in: Detection of ——. (Lemaire) 840
from British Central Africa. (T.R.) 806
of British India. (Hooper) 828
"Extraction"; Characteristics of ——. (Hirschel) 327
See also under Wax.

Cedar Wood; Essential Oil of ——. *See under* Oils, Essential.

Celery: Constituents of ——. (Bamberger and Landsiedl) 1157

Cellotropin (Monobenzoylarbutin); Manufacture of ——. (P) Vilmar 503
  (Monobenzoylarbutin); Preparation of —— 453

Celluloid: Apparatus for Treatment of ——. (P) Cave-Browne-Cave 909
  Articles; U.S. Customs Decision on ——. (T.R.) 42
  Artificial ——. (P) Schmerber 758
  Compound. (P) Meister, Lucius und Bruning. From Schmidt 558
  Manufacture of ——. (P) Schmerber and Morane 382

Celluloid—*cont.*
  Material Resembling ——. (P) Chem. Fabr. vorm. Weiler-ter Meer 880
  New Composition of ——. (P) Ortmann 949
  Objects; Imparting Lustre to ——. (P) Homberger 997
  in Paste Form; Manufacture and Application of ——. (P) Didier 453
  Rendering —— Non-Inflammable:
    (P) Parkin 1111
    (P) Woodward 1111
  Solubility of ——. (Flemming) 335
  Substitute for ——; Transparent and Non-Inflammable. (P) Provenx 1234
  Utilisation of Waste ——. (P) Kitsee 880

Cellulose Acetate; Manufacture of ——. (P) Newton. From The Farb. vorm. F. Bayer 337
  Acetate; a Substitute for Horn. (P) Walker 1129
  Apparatus for Controlling the Flow of —— in the Manufacture of Filaments. (P) Stearn and Topham 834
  Bleaching of Sulphite ——. (Montanus) 948
  and Collodion Solutions; Apparatus for Treating ——. (P) Soc. Desmarais et Morane and Denis 933
  Compounds; Industrial Objects from ——. (P) Lederer. 501
  Constitution of ——. (Green) 382
  Decomposition of —— by Aerobic Micro-Organisms. (Van Iterson, jun.) 619
  Derivatives; Soluble Acetylised ——. (P) Balston and Briggs 557
  Factories; Utilisation of Waste from ——. (P) de Pass. From Gaertner 453
  from Green Alfa (Esparto); Preparation of ——. (P) Bouby and Deiss 909
  Liquid for Preparation of ——. (P) Braun, jun. 369
  Manufacture of ——. (P) Kellner 1159
  Manufacture of Tissue Paper from Sulphite ——. (Meyer) 948
  Nitrated; Dissolving of ——. (P) Kitsee 880
  Nitrated: Manufacture of ——. (P) Atkins 385
  Nitrate; Unstable ——. (Knecht) 335
  and its Nitrated Derivatives; Optical Activity of ——. (Vignon) 202
  Nitration of ——. (P) Selwig 950
  Wood-; Conversion of ——. (P) Ewen and Tomlinson 797
  Xanthate; Purification of ——. (P) Soc. Française de la Viscose 75, 501, 1111

Cements. (Class IX.) 19, 63, 116, 187, 253, 278, 323, 372, 442, 490, 546, 607, 661, 715, 750, 788, 824, 866, 901, 936, 984, 1028, 1090, 1148, 1217

Cement: Action of Denatured Spirits on ——. (Heinzelmann) 995
  Apparatus for Determination of the Specific Gravity of ——. (Jackson) 593
  Apparatus for Drying ——. (P) Ragan and Cornette 937
  Apparatus for Manufacture of ——. (P) Crozier. From Jaques 867
  Artificial; Composition of ——. (P) Candlot 116
  from Ashes, and Manufacture of same. (P) Marsden 751
  Asphalt Paving ——. (P) Warren 936
  Basic ——. (P) Macfarlane 546
  Bituminous ——. (P) Briggs 372
  from Blast-Furnace Slag. (P) von Forell 663
  Boiling Test for ——. (Lewis) 1091
  Burning of ——. (P) Williams 1217
  "Carborundo" ——. (P) Muller 985
  or Cementitious Material; Production of ——. (P) Jaques 825
  Clinker, &c.; Apparatus for Burning ——. (P) Edison 608
  Clinker, &c.; Burning of ——. (P) Edison 608
  for Coal Briquettes, Artificial Stone, &c. (P) Weiss 607
  Composition for ——. (P) Ginter 751
  Composition for Use as a ——. (P) Ducastel 867
  Drying Chambers; Light Dust in ——. (Seger and Cramer) 661
  Furnace for Burning ——. (P) Sheneman 443
  Furnaces for Manufacture of ——. (P) Smidth et Cie. 1218
  Hydraulic; Manufacture of ——:
    (P) Brown 937
    (P) Gresly 116
  Imports of the United States. (T.R) 278
  Improvement of ——. (P) Denayer 715
  Industry of Germany. (T.R.) 1007
  Kilns. *See under* Kilns.
  Lime in; Rapid Determination of ——. (Enright) 912
  for Linoleum, &c. (P) Suter 1154
  Magnesia-; Composition of ——. (P) Mielck 825
  Manufacture of ——:
    (P) Canaris, jun. 116
    (P) Geissler 788
    (P) Grau 985
    (P) Joseph 19
    (P) Liebold 490, 985
    (P) Müller 825
  Manufacture of ——, from Clinker, Slag, &c. (P) Bond 1091
  Manufacture of —— from Slag. (P) von Forell 65
  Manufacture of Vitreous ——. (P) Steenbock 1090
  Mortar; Influence of Size of Blocks of —— on Strength. (Burchartz) 187
  for Porcelain, &c.; Material for ——. (P) Steenbock 901
  Portland; Action of Acetic Acid on ——. (Hart) 683
  Portland; Amended Definition for —— in Germany 1122
  Portland, and Blast-Furnace Slag. (Passow) 661
  Portland; Chemical and Mechanical Testing of ——. (Gemmell) 306
  Portland, in Concrete. (Pars) 187
  Portland; Constitution of ——. (Richter) 64
  Portland, and Lime; Preparation of ——. (P) Winstanley 750

  Action of Low Temperatures on ——. (Schmidlin) 1143
  Aldehydes; New Reactions of ——. (Prud'homme 542
  Alizarin Blue G.W.; U.S. Customs Decision on ——. (T.R.) 141
  Alizarin; Manufacture of ——. (P) Badische Anilin und Soda Fabr. 1210
  Amidines, Trialkylated; Preparation of ——. (von Braun) 781
  o-Amidophenolsulpho Acid; Derivatives of ——. (P) Ransford. From Cassella and Co. 56
  p-Amidoxylyl-*p*-oxyphenylamine and Dyestuffs therefrom. (P) Levinstein and others 16
  Amino- and Aminohydroxydiphenylamines. (Gnehm and Weber) 184
  Amino- and Aminohydroxydiphenylamines for Blue Sulphide Dyestuffs. (Gnehm and Bots) 366
  Amino-Orsellinic Acid Ethyl Ester; Derivatives of ——. (Henrich and Dorschky) 485
  Aminothioalphyl Derivatives and Azo Sulphide Dyestuffs therefrom. (P) Soc. pour Chim. Ind. à Bâle 486, 783
  Aniline; Action of Carbonic Acid on Solutions of —— in presence of Nitrites. (Meunier) 56
  Aniline Dyeing Compound. (P) Rowland 543
  Anthracene:
    (P) Badische Anilin und Soda Fabr. 318
    (P) Badische Anilin und Soda Fabr. From Weltz .. 747
    (P) Badische Anilin und Soda Fabr. From Bohn .. 1025
    (P) Comp. Parisienne de Coul. d'Aniline 783
    (P) Imray. From Meister, Lucius und Brüning . 931, 1143
    (P) Johnson. From The Badische Anilin und Soda Fabr. 319
    (P) Soc. F. Bayer et Cie. 1026
  Anthracene ——, and Intermediate Products. (P) Johnson. From The Badische Anilin und Soda Fab. 319
  Anthracene ——, and Manufacture of same:
    (P) Badische Anilin und Soda Fabr. From Bally .. 368
  Anthracene Derivative. (P) Badische Anilin und Soda Fabr. From Bohn 368
  Anthracene Derivatives (Nitroamidoanthraquinones). (P) Newton. From Bayer and Co. 543
  1.2-Anthrahydroquinone, and its Conversion into Alizarin. (Lagodzinski) 16
  Anthranilic Acid and its Derivatives. (P) Imray. From Meister, Lucius und Brüning 16
  Anthraquinone ——:
    (P) Meister, Lucius und Brüning. From Hepp and Wolpert 368
    (P) Soc. F. Bayer et Cie. 113, 820
  Anthraquinone Derivatives. (P) Soc. F. Bayer et Cie. .. 898
  Anthraquinone; Diazonium Compounds of ——. (Kacer and Scholl) 1142
  Anthraquinone Series; New Derivatives of the ——. (P) Newton. From F. Bayer and Co. 367
  Anthraquinone-α-Monosulphonic Acid:
    (Dunschmann) 248
    (Liebermann and Pleus) 318
  Anthraquinone-α-Sulphonic Acids:
    (P) Newton. From F. Bayer and Co. 438
    (Schmidt) 182
  Anthraquinone; β-Substitution Products of ——. (Kaufler) 182
  Anthraquinone: Symmetrical-γ-dihydroxy-γ diphenyl Anthracene Dihydride from ——. (Haller and Guyot) 248
  Anthrarufin; Manufacture of ——. (P) Soc. F. Bayer et Cie. 438
  Aromatic Amino- and Hydroxy-Compounds; Action of Sulphites upon ——. (Bucherer) 1207
  Arylated 1.8-Naphthylamine Sulphonic Acids. (P) Actienges. fur Anilinfabr. 1210
  from Asphodel Roots. (P) Badoil and Valadon 712
  Azo ——:
    (P) Boehringer und Soehne. From Loeb 712
    (P) Johnson. From The Badische Anilin und Soda Fab. 183
    (P) Lake. From Oehler 249
    (P) Newton. From F. Bayer and Co. 183
  Azo Direct; Action of Copper Sulphate on ——. (Mueller) 543
  Azo; Electrolytic Preparation of ——. (Lob) 445
  Azo ——, and Intermediate Products. (P) Nuth, Holl, and Ruegg 1210
  Azo ——, and Lakes therefrom. (P) Soc. Bayer et Cie. 543, 713
  Azo ——, and Materials therefor. (P) Johnson. From Badische Anilin und Soda Fabr. 712
  Azo —— and New Intermediate Products. (P) Soc. F. Bayer et Cie. 16
  Azo and other ——. (Paul) 817
  Azo ——, and Production thereof. (P) Badische Anilin und Soda Fabr. From Julius, Reindel and Gunther . 932
  Azo ——, derived from 2:2-Dinaphthol. (Pozzi-Escot) 746
  Azo ——, for Wool. (P) Badische Anilin und Soda Fabr. . 16
  Azo ——, from 1.8-Azimidonaphthalene-4-sulphonic Acid. (P) Imray. From Meister, Lucius und Bruning . .. 16
  Azo ——, Insoluble in Water. (P) Comp. Parisienne de Coul. d'Aniline 16

    (P) Meister, Lucius und Bruning. From Mathe ... 747
  Bluish-Black Sulphide ——. (P) Comp. Parisienne de Coul. d'Aniline 184
  Brasilin and Hæmatoxylin. (Herzig and Pollak) 1024
  Brasilin; Preparation of —— from Brasileïn. (Herzig and Pollak) 16
  Brown Mordant Azo ——. (P) Oehler. From Laska 863
  Brown Sulphide ——. (P) Soc. pour Chim. Ind. à Bâle 486
  Carbinol Salts; Phenomena of Decolorisation of ——. (Schmidlin) 979
  Catechins; Note on the ——. (Perkin) 746
  Catechu; Preparation and Properties of ——. (Ridenour) 15
  Chloranil; Preparation of ——. (Witt and Toeche-Mittler) 56
  Chromophors; Ionisation of ——. (Decker) 1025
  Chrysazin; Manufacture of ——. (P) Soc. F. Bayer et Cie. 438
  Coal-Tar; Behaviour of —— towards Starch, &c. (Suida) 1144
  Coal-Tar; U.S. Customs Decision on ——. (T.R.) 507
  Colour Acids; Action of —— on Cellulose, Alcohol, &c. (Heidenhain) 183
  Cyanides, Acid; Production of ——. (P) Badische Anilin und Soda Fabr. 820
  Cyanine; Constitution of ——. (Miethe and Book) .. 712, 862
  Cyanomaclurin; Characteristics of ——. (Perkin) 746
  ω-Cyanomethylaniline Derivatives. (P) Badische Anilin und Soda Fabr. 826
  Dark Brown Azo ——, for Wool. (P) Oehler. From Laska 863
  1.5-Diaminoanthraquinone; Bromination of ——. (Scholl and Berblinger) 1142
  3.8-Diaminodiphenazone; Preparation of ——. (Fichter and Dieterle) 603
  p-Diaminodiphenylmethane; Derivatives of ——. (von Braun and Kayser) 781
  p-*p*′-Diaminoformyl-(acetyl)-diphenylamine. (P) Comp. Parisienne de Coul. d'Aniline 320
  Diazoamino-Compounds of the Aminonaphtholsulphonic Acids. (Paul) 437
  Diazoamino-fuchsine; Preparation of ——. (Pelet and Redard) 656
  Diazoaminorosaniline; Preparation of ——. (Pelet and Redard) 656
  Diazobenzene and Phenol; Limit of Coupling of ——. (Vignon) 655
  Dibenzalacetone and Triphenylmethane. (Baeyer and Villiger) 318
  Dibenzalacetone; Preparation of ——. (Baeyer and Villiger) 862
  2.6-Dibromo-*p*-phenylenediamine; Action of Bromine on ——. (Jackson and Calhane) 366
  Dihydroxyflavonol; 3.2′-, 3.3′-, and 3.4′-. (Kostanecki and others) 1208
  2.2′-Dihydroxyflavonol; Synthesis of ——. Katschalowsky and Kostanecki) 712
  2.3′ Dihydroxyflavonol; Synthesis of ——. (Kostanecki and Ottmann) 367
  2.4′-Dihydroxyflavonol; Synthesis of ——. (Kostanecki and Stoppani) 867
  Dihydroxytetramethylrosaminesulphonic Acid; Decomposition of ——. (Liebermann and Glawe) 182
  Dimethylaniline; Addition Products of ——. (Jackson and Clarke) 182
  Dinitrophenylethers of 3-chloro-4-aminophenol and of 4-aminophenol. (Reverdin and Dressel) 603

  the Triphenylmethane Series. (P) Newton. From F. Bayer and Co. 604
  Triphenylmethane Series; Some Reactions in the ——. (Vongerichten and Weilinger) 710
  Triphenylmethyl; Preparation of ——. (Gomberg) 711
  Triphenylmethyl; Research on ——. (Gomberg and Cone) 1083
  Triphenylpararosaniline Blue; Colour Base of ——. (Baeyer and Villiger) 863
  U.S. Customs Decisions on —— 770
  Uric Acid Derivatives; Constitution of some ——. (Piloty and Finckh) 656
  Violet Azo ——. (P) Comp. Parisienne de Coul. d'Aniline 113
  Violet-Red Sulphurised ——. (P) Raison Commerciale Kalle et Cie. 183
  Violet Tetrazo ——. (P) Soc. Chim. Ind. Bâle. From Jedlicka 604
  Viridine; Colour Base of ——. (Baeyer and Villiger) 863
  for Wool; New Classes of ——:
    (Noelting) 748
    (Prud'homme) 542
  Yellow Monazo ——. (P) Comp. Parisienne de Coul. d'Aniline 657, 1084
  Yellow-Red Azo ——. (P) Badische Anilin und Soda Fabr. From Julius and Osthelder 819
  Yellow Sulphide ——. (P) Actienges für Anilinfabr. . 16, 898
  Yellow Sulphurised ——:
    (P) Abel. From Actienges für Anilin Fabr. 16, 656
    (P) Imray. From Meister, Lucius und Brüning ... 863
    (P) Manuf. Lyonnaise de Matières Colorantes 57
  Yellow to Deep Brown ——. (P) Soc. des Matières Col. de St. Denis 368

Dynamite; Four New Types of ——. (Lheure) 385
  No. 0; Modification of ——. (Lheure) 385

E

Earth, Green; U.S. Customs Decision on ——. (T.R.) 806

Earths, Natural Raw or Burnt; Colouring ——. (P) Boyeux and Mora 116
  Rare; Bismuth as an Agent of Separation in the Series of ——. (Urbain and Lacombe) 128
  Rare; Research on the ——. (Biltz) 341
  Rare —— of the Yttrium Group, near to Gadolinium. (Urbain) 1160

Earthenware; Applying Glazes or Enamels to ——. (P) Stanley and Jefcote 1028
  Bodies: Production of Hollow ——. (P) Delattre 607
  Vitreous Cement for ——. (P) Steenbock 1090
  See also under Ceramic *and* Pottery.

Ebonite: Artificial Substitutes for ——. (P) Lucas 67
  Regeneration of ——. (P) Karavodine 991

Effluents: Bacterial Treatment of ——. (P) Cowie 947
  Purification of ——. (P) Serpin and Bertrand 676
  Treatment of ——. (P) Hunter 500
  Treatment of Organic ——. (P) Anderson 334
  Treatment of Trade ——. (P) Turner 909
  from Wood-Pulp Mills; Neutralising ——. (P) Doughty 1233

Eggs; Compound for Preserving ——. (P) Grenard 1040

Egypt; Gum Arabic from the Soudan ——. (T.R.) 1170
  Market for Chemical Products and Manures in ——. (T.R.) 343
  Revised Tariff Valuation for Metals, &c. in —— (T.R.) ... 1169

Electric Accumulators. *See under* Batteries, Secondary.
  Currents: Apparatus for Regulating the Intensity and Heating Effect of ——. (P) Soc. l'Ind. Verrière et ses Dérivés 666
  Conductors; British Standard for Copper ——. (T.R.) ... 918
  Energy; Accumulating and Using ——. (P) Betts 611
  Energy; Generation of ——. (P) Keyzer 611
  Material; Incandescent ——. (P) Voelker. Assignor to Soc. Anon. Ind. Verrière et ses Dérivés à Bruxelles 987
  Power Stations; Peat Gas Works for ——. (Frank) 538
  Production of ——:
    (P) Jone 1223
    (P) Tourneur 987
  Resistance Materials. (P) Chem. Elektrische Fabrik "Prometheus" 1034
  Treatment of Materials. (P) Conlin. From Franklin 1225

Electro-Chemistry. (Class XI.) 24, 41, 67, 119, 191, 256, 326, 376, 445, 493, 548, 611, 665, 717, 753, 792, 827, 869, 903, 940, 987, 103, 1096, 1151, 1222

Electro-Metallurgy. (Class XI.) 24, 41, 67, 119, 191, 256, 326, 376, 446, 493, 548, 611, 665, 717, 753, 792, 827, 869, 903, 940, 987, 1032, 1096, 1151, 1222

Electro-Chemical Apparatus; Connector for ——. (P) Fritchle 904
  Industries. (Crocker and Arendt) 326

Electro-Plating Apparatus. (P) Bailey 941
  Baths for ——. (Griesl) 904
  Chemistry of ——. (Bancroft) 1098
  Composition of Baths for ——. (Namias) 754

Electrodes for Arc Lamps:
    (P) Edelmann 247
    (P) Lilienfeld 930
    (P) Vogel 365
    (P) Gerard and Fiedler 1205
    (P) Blondel 112
  for Arc Lamps; Mineralised ——. (P) Soc. Française d'Incandescence, &c. 317
  for Electrolysis. (P) Hargreaves 68

Electrolysis with Alternating Current. (Brochet and Petit) 256, 1222
  Alternating Currents; Phenomena of Reduction Produced by ——. (Pearce and Couchet) 257
  Anodes for ——. (P) Greenfield 493
  Applied to the Sugar Industry. (Gurwitsch) 993
  Note on ——. (Ostwald) 1096
  Producing Movement of Liquid during ——. (P) Soc. Consortium für Elektrochem 377
  with Rotating Cathode. (Medway) 952
  with Well-stirred Electrolytes. (Sand) 792

Electrolytic Apparatus:
    (P) Blackmore 613
    (P) Schweitzer 870
    (P) Soc. Usines de Rioupéroux 25
    (P) Solvay Process Co. From Brichaux 1152
  Apparatus: Device for ——. (P) Wright 549
  Cells; Agitating the Fused Contents of ——. (P) Ashcroft 67
  Processes; Producing a Suitable Circulation of the Electrolyte in ——. (P) Koller and Askenasy 24
  Separations possible with Rotating Anode. (Ashbrook) .. 1115

Electrostatic Separation; Process of ——. (P) Schnelle 1098

Emanium; Observations on ——. (Giesel) 627

Emery; Substitute for ——, from Slag. (P) Wirtz 824

Emodin; Constitution of ——. (Jowett and Potter) 787

Emulsifying Apparatus. (P) Howorth. From Bazzi and Co. 265

Enamels. (Class VIII.) 19, 41, 62, 116, 187, 213, 253, 328, 371, 489, 516, 606, 660, 715, 750, 787, 823, 836, 901, 936, 984, 1028, 1090, 1147, 1216

Enamel, White; U.S. Customs Decision on ——. (T.R.) 143

Enamels, Coloured Transparent: Obtaining —— in the Cold. (P) Westphal and Maillard 1028

Enamelled Objects; Production of Coloured Images on ——. (P) Zerr 824
  Ware: Manufacture of ——. (P) Central Stamping Co. From Lunan 546

Enamelling Metal Articles, and Apparatus therefor. (P) Reed 63

Endotryptase in Dead Yeast Cells: Activity of ——. (Gromow and Grigoriew) 995

Entada Scandens; Saponins of ——. (Rosenthaler) 502

Enzyme Action; Studies on ——. (Armstrong) 388
  (Anaëroxydase): Action of an Indirect Oxidising ——. (Bourquelot and Marchadier) 721
  Oxido-reducing; Existence and Conditions of Action of —— in Plants. (Abelous) 766

Enzymes and Acids; Sucroclastic Actions of —— contrasted. (Armstrong and Caldwell) 1165
  Connection between Instability and Activity in ——. (Loew) 687
  that Decompose Amides; Occurrence of —— in Mould Fungi (Shibata) 802
  Fermentative ——, Isolated from Cells of the Higher Animals. (Stoklasa and Cerny) 38
  Influence of Acidity on ——. (Petit) 554
  Instability of ——. (Aso) 842
  Mineral; Preparation of Artificial ——. (P) Bounet 724
  Origin of ——. (Beckenhaupt) 954
  Oxido-reducing —— in Plants. (Abelous and Aloy) 275
  Research on ——. (Johnson) 331
  Sensitiveness of —— to Alcohol and Acids. (Bokorny) ... 31
  Yeast; Researches on ——. (Gruss) 1106

Ephedrines; Synthetic ——. (Fourneau) 1234

Epinephrine: Constitution of ——. (Jowett) 203

Erucic Acid, Iso-; Preparation of ——. (Ponzio) 942

Erythrohydroxyanthraquinone. *See under* Dyestuffs.

Erythroxylon Monogynum; Essential Oil of ——. *See under* Oils, Essential.

Eschka's Method of Determining Sulphur. (Pfeiffer) 132

Esparto; Utilisation of Residues from Treatment of ——. (P) Strange and others 1207

Essences. (Class XX.) 35, 42, 75, 81, 128, 143, 202, 266, 335, 345, 383, 453, 501, 558, 620, 677, 725, 758, 797, 834, 880, 910, 949, 997, 1041, 1111, 1159, 1234
  Apparatus for Extracting ——. (P) Hand 910
  Concrete; U.S. Customs Decision on ——. (T.R.) 345

Essential Oils. *See under* Oils.

Esters, Aromatic; Electrolytic Reduction of ——. (Mettler). 1096
  Aromatic ——, and Making same. (P) Ritsert 383
  Aromatic: Manufacture of New ——. (P) Ellis. From Chem. Fabr. von Heyden, Actienges 204
  of 3.4-Diaminobenzoic Acid; Alkyl ——. (P) Ritsert and Epstein. Assignors to Meister, Lucius und Bruning ... 727
  of Fatty Acids; Preparation of Pure ——. (Krafft) 68
  Fatty; Hydrolysis and Synthesis of ——. (Neilson) 416
  Production of —— in Alcoholic Fermentation. (Bokorny) 451

Esterifications by means of Sulphuric Acid. (Meyer) ......

Fusel Oil formed by the Alcoholic Fermentation of Acorns:
Composition of ——. (Rudakow and Alexandrow) 674
Origin of ——. (Emmerling) 1107
Fuses; Means for Igniting ——. (P) Reine 837
See also Explosives.

G

Galactosides and Glucosides; Hydrolysis of Isomeric ——. (Armstrong) 1165
Galangin. *See under* Dyestuffs.
Gallobromine. *See under* Dyestuffs.
Gallic Acid; Determination of ——. (Dreaper) 913
Golloflavin. *See under* Dyestuffs.
Gallorubin. *See under* Dyestuffs.
Gallo-Tannic Acid; Detection of —— on the Fibre. (Menger) 135
Garbage; Apparatus for Cooking —— and Removing Oil therefrom. (P) Wheelwright and Fiske, jun. 879, 879
Apparatus for Treatment of ——. (P) Wheelwright and Fiske, jun. 909
See also under Offal, Waste, and Residues.
Gardenia Oil. *See under* Oils, Essential.
Garments; Dry-cleaning of ——. (P) Barbe 1145
Garnet; New Source of ——. (T. R.) 1245
Gas. (Class II.) 14, 40, 54, 79, 111, 141, 181, 246, 278, 316, 364, 435, 483, 538, 601, 652, 709, 744, 779, 815, 859, 895, 929, 976, 1021, 1081, 1140, 1203
Acetylene; Apparatus for Generating ——. (P) Fescourt and Maurin 780
Purification of ——. (P) Landriset 483
Aerogen; Preparation of ——. (Stern) 977
and Air; Apparatus for Mixing ——:
(P) Dodge 1204
(P) Actien Ges. fur Selas-Beleuchtung 977
(P) Lake. From Selas Ges. 483, 653, 859
and Air; Method and Apparatus for Obtaining ——. (P) The Scott-Snell Phillips Syndicate, Ltd. 1081
Gas, Air; Apparatus for Production of ——:
(P) Diehl and others 896
(P) Gersaheck 1082
(P) Pichegru 317
Analyses by Combustion; Calculation of ——. (Wohl)... 269
Apparatus for Absorption of Liquids by ——. (P) Vereinigte Thonwaarenwerke Akt.-Ges. 900
Apparatus (Electrical) for Cleaning ——, (P) Hardie ... 904
Apparatus for Enriching —— with Benzol. (P) Pooley and Poulson 181
Apparatus for Generating ——:
(P) Bradley Universal Heat, Light, and Power Co. From Bradley 1141
(P) Comp. du Carburateur Claudel. From Claudel. 1021
(P) Dempster 1081
(P) Desouches 1021
(P) Guilbaud 896
(P) Ingham 1141
(P) Kiderlen 54
(P) Lord 861
(P) Naef 540
(P) Stut 860, 860
(P) Wesselsky 977
Apparatus for Generating Low-grade ——. (P) Lerouge, Fornas et Cie 710
Apparatus for Generating Weak ——. (P) Genty and others 1021
Apparatus for Manufacture of Crude ——. (P) Heenan.. 1140
Apparatus and Means for Enriching ——. (P) Brookes. From Makeever 709
Apparatus for Producing Mixed ——:
(P) Boivinet and Soc. Popineau, Vizet Fils et Cie... 931
(P) Vizet 930
Apparatus for Producing Poor —— free from Tarry Matters. (P) Boutillier 317, 709, 930, 977
Apparatus for Purification of ——:
(P) Brown 1021
(P) Everitt and Redman 930
(P) Good and Spencer 483
(P) Jas 539
(P) Prégardien 930
(P) Camden Iron Works. From Matton 1205
(P) Dempster and Sons and Broadhead 112
(P) Steinbart 1205
(P) Winand 653
Apparatus for Testing ——. (P) Lymn 1113
Apparatus for use in Manufacture and Burning of ——:
(P) Stiens 977
Apparatus for Washing ——:
(P) Guldlin 816
(P) Hunt and Dole 897
(P) Imray. From Burgemeister 709

PAGE
Gas—*cont.*
Benzene in; Determination of ——. (Pfeiffer) 1116
Blast-furnace —— as the Sole Source of Power for a Metallurgical Works. (Gruber) 118
Carbon Monoxide or Producer-; Manufacture of ——. (P) Lummis 14
Coal-; Apparatus for Carburetting ——. (P) The Gas Economising, &c., Co., and McColl 317
Coal-; Extraction of Cyanogen from ——. (Feld) 316
Committee of Enquiry on Illuminating Power and Purity of ——. (T.R.) 141
Compressors; Compound ——. (P) Douane 1203
Condensation of Illuminating ——. (Coloman) 744
Condensing Bodies; Production of ——. (P) Tissier 602
Condensing and Cooling of ——. (P) Browne and Chandler 858
Fermentation; Wittemann's Collecting and Carbonating System for ——. (Steuemann) 618
Fuel-; Manufacture of ——, and Apparatus therefor. (P) Pearson 539
from Gas-Producers; Purification of ——. (P) Capitaine 930
Generated by Aluminium Alloys; Incandescence Lighting with ——. (P) Hélouis and others 540
Generation of —— from Carbonaceous Liquids. (P) Cotton 1021
Generator for Low-Grade ——. (P) Lerouge, Formas, et Cie. 860
Generator for Production of Heating and Lighting ——. (P) Meininghaus 181
Generators for Low-Grade ——. (P) Gay and Vivier..... 830
Light, Incandescent; Increasing the Intensity of ——. (P) Lake 977
and Lime; Combined Manufacture of ——. (P) Chalk Power Gas Syndicate 436
Manufacture of ——:
(P) Bougault, Assignor to Soc. Franc. de Constructions Mécaniques 978
(P) Boult. From Goldschmid 317
(P) Brush 14
(P) Deutsche Continental Gas Ges. and Bueb 709
(P) Duttenhofer 745
(P) Johnson. From Deutsche Cont. Gas Gesell. and Bueb. 602
(P) Jones 364
(P) Könemann 247
(P) Maly. From Turk 780
(P) Naef 181, 365, 365
(P) Settle and Padfield 709 1021
(P) Stut 860, 860
(P) Westinghouse 55
(P) Woodall and McD. Duckham 744
Manufacture of ——, and Apparatus therefor:
(P) Herzog 181
(P) Marconnet 745
(P) Westinghouse. From Gow 780
Manufacture of —— continuously. (P) Clauss 317
Manufacture and Purification of ——. (P) Colson 1141
Mixtures; Apparatus for Producing ——. (P) Lake. From Selas Ges., Berlin 483
Natural; Production of —— in U.S.A. 1120
Oil-; Apparatus for Manufacturing ——:
(P) Dempster 14, 112
(P) Lyon. From Vincent 1205
for Oil Engine; Apparatus for Generating ——. (P) Goss. From Salisbury 860
Oil-; Generation of ——. (P) Bridson 483
Oil-, of High Combustible Value. (P) Blau 317
Oil-; Production of ——. (P) Rincker and Wolter 1141
from Petroleum Oil or other Fluids. (P) Kuenzel 816
from Petroleum Oils; Generation of ——. (P) Bridson .. 483
Plant for Production of ——. (P) Hillenbrand 896
Plant for Purifying ——. (P) Klein 860
Power-; Process and Apparatus for Production of ——. (P) Wigelius and Laurell 365
Producer-; Manufacture of ——. (P) Loomis and Pettibone 602
Producer-; Manufacture of ——, and Apparatus therefor:
(P) Armstrong 1140
(P) Jahns 181
Production of ——. (P) Kent 709
Production of —— in America, in 1902. (T.R.) 390
Production of ——, and Apparatus therefor. (P) Elworthy 112
Production of Combustible —— from Bituminous Fuel. (P) Société F. Krupp 1206
from Pulverised Combustibles; Manufacture of ——. (P) Marconnet 484
Purification of ——:
(P) Boult 977
(P) Felt 930
Purified Weak; Generators for ——. (P) Heinen 1206
Purifying and Distributing ——. (P) Meininghaus....... 181
Recovery of Residual Products in the Purification of ——. (P) Gutknecht 539
Report of Committee on Testing of ——. (T.R.) 691
Retort; Horizontal or Vertical ——. (P) Gielis 653
Retort Mouth-Pieces; Inclined ——. (P) Gibbons and McEwen 364
Separating Mixtures of ——. (P) Soc. pour l'Exploitation des Procédés Georges Claude 750
Water-; Apparatus for Generating. (P) McDonald 745
Water-; Apparatus for Manufacture of Carburetted ——. (P) Addicks 602
Water-; Defects of Uncarburetted —— as Fuel for Laboratory use. (Chikashige and Matsumoto) ....

PAGE

Gas—*cont.*
  Water-; Double Generators for ——. (P) Thuman....... 930
  Water-; Generation of ——, and Apparatus therefor. (P) Bauke and Fuchs....... 246
  Water-; Introduction of —— into the Carbonising Retorts. (Croissant)....... 364
  Water-; Manufacture of ——:
    (P) Boult. From Koneman 317
    (P) Bowing 1140
  Water-; Production of ——, and Apparatus therefor. (P) Schmidt and Desgraz....... 653
  Water-; Production of —— by Dellwik-Fleischer and Strache Systems. (Placidi and Kettner) 435
  Water-; Theory of Production of ——. (Jüptner) 977
  Wood-; Apparatus for Generation of ——. (P) Brooks 364
  Wood-; Manufacture of ——. (P) Loomis and Pettibone. 602

Gases: Apparatus for Analysis of ——. (P) Bayer 1239
  Apparatus for Disseminating in Finely Divided State. (P) Nordtmeyer 54
  Apparatus for Electrical Treatment of ——. (P) Pauling.. 611
  Apparatus for Exhausting ——. (P) Schwaninger. 858
  Apparatus for Filtration of ——. (P) New Jersey Zinc Co. From Stone 538, 538
  Apparatus for Liquefying ——. (P) Knudsen 315, 434
  Apparatus for Ozonising ——. (P) Wood-Smith 792
  Apparatus for Producing Combustible —— from Volatile Liquids. (P) Jas....... 539
  Apparatus for Treating Materials with ——. (P) Haas ... 659
  Blast-Furnace; Determination of Calorific Value of ——. (Arth) 664
  Centrifugal Apparatus for Treating ——. (P) Thiesen.... 434
  from Chamber Process of Making Sulphuric Acid; Method for Estimating Total Acidity of ——. (Watson)....... 6
  Chimney-; Determination of Unburnt Products in ——. (Sodeau) 266
  Combustible; Mixtures of —— with Oxygen. (P) Société L'Air Liquide, &c....... 15
  containing Hydrogen; Fractional Combustion of ——. (Richardt) 764
  Electrical Treatment of ——. (P) Birkeland....... 1097
  Expansibility of —— between 0° and 1000° C. (Jacquerod and Perrot)....... 564
  Flue-; Rapid Method for Testing —— (Le Chatelier)..... 951
  Furnace-; Apparatus for Arresting Impurities from ——. (P) Baggaley 23, 23, 24
  Generators for Power ——. (P) Catier 517
  Liquid; Preventing the Freezing of —— on their Discharge from Storage Vessels. (P) von Orth 483
  and Liquids; Apparatus for Mixing ——. (P) Wood-Smith 537
  Manufacturing and Mixing ——. (P) Loomis and Pettibone 929
  Preparation and Compression of Pure —— for Experimental Work. (Hutton and Petavel) 87
  Principles of the Separation of —— by Centrifugal Force. (Bredig and Haber) 489
  Production of Chemical Reactions in ——. (P) de Montlaur....... 1031
  Purification of —— (for Manufacture of H_2SO_4) (P) Johnson. From Badische Anilin und Soda Fabr 659
  Removing Sulphuretted Hydrogen from ——. (P) Burschell 486
  Separating Mechanically entrained Globules from ——. (P) Edison Storage Battery Co. From Edison 827
  Separation of —— from Gaseous Mixtures. (P) Levy.... 442
  Smelter-; Apparatus for Precipitating Fumes from ——. (P) Baggaley....... 23, 23, 24
  Smelter-; Apparatus for Recovering Values from ——. (P) Baggaley 24
  Waste; Utilisation of ——. (P) Schutt 897

Gas-Burners; Bunsen ——. (P) Davies 14

Gas-Burners for Testing Gas. (P) Sugg....... 205

Gas-Generators:
    (P) Construction Co. 1206
    (P) George....... 15
    (P) Heinen 1206
    (P) Lafond 1205
    (P) Lyon. From Vincent....... 1205
    (P) Mattes 653
    (P) Schweizerische Locomotiv-fabr. From Weighlé 1205
    (P) Vereinigte Anthracit Werke 181
    (P) Williamson. From Eustace 897
  Suction ——. (P) Dowson....... 601

Gas-Lime, Cement from ——. (P) Bond....... 1091
  Utilisation of ——. (P) Lowden 253

Gas-Liquor; Treatment of ——. (P) Moor....... 318

Gas-Mantles. *See under* Mantles.

Gas-Producer:
    (P) Boyd 435
    (P) Buckley 780
    (P) Campion and Wyant 15
    (P) Cerasoli 816
    (P) Crossley and Rigby 897, 930
    (P) Deschamps 929
    (P) Dixon Co. From Dixon....... 1205
    (P) Duff 436
    (P) Fielding....... 780
    (P) Gautier....... 1081
    (P) Grice 929
    (P) Herrick....... 1081
    (P) Holcroft 602
    (P) Hovine and Breuille....... 365

Gas-Producer—*cont.*
    (P) Mond....... 1204
    (P) Morgan Construction Co. From George 860
    (P) Mongeotte 1082
    (P) Nash 1081
    (P) Paul....... 602
    (P) Poetter....... 860
    (P) Robson 1204
    (P) Rowe and Bickerton....... 539
    (P) Sanderson 436
    (P) Soc. Menot Père et Fils et Deneuville....... 1206
    (P) Thompson. From Schweizerische Lokomotiv- und Maschinen-Fabr....... 316
    (P) Viarmé. 510
    (P) Wight and Hyatt 365
    (P) Wilson....... 745
    (P) zur Linden 1081
  Apparatus for Feeding Material to ——. (P) Bild....... 709
  Apparatus for Regulating Supply of Steam to —— (P) Gugnard 89
  Arrangement for Supplying Water and Steam in ——. (P) Pagny 860
  Charger for ——. (P) Morgan Construction Co. From Carroll 1141
  for Poor Gas free from Tarry Matters. (P) Boutillier ... 653
  Regulation of ——. (P) Crossley and Rigby 779
  and Steam-Generators combined. (P) Neuman....... 1204
  Stoppers for ——. (P) Tweedale and Smalley....... 247
  Suction ——. (P) Capitaine 859
  Suction ——. (P) Crossley and Rigby....... 780
  Superheater for ——. (P) Duff 816

Gas-Producing Plant for Heating Retort Furnaces. (P) Poetter....... 860

Gas-Purifying Materials; Revivification of ——. (P) Delcourt 247

Gas-Retorts; Manufacture of ——. (P) Cottancin....... 247

Gas-Scrubber. (P) Steinbart 1141
    (P) Valetto 247

Gas-Washers. (P) Bousfield. From Gerdes 317

Gaseous Bodies; Chemical Action of Rays of Short Wave-Length on ——. (Warburg and Regener) 1003
  Material: Separating Non-Gaseous Material from ——. (P) McKee 1202
  Media; Electrical Generation of —— from Air. (P) Alsop 611
  Mixture; Production of Dry ——. (P) Rüdemann....... 112
  Mixtures and Air: Separating —— into their Elements. (P) Soc. l'Air Liquide. (Soc. Anon. pour l'Etude et l'Exploit des Procédés G. C. and R. J. Lévy) 823, 1216
  Mixtures; Combustion of ——. (P) Lucke 436
  Mixtures; Determination of Hydrogen Content of ——. (P) Thompson 951
  Mixtures; Intense Chemical Reactions in ——. (P) Eyde and Birkeland....... 193
  Reactions; Facilitating Electro-Chemical ——. (P) Ostwald....... 193

Gelatin; Artificial Fibre From ——. (P) Jannin....... 899
  Manufacture of ——. (P) Faucheux and Bossière 553
  Production of —— from Bones. (P) Hilbert 553
  Setting and Swelling of ——. (Schroeder) 1227
  Solubility of —— in Spirit. (Heinzelmann) 380
  Solution and Swelling of ——. (Spiro) 1227
  Treating Leather Waste for Manufacture of ——. (P) Weiss....... 755

Gelatinous Precipitates. *See under* Precipitates.
  Product; Insoluble ——. (P) Casein Co. of America. From Dunham 128

Geraneol Derivative: Manufacture of ——. (P) Farbenfabriken of Elberfeld. From Hofmann....... 204

Geranium Oil, Essential. *See under* Oils, Essential.

German-French Tariff and Trade Relations 768

Germany; Alcohol Production of —— in 1903. (T.R. 393
  Amended Definition for Portland Cement in —— 1122
  Calcium Carbide Industry in ——. (T.R.) 732
  Cement Industry of ——. (T.R.) 1007
  Chemical Exports from —— 769
  Glass Manufacture in ——. (T.R.) 213
  India Rubber Cultivation in the Colonies....... 771
  Indigo Exports of ——. (T.R.)....... 507
  Lead-Zinc Deposit in ——. (T.R.) 391
  Mineral Salts Produced by —— in 1903. (T.R.) 508
  Mineral Wax Classification in ——. (T.R.) 566
  Pig-Iron Production of ——. (T.R.) 1007
  Pollution of Waterways in —— by Factories. (T.R.) 1053
  Position of the Spirit Market, October 1904. (T.R.) 1247
  Potash Syndicate in ——. (T.R.) 1006
  Profits in the Chemical Industry of ——. (T.R.) 1244
  Retail Price of Denatured Spirit in ——. (T.R.) 143
  Spirit Industry of ——. (T.R.) 1247
  Sugar Production of ——. (T.R.) 462, 957
  Tariff Modifications of ——. (T.R.) 343
  Trade of ——. (T.R.) 565
  Trade of —— in 1903. (T.R.) 804
  Trade of —— with Natal. (T.R.) 630
  Wine Trade of ——. (T.R.) 393

Germicide; Gaseous ——. (P) Marot 879

Ginger-grass; Essential Oil of ——. *See under* Oils, Essential.

Giobertite. *See under* Magnesium Carbonate.

Geumurbanum; Essential Oil of ——. *See under* Oils, Essential.

Glass. (Class VIII.) 19, 41, 62, 116, 187, 213, 253, 323, 371, 489, 546, 606, 660, 715, 750, 787, 823, 866, 901, 936, 984, 1028, 1090, 1147, 1216
Action of Certain Gases on —— near Heated Metals. (Beilby) 984
Apparatus for Making Sheets of. (P) Window Glass Machine Co. From Chambers 750
Apparatus for Manufacture of ——. (P) Gordon and others. From Wilson and Dull 1216
Articles; Drawing of ——. (P) Window Glass Machine Co. From Chambers 750
Articles; Manufacture of ——. (P) Richardson 490
Articles; Manufacture of —— from Slate or Slate Refuse. (P) Frydenlund 546
Articles; Ornamented or Lettered ——. (P) Duncan Chem. Co. From Duncan 116
Borax; U.S. Customs Decision on ——. (T.R.) 461
Crucible for Working of ——. (P) Lang 1090
Devitrification; Characteristics of ——. (Guertler) 1216
Devitrified; Manufacture of ——. (P) Garchey 19
Drawing of ——. (P) Window Glass Machine Co. From Chambers 750
Drawing and Annealing ——. (P) Imray. From The Window Glass Machine Co. 371
Electrochemical Determination of Solubility of ——. (Haber and Schwenke) 326
Furnace for Manufacture of ——. (P) Orrock 607
Manufacture of ——. (P) Richardson, jun. 823, 866
Manufacture of —— in Germany and Austria. (T.R.) 213
Metal; Melting of —— for Plate Glass. (Knoblauch) 62
Method of Blowing ——. (P) Toledo Glass Co. From Owen 607
Plate-; Apparatus for Manufacture of ——. (P) Mielisch 371
Plates or Sheets; Manufacture of ——. (P) Hirst 63
Pot-Furnace for Melting ——. (P) Nicholls 1147
Quartz; Manufacture of ——. (P) Bredel 1090
Quartz; Manufacture of Objects of ——. (P) Bredel 1090
Sheet; Apparatus for Manufacture of ——. (P) Rowart and Francq 660, 715
Sheet; Manufacture of ——. (P) Page and Wadsworth 19
Sheet; Manufacture of —— and Apparatus therefor. (P) Fourcault 823
Silica; Furnaces for Manufacture of ——. (P) Shenstone 253
Silica; Manufacture of:
(P) Bredel 1028
(P) Kent 19
Surfaces; Gilding of ——. (P) Herrmann 607
Synthetic Granite; Garchey ——, and Manufacture of same. (P) Garchey 253
Use of Electric Current in Working of ——. (P) Hays 546

Glassware; Manufacture of ——. (P) Arbogast 490
Manufacture of —— and Apparatus therefor. (P) Meister 984

Glassworks; Bricks and Agglomerates from Waste Moulding-Sand of ——. (P) Blottefière 751
Highly Regenerative Circular Gas Furnace for ——. (P) Deselles 1216, 1216

Glauber's Salt; Manufacture of ——. (P) Gilman 26, 670
Production of ——. (P) Parker 252, 714
Recovery of ——. (P) Gilman 983
See also Sodium Sulphate.

Glazes; Crystalline ——, and their Application to Pottery. (Burton) 606
of Low Solubility; Preparation of Lead ——. (Thomason) 470

Gliadin in Wheat Flour; Determination of ——. (Snyder) 387

Glucinium Hydroxide; Preparation of Pure ——. (P) van Oordt 799

Glucose; Bi-rotation of ——. (Behrend and Roth) 388
Manufacture of ——. (P) Gentzen. From Roth 29

Glucoses; Correlation of the Stereoisomeric α- and β- Glucosides with the Corresponding ——. (Armstrong) 388

Glucosides and Galactosides; Hydrolysis of Isomeric ——. (Armstrong) 1165
Benzalmethyl-; Preparation of ——. (van Ekenstein) 341

Glue. (Class XIV.) 27, 41, 71, 122, 195, 260, 329, 344, 378, 448, 495, 552, 615, 671, 719, 755, 794, 830, 873, 906, 943, 991, 1036, 1104, 1155, 1227
Differentiation of the Different Forms of Nitrogen in ——. (Trotman and Hackford) 1072
and Glue Testing; Notes on ——. (Watson) 1189
Manufacture of ——. (P) Faucheux and Bossière 553
Manufacture of —— from Hides. (P) Hewitt 123
Material Suitable for use as ——. (P) Préaubert and Thubé 448
Oxidation of —— by Calcium Permanganate. (Kutscher and Schenck) 992
Production of —— from Bones. (P) Hilbert 553
Size; Manufacture of a Special ——. (P) Vierne and Kowachiche 1227
Solid Vegetable; Manufacture of ——. (P) Virneisel 449
Solutions; Clarifying ——. (P) Hewitt 123
Treating Leather Waste for Manufacture of ——. (P) Weiss 755
for Warp Threads of Fabrics. (P) Haddan. From Oliva 251

Gluten; Drying and Bleaching of ——. (P) Morel 1232

Glycerides; Characteristics of the Higher ——. (Hannay) 447
Solutions of —— in Acetic Acid. (Hoton) 810

PAGE

Glycerin; Apparatus for Extracting ——. (P) Col 872
Distillation of Crude ——. (P) Carrigues 1158
Extraction of —— from Residues. (P) Barbet 1108
Formation of —— during Fermentation. (Seifert and Reisch) 1107
Recovery of —— from Spent Lyes. (P) Carrigues 1153
Tannate; U.S. Customs Decision on ——. (T.R.) 845
Treatment of Liquids containing ——. (P) Passerini 1035
in Wine; Determination of ——. (Schuch) 730

Glycerol; Determination of ——. (Taurel) 841
in Fats; Determination of ——. (Fanto) 158
and Phosphoric Acid; Esterification of ——. (Carré) 35
Phosphoric Esters of ——. (Carré) 128

Glycocoll as a Photographic Developer. (P) Meister, Lucius und Bruning. From Homolka and Schwan 882

Gold; Apparatus for Extraction of ——. (P) Blake 1032
Apparatus for Recovering Float ——. (P) Sachse 1221
Apparatus for Separating and Recovering ——. (P) Laudahn 716
Bullion; Notes on ——. (Claudet) 1149
Colloidal ——. (Hanriot) 564
Concentration of —— in Iron Bottoms. (Bolles) 663
in Cyanide Solutions; Colorimetric Determination of ——. (Prister) 207
Determination of —— by the Purple of Cassius Test. (Prister) 912
Determination and Separation of —— Electrolytically. (Miller) 1115
Discovery of —— in Canada. (T.R.) 391
Electrolytic Analysis of ——. (Perkin and Prebble) 339
Electrolytic Precipitation of —— from Cyanide Solutions. (Hamilton) 120
Electrolytic Refining of ——. (Wohlwill) 717
Extraction of ——. (P) Worsey and Hoal 1031
Extraction of —— in Colorado. (Perkins) 546
Extraction of —— from Ores:
(P) Cassel 1225
(P) Broadwell, Assignor to Lyons and Starring 375
(P) Stark 939
Extraction of —— from Sea-Water. (P) Peet 190
Industry in Russia. (T.R.) 887
Influence of Sunlight on Solution of —— in Aqueous Potassium Cyanide. (Caldecott) 1094
Melting Point of:
(Berthelot) 609
(Jacquerod and Perrot) 547
Metallurgy of —— on the Rand Goldfields. (Dixon and Torrente) 715
Microchemical Detection of ——. (Donau) 837
Occurrence of —— in Great Britain and Ireland. (T.R.) 213
Ore; Finer Crushing of —— on the Witwatersrand. (Caldecott) 1093
Precipitates; Refining of ——. (Clevenger) 825
Production of Australia 1124
Production of Australia in 1903. (T.R.) 508
Production of Canada 1122
Production of the World in 1903 1124
Recovery of —— from Sand. (P) Lovett 1221
Recovery of —— from Solutions. (P) Christy 494
in the Residues from the Zinc Boxes; Determination of ——. (Lodge) 272
Slime; Filtering of ——. (P) Cassel 1151
Slimes; Trapezoidal Agitator for ——. (De Kolb) 324
Slimes; Treatment of ——. (Torrente) 1031
Slimes; Treatment of —— by the Decantation Process. (Laschinger) 663
Solubility of —— in certain Oxidising Agents. (Lenher) 612
in Zinc Ores; Crucible Charge for ——. (Hall and Popper) 952

Gold-Copper Alloys. *See under* Alloys.

Gold-Field at Murchison, Western Australia. (T.R.) 805

Gold-Mining; Application of the Modern Theories of the Flow of Water in ——. (Hele-Shaw) 753

Grain; Apparatus for Germinating ——. (P) Lapp 556
Catalytic Properties of ——. (Wender and Lewin) 675
Drums for Malting ——. (P) Schreier 877
Drums for Malting and Drying ——. (P) McKenna. From Holst and Fleischer 877
for Malting, Distilling, &c.; Apparatus for Aerating ——. (P) Henry 877
Process and Apparatus for Drying, &c. (P) Imray 618
for Production of Malt; Treatment of ——. (P) Sleeman 877

Granite, Artificial; Manufacture of ——. (P) Garchey 1216
See also Stone.

Granular Materials; Apparatus for Washing ——. (P) Hoffman and Gibson 744

Grapes; Process and Apparatus for Treating ——. (P) Egrot, Grangé et Cie. 1231

Graphite Deposits in the Himalayas. (T.R.) 508
Formation of ——. (Ditz) 322
Preparation of —— from Wood Charcoal. (Weckbecker) 1034
Production of —— in the United States. (T.R.) 1006
Separation of Impurities from ——. (P) Glogner 489
Separation of —— from other Minerals. (P) Kendall 983

Graphitic Acid or Oxide. (Hyde) 3
Substances; Separation of —— from other Bodies. (P) Kendall 115

  in Commercial Zinc Ores; Determination of ——. (Waring) 912
  Conversion of Crude —— into Malleable Iron or Steel. (P) Deemer 492
  Critical Point of; Determination of ——. (Boudouard) .. 20
  Cupola Furnaces for Melting ——. (P) Higham 902
  Dechromising ——. (P) Massenez 1032
  Deformation and Rupture of ——. (Osmond and Fremont) 609
  Determination of —— Colorimetrically. (Pulsifer) 913
  Effects of Certain Substances on the Rusting of ——. (Lindet) 1219
  Electrical Manufacture of ——. (Neuburger) 258
  Electro-metallurgy of ——:
      (Harmet) 194
      (Héroult) 1027

  Electrolytic ——. (Burgess and Hambuechen) 667
  in the Ferric State; Iodometric Determination of ——. (Namias and Carcano) 456
  Industry of the Transvaal 770
  Ingot; Manufacture of ——:
      (P) Continuous Metal Refining Co. From Talbot and Gredt 119
      (P) Talbot 939
  Magnetic Oxide of: Recovery of —— from Sand. (P) Lovett 1221
  Malleable; Manufacture of ——. (P) Young 118
  Manufacture of ——:
      (P) De Alzugaray 903
      (P) Fleischer 1032
      (P) Massenez 609
      (P) Talbot 191
      (P) Talbot and Gredt 610
  Manufacture of —— in Blast-Furnace. (P) Foster 1220
  Manufacture: Effect of Addition of Limestone in the Cupola. (Wust) 117
  Manufacture of —— and Refining same. (P) De Alzugaray 118
  Nitrogen in: Determination of ——. (Braune) 1114
  in Ores and Alloys: Volumetric Determination of ——. (Glasmann) 1046
  Pig-; Canadian Production of ——. (T.R.) 916
  Pig- ——, and its Constituent Elements. (Williams) 751
  Pig-; Glazing of Certain Kinds of Siliceous ——. (Hudson) 595
  Pig-; Manufacture of —— from Briquettes at Herrang. (Louis) 608
  Pig-; Production of —— in Canada in 1903. (T.R.) 343
  Pig-; Production of —— in Germany in 1903. (T.R.) 279
  Pig-; Production of —— in Germany. (T.R.) 1007
  Pig-; Production of —— in the U.S.A. in 1903. (T.R.) ... 278
  Pig-; Russian Production of ——, Jan.–June, 1903. (T.R.) 1169
  Pig-; Specifications for ——. (Job) 444
  Production of ——:
      (P) Bloxam. From La Soc. Electro-Metall. Française 118
      (P) Brown and Reynolds 610
      (P) Otto 325
  Production of —— by Electrolysis. (Skrabal) 987
  Production of —— in France, Jan. to June 1904. (T.R.) .. 956
  Production of —— in Great Britain 567, 1123
  Production of Russia. (T.R.) 1246
  Production of the World 1122
  Protection of —— from Corrosion. (Cowper-Coles) 790
  "Reduced": Determination of Arsenic in ——. (Hill and Umney) 1046
  Scrap; Classification of ——. (Scott) 752
  Separation of Aluminium from ——. (Leclère) 206
  Separation of —— from Nickel and Cobalt. (Borgstrom) . 1239
  Sheet; Method and Apparatus for Treating ——. (P) Goodsell 1094
  Silicon in; Determination of ——. (Thiel) 1114
  Sulphur in: Determination of ——. (Pulsifer) 1162
  Sulphur in: Rapid Determination of Total ——. (Knight) 800
  Sulphuric Acid in Presence of; Determination of ——. (Lunge) 760
  Treatment of ——. (P) Koller 118
  Treatment of —— with Carbides. (P) Engels 118
  Vessels used in Brewing, &c.: Protective Coating for ——. (P) Lapp 556
  Volumetric Determination of ——. (Tarugi and Silvatici) 1114
  Wastes or Sands; Converting —— into Briquettes. (P) Rouse and Cohn 1031
  and Zirconium: Separation of ——. (von Knorre) 624

Iron Carbonylferrocyanides in Spent Oxide. (Stoecker) 488
  Oxide; Formation of Magnetic ——. (Donau) 341
  Oxide. Kilns for Manufacture of ——. (P) Hemingway . 1153
  Oxide; Production of Black Magnetic ——. (P) Parker . 606
  Salts; Preparation of ——. (P) Vidal 755
  Pyrites, &c., Opening for —— in Russia 1121
  Pyrites; Preparation of —— for Desulphurisation. (P) Wedge 545, 936

  Pyrites. *See also under* Pyrites.
  Sulphate; Utilising Gases from Calcination of ——. (P) Campbell 18

Milk—*cont.*
  Product Resembling Butter. (P) Campbell 152
  Purifying and Preserving ——. (P) Pasekting and Paradies 381
  Soluble Albumin from; Manufacture of ——. (P) Lewis 797
  Sterilising ——. (P) de Jong and van der Heide 201
  Vacuum Apparatus for Treating ——. (P) Ekenberg's Aktiebolag. From Ekenberg 1158
Milk-Powder; Production of Milk in the Form of ——:
    (P) Butler 1157
    (P) Hatmaker 757
    (P) Maggi 909
    (P) Rayner. From Maemecke 1232
Milk Sugar; Decomposition of —— by Caustic Lime. (Kiliani and Loeffler) 449
Mill; Grinding ——:
    (P) Robinson 434
    (P) Stark 976
  Grinding ——, for Gradual and Variable Pulverisation. (P) Rakowski 928
  Roller Crushing ——. (P) Edison Ore Milling Syndicate. From Edison 110
Millboard; Manufacture of Incombustible ——. (P) Soc. Schneider and Demole 383
Mineral containing Radium in Province of Quebec. (Obalski) 388
  Exports of Spain. (T.R.) 918
  Oil. *See under* Oil *and* Oils.
  Output of California. (T.R.) 1050
  Output of Great Britain in 1903 1122
  Output of Western Australia. (T.R.) 770
  Production of India 1123
  Production of New South Wales. (T.R.) 843
  Production of New Zealand in 1903. (T.R.) 1245
  Production of Ontario. (T.R.) 568
  Production of Queensland in 1903. (T.R.) 567
  Production of Tasmania. (T.R.) 916
  Production of the Transvaal in 1903. (T.R.) 692
  Production of the U.S. in 1903. (T.R.) 142
  Resources of the Dutch East Indies. (T.R.) 509
  Salts; German Production of —— in 1903. (T.R.) 508
  Substances; Separation of ——. (P) Kendall 983
  Waxes. (Class III.) 15, 40, 55, 112, 182, 213, 247, 278, 317, 365, 436, 484, 540, 602, 654, 710, 745, 780, 816, 861, 897, 931, 978, 1022, 1082, 1141, 1206
  Wax; U.S. Customs Decision on ——. (T.R.) 722

Minerals; Apparatus for Concentration of ——. (P) van Meter and Bess 716
  Concentration of ——. (P) Cattermole and others 902
  Containing Lead and Zinc; Treatment of ——. (P) Havemann 1095
  Draining Water from ——. (P) Baum 539
  Electrostatic Separation of ——. (P) Schnelle 1098
  Enrichment of ——. (P) Blanc 365
  Output of Certain —— in 1902. (T.R.) 733
  Photographic Examination of ——, with regard to Radio-Activity. (Kolbeck and Uhlich) 801
  Produced in Barcelona. (T.R.) 844
  Production of —— in Canada in 1903 (T.R.) 391
  Production of —— in Sardinia. (T.R.) 956
  for Research; Offer of Rare —— 1015
  Separation of ——. (P) Goyder and Laughton 67, 753
  Separation of —— from Ores and Gangue. (P) Sulman and Kirkpatrick-Picard 1150
  Washing of ——. (P) Evrard 409

Mines of British Columbia. (T.R.) 733
  in Korea. (T.R.) 1051
  and Quarries; Report and Statistics for 1903. (T.R.) 342, 733

Mining Industry of Belgium in 1902. (T.R.) 80
  Industry at Broken Hill in 1903. (T.R.) 887
  Industry of New South Wales. (T.R.) 508
  Industry of Sweden. (T.R.) 917
  in Spain. (T.R.) 213
Mixing Apparatus:
    (P) Bonnet 1080
    (P) Gandolfo 976
    (P) Hetherington 976
    (P) Reese 895

"Mixtion Clarifié"; U.S. Customs Decision on ——. (T.R.) 314
Molasses; Apparatus for Drawing off ——. (P) Gade 1229
  Barbados and Porto Rico —— 196
  Destruction of Sulphurous Acid in Sulphited ——. (Pozzi-Escot) 946
  Drying and Preserving ——. (P) Hoppe 472
  Electrolytic Purification of ——. (Gurwitsch) 993
  Entry of —— into Canada. (T.R.) 81
  Extracting Betaine or its Salts from ——. (P) Stiepel 1229
  Extraction of —— from Refuse. (P) Meisels 944
  Extraction and Utilisation of the Organic Acids of the "Vinasse" of ——. (P) Schrader 197
  Obtainment of —— direct. (P) Kohn 449
  Preparation of Betaine from Waste Lyes of ——. (Andrlik) 672
  Sulphurous Acid in; Determination of ——. (Pozzi-Escot) 1047
  Unfermentable Sugar in Cane ——. (Pellet and Meunier) 533
  Use of Oxidising Agents for Fermentation of ——. (Alliot and Gimel) 946
  Water in; Determination of ——. (Testoni) 883
Molybdenum; New Reaction of ——. (Lecocq) 205
  in Steel and Alloys; Determination of ——. (Cruser and Miller) 762

PAGE

Molybdenum; New Carbides of ——. (Moissan and Hoffmann) 751, 985
  Ores. *See under* Ores.

Monazite Production of the United States. (T.R.) 916
Monell Process for Production of Steel. (Leo) 825
Mono-amino Acids and their Amides; Determination of —— 274
Monobenzoylarbutin. *See* Cellotropin.
Monobromo Indigo in Dyeing and Printing. (Sansoné) 1086
Monodora Myristica Seeds; Essential Oil of ——. *See under* Oils, Essential.
Monoformyl Derivatives of 1.3-Dimethyl-4.5-diamido-2.6-dioxypyrimidine. (P) Newton. From Bayer and Co. 593
Montanin (Hydrofluosilicic Acid) as a Disinfectant in Brewing. (Will) 126
"Montanin": A New Disinfectant. (Lindner and Mathes) 34
Montserrat; Lemon-grass Oil from ——. (Bull) 997
Mordant; Stearamide as a ——. (P) Muller-Jacobs 864
Mordants; Dyeing on ——. (Prud'homme) 1211
  Form in which Primary Metallic —— are Present in Mordanted Fibres. (Heermann) 1143
  Rare-Earth ——. (Baskerville and Foust) 104
  Theories of Working of ——. (Heermann) 381
Mordanting Apparatus. (P) Dargue and Barker 251
  Process of ——. (P) Muller-Jacobs, Assignor to Cosmos Chemical Co. 933
  Research on ——. (Heermann) 57
  Theories of ——. (Heermann) 820
  Tubes for Holding Yarns during ——. (P) Détre 487
Morphine; Action of Indirect Oxidising Ferment on ——. (Bourquelot and Marchadier) 783
  Derivatives; Synthetic ——. (Coblentz) 94
  New Reaction of ——. (Reichard) 763
  in Opium; Determination of ——. (Schidrowitz) 626
  in Opium and Opium Tincture; Determination of ——. (Dowzard) 38
  Reactions of ——. (Reichard) 1163
Mortars. (Class IX.) 19, 63, 116, 187, 253, 278, 323, 372, 412, 490, 546, 607, 661, 715, 750, 788, 824, 855, 901, 936, 984, 1028, 1090, 1148, 1217
Mortar, Cement; Preserving the Binding Properties of ——. (P) Magens 254
  Fireproof; Manufacture of ——. (P) Spatz 824
  Water-Resisting ——. (P) Staab 254
Motive Power; Generation of ——. (P) Schutt 246, 246
Mould Fungi; Influence of some Salts and Monatomic Alcohols on Development of ——. (Iwanhoff) 1109
Moulds for Treating Sugar by Centrifugal Action. (P) Lafeuille 994
Muffle Furnace. *See under* Furnaces.
Muffles of Graphite or Asbestos. (Pickle and Williams) 131
Murexide. *See under* Dyestuffs.
Mustard Oil. *See under* Oils, Essential.
Must; Treatment of —— and Apparatus therefor. (P) Monti. 993
Musts; Apparatus for Determining Dry Extract, &c., in ——. (P) Darbois 1230
Myrobalan Extracts; Behaviour of —— when kept under various conditions. (Paessler) 71

N

Nan-ta-Yok (Burmese Storax); Properties of ——. (Hooper) 990
Naphtha; Aniline-Toluidine Oil from Russian ——. (Ogloblin) 654
  and Gas at Berekei (Daghestan); Examination of ——. (Charitschkoff) 716
  near the Bagdad Railway, Asia Minor. (T.R.) 278
  See also under Mineral Oil *and* Petroleum.
Naphthalene; Carburetting by Means of ——. (P) Lion 436
  in Gas and Tar; Determination of ——. (White and Ball) 1240
  Purification of ——. (P) Paradell-Mateu 182
Naphthoquinonesulphonic Acid. *See under* Dyestuffs.
1.8-Naphthylaminesulphonic Acids. *See under* Dyestuffs.
α-Naphthylmagnesiumbromide. *See under* Dyestuffs.
Narcosis; Theories of ——. (Traube) 1242
Natal; Trade of —— with the United Kingdom. (T.R.) 1049
  See also Africa, South.
Neodymium; Hydrides and Nitrides of ——. (Muthmann and Beck) 274
Neroli Oil. *See under* Oils, Essential.
New South Wales; Mineral Production of ——. (T.R.) 843
  Mining Industry of ——. (T.R.) 508
New Zealand; Castor Oil Production in —— 770
  Mineral Production of —— in 1903. (T.R.) 1245
  Preferential and Reciprocal Trade Act in ——. (T.R.) 139
Nicaragua; Cane-Sugar Yeast from ——. (Pozzi-Escot) 497

Oil from Rind of Limes, &c.: Apparatus for Extracting ——. (P) Hunter 836

of Rose; Analytical Characteristics of ——. (Jeancard and Satie) 880

„ Rose, Artificial; U.S. Customs Decision on ——. (T.R.) 806

Rose: Commercial Position of Essential ——. (T.R.) 694

Rose (Otto of Rose): Production of Turkish ——. (T.R.) 1248

Rose, Otto of ——; Examination of ——. (Simmons) 1042

Rose, Otto of: Analytical Characters of ——. (Jeancard and Satie) 880

Rose, Otto of; Newly Discovered Constituents of ——. (von Soden and Treff) 454

of Roses: Iodine Absorption Test a Factor in Examination of ——. (Cox and Simmons) 686

Santal-wood: Examination of ——. (Parry and Bennett) 203

of Siberian Fir. (Schindelmeiser) 1042

Spike; Adulterated ——. (Parry and Bennett) 37

of Tanacetum Boreale; Characteristics of —— 1236

„ Thuja Articulata; Characteristics of ——. (Grimal) .. 1235

Turpentine: Determination of Iodine Absorption of ——. (Harvey) 413

U.S. Customs Decision on ——. (T.R.) 845

Volatile, of Mustard: Determination of ——. (Vuillemin) 914

of the Wood of Erythroxylon Monogynum 679

Oils of Amorpha Fruticosa. (Pavesi) 558

of the Citrus Series: Examination of ——. (Burgess and Page) 1112

Determination of certain Aldehydes and Ketones in ——. (Sadtler) 303

obtained by Extraction of Fresh Blossoms with Volatile Solvents. (von Soden) 501

Pine; Production of —— from Wood. (P) Georgia Pine Turpentine Co. From Clark and Harris 1082

Sulphuric Acid applied to Identification of ——. (Duyk). 1116

and Terpenes; Research on ——. (Wallach) 621, 997

Two New Algerian. (Goult and Sheith) (Jeancard and Satie) 758

Synthetic; U.S. Customs Decision on ——. (T.R.) 734

Turpentine; Apparatus for Distilling Crude ——. (P) J. J. Mallonee. From J. C. Mallonee 829

Oils; Fatty ——:

Oil, Almond and Allied: Characteristics of ——. (Lewkowitsch) 494

Apparatus for Extraction of ——. (P) Kirshner 719

Apparatus for Purifying ——. (P) Koelloer 1226

of Aspidium Spinulosum. (Farup) 259

from the Seeds of Aleurites Moluccana. (Fendler) 613

"Ben": Nature and Commercial Uses of —— 793

Castor: "Floricin" a Product of ——. (Fendler) 495

Chaulmoogra or Gynocard ——. (Lemarie) 120

Chinese Tallow-Seed (Stillingia Oil); Characteristics of ——. (Nash) 494

Chinese Wood-: Exports of ——. (T.R.) 344

Chinese Wood-; U.S. Customs Decision on ——. (T.R.) .. 41

Cocoanut: Constants of ——. (Lane) 1019

Cod-Liver and its Adulterants; Tests for ——. (Gane) ... 136

Cod-Liver; Norwegian ——. (T.R.) 142

Cod-Liver; Substitute for ——. (P) Tollner 836

Copra: Saponification of —— by Cytoplasm. (Urbain, Saugon and Feize) 1152

Cotton-Seed: Detection of —— in Olive Oil. (Milliau) ... 1163

Cotton-Seed: Imports of —— at Trieste. (T.R.) 145

Drying ——. (P) Blakeman, jun. 873

Filter for Waste ——. (P) Barratt and the United Asbestos Co., Ltd. 1226

Fish: Manufacture of ——. (P) van Meerdervoort 670

Fixed —— from the Seeds of Rhus Glabra. (Frankforter and Martin) 613

Linseed; Composition of ——. (Fahrion) 26

Linseed; Determination of Unsaponifiable Matter in ——. (Nagemann) 207

Linseed: Differentiation of —— from Boiled Oils. (Lewkowitsch) 146

Melon-Seed: Characteristics of ——. (Fendler) 613

Mustard; Use of —— as a Lubricant. (Rohrbach) 719

for Oiling Fibres: Preparation of ——. (P) Kuess 488

Olive: Action of Concentrated Sulphuric Acid on ——. (Herbig) 251

Olive; Detection of Cotton Seed Oil in ——. (Milliau) ... 1163

Olive; Formation of free Acid and Production of Rancidity in ——. (Marcille) 1102

Olive kernel; Influence of —— on Olive Oil. (Passerini). 1035

Olive; Production of —— in Austria. (T.R.) 41

Olive: Production of —— in Italy 1124

Olive: Production of —— in Sardinia. (T.R.) 957

Olive; Production of —— in South Australia. (T.R.) 344

Olive; Production of —— in Spain. (T.R.) 844

Olive, U.S. Customs Decision on ——. (T.R.) 342

Refinement of ——. (P) Fleming 195

Rice ——. (Schweiz) 259

Safflower: Character of ——. (Fendler) 942

Seed and Oil-cake Exports from Odessa. (T.R.) 957

Seeds of Acrocomia Vinifera. (Fendler) 613

Sesame and Peanut; U.S. Customs Decision on ——. (T.R.) 1052

Sperm; Examination of ——. (Nash) 136

Trade of Marseilles in 1903. (T.R.) 805

Turkey-red ——, and the Action of Concentrated Sulphuric Acid on Olive Oil. (Herbig) 251

Whale: U.S. Fish Commission Report on ——. (T.R.) ... 568

Wood (Tung Oil): Treatment of ——. (P) Dewar and others 328

PAGE
Oils: Fatty—*cont.*
Oils, Apparatus for Detecting Adulteration of ——: the Therm-oleometer. (Tortelli) 668
Apparatus for Filtering and Washing Lubricating ——. (P) Brown. From Warden 905
Apparatus for Purifying ——. (P) McClelland and Risk . 871
Apparatus for Washing —— by Decantation. (P) Coq ... 614
Decolorisation of —— with Aluminium Magnesium Hydrosilicate. (Hirzel) 755
Decolorising ——. (P) Godard.......... ... 69
Enzymic Decomposition of ——. (P) Nicloux.......... 327
Enzymic Saponification of ——. (P) Nicloux 942
Expressing ——. (P) Thompson. From Anderson....... 260
and Fats; Uses and Applications of ——. (Lewkowitsch) 1098
Fatty ——. (Class XII.) 25, 41, 68, 120, 142, 194 214, 259, 279, 327, 314, 378, 416, 494 550, 613, 668, 719, 755, 793, 828, 871, 905, 942, 988, 1035, 1098, 1152, 1226
Fatty; Colour Reactions of ——. (Kreis) 1001
Fatty: Relative Inner Friction of Edible ——. (Pleissner) 273
Halogen Absorption of; Comparison of Methods for Determining ——. (Tolman).......... 841
Heating or Drying ——. (P) Leppert and Rogovin....... 26
Hydraulic Press for ——. (P) Santisteban.......... 195
Indian; Characteristics of certain —— 25
Lamp; Manufacture of ——. (P) Dreymann 988
Material for Filtering ——. (P) Gautier 829
Press for Extraction of ——. (P) Lebre Freres.......... 614
Purifying and Deodorising ——. (P) Godard 69
Refining ——, and Appliance therefor. (P) Macalpine . . 793
Refractometer Scale for Use with ——. (Leach and Lythgoe) 1113
and Sulphonated Fats; Compounds from ——. (P) Stockhausen 1102
Treatment of ——. (P) Swenson and Fleming. From Pope 195
Unsaponifiable Matter in; Determination of ——. (Huwart) 841
Oils: Hydrocarbon ——:
Apparatus for Vaporising and Burning ——. (P) Dumontier and others 815
Desulphurising ——. (P) Macy. From Amend. 55. 55
or Distillate; Desulphurising ——. (P) Amend. 817
Distillation of ——. (P) Bokelberg and Sachse.......... 655
Distilling or Refining ——. (P) Gathmann 931
Mineral Lubricating: Manufacture of ——. (P) Tabourin 137
Mineral: Occurrence of —— in the Lueneburger Heide. (Haepke).......... 715
Mineral and Rosin; Watery Solutions of ——. (P) Boleg 710
Mineral: Solidifying —— and Applying as Fuel. (P) Kuess 817
Shale: Desulphurising ——. (P) Adiassewich 247
Transformer; Properties of ——. (Holde).......... 1206
Vaseline ——. (Girard) 55
Oil-Cakes; Obtainment of ——. (P) Bisbee and Elmes...... 260
Oilcloth: Substitute for ——. (P) Melville and others 829
Oil-Fields of India: Development of the —— (T.R.).......... 1168
Oil-Gas. *See under* Gas.
Oil-Press. (P) Pifre et Cie 829
Ointments: Production of Readily Resorbent ——. (P) Reiss 195
Oleic Acid Series: New Acids of the ——. (Ponzio) 942
Acid: Solidifying —— with Sulphuric Acid. (P) Hartl, jun. 327
Oleine: U.S. Customs Decision on ——. (T.R.) 1052
Oleines, Grease; Detection of Mineral Oil in Distilled ——. (Gill and Mason).......... 703
Wool-Fat; Detection of Mineral and Rosin Oils in ——. (Marcusson) 1001
Olive Oil. *See under* Oils, Fatty.
Olives; Preservation of —— before Expression. (Mastbaum) 613
Onyx; Colouring ——. (P) Boyeux and Mora.......... 116
Opium, Codeine in: Determination of ——. (Caspari)........ 1164
Morphine in; Determination of ——. (Schidrowitz) 626
and Opium Tincture; Morphia in ——. (Dowzard) 58
Powdered; U.S. Customs Decision on ——. (T.R.)....... 734
Opopanax: Essential Oil of ——. *See under* Oils, Essential.
Orange-Flower: Distribution of Certain Organic Matters in the ——. (Charabot and Laloue).......... 726
Water; U.S. Customs Decision on ——. (T.R.) 734
Orange Oil. *See under* Oil.
Orange River Colony; New Customs Duty respecting Methylated Spirits in ——. (T.R.) 81
See also Africa, South.
Orchella Lichens; Some Substances present in ——. (Ronceray).......... 1042
Ore, Banket Gold; Finer Crushing of —— on the Witwatersrand. (Caldecott) 1093
Bricks of ——. (P) Koeniger 444
Chromic Iron —— in Cuba. (T.R.).......... 461
Copper; Smelting of ——. (P) Baggaley and Allen 869
Crushing in Cyanide Solution in South Dakota. (Fulton) 1219
Ferruginous: Treatment of ——. (P) Moore and Heskett 828
Gold; Apparatus for Treating ——. (P) Helm.......... 444
Gold; Regrinding of ——. (Butters and Hamilton)...... 1030
Iron —— from Bilbao, Spain. (T.R.) 568
Iron: Converting —— into Briquettes. (P) Rouse and Cohn.......... 1031
Iron: Hardening Lumps of Concentrated Powdered —— for Transport, &c. (P) Rouse and Cohn.......... 664
Iron; Reducing —— to Iron Sponge. (P) Greendal 190
Iron; United States Production of —— in 1903. (T.R.)... 917

PAGE
Ore—*cont.*
Manganese; Russian Output of ——. (T.R.) 1007
Separation of Metalliferous —— from Gangue. (P) Lindley. From Schwartz 829
Separator; Magnetic ——. (P) Snyder 259
Spathic Iron; Calcination of ——. (Laroisne) 788
Uranium Pitchblende —— 514
Zinc; Magnetic Concentration of —— in Virginia. (Payne) 752
Ores, Aluminium; Obtaining Alumina from ——. (P) Boult. From Soc. Romana Solfati.......... 186
Aluminous; Utilising Natural ——. (P) Joss.......... 696
Apparatus for Concentrating ——. (P) Abelspies 1222
Apparatus for Pulverising ——. (P) Benjamin.......... 903
Apparatus for Separating ——. (P) Kistler. From Pettengill.......... 1151
Apparatus for Separating and Classifying ——. (P) Swyny and Plucknett.......... 1150
Apparatus for Treating ——. (P) Hubbard 22
Apparatus for Treating —— with Liquids or Gases. (P) Naef 414
Barytic: Preparation of —— for Production of Double Carbide of Barium and Calcium. (P) Cartier 991
Calcareous; Enrichment of ——. (Leduc and others) 826
Classification of Metallic Constituents of ——. (P) Cattermole.......... 118
Complex Sulphide: Electrolytic Production of Zinc and Lead from ——. (Burleigh).......... 941
Complex: Treatment of ——. (P) de Alzugaray 65
Concentration of ——:
(P) Elmore.......... 22
(P) Schwarz Ore Treating Co. From Schwarz 1052
Copper; Determination of Minute Quantities of Arsenic in ——. (Cloud).......... 524
Copper: Determination of Minute Quantities of Bismuth in ——. (Cloud).......... 523
Copper; Reduction of ——. (P) Baltzley. From Clark.. 610
Copper: Smelting of ——. (P) Aiken 66
Copper Sulphide: Fusing of ——. (P) Lebedeff.......... 1005
Copper: Technical Experiments in Smelting of ——. (Vattier).......... 25
Copper: Treatment of ——:
(P) Hybinette.......... 256
(P) Rider.......... 610
(P) Seeman. From Porter.......... 610
Cyaniding of ——. (P) Smith 444
Draining Water from ——. (P) Baum.......... 539
Electrical Treatment of ——. (P) Perreur-Lloyd 550
Extraction of Copper and Zinc from —— Electrolytically. (P) Laszczynski 547
Extraction of Metals from ——. (P) Alzugaray 24
Ferruginous; Treatment of ——. (P) Moore and Heskett 827
Friable; Manufacture of Briquettes from ——. (P) Schulte-Steinberg 414
Furnace for Roasting ——.
(P) Smyth 665
(P) Wilson. 665
Furnaces for Roasting and Desulphurising Mineral ——. (P) Edwards.......... 1150
Gold-Selenium-Silver; Treatment of ——. (Merz) 491
Iron; Briquetting of ——. (Weiskopf).......... 824
Lead-Bearing; Treatment of ——. (P) Rider.......... 610
Lead: Desulphurisation of ——. (P) Savelsberg 376
Lead-Zinc; Treating Refractory ——. (P) Miller 118, 256
Lixiviating ——. (P) Naef.......... 190
Magnetic Apparatus for Separating ——:
(P) Dawes.......... 1031
(P) Edison 610
(P) King 792
(P) Moss 1031
Molybdenum; Treatment of ——. (P) Herrenschmidt .. 68
Molybdenum; Utilisation of ——. (Wells) 118
Nickel; Treatment of —— and Apparatus therefor. (P) Gin 1090
Plumbiferous; Vessels for Treating ——. (P) Engels 144
Quicksilver; Furnace for Calcining ——. (P) Cutler 826
Recovering Copper, &c., from ——. (P) Baggaley and Allen 869
Reduction of ——. (P) Brown.......... 1221
Reduction of Metallic ——. (P) Bradley 66
Refractory: Furnace and Method for Treating ——. (P) Galbraith and Steuart.......... 378
Separating Zinc Blende from ——. (P) Jamieson and Odling 190
Separation of —— from Magnetic Gangue. (P) Edison .. 375
Separation of Metallic Constituents of —— from Gangue. (P) Cattermole 118, 256
Silicious; Recovering Values from ——. (P) Baggaley... 23
Silver; Amalgamation and other Wet Processes for ——. (Collins) 24
Smelting of ——:
(P) Page. From Partridge 192
(P) Schwartz 255
Smelting of Poor Copper —— containing Sulphur, &c. (P) (Torkar).......... 609
Sulphide: Separation of Metals from ——. (P) Potter... 1222
Sulphide; Smelting of ——. (P) U.S. Sulphide Smelting Furnace Co. From MacDonald 66
Sulphide; Treatment of ——. (P) Huntington and Heberlein.......... 791
Tin; Losses in Vanning ——. (Pearce) 275

Ores—*cont.*
  Treatment of ——:
    (P) Browning. From Hannes 547
    (P) Potter 375
    (P) Rapid Cyanide Treatment, Lim. 792
    (P) Sanfilippo 326
  Treatment of —— and Apparatus therefor. (P) Goldschmid 1032
  Treatment of Low-Grade —— by Electrolysis. (P) Fahrig 494
  Vanadiferous: Treatment of ——. (P) Herrenschmidt ... 66
  Vanadiferous ——, and Products: Treatment of ——. (P) Herrenschmidt 65
  Zinc: Determination of certain Metals in Commercial ——. (Waring) 912
  Zinc Sulphide or Complex: Treatment of ——. (P) Cory 791

Organic Acid from Beetroot Molasses. (P) Schrader 672
  Acid Compounds: Manufacture of ——. (P) Badische Anilin und Soda Fabr. From Bäuml 336
  Acid; Esterification of ——. (Werner and Seybold) 1111
  Acid of "Vinasse" of Molasses; Extraction and Utilisation of ——. (P) Schrader 197
  Acids: Manufacture of —— from Petroleum. (P) Zelinsky 55, 318

Organic Compounds; Determination of Halogens in ——. (Baubigny and Chavanne) 156
  Compounds; "Iodine Value" of Unsaturated ——. (Ingle) 422
  Compounds; Rapid Determination of Chlorine, Bromine, or Iodine in ——. (Pringsheim) 76
  Matter; Electrolytic Destruction of —— in Toxicological Analysis. (Gasparini) 952
  Matter; Incineration of —— facilitated by Pumice Stone. (Duyk) 841
  Matter in Soils and Subsoils; Determination of ——. (Cameron and Breazeale) 207
  Salts; Electrolysis of Fused ——. (Berl) 257
  Substances: Analysis of ——. (Pringsheim) 504
  Substances; Apparatus for Dry Distillation of ——. (P) Mark. From Aminoff 113
  Substances: Electrolytic Reduction of ——. (P) Imray. From Meister, Lucius und Bruning 717
  Substances; Electrolytic Reduction of ——. (P) Meister, Lucius und Bruning 987

Orsellinic Acid. *See under* Dyestuffs.

Orthonitrophenyllactoketone; Printing Compounds of ——. (P) Soc. Chim. des Usines du Rhone. From Eichbart 1026

Ortho-oxy-carbon Acids (Hydroxy-Carboxylic Acids): Manufacture of ——. (P) Chem. Fabr. vorm. E. Schering. From Wichmann 559

Osmosis: Theories of ——. (Traube) 1242

Otto of Rose. *See under* Oils, Essential.

Oven: Coke ——
    (P) Beam Coke-Oven, &c., Co. From Beam 658
    (P) Bowling 980
    (P) Maxwell 709
    (P) Ramsay 1141
    (P) Schroeter 709
  Coke-; Electric ——. (P) Conley 745
  Coke-: Horizontal ——. (P) Poetter 860
  Continuous Drying —— for Combustibles. (P) Putte-Cotte de Renéville 978
  Drying ——. (P) Suppes and Phelps 895
  Retort-Coke- ——. (P) Scott 510

Ovens: Coke ——:
    (P) Collin 112
    (P) Koppers 365, 1020
    (P) Redfern. From Poetter and Co. 1140
    (P) von Bauer 183
  Electric ——. (P) Bauer 686
  for Manufacture of Smokeless Briquettes. (P) Mackenzie 709
  for Pottery and Bricks. (P) Owen 253
  See also Kilns.

Oxalacetic Ester; Spontaneous Decomposition of ——. (Simon) 730

Oxalates; Decomposition of —— by Heat. (Scott) 786
  Manufacture of —— from Formates. (P) Koepp and Co. From Reche and Saame 129
  Preparation of —— from Formates. (P) Johnson. From Koepp and Co. 203

Oxalic Acid: American Trade in —— in 1903. (T.R.) 139

Oxidation caused by Manganese; Influence of Albuminoid Substances on ——. (Trillat) 158

Oxides of Metals: Production of —— by Electrolysis. (P) Maas and Waldstein. From Hunt 119
  Metallic; Action of Potassium Thiocyanate on —— at High Temperature. (Muhlhauser) 405
  Metallic; Preparation of ——:
    (P) Fink-Huguenot 133
    (P) Weiler 445, 903
  Metallic: Treatment of —— for Manufacture of Electrodes. (P) Wedekind 612
  Nitrogen: Electric Production of ——. (P) Siemens and Halske Actienges. 193
  Recovery of —— from Solutions. (P) Gutensohn 1222
  Transformation of —— into Chlorides. (Matignon and Bourion) 441

Oxidising Substances: Use of Hydrazine Sulphate in the Determination of ——. (Roberto and Roncali) 941

Oxybenzaldehydes and Intermediate Products. (P) Johnson. From The Badische Anilin und Soda Fabr. 758

Oxybenzoic Acids: Manufacture of ——. (P) Johnson. From The Badische Anilin und Soda Fabr. 758

Oxybenzyl Sulphonic Acid: Meta-amido-ortho —— for Use as a Photographic Developer. (P) Newton. From The Farb. vorm. F. Bayer and Co. 204

Oxychlorides, Alkaline: Preserving the Strength of Solutions of ——. (P) Atkins and Oxychlorides, Ltd. 1088

Oxydases: Chemical Nature of the ——. (Chodat and Bach). 210

Oxygen; Active ——. (Autoxidation of Cerous Salts.) (Engler) 209
  Active, in Organic Per-sulphates: Quantitative Determination of ——. (Wolff and Wolffenstein) 1046
  Active; Preparation of Salts containing easily Liberated ——. (P) Jaubert 823
  Active; Salts of Acids containing easily Liberated ——. (P) Jaubert 323
  Apparatus for Manufacture of ——. (P) Artigue 866
  Apparatus for Producing Strongly Ozonised ——. (P) Déchaux 193
  Apparatus for Separating —— from Air. (P) Price 787
  Extraction of —— from the Atmosphere. (P) Benier 257
  Liquid; Preparation and Characters of Pure ——. (Erdmann and Bedford) 441
  Liquid; Solubility of Nitrogen in ——. (Stock) 489
  Manufacture of ——:
    (P) Claude 606
    (P) Cie. Franç. de l'Acetylene Dissous 936
  and Nitric Oxide; Reaction between —— at Low Temperatures. (Francesconi and Sciacca) 866
  and Nitrogen; Apparatus for Separating Atmospheric ——. (P) Pictet 371
  Ozonising of ——. (Warburg) 191
  Preparation of ——. (P) Jaubert 787, 1215
  Relation of —— to Copper and Tin. (Heyn and Bauer) .. 1219
  Solubility of Atmospheric —— in Sea Water and in Water of Different Degrees of Salinity. (Clowes and Biggs). 358
  Withdrawal of —— by Platinum. (Goldstein) 1147
  in Working Cyanide Solutions; Industrial Method for Determination of ——. (Pfister) 684

Oxy-Hydrogen Combustion Apparatus. (P) International Oxy-Generator Syndicate and Rosenberg 815

Oxy-Salts; Transformation of —— into Chlorides. (Matignon and Bourion) 441

Ozone; Action of —— on Ethane. (Bone and Drugman) 629
  Action of —— on Hydrogen. (Pickel) 183
  Apparatus for Generating —— by Electricity. (P) Wokes and Street 445
  Apparatus for Production of ——. (P) Gosselin 941
  Formation of —— at High Temperature. (Clement) 822
  Production of;
    (Gray) 191
    (Warburg) 191
  Production of —— for Use as a Disinfectant. (P) D'Arsonval and others 580
  Quantitative Precipitations and Separations by Means of ——. (Jannasch and Gottschalk) 1000

Ozonising Apparatus:
    (P) Labille 377
    (P) Wood-Smith 792

"Ozotype" Photographic Process: Theory of the ——. (Manly) 129

P

Paints. (Class XIII.) 26, 41, 69, 81, 121, 143, 195, 211, 260, 328, 341, 378, 447, 495, 551, 615, 670, 719, 755, 793, 829, 872, 905, 913, 989, 1036, 1102, 1153, 1226

Paint; Composition of ——:
    (P) Blakeman, jun. 873
    (P) Hall 328
  Fireproof ——. (P) Nettleton. From Stowell 1148
  Incorrodible ——. (P) Gesner 989
  Manufacture of a White ——:
    (P) Kollinger 69, 328
    (P) Scholz 26
  Preparation of Zinc for Use as ——. (P) Malzac 905
  Vehicles for ——. (P) Strange and Graham 448
  White Oil ——, and Manufacture thereof. (P) Farbwerke W. A. Hospelt 121

Paints; Manufacture of ——. (P) Girard and Tabourin 484
  Medium for Oil ——. (P) Kollinger 328
  Zinc-White: Substitution of —— for White-Lead Paints. (Breton) 195

Palladium; Determination and Separation of ——:
    (Erdmann and Makowka) 761
    (Jannasch and Bettges) 729
  Electro-deposition of ——. (Amberg) 667
  Separation of —— from other Metals. (Jannasch and Rostosky) 760

Palm of Madagascar; Alimentary Pith from a ——. (Gallerand) 619

Palmetto Extract; Manufacture of ——. (Kohnstein) 671

Papain and Papaw. (Watts) 203

Papaverine: Preparation of ——. (Freund and Beck.) 197

    (P) Bradley ... 1041
    (P) Case ... 677
    (P) Taiffer ... 558
    (P) Waite ... 909
  Apparatus for Preparing Fibre for Manufacture of ——. (P) Cloudman ... 1233, 1233
  Apparatus for Printing —— intermittently. (P) Grantil. 1145
  and Cardboard: Sizing of ——. (P) Dobler ... 335
  "Carton Pierre"; Preparation of ——. (P) Jackson ... 335
  Coated on one or both Sides. (P) Rolier ... 453
  Coated on one Side with Coloured Material ... 834
  Coloured Effects on Dyed ——. (P) Imray. From The Farb. vorm. Meister, Lucius und Bruning ... 17
  Coloured on one Side, and Apparatus for making same. (P) Leykam-Josefstahl Act.-Ges. ... 1041
  Colouring ——. (Class VI.) ... 17, 59, 115, 185, 321, 369, 440, 488, 514, 834, 1115, 1215
  Colouring, Decorating, &c., ——. (P) Maunsell-Smyth ... 488
  Composition for Coating or Enamelling ——. (P) Hall... 725
  Depositing Silver and other Metals on ——. (P) Soc. F. Pauli and Co. ... 59
  Dyeing of —— (Nonnenmuhlen) ... 864
  Factories; Utilisation of Waste from ——. (P) de Pass. From Gaertner ... 453
  Improved ——, and Manufacture thereof. (P) Fowler and Hoover ... 128
  and Ink; Safety Commercial ——. (P) Rowan ... 155
  Lignified Fibres in; Colorimetric Determination of ——. (Valenta) ... 685
  Machine; Cleaning the Wire Cloth of the —— ... 334, 948
  Machines for Making ——. (P) Farwell ... 292
  Machines; Shower-Pipes or Cleansing Apparatus for ——. (P) Howarth ... 997
  for Manifolding; Preparing and Printing ——. (P) Hutchinson ... 335
  Manufacture of ——:
    (P) Case ... 909
    (P) Thorp and others. From Meixell and Holt ... 128
  Manufacture of —— from Maize Stalks, &c. (P) Drewsen 1233
  Manufacture of Pressed or Gauffered ——. (P) Hennessen and Spix ... 1040
  Manufacture of —— from Sawdust. (P) Pfeifer ... 620
  Metallic ——, Impermeable to Air, &c. (P) Suddeutsche Patent-metallpapier Fabr. ... 266
  Metallisation of ——. (P) Forster ... 184
  Moisture or Grease-proof; Manufacture of ——. (P) Kitsee ... 1110
  for Obtaining Fast Copies of Aniline Inks. (P) Wyckoff, Seamans, and Benedict. From Chapin ... 202
  Obtaining Pearly Effects on ——. (P) Dejey ... 821
  Printing Patterns upon ——. (P) Schoening and others. 605
  Production of Algeria. (T.R.) ... 570
  and Pulp Machines. (P) Milne ... 335
  Printing or Decorating ——. (P) Burdick and Pervilhac. 185
  Remanufacture of Waste —— in America ... 127
  Resistance of —— to Moisture. (Winkler) ... 334
  and Similar Substances: Toughening ——. (P) Vellumoid Paper Co. ... 128
  Sizing of ——. (P) Dobler ... 1041
  Tissue; Sulphite Wood Pulp for —— ... 127
  Utilisation of Waste from Manufacture of ——. (P) Cornell ... 501
  Waste; Machine for Reducing, Mixing, &c., ——. (P) Dietrich ... 266
  Waterproof; Manufacture of ——. (P) Harrison. From The Vellumoid Paper Co. ... 880
  Waterproofing of ——. (P) Serkowski ... 659
Papers, Bank-Note; Examination of ——. (Liber) ... 948
  Knots in Cotton-Rag —— ... 127, 201
  Normal; Transparency of ——. (Herzberg) ... 500
  Printing; Manufacture of ——. (P) von Schmaedel ... 949
  Printing; Production of Dust by —— ... 1110
  Writing; Penetration of the Ink through ——. (Klemm) 677
Paper-making; Means for Dissolving Size for ——. (P) Kmiller ... 1110
  Products for —— from Cornstalks, &c. (P) Drewsen ... 1040
Para (Brazil): Trade of ——, for 1902. (T.R.) ... 40
Paraldehyde; U.S. Customs Decision on ——. (T.R.) ... 394
Paraffin; Action of Sulphuric Acid on —— (Istrati and Michailescou) ... 1206
  Composition of Commercial ——. (Mabery and Payne) .. 1022
  Hydrocarbons; Separation of Solid —— from Petroleum without Distillation. (Mabery and Sieplein) ... 1022
  Hydrocarbons; Solid —— in certain Pennsylvanian Oil Wells. (Mabery) ... 1022
  Liquid and "Paraffinum Molle"; U.S. Customs Decision on ——. (T.R.) ... 732
  U.S. Customs Decision on ——. (T.R.) ... 40
  Wax. *See under* Wax.
Paraformaldehydes: Action of —— on Sesquiterpenes. (Genvresse) ... 621
Parafuchsine. *See under* Dyestuffs.
Paraguay; Petit-Grain Oil Exports of ——. (T.R.) ... 845
  Quebracho Trade of ——. (T.R.) ... 845
Paranitraniline: Blue-Red Prints with ——. (von Black) ... 878
  Red: Action of the Amines on the "Mordant" of ——. (Favre) ... 981
  Red: White Discharge on ——. (Kurz) ... 58
  See also under Dyestuffs.
Paranitrophenol as Indicator. (Spiegel) ... 682
Parasaccharin. *See under* Saccharin.
Parasites in Agriculture; Use of Calcium Sulphide for Destruction of ——. (Garrigou) ... 729
Parsley- and Dill-Apiols; Constitution of ——. (Thoms) ... 797
Pasteboard. (Class XIX.) ... 34, 42, 75, 127, 201, 265, 280, 334, 382, 453, 500, 557, 620, 677, 725, 758, 797, 834, 879, 909, 947, 997, 1040, 1110, 1158, 1233
Patchouli Leaves; Essential Oil of ——. *See under* Oils, Essential.
Patents; Lists of —— ... 43, 82, 143, 214, 280, 346, 394, 463, 504, 570, 636, 694, 734, 773, 807, 845, 888, 919, 958, 1010, 1053, 1125, 1171, 1210
  Act, 1902; Official Notice relating to the. (T.R.) ... 955
  in Canada. (T.R.) ... 463
  Rules for ——, 1905. (T.R.) ... 1166
Patterns; Apparatus for Printing ——. (P) Burdick ... 864
Pavement; Rendering —— free from Dust. (P) Chem. Werke Muglu ... 1218
Pavements, Bituminous; Preparing Compositions for ——. (P) Ames Asphalt Co. ... 662
Paving Blocks. Production of —— from Towns' Refuse. (P) Weaver ... 1091
  Flags: Manufacture of —— from Destructor Slag ... 750
  Material for:
    (P) Morin ... 254
    (P) Peest ... 1024
    (P) Thompson ... 61
Peanut Oil. *See under* Oils, Fatty.
Pearl, Imitation; Preparation of ——. (P) Soc. Anon. La Cornalithe ... 553
Peat: Apparatus for Treatment of ——. (P) Carmichael ... 847
  Blocks; Manufacture of ——. (P) Gaertner ... 896
  Bricks. *See under* Bricks.
  Briquettes. (P) White and Griffin ... 317
  Briquettes; Treatment of ——. (P) McLean and Peterson ... 815
  Conversion of Raw —— into Solid Fuel. (P) Schlickeysen 1204
  Distillation of ——. (P) Hammer ... 978
  Fuel from ——. (P) Bessey ... 112
  -Gas Works for Electric Power Stations. (Frank) ... 538
  Oven for Coking ——. (P) Bremer ... 934
  Removing Water from ——. (P) Kittler ... 326
  Spirit Manufactured from ——. (T.R.) ... 570
  Wax and Analogous Products: Manufacture of ——. (P) Bouchaud-Praceiq ... 710
Pentane Lamp; Investigations on the ——. (Paterson) ... 895
Peppermint Oil. *See under* Oils, Essential.
Perborates: Action of Boric Acid on Alkaline Peroxides. (Jaubert) ... 1145
Perchlorate; Reduction of —— in the Wet Way. (Sjollema). 1162
Perchromic Acid; Preparation of ——. (Riesenfeld) ... 983
Perfume, Artificial; Manufacture of ——. (P) Imray. From Meister, Lucius und Bruning ... 203
  from Citrylidine Aceto-acetic Ether. (P) Knoevenagel... 204
  "Farnesol," a Substance suitable for ——. (P) Bloxam. From Fab. Prod. de Chimie Organique de Laire .. 203, 204
  Hints to Exporters of. (T.R.) ... 214
Periodates: Electrolytic Production of ——. (Müller) ... 191
Periodic Acid and Periodates; Electrolytic Production of ——. (Muller) ... 191
Permanganates; Manufacture of ——. (P) Tixier and others 489
Peroxides; Functions of —— in the Chemistry of Living Cells. (Chodat and Bach) ... 210, 505, 802
Peroxydase Reaction; Velocity of the ——. (Bach and Chodat) ... 765, 802
Peroxydases; Nature of the Action of ——. (Bach and Chodat) ... 505
Peroxylaminesulphonates; Preparation of ——. (Haga) ... 59
Peroxylaminesulphonic Acid; Examination of ——. (Divers) 60
  Formation of ——. (Divers) ... 185
Persulphates; Quantitative Determination of ——. (Pannain) 882
  Quantitative Separations by means of ——. (von Knorre) 135
  Preparation of ——. (Muller) ... 987
Peru; Cocaine Production in ——. (T.R.) ... 571
  Trade of ——. (T.R.) ... 1005
Petit-Grain Oil. *See under* Oils, Essential.
Peruvian Balsam, White: Constituents of —— (Thoms and Biltz) ... 1111
Petroleum. (Class III.) ... 15, 40, 55, 112, 182, 213, 217, 278, 317, 365, 436, 84, 540, 602, 654, 710, 745, 780, 816, 861, 897, 931, 978, 1022, 1082, 1141, 1206
  Apparatus for Distilling ——. (P) Gathmann ... 437
  Apparatus for Producing Gas from ——. (P) Kuenzel... 813
  Apparatus for Refining ——. (P) British-American Power Co. From O'Neall ... 966
  Borings: Superheated Steam for ——. (Szaynok) ... 182

PAGE

Petroleum—*cont.*
- Bounties on Crude ——. (T.R.) 915
- in California in 1903. (T.R.) 769
- Canadian —— 112
- Coal-like Substance accompanying Caucasian ——. (Charitschkoff) 14
- Desulphurisation of ——. (P) Colin 15
- and its Distillation Products; Action of Formalin on ——. (Nastjukow) 1082
- and its Distillation Products; Optical Examination of ——. (Rakusin) 816
- Field; New ——, in Russia. (T.R.) 390
- and its Homologues; "Saponifying" ——. (P) Lothammer and Trocquenet 655
- Hydrocarbons in Canadian —— with High Boiling Points. (Mabery and Numsen) 1022
- Hydrocarbons in Ohio Trenton Limestone —— with Boiling Points above 216° C. (Mabery and Palm) 1022
- Hydrocarbons in Santa Barbara Crude Oil. (Mabery and Zoul) 1022
- Impurities in Boryslaw: Determination of ——. (Wielezynski) 504
- Impurities in Crude: Determination of ——. (Nettel) 952
- Industry in the Caucasus. (T.R.) 691
- Neutral Sulphuric Ester in Commercial ——. (Heusler and Dennstedt) 317
- Occurrence of —— in Pedernales, Pesquero, and del Plata, Venezuela. (Hirzel) 112
- Organic Acids from ——. (P) Zelinsky 318
- Quality of Austrian Export ——. (Zaloziecki) 654
- Parliamentary Acts relating to —— 540
- Production of —— in Borneo. (T.R.) 507
- Production of —— in California. (T.R.) 1215
- Production of Roumania. (T.R.) 566, 1049
- Production of Russia. (T.R.) 769
- Production of Russia; Decline in ——. (T.R.) 1168
- Production of the United States in 1903. (T.R.) 1049
- Products, Countervailing Duty on; U.S. Customs Decision on ——. (T.R.) 886
- Products: Definitions of Nomenclature of ——. 55
- Radio-active Gas from Crude ——. (Burton) 1003
- Refining of ——. (P) Durupt 1082
- Refining of —— in France. (T.R.) 566
- Rendering —— Uninflammable. (P) Dilette and Telabot. 898
- Russian Exports of ——. (T.R.) 566
- Russian Production for 1903. (T.R.) 213
- from Saghalien. (Klei) 55
- Solidifying —— and Applying as Fuel. (P) Kuess 817
- Spirit or Benzine; Notes on ——. (Garry and Watson) 701
- from Trinidad 113
- Wasteful Methods of Winning ——. (Angerman) 654

Pharmaceutical Compound; Manufacture of ——. (P) Newton. From F. Bayer and Co. 203, 798

Phellandrium Aquaticum; Essential Oil of ——. *See under* Oils, Essential.

Phenacetin; New Colour Reactions for ——. (Barral) 339

Phenocoll; Detection of —— in Cases of Poisoning. (Archetti) 763

Phenol Compound: Preparation of ——. (P) Farbenfabr. of Elberfeld Co. From Gentsch 1237
- and Formaldehyde; Condensation Product of ——. (P) Stephan 1233
- Volumetric Determination of ——. (Moerk) 953

Phenols; Composition of the Series of ——. (P) Cross 85
- Polyhydric: Action of Molybdates on ——. (Frabot) 685
- Separation of —— from Mineral Tar. (P) Chem. Fabr. Ladenburg 55

Phenolphthalein. *See under* Dyestuffs.

Phenylacenaphthylmethane; Preparation of ——. (Dziewonski and Dotta) 459

Phenyldiazoaminobenzene Derivatives. *See under* Dyestuffs.

Phenylenediamine: Distinguishing between *m*- and *p*- ——. (Frabot) 685

p-Phenylenediamine; Oxidation-Products of ——. (Erdmann) 885

Phenylglycine-*o*-carboxylic Acid. *See under* Dyestuffs.

Phenyl-glycine-carboxylic Acid Nitrile. *See under* Dyestuffs.

Philippines: Ilang-Ilang Oil Produced in the ——. (T.R.) 918

Phlegms: Continuous Direct Rectification of ——. (P) Baudry 1167, 1168
- Rectification of ——. (P) Baudry 1231

Phonographic Cylinders: Composition for Manufacture of ——. (P) Defavrie 834
- Records; Composition for ——. (P) Lumière 1011

Phosphate Deposits of South Australia. (T.R.) 80
- Ferric and other: Soluble Colloidal Form of ——. (Sell) 687
- Purification of ——. (P) Reymond 823
- Rock-; Discoveries of —— in Tunis. (T.R.) 42
- Rock-; New Source of ——. (T.R.) 1245
- Rock-; Output of —— in the United States. (T.R.) 916
- Trade of Africa. (T.R.) 707
- Wolter; Characteristics of ——. (Wagner) 615

Phosphates: Action of Water and Saline Solutions upon certain. (Cameron and Hurst) 966
- Colorimetric Determination of ——. (Schreiner and Brown) 1240
- American Trade in —— in 1903. (T.R.) 140
- Conversion of —— into Dicalcium Phosphate, &c. (P) De Wilde 116

"Phospho-zinco-alumino-magnesien" for Treatment of Sewage and Water. (P) Lallemand and Gautierre 536

PAGE

Phosphorescent Substances: Research on ——. (Hofmann and Ducca) 1102

Phosphoric Acid and Crude Phosphates; Rendering —— Soluble, for Manuring. (Ystgaard) 329
- and Glycerol: Esterification of ——. (Carré) 35
- Manufacture of ——. (P) Powter and Fallows 252
- of Manures; Effect of Liming on ——. (Schulze) 1036
- Soluble in Citric Acid in Basic Slag; Determination of ——. (Sorge) 457
- of Tricalcium Phosphate; Action of certain substances on ——. (Stalstrom) 615
- Production of ——. (P) Brandon frères 787
- and Silicic Acid: Soluble Compound of ——. (P) Wolters 261
- Esters of Glycerol. (Carré) 128
- Oxide in Magnesium Pyrophosphate; Calculation of ——. (Kampter) 132

Phosphorite: Increased Solubility of —— in Presence of "Physiologically Acid Salts." (Schulow) 195

Phosphorus in Calcium Carbide: Determination of ——. (Lidholm) 951
- in certain Foods: Status of ——. (Hart and Andrews) 53
- Compound in Wheat Bran; Nature of the Principal ——. (Patten and Hart) 618
- in Iron Ores: Determination of ——. (Rowland and Davies) 1186
- in Organic Bodies: Determination of ——. (von Konek) 763
- Scarlet; Investigations on ——. (Schenck) 17
- in Solutions; Quantitative Determination of ——. (Christomanos) 1000

Phosphorus Sesquisulphide and Sulphur in Carbon Bisulphide: Action of Heat and Light on Mixed Solutions of ——. (Dervin) 274
- Sulphides: Preparation of —— in the Cold. (Boulouch) 274

Photographic Materials and Processes. (Class XXI.) .. 35, 76, 129, 204, 267, 336, 383, 455, 503, 559, 622, 680, 727, 799, 836, 884, 911, 950, 998, 1043, 1112, 1161, 1238

Photochemical Reactions in a Homogeneous System; Reversible ——. (Luther and Weigert) 842

Photographs in Colours:
- (Lumière) 680
- (P) Riebensahm and Posseldt 622
- (P) Szczepanik 76
- Development of —— in Daylight. (Lumière and Seyewetz) 560
- resembling Engravings or Sepia Prints. (P) Van Meurs et Cie 882
- on Linen, &c.: Production of ——. (P) Fulton and Gillard 622
- prepared by Lippmann's Process; Zenker's Stripes on Spectra Covering ——. (Pfaundler) 1238
- in Natural Colours: Use of Leuco-Bases for Preparation of ——. (König) 998
- Positive Stripping-film for ——. (P) Thornton and Rothwell 680
- and Prints; Coloured ——. (P) Gurtner 357
- Production of Multi-coloured ——. (P) Lemberger and Bohm 204

Photographic Developer: Acid ——. (P) Balagny 680
- Developer: Glycocoll ——. (P) Meister, Lucius und Brüning. From Homolka and Schwan 882
- Developer, "Metoquinone." (P) Mills. From La Soc. Anon. A. Lumière et ses fils 268
- Developer; Properties of the Pyrogallol ——. (Vaubel) 336
- Developers: *m*-Amido-*o*-oxybenzyl Sulphonic Acid for Use as a ——. (P) Newton. From the Farb. vorm. F. Bayer and Co. 204
- Developers: Constitution of ——. (Lumière and Seyewetz) 258
- Developers; Manufacture of ——. (P) Comp. Parisienne de Coul. d'Aniline 36
- Developing Paper with Covering. (P) Chem. Fabr. vorm. E. Schering 268
- Development with an Acid Developer. (Maes) 1238
- Development and Fixing Combined. (Baker) 336
- Development; Separation of —— into Primary and Secondary Actions. (Sterry) 384
- Emulsions: Cyanine Dyestuffs for Sensitising ——. (P) Imray. From Meister, Lucius und Brüning 384
- Emulsions: Pyridine as a Ripening Agent for ——. (Witt) 836
- Films. (P) Beckwith and Carten 268
- Films; Cellulose Acetate for ——. (P) Newton. From Bayer and Co. 337
- Films; Centrifugal Spreader for ——. (P) Penrose. From Hinton 882
- Films; Manufacture of ——. (P) Smith 1112
- Films: Self-Detaching ——. (P) Bry et Cie 1238
- Flash-light Powder. (P) Actien Ges. für Anilinfabr. 855
- Half-Tone for Book-printing, &c. (P) Vidam and Hauser. 455
- Images of Fine Grain; Development for Production of ——. (Lumière and Seyewetz) 1014
- Intaglio Printing on Cylindrical Surfaces. (P) Lake. From McIndoe 680
- Paper: Influence of Atmospheric Moisture on Drying of ——. (Baekeland) 560
- Paper; Preparation of Matt Gelatin ——. (Hanneke) 267
- Paper for Printing. (P) Hoffsummer 357
- Paper: Production of ——:
  - (P) Hoffsummer 622
  - (P) von Germanow-Trauttenberg and Fabian 1044
- Paper; Sensitive Coating for ——. (P) Hauser 1238
- Pictures: Colouring Silver ——. (P) Gros 1238
- Pictures: Developing ——. (P) Newton. From F. Bayer and Co.
- Pictures in Natural Colours. (P) Butler 130

  Sumach Trade of ——. (T.R.) 41

Sidot's Blende. *See under* Blende.
Siemens Process for Winning Copper; Studies on ——. (Thompson, jun.) 717
  Regenerative Furnaces; Improved ——. (P) Kurzwernhart.......... 816

Sienna, Burnt Italian; U.S. Customs Decision on ——. (T.R.) 814
Silica and Fused Alkali Carbonates; Reaction between ——. (von Wittorf) 488
  Reduction of —— by Hydrogen. (Dufour).......... 545

Silicate Cotton; Manufacture of ——. (P) Nelson. (McNeill and Co.).......... 1148

Silicates; Reduced ——. (Simmonds) 516
  Refractory; Decomposition of ——. (P) Gibbs 1089, 1089
  Manufacture of ——. (P) Granger. From Mills 442

Silicic and Phosphoric Acids; Soluble Compound of ——. (P) Wolters.......... 261

Silicon; Action of —— on Water at Temperatures near 100° C. (Moissan and Siemens).......... 564
  Apparent Volatilisation of —— in Hydrogen. (Dufour) .. 627
  Crystalline ——, Soluble in Hydrofluoric Acid. (Moissan and Siemens).......... 687
  in Iron and Steel; Determination of ——. (Thiel) 1114
  Solubility of —— in Silver. (Moissan and Siemens) 687
  Solubility of —— in Zinc and in Lead. (Moissan and Siemens) 374

Silicon Carbide, Crystalline or Amorphous: Incorporating —— with Steel. (P) Kaufmann and Bouvier.......... 1222
  and Carbon; Compounds of —— with Metals. (Hempel) . 492
  Chlorides, &c.; Production of ——. (P) Lyon. From Machalske 18
  Fluoride; Preparation and Physical Constants of ——. (Moissan).......... 1161

Silk; Artificial ——:
   (Matthews) 176
   (P) Turgard 1212
  Artificial; Apparatus for Manufacture of ——. (P) Thiele 59
  Artificial; Apparatus for Regulating Solutions of ——. (P) Soc. Franç. de la Viscose 1212
  Artificial; Apparatus for Spinning, &c. ——. (P) Soc. Franç. de la Viscose.......... 1212, 1212
  Artificial; Manufacture of ——. (P) Crespin.......... 899
  Artificial: Non-Inflammable and Non-Explosive ——. (P) Valette.......... 1212
  Brightening of ——. (Knapstein).......... 487
  Collodion; Apparatus for Spinning —— (P) Denis....... 864
  Dyeing —— Blue-Black after Weighting. (P) Knup..... 899
  Excessive Weighting of —— on Present Position of the Silk Industry. (T.R.) Bolis 956
  or Mixtures; Multicolour Effects on ——. (P) Mennweg. 185
  Mordanting of ——. (Knapstein) 898
  Natural and Artificial; Differentiation of ——. (Herzog) 783
  Printed with a Fatty Reserve; Dyeing of ——. (Haas) .. 1085
  Printing Effects Resembling ——. (P) Société Englische Wollenwaaren-Manufact.......... 17
  Weighted; Action of Hydrofluosilic Acid on ——. (Gnehm) 783
  and Wool as Dyestuff Components. (Pauly and Binz) 1085
  in Woollen Rags: Carbonising ——. (P) Roberts and Crossley.......... 320

Silk-Cocoon; Destruction of Chrysalis of —— by Action of Cold. (Loverdo).......... 713

Silver in Alloys; Modification of Volhard's Method for Determining ——. (Hoitsema) 624
  Concentration of —— in Iron Bottoms. (Bolles) 662
  Electrolytic Precipitation of —— from Cyanide Solutions. (Hamilton).......... 120
  Extraction of —— in Colorado. (Perkins).......... 546
  German-; U.S. Customs Decision on ——. (T.R.) 805
  Metallic; Preparation of ——. (Thallwitz).......... 902
  in Ontario. (T.T.).......... 81
  Precipitates: Refining of ——. (Clevenger).......... 825
  Production of the World in 1903.......... 1124
  Pure Colloidal: Preparation and Properties of ——. (Chassevant).......... 128
  Recovery of —— from Solutions. (P) Christy.......... 494
  Trial Plates: Constant Standard ——. (Matthey)........ 373
  in Zinc; Determination of ——. (Friedrich) 1114
  in Zinc Ores: Crucible Charge for ——. (Hall and Popper) 952

Silver Bromide; Centrifugalised ——. (Baekeland) 559
  Bromide; Studies on Unemulsified ——. (Schaum) 1043
  Chloride Sensitive to Colour. (Baur).......... 204
  Chromate; Use of —— in Determination of Sulphates and Chlorides. (Andrews) 1162
  Cyanide and Silver Chloride; Separation and Determination of ——. (Plummer) 76
  Double Salts of ——. (Bodlander and Eberlein).......... 493
  Halides: Photo-chemical Behaviour of Unemulsified ——. (Schaum and Braun).......... 336
  Nitrite; Action of Iodine on ——. (Neelmeier).......... 505
  Oxide; Sensitiveness of —— to Light. (Luppo-Cramer) .. 1043
  Salts; Colloidal ——. (Paal and Voss).......... 1159
Silver-Plating: Current Efficiency in ——.......... 25
  Current Efficiency in ——. (Pfanhauser).......... 194

Slabs; Manufacture of ——. (P) Thompson..... 1148

Slag, Basic; Determination of the Phosphoric Acid Soluble in Citric Acid in ——. (Sorge)..... 457
  Blast-Furnace; Action of Acetic Acid on ——. (Hart)... 683
  Blast-Furnace, and Portland Cement. (Passow)..... 661
  Blast-Furnace; Transformation of —— into Powder Resembling Cement. (P) Mathesius..... 663
  Cement. *See under* Cement.
  Cleaning of Converter ——. (P) Baggaley and Allen..... 869
  Manufacture of Cement from ——. (P) Bond..... 1091
  Substitute for Emery from ——. (P) Wirtz..... 824
  Wool; Manufacture of ——. (P) Nelson. (McNeill & Co.) 1148

Slags; Composition of —— in Ferromanganese Production. (Wittmann)..... 117
  Treatment of Blast-Furnace and other ——. (P) Passow. 116

Slate; Hardening of ——. (P) Rovere..... 957

Slimes; Apparatus for Washing ——. (P) Forter.....1095, 1095

Slimes, Gold; Trapezoidal Agitator for ——. (De Kalb)..... 324

Smelter-Gases. *See under* Gases.

Smelting and Cupellation. (Piddington)..... 189
  Electrical Process of ——. (P) Cowles..... 666

Smoke Consumers and Flue Gases. (Cohoe and Milne)..... 1132

Smoothing Substances; Electrical Production of ——. (P) Spatz..... 824

Soap. (Class XII.)...... 25, 41, 68, 120, 142, 194, 214, 239, 279, 327, 344, 378, 446, 494, 550, 613, 668, 719, 755, 793, 828, 871, 905, 912, 988, 1035, 1098, 1152, 1226
  containing Alcohol:
    (P) Lebreton-Deshayes..... 195
    (P) Wolff..... 793
  Apparatus for Manufacture of ——. (P) Soc. Talvande Frères and Donault..... 1102
  Apparatus for Rapidly Cooling Liquid ——. (P) Roth... 905
  containing Benzene. Manufacture of ——. (P) de Roussy de Sales..... 872
  from the Castor Bean. (T.R.)..... 462
  Finishing; U.S. Customs Decision on ——..... 770
  Floating —— and Manufacture thereof. (P) Zimmermann and Stohr..... 871
  Hard Resin; Manufacture of ——. (P) Fischer..... 1036
  Hints to Exporters of ——. (T.R.)..... 214
  containing Lemon Juice. (P) Girandet and Neuberger.. 121
  Liquid Sanitary, containing Benzene; Manufacture of ——. (P) Jodoche..... 905
  Lyes; Recovery of Glycerin from ——. (P) Garrigues... 1153
  Manufacture of ——:
    (P) Klopper..... 942
    (P) Knox..... 378
    (Lewkowitsch)..... 1100
    (P) Parziale..... 447
  Manufacture of Neutral ——. (P) Horn..... 1226
  and Manufacture of same. (P) Schmidt..... 447
  Petroleum or Gasoline ——, and Manufacture thereof. (P) Lebreton-Deshayes..... 1226
  Powders; Manufacture of Dry ——. (P) Harvey..... 942
  Preparation of ——. (P) Finlay..... 447
  Preparation of Insoluble ——, so as to Separate the Glycerin. (P) Krebitz..... 495
  Preparation for Preventing Metallic Poisoning. (P) Nusch. From Chem. Werke G. m. b. H. vorm. C. Zerbe..... 1226
  Rosin ——, for Sizing Paper and Millboard. (P) Sauvage 910
  Stock; U.S. Customs Decision on ——..... 771
  Trade of Marseilles in 1903. (T.R.)..... 805
  Tree of Algeria. (T.R.)..... 344
  for Use by Lead Workers. (P) Chem. Werke..... 829

Soaps, Calcium; Dissolving —— by Means of Ammonium Citrate. (Justin-Mueller)..... 1211
  Developing Active Oxygen, and having an Antiseptic, &c., Effect. (P) Giesser and Bauer..... 327
  Grading —— as to their Detergent Power. (Hillyer)..... 157
  Hard Alcoholic; Manufacture of ——. (P) Falck..... 195
  Manufacture of ——. (P) Dreymann..... 988
  Manufacture of "Savons de Marseille." (P) Garbet..... 417
  Medicated; Production of Readily Resorbent ——. (P) Reiss..... 195
  Sodium Hydroxide and Carbonate in; Determination of Small Proportions of ——. (Heermann)..... 134
  Use of "Tangue" in Manufacture of ——. (P) Sizaret... 1035

Soap-suds; Treatment of Refuse ——. (P) Turner..... 378

Soapstone Fibres; Examination of ——. (Guthe)..... 728
  Production of the United States. (T.R.)..... 916

Soda, Ammonia-; Process of Manufacture of —— from the Standpoint of the Phase Rule. (Fedotieff)..... 865
  Caustic; Electrolysis of Solid ——. (Haber and St. Tolloczko)..... 1033
  Caustic; Manufacture of:
    (P) Dolbear..... 62
    (P) Girard..... 984
  Caustic; Manufacture of —— by Electrolysis:
    (P) Heibling..... 822
    (P) Escrive de Romani..... 68
  Caustic; Obtaining Strong Solutions of —— by Electrolysis. (P) Escrive de Romani..... 68
  Caustic. *See also under* Sodium Hydroxide.

Soda-Waste; Use of —— in Making Artificial Stones or Bricks. (P) Ahrendts..... 490

Sodium; Production of —— Electrically:
    (Carrier)..... 828
    (P) Parker..... 1035

Sodium Bisulphate; Utilisation of —— as a Manure. (P) Angibaud..... 720
  Bisulphate; Alteration of —— when Exposed to Air. (Lumière and Seyewetz)..... 799
  Carbonate as a Disinfectant in Brewing. (Will)..... 125
  Carbonate; Rapid Preparation of —— in Small Crystals. (P) Soc. Hofmann and Bros..... 823
  Chloride; Electrolysis of ——. (Kettembeil and Carrier). 827
  Chloride and Potassium Chloride; Differences in Electrolysis of ——. (Winteler)..... 1087
  Ferric Sulphates; Preparation of Two ——. (Skrabal)... 185
  Ferrocyanide; Manufacture of ——. (P) Admins. des Mines de Bouxviller..... 714
  Formaldehyde-Hydrosulphite of ——. (Baumann and others)..... 1211
  Hydrosulphite; Action of —— upon Metallic Salts. (Brunck)..... 1146
  Hydrosulphites; Electrolytic Preparation of ——. (Frank) 792
  Hydroxide; Formation of ——. (Brand)..... 713
  Hydroxide; Manufacture of ——. (P) Latham and Kinsbourg)..... 253
  Hydroxide; Preparation of Pure ——. (Kuster)..... 1027
  Hydroxide. *See also under* Soda, Caustic.
  Nitrate; American Trade in —— in 1903. (T.R.)..... 140
  Nitrate; Effect of Long Use of —— on Constitution of Soil. (Hall)..... 756
  Nitrate; Reasons for Advanced Price of ——. (T.R.)..... 1168
  Nitrate; Statistics of ——. (T.R.)..... 79
  Nitrate Trade of Chili. (T.R.)..... 460
  Nitrite; Action of Carbon Dioxide on ——. (Meunier)... 321
  Nitrite; Action of Carbon Dioxide on Solutions of ——. (Marie and Marquis)..... 252, 369
  Nitrite; Analysis of ——. (Lunge)..... 683
  Nitrite; Manufacture of ——. (Liebig)..... 1087
  Peroxide; Use of —— in Analysis of Organic Bodies. (Pringsheim)..... 504
  Picrate; Action of —— on Sodium Carbonate Solutions. (Reichard)..... 682
  Sulphate; Titanous —— and Production thereof. (P) Spence and Sons. From Spence..... 515
  See also Glauber's Salt.
  Sulphide as an Indicator with Fehling's Solution. (Beulaygue)..... 137
  Sulphide; Manufacture of ——. (P) Gen. Chem. Co. From White..... 442
  Sulphite; Spontaneous Oxidation of —— in Air. (Lumière and Seyewetz)..... 188
  Sulphite; U.S. Customs Decision on ——. (T.R.)..... 343
  Thiosulphate; Electrolytic Oxidation of ——. (Thatcher) 493
  Thiosulphate; Oxidation of ——. (Sedlaczek)..... 605
  Tungstates; Action of Zinc on ——. (Hallopeau)..... 866
  Vanadate Liquors; Purification of ——. (Herrenschmidt) 1214
  Water-Glass; Analysis of ——. (Heermann)..... 1000

Soil Acidity; Comparison of Methods for Determination of ——. (Veitch)..... 762

Soils and Subsoils; Organic Matter in ——. (Cameron and Breazeale)..... 207

Solanin; Sugar Compounds of ——. (Votoček and Vondráček) 75

Solder for Aluminium and its Alloys:
    (P) Forest..... 376
    (P) Pelletier and Semprun..... 986

Soldering; Composition for ——. (P) Kuppers..... 67

Solids; Apparatus for Treating ——. (P) Luhne..... 538
  Apparatus for Treating —— with Liquids or Gases. (P) Naef..... 414

  Synthesis of —— from Trioxymethylene. (Seyewetz and Gibello) 209
  in Vegetable Substances; Determination of ——. (Ford) 953

ugar-Cane; Apparatus for Extracting Sucrose from ——. (P) Christie Engineering Co. From Gibbons and Christie. 496
  Deterioration of Cut —— 124
  Fibre; Hydrolytic Products of ——. (Browne, jun.) 1110
  Manufacture of Products from ——. Drewsen 1040
  Protection of —— from Air, during Treatment. (P) Tauer 1105
  Treatment of ——. (P) Weinrich 72
  Grown on Heavy Lands; Influence of Manures on —— ... 71

ugar-Filling Masses; Crystallisation Vessels for ——. (P) Folsche, Folsche, and Nowak 72

ugar-Juice; Continuous Carbonation of ——. (P) Naudet .. 72
  Treatment of Cane or Beetroot for Production of ——. (P) Tauer 1105

ulphates, Acid; Decomposition of —— in Consequence of Mechanical Deformation. (Spring) 801
  of the Alkali Metals; Manufacture of Dry Acid ——. (P) Trivick 545
  Complex Nature of Dissolved ——. (Colson) 1214
  Metallic, or other Salts Production of ——. (P) Meurer. 1027

Sulphates—*cont.*
  Native Alkali: Treatment of ——. (P) Hildt 603
  Reduction of Alkaline Earth and Alkali ——. (P) Castiglioni and Calastretti 1090
  of Tetravalent Cerium. (Meyer and Aufrecht) 202
  Volumetric Determination of Soluble ——. (Monhaupt) . 1161

Sulphides; Apparatus for Separation and Recovery of —— from Ores. (P) Gillies 1150
  Apparatus for Use in Extracting —— from Ores. (P) Broken Hill Proprietary Co. From Delprat 791
  Determination of —— in Mixture with Haloids and Thiosulphates. (Feld) 132
  Extraction of —— from their Ores:
    (P) Delprat 903
    (P) Marks. From Delprat 610
  Metallic; Treatment of ——. (P) Contardo 24

Sulphites; Electrolytic Oxidation of ——. (Friessner) 548

Sulpho-Compounds. *See under* Dyestuffs.

Sulpho-iodine Compound of Hydrocarbon. (P) Stephenson .. 559

Sulphur; American Trade in —— in 1903. (T.R.) 140
  Apparatus for Burning ——. (P) Paul and Tromblee. From Marsden 186
  Baths; Preparing Compositions for ——. (P) Matzka 836
  Baths; Substance suitable for Preparing ——. (P) Matzka 334
  in Calcium Carbide: Determination of ——. (Lidholm) .. 704
  Calorific Values of Different Forms of ——. (Somermeier) 815
  in Coal and Coke; Rapid Determination of ——. (Pennock and Morton) 131
  in Coal; Forms in which —— Occurs, its Effects, &c. (Somermeier) 601
  in Coal: Photometric Determination of ——. (Parr and McClure) 1010
  Combination; Progress of the Anglo-Sicilian ——. (T.R.) 1169
  in Commercial Zinc Ores; Determination of ——. (Waring) 912
  Deposits of —— in Canada (T.R.) 141
  Determination of —— by Eschka's Method. (Pfeiffer) ... 132
  Dyestuffs. *See under* Dyestuffs.
  Extraction of —— by Continuous Working. (P) Lalbin .. 62
  Extraction of —— from Residues. (P) Vaton and Zuaznavar 371
  Extraction of —— from Spent Oxide. (P) Brégneul 1216
  Forms in which —— occurs in Coal. (Somermeier) 815
  in Golden Antimony Sulphide; Determination of ——. (Esch and Balla) 761
  in Iron; Rapid Determination of Total ——. (Knight) .. 800
  in Irons and Steels; Determination of ——. (Pulsifer) ... 1162
  in Oils, &c.: Determination of ——. (Graefe) 563
  in Organic Substances; Determination of ——. (Barlow) 562
  and Phosphorus Sesquisulphide in Carbon Bisulphide; Action of Heat and Light on Mixed Solutions of ——. (Dervin) 274
  in Pig-Iron; Irregular Distribution of ——. (Porter) 751
  Production of Sicily in 1902. (T.R.) 80
  Retort for Continuous Sublimation and Refining of ——. (P) Consoli 186
  Sicilian; Statistics of ——. (T.R.) 160
  Sublimed ——, and "Flowers of Sulphur." (Domergue) .. 1214
  Trade of Sicily. (T.R.) 843
  for Vulcanising India-Rubber; Properties of ——. (Weber) 70
  Valuation of Commercial ——. (Ceruti) 883
  Bromide: Characteristics of ——. (Korndoerfer) 444
  Dioxide as a Disinfectant in Brewing. (Will) 125
  Trioxide Catalysis. (Kuster) 982
  Trioxide; Catalytic Production of ——. (Lunge and Reinhardt) 821
  Trioxide. *See also under* Sulphur Anhydride.

Sulphuric Acid: American Trade in —— in 1903. (T.R.) 130
  Apparatus for Concentrating ——. (P) Kessler 1089
  Apparatus for Making ——. (P) Hegeler and Heinz 822
  Chambers; Oblong and Tangential. (Meyer) 749
  Chambers; Pulverisation of Water in ——. (P) Delplace 900
  in Commercial Acetic Acid; Determination of Free ——. (Rossi) 1113
  Determination of ——
    (Lange) 760
    (Silberberger) 338
  Esterifications by Means of ——. (Meyer) 85
  Examination of Methods for Estimating Total Acidity of Gases Escaping in Chamber Process of Manufacture of ——. (Watson) 53
  and Hydrochloric Acid; Production and Separation of ——. (P) Consortium für Elek. Chem. Ind. 603
  and Hydrochloric Acid: Simultaneous Production and Separation of ——. (P) Consortium fur Elek. Chem. Ind. 1215
  and HCl; Production of —— Simultaneously. (P) Consortium fur Elek. Chem. Ind. 252
  Lead-Chamber Process; Physical Chemistry of the ——. (Trautz) 440
  Lead Chambers for the Production of; Effect of Blackening on ——. (Bakern) 935
  in Leather; Determination of ——. (Lamb and Lamb) .. 134
  Manufacture of ——:
    (P) Heinz and Hegeler 370
    (P) Niedenfuhr 714
    (P) Salom 442
    (P) Schwab and Green and Sons, Ltd. 985
  Manufacture of —— from Arsenical Pyrites. (Hardwick) 218, 291

Sulphuric Acid—*cont.*
Manufacture of —— by Chamber Process. (P) Lake. From Soc. Anon. Ing. (L. Vogel) 1038
Manufacture of —— in the Glover Tower. (P) Hegeler and Heinz 489
Meyer's Tangential System for Manufacture of ——. (Hartmann and Benker) 488
and Nitric Acid; Properties of Mixtures of ——. (Saposchnikoff) 835
Plant for Denitrating ——. (P) Evers 836
Plant for Manufacture of ——. (P) Zanner 900
Purification of Gases for Manufacture of ——. (P) Johnson. From Badische Anilin und Soda Fabr. 659
Raschig's Theory of the Chamber Process for Making ——. (Divers) 1178
in Tanning Liquors, &c.; Determination of ——. (Parker and Payne) 457
Theory of the Chamber Process:
(Lunge) 1213
(Raschig) 934, 1213
Utilisation of Waste ——. (Donath) 1228
Sulphuric Anhydride; Apparatus for Making ——. (P) Badische Anilin und Soda Fabr. From Knietsch 1147
Contact Apparatus for Production of ——. (P) Verein Chem. Fabr. From Hasenbach 323
Manufacture of —— :
(P) Blackmore 936
(P) Garroway 252
(P) Raynaud and Pierron 252
(P) Thompson. From Wischin 714
Manufacture of —— by Catalysis:
(P) Verein Chem. Fabr. Mannheim. From Lunge and Pollitt 606
(P) Kauffmann 489
and Similar Bodies; Condensation of ——. (P) Perret .. 1215
See also under Sulphur Trioxide.
Sulphurous Acid in Dried Fruit. (T.R.) 309
Influence of Hydriodic Acid on the Oxidation of ——. (Berg) 488
in Molasses; Determination of ——. (Pozzi-Escot) 1017
Recovery of —— from Mixed Solutions. (P) Rheinische Gelatinwerke and Arens 371
See also under Sulphur Dioxide.
Sumac; Mineral Constituents of ——. (Trotman) 1137
Ground; U.S. Customs Decision on ——. (T.R.) 344
Trade of Sicily. (T.R.) 41
Sumatra; Mineral Resources of ——. (T.R.) 509
Superheater for Gas-Producers. (P) Duff 716
Superphosphate: Production of ——. (P) Angibaud 553
Superphosphates; Manufacture of ——. (P) Fournier 448
Supersaturator for Brine Solutions. (P) Gauthier 364
Suprarenal Glands; Compounds of the Active Substance of ——. (P) Imray. From Meister, Lucius und Brüning 910
Suprarenine. *See under* Adrenaline.
Sweden; Export Duties on Wood-Pulp in ——. (T.R.) 280
Export Trade of —— in 1903. (T.R.) 460
Mining Industry of ——. (T.R.) 917
Sweetening Agent; New ——. (P) Tissot 196
Switzerland; Trade of —— in 1902. (T.R.) 211, 630
Syrup, Maple; Composition, Analysis, and Adulteration of ——. (Hortvet) 1241
Syrups of Acid Fruit Juices; Inversion of Sucrose in ——. (Queriault) 1154
Green; Treatment of —— by the Karlik-Czapikowski Method. (Andrlik and Stanek) 495
Purification of ——. (P) Kowalski 907
Starch; Examination of ——. (Rossing) 953

T

Tables; Alcoholmetric ——. (Morley) 1107
Tacamahac Resin; Constitution of Commercial ——. (Tschirch and Saal) 798
Tailings: Treatment of Low-Grade —— by Electrolysis. (P) Fabrig 494
Talc Production of the United States. (T.R.) 916
Tallow; Chinese Vegetable ——. (Lemarié) 120
Composition of Borneo ——. (Klimont) 1152
Vegetable; U.S. Customs Decision on ——. (T.R.) 392
Tallow-Seed Oil; Chinese ——. *See under* Oils, Fatty.
Tan; Furnaces for Burning ——. (P) Myers 653
Tanacetum Boriale Essential Oil of ——. *See under* Oils, Essential.
Tankage: U.S. Customs Decision on ——. (T.R.) 293
Tanks; Settling or Filtering ——. (P) Farrell 620
Septic or Bacterial: Treatment of ——. (P) Bordigoni ... 833
Sewage; Apparatus for Emptying ——. (P) Adams 676
for Sewage Treatment. (P) Dibdin 201
Settling or Precipitating ——. (P) Fidler 833
Tannalbin; Official Method for Preparing and Testing —— ... 129
Tanneries; Water Softening in ——. (Hulsen) 552

Tannic Acid; Determination of ——. (Dreaper) 913
Tannin Analysis: Present Methods of ——, and their Influence on Manufacture of Leather. (Mardick) 1187
Apparatus for Analysis of ——. (Earp) 77
Cold Extraction of ——. (P) Castets 1036
Constituents of Barley, Malt, &c. (Reichard) 498
Content of Liquors from Different Materials; Variation of ——. (Paessler) 991
Determination of ——. (Schorlemmer) 730
Determination of —— without Hide Powder. (Wislicenus) 765
Export Trade of —— in India. (T.R.) 806
Extract, Soluble in the Cold and Colourless. (P) Klenk .. 830
Extracts: Behaviour of Sulphites in ——. (Lepetit and Satta) 1227
Extracts; Clarifying ——. (P) Soc. des Extraits de Chêne en Russe 1227
Gravimetric Determination of ——. (Paessler) 458
Matters; Analysis of ——. (Lepetit) 1227
Solutions; Sugar in ——. (Nové) 1228
and Tannin Materials; Analysis of ——. (Parker and Payne) 648, 1074
Tannins: Preparation and Elementary Composition of ——. (Koerner and Petermann) 1155
Tanning. (Class XIV.) 27, 41, 71, 122, 195, 260, 329, 341, 378, 418, 495, 552, 615, 671, 719, 755, 794, 830, 873, 906, 943, 991, 1036, 1101, 1155, 1227
Analysis; Notes on ——. (Schweitzer) 207
Apparatus for ——. (P) Glasel 71
Bath for Chrome ——. (P) Rosell 615
Drum. (P) Allen, jun. 495
Extracts and Liquors; Identification of Admixtures in ——. (Parker and Payne) 648
Extracts; Manufacture of ——. (Buhler) 991
Industry in Burma. (T.R.) 344
Infusions and Extracts; Action of Saline Substances on ——. (Nihoul) 1155
Liquors; Determination of Sulphuric Acid in ——. (Parker and Payne) 457
Mangrove Bark as a Material for ——. (Paessler) 123
Materials: Apparatus for Cold Extraction of ——. (P) Lautard 615
Materials; Changes which take place in Infusions of ——. (Nihoul and van de Putte) 195
Materials; Composition of Liquors from Various ——. (Paessler) 552, 719
Materials; Extraction of Vegetable ——. (Manstetten) .. 671
Materials and Extracts; Determination of the Weight-giving and Leather-forming Properties of ——. (Parker) 37
Materials; Influence of Chlorides, &c., in Waters on Extraction of ——. (Nihoul and van de Putte) 122
Rapid Vegetable ——. (P) Berthon 943
by Use of Tawed Skins. (P) Berthon 27
Vegetable; Fixing —— on Hides and Skins. (P) Carmichael 944
-Wheel. (P) Allen, jun. 495
Tantalum Metal; Purification of ——. (P) Siemens and Halske 1225
Production of Homogeneous Bodies of ——. (P) Siemens and Halske 494
Tar Products. (Class III.) 15, 40, 55, 112, 182, 213, 247, 278, 317, 365, 435, 484, 540, 692, 654, 710, 745, 780, 816, 861, 897, 931, 978, 1022, 1082, 1141, 1206
Coal-; Distillation of ——. (P) Weyl 861
containing Water; Treatment of ——. (P) Scholvien.... 55
Lignite; Bases in ——. (Hilder) 1082
for Manufacture of Briquettes Duty-free in Russia. (T.R.) 691
Mineral; Separation of the Phenols from ——. (P) Chem. Fabr. Ladenburg 55
Non-Inflammable Protective Coating made from ——. (P) Mahieux 710
-Products; Production of —— in America in 1902. (T.R.) 890
Solidification of —— for Briquettes. (P) Coulson 789
from Water-Gas; Utilisation of the ——. (P) Scholvien . 861
Tars; Distillation of ——. (P) Bokelberg and Sachse 655
Tarring or Asphalting Composition. (P) Préaubert and Thubé 1029
Tartar, Cream of; Manufacture of —— :
(P) Faucheux and Boissière 680
(P) Roux 336
Materials; Export of —— from Italy. (T.R.) 278
Tartaric Acid; Characteristic Reaction of Free ——. (Ganassini) 136
Detection of —— in Citric Acid. (von Spindler) 136
Determination of ——. (Ley) 626
Lead in: Determination of ——. (Bennett) 624
Manufacture of ——. (P) Faucheux and Boissière 680
Materials; Exports of —— from Italy. (T.R.) 1170
Tartrates, Alkaline Earth; Solubility of —— in Water. (Cantoni and Zachovers) 1160
Tasmania; Mineral Production of ——. (T.R.) 916
Tea; Rendering —— Nourishing and Digestible. (P) International Plasmon, Ltd. From Bergheim 33
Technology: The University and ——. (Procter) 1074
Tellurium; Action of Hydrogen Peroxide on ——. (Gutbier and Resenscheck) 1214
Radio-; Examination of Radio-Active ——. (Debierne) .. 884
Use of Phosphorous Acid in Quantitative Determination of ——. (Gutbier) 1040

Trimethylcyclohexenonecarboxylic Ester; Manufacture of —. (P) Cie. Parisienne de Coul. d'Aniline 826

Trinidad; Chemical Trade of —. (T.R.) 689
Cotton from — 980
Natural Pitch, or Manjak, from —. (T.R.) 113
Petroleum from —. (T.R.) 113

Trinotrotoluol; U.S. Customs Decision on —. (T.R.) 460

Trinitroxylenol. *See under* Dyestuffs.

Trioxymethylene; Determination of —. (Kleber) 626
Synthesis of Sugars from —. (Seyewetz and Gibello) ... 209
See also Formaldehyde.

Triphenylmethane. *See under* Dyestuffs.

Triphenylmethyl. *See under* Dyestuffs.

Troostite; Characteristics of —. (Boynton) 608

Tulle: Finishing of —. (P) Soc. Boullier et Pravaz fils 487

Tungsten; Treatment of Ores, &c., containing —. (P) Herrenschmidt 66
in Tungsten Steel and Ferrotungsten; Determination of —. (Kuklin) 134

Tung Oil. *See under* Oils, Fatty.

Tunis; Export Trade of — in 1903. (T.R.) 1005
Lentisk Leaves in —. (T.R.) 1068
Nitrate Deposits in —. (T.R.) 390
Phosphate Rock Discoveries in —. (T.R.) 42

Turf Bricks. *See under* Bricks.
Distillation of —. (P) Hantoer 978

Turkestan; Beet-Sugar Factory in —. (T.R.) 42
Sugar Factory in —. (T.R.) 888

Turkey-Red; Discharge with Prussian Blue on —:
(Bontemps) 486
(Schmid) 486
Oils. *See under* Oils.

Turpentine; Apparatus for Production of —. (P) J. J. Mallonee. From J. C. Mallonee 829
in Denatured Spirit; Determination of —. (Chierego) . 274
Examination of —. (Herzfeld) 274
Industry of India. (T.R.) 1169
Iodine Absorption of Spirits of —. (Worstall) 302
Oil; Action of Salicylic Acid on —. (Tardy) 797
Oil; Determination of Iodine Absorption of —. (Harvey) 413
Oil; Rendering — Uninflammable. (P) Dilette and Talabot 898
Oil. *See under* Oils, Essential.
Production of — from Wood. (P) Hoskins 490
Russian Oil of; Treatment of —. (P) Heber 448
Spirits; Technical Analysis of —. (McCandless) 913
Still:
(P) Bailey 943
(P) Standard Turpentine Co. From Krug 69
Wood: Manufacture of — in Savannah. (T.R.) 844

Tyrosine in Elder-Berries. (Sack and Tollens) 1243
Purification of —. (Brown) 275

U

Ultramarine; Constitution of —. (Rohland) 551
Manufacture of —. (P) Cross 69

United Kingdom; Trade of — with some Foreign Countries. (T.R.) 690

United States; Alcohol Tax in —. (T.R.) 734
Annual Report of Director of National Bureau of Standards. (T.R.) 842
Arsenic Mine in Virginia. (T.R.) 508
Asbestos Production of the —. (T.R.) 946
Asphalt Production in the —. (T.R.) 916
Bauxite Production of the —. (T.R.) 1168
Bessemer Steel Production of — in 1903. (T.R.) 768
Borax Production of —. (T.R.) 1066
Bromine Production of — in 1903. (T.R.) 141
Cascara Sagrada Production in Oregon. (T.R.) 772
Cement Imports of the —. (T.R.) 278
Cement Production of the —. (T.R.) 1215
Chemical Imports of New York. (T.R.) 343
Coal-Tar and Ammonia Production of —. (T.R.) 79
Copper Production of — in 1903. (T.R.) 1124
Customs Decision on Acetin. (T.R.) 773

    (P) Lake. From Syndicat pour l'Exploitation des Inventions du Prof. Oettli 551
    (P) Montgomery 26, 121
    (P) Oettli, Assignor to Syndicat pour l'Exploitation des Inventions du Prof. Oettli 989
  Manufacture of — by French Process. (Liebig) 1102
  Manufacture of — by German Process. (Liebig) 1102
  Non-Poisonous —. (P) Dodé 106
  Raw Materials for Preparation of —. (Liebig) 1102
  Substitute for —. (P) Gendre 121
  Treating the Residue from Manufacture of —. (P) United Lead Co. From Bailey 829

"White Precipitate" formed in the Zinc Boxes of Cyanide Works. (Prister and Fay) 1119
  of the Precipitating Boxes in Cyaniding Works. (Prister) 1051

Whizzers. *See under* Hydro-extractor.

Wicks of Artificial Silk for Candles. (P) Pfersdorff 978

Wiesbaden: Radio-active Gas in the Hot Springs of —. (Henrich) 1164

Wines. (Class XVII.) 30, 42, 77, 87, 124, 143, 197, 261, 279, 330, 345, 379, 449, 497, 551, 616, 672, 721, 756, 795, 831, 874, 907, 944, 984, 1058, 1165, 1136, 1229

Wine, Abrastol in; Detection of —. (Gabutti) 884
  Aldehydes in: Determination of —. (Mathieu) 884
  Australian; Manufacture of —. (Stoward) 876
  Brandies. *See under* Brandies.
  Citric Acid in; Detection of —. (Devarda) 273
  Concentration of —. (P) Monti 675
  (Currant) Disease; Fermentation of Citric Acid as a Cause of —. (Seifert) 31
  Lees and other Residues of; Extracting Alcohol from —. (P) Grimard 1039
  Manufacture of — by Sulphuring and Fermenting the Grapes. (Lacassagne) 908
  Presence of Lecithin in —. (Rosenstiehl) 757
  Production of Italy in 1903. (T.R.) 345
  Production of Mannitol by Disease Organisms of —. (Maze and Perrier) 200
  Production of — in South Australia. (T.R.) 345
  Rendering New — Suitable for Bottling. (P) Faller... 1108
  Sherry Production in Spain. (T.R.) 280
  Sulphurous Acid in —. (Kerp) 832
  Trade of Germany. (T.R.) 393
  Treatment of — and Apparatus therefor. (P) Monti ... 996

Wines; Apparatus for Determining Dry Extract, &c., in —. (P) Darbois 1239
  Apparatus for Manufacture of —. (P) Driancourt 264
  Continuous Direct Rectification of —. (P) Baudry 1107, 1108
  Effervescent; Process and Apparatus for Manufacture of —. (P) Kuhn 675
  Electrical Sterilisation of —. (P) Dorn 878
  Ferment of "Pousse" —. (Laborde) 290
  Filtering —, and Apparatus therefor. (P) Johnson and S. H. Johnson and Co., Ltd. 757
  Manufacture of Sparkling —. (P) Kuhn 675
  Organic Phosphorus Compound in —. (Weirlich and Ortlieb) 333, 451
  Rectification of —. (P) Baudry 1231
  Turbidities of Sparkling —. (Mathieu) 380

Wittemann's Collecting and Carbonating System for Fermentation Gas. (Steinemann) 618

Wollastonite Found in Sumatra; Platinum in —. (Hundeshagen) 791

Wolter Phosphate. *See under* Phosphate.

Wood; Action of — on a Photographic Plate in the Dark. (Russell) 993
  Apparatus for Distillation of — and Production of Charcoal. (P) Wood. From Mackie 542
  Apparatus for Distilling —:
    (P) Douglas 365
    (P) Illinois Investment Co. From Gilmer 437
    (P) Mathieu 931
    (P) Moldenke. From Viola 861
    (P) Palmer 366
    (P) Spurrock 248
  Apparatus for Distilling and Preserving —. (P) Richardson. From Davis 1142
  Avens. *See* Geum Urbanum.
  Colouring —. (Class VI.) 17, 59, 115, 185, 321, 369, 440, 488, 544, 637, 864, 934, 1145, 1213
  Composition for Preservation of —. (P) Zimmer 254
  Destructive Distillation of —. (P) Illinois Investment Co. From Gilmer 780

PAGE

Wood—*cont.*
- Destructive Distillation of Resinous ——. (P) Broughton ... 1023
- Distillation of ——. (P) Hoskins ... 990
- Dyeing of ——. (P) Brenner ... 110
- Fibre: Chemical Investigation of ——. (Grafe) ... 1158
- Fireproofing of ——. (P) Ferrell ... 115, 116, 867
- Impregnation of ——:
  - (P) Hodgkinson ... 1028
  - (P) Wetter. From Heise ... 64
- Insulating Coating for ——. (P) Béthisy and Soc. Myrthil Rose et Cie. ... 825
- Obtainment of Products from ——. (P) Wood Distillates and Fibre Co. From Dobson ... 1111
- Pine-; Distillation of Crude Oils from ——. (P) J. J. Mallonee. From J. C. Mallonee ... 861
- Preservation of ——:
  - (P) Arzt and Sostman. From Gordon ... 254
  - (P) Reichel ... 254
- Preserved —— and Preparation of same. (P) Grasselli Chemical Co. From Lihme ... 443
- Preserving and Fireproofing ——. (P) Beaulieu-Marconnay ... 254
- Production of Pine Oils from ——. (P) Georgia Pine Turpentine Co. From Clark and Harris ... 1082
- Rapid Drying of ——. (P) Soc. Anon. Le Tremaillage ... 439
- Rendering —— More Absorbent of Colours. (P) von Brenner ... 115
- Rendering —— Uninflammable. (P) Wetter ... 188
- Solution for Waterproofing ——. (P) Gare ... 1148
- Treatment of —— by Antiseptic Substances. (P) Conti-Vecchi ... 1091
- Treatment of —— with Soda Silicate. (P) Boissi ... 937
- Utilisation of Residues from Treatment of ——. (P) Strange and others ... 1207
- Vulcanised ——. (P) Powell ... 443

Wood-Charcoal: U.S. Customs Decision on ——. (T.R.) ... 330

Wood-Gas. *See under* Gas.

Wood-Grinding Mills: Utilisation of Waste from ——. (P) Le Pass. From Gaertner ... 453

Wood-Oil, Chinese ——. *See under* Oils, Fatty.

Wood-Tar; Disinfectant from ——. (P) Lingner ... 34

Wool: Apparatus for Degreasing ——. (P) Rousselle ... 659
- Apparatus for Washing of ——. (P) Lesenne ... 748
- Blue and Blue-Black Shades on ——, Fast to Light and Fulling. (P) Badische Anilin und Soda Fabr. ... 899
- Dry Cleaning of Raw ——. (P) Boullaut ... 933
- Felting; Study of ——. (Justin-Mueller) ... 747
- -Grease: U.S. Customs Decision on ——. (T.R.) ... 1052
- Mordanting —— with Aluminium Sulphate and Lactic Acid:
  - (Abt) ... 58
  - (During) ... 58
- New Class of Dyestuffs for ——. (Noelting) ... 748
- -Oils: Detection of Mineral Oil in Distilled ——. (Gill and Mason) ... 763
- Production of Blue and Blue-Black Shades on ——, Fast to Fulling and Light. (P) Badische Anilin und Soda Fabr. ... 1027
- Reducing Powers of Various Assistants in Mordanting —— with Chromium. (Schnabel) ... 114
- and Silk as Dyestuff Components. (Pauly and Binz) ... 1085
- Use of Electrolysis in Removing Fat from ——. (P) Baudot ... 899

Wool-Fat Oleines: Detection of Mineral and Rosin Oils in ——. (Marcusson) ... 1001
- Recovery of ——. (P) Hutchinson. From Swett ... 719

Woollen Fabrics: Fulling of ——:
  - (P) Haddan. From Elosegui ... 898
  - (P) Soc. Reyes et Michel ... 899
- Goods: Increasing Fastness to Wear of Indigo-Dyed ——. (P) Imray. From Peterhauser and Rechburg ... 713
- Rags; Carbonising Cotton or Silk in ——. (P) Roberts and Crossley ... 320

Wort and Beer Pipes; Infection in ——. (Luff) ... 757
- Coolers: Use and Abuse of ——. (Briant) ... 722
- Determination of Colour of ——. (Hanow) ... 380
- Determination of Degree of Infection of ——. (Schönfeld) ... 995
- Preparation of ——. (P) Aspinall ... 618
- Rapid Extraction of ——. (P) De Meulemeester ... 264
- Running off the —— from the Mash. (Pankrath) ... 1157
- Starch Reaction in a Fully Saccharified ——. (Schönfeld) ... 555
- Unhopped; Tannin Constituents of ——. (Reichard) ... 498

Wurtzilite; Treatment and Solution of ——. (P) Whitall and Edson. From Whitall ... 906

X

Xanthine Derivatives; Preparation of ——. (P) Boehringer und Söhne. From Ach ... 503
- Derivative (Theobrominecarboxylic Acid); Preparation of ——. (P) Boehringer und Söhne. From Massie ... 881
- Preparation of ——. (P) Boehringer und Söhne. From Massie ... 881

Y

PAGE

Yarn; Apparatus for Bleaching ——. (P) [illegible] Parker ... 748
- Apparatus for Colouring ——. (P) Carpet Yarn Printing Co. From Fornander ... 271
- Apparatus for Dyeing ——. (P) Storr ... 820
- Apparatus for Mercerising, Bleaching, &c. ——. (P) Crompton and Horrocks ... 659
- Apparatus for Printing —— in Several Colours. (P) Hofmann ... 1212
- Dry Cleaning of ——. (P) Boullaut ... 933
- Dyeing Hanks of ——. (P) Destrée and Wiescher ... 1087

Yarns. (Class V.) 16, 57, 114, 184, 219, 323, 368, 438, 483, 543, 644, 65, 713, 747, 783, 820, 864, 898, 932, 989, 1026, 1085, 1112, 1231
- Apparatus for Dyeing and Printing ——. (P) Masurel-Leclercq ... 864
- Apparatus for Mercerising ——. (P) Palmer ... 820
- Apparatus for Printing ——. (P) Shaw ... 824
- Apparatus for Scouring ——. (P) Carter and Baldwin ... 16
- Apparatus for Treating —— with Fluids. (P) Gebauer ... 932
- on Bobbins; Sizing of ——. (P) Möller-Holtkamp ... 1115
- Dyeing of ——. (P) Donisthorpe, White, and Ellis ... 1086
- Dyeing, Bleaching, &c., of ——, and Apparatus therefor. (P) Reid ... 713
- Impressing Designs on Warp ——. (P) Hofmann ... 59
- Multi-coloured Dyeing of ——. (P) Donisthorpe and White ... 1087
- Printing of ——. (P) Keefer ... 487
- Vat for Dyeing ——. (P) Henser ... 282

Yeast. (P) Davies and Wilding ... 996
- Application of Hansen's System of Pure Cultures of —— for English Stock Beers. (Claussen) ... 721
- Bakers'; Determination of Dough-raising Power of ——. (Pollak) ... 452
- Behaviour of —— in Mineral Nutritive Substances. (Kossowicz) ... 71
- Cane-Sugar —— from Nicaragua. (Pozzi-Escot) ... 497
- Constituents of ——. (Hinsberg and Roos) ... 1106
- Crop; Determination of —— from Nitrogenous Assimilation. (van Hest) ... 73
- Culture; Longevity of ——. (Wichmann) ... 844
- Culture: Vitality of Certain Races of ——. (Henneberg) ... 672
- Cultures; Production of Pure ——. (P) Claussen ... 1230
- Determination of number of Cells per litre in Top Fermentation Pitching ——. (van Hest) ... 50
- Extract in Meat Extract; Detection of ——. (Wintgen) ... 1116
- Extracts: Eliminating the Bitter Flavour from ——:
  - (P) Elbs ... 1259
  - (P) Jensen ... 996
- Extracts: Preparation of Alimentary ——. (P) Elb ... 127
- Ferments: Properties of ——. (Shiga) ... 1106
- Infection; Wild ——. (Chapman) ... 875
- Invertase of ——. (Hafner) ... 367
- Manufacture of ——. (P) Maschinenbau Aktienges. Golzern-Grimma ... 995
- Manufacture of Products from Waste ——. (P) Schidrowitz and Kaye ... 290
- Mash, Distillery: Heating —— to 75–80° C. (Schürmann) ... 1239
- Nutrition of —— with Sugar. (Richter) ... 124
- Oxydase; Examination of ——. (Issajew and Kalliski) ... 907
- Period of Vitality of Dried ——. (Will) ... 197
- Pitching: Determination of Number of Wild Yeast Cells in ——. (Bergsten) ... 73
- Preparation of ——:
  - (P) Jacquemin ... 254
  - (P) The Granular Yeast Co. ... 7475
- Pressed; Detection of Bottom-fermentation Beer Yeast in ——. (Lindner) ... 497
- Reductase of; Conversion of Nitrobenzene into Aniline by Philothion and ——. (Pozzi-Escot) ... 628
- Research on ——. (van Hest) ... 30
- Respiration, and Respiratory Enzymes of ——. (Gruss) ... 1106
- Testing the Homogeneity of ——. (Lindner) ... 995
- Top Fermentation ——. (van Hest) ... 30, 831
- Top Fermentation: Experiments with Cell Juice from ——. (Harden and Young) ... 459
- Top Fermentation: Relations between Quantity of Pitching Yeast and Attenuation and Yeast Crop with ——. (van Hest) ... 935
- Toxic Action of Chromium Compounds on ——. (Pozzi-Escot) ... 721
- Treating —— for Use as Manure. (P) Baker ... 333
- Use of —— instead of Krausen. (Henneberg) ... 795
- Utilisation of —— for Making Manures. (P) Wardle ... 379

Yeasts, Bottom Fermentation; Investigation of Four ——. (Will) ... 150
- Culture: Abnormal Cell Forms of ——. (Henneberg) ... 394
- Culture; Behaviour of —— at Various Temperatures. (Henneberg) ... 875
- Culture; Researches on ——. (Henneberg) ... 1229
- Fermentation and Respiration of Various ——. (Leschtsch) ... 1106
- Pressed ——, with Squarrose Budding Chains. (Lindner) ... 173
- Pure Wine; Use of ——. (Stoward) ... 876

Yohimbine: Composition of ——, &c. (Spiegel) ... 621

Yohimboaic Acid; Relation of Yohimbine to ——. (Spiegel) ... 621

Yorkshire Section: Address to ——. (Procter) ... 1074

Yttrium Group; Rare Earths of the ——. (Urbain) ... 1260

Z

Zinc: Action of certain Solutions upon ——. (Smith) 475
  Electrolytic Production of ——. (Burleigh)............. 941
  Extraction of —— Electrically:
    (P) Edelmann and Wallin........................... 1035
    (P) Laszczynski................................. .. 547
    (P) Rodriguez..................................... 988
  Extraction of —— Free from Lead. (P) Brand 827, 827
  Extraction and Purification of ——. (P) Cunnington 1220
  Extraction of —— from its Sulphide. (P) Imbert........ 376
  Furnace for Production of ——. (P) Schmieder......... 492
  Industry of Poland. (T.R.).............................. 917
  Manufacture of ——. (P) Kunze and Danziger.......... 118
  Metallurgy of ——. (Brandhorst)......................... 491
  Obtainment of ——. (P) Hopkins........................ 575
  Production of —— and Apparatus therefor. (P) Babé and Tricart... 415
  Production of —— by Electrolysis. (P) Kaiser.......... 327
  Production of —— from Sulphate Solutions by Electrolysis. (P) Abel. From Siemens and Halske......... 1098
  Recovery of —— from Sulphide Ores. (P) Danckwardt .. 66
  Sheets, Nickel Plated: U.S. Customs Decision on. (T.R.) 392
  Silver-content of Varieties of Commercial ——. (Friedrich) 1114
  Silver in; Determination of ——. (Friedrich)........... 1114
  Soft: Manufacture of ——. (P) Guhrs.................... 191
  Treatment of Metallic ——. (P) Guhrs.................. 492
  Waste; Utilisation of ——. (P) Cehak and de Szczytnicki 605

Zinc Blende: Luminescent ——. (Eakle and Sharwood)..... 765
  Blende: Roasting of ——. (Kellermann)................. 255
  Blende; Separating Iron Pyrites from ——. (P) Danziger 375
  Blende; Separating —— from Ores. (P) Jamieson and Odling... 190
  Blende; Smelting of ——. (Ritter)........................ 716

Zinc—*cont.*
  Chloride and Alkali Chlorates; Simultaneous Production of ——. (Friderich and others)......................... 865
  Chloride; Preparation of Pure Fused —— and its Electrolysis. (Gruenauer).................................. 718
  Chloride: Production of ——. (P) Gilman................ 61
  Chloride; Specific Gravity of ——. (Baxter and Lamb) .. 388
  Chromate: Examination of ——. (Groger)............... 822
  Hydrosulphite Difficultly Soluble in Water; Solid ——. (P) Bollé. From Chem. Fabr. Grunau............... 603
  Ore Exports from Carthagena............................. 770
  Oxide: American Trade in —— in 1903. (T.R.).......... 110
  Oxide; Electrolytic Manufacture of ——. (P) Lake. From Syndicate des Inventions Oettli....................... 611
  Oxide; Manufacture of —— Electrically. (P) Barbier... 1034
  Oxide: Reduction Temperature of ——. (McA. Johnson) 664
  Oxide Reserves under Prud'homme's Black. (Lauber).. 1144
  Peroxide; Production of —— by Electrolysis. (P) Hinz. 549
  Salts: Study of Complex ——. (Kunschert)............. 1032
  Sulphide: Extraction of —— from Ores. (P) Marks. From Delprat... 610
  Sulphide; Phosphorescent ——. (Grune)................ 1002
  Sulphide: Production of ——. (Candau)................ 606
  Sulphide: Production of Hydrated ——. (P) Bermont .. 252
  Sulphides: Extraction of ——. (P) Delprat.............. 903

Zinc-Dust; Gasometric Assay of ——. (Wohl)............... 273

Zinc-White: Covering Power of —— compared with White Lead. (Lenoble)....................................... 829
  Manufacture of ——. (P) Oettli, Assignor to Syndicat pour l'Exploitation des Inventions du Prof. Oettli.... 989
  Substitute for ——. (P) Gendre.......................... 121

Zircon Production of the United States. (T.R.)............ 917

Zirconium Sulphate; Basic ——. (Hauser).................. 677

Zymase: Action of Alcoholic Fermentation on ——. (Mazé). 721
  in Dead Yeast Cells: Activity of ——. (Gromow and Grigoriew)... 995

LIST OF NEW BOOKS.

PAGE
A Compendium of Chemistry, including General, Inorganic, and Organic Chemistry. (Arnold. Translated by J. A. Mandel) 689
A Method for the Identification of Pure Organic Compounds by a Systematic Analytical Procedure based on Physical Properties and Chemical Reactions. (Mulliken.) Vol. I. 505
Analytical Chemistry. (Treadwell.) Translated from the Second German Edition by W. T. Hall. Vol. II. "Quantitative Analysis" 767
An Attempt towards a Chemical Conception of the Ether. (Mendeléeff. Translated by Kamensky) 276
Anilinschwarz und seine Anwendung in Färberei und Zeugdruck. (Noelting und Lehne) 389
Anleitung zur Quantitativen Bestimmung der Organischen Atomgruppen. (Meyer) 342
Anleitung zur Verarbeitung der Naphtha und ihrer Produkte. (Kwjatkowsky) 951
Annual Statement of the Trade of the United Kingdom with Foreign Countries and British Possessions, 1903 565
Annual Statement the Trade of the United Kingdom with Foreign Countries and British Possessions 689
Application of some General Reactions to Investigations in Organic Chemistry. (Lassar-Cohn.) Translated by J. Bishop Tingle 1165
Artificial Graphite. (Fitz-Gerald) 1048
A Scheme for the Detection of the more Common Classes of Carbon Compounds. (Weston) 1048
A Systematic Handbook of Volumetric Analysis. (Sutton.) Ninth Edition. Revised and Enlarged 767
A Systematic Survey of the Organic Colouring Matters. Founded on the German of Schultz and Julius. (Green) 138
A Text-Book of Quantitative Chemical Analysis by Gravimetric, Electrolytic, Volumetric, and Gasometric Methods. (Olsen) 1118
A Text-Book on Ceramic Calculations, with Examples. (Jackson) 506
Calculations used in Cane-Sugar Factories. (Morse) 767
Carborundum. (Fitz-Gerald) 885
Chapters on Paper-making: a Series of Lectures Delivered in 1902. (Beadle) 565
Chemical Technology and Analysis of Oils, Fats, and Waxes. (Lewkowitsch.) Third Edition 802
Chemiker-Kalender, 1905. (Biedermann) 1244
Chemisch-Technische Untersuchungsmethoden. (Lunge) 893, 1165
Das Photographieren mit Films. (Holm) 842
Die Chemie und Technologie der Naturlichen und Kunstlichen Asphalte. (Kohler) 389
Die Darstellung des Zinks auf Elektrolytischem Wege. (Guenther) 1166
Die Elektrochemische Reduktion der Nitro-derivative Organischer Verbindungen in Experimentaller und Theoretischer Beziehung. (Moeller) 767
Die Elektrochemische Industrie Deutschlands. (Ferchland) 767
Die Elektrometallurgie der Alkalimetalle. (Becker) 276
Die Elektrolytische Raffination des Kupfers. (Ulke) 506
Die Fabrikation der Soda nach dem Ammoniakverfahren. (Schreib) 1166
Die Farben-Photographie: eine Gemeinverstandliche Darstellung der verschiedenen Verfahren, nebst Anleitung zu ihrer Ausführung. (Koenig) 731
Die Galvanoplastik. (Pfanhauser) 688
Die Herstellung von Diapositiven zu Projektionszwecken, Fenstertransparenten und Stereoskopen. (Hanneke) 731
Die Trockenplatte: ihre Eigenschaften und ihre Behandlung in der Photographischen Praxis. (Lupno-Cramer) 276
Directions for Laboratory Work in Physiological Chemistry. (Jackson.) Second Edition 342
Electro-Chemistry. Part I. General Theory. (Lehfeldt.) Including a Chapter on the Relation of Chemical Constitution to Conductivity. (Moore) 842
Elements of Inorganic Chemistry. (Jones) 211
Elements of Water Bacteriology with Special Reference to Sanitary Water Analysis. (Prescott and Winslow) 629
Food Inspection and Analysis for the Use of Public Analysts, Health Officers, Sanitary Chemists, and Food Economists. (Leach) 955
Gas Undertakings (Local Authorities) 139
Gas Undertakings. Return relating to all Authorised Gas Undertakings in the United Kingdom, other than Local 139
Gas Works, their Construction and Arrangement, and the Manufacture and Distribution of Coal Gas. (S. Hughes. Ninth Edition, Revised and Improved, by H. O'Connor) 629
PAGE
Gold Assaying: A Practical Handbook on the Subject with Appendix of Tables and Statistics. (Philips) 565
Grundriss der Physikalischen Chemie. (Traube) 688
Handbook of Chemical Engineering. (Davis) 1118
Iron and Steel, 1903. Statistical Tables 803
Jahrbuch der Elektrochemie. (Nernst and Borchers) 689
Karl Heumann's Anleitung zum Experimentiren bei Vorlesungen über Anorganische Chemie, zum Gebrauch an Universitäten, Technischen Hochschulen und Höheren Lehranstalten. (Kuhling) 210
Laboratory Manual of Organic Chemistry for Beginners. (Holleman.) Translated from the Dutch by A. Jameson Walker 955
Laboratory Studies for Brewing Students. (Brown) 1004
Lehrbuch der Mikrophotographie. (Kaiserling) 276
Les Nouveautés Chimiques pour 1904. (Poulenc) 688
L'Ozone et ses Applications Industrielles. (de la Coux) 1004
Mineral Resources of the United States. (Day) 803
Mineral Tables for the Determination of Minerals by their Physical Properties. (Eakle) 342
Mines and Quarries. General Report and Statistics for 1902. Part IV. Colonial and Foreign Statistics 689
Monographs on Applied Electrochemistry. Elektrolytisches Verfahren zur Herstellung Parabolischer Spiegel. (Cowper-Coles) 1048
Notes on Assaying and Metallurgical Laboratory Experiments. (Lodge) 1241
Oils and Fats: their Uses and Applications. (Lewkowitsch.) Cantor Lectures 1165
Radium and other Radio-Active Elements. (Levy and Willis) 731
Report on Air Tests in Humid Cotton-Weaving Sheds. (Scudder) 767
Report to the Board of Trade by the Advisory Committee on Commercial Intelligence, with Reference to their Proceedings 565
Rubber, Gutta-Percha, and Balata. (Clouth) 78
St. Louis Exhibition, 1904. German Educational Exhibition. Chemistry. (Büxenstein) 1048
Smoke Prevention and Fuel Economy. (Based on the German Work of E. Schmatolla.) (Booth and Kershaw) 1048
Special Technical Schools for the Ceramic Industries in Germany 893
Subject List of Works on Electricity, Magnetism, and Electro-Technics in the Library of the Patent Office 731
Tables for Qualitative Chemical Analysis, arranged for the Use of Students. (Liversidge) 1005
Technisch-Chemisches Jahrbuch, 1902. (Biedermann) 1118
Traité d'Analyse des Substances Minérales. (Carnot) 275
The Analysts' Laboratory Companion. (Johnson.) Third Edition 1004
The Century in Phosphates and Fertilisers. (Chazal) 1244
The Chemical Synthesis of Vital Products and the Inter-Relations between Organic Compounds. (Meldola.) Vol. I. 1118
The Cultivation and Preparation of Para Rubber. (Johnson) 1118
The Electric Furnace. (Moissan.) Translated by A. T. de Mouilpied 1004
The Electrolysis of Water: Processes and Applications. (Engelhardt.) Translation by J. W. Richards 276
The Elements of Chemistry. (Pattison Muir) 506
The Experimental Bacterial Treatment of London Sewage. (Clowes and Houston) 506
The Extra Pharmacopœia of Martindale and Westcott. Revised Edition. (Martindale and Westcott) 688
The Grant and Validity of British Patents for Inventions. (Roberts) 39
The Industrial and Artistic Technology of Paint and Varnish. (Sabin) 954
The Occurrence of Aluminium in Vegetable Products, Animal Products, and Natural Waters. (Langworthy and Austen) 767
The Phase Rule and its Applications. (Findlay.) Together with an Introduction to the Study of Physical Chemistry by Sir W. Ramsay 211
The Textile Fibres, their Physical, Microscopical, and Chemical Properties. (Matthews) 1118
The Textile Technical Schools and Development of the Textile Industries: Germany 342
The Vegetable Alkaloids, with Particular Reference to their Chemical Constitution. (Pictet. Translated and Revised by H. C. Biddle) 506
Ueber Herkommen und Chemie des Kautschuks. (Marckwald und Frank) 1048
West Indian Bulletin. (Vol. IV.) 39

ERRATA, 1904.

Vol. XXIII.	Page.	Column.	Line from Top.	Line from Bottom.	Corrigenda.
No. 1—Jan. 15	25	1	..	25	*In title, add name,* "Langbein" *before* "Zeits. f."
" "	7	1	..	31	*For* "qrs." *read* "grs." *Delete lines 26 to 24 from bottom, and substitute* "This escape was a small one, and although water, or water *plus* $H O_2$, gave practically the same result, they might not have done so if the escape had been high."
" "	7	2	41	..	*For* "the chambers were 100 ft. in length and 30 ft. high" *read* "the chambers were 105 ft. long, 25 ft. wide, and 20 ft. high."
No. 3—Feb. 15	107	1	45	..	*For* "neutral" *read* "natural."
No. 5—Mar. 15	261	2	..	2	*For* "0·1 per cent." *read* "5 per cent."
" "	220	2	..	8	*For* "included in the precipitate a sulphide" *read* "occluded in the precipitate some nitric peroxide."
" "	220	2	..	5	*Before* "If vitriol, &c." *insert* "In such a case."
No. 7—Apr. 15	357	..	..	..	*Table of Formulæ, under No. 11, for* "P. 7" *read* "F. 7" or "No. 7" above.
" "	358	..	Last 8 lines of paper		*For* "pages 21, 22" *read* "page 355, col. 2."
No. 8—Apr. 30	414	2	..	Bottom line; 15 lines up.	*For* "amylotic" *read* "amylolytic."
" "	421	1	25	..	
" "	422	2	7	..	
" "	416	1	..	Bottom line	The * (and corresponding footnote) should be after "phosphates." page 415, col. 2, line 5 from bottom.
" "	419	2	37	..	*For* "cæteribus" *read* "cæteris."
No. 9—May 16	494	2	..	5	*Transfer* "about" to follow the – sign; (a_D = about −4°).
" "	494	2	..	4	"v_D" *to read* "n_D."
" "	572	2	15	..	*In title,* "scandens" *to read* "scandens."
No. 12—June 30	659	1	..	30	*After* "Eng. Pat." *insert* "15,108."
" "	643—645	..	..	..	(See this J., 1904, 778, col. 2.)
" "	645	1	..	..	(See this J., 1904, 699, col. 1.)
No. 19—Oct. 15	934	1	..	4	*For* "hydroxylamine" *read* "dihydroxylamine."
" "	935	2	12	..	*In Table, col. 4 to right, bottom number,* "1067," *to read* "106·7.
" "	942	2	32	..	*After* "into" *insert* "one of."
" "	942	2	37	..	*After* "chloride" *insert,* "previously ground like the hard soap, in others of the series of disintegrators already referred to."
" "	942	2	39	..	*After* "carbonate" *delete* "(crystals)," *and for* "69 parts" *read* "26 parts."
" "	942	2	40	..	*Before* "anhydrous" *insert* "combined water, 43 parts;"
No. 20—Oct. 31	975	2	31	..	*For* "One could" *read* "One could not."
" "	975	2	35	..	*For* "or higher" *read* "of higher."
No. 24—Dec. 31	1179	2	..	18	*For* "up of" *read* "up to."
" "	1179	2	..	16	*For* "to" *read* "of."
" "	1179	2	..	3	*Delete* "as."
" "	1183	2	10	..	*Delete* "actually."
" "	1184	1	..	11	Put *semicolon after* "Nitric acid" *and delete comma after* "Nitrous acid."
" "	1198	1	37	..	*For* "their" *read* "other."
" "	1216	2	..	28	*For* "Deselles" *in title, read* "Deselle."

JOURNAL OF THE
Society of Chemical Industry.

A RECORD
FOR ALL INTERESTED IN CHEMICAL AND ALLIED MANUFACTURES.

ISSUED TWICE A MONTH.

No. 1.—Vol. XXIII. JANUARY 15, 1904. No. 1.—Vol. XXIII.

Subscription of Members 25/- per annum;
Entrance Fee 21/-;
Election by the Council.

Price to Non-Members 36/- per annum;
To Members 25/- per Set of extra or back numbers.
Single copies (Members and Subscribers only),
1882—1901, 2/6 each; 1902 *et seq.*, 1/9 each.

The Society of Chemical Industry.

Past Presidents:

Sir Henry E. Roscoe, B.A., D.C.L., LL.D., Ph.D., F.R.S.	1881—1882.

Notices.

ANNUAL GENERAL MEETING, NEW YORK, 1904.

Members who contemplate attending the next General Meeting, in New York, are requested to communicate with the General Secretary as soon as possible, in order that suitable travelling arrangements may be made. A draft of the Programme of Arrangements will appear in the next issue of the Journal.

COMMUNICATIONS.

Authors of communications read before the Society, or any of its Local Sections, are requested to take notice that under Rule 43 of the Bye-laws the Society has the right of priority of publication for three months of all such papers. Infringement of this Bye-law renders papers liable to be rejected by the Publication Committee, or ordered to be abstracted for the Journal, in which case no reprints can be furnished to the author.

Changes of Address.

When notifying new addresses, members are requested to write them distinctly, and state whether they are temporary or permanent. Multiplication of addresses is also to be avoided as tending to create confusion. When sending subscriptions, the use of the form attached to the application helps in the verification of addresses, on which the safe delivery of the Journal depends.

DR. J. T. DUNN IN THE CHAIR.

THE COMPOSITION OF MILK IN THE NORTH OF ENGLAND.—PART II.

BY S. H. COLLINS, F.I.C.

The first part of this paper, which was read before this ociety a year ago, and published in this Journal, 1902, 512, was merely introductory, and served to draw attention o the matter. As a result, considerable interest was aroused n the subject, and several farmers in the North of England ame forward and offered their herds to the College for xperimental purposes. The principal objects of these exeriments was to test milk under as practical conditions as ossible, and over as long a period as possible. Two herds vere selected, and examined once a fortnight. I have to hank the owners of the herds, Mr. McLaren and Mr. Iarshall, for the ready help they have given me on all ccasions. I know it has meant no little trouble on their art and on the part of their servants.

These experiments will serve to illustrate facts already hown by others, but perhaps not sufficiently realised, to how local variations from accepted standards; and I trust o show some new aspects of the question, and to suggest leas which I believe will be useful in future investigations. Droop-Richmond gives, as the average of 200,000 analyses ver many years, the composition of milk as 3·9 per cent. f fat and 9·0 per cent. of solids not fat. These figures are ommonly given in support of the "legal" standard of per cent. and 8.5 per cent. respectively. These figures ave, however, been derived from the milk of cows in the outh of England. There are plenty of analyses which rove that milk below the standard may be genuine; these xperiments will serve to confirm this fact, which is perhaps ot as well known as it should be. To show that milk elow the standard may be genuine is, however, only a first tep, and is of little use unless it is followed up by the ttempt to determine the degree of probability that milk elow the standard may be genuine. It is to this point hat I invite your attention this evening. The experiments re still in progress, and will probably continue for some time.

Sampling.—Samples of the milk of about a dozen cows vere taken, in one case twice a day, and in the other case hrice a day. In addition to the samples of the individual ows, samples of the mixed milk of the entire herd were aken. Samples were taken once a fortnight. As careful upervision by experienced persons is essential at this tage, a representative of the College was always present at he sampling, for which assistance I have to thank Dr. Potts, Iessrs. McLaren, Short, Swann, and Willis. The method f sampling adopted was always to pour the milk from one ail to another, and then to pour it into the sample bottle. n the case of the mixed milk of the herd, it was not always ossible to wait for all the milk to be mixed up together, s such a procedure would have interfered too much with he business; but all the milk was passed through a strainer nd cooler, and, as it ran out, small samples of the milk were aken and mixed up; from this mixture a sample was taken o represent the mixed milk of the whole herd.

Preserving.—As there was other work to be attended to besides this milk-testing, it was necessary to preserve the milk in such a way that the analysis could be made as time permitted. For this purpose a preservative had to be found that would not interfere with the determinations of specific gravity, fat, or total solids.

The following preservatives were made:—

(1) *For use in Cold Weather.*—A mixture of chloroform and ether of the specific gravity of 1·032. Of this, 1 c.c. was used to preserve 100 c.c. of milk.

(2) *For use in Hot Weather.*—A mixture of alcohol, chloroform, and formalin of the specific gravity of 1·032, and containing about 1 per cent. of pure formaldehyde. Of this, 1 c.c. was used for 100 c.c. of milk.

The reason of this double arrangement was to avoid the use of formalin as much as possible, this substance being supposed to hydrolyse the milk sugar and thereby increase the amount of total solids in the milk. In the small proportion used I could not find any evidence of such an action. The milk generally kept about two or three weeks. The specific gravity was not altered, and the correction for dilution was so very small that it made little difference to the amount of fat or total solids.

Analysis.—The specific gravity was taken sometimes with the lactometer, but mostly with the "Westphal" balance, both having been checked against the specific gravity bottle. All specific gravities are given corrected to $15\frac{1}{2}$° C., or 60° F. The fat was determined by the "Gerber" centrifugal method, constantly checked by the "Adams coil" and "Werner-Schmidt" methods. The solids not fat were found by calculation, using the formula $G/4 + F/5 + 0{\cdot}14$ = solids not fat. The total solids were frequently checked by direct determination, the difference between the calculated and found amounts of total solids being as a rule less than 0·1 per cent., although a few cases occurred with differences of 0·2 per cent.

My thanks are due to Messrs. Short and Swann for the greater part of the analytical routine work.

The Herds.—Herd No. 1 were all shorthorns of various ages and in various stages of lactation. They were milked three times a day—at 5 a.m., 1 p.m., and 6 p.m. Twelve cows were selected to represent the herd, samples being taken of the milk of the individual cows and of the mixed milk of the herd once a fortnight. The experiment started in January and terminated in March, there being six days in all when the cows were tested. Herd No. 2 were also all shorthorns of various ages and in various stages of lactation. They were only milked twice a day—at 5.30 a.m. and 4.30 p.m. For convenience the milk of one evening and the next morning was taken to represent the day's milk. 22 cows were selected, the first 12 or 13 on the list being tested once a fortnight, and the mixed sample of milk of the whole herd obtained at the same time. As the original cows went dry their place was taken by those further down the list. When cows came in to milk again they were tested again as soon as there was a vacant place for them. Records of temperature, weather, feeding, and many other matters of practical importance have also been kept.

For the sake of ready comprehension, all the analyses have been put into diagrammatic form as curves. To avoid the crossing of lines and yet keep the fat, solids not fat, and yield on one diagram, the scales of all three are different, but are given on the margins of each diagram. The most notable points on studying these curves are: (1) some cows are very regular, some are very erratic (Curves 3 and 8); (2) the fluctuations in the composition of the mixed milk (A) are as nothing to those of the erratic cows (8), but are nearly of the same order of magnitude as those of the regular cows (3); (3) the fluctuations in the amount of fat in the milk of the regular cows and in the mixed milk exhibit no regular rise and fall, giving no clue to the cause of the fluctuation; (4) the solids not fat of the milk of the regular cows and of the mixed milk shows a slight falling off during the period, which may be due to some fixed cause (temperature) (3 and A); (5) the greater part of these fluctuations does not depend upon any regular cause, but is due to the irregular behaviour of the cows; that is, it is "chance." To show the bearing of these results on the chance or probability of milk under the standard being genuine, the following statistical analysis is given :—

Statistical Analysis.

Herd No. 1.

Fat under 3 per cent.	on	15	out of	72	occasions in the	morning.
	„	0	„	71	„	noon.
	„	5	„	72	„	evening.
	„	20	„	215	„	day.
Solids not fat under 3½ per cent.	„	1	„	72	„	morning.
	„	0	„	71	„	noon.
	„	0	„	71	„	evening.
	„	1	„	214	„	day.

or, 21 tests out of 419 have been below standard, of which seven are due to cow No. 27, and five to cow No. 64.

The mixed milk of this head was never under the standard during the period of testing.

Herd No. 2.

Individual Cows.

Fat under 3 per cent.	on	5	out of	124	occasions in the	morning.
	„	11	„	123	„	evening.
Solids not fat under 8½ per cent.	„	16	„	122	„	morning.
	„	21	„	124	„	evening.

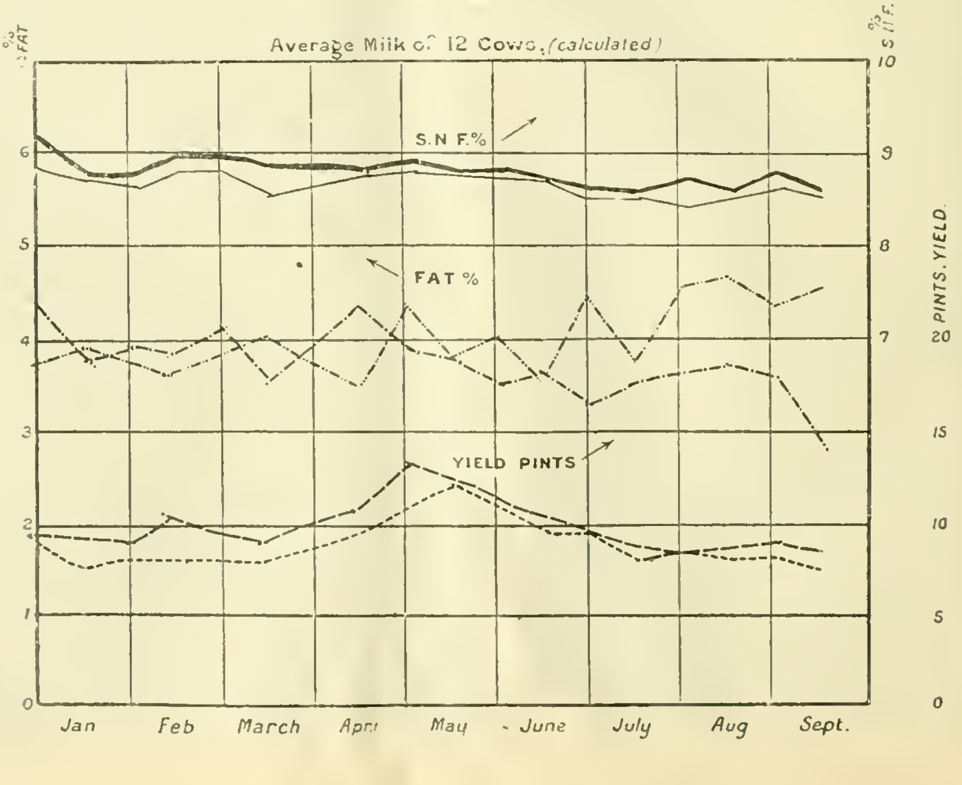
or, 53 out of 493 tests were below the standard in all, of which 16 are due to cow No. 12, 10 to cow No. 17, and six to cow No. 11. The mixed milk of this herd was never under the standard from January to June (inclusive). It is, however, only right to state that the mixed milk has been below the standard in some later tests that I hope to communicate at a later date. It will be noticed that while in herd No. 1 it is the fat that it is generally deficient, in herd No. 2 it is the solids not fat that are generally deficient.

North v. *South.*—If we add up all the results published in both parts of this communication we find that in 96 tests out of 984 the milk was below standard; that is, in nearly 10 per cent.

Ingle, in the Report of the Yorkshire College and in other publications, gives figures which show that he obtained about $3\frac{1}{2}$ per cent. of his tests below standard; and Droop Richmond, in a recent communication to the Society of Public Analysts, gives a case of what he evidently considers a very remarkably bad cow, which was below standard on $5\frac{1}{3}$ per cent. of the tests made. These figures suggest that there is some truth in the opinion that milk in the North of England is not as rich as that in the South, and cannot be judged by the same standard.

The probability of mixed Milk being below the Standard.—Once we have established the probabilities of cows giving milk of certain strengths, it becomes simply a case of an investigation of mathematical "probability" to find the probability of a herd of any number of cows giving milk below the standard. For if p be the probability that any sample of milk is below the standard, then the probability is that in a herd of two cows both will be below standard on p^2 occasions, and one cow only will be below standard on $2p\ (1-p)$ occasions, whilst on $(1-p)^2$ occasions both will be above the standard. It then remains to solve the statistical problem of the probability of a mixture of milk below and milk above the standard being below the standard. If we call this probability n, then the probability that the mixed milk of two cows is below standard is $p^2 + 2np\ (1-p)$, which is $2np + (1-2n)p^2$. As, however, p is a fraction, p^2 will always be small, and is likely to be less than the error of determining p and n, and may for the present be eliminated. From study of the times when milk occurs at each tenth per cent. I think that n may be provisionally taken at about $\frac{1}{4}$. As each cow has to satisfy two tests, and they are rarely both below the standard, the probability is more than 10 per cent. and less than 20 per cent., and nearer the latter than the former—say 16 per cent. Then the probability of the mixed milk of two cows being below standard is $2np = 8$ per cent., that of four cows 4 per cent., and that of eight cows 2 per cent. These calculations are given rather as a demonstration of the value of such methods of investigation than as any attempt to finally determine the probability of cows in the North of England giving milk below the standard. No account has been taken of the fact that the yields of the cows need not be the same, nor that there will be some causes that will tend to make all the cows of a herd give lower-quality milk than

A.

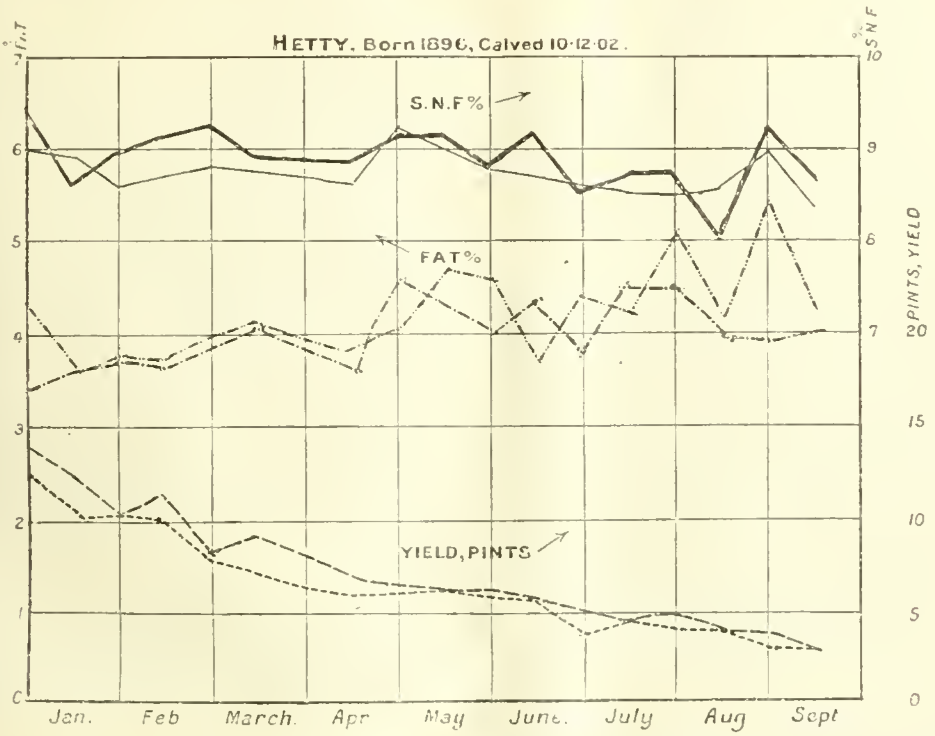


hey would do under average circumstances. In the ormer case, if low yields are accompanied by low per-entages, then the probability of milk being below standard vill be less, and *vice versa*. In the latter case the probability vill be increased.

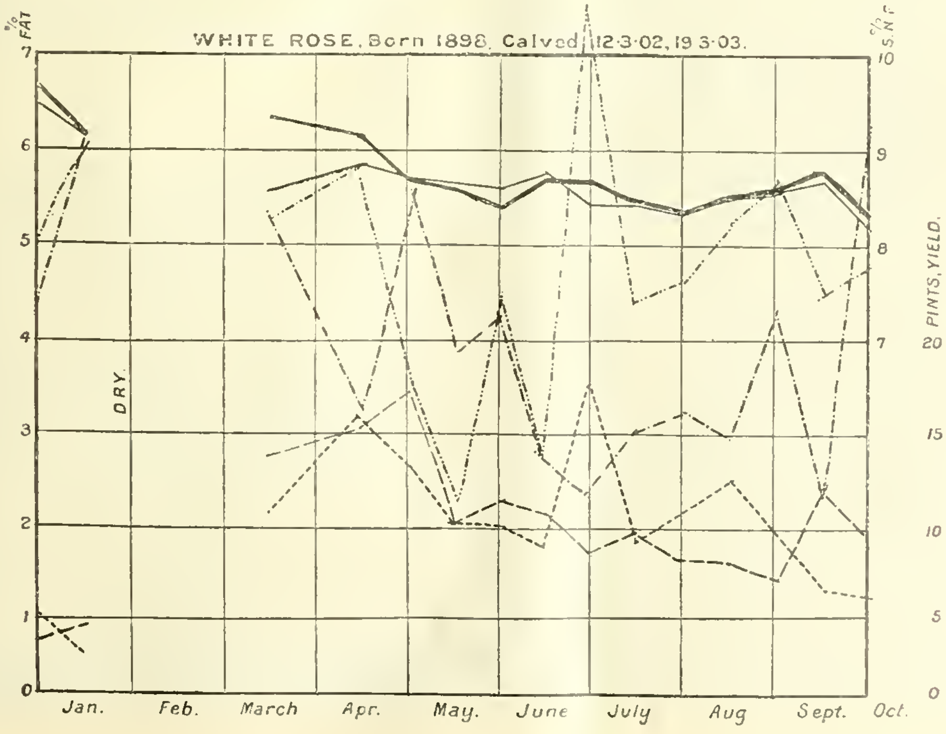
Explanatory Notes to Curves.

At the paper as read, 35 slides of curves were exhibited; the following have been modified so as to be representative of the different types.

3.



8.



3. Represents a regular cow.
8. Represents an irregular cow.
A. Represents the mixed milk calculated from the analyses of the milk of individual cows.

━━━━ solids not fat per cent., morning.
──── „ „ „ evening.
— · — fat per cent., morning.
– · · – „ evening.
— — — yield in pints, morning.
- - - - - „ „ evening.

Of 26 cows tested regularly, 7 give curves resembling No. 3, 10 resembling No. 8, and the remainder, 9, being intermediate.

The most regular cows give milk which, for the greater part of their time, fluctuates less in composition and amount than the mixed milk of 12 cows.

Discussion.

Prof. **Gilchrist** said that the first thing that struck him in connection with the Offerton diagrams was the remarkably low standards for the morning's milk; it seemed as if, when it was necessary to milk three times a day, there was a very great risk of that milk coming under the standard. He was also struck with the remarkably high midday standard. Perhaps the point that came out strongest was the difference in the qualities of milk in the North compared with the South of England. This was certainly not because of the feeding, but was more probably due to the changeability of the weather. Tests made daily with one cow at Cockle Park showed that when the cow was out all night and there was a touch of frost, the quality of the milk next morning was very much lower. He was rather struck with the Gothenburg system. Twice a month (or week; he was not sure which) samples of milk were obtained from the dairymen, and the percentages of fat published in the daily papers, the milks being classified as follows:—3·5 per cent., very good; 3 per cent., good; under 3 per cent., poor.

Mr. **Marshall** thought the analysis of the mixed milk of herds was of much more importance than the analysis of that of single cows, because it had been sufficiently proved that individual cows were most erratic, whereas the mixed milk of a herd as a rule did not vary so much. This year most of his herd had been young cows, and the quality of the milk had been better than usual. During the spring of last year he had been living in perpetual dread of the inspector; his milk was extremely poor, and, do what he would, he could not raise the quality up to the standard. Poor feeding was not the cause of it, because at that time he was feeding them extravagantly, each cow getting a stone of concentrated food per day. As soon as the cows were put out to grass, however, both quantity and quality went up. This is quite in accordance with our experience, but several South-country witnesses before the Standard Committee recommended a lower standard during early grass time. With regard to the difference of the milk in the North as compared with that in the South of England, he could not trace any relation between geology and the quality of the milk. We had still a great deal to learn on these points, and he would like to see some scheme formulated for their further investigation.

Mr. **Smith** said that during last year he had examined between four and five hundred samples of milk, and about 21 per cent. of these were below the standard either in fat or in solids not fat; this is much higher than Mr. Collins' percentage, but there was no doubt that some of the samples had been tampered with. On the whole he agreed with Mr. Collins that the quality of the milk was lower in the North than in the South. In an analysis of 420 samples the percentage of fat was about 3·46, and the solids about 8·88, but as some of these samples were adulterated, these figures might be increased by, say, 20 per cent. Solids not fat very rarely fell below the standard; when they did he was generally able to trace it to irregular feeding. It was almost impossible for anyone to say with absolute certainty that milk had been adulterated simply because it fell below the standard. On one occasion he went out to a farm where there were 42 cows; the percentage of fat in the milk of the herd was under 2½. He did not know the reason, but he believed Prof. Gilchrist considered excessive feeding produced this result; certainly, when the amount of food was reduced the quality of the milk increased very considerably. In another case the reduction of the amount of food immediately increased the percentage of fat from 2·8 to 3, and the substitution of 1 lb. of cake for 7 to 8 lb. a day raised the proportion of fat to over 3 per cent.

Mr. **Garrett** thought that the figures given suggested that as a rule the cow that gave poor milk also gave a poor yield, and would like to know if this has been proved.

Dr. **Potts** also noticed that the percentage of fat seemed to be increased when the cow gave an increased yield, particularly in the Offerton herd. At the second sampling, on the 24th January, the yield and the fat were both high, whereas, at the third and fourth samplings, the yield and the fat were both low. Some two years ago there was a very extensive series of investigations carried out by the South-Eastern Agricultural College, Wye; the milk of about six cows, and also the mixed milk of the herd, was analysed morning and evening; a careful record was also made of the food, and the only factor which was found to alter the quality of the milk was the temperature. Referring to Mr. Marshall's suggestion that further experiments should be devoted to the effect of food on milk, nine-tenths of all milk investigations had been conducted with that end in view. The Americans had done much work in that direction, and had found that food had no effect on the quality of the milk, but that it increased the quantity. It was usually assumed that solids not fat were pretty constant, but one of the outstanding features of last summer's milk was that it was particularly poor in this respect.

Mr. **Collins** replied that he thought the small yields were generally due to the late period of lactation. He did not think that the figures showed that when the yield was high it was therefore rich, or *vice versa*. As to the effect of temperature on the composition of milk, Mr. Dymond had done some work on the subject, and had come to the conclusion that there was no connection between weather and the composition of milk.

The **Chairman** said that researches like these must ultimately lead to important results, and he hoped that Mr. Collins would continue to carry on his experiments, and from time to time acquaint the Section with the result.

PROF. F. STANLEY KIPPING, F.R.S., IN THE CHAIR.

EXAMINATION OF METHODS EMPLOYED IN ESTIMATING THE TOTAL ACIDITY OF GASES ESCAPING FROM THE CHAMBER PROCESS FOR THE MANUFACTURE OF SULPHURIC ACID.

BY H. J. WATSON.

(This Journal, 1903, 1279—1284.)

Discussion.

Mr. **Jas. Kay Hill** wrote as follows:—The sulphazotised compound referred to in Mr. Watson's paper is probably formed in the Gay Lussac tower when the supply of oxygen is deficient, and in the chambers when there is a deficiency of oxygen and steam, but with a properly regulated air supply it should not be formed in measurable quantity. We have here, probably, the last of the mysterious causes of loss of nitric and diminished sulphuric acid production. Some may possibly be inclined to attribute its occurrence to deficient chamber space; but I think that even with the highest possible consumption of sulphur per cubic foot of space, there should be no appreciable loss from this source if sufficient draught be maintained to ensure the requisite proportion of oxygen in the chambers. The results of the experiments described, taken altogether, seem to indicate the absolute necessity of regularly testing the exit gases for oxygen, and of using the new absorbents to detect this sulphazotised compound, which, so long as it remains unoxidised, seems capable of passing unabsorbed, through any number of wash bottles containing water, sulphuric acid, or caustic soda, and is not completely absorbed even by such an oxidising agent as non-alkaline hydrogen peroxide. The behaviour of the compound towards caustic soda in solution seems to prove that it is not really an acid at all, properly speaking, being quite devoid of acid properties until decomposed by oxidation, and this is doubtless why it has so long escaped observation.

Mr. F. J. R. **Carulla** said that sulphuric acid manufacturers were allowed to let gases into the atmosphere providing they did not contain over 4 grs. of acid per cb. ft. There were variations, as apparently the escape was at one time 0·089 gr. per cb. ft. and at another 2·64 per cb. ft. The work was done as rapidly as possible, Mr. Watson making in all eight experiments, each occupying 40 minutes, or 5 hours and 20 minutes in all. In that time it was quite possible for such changes to take place in the working of the chambers as to render his figures not comparable. To compare the experiments they should be done almost simultaneously and not one after the other. Then again they ought to know something about the size of the chambers, because very large chambers would not get into disorder so rapidly as small chambers. He was not questioning the accuracy of the facts as to the absorbing mediums; he was only questioning whether the very large differences shown were to be relied upon.

He had that morning absorbed four escapes with the following results:—

—	Water.	H_2O_2.	Absorption.
	c.c.	c.c.	grs. per cb. ft.
1	200	0	0·367
2	200	5	0·432
3	200	0	0·432
4	200	5	0·367

In the last case the escape was a very small one, and although water or water plus H_2O_2 might be the same thing, the escape might be small, and yet not be high. Mr. Watson in his paper said "In February 1903 I made comparative bellows tests with these two absorbents, and always found that the alkaline hydrogen peroxide gave a higher result than neutral hydrogen peroxide, the difference varying in amount from 0·5 with ordinary working conditions to 3 grains of sulphuric anhydride per cubic foot at a period of disorganisation." Now the same thing might happen with water and with water plus H_2O_2. Personally he would prefer the escape to be a sulphurous one rather than lose nitre. The difference in values was immense.

Dr. R. M. **Caven** remarked that, whilst the interaction of sulphuric acid and nitrous fumes resulted in the formation of nitrosulphonic acid, when nitrous and sulphurous acids interacted under certain circumstances, hydroxylamine disulphonic acid, $N(SO_3H)_2OH$, and nitrilosulphonic acid, $N(SO_3H)_3$, were produced. Low temperature and the presence of alkali were generally supposed necessary for the production of these compounds, but if it were possible for them to be formed in vitriol chambers or the Gay Lussac Tower, their hydrolytic reduction in presence of nitrous acid might result in the evolution of nitrous oxide or nitrogen. What evidence was there for the existence of these sulphazotised bodies? It was difficult to understand how such a body could pass unabsorbed through alkaline hydrogen peroxide solution.

Mr. H. J. **Watson**, in reply, said that special precautions were not taken to exclude carbon dioxide before titration. The sodium hydroxide solution, 10 c.c. of N/2 NaOH diluted with 200 c.c. of water, in the experiments performed, was so dilute that little absorption of CO_2 could take place. In order to see how far this was the case he had that day fitted four flasks exactly as in his former experiments. In No. 1 was 200 c.c. H_2O + 5 c.c H_2O_2; in No. 2, 200 c.c. H_2O + 10 c.c. N/2 NaOH; in No. 3, 200 c.c. H_2O + 10 c.c. N/2 NaOH, and in No. 4, 100 c.c. H_2O + 100 c.c. saturated clear solution of barium hydroxide. The four flasks were connected to a filter pump, the pump started and the aspiration of air through the four flasks regulated to, as near as could be judged, the same rate as the chamber escape gases were drawn through in other experiments. The pump was allowed to work for 40 minutes and then stopped. A milkiness was produced in No. 4; No. 1 was found to be neutral, and then No. 3 and No. 4 titrated with N/2 acid without any special precautions regarding carbon dioxide. They each required 9·75 c.c. of N/2 acid, but when boiled the other 0·25 c.c. was required, so that the combined acidity in the two flasks was equal to 0·5 c.c. of N/2 NaOH (0·154 grain of SO_3) on an approximate cubic foot—not a very large acidity. It might be suggested that the increased acidity in vessels containing alkali was due to CO_2. The experiments themselves, however, did not seem to indicate this. In the case of experiment 20, the combined acidity of 5 and 6 in an alkali solution was equal to 0·18 gr. of SO_3 per cb. ft., and the total acidity of 7 and 8 equal to 0·36 gr. of SO_3 per cb. ft. It was hardly possible that the increase in 7 and 8 could be due to CO_2 following after alkali in 5 and 6, but without hydrogen peroxide present. Nitrous acid was proved to be present in experiment 17, and the presence of more active acid gases would probably retard the action of carbon dioxide. With regard solution of H_2O_2 and Na NO_2 in the experiments performed the solutions were exactly neutral.

The chambers were 100 feet in length and 30 feet high. There were three in the set and one set of burners. He was inclined to agree with Mr. Carulla in the matter of the escape of sulphur and nitre. With regard to the theoretical points raised by Dr. Caven, he had not had time to go into them, and he was not at all sure what the compound was. That there was some compound present, and that it was decomposed by water, was shown afterwards. It was to some extent absorbed in alkali, but not altogether. When experiment 21 was performed they were using a very high amount of nitre: 31 lb. to the ton of stone. Calculating the difference from the result of the experiment, the waste came out almost too high, *viz.*, 56 per cent., which was equal to 17½ lb. per ton. When they tried to work with 13½ lb. the escape was very high.

ERRATUM.

EXAMINATION OF METHODS EMPLOYED IN ESTIMATING THE TOTAL ACIDITY OF GASES ESCAPING FROM THE CHAMBER PROCESS FOR THE MANUFACTURE OF SULPHURIC ACID.

BY R. FORBES CARPENTER AND ERNEST LINDER.

(This Journal, 1902, 1490—1508.)

For "metaphenylene diamine" read "metaphenylene diamine hydrochloride" throughout, as in Table VIII. This indicator has an acid reaction.

Yorkshire Section.

Meeting held on Monday, December 14th, 1903.

MR. JAS. E. BEDFORD IN THE CHAIR.

SOME RECENT METHODS OF TECHNICAL WATER ANALYSIS.

BY PROF. H. R. PROCTER.

The analysis of water for technical purposes usually only extends to its mineral constituents, the traces of organic impurity which are important in potable waters, having but little effect on most chemical and technical uses. Bacteriological examination has probably received far too little attention from the technical chemist, since there are many manufactures in which the presence of organised ferments is of an importance only second to that of their existence in drinking water; but on this point I do not intend to touch. The "hardness" of water is, on the whole, of the greatest manufacturing moment, but in my opinion has been considered far too exclusively from the point of view of the soap user, which often differs widely from that of other chemists, and although, viewed merely as an empirical method for determining the quantity of soap likely to be destroyed by a given water, the soap-test has its practical value, there are other and easier ways of learning with so much greater exactitude, what the actual qualitative and quantitative character of the hardness is, that even for the soap-user I believe, with increasing knowledge, this information will come to be of greater value than any merely empirical test. If no other fault existed in the soap-test than that it became practically useless in the presence of much magnesia, it would be sufficient to condemn it for general purposes, but, when the somewhat indefinite character of the reagent, and the still more indefinite character of the reaction is considered, it becomes unnecessary to labour the subject. It is now possible, by simple volumetric methods, and with a high degree of accuracy, to determine not merely temporary and permanent hardness, but the actual quantities of lime, magnesia, iron, carbonic and sulphuric acids, and chlorine contained in a water, and with this information, the effect of the water on any chemical reaction may in most cases be completely foretold. It is because I think that some of these methods are not so familiar to technical chemists as they deserve to be, that I venture to bring forward matter which is not at all original, and which must be familiar to many. The only points on which I may be able to claim the merit of novelty are observations on some of the sources of error which become important in working with such very dilute solutions, and suggestions as to how they may be avoided. In this connection it may be pointed out that a water with "total hardness" equal to 50 parts of calcium carbonate per 100,000 is a very hard one, but looked at as a volumetric solution it is only centinormal, and must be determined with an accuracy which should reach 1/50th of its strength. To do this successfully involves many precautions which are quite unnecessary in the use of normal solutions.

So far as I am aware, the credit of having first introduced a practical and scientific method of hardness determination belongs to Mr. Hehner, who titrates the temporary or bicarbonate hardness with N/10 HCl, using Methyl Orange as an indicator, which is practically insensitive to carbonic acid. The method gives very exact results if certain precautions are taken. Methyl Orange is the sodium salt of a colour acid of moderate strength, and the change from the yellow salt condition to the red colour of the free acid marks the end point, which is sharp and exact when working with strong mineral acids, and with normal solutions. Even in this case it is desirable to use the smallest possible amount of the indicator, but, in working with N/10 solutions, the amount of acid required to completely decompose the colour salt becomes very perceptible, and the change from yellow to red is not instantaneous, but passes through orange to pink with the consumption of an appreciable amount of acid. Thus it was found that, using a 10 grm. per litre solution of the indicator in 25 c.c. of water freed from carbonic acid by previous boiling, the following quantities of N/10 HCl were required to produce a clear pink:—8 drops of methyl-orange solution = 1·5 c.c., 4 drops = 0·5 c.c., 2 drops = 0·5 c.c. As even 0·5 c.c. in titrating 100 c.c. of water would correspond to 2·5 parts of hardness per 100,000 and there is always a question as to what particular colour corresponds to the neutral point, the following procedure may be recommended. To 100 c.c. of distilled water, one drop, or some other definite quantity of the indicator is added, and titrated to orange, or to the tint to the change of which the eye of the individual operator is most sensitive. The water of which the hardness is to be determined is similarly titrated with the same quantity of indicator, and in a similar beaker, until it exactly matches the distilled water, and from the amount of acid so used the quantity is deducted as a correction which was required to produce the same colour change with distilled water only. The results so obtained accurately correspond with those got by using alizarin as an indicator in boiling solution though in the latter method the end reaction is sharper. It may be noted that Methyl Orange is not absolutely unaffected by carbonic acid, a somewhat crocus-yellow being attained instead of the lemon yellow reached with pure boiled water, but the difference is insufficient to interfere with its satisfactory use as an indicator.

Mr. Hehner's method for the determination of permanent hardness is less satisfactory than the foregoing. It consists in evaporating 100 c.c. of the water to dryness with a known excess, say 20 c.c., of N/10 sodium carbonate solution, taking up the soluble matter with cold distilled water, filtering off the precipitated calcium carbonate and magnesia on a small filter, washing the precipitate with cold water, and titrating back the excess of sodium carbonate in the filtrate with Methyl Orange or rosolic acid as indicator. With lime-hardness only, and with the precautions above described, the method may be pronounced fairly satisfactory; with magnesia, it is well not merely to evaporate to dryness but to slightly heat the residue to thoroughly decompose any magnesium carbonate present, and even then, the washing should not be excessive, as calcium carbonate is soluble to the extent of 3 parts per 100,000, and magnesia to about 2·5 parts. A more accurate, as well as a more rapid method is to employ a fair excess of sodium carbonate, and to make up the solution to a known volume, say 100 c.c., and pipette off an aliquot part for titration, as the presence of excess of sodium carbonate materially reduces the solubility both of calcium and magnesium carbonates. Both these methods, however, should be superseded, where really accurate work is required, by those introduced by Pfeifer and Wartha* (Zeits. angew. Chem., 1902, 198). That for the determination of temporary hardness is identical with that of Hehner, except that, in place of Methyl Orange, a drop of a mixture of about 1 grm. of the purest alizarin paste in 200 c.c. of distilled water is employed. This indicator is surprisingly sensitive; even more so I think than phenolphthalein, but as it is unfortunately affected by carbon dioxide, it is necessary to complete the titration at a boiling temperature. The change is from violet in alkaline solution (perhaps slightly varying in shade with the nature of the particular base present) to a perfectly clear pale lemon-yellow when neutral or acid. The titration of the water should be done with N/10 HCl or H_2SO_4 in a silver, platinum, or hard porcelain basin. The acid should be added in the cold till the violet shade gives place to a clean yellow, and the liquid then brought to a boil, when, with the escape of carbonic acid, the violet colour will return, and should at once be destroyed by the addition of another drop of the acid, and so on, until no further change of colour takes place. It is undesirable to boil the indicator long, especially in an alkaline condition, as a violet deposit is

---

* Prof. Lunge states, in a private letter, that the use of alizarin for this purpose was originated in the laboratory of the Zurich Polytechnicum by Weithi.

formed on the sides of the basin, presumably of calcium and magnesium alizarates, which can only be dissolved by excess of acid, and is thus apt to cause perceptible errors. In place of titrating to exact neutrality, the acid may be added in very small excess, and the whole of the liberated carbon dioxide boiled off at once, and the solution then brought back to neutrality by N/10 NaOH, the solution boiled for a moment, and the titration completed. The results in either case are exact, a fraction of a drop of alkali changing the clear lemon-colour to a dirty yellow. If 100 c.c. of water are used, multiplication of the c.c. of acid by 5 gives the temporary hardness in parts of $CaCO_3$ per 100,000. The boiling must in no case take place in an ordinary glass beaker or flask, as an amount of alkali is dissolved which may lead to serious inaccuracy. Even hard Jena glass is not free from this effect, though the amount dissolved is so small that for most practical purposes it may be neglected. The following experiment will illustrate the point. 100 c.c. of distilled water boiled for an hour (with additions to maintain the volume in a Berlin porcelain basin showed no alkalinity or colour-change with alizarin; in a Jena flask a perceptible change of colour was visible, but pure yellow was restored with one drop of N/10 acid, while when boiled in an ordinary Bohemian flask, 0·4 c.c. of acid was consumed, and if the neutralised liquid were boiled further it again became alkaline, and further additions of acid were required, so that no coincident results could be obtained. With the precautions named, the results with a known solution of hydric calcic carbonate containing only 5·5 parts of temporary hardness, and whether titrated alone or with additions of magnesium sulphate, were accurate within one part in 100,000, and experiments with other quantities were equally satisfactory.

In the determination of permanent hardness, Pfeifer and Wartha, in addition to the use of alizarin as indicator, have introduced the important improvement of replacing the sodium carbonate of Hehner's method by a mixture of equal parts of N/10 sodium carbonate and hydroxide solutions. While, as has been already explained, sodium carbonate perfectly precipitates calcium salts as carbonates on merely boiling, it becomes necessary to evaporate to dryness and to heat whenever any magnesium salt is present, in order to convert magnesium carbonate into oxide, since magnesium carbonate is not sufficiently insoluble. In presence of sodium hydroxide, however, the magnesium carbonate is at once converted into magnesium hydroxide, and perfectly efficient precipitation is obtained by merely boiling for some time with sufficient excess of the reagent. A good excess, say 50 per cent. or more, is essential, not only because it is impossible to say before analysis what proportion of sodium carbonate and what of caustic will be required, but because the presence of the CO_3 ions of the sodium carbonate in the solution greatly lessens the solubility of the calcium carbonate, and similarly the OH ions of the sodium hydroxide lessen that of the magnesium hydroxide. Unless the water is extremely hard, 50 c.c. of the N/10 mixed solution to 200 c.c. of water is a convenient and sufficient quantity. The mixture may be boiled until reduced within 200 c.c. in a platinum or porcelain basin, or, more conveniently, and with no material loss of accuracy, in a 300 c.c. Jena flask, but on no account in ordinary Bohemian glass. Even the Jena flask will become perceptibly etched at the water line if used repeatedly. The solution after cooling, is made up to 200 c.c. with distilled water in a gauged flask, and allowed to stand till the precipitated bases have settled, and 100 c.c. is pipetted or siphoned off and titrated. As the quantity named corresponds to 100 c.c. of the original water, and 25 c.c. of N/10 alkali, the difference between the acid actually used and 25 c.c. will correspond to the amount of alkali neutralised by the acids of the permanent hardness, and multiplied by 5 will give the latter in terms of milligrammes per 100,000 calculated as calcium carbonate. The temporary hardness will also be precipitated; but, containing no fixed acids, will not interfere. Pfeifer employs the water which has been neutralised in the titration of temporary hardness, in place of the original water. In this case the result obtained will represent total hardness, from which the permanent hardness is obtained by deducting the temporary. In place of allowing the precipitate to settle, the solution may be filtered through a small filter, which is carefully washed with the solution, of which the first 50 c.c. or so is rejected, as filters are rarely absolutely free from acidity or alkalinity, and even if at first perfectly neutral, easily absorb acids or ammonia from the laboratory air, unless very carefully protected. Many irregularities occurred in the determinations until this source of error was detected. 15 cm. filters of three different makes were macerated with distilled hot water, and proved in all cases alkaline to Methyl Orange and acid to phenolphthalein, the difference between the two indicators, + or −, amounting in each case to about 0·75 c.c. of N/10 solution. A case must now be considered which is not very infrequent in Yorkshire waters; it occasionally happens that in the determination of permanent hardness, a larger quantity of acid is required to neutralise the mixture than corresponds to the volume of N/10 alkali which has been added, and that therefore the permanent hardness would appear as a minus quantity. This somewhat puzzling result is due to the presence of sodium carbonate in the original water, which in this case can have no permanent hardness other than that due to the solubility of calcium carbonate, which cannot be removed by softening, but which is not reckoned in the above methods of analysis, though it is counted in the soap test. Where sodium carbonate is thus found, a proportionate amount must be deducted from the temporary hardness. If the total hardness after neutralisation is determined after Pfeifer's method, the presence of sodium carbonate will be indicated by the total hardness coming out as less than the temporary, the difference being obviously the alkalinity due to the soda; each part of hardness corresponding to 1·06 part of sodium carbonate. Since in the ordinary methods of water softening, lime is precipitated as carbonate, but magnesia as oxide, with the consumption of a double quantity of caustic lime or caustic alkali, it is impossible from hardness-determinations alone to calculate the materials required for softening, or the actual weights of the bases titrated, so long as it is uncertain whether or in what proportion magnesia is present. Pfeifer determines this in the following manner:—100 c.c. of the water is neutralised with N/10 acid in presence of alizarin, in boiling solution, exactly as in the determination of temporary hardness, which may be combined with that of magnesia. A known quantity of clear limewater (25 or 50 c.c.) which should be at least 50 per cent. in excess of that required for precipitating the magnesia present, is measured into a 200 c.c. flask, the hot neutralised solution is rinsed in with boiling distilled water free from carbonic acid, and made up with the latter to 5 c.c. above the mark to allow of contraction in cooling; the flask is tightly corked or stoppered, and well shaken to mix, for which purpose the neck above the mark must be a long one, and set aside to cool and settle. Though not essential, it probably increases the completeness of the precipitation if the corked flask is heated for half an hour or so on the water-bath. I prefer to allow sufficient time for the liquid to completely clear, and to pipette off 100 c.c. to titrate back with N/10 acid, which may be done cold with phenolphthalein, or hot with alizarin with equal accuracy. Pfeifer filters, but in this case the strength of the limewater must be determined by a blank experiment conducted in exactly the same way with distilled water; and it is better to reject the first 50 c.c. in each case to avoid error from want of neutrality of the filter-paper, and great care must be taken to filter rapidly, and to avoid possibilities of carbonation by the atmosphere, for which purpose a suction filter with a perforated porcelain disc, covered with a neatly-fitted disc of filter-paper answers well. If, on the other hand, the liquid is settled and pipetted, the risk of carbonation is so small that an equal quantity of the same limewater may be measured direct, and titrated, using the same indicator as has been employed for the water, phenolphthalein in the cold being on the whole preferable. Deducting the N/10 acid required for the mixture of limewater and water from that employed for the limewater alone, and multiplying the difference by five, gives the hardness due to magnesia in terms of milligrammes of calcium carbonate per 100,000, from which actual Mg may be reckoned by multiplying by 0·24; or MgO multiplying by 0·4. Carefully conducted, the method is extremely exact, its accuracy being quite equal to that of the determination of hardness, and probably superior to that of any gravimetric method for such minute quantities. The theory of the process is that, while calcium hydrate will precipitate magnesia, it has no action on lime salts; and a good excess of lime serves not only to quicken the reaction, but to diminish the solubility of the magnesia. If iron is present it will of course be reckoned with the magnesia, and should be determined colorimetrically with thiocyanate (also a process of great accuracy for small quantities), and deducted. It may be assumed that it is present in the ferric state, and that therefore 0·24 of Mg corresponds to 0·3733 of Fe. Aluminium, if present, would behave like iron, any traces of alumina dissolved by lime having no effect (on phenolphthalein at least), but it is rare that more than traces of alumina exist in natural waters, though it would have to be reckoned with in river-waters receiving manufacturing effluents, and its estimation would not be particularly easy. Possibly a colorimetric method with alcoholic extract of logwood or some other mordant dyestuff might be devised where the water was required for dyeing, but it is not likely that it would introduce any material error into water-softening calculations, and it would be removed with the other impurities. Having determined the magnesia, or, more strictly, the acid with which it and any other bases are combined which are precipitable by lime, it becomes possible to calculate the calcium present in the water, by deducting the magnesia-hardness from the total hardness, and calculating the remainder into Ca by multiplication by 0·4. The carbon dioxide present as hydric carbonate is given in parts per 100,000 by multiplication of the temporary hardness by 0·88 for CO_2 or 1·2 for CO_3. When the proportion of hardness due to magnesia is known, it is possible to calculate the quantities of lime and sodium carbonate required for softening, since magnesium salts, as has been stated, cannot be satisfactorily removed as carbonates, but must be converted into hydroxides by lime or some other caustic alkali; and this applies to the permanent hardness which is converted into carbonate by sodium carbonate, as well as to the bicarbonate reduced to carbonate by lime. Thus each equivalent of magnesia present requires an additional equivalent of lime beyond that required by the corresponding calcium salt. Pfeifer gives a formula for this purpose, calculated for German degrees of hardness, which are reckoned in parts per 100,000 of CaO instead of parts of $CaCO_3$, as is customary in France and England. I have, therefore, taken the liberty of transposing it into terms of parts of $CaCO_3$ per 100,000. *Ht* in the formula signifies temporary, and *Hp* permanent hardness, and *Hm* hardness due to magnesia, whether temporary or permanent. The quantities given are in milligrammes per litre, grammes per cubic metre, or lb. per 100,000 gallons of the water to be treated. $5{\cdot}6\,(Ht + Hm)$ = lime (CaO) required; $10{\cdot}6\,Hp$ = dry sodium carbonate; or $28{\cdot}6\,Hp$ = soda crystals ($Na_2CO_3 . 10H_2O$). If only temporary hardness is to be softened by liming only, the quantity required is $5{\cdot}6\,(Ht + Hm - Hp)$ if *Hm* is larger than *Hp*, but if not, only the temporary hardness need be taken in account. Finally, for softening with sodium hydroxide and sodium carbonate only, which is sometimes convenient for small boiler installations, we have $8\,(Ht + Hm)$ = NaOH required; $10{\cdot}6\,Hp - (Ht + Hm)$ = Na_2CO_3 required. Consequently, if the water has less permanent hardness than the sum of the temporary and magnesia hardness, it cannot be softened completely in this way without leaving excess of sodium carbonate in the water.

Some waters contain large quantities of dissolved free carbon dioxide in addition to the "half-combined" present as temporary hardness, and though this is not included in any hardness determination, it, of course, combines with and renders useless an equivalent quantity of the lime added for softening, and must, therefore, be taken into account in reckoning the lime required. The free CO_2 is easily estimated by a method, I believe, due to Archbutt, though I have been unable to find its original publication. 100 c.c. of the water is titrated slowly with N/10 solution of Na_2CO_3 and phenolphthalein, till a tinge of permanent pink is produced, when the number of c.c. used, multiplied by 2·2, will give the parts of CO_2 per 100,000, or by while multiplication by 2·8 will give the weight of lime required to remove it. Of course, such a determination is of no use unless there is some security that the sample of water really represents the average, and has not lost carbonic acid by exposure. The reaction depends on the fact that sodium bicarbonate is neutral to phenolphthalein, while the normal carbonate is alkaline. It must be remembered that the theoretical quantity of precipitants does not always give the best practical results, owing to difficulties of settling and filtration, and in some cases it is necessary to be content with less than the theoretical softening (see Archbutt and Deeley, this Journal, 1891, 511).

It is sometimes necessary to determine not only the bases, but the acids present in a technical water. Several colorimetrical methods exist for the determination of the traces of nitric and nitrous acid sometimes present; chlorine is of course easily determined with silver nitrate with chromate as indicator; and for sulphates the recent volumetric method of Wolf-Muller (Ber., 1902, 1587) with benzidine hydrochloride gives excellent results. This method depends on the fact that benzidine sulphate is very slightly soluble: and especially so in solutions containing excess of benzidine hydrochloride. Benzidine is so weak a base that the hydrochloric acid combined with it can be titrated in presence of phenolphthalein as if it were free, while the sulphate, being insoluble can be filtered off, and calculated from the loss of acidity. I have been making some experiments with this method, and shall be glad at a future date to give some further particulars of the practical working of it, if these would be of interest to the Section.

DISCUSSION.

Mr. F. W. **RICHARDSON** said he thought the paper was a very interesting one for members of the Section, especially in regard to boiler-feed waters, which question assumed great importance in the district. He referred members to a paper he had found very useful and which was published a few years ago in the *Dyers and Colourists Journal* on the analysis of waters, including the estimation of calcium. Ammonium oxalate was added to the water in excess, and the excess estimated in the filtrate by means of standard potassium permanganate solution. As the quantity of water sent for analysis was sometimes very small, he chose to use gravimetric rather than volumetric processes, as being more accurate when working on small quantities of water. As regards Methyl Orange, he had also found it necessary to test each different sample of the dye in distilled water. With regard to the softening of feed-waters, he had found that firms would not go to the expense of putting down plant for that purpose, and so nothing remained but to advise what to put into the boilers. He recommended soda ash in quantity, sufficient to react with the sulphate of magnesia and the soluble salts of lime. He asked Mr. Procter as to whether he thought anything else was necessary for boiler-feed waters.

Mr. W. McD. **MACKEY** was inclined to agree with the last speaker in his preference for gravimetric processes. He never used the soap test unless asked for it, and calculated the hardness from the analysis. He found he could obtain a good indication of what was required on the large scale by using, say, 500 c.c. of water, and weighing out the caustic lime, when it was possible to get reliable data as to the amount of lime to be used in practice on the large scale. He was afraid Archbutt's process for estimation of free CO_2 could not be used in this way. In the case of a water containing much magnesia and chlorine, it was generally considered that acidity was generated in the boiler. He asked Prof. Procter if, in his opinion, the calcium carbonate present in the water was a protection against corrosion arising from this cause, seeing it would be precipitated on boiling.

The **CHAIRMAN** said that, although opinions might differ as to the composition of the water of the River Aire, there was no doubt that it was good for boiler purposes, and to prevent corrosion a little caustic soda was all that was necessary. A little hard scale might be formed, but that was all; he had found also a little "pitting," but thought this might be due rather to electrochemical phenomena. He had found numerous pin-holes in the feed-water pipes when wrought iron was used, but on changing to cast iron his objection disappeared.

Mr. G. Ward upheld the view that caustic soda was valuable for use in boilers, and its usefulness was increased if a mixture of caustic soda and crude gallotannate of soda were used. The gallotannate of soda was readily made by dissolving catechu in caustic soda, and the mixture was one which was used by many large companies who worked their boilers hard.

Prof. Procter, in reply, said that even when small quantities of water were dealt with it was only a question of taste whether gravimetric or volumetric processes were used, and he thought that to get any advantage gravimetrically large quantities should be used. With regard to the softening of water, he agreed that sodium carbonate and caustic soda with almost any tanning substance was very good. He had found Archbutt's process to be very satisfactory, but whether such exact analysis was necessary for softening calculations was open to question, as in practice they were unable to tell whether their instructions would be carried out with a lime containing 30 per cent. or 90 per cent. of CaO. Like Mr. Mackey, he could obtain a good approximation by adding excess of lime to the water, allowing to stand in a stoppered bottle for, say, 12 hours, and then titrate the excess of lime, and so find the amount of lime consumed. With regard to magnesium chloride, the view at present held was that it did not dissociate when alone, but the iron combined with the chlorine, and this led to "pitting"; but he thought this was not to be feared if calcium carbonate were present. The precipitation of calcium carbonate was most to be feared in presence of fats, preventing contact with the water and causing overheating of the boiler-plates. Heavy mineral oils had not this effect, and had been found useful for loosening the hard scale.

The Chairman said he believed the introduction of heavy mineral oils into boilers working at high pressures was dangerous, as it was supposed to induce the water to take the spheroidal condition and prevent it actually touching the plates, and explosions had resulted therefrom.

COAL-ASH.

BY JOHN W. COBB, B.Sc. (LOND.).

The laboratory examination of coal-ash is usually limited to a determination of quantity, but the influence of the nature of the ash is often of so much importance that I thought some notes on methods of examining ash which I have found useful, and on the significance of the results, might not be without their value.

The quantity of ash is interesting in the first place because the ash is the inert and thermally useless constituent of a coal, and, allowing for moisture, the variation in quantity of ash gives a sufficiently good criterion for many purposes of the variation in calorific value. I do not mean that one coal is necessarily of less heating power than another coal because it contains more ash, but if it is required to compare successive consignments of the same coal or of similar coals the quantity of ash forms the readiest basis of comparison. The ash determination can be made in many cases where the tedium of calorimetric determinations renders it impracticable to make them sufficiently often, as in controlling the heat efficiency of a piece of plant such as one particular furnace or range of boilers. I might point out that the loss by ash is larger than at first sight appears. Taking the familiar case of a steam-boiler, the rate of combustion per unit of grate area and rate of steam-raising are determined by the amount of air penetrating to the coal through the interstices beneath it; this quantity diminishes as the ash accumulates on the grates, and although the thermal efficiency, as expressed by the percentage of heat units utilised, is not necessarily lowered, the economic efficiency suffers severely by the reduction of output; the difficulty of keeping up steam pressure is also increased by the excessive time taken in removing clinker, which involves admission of quantities of cold air. Heat losses are even more noticeable in a kiln or furnace fired for the obtaining of a high temperature. As the ash accumulates, the rate of combustion diminishes, and the temperature rises more slowly until, if cleaning-out is delayed too long, the coal which the grates will burn, though perhaps a very appreciable quantity, is not sufficient to raise the temperature at all. The removal of ash in such a case usually means a lowering of the temperature inside the furnace, and hard and unpleasant work outside, and has to be followed by firing for what may prove to be a considerable time, simply to make up lost ground. Taking another case, that of a gas producer, the gradual accumulation of ash is distinctly detrimental to its working, and in some types the output of gas is stopped completely during the periods of ash removal.

The preceding remarks make it unnecessary to insist on the importance attaching also to the fusibility of ash. The checking of air-supply and rate of combustion, by accumulating ash, is greater if the particles fuse together into a clinker, and the heat losses are increased by the difficulty of removing the clinker. This consideration becomes of fundamental importance in the working of inaccessible fires, such as those of the modern blast-blown gas-producer with water-seal. One of the most valuable practical advantages of the Mond gas process is that by the use of a large excess of steam in the blast (an essential feature of the process), the temperature of the fires is kept low; therefore the ash does not melt together into lumps of clinker, and can be drawn easily with the minimum of interference with ordinary working conditions.

It may be noticed that completeness of combustion hinges very largely upon absence of fusion in the ash; the enclosing of unburnt carbon by the melting of surrounding ash, and consequent stoppage of further combustion, is easy to realise.

The composition of ash is usually of importance, mainly in so far as it effects fusibility, but when the solid fuel comes into direct contact with the material of the process, as in blast-furnace work and lime and cement burning, the increased importance of ash composition is evident. In blast-furnace practice, a change in the coke used may make a complete change necessary in the proportions of ore and limestone: this is largely because the slag must retain constant properties, and the coke-ash ingredients (with the exception of the iron) are, roughly speaking, transferred bodily to the slag, and must be allowed for. Harmful elements, such as sulphur and phosphorus, have their own significance, and, altogether, the influence of ash composition is so considerable in such cases as to necessitate complete analysis. The influence of certain properties of ash has been noticed. The laboratory methods of examination now claim attention.

The determination of quantity of ash is simple, so simple that errors are common and considerable. The importance of sampling has been rightly insisted on, and the avoidance of draughts on the crucible, which carry away light particles of ash. If the crucible is heated in a laboratory muffle it is sometimes necessary to guard against too high a temperature, or fusion of the ash may take place before completion of the combustion, in which case unburnt carbon may be enclosed by the ash.

The composition of the ash requires a fusion with alkali carbonates, followed by the methods applied to silicates and iron ores. The process can be quickened somewhat by volumetric determination of the iron, lime, and phosphorus.

My own practice is as follows:—

The silica is separated as usual, and the filtrate made up to 250 c.c., of which aliquot portions are measured off for the succeeding determinations. The alumina, iron, manganese, phosphorus, and titanium are precipitated by ammonia and a drop of ammonium sulphide. (More elaborate separation of manganese, *e.g.*, by ammonium acetate, is occasionally called for.) Only slight alkalinity is allowed; the precipitate settles quickly, and the solution above it is decanted through the filter-paper. The precipitate is redissolved in hydrochloric acid and the solution diluted to the same volume as before precipitation. Ammonia and a drop of ammonium sulphide are added, and the precipitate filtered off, washed, and ignited for some time before weighing to ensure complete oxidation. This precipitate has been obtained in a solution largely freed from alkali and calcium salts; it therefore resembles that obtained by redissolving the alumina and iron precipitate from the filter-paper (which I have not found an easy thing to do quickly and completely), and reprecipitating.

The *Lime* is precipitated by ammonium oxalate for the iron and alumina filtrate after concentration of the latter, but before adding ammonium oxalate the solution is rendered distinctly alkaline with ammonia and allowed to stand 15 minutes. Traces of alumina and iron sometimes come down. The ammonium oxalate precipitate is redissolved in standard sulphuric acid and titrated with potassium permanganate.

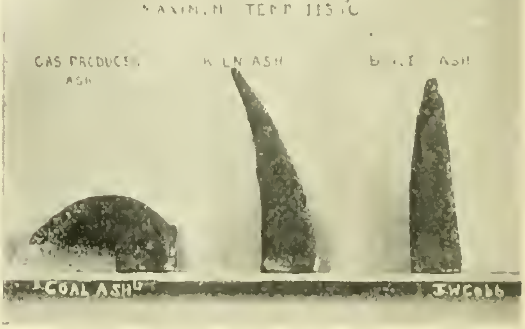
The *Phosphorus* is determined by a process which is not, I believe, in common use, but appears to be quite accurate enough for most purposes and is neat and rapid. 100 c.c. of the 250 c.c. SiO_2 filtrate (a portion representing say 1 grm. of the ash), is taken, diluted to about 500 c.c., ammonia added until a slight permanent precipitate forms, and nitric acid added to re-solution. 50 c.c. of ammonium molybdate solution is then poured into the solution (warm to the hand), and shaking for 5 minutes is followed by settling for 15 minutes. Filtration through asbestos in a Gooch crucible with vacuum, washing with 1 per cent. HNO_3 and with 0·1 per cent. KNO_3 until no acidity remains, solution in standard soda of the molybdate precipitate, and titration of the solution against standard sulphuric acid, using phenolphthalein as an indicator, complete the process of estimation.

A further note on this method will follow.

The fusibility of an ash is, of course, dependent upon the composition; the oxides composing it are infusible separately at ordinary fire temperatures, but are present in the proportion to form some compound of the type $x\mathrm{RO}.y\mathrm{R_2O_3}.z\mathrm{SiO_2}$ and are in intimate contact. Many such compounds are easily fusible, and so the ash melts in the fire to a slag or clinker. The forecasting of the fusibility of any particular mixture of oxides constituting a coal-ash is not practicable yet, although something may be done in that direction; a direct determination of the fusibility is the simplest way to arrive at useful information. The method I have long used for this purpose, and one of very general application, is due in essence to Seger, who used the bending of small pyramids of known composition as a means of measuring temperature. Suppose the fusibility of ash A is to be compared with that of ash B; each is ground to powder—the finer the better, but 100 in. linear sieving is fine enough—and made into a pyramid. This is not a difficult operation, especially if dextrin solution is used to increase coherence during the making and hardness afterwards.

The use of dextrin is unnecessary if the material has been ground to impalpable powder, which is easily done in a pebble-mill, using water. No appreciable effect on fusibility seems to result from any difference in fineness which occurs in practice. The pyramids should be approximately, but need not be exactly, geometrically similar. In some cases all the constituents of an ash are not naturally in a state of intimate admixture, but the conclusions drawn from pyramid experiments are rarely, if ever, invalid for this reason, if discretion is exercised when obviously demanded. The pyramids I use are considerably larger than the Seger cones; they are nearly 1 in. square on the base and 3 in. high, one face standing vertical.

After drying, the pyramids are set in a laboratory furnace, and the temperature is gradually raised until one of the pyramids bends over to touch with its point the surface on which it was set. The firing is then stopped, and the pyramids are examined. It is essential to success that temperature distribution in the space where the pyramids are set be uniform; I have not found a laboratory natural-draught muffle furnace satisfactory, but use a circular regenerative down-draught furnace heated by eight burners arranged equidistant on the periphery. It is often convenient to refer to some constant standard, and in this case an ordinary pyrometric pyramid is useful. If an absolute determination of the fusibility of a pyramid is required, referred to the ordinary centigrade scale of temperature (and such a determination is certainly advisable if work of this kind is to have outside value), a thermo-couple may be put into the furnace with its junction near the pyramids. The rise of temperature should not be too rapid, and as soon as the pyramid bends a little at the point should be checked altogether. This is necessary, because the bending of the pyramid is a summation of all softening effect above the point of incipient fusion; it cannot take place instantaneously, and if the temperature is allowed to go on rising quickly while the pyramid is bending, the reading will be altogether too high when the pyramid touches. The bending should take place slowly through a small range of temperature; in this way an approximately correct reading in degrees Centigrade for the touching of the pyramid can be obtained. The accompanying photograph illustrates results obtained in one experiment.



The unburnt combustible matter in the ash can be determined accurately enough for process control by grinding the dry ash to very fine powder and igniting it; the loss on ignition gives the unburnt carbon directly. It may be pointed out that the permissible percentage of unburnt carbon in the ash is smaller as the percentage of ash in the coal is larger. Thus, assuming a coal to contain 70 per cent. of carbon and 5 per cent. of true ash, if 5 per cent. of the carbon present came unconsumed into the works ash, it would show itself as 41 per cent. of unburnt matter on examination of the works ash. If, however, the coal contained 55 per cent. of carbon and 20 per cent. of true ash, and 5 per cent. of the carbon present again came unconsumed into the works ash, it would show itself as 12 per cent. of unburnt matter on analysis—a very different result at first sight, but really indicating the same amount of waste. If the ash contains a considerable quantity of partially reduced matter, particularly iron, this increases in weight on oxidation, and therefore direct ignition gives too low a result for perfect accuracy, but cases in which this amount of error is of any consequence are rare, I believe. I have several times checked the ignition result by a combustion with quite satisfactory results.

I might point out that part of the loss of ignition of a works ash, though not a large part, may be due to the loss of sulphur. It was once interesting to me to find out how long glowing ashes would give off sulphur compounds when moist air was passing over or through them. Three kinds

Sulphur Account for Clinker from Three Coals.

of ash were sampled as drawn from a glazed brick kiln when just finishing firing. Air, moistened by bubbling through water, was passed through the finely-ground ash heated to redness in a combustion tube. The sulphur compounds evolved were absorbed in bromine water acidified with hydrochloric acid and estimated by precipitation with barium chloride; the sulphur in the ash before and after heating was determined by fusion with the mixed carbonates and precipitation with barium chloride; the sulphur present in the three ashes was approximately 3 per cent., 2 per cent. and 1 per cent. The results are tabulated.

It is noticeable that the sulphur compounds were almost completely expelled, but very slowly; in cases where small quantities of sulphur gas are believed to work for evil, it may then be advisable to draw the ashes as soon as the firing is finished.

In any industrial process one characteristic of an ash may assume a special prominence for evil or good. Thus the phosphorus, generally unimportant, assumes prominence for blast-furnace work. So, too, the light ash of a coal scattered by the draught over the surfaces of burning bricks may induce material disfigurement, if fixed by wet products of combustion or by fusion. Many other examples might be given, but I limit my remarks to my own experience. Finally, let me express my thanks to Mr. C. P. Finn for assistance given me in some of the laboratory work, and in preparing the photographs, as also to the directors of the Farnley Iron Company, in whose laboratory all the experimental work has been done.

Discussion.

The Chairman drew attention to the importance of the subject to all works, and said that the interest of the paper would have been increased if it had been possible to compare the characters of the different West Riding coals, and their suitability to various industries.

Mr. W. McD. Mackey asked if a number of determinations of phosphorus in local coals could be placed on record, as these would be of value for reference in the future, and as on the West Coast a non-phosphorus pig was a speciality. He drew attention to the importance of maintaining an oxidising atmosphere in the muffle during the estimation of ash.

Mr. F. W. Richardson pointed out that the estimation of arsenic in coal ash was not a very simple matter. His own method was to fuse the ash with the double carbonates of sodium and potassium and so get the arsenic in a soluble form, after which the estimation was easy. He thought there was some need of a standard method.

Mr. Cobb, in reply, agreed that the various properties of coals would form interesting subject-matter for not one but quite a number of papers. He thought Mr. Mackey rightly emphasised the necessity for an oxidising atmosphere in ash determinations. The molybdate method was essentially one for the estimation of small quantities of phosphorus, the volume and weight of the precipitate being so great; this would, however, be dealt with at greater length in a special note.

Patent Specifications may be obtained by post by remitting as follows:—

English.—8d. each, to the Comptroller of the Patent Office, C. N. Dalton, Esq., Southampton Buildings, Chancery Lane, London, W.C.

United States.—1s. each, to the Secretary of the Society.

French.—1 fr. 25 c. each, to Belin et Cie., 56, Rue des Francs-Bourgeois, Paris (3ᵉ).

I.—PLANT, APPARATUS AND MACHINERY.

English Patents.

Drying and Roasting Apparatus. M. Hecking, Dortmund, Germany. Eng. Pat. 25,209, Nov. 17, 1902.

The apparatus consists of a horizontal mixing drum, mounted on rollers, and adapted to be supplied with hot air or steam from a furnace at the head of the drum. The drum has also a feeding funnel at the head, and a collector for the dried or roasted material at the foot. The collector has an exhaust pipe for gases at the top, and an outlet channel at the bottom, the outlet channel and feeding funnel being provided with counterweighted traps. On the inner surface of the drum are arranged projecting ribs parallel with the axis of the drum, and adjustable crossbars between the ribs, the crossbars having the shape of a part of a spiral. Instead of the crossbars, chains hanging loosely between the ribs may be employed. (See also Eng. Pats. 4560 of 1900 and 14,054 of 1902; this Journal, 1901, 344, and 1902, 1126.)—R. A.

Flasks for Volatile and other Liquids. H. Goetz, Frankfurt a/Main. Eng. Pat. 26,461, Dec. 1, 1902.

See Fr. Pat. 322,141 of 1902; this Journal, 1903, 288. —T. F. B.

Evaporators: Impts. in ——. D. A. Blair, Glasgow. Eng. Pat. 2731, Feb. 5, 1903.

In evaporators of either the single- or multiple-effect type, a tube or pipe is arranged either within or outside the calandria steam-heating vessel, in combination with a spiral or propeller-bladed conveyer, by means of which substances of a viscous or semi-liquid nature can be circulated downwards through the tube while they are being concentrated. —R. A.

Forcing and Drawing off Liquids Evolving Ignitable or Explosive Gases; Process and Apparatus for ——. C. Martini and H. Hüneke, Hanover, Germany. Eng. Pat. 4233, Feb. 23, 1903.

A non-oxidising gas, such as carbon dioxide, coal-gas, or ammonia, is forced under pressure into the reservoir containing the liquid, such gas serving to prevent the formation of an explosive gas mixture during the emptying of the reservoir.—R. A.

Apparatus and Process for the Centralisation of every kind of Chemical or Industrial Treatment of and Operation on any kind of Substances. J. Lühne, Aix-la-Chapelle. Eng. Pat. 8313, April 9, 1903.

See Fr. Pat. 330,322 of 1903; this Journal, 1903, 1078. —T. F. B.

[*Centrifugal*] *Liquid Diffuser.* W. Schwarzhaupt, St. Goar-on the-Rhine, Germany. Eng. Pat. 19,964, Sept. 16, 1903.

The liquid is raised by suitable lifting appliances, and distributed on the inner surface of a rotating cylindrical ring, which has a horizontal projecting flange or rim. By the centrifugal action, the liquid is spread evenly over the rim, and discharged from the circumference of the rim against "rebounding" plates, the coarser particles being caught on these plates and returned to the receptacle, while the finer particles pass through.—R. A.

United States Patent.

Centrifugal Separator. A. C. Van Kirk, Tiffin, Ohio. U.S. Pat. 745,696, Dec. 1, 1903.

The rotating chamber of the separator is formed with its walls inclined outwardly from the bottom, and then inwardly towards the top, a feed cone being mounted concentrically within the chamber. The discharge-opening is formed at the greatest periphery of the chamber, and the liquid outlet at the centre. The discharged matter is delivered into a movable accumulator, which is connected to a valve controlling the discharge opening, so that the valve is operated by the accumulation of the discharge. —R. A.

French Patents.

Vessels Unattacked by Acids; Manufacture of [*Acid Proof*] *——.* J. K. Field. Fr. Pat. 333,928, July 4, 1903.

See Eng Pat. 21,650 of 1902; this Journal, 1903, 1188. —T. F. B.

Centrifugal Apparatus; Arrangement for the complete Separation of Products expelled from ——, within the same Apparatus. Soc. F. Meyer's Sohn. Fr. Pat. 334,041, July 22, 1903.

The products expelled in a centrifugal machine are caught against an annular envelope, constructed in several pieces, surrounding the rotating basket, so that the lower border of the envelope may be moved outwards or inwards from or towards the axis of rotation, whereby the products projected against the sloping sides may be caused to flow into one or other of a series of conduits beneath, leading to separate receivers.—E. S.

II.—FUEL, GAS, AND LIGHT.

Coal-like Substance accompanying Caucasian Petroleum. K. Charitschkoff. J. russ. phys.-chem. Ges., **35**, 695—701. Chem. Centr., 1903, **2**, [23], 1297.

At Grosny and Tschatma the petroleum is accompanied by a coal very similar to lignite, but lighter, and containing less moisture than the latter. The coal cannot be regarded as of vegetable origin, since at Grosny it occurs in thin, regular strata above those in which the petroleum occurs, whilst at Tschatma it occurs in the same strata as the petroleum. The author considers that the coal is formed from the petroleum by dehydrogenisation, and in support of this view cites the formation of hydrogen sulphide from sulphur and petroleum, and the decomposition of petroleum by long-continued heating. Coal similar to that occurring at Tschatma has been found by the author in hot-petroleum mains.—A. S.

English Patents.

Oil-Gas; Apparatus for Making ——. R. Dempster, Marietta, Ohio, U.S.A. Eng. Pat. 16,764, July 30, 1903.

The apparatus consists of an oil-containing tank, in which a heating and agitating device is arranged. This consists of an upper and lower set of hollow horizontal arms, connected by vertical pipes, the lower set being provided with supporting rollers, which rest on the bottom of the tank. Steam is made to circulate through this device, being supplied by a pipe passing through a stuffing-box at the top of the oil tank, and withdrawn through a similar pipe at the bottom, and means are provided for causing the device and steam pipes to rotate. Pipes are arranged to supply steam to the tank, both above and below the surface of the oil By means of an air force-pump attached to the tank, air is made to enter the tank below the surface of the oil.—W. C. H.

Gas Burners; Impts. in Bunsen ——. E. Davies and D. Davies, both of Pontypridd. Eng. Pat. 17,319, Aug. 10, 1903.

The burners are adapted for use in gas heating apparatus and are made wholly or partly of heat non-conducting materials, such as asbestos and porcelain. The upper end of the chamber, in which the gas and air are mixed, is bell-shaped, and contains one or more perforated metal discs or caps, which are said to ensure proper mixing of the gas and air. The receiving pipe of the gas heating apparatus is made bell-shaped, and slightly larger than the upper end of the burner, to allow of the passage of air between the burner and receiving pipe.—W. C. H

Fuel from Peat, Waste Wood, Coal Substances, &c.; Manufacture of ——. M. Ekenberg, Stockholm. Eng. Pat. 20,420, Sept. 22, 1903.

See Fr. Pat. 331,720 of 1903; this Journal, 1903, 1120. —T. F. B.

United States Patents.

Gas [*Carbon Monoxide or Producer*]*; Method of Manufacturing ——.* C. W. Lummis, Cleveland, Ohio. U.S. Pat. 745,635, Dec. 1, 1903.

Powdered coal is introduced into a highly heated chamber, together with air and steam, the volume of steam and air being limited, so as to supply only sufficient oxygen to effect the conversion of the coal into carbon monoxide. The air and steam may be introduced at one or more stages of the process; when at more than one stage, provision is made for maintaining the heat of the gas generated on the first introduction.—R. A.

Gas; Method of Manufacturing ——. C. F. Brush, Cleveland, Ohio. U.S. Pat. 746,452, Dec. 8, 1903.

Water-gas is produced by subjecting bituminous coal or similar solid fuel at a high temperature to the action of steam and sufficient oxygen to maintain the necessary temperature. The volatile constituents of the fuel are led

from the chamber, in which the fuel is heated, into a second chamber containing checker brickwork, and there simultaneously subjected to the action of steam and oxygen.
—W. C. H.

Gas-Producer. G. Campion and M. Wyant, Anderson, Ind. U.S. Pat. 745,781, Dec. 1, 1903.

The fire-box of the gas-producer is polygonal, with portions of the internal walls shelving downwards and inwards towards the bottom. Pyramidal grates, inclined in alignment with the inclined portions of the walls, are mounted on ledges or supports in the bottom corners. In conjunction with the corner supports and ledges, a body is provided having "downward and inward inclined inner wall portions and triangular gates on the ledges" of such supports, and this body portion is adapted to bridge over the branches of a "branched water bosh" between the supports.—R. A.

French Patents.

Briquettes, Coal and Coke; Manufacture of ——. C. Plate and J. Lieb. Fr. Pat. 334,257, July 30, 1903.

This is a process by which the quantity of binding material, such as rosin, pitch, &c., usually employed in making briquettes, can be considerably reduced, and consists in mixing the coal or coke with the binding material, moistened with water, this water, either before or after passing the briquette press, being evaporated, so that the binding material is distributed in the finest condition between the different particles of coal or coke.—W. C. H.

Mixtures of Combustible Gases with Oxygen; Manufacture, Distribution, and Use of ——. Soc. L'Air Liquide (Soc. pour l'étude et l'exploitation des Procédés G. Claude). Fr Pat. 333,984, July 20, 1903.

Coal- or water-gas, or combustible gaseous mixtures, are mixed with so much oxygen as may be safely used, for lighting and heating purposes, without incurring danger of explosion.—E. S.

Gas Generators. J. R. George. Fr. Pat. 334,235, July 29, 1903.

See Eng. Pat. 16,263 of 1903; this Journal, 1903, 1189.
—T. F. B.

Acetylene; Purifying Material for ——. P. Grel. Fr. Pat. 334,111, July 24, 1903.

Ten parts of chromic acid are dissolved in 30 parts of nitric acid, and the solution is absorbed in 100 parts of kieselguhr. The product is claimed to extract organic compounds of sulphur, basic compounds formed by polymerisation, as well as the phosphine of crude acetylene.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM, AND MINERAL WAXES.

Coal-like Substance accompanying Caucasian Petroleum. K. Charitschkoff. II., page 14.

United States Patent.

Petroleum; Process of Desulphurising Sulphur-bearing ——. T. F. Colin, Elizabeth, N.J. U.S. Pat. 744,720, Nov. 24, 1903.

Petroleum and its distillates are desulphurised by agitating, by means of air, with a slightly acid solution of ferrous sulphate, copper sulphate, and sodium chloride, or, in general, "with a salt of a metal having two or more easily interconvertible states of oxidation, a salt of a metal forming a sulphide insoluble in acid solution, and a halogen compound." (See also U.S. Pat. 723,368 of 1903; this Journal, 1903, 547.)—T. F. B.

IV.—COLOURING MATTERS AND DYESTUFFS.

Indigo; Manufacture of —— *[from the Plant].* L. Bréaudat. Bull. Econ. de l'Indo-Chine; through Rev. Gén. Mat. Col., 1903, **7**, [84], 357—360.

One of the greatest difficulties in the manufacture of indigo in Cambodia and British India is the bad quality of the water; this may be remedied very largely by the addition of milk of lime, with subsequent filtration through flints and sand. The author finds also that a freshly prepared and rapidly dried sample of indigo shows, on titration with permanganate, 15—18 per cent. more indigotin than a sample dried slowly, under a heavy bed of mould, in the usual way. This difference is not due to the action of micro-organisms, these tending rather to purify the indigotin by decomposing the foreign nitrogenous matter; air has also no action on indigotin, neither has the precipitated proteid matter of the crude indigo; the amount of albuminous substances present is not alone sufficient to account for the large discrepancy, although permanganate is reduced by gluten in sulphuric acid solution. On extracting a poor (50 per cent.) indigo with boiling water, a solution is obtained which reduces permanganate, and which, on evaporation, gives a black residue of nitrogenous organic matter yielding ash; this residue appears to be a compound of indigo, since the author has succeeded in producing indigotin from it; it is also soluble in Nordhausen sulphuric acid, which should not, therefore, be used in the determination of indigotin. The following method appears to reduce the error to a minimum:—1 grm. of indigo is heated with 12 c.c. of sulphuric acid (sp. gr. 1·84) to 70° C. for an hour, poured into about 500 c.c. of water, and the whole made up to 1 litre; 25 c.c. of this solution, added to 250 c.c. of water, are used for the titration, the permanganate being preferably of such a strength that 1 c.c. = 0·0015 grm. of indigotin.—T. F. B.

Catechu. W. E. Ridenour. J. Franklin Inst., 1903, **156**, [6], 417.

Preparation and Purification of Tannin from Catechu.—The clear acetone extract of the powdered cutch is evaporated to dryness and the residue dissolved in hot water, cooled, and water added until it ceases to give a precipitate. The clear filtrate is shaken with ether to remove catechin, and then the tannin is removed by agitation with successive portions of acetic ether. The acetic ether is recovered, the residue dissolved in water, the solution diluted until it ceases to give a precipitate, and the clear filtrate agitated with acetic ether; this process of solution in water and extraction with acetic ether is repeated until the tannin is completely soluble in water. The tannin is then dissolved in a mixture of alcohol and ether, the solution filtered, and evaporated to dryness under reduced pressure, the tannin being obtained in a porous condition.

Properties.—Catechu tannin, as prepared by the above process, is of a reddish-brown colour, and completely soluble in water and alcohol. Ether containing alcohol and water dissolves it, but stronger ether has little solvent action. It behaves like the tannins from mangrove, canaigre, hemlock, rhatany, and the oaks, giving green precipitates with ferric salts.—R. S.

Triphenylcarbinol; Preparation of ——, *from Benzophenone.* R. Delange. Bull. Soc. Chim., 1903, **29**, [23], 1131—1132.

100 grms. of benzophenone are heated with 100 grms. of dry potassium hydroxide, to 170° C., for 20 hours under a reflux condenser; the product when distilled yields 15—16 grms. of benzene, whilst 45 grms. of benzoic acid are obtained from the aqueous extract of the residue; if, however, the aqueous extract, before acidification, be extracted with ether, 25 grms. of triphenylcarbinol are obtained; the reaction may be represented by the equation $3\,(C_6H_5)_2CO + 2\,KOH = (C_6H_5)_3C.OH + 2\,C_6H_5CO.OK + C_6H_6$. It is probable that an addition compound, $(C_6H_5)_2C.(OH).OK$, is formed at first, two molecules of

which react, with elimination of water, giving potassium benzoate and triphenylcarbinol.—T. F. B.

1.2-*Anthrahydroquinone and its Conversion into Alizarin.* K. Lagodzinski. Ber., 1903, **36**, [16], 4020—4022.

1.2-Anthrahydroquinone is prepared by the reduction of 1.2-anthraquinone suspended in acetic acid, with zinc dust. It forms greenish-yellow scales, easily soluble in organic solvents, and melting at 131° C. with decomposition. Acetic anhydride converts it into the diacetyl derivative of 1.2-dihydroxyanthracene, m. pt. 145° C. Treatment of the latter with acetic chromic acid mixture gives diacetylalizarin. This is easily saponified with alkalis to an alkali salt of alizarin, from which free alizarin is liberated by addition of acid.—A. B. S.

Brasilin from Brasileïn. J. Herzig and J. Pollak. Ber., 1903, **36**, [16], 3951—3953.

The quinonoid formula for brasileïn would be established were it found possible to convert the compound into brasilin by reduction, but this has never yet been accomplished. The triacetyl derivative $C_{16}H_9O(C_2H_3O_2)_3$ is obtained by the combined reduction and acetylation of brasileïn. A similar treatment of brasilin gave a substance having the same melting point and being almost certainly identical with the compound from brasileïn. This result does away with the chief objection to the quinonoid formula for brasileïn. The abnormal behaviour of the latter is due to the fact that, instead of a normal reduction, a series of complicated secondary reactions takes place.—A. B. S.

English Patents.

Azo Dyestuffs from 1.8-Azimidonaphthalene-4-sulphonic Acid; Manufacture of ——. O. Imray, London. From Farbwerke vorm. Meister, Lucius und Brüning, Höchst a/M. Eng. Pat. 953, Jan. 14, 1903.

Picramic acid, 6-nitro-2-aminophenol-4-sulphonic acid or 4-nitro-2-aminophenol, is diazotised and coupled, in alkaline solution, with 1.8-aziminonaphthalene-4-sulphonic acid. The resulting dyestuffs are identical with those obtained according to Fr. Pat. 316,866. (See this Journal, 1902, 911.)—T. F. B.

Anthranilic Acid and its Derivatives; Manufacture of ——. O. Imray, London. From Farbwerke vorm. Meister, Lucius und Brüning, Höchst a/M. Eng. Pat. 2302, Jan. 30, 1903.

An alkali salt or an alkaline earth salt of *o*-chloro- or *o*-bromobenzoic acid is heated, preferably under pressure, with ammonia or a primary fatty or aromatic amine, or a carboxylic or sulphonic acid of a primary aromatic amine, together with a small proportion of copper powder or of a copper salt. In most cases an alkali salt of the desired product separates on cooling.—A. B. S.

Sulphurised [Sulphide] Dyestuffs; Manufacture of Yellow ——. C. D. Abel, London. From Act.-Ges. f. Anilinfabr., Berlin. Eng. Pat. 3480, Feb. 13, 1903.

See Fr. Pat. 329,481 of 1903; this Journal, 1903, 1042.
—T. F. B.

p-Amidoxylyl-p-oxyphenylamine, and Analogous Compounds and Dyestuffs [Sulphide Dyestuffs] therefrom; Manufacture of ——. I. Levinstein, C. Mensching, and Levinstein, Ltd., Manchester. Eng. Pat. 2617, Feb. 4, 1903.

p-Aminoxylyl-*p* hydroxyphenylamine is produced by simultaneous oxidation of *p*-aminophenol with *p*-xylidine [$CH_3:NH_2:CH_3 = 1:3:4$] and subsequent reduction by sodium sulphide. If the *p*-aminophenol be replaced by *o* chloro-*p*-aminophenol, there is produced in an analogous manner *p*-aminoxylyl-*p*-hydroxy-*m*-chlorophenylamine. Analogous compounds are produced in the same way from *p*-aminophenol with mixtures of *o*-toluidine and *p*-xylidine, and from *o*-chloro *p*-aminophenol with *o*-toluidine. The compounds thus produced yield blue to greenish-blue sulphur dyestuffs on heating with sulphur and sodium sulphide for a prolonged period. The dyestuff formed from *p*-aminoxylyl-*p*-hydroxyphenylamine dyes unmordanted cotton bright blue shades, fast to acids, alkalis, and light. If *o*-chloro-*p*-aminophenol be used, the dyestuffs are slightly greener.—E. F.

Indigo; Manufacture of ——, *and of an Intermediate Product therefor.* O. Imray. From Farbwerke vorm. Meister, Lucius und Brüning, Höchst a/M., Germany. Eng. Pat. 4538, Feb. 26, 1903.

Glycollide or glycollic acid is heated with anthranilic acid, preferably in equimolecular proportions. Glycollic acid anilide *o*-carboxylic acid is thus formed. The alkali salts of this compound, when heated with a fixed alkali, yield a leuco compound, from the aqueous solution of which indigo is precipitated on oxidation, either with a current of air or in any other suitable manner.—E. F.

French Patents.

[*Azo*] *Dyestuffs for Wool; Production of* ——. Badische Anilin und Soda Fabrik. Fr. Pat. 328,086, Sept. 15, 1902.

See Eng. Pat. 20,000 of 1902; this Journal, 1903, 903.

T. F. B.

Azo Dyestuffs; Preparation of New Intermediate Products and New ——. Soc. Anon. des Prods. F. Bayer et Cie. Fr. Pat. 334,140, July 25, 1903.

Mono-acetyldiaminobenzene and mono-acetyldiaminotoluene are prepared by the moderate reduction of 2.4-dinitro-acetanilide or 2.4-dinitroaceto-*o*-toluide with iron and acetic acid. One mol. of a *p*-diamine is diazotised and coupled with 1 mol. of aminonaphthol sulphonic acid (2:8:6). The tetrazo compound obtained, is then coupled with 2 mols. of mono-acetyldiaminobenzene, or the similar toluene compound. The tetrazo compound can also be coupled with 1 mol. of one of the above compounds and 1 mol. of a suitable non-sulphonated base, such as phenylenediamine. In either case the product dyes unmordanted cotton in various shades of black.—A. B. S.

V.—PREPARING, BLEACHING, DYEING, PRINTING, AND FINISHING TEXTILES, YARNS, AND FIBRES.

English Patents.

Scouring or Cleaning Yarns; Machine for ——. G. Carter, Leicester, and J. & J. Baldwin and Partners, Ltd., Huddersfield. Eng. Pat. 27,991, Dec. 18, 1902.

In the usual yarn-scouring machine with radial arms, an upper row of revolving rollers is provided, pressing on the lower ones, either with their own weight or by means of springs, and so squeeze the yarn as it revolves on the lower rollers. Arrangements are added to prevent the yarn from getting entangled round the lower rollers.—A. B. S.

Indigo; Manufacture of Fabrics coloured with ——. J. Ribbert, Kreis Hagen, Germany. Eng. Pat. 28,646, Dec. 27, 1902.

See Fr. Pat. 327,763 of 1902; this Journal, 1903, 948.
—T. F. B.

Dyeing Mixed Silk and Cotton Goods with Sulphurised Dyestuffs. C. D. Abel, London. From Act. Ges. f. Anilinfabr., Berlin. Eng. Pat. 3479, Feb. 13, 1903.

See Fr. Pat. 329,422 of 1903; this Journal, 1903, 1044.
—T. F. B.

French Patent.

Printing Effects resembling Silk; Process for Obtaining ——. La Soc. Englische Wollenwaaren-manufact. (formerly Oldroyd and Blakeley). Fr. Pat. 333,835, July 15, 1903.

The process consists in printing a mixture of finely-powdered mica with some cellulose derivative, such as viscose. The mica and cellulose compound can be coloured previously. After printing, the material is dried on ordinary calendering cylinders.—A. B. S.

VI.—COLOURING WOOD, PAPER, LEATHER, Etc.

English Patent.

Dyed Paper; Process for Producing Coloured Effects on ——. O. Imray, London. From Farbwerke vorm. Meister, Lucius und Brüning, Hoechst a/Main. Eng. Pat. 2809, Feb. 5, 1903.

Designs are produced on dyed paper by applying to the paper a solution of a substance or substances which changes the shade of the dyestuff or dyestuffs used. For instance, substances which, by oxidation or reduction, destroy the dyestuff are suitable: such are sulphites or bisulphites, used with many triphenylmethane dyestuffs; hydrosulphite solutions, alkali chlorates, chlorites, bromites, hypochlorites, &c. may also be used. If two or more dyestuffs be used to dye the paper, the results are more marked; for instance, orange-yellow designs on a garnet-red ground are obtained by treating with potassium sulphite, paper dyed with an orange azo dyestuff and Magenta. Contrast effects may be produced if the discharge solution contain some dyestuff not destroyed by the substance used.—T. F. B.

VII.—ACIDS, ALKALIS, AND SALTS.

Hydrobromic Acid; Preparation of ——. R. L. Taylor. Lit. and Phil. Soc. of Manchester, Jan. 5, 1904.

It is well known that by the action of sulphuric acid on an alkali bromide, hydrobromic acid mixed with free bromine is obtained. If a strong solution of phosphoric acid be substituted for the sulphuric acid, pure hydrobromic acid will be obtained on distilling. The author proposes, however, a cheaper and equally efficacious method. A little amorphous phosphorus is added to the bromide and then a very little water. Strong sulphuric acid is next added and the mixture is heated, when hydrobromic acid is generated, free from bromine. It is stated that thus hydrobromic acid may be prepared, in quantity, just as conveniently as hydrochloric acid is, by the action of sulphuric acid on common salt. This hydrobromic acid is, however, not yet quite pure, since it contains a small amount of sulphur dioxide.—A. S.

Hydrofluosilicic Acid; Distillation of ——. E. Baur. Ber., 1903, **36**, [16], 4209—4214.

Stolba, in 1863, noticed that when hydrofluosilicic acid is boiled down in platinum, the residual liquid dissolves silica; an excess of hydrofluoric acid over the proportion 2HF:SiF_4 thus remaining, an excess of silicon fluoride must have been contained in the vapour. The hydrofluoric acid in the residue being itself volatile, regular results in investigating the progress of the distillation are only to be obtained by distilling from excess of silica. Looking at the reactions—

$$SiO_2 + 4HF \rightleftarrows SiF_4 + 2H_2O$$
$$SiO_2 + 6HF \rightleftarrows H_2SiF_6 + 2H_2O,$$

it would seem that dilution of the acid should increase the tendency to form hydrofluoric acid, and that the vapour from the dilute acid should contain more hydrofluoric acid, that from the concentrated acid more silicon fluoride, than the proportion 2HF : SiF_4. This the author has found to be the case. An acid containing 13·3 per cent. of hydrofluosilicic acid gives a distillate also containing H_2SiF_6 or (2HF:SiF_4); weaker acids give distillates containing relatively more hydrofluoric acid, and stronger acids distillates containing relatively more SiF_4. From these latter, silica separates after a time, from the reaction of the silicon fluoride on the water. If then concentrated hydrofluosilicic acid be evaporated alone, the residual acid will be capable of dissolving silica; whilst if a weak acid (5—10 per cent.) be evaporated, silica should deposit from the residue. This is found by experiment to be the case. Hence the etching effect on glass when hydrofluosilicic acid is evaporated in glass vessels. The author has shown that concentrated hydrofluosilicic acid contains no free hydrofluoric acid, and that on dilution no hydrolytic dissociation of the acid and consequent deposition of silica occurs. Possibly this is due to complete electrolytic dissociation into SiF_6-ions and H-ions. The concentrated acid (30 per cent.), heated with silica, does not undergo any such reaction as $5H_2SiF_6 + SiO_2 = 6HSiF_5 + 2H_2O$; the boiling filtrate deposits no silica on cooling and standing, and has the composition H_2SiF_6.—J. T. D.

Nitrites; Electrolytic Preparation of ——, *from Nitrates.* W. J. Müller. Zeits. f. Elektrochem., 1903, **9**, [51], 978.

On electrolysing hot saturated solutions of nitrates with a cathode of amalgamated copper at a current-density of 1—0·5 ampère per sq. dcm., nitrites are at first produced with a current-efficiency of 85—92 per cent. When the yield of nitrite reaches 50—60 per cent. however, the current-efficiency sinks to less than 40 per cent., owing to formation of ammonia. Attempts to separate mixtures of alkali nitrates and nitrites by crystallisation were unsuccessful. (See also Divers. J. Chem. Soc., 1899, **75**, 85; also this Journal, 1899, 273.)—W. A. C.

Alkaline-earth Metals; Acetates of ——. A. Colson. Comptes rend., 1903, **137**, [24], 1061—1063.

Solutions of calcium or magnesium acetate in glacial acetic acid, when saturated with chlorine, do not yield (as does the corresponding barium compound) acetochlorides; the original acetates are precipitated from the solution. Some reaction between the chlorine and the acetate does occur, especially in the case of magnesium; for the solution, evaporated *in vacuo*, yields a residue containing 1—2 per cent. of magnesium chloride. Glacial acetic acid acts but slowly on calcium oxide, and acetic anhydride appears to be without action on it, though the addition to the acetic anhydride of even a small proportion of acetic acid starts a reaction, which then proceeds as rapidly as though the whole of the liquid were acetic acid.—J. T. D.

Phosphorus [Scarlet]; Investigations on ——. R. Schenck. Ber., 1903, **36**, [16], 4202—4209.

Continuing his investigations on scarlet phosphorus (this Journal, 1902, 368; 1903, 494 and 1225) and the black substances formed by its reaction on ammonia and other bases, the author finds that the black compound produced by reacting with piperidine on solid phosphorus hydride, P_4H_2, almost certainly has the formula $P_4H_2.C_5H_{11}N$. It always contains an excess of phosphorus, however, which proceeds from decomposition of some of the phosphorus hydride into hydrogen, phosphine, and phosphorus. The compound is readily dissociated by water; and the hydrolytic decomposition is supplemented by reaction of hydroxyl-ions on the liberated phosphorus hydride, with production of hydrogen, phosphine, and hypophosphorous acid. For this reason the piperidine used in preparing the compound must be dehydrated with the utmost care by metallic sodium. The author has suggested that the black substance formed by acting with piperidine on his scarlet phosphorus is the same compound as the above, and that formed by substituting ammonia for piperidine is $P_4H.NH_4$ or $P_4H_2.NH_3$. A difficulty was felt here, inasmuch as ammonia was thought not to form a black compound with phosphorus hydride; but it is now found that this depends on the velocity of reaction, and that the black compound is formed if the two reagents be heated together in warm water. The black compound recently obtained by Stock by reacting with liquefied ammonia on yellow phosphorus is no doubt the same substance, formed probably by some such reaction as the following: $14P + 7NH_3 = 3P_4H(NH_4) + 2(NH_2.P{:}NH)$. Stock found that aqueous ammonia at a high temperature dissolved ordinary phosphorus completely, forming phosphine and ammonium hypophosphite only; but the author finds that if the temperature be not too high there is formed, especially in the sunlight, a black substance, no doubt $P_4H.NH_4$. In all probability this is, too, the substance long ago obtained by Flückiger from aqueous ammonia and white phosphorus, and supposed by him to be arsenic.

Leucitic Product; New or Improved ——, for the Manufacturing of Products or Compounds of Aluminium, Potassium, and Silicon. J. J. O'Brien, Manchester. From F. Ceribelli, Rome. Eng. Pat. 27,189, Dec. 10, 1902.

Rocks in which leucite occurs in an unaltered condition are reduced to a granular form, and sorted and sifted in suitable apparatus to obtain a product having from 50 to 90 per cent. of leucite associated only with minerals not attacked by ordinary acids. The product may then be treated with sulphuric acid, for instance, to obtain a solution from which compounds of aluminium, potassium, and silicon can be produced.—E. S.

Potassium Bichromate; Manufacture of ——. P. Spence and Sons, Ltd., H. Spence, and T. J. I. Craig, Manchester. Eng. Pat. 2211, Jan. 30, 1903.

A solution containing ammonium chromate (such as the solution of ammonium and of sodium chromate produced as described in Eng. Pat. 5015 of 1901; this Journal, 1902, 253) is treated with calcium hydroxide to precipitate calcium chromate, with liberation of ammonia, which is recovered. If sodium chromate is present, it remains undecomposed, and may be utilised by known means. The calcium chromate obtained as described, or otherwise, is suspended in water with potassium carbonate, ammonia, and carbon dioxide (or the two latter combined as ammonium carbonate) in such proportion as to form an equimolecular mixture of potassium chromate and of ammonium chromate. This is boiled as described in Eng. Pat. 11,847, 1900 (this Journal, 1900, 1014), to expel the ammonia, leaving a solution of potassium bichromate.

—E. S.

Ammonium Bichromate; Manufacture of ——. P. Spence and Sons, Ltd., H. Spence, and T. J. I. Craig, Manchester. Eng. Pat. 2223, Jan. 30, 1903.

Calcium chromate, obtained, for instance, as described in the preceding abstract, is suspended in water with ammonia and carbon dioxide, or with ammonium carbonate, and after separation of the precipitated calcium carbonate, the solution of ammonium chromate is boiled to drive off about one-half of the ammonia, which is recovered for re-use, and the solution of ammonium bichromate produced may be used in the production of other compounds of chromic acid, or in any desired way. Reference is made to Eng. Pat. 3895 of 1885, to U.S. Pat. 342,647 of 1886, and to Eng. Pat. 5015 of 1901; this Journal, 1902, 253.

—E. S.

Copperas or Sulphate of Iron; Utilising the Gases given off in the Calcination of ——. A. Campbell, Rugeley, Stafford. Eng. Pat. 2440, Feb. 2, 1903.

The gases evolved in the calcination of ferrous or ferric sulphate, are passed through a suitable apparatus for absorption by iron oxide, such as the scale from rolling mills, iron pyrites cinders ["purple ore," black peroxide from aniline works, &c.], &c. The ferric sulphate thus produced is stated to yield, when calcined, pigments of red and purple shade. Reference is made to Eng. Pat. 17,012 of 1888 and to Eng. Pat. 4001 of 1893; this Journal, 1894, 163.—E. S.

Electrolysis; Process for Decomposing Water by ——. G. T. Fuery, Birmingham. From W. F. M. McCarty and W. S. Beebe, U.S.A. Eng. Pat. 17,399, Aug. 11, 1903.

One oz. of sodium peroxide and 1 lb. of potassium citrate are dissolved in 2,000 lb. of water, and sulphuric acid of 66° B., is added in the proportion of 1 of acid to 500 parts of water; the liquid is subjected to electrolysis and the liberated gases are collected.—B. N.

Electrolysis of Chlorides of the Alkalis; Process and Apparatus for the ——. C. Kellner. Eng. Pat. 20,889, Sept. 29, 1903. XI. A., page 24.

Town Refuse; Methods of Destroying ——, by Burning and the Utilisation of certain Valuable Ingredients thereof. W. Naylor. Eng. Pat. 26,201, Nov. 28, 1902. XVIII. B., page 34.

United States Patent.

Silicon Chlorides, Hydrochloric Acid, and Alkali Hydroxides; Process of Producing ——. F. J. Machalske, Assignor to C. H. Lyon, both of Chicago, Ill. U.S. Pat. 745,966, Dec. 1, 1903.

A mixture of silica and a chlorine compound (such as sodium chloride) is electrically heated, with the use of silicon electrodes, to a sufficient temperature to bring about reaction, and produce silicon chlorides. To produce silicon tetrachloride, one part of silica is used, mixed with four parts of an alkali chloride. To obtain hydrochloric acid, the silicon chloride is brought into contact with water, and the silica produced is used as part of a new charge. The alkali oxide also produced in the process, is treated with water separately from the silicon chloride, to obtain an alkali hydroxide.—E. S.

French Patents.

Liquid Air; Manufacture of ——. J. Loumiet. Fr. Pat. 334,205, July 11, 1903.

The production of cold by the transformation of internal calorific energy into kinetic energy, as based on the difference of the specific heat in air under different degrees of compression, and hence in the passage of highly compressed air at a low temperature to a state of moderate compression, *i.e.* by expansion, for the production of a much lower temperature, is claimed. The apparatus includes a powerful compressor, a system of driers and purifiers, a long horizontal conical tube, with its contracted end outwards, communicating at its enlarged end with a vertical bottle, which latter also communicates by a valve at the side with a tube enclosing, with a small space between, the conical or expansion tube. The highly compressed air enters the apparatus at the outer end of the enclosing tube, passes through the valve at the opposite end into the bottle, and then through another valve into the conical tube, in which its expansion occasions a great fall of temperature. A turbine is connected to the end of the tubes to utilise the force available. A second bottle, to receive the liquid air produced, is arranged below the above-described bottle. Reference is made to Fr. Pat. 323,400 of 1902.—E. S.

Glass; Method and Apparatus for Manufacturing Sheet ——. W. A. Page, Morgantown, West Virginia, and F. L. O. Wadsworth, Allegheny, Pa., U.S.A. Eng. Pat. 22,575, Oct. 19, 1903.

The process consists in depositing a mass of glass between two rollers, and rolling it into sheet form by applying a positive pressure to hold the sheet in contact with one of the rollers, while it is acquiring a set, and then transferring the sheet to a table having the same cross-sectional contour as one of the rollers. Means are employed for holding the sheet upon the table, which by suitable gearing is made to travel with a speed equal to that of the surface of the roller that deposits the glass on the table. Figured glass sheets are produced by the use of a figured roller and similarly figured table. The glass is held in contact with the depositing roller and table by the application of an exhaust behind the glass. This is effected by using a hollow perforated roller, mounted on a hollow shaft, the end of which is connected with an exhausting apparatus. The hollow shaft is surrounded by a sleeve with radial partitions, which bear upon the inner surface of the roller and form with it a longitudinal vacuum chamber. The surface of the roller being perforated, the partial vacuum in the longitudinal chamber holds one surface of the glass sheet in contact with the surface of the roller. The travelling table is also hollow and perforated on the surface that receives the glass sheet. A partial vacuum is produced in the table by the exhausting apparatus, which is connected to a rectangular cross-head, fitted with suitable packings into the cavity of the table.—W. C. H.

Filter Presses [Potters' Slip]. T. Willett, Milton, Staffordshire. Eng. Pat. 1194, Jan. 17, 1903.

Each of the frames of the press consists of an outer rectangular frame of wood, &c., with two perforated plates or diaphragms, and staves or stiffening pieces between these plates. When the series of frames are assembled, they form chambers or cavities between them to receive the slip, the liquid from the slip passing through the perforated plates into the intermediate chambers formed between the plates, and being discharged through apertures in the lower parts of the frames.—R. A.

Kilns or Ovens for Burning Earthenware or Pottery or the like. G. J. Chambers and The Fulham Pottery and Cheavin Filter Co., Ltd., both of London. Eng. Pat. 1384, Jan. 20, 1903.

In order to prevent the emission of smoke, one or more shallow air flues are placed immediately above the furnace, extending horizontally to the back thereof, and then descending vertically or in an inclined direction so as to open into the furnace adjacent to the arch. The flue or flues are of a horizontal width equal to that of the furnace itself; they may be provided with tapering exits, and are regulated by means of a shutter, which also regulates the feed-hole. By means of a valve placed in this shutter the air-flues may be opened even when the feed-hole is shut.
—A. G. L.

Silica Glass; Manufacture of ——, *and Means to be employed therein.* H. A. Kent, London. Eng. Pat. 23,492, Oct. 29, 1903.

The apparatus, in which silica is melted by the oxyhydrogen flame or by electric heat, or by both together, is made of iridium or of iridium alloy in all such parts as may come into contact with the molten or softened silica; and the furnace walls are built of such resisting material as magnesia bricks, lined internally with silica glass. The vessel to contain the silica for fusion is closely covered, and may be shaped at the bottom according to requirements. An iridium tube of an external diameter corresponding to the internal diameter of the tube to be made, projects centrally through its side into the vessel containing the silica, and then bending downwards when in the middle, descends centrally through the bottom of this vessel. Compressed air may be blown through this tube; another tube enters the vessel near the top, into which air may be passed to press the molten or softened silica through the outlet at the bottom.—E. S.

Ceramic Ware; Manufacture of Glazed or Enamelled ——. A. Bigot, Paris. Eng. Pat. 3632, Feb. 16, 1903.

See Fr. Pat. 323,657 of 1902; this Journal, 1903, 496.

IX.—BUILDING MATERIALS, CLAYS, MORTARS AND CEMENTS.

Bricks; Re-pressing of ——, *and the Influence of the Amount of Water present during the Pressing.* C. Mühlhaeuser. Zeits. angew. Chem., 1903, **16**, [51], 1224.

A number of spherical bricks, each weighing 100 grms. in the wet state, and containing 15 per cent. of water, were formed from a mass consisting of 45 per cent. of clay and 55 per cent. of fireclay sand. One of these bricks was allowed to dry as usual, a second was subjected to a hydraulic pressure of 4,410 kilos. per sq. cm. after it had lost four per cent. in weight by drying, whilst two others were treated in the same way after their weights had decreased by 7 and 10 per cent. respectively; the three last balls were allowed to dry as usual after pressing, and their volume and porosity compared with that of the unpressed one. Burning tests were also carried out on these and some other similar bricks. From the results of these tests, it appears that, after drying, the re-pressed bricks occupy a smaller volume than the others, and that the volume and porosity of the bricks depend quantitatively on the amount of water present when pressed, both volume and density approaching a fixed limit, beyond which a decrease in the water content does not cause a decrease in volume or an increase in density. The diminution in volume on burning is about the same for both classes of bricks, the re-pressing being without any influence thereon.
—A. G. L.

English Patents.

Cement. T. B. Joseph, San Francisco. Eng. Pat 18,736, Aug. 31, 1903. Under Internat. Conv., Aug. 30, 1902.

Stone; Artificial ——. E. R. Sutcliffe. Fr. Pat. 333,826, July 15, 1903.

From 15 to 40 per cent. of cement, preferably Portland cement, is made into a paste with boiling water, or else mixed with cold water, and the mixture heated by steam, and, after being kept at about 100° C. for 15 to 20 minutes, is intimately mixed with 85 to 60 per cent. of any suitable waste material, such as slag, cinders, &c. The mixture is pressed into the required shape by means of a hydraulic press, the blocks produced being then hardened by exposing them to steam at a pressure of 7 to 10·5 kilos. per sq. cm. for 5 to 10 hours. In certain cases they may be immersed in water for some time before being heated. Lime may also be added to the mixture used.—A. G. L.

Plaster of Paris; Manufacture of ——. W. Brothers. Fr. Pat. 333,858, July 16, 1903.

Powdered calcium sulphate or gypsum is heated in water or in a solution of potassium sulphate, alum, or borax, to a temperature of from 100° to 130° C. The crystals formed are separated and dried without allowing them to cool to a temperature lower than 80° C.—A. G. L.

X.—METALLURGY.

Critical Points of Irons and Steels; Method of Determining ——. O. Boudouard. Comptes rend., 1903, **137**, [24], 1054—1056.

The author has already shown the importance of the thermo-electric properties of a heated iron bar during the process of cooling, as throwing light on the transformation temperatures. He has now adapted to this end Saladin's method of photographic registration. The bar of metal (10 cm. long, 1 cm. diameter) has a 5-mm. hole drilled in its centre to take the junction of a thermo-couple, and a saw-cut at either end, in which are fastened platinum wires leading to a sensitive galvanometer. The reflected rays of light from this and from the galvanometer of the thermopile are focussed on a sensitive plate, and the mirrors are so arranged that the oscillations of the two rays are in planes at right angles to one another. The bar is heated in a porcelain tube in an electric-resistance furnace for an hour and a quarter, and then allowed to cool slowly (six hours at least); during the time of cooling a record is left on the photographic plate.—J. T. D.

Silicon Steels; Composition and Properties of ——. L. Guillet. Comptes rend., 1903, **137**, [24], 1052—1054.

Micrographically, the appearance of silicon steels depends only on the amount of silicon they contain, and is not influenced by the amount of carbon. They form three groups:—1. Steels containing up to 5 per cent. of silicon, and in which the carbon is wholly combined. 2. Steels with 5—7 per cent. of silicon, and in which the carbon is partly combined, partly graphitic. 3. Steels containing more than 7 per cent. of silicon, and in which the carbon is wholly graphitic. This last group divides into two: those formed of a solution of silicon in iron, and containing rare scattered brilliant granules of Fe_2Si, and those containing a relatively large proportion of clean crystals of FeSi. Mechanically, the only silicon steels of any use are those containing less than 5 per cent. of silicon. These show a greater breaking stress and a higher elastic limit than non-silicon steels with the same amount of carbon, but the rise in these constants does not seem to depend on the amount of silicon in the steel above a certain minimum quantity. They show a greater resistance to shock after tempering than before, and this resistance is relatively high for the high-carbon steels. The constitution of silicon steels does not seem to be the same as that of ferrosilicons; especially do they differ in regard to the existence of the compound Fe_2Si. Most probably there are two solutions of silicon in iron—one containing dissolved silicon itself, the other containing Fe_2Si.—J. T. D.

Schuch Cyanide Process. Australian Mining Standard, Sept. 3, 1903; through J. Chem., Metall., and Mining Soc. of South Africa, 1903, **4**, [4], 185.

Low-grade ores are superheated, by steam, with cyanide solution (1 : 1), in air-tight tanks, compressed air is introduced through the bottoms of the tanks, and the contents are mechanically agitated. The solution is run over limestone and then through wood ashes, and passed through an asbestos filter previous to the zinc treatment. This process of first "refining" the solution before passing through the zinc shavings has proved to be a feature of importance, the solution, rid of impurities, becoming clear and active, so that the zinc shavings readily take up the gold contents, and it is said that ores containing not more than 3 per cent. of copper can be treated in less than eight hours.—T. F. B.

Silver Ores; Amalgamation and other Wet Processes for ——, in Mexico. H. F. Collins. Trans. Inst. of Min. and Metall. Paper read Dec. 17, 1903.

At Hacienda del Carmen, the ores, after "cobbing" and "sorting," are crushed (dry) in (7) large Chilian mills provided with steel tyres running on steel paths, of a capacity of 6—10 tons per day each. After passing through $\frac{1}{4}$-in. holes the ore is ground (wet) in *tahonas* or *arrastres*, 20 ft. in diameter, the daily charge being 4 tons. Only sufficient water is added during the grinding to yield a pulp in suitable condition for the subsequent treatment. The pulp is made up into *tortas* of 100 tons, and the amalgamation takes from 10 to 12 days in summer and up to 15 days in winter. The routine is as follows:—First day: Additions are made separately of 5—6 per cent. of salt and from $5\frac{1}{2}$ up to as much as $17\frac{1}{2}$ lb. per ton of copper sulphate, the average of the latter being from 6—9 lb. Second day: Mercury is added, 6 to 8 times the weight of silver present. Third day: After turning over, "copper precipitate" (prepared on the spot) is added, 7 to 18 oz. per ton of ore (45 to 110 lb. per *torta* of 100 tons). The *torta* is well trodden each day, and on the last, mercury is added to the amount of four times the weight of silver present, in order to collect the amalgam. The *lavaderos* in which the torta mud is washed, consists of pits 9 ft. in diameter by 10 ft. deep, in which, after charging, the agitators are kept going slowly for 25 minutes in order to settle most of the amalgam, and then the fluid mud, together with most of the coarse sand, is run out through launders. In the launders a considerable quantity of rough concentrates are deposited, which are rewashed on *planillas* to recover the small quantity of amalgam they retain; concentrates equal to about 7 per cent. of the weight of crude ore are obtained, the assay value being very little more than that of the original ore. These are sold to the smelters. The strained amalgam is formed into balls and retorted under a large cast-iron bell (*capellina*). Retorting takes 10 to 12 hours; the condensed mercury collects in a tank below, and the loss of that metal in the retorted silver and by leakage does not exceed $\frac{1}{2}$ per cent. of the total handled. The following figures show the costs per ton treated for 1900:—Crushing and grinding, 1·42 dols.; patio labour, washing *tortas* and concentrating sulphides, 0·57; Retorting, repairs, salaries, and general expenses, 1·18; salt, 110 lb. at $8\frac{1}{2}$ c., 0·94; bluestone, 8·4 lb. at 14 c., 1·17; precipitate, charcoal, castings, &c., 3·49; mercury, 2·73 lb. at 1·0 dol., 2·73; total, 11·50 Mexican silver dols. At *El Bote* a hard quartz ore is treated which averages about 28 oz. of silver and 8 dwts. of gold per short ton. It passes first through a Gates crusher, then through rolls, after which it is fed by Challenge feeders to a battery of (2) Chilian mills, which crush wet until 94 per cent. of the pulp will pass 120 mesh; the capacity of each mill is 10 tons per day. The pulp then passes to (10) large "spitzkasten," 12 ft. long by 7 ft. wide, provided with the Ayton intermittent discharge for the thickened pulp, which enters a series of (18) Boss pans. In the first pan additions of salt and copper sulphate are made—about 2 per cent. of the first and from 0·6 per cent. to 0·8 per cent. of the second. Lime is fed into the last of the pans to neutralise any remaining copper sulphate or free acid. The loss of mercury averages 2 oz. per ton of ore. From the settlers the pulp passes to (8) 6-ft. end-shake vanners, which yield about 15 tons per month of pyritic concentrates containing 32 oz. to 64 oz. of silver and 15 to 24 dwts. of gold per ton, with about 7 per cent. of zinc, 30 per cent. of silica, and 50 per cent. of iron pyrites. The tailings average about 4 oz. of silver and $1\frac{1}{2}$ dwt. of gold per ton. At the *Hacienda de Loreto, Pachuca*, the ore is crushed when necessary in (2) Blake stonebreakers, having a total capacity of 120 — 140 metric tons per 24 hours. The crushed ore passes to the (12) Chilian mills, arranged in two sets, one of eight and the other of four. Each mill is furnished with a Tulloch feeder, the feed being kept as low as possible. The screens are of 60 to 70 mesh; the capacity of each mill is 10 tons per 24 hours of very hard silicious ore. From the mills the pulp passes to a concentration plant of (3) Bartlett tables and (1) Wilfley, (*a*) in order to take out as much as possible of the silver values as a rich concentrate suitable for shipment to smelters; (*b*) to remove the particles of iron introduced by the process of crushing. With average Pachuca ore nearly one-half of the silver contents are thus taken out in a concentrate worth, say, 90 oz. of silver, from ore originally carrying 32 oz. per metric ton, leaving, say, 16 oz. in the tailings, which pass to masonry settling tanks, each having a capacity of 440 to 500 tons. After draining, the mud is run out and formed into a *torta*. The time occupied in amalgamation is from 15 to 22 days. The loss of mercury averages about 1½ oz. per oz. of silver recovered. The retort silver, which carries enough gold to pay for parting, is charged, 60 kilos. at a time, into one of (6) cast-iron pots, 2 ft. diameter, heated by wood fires, and with covers provided with pipes to convey the fumes to (3) chambers where sulphuric acid is produced by burning native sulphur in retorts. The gold obtained amounts to 1 to 1·2 oz. per 1,000 oz. of silver. The hot copper solution from the silver precipitation vats is siphoned off into a series of shallow lead-lined masonry tanks; in cooling it deposits on lead strips crystals of copper sulphate, which are utilised again in the patio. Practically the whole of the copper sulphate originally added to the torta is in this way regenerated. The mother liquors from the crystallising tanks, called *acido negro* (and still at a strength of 30° B.) are concentrated in a platinum still to 60 B°., and again utilised in the boiling pots, except a small quantity which is added at the end of the boiling operation in order to dilute the silver sulphate sufficiently to enable the gold slimes to settle out. After a considerable time the mother liquor becomes heavily charged with iron. It is then boiled down in shallow leaden pans till it begins to crystallise, when, upon cooling, it deposits nearly the whole of its sulphate of iron, which is utilised in the patio in place of copper sulphate. From the long masonry channels below the *lavadero* the slimes-pulp from the patio, after depositing its amalgam, passes through a series of (7) tanks, each 47 ft. long by 6 ft. 6 ins. wide by 5 ft. deep, where a portion of the slime settles out and is separately treated by concentration on (4) Wilfley tables. The middlings from the Wilfleys are returned; the tailings are said to contain but ¾ oz. of silver per ton. At the *Hacienda de La Union* the "Kröhnke" process is in operation. The pulp from the mills is spread out on huge floors to dry, after which the ore is treated with cuprous chloride solution in (13) large barrels about 8 ft. long by 5 ft. diameter, resting on rollers and rotated, by means of a spur wheel fixed on one end, from four to five times per minute; the charge of each is 4½ tons. The process is as follows: Salt is charged into an empty barrel equal to 25 per cent. of the silver present, sufficient hot water is then added to convert the ore into a thin mud, then mercury equal to eight times the weight of silver present, then the ore itself is run in. Scrap zinc is also added equal to 8 to 10 per cent. of the mercury to decompose the calomel formed by the reaction. The barrel is rotated for 5 or 10 minutes, and the cuprous chloride is then added, containing copper equal to from 50 to 80 per cent. by weight of the silver. The barrel is then rotated for six hours, the door is removed, and the contents are discharged into an inclined masonry channel which leads to the *lavadero*. The washing of the pulp and the treatment of the amalgam are effected in the usual way, except that a solution of ammonium carbonate is employed to remove cuprous oxide. The washed pulp is elevated by means of a tailings wheel, and run over a concentration plant comprising Bartlett tables, round buddles, and *planillas*. The concentrates recovered are of much lower grade than those at Hacienda de Loreto, owing to the greater perfection of the amalgamation. The final loss in tailings is said to be 0·3 oz., or only about one-third of the loss by the patio process, and the extraction is said to reach 99 per cent. of the silver contents of the original ore. The loss of mercury is only 7 oz. per 32 oz. of silver recovered. This process is much more expensive in working than the patio process, and the drying between the crushing and amalgamation is a great drawback, as it necessitates a large area, costly handling, and involves a considerable dust loss. The *Hacienda de San Francisco* employs the pan process. It is well arranged, and works at a low cost for labour, though the cost for power is high. It comprises 50 heavy stamps which supply (6) grinding pans, from which the pulp passes successively through one chemical pan, where salt (44 lb. per ton of ore), copper sulphate (19 lb.), and lime are automatically fed, then a series of (16) Boss pans in two rows, and lastly, (4) Boss settlers. The tailings from the settlers go to a concentration plant of (7) frue-vanners, the tailings from which are re-treated on (5) Wilfley and (1) New Standard tables; the concentrates from the tables treating vanner tailings are of higher value than the vanner concentrates, though smaller in quantity. The value of the tailings is 3 to 4 oz., so that on ores of 25 to 30 oz. the high losses in tailings more than offset the saving in treatment costs over the patio process. The *Hacienda de San Antonio* still employs the old Freiberg barrel process. At *Minas Nuevas*, near Parral, there are three lixiviation mills, only two being in working order. The capacity of No. 3 mill is 70 tons per day, which varies from 12 up to 30 oz., average about 25 oz. The ore is chiefly specular hematite disseminated through a limestone gangue, with some galena; it is tipped over grizzlies, the roughs are fed into two Blake stone-breakers, the crushed product is delivered to a rotary drier. The dried ore is mixed with about 10 per cent. by weight of inferior salt. Rotary self-feeders of simple construction then deliver the mixture to rolls, and the crushed material, after tromelling through a 35 mesh, is elevated and taken by belt conveyors to the roasters, (2) of White-Howell pattern, 33 ft. long by 5 ft. wide, making one revolution per minute. The leaching plant consists of 12 vats, each 14 ft. diameter by 7 ft. deep, and taking a charge of 25 tons. 880 charges are put through per year, which gives about five days for each charge, including filling and emptying. When full and levelled off, base-metal leaching is started by running on hot water and allowing it to leach through for 10 to 12 hours. Sodium thiosulphate solution (0·44 per cent.) is then run on, and 5 to 6 hours after, traces of thiosulphate appear in the effluent liquor, which is then turned from the base metal to the precipitating tanks. Leaching is continued for from 30 to 40 hours, when the level of the solution is allowed to fall below the surface and water is run on. Five or six hours after, the effluent liquor is found to have a strength of under 20 per cent. of thiosulphate, whereupon the weak liquors are turned back into the same tank in which the base-metal leach was already precipitated, and precipitated in the same way as was that leach. There are four precipitating tanks for the base-metal leach, and five for the thiosulphate solution, each 14 ft. diameter by 14 ft. deep. In treating the base-metal leach, from two to three times its volume of clean water is first added, and then 35—48 gallons of strong sodium sulphide solution. The contents of the tank are stirred up with a jet of compressed air and allowed to settle for one hour. For the precipitating tanks only 3 to 5 gallons of sodium sulphide solution are required for each charge, the stirring by means of compressed air is continued much longer, and from 2 to 3 hours are allowed for settling. The precipitate flows direct to the precipitate pumps feeding Johnson's filter presses. Once a month a general clean up is made; the total extraction on the whole process, notwithstanding the volatilisation loss in the furnaces, is 80 to 85 per cent. The press cakes are roasted, fused on a lead bath in cupel furnaces with Lynch test supports, a blast being produced by a No. 2 Root blower running at 85 revolutions per minute. The cupel bottoms are made in two layers, the lower of clay and ashes tamped in and dried slowly in the usual way. The upper or working test is formed of cement, which is mixed with water on the floor until it sets, the mass being then broken up and beaten into shape on the test with hot irons. Each hearth will last six months, but the working surface is renewed after each run by beating fresh cement upon it. Each campaign is commenced by melting down 175 kilos. of lead, and if high grade sulphides are being refined, the total charge is 500 kilos. of roasted sulphides, charged two shovelfuls at a time every few minutes until the whole has been absorbed and slagged, the operation taking about 24 hours. The silver obtained is poured into moulds, forming bars of about 75 lb. each. When low-grade sulphides are refined, each campaign lasts two to three days, lead is charged as required, and the total charge of the campaign is 500 kilos. of sulphides per day, together with 700 to 800 kilos. of wash-water precipitates and trough deposits. Each furnace uses per 24 hours about three cords of hard wood. The slags average 60 per cent. of lead and 250 oz. of silver per ton. At intervals they are smelted with iron ore in a small water-jacketed cupola. The resulting lead bullion is utilised for refining the high-grade sulphides. At the present time the high cost of fuel renders this the cheapest and most convenient reduction process for these ores in spite of the low extraction, but when other classes of ores become available it may prove cheaper to adopt a direct smelting process, by which 97 per cent. of the values could be realised in place of 80 to 85 per cent.—J. H. C.

Hydrochloric Acid and Oxygen; Action of ——, on Metals. C. Matignon. Comptes rend., 1903, **137**, [24], 1051—1052.

Hydrochloric acid gas in presence of oxygen attacks all the metals of the platinum group—palladium, ruthenium, iridium, rhodium, and osmium. The ease of attack is in the order given, palladium being attacked slowly in the cold, and very rapidly when heated in sealed tubes to 125° C., while osmium is but slowly acted upon in sealed tubes at 150° C. The mixture of hydrochloric acid gas and oxygen forms an excellent reagent for detecting the presence of iron in metallic gold, iridium, or rhodium.
—J. T. D.

English Patents.

Ore-Roasting Furnace. W. A. Maddern, Boulder City, Australia. Eng. Pat. 24,124, Nov. 4, 1902.

The furnace, of the horizontal type, may have one or any number of superposed hearths, on to the topmost of which, at the fireplace end, the ore is passed, and is mechanically rabbled to the opposite end, from which it passes on to the finishing hearth, along which it is rabbled in the opposite direction, for delivery on to the "cooling and regenerating" hearth, to which air is supplied at the delivery end, and as the ore is rabbled along this hearth, the air cools the ore and so abstracts the heat. This highly heated air is then passed or drawn onwards for oxidising in the furnace. The rabbling is effected by radially moved semi-rotating arms having blades on the under side, set at an angle, so as to turn the ore over on both forward and backward strokes to suit the traverse of the ore. Cold air is drawn through the rabble and passes into the furnace when heated. Water-cooled rabbles are also used. A special "toggle-joint" for the rabbler is described and claimed.—E. S.

Metals, Metalloids, and Compounds of the same [free from Carbon]; Process and Furnace for Obtaining ——. J. G. Lorrain, London. From Electricitäts Act.-Ges. vorm. Schuckert and Co., Nuremburg. Eng. Pat. 25,954, Nov. 25, 1902.

See Fr. Pat. 324,621 of 1902; this Journal, 1903, 636.
—T. F. B.

Ores; Concentrating —— [by Oil Process], and Apparatus therefor. A. S. Elmore, London. Eng. Pat. 184, Jan. 3, 1903.

Pulped ores are treated with oil, to separate the mineral valuable constituents, in apparatus comprising a mixing tank, a pump or other mixing device, and a floating oil seal to exclude air during the mixing; also, a settling tank having an outlet pipe in the bottom leading to the mixing tank of an auxiliary apparatus for treatment of the tailings, the overflow of the outlet pipe being below the level of the lip of the subsiding tank. The upper layer of mineral-charged oil is drawn or skimmed off, and treated with aid of heat in a centrifugal machine. Before separating, the oil may be thinned by some suitable solvent, in which case the recovered oil is subjected to a blast of cold air before re-use. Compare Eng. Pats. 6519 and 15,526 of 1901, and U.S. Pat. 692,643 of 1902; this Journal, 1902, 349, 862, and 618 respectively.—E. S.

Metallic Compounds, having Iron Partly or Wholly Decarbonised for their Principal Constituent; Manufacture of ——. S. Parfitt, Cardiff. Eng. Pat. 2612, Feb. 4, 1903.

Iron is melted and decarburised in the usual way until not more than about 0·1 per cent. of carbon remains, when it is "tempered" by addition of aluminium, or of aluminium and tungsten, instead of the usual carbon-carrying material. Suitable proportions to be added are 0·5 per cent. of aluminium and 0·3 per cent. of tungsten. The metal thus produced is stated to have similar properties to mild steel, but offering greater resistance to oxidation or attack by acids.—E. S.

Crucible Filling or Charging Apparatus. W. S. Mather, Newark, New Jersey, U.S.A. Eng. Pat. 18,751, Aug. 31, 1903.

The material is conveyed, in predetermined charges, in travelling pans or buckets, and discharged mechanically into the crucible, the holder of which is rocked or shaken, both vertically and horizontally, to settle or shake down the material.—R. A.

Aluminium Alloy, and Process of Producing the Same. A. J. C. de Monthy, L. Trézel, and V. Coppée, Paris. Eng. Pat. 19,504, Sept. 10, 1903.

See Fr. Pat. 325,191 of 1902; this Journal, 1903, 635. Silver (7·5 parts) may also be added to the mixture.
—T. F. B.

Air for Blast Furnaces and the like; Extracting Moisture from ——. J. Gayley, New York, U.S.A. Eng. Pat. 19,933, Sept. 16, 1903.

The air is drawn through a chamber, in which it is cooled to or below 0° C., thus causing its moisture to be eliminated, or reduced to a small and practically uniform proportion. From the cooling chamber, the dried air is fed by the blowing engine, and maintained constantly under compression until it enters the furnace or converter. (See also Eng. Pat. 11,091 of 1900; this Journal, 1901, 27.)—R. A.

Furnace or Kiln for Roasting Finely-crushed Ore, Burning Dolomite, and for other Purposes. G. O. Petersson, Dalsbruk, Finland. Eng. Pat. 22,162, Oct. 14, 1903.

Arches are "arranged in a shaft at different levels, zigzag with reference to one another, and with the space beneath the bottom arch or arches communicating at one end with the outer air, and at the other end with a [gas] fire-chamber, which in its turn communicates with one end of the space beneath the arch or arches above, while the other end of the latter space is in communication with a chamber in its turn communicating with the space beneath the top arch or arches, said space last mentioned communicating with a chimney, either directly or through the aid of other arches, compelling the gases to flow repeatedly back and forth in the furnace."—E. S.

United States Patents.

Steel; Manufacturing ——. C. V. Burton, London. Assignor to W. J. Hartley, London. U.S. Pat. 746,281, Dec. 8, 1903.

Acetylene, diluted with a "less explosive" gas, is blown through molten metal, the waste gases being brought into contact with the metal at an earlier stage of the process.
—E. S.

Ores; Apparatus for Treating ——. W. H. Adams, jun., Assignor to O. H. Hubbard, both of Los Angeles, Cal. U.S. Pat. 745,472, Dec. 1, 1903.

A tank is connected by a horizontal pipe near its top to a precipitation box containing a removable frame having precipitating devices with inclined collecting faces. A pump below the box draws liquid from it, which liquid is discharged into the tank near to the bottom, and also higher up at different levels, through pipes extending around the tank, having nozzles, some of which are pointed in opposite directions to others, the effect being that a rotary movement is imparted to the liquid in the tank, whilst a circulation of liquid goes on between the tank and the box. The bottom of the tank is conical, sloping upwards and inwards;

and there is a gutter around the base of the conical part in which amalgamated plates are fitted between the cone and the walls.—E. S.

Precious Metals; Process of Extracting —— [from Slimes]. T. J. Grier, Lead, S.D. U.S. Pat. 745,490, Dec. 1, 1903.

The slimes are placed in a settling tank, from which the thicker portion is drawn off into a leaching vat having a false bottom, through which a cyanide solution is passed under pressure, so as to displace the water in the slimes. The charge is then treated with air under pressure, after which the cyanide solution is displaced by a salt solution of greater density. In some cases, the slimes are first sprayed with a "protective solution to neutralise the acids therein," and the contents of the vat above its false bottom are heated in order to reduce the density of the upper portion of the liquid.—E. S.

Ore-Roasting Furnace. A. M. Bean, Assignor to the National Automatic Furnace Mills and Mining Co., both of Denver, Colo. U.S. Pat. 745,765, Dec. 1, 1903.

The ore-roasting cylinder, built in sections and capable of being revolved, is fitted centrally, by means of radial arms, within a double flue cylinder, arranged at a slight incline between the stack and combustion-chamber ends of the furnace, with which chamber the flue is in communication. The ore cylinder is fitted with spirally and longitudinally arranged perforated partitions, and the ore is fed by a conveyor in a casing, immediately above and the entire length of the furnace, and through a drier, from above the combustion chamber, and into a hopper, whence it passes through a horizontal pipe connected to a blower into the stack end of the ore cylinder, in which it is carried forward a certain distance by revolving blades, and then taken further by the spiral partitions, and has exit through the combustion chamber into a hood, whence means are provided for its discharge. Air is blown into the ore cylinder, and the sulphurous gases produced are exhausted through a pipe proceeding from a hollow trunnion at the delivery end, into a series of dust-collecting receptacles and condensers for the gases. A supplementary combustion chamber is arranged about the entrance end of the flues and ore cylinder. Numerous claims are made for details of the furnace. Compare U.S. Pat. 708,615 of 1902; this Journal, 1902, 1400; and U.S. Pats. 737,059 and 737,060 of 1903; this Journal, 1903, 1052.—E. S.

Metals; Process of Extracting ——, from Ores. E. B. Hack, Assignor to the American Filter Press Extraction Co., both of Denver, Colo. U.S. Pat. 745,828, Dec. 1, 1903.

Ore pulp is caked by pressure in such manner as to permit the moisture to escape, and a weak solution of the solvent (a cyanide, for instance) of the metals to be extracted, is passed through with compressed air; the pulp is then dried by air under pressure, followed by passage of a stronger solution of the solvent under the same conditions as before, the pulp being finally dried by air under pressure.—E. S.

Magnetic Composition [Alloy], and Method of Making Same. R. A. Hadfield, Sheffield. U.S. Pat. 745,829, Dec. 1, 1903.

A magnetic body is alloyed with from 1 to 5 per cent. of silicon; the alloy is heated to between 900° and 1,100° C., allowed to cool, and reheated to from 700° to 850° C., when it is allowed to cool slowly, to produce a magnetic material of "high permeability and low hysteresis action."—E. S.

Matte; Method of Converting ——. R. Baggaley, Pittsburg, Pa. U.S. Pat. 746,241, Dec. 8, 1903.

The method consists in introducing solid flux into the converter, fusing it with auxiliary heat, and then pouring the matte on the flux. Compare U.S. Pats. 722,198 and 727,057 of 1903; this Journal, 1903, 424 and 701.—E. S.

Copper Matte; Converting ——. R. Baggaley, Pittsburg, Pa. U.S. Pat. 746,249, Dec. 8, 1903.

The molten matte is intensely heated by the introduction into it of a large volume of air; a portion of the heat so produced is abstracted by a cooling medium at the beginning of the blow, while the oxidation is rapid, and at the end of the blow, when the oxidation fails, the heat is supplemented by a flame.—E. S.

Copper; Refining ——. R. Baggaley, Pittsburg, Pa. U.S. Pat. 746,246, Dec. 8, 1903.

A regulated stream of a reducing gas, independently generated, is forced through the copper when molten, after oxidation and removal of its impurities, and the stream is continued until a specimen of the copper cast in a test-mould, remains substantially level.—E. S.

Silicious Ores; Method of Recovering Values from ——. R. Baggaley, Pittsburg, Pa. U.S. Pat. 746,260, Dec. 8, 1903.

Silicious ores containing valuable substances are introduced in "solid lumps or particles" into a copper converter, and heated with an "auxiliary heat"; molten matte is then added, and the charge is Bessemerised and the ore fused. The valuable constituents contained in the product are recovered, and the gangue is used in the next operation as a flux.—E. S.

Smelter-Gases; Apparatus for Precipitating Injurious Fumes from ——. R. Baggaley, Pittsburg, Pa. U.S. Pat. 746,236, Dec. 8, 1903.

A succession of screens of "vegetable matter," carried by series of hollow and water-cooled rollers, are interposed in the path of the smelter-gases. The series of rollers are each set in a vertical perforated column, the perforations in which are upwardly inclined. The material of which the screens are composed is fed by hoppers, and a horizontal conveyor below the series of the vertical columns of the rollers removes the descending material. The screens referred to are kept wetted during the process.—E. S.

Arsenic Fumes; Method of Arresting ——. R. Baggaley, Pittsburg, Pa. U.S. Pat. 746,251, Dec. 8, 1903.

The arsenic fumes are arrested from smelter-gases by passing the latter through charcoal filters, wetted with an alkaline solution, such as of calcium sulphide.—E. S.

Furnace Gases; Apparatus for Arresting Impurities from ——. R. Baggaley, Pittsburg, Pa. U.S. Pat. 746,254, Dec. 8, 1903.

A travelling screen having filtering material between oppositely-acting rods with spring-backed faces, adapted to grip and move the screen, is arranged in the path of the gases. The rods are mounted on alternate cranks for reciprocal movement, and are parallel to each other, needful mechanism being provided.—E. S.

Furnace Gases; Apparatus for the Treatment of ——. R. Baggaley, Pittsburg, Pa. U.S. Pat. 746,255, Dec. 8, 1903.

The apparatus comprises a screen chamber through which "broken" filtering material is passed through a vertical column by means of an endless chain, the material having a series of pivoted supports separating it into layers, or portions of little depth, the supports constituting the links of the chain which engage with the rotating wheels, discharging the filtering material as they pass outside the chamber. The filtering material is supplied through a hopper to the top of the vertical column through which the material passes. There are cutters to the machinery moving within the chamber, whereby incrustations are removed from the walls. Means for wetting the screen material are provided.—E. S.

Smelter-Gases; Apparatus for Precipitating Injurious Fumes from ——. R. Baggaley, Pittsburg, Pa. U.S. Pat. 746,256, Dec. 8, 1903.

The gases traverse a chamber in which a series of inclined surfaces, with inclined gas passages, support a filtering material in "solid pieces" (or grains); there are feeding openings at the upper end, and a screw conveyor removes the material as it descends to the base of one column, and an elevating conveyor delivers it to the feeding opening of another column. Water is discharged upon the filtering material. The supports are movable by rocking mechanism. —E. S.

Smelter-Gases; Apparatus for Precipitating Injurious Fumes from ——. R. Baggaley, Pittsburg, Pa. U.S. Pat. 746,257, Dec. 8, 1903.

The gases pass through a chamber in which is arranged filtering material, carried by a travelling rack between adjacent chains or ropes having alternately arranged cross bars. The two sets of endless chains can be worked independently by apparatus outside the walls of the chamber, which the two chains only enter as they form a column in contact, face to face. The screen material is supplied from a hopper above the column, and provision is made for keeping it wet.—E. S.

Smelter-Gases; Process of Recovering Values [Valuable Dust] from ——. R. Baggaley, Pittsburg, Pa. U.S. Pat. 746,259, Dec. 8, 1903.

Valuable dust is recovered from smelter gases by causing them to come into contact with wet filtering material composed of ore, matte, or converter-slag, containing metals fit for reduction or smelting with the dust, so that the metals in both the dust and the filtering material may be recovered together. The apparatus shown for carrying out the process is the same as that described in the abstract of U.S. Pat. 726,256, above.—E. S.

Furnace-Gases; Apparatus for Removing Impurities from ——. R. Baggaley, Pittsburg, Pa. U.S. Pat. 746,261, Dec. 8, 1903.

In the chamber through which the gases pass, reciprocating bars are set in grooves in the chamber wall, carrying cutter bars so actuated as to dislodge deposited impurities from the walls. A charcoal screen is interposed in the path of the gases, means for removing which when impregnated, and for its replacement by fresh material, are provided. —E. S.

French Patents.

Sulphides, Metallic; Treatment of ——. R. C. Contardo. Fr. Pat. 334,103, July 24, 1903.

See Eng. Pat. 26,090 of 1902; this Journal, 1903, 1093. —T. F. B.

Aluminium; Manufacture of ——. G. Gin. Fr. Pat. 334,132, July 25, 1903.

Aluminium chloride is reduced by the zinc-sodium alloy ($ZnNa_2$) containing 40 per cent. of zinc. The sodium-zinc chloride formed is then employed as the fused electrolyte for the preparation of a further quantity of the $ZnNa_2$ alloy, and there is therefore a complete cycle of operations. —W. G. M.

Complex Ores; Extraction of the Metals from ——. J. Baxères De Alzugaray. Fr. Pat. 334,272, July 30, 1903.

Ores containing copper, lead, and zinc in relatively large proportion are digested with an acidulated solution of a chloride, whereby the copper is dissolved. Alkali and alkaline earth chlorides and ferrous and ferric chlorides are definitely enumerated as suitable. The copper is separated from the solution by usual means. The treated ores are washed, dried, and roasted at a comparatively low temperature. The roasted mass is treated with a weak acidulated chloride solution, and from the solution thus obtained, after concentration, the lead separates as chloride, and the zinc is precipitated by an alkaline-earth oxide. Sulphuric acid and sulphates may replace chlorides in the process, with certain modifications.—E. S.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

(A.)—ELECTRO-CHEMISTRY.

Nitrites; Electrolytic Preparation of ——, *from Nitrates.* W. J. Müller. VII., page 17.

English Patents.

Storage Batteries, and Apparatus to be Employed in the Manufacture thereof. T. A. Edison, Llewellyn Park, N.J. Eng. Pat. 322, Jan. 6, 1903.

See U.S. Pats. 721,682 and 727,118 of 1903; this Journal, 1903, 425 and 701.—T. F. B.

Water; Purification of ——. M. Otto. Eng. Pat. 12,522, June 2, 1903. XVIII. B., page 34.

Electrolysis; Process for Decomposing Water by ——. G. T. Fuery. From W. F. M. McCarty and W. S. Beebe. Eng. Pat. 17,399, Aug. 11, 1903. VII., page 18.

Electrolysis of Chlorides of the Alkalis; Process and Apparatus for the ——. C. Kellner, Vienna. Eng. Pat. 20,889, Sept. 29, 1903.

The electrolyte is admitted as a hot solution, in the case of sodium chloride about 22 per cent. in strength, into the anode compartment, and then made to traverse a filtering diaphragm forming the base of the anode compartment. The latter is supported, in a shallow trough forming the cathode and cathode compartment, in such a way that the cathode is not in contact with the diaphragm. This latter is constructed of asbestos or cellulose covered with powdered barium sulphate, and supported by slotted or perforated metal sheets or metal netting or grating of such wide mesh as not to act as electrodes. By maintaining a higher level of liquid in the anode compartment, or by applying suction to the cathode compartment, the liquid is forced from one compartment to the other. The cross sectional current-conducting area of the diaphragm is diminished by arranging insulating material in or upon the same, so that the flow of electrolyte through the filtering diaphragm is somewhat greater than the velocity of travel of the hydroxyl ions, which are moving in the opposite direction to the liquid. A modification is described, in which frames are arranged in series, after the manner of a filter-press. Each frame is divided into two parts by a grating carrying bi-polar electrodes, and the parts of the frames forming the anode compartments are separated by the filtering diaphragms from the parts of the adjacent frames forming the cathode compartments. Various forms of bi-polar electrodes are described, consisting of carbon rods passing at right angles through apertures in a plate of slate, wires wrapped round plates of glass, &c., or platinum foil wrapped round a carbon plate and lying with its cathode side on a plate of iron, nickel, or lead.—B. N.

Circulation of the Electrolyte in Electrolytic Processes; Method and Apparatus for Producing a Suitable ——. H. Koller, Vienna, and P. Askenasy, Nürnberg, Germany. Eng. Pat. 23,151, Oct. 26, 1903.

The diaphragm is arranged in wedge-shaped parts in such manner that the interstices between them form a zigzag path for the electrolyte introduced from the side of the anode, whereby the fresh electrolyte is caused to flow at right angles, or nearly so, to the lines of electrical force and to the direction of the diffusion within the diaphragm, thus effecting a "systematic lixiviation of the reaction-products formed at the cathode from the diaphragm." The arrangement described may be modified by building up the diaphragm parts, which are of parallelopiped form, so that they shall break joint in such a manner that "the electrolyte introduced from the side of the anode is forced on its way through the interstices to the cathode compartment to flow all around the diaphragm parts."—E. S.

United States Patents.

Carbon Chlorides and Silicon. F. J. Machalske, Brooklyn. U.S. Pat. 745,637, Dec. 1, 1903.

A mixture of silica and an alkali chloride is decomposed by heating electrically, and the silicon tetrachloride formed, is heated, by electric arcs, with carbon bisulphide, also produced electrically in an adjoining furnace; carbon tetrachloride and silicon bisulphide are thus produced. The

latter is heated in presence of carbon, thus producing silicon and regenerating carbon bisulphide. (See also U.S. Pat. 742,340 of 1903; this Journal, 1903, 1298.)
—T. F. B.

Silicon Chlorides, Hydrochloric Acid, and Alkali Hydroxides; Process of Producing ——. F. J. Machalske, Assignor to C. H. Lyon. U.S. Pat. 745,966, Dec. 1, 1903. VII., page 18.

Electrolysis of Metallic Oxides or Salts; Apparatus for the ——. Soc. Usines de Riouperoux. Fr. Pat. 334,229, July 29, 1903.

The current is taken out at the upper part of the vessel without traversing the base, the latter being separated from the walls by an insulating material, such as brick, set back in such a position that the electrolyte is not melted at this point. The electrolysis between the vessel and the anode is thus suppressed. The process is applicable to the electrolysis of all oxides and salts containing a metal lighter than the electrolyte.—B. N.

(*B.*)—ELECTRO-METALLURGY.

Copper Ores; Technical Experiments in the Smelting of ——, *in the Electric Furnace.* C. Vattier. Berg- u. Hüttenm. Zeit., 1903, **62**, 549. Chem.-Zeit., 1903, **27**, [99], Rep. 323.

Chili copper ores were smelted with carbon electrodes in quadrangular crucibles, using a current of 3,500—4,000 ampères at 110 volts. Eighteen tons of a 7 per cent. ore were thus concentrated to a 43—45 per cent. matte, the slag containing 0·1—0·2 per cent. of copper. In other experiments the same ores were fused with two carbon electrodes in a crucible 1·8 × 0·9 × 0·9 m. When the crucible was full it was tapped into a kind of fore-hearth, and the mass was reheated to facilitate the separation of the matte from the slag. In this way 25 tons of ore were smelted in 25 hours, using a current of 4,750 ampères and 119 volts. The matte contained silica, 0·8; aluminium, 0·5; iron, 24·3; manganese, 1·4; sulphur, 22·96; phosphorus, 0·005; and copper, 47·9 per cent. The slags may be treated in another furnace for the preparation of ferrosilicon, ferromanganese, and spiegeleisen. The cost, calculated for conditions of work in Chili (1 ton of coke = 80 M.; 1 kw. year = 30·40 M.), works out at 66·40 M. per ton of ingot copper from 16 tons of ore containing 7 per cent. of copper, or from a 4 per cent. ore at only 18 M.
—W. G. M.

Silver-Plating; Current Efficiency in ——. Zeits. f. Elektrochem., 1903, **9**, [51], 979.

The current-efficiency in a cyanide bath containing 1 per cent. of silver is 99·4—99·2 per cent., and in a bath containing 2½ per cent. of silver, 99·3—99·6 per cent. When a bath has been in use for a long time, foreign metals are dissolved, and the current-efficiency decreases slightly. In all cases the agitation of a plating bath lowers the current efficiency by ½—1 per cent., owing to absorption of oxygen.
—W. A. C.

English Patent.

Alkali Group; Production of Metals of the ——, *by Electrolysis.* E. A. Ashcroft, Runcorn. Eng. Pat. 12,377, May 30, 1903.

The alkali chloride is electrolysed in a cell with anode of carbon or carbon and lead, and a cathode of lead or other metal forming a fusible alloy with the alkali metal; the alloy thus formed is run off into a second cell, where it is used as the anode, in an electrolyte of alkali metal hydroxide; the cathode may be of nickel or iron; the contents of each cell are thoroughly agitated. The second cell may contain, instead of the hydroxide, sodium chloride, bromide, or iodide, or halides of the alkaline earths. Suitable apparatus is described, including a form in which the two cells are combined.—T. F. B.

French Patent.

Steel; Electro-Metallurgical Process for the Manufactur of ——. Soc. Electro-Metall. Française. First Addition, dated July 10, 1903, to Fr. Pat. 328,350 of Jan. 7, 1903. (See this Journal, 1903, 955.)

The oxidation of phosphorus is rendered complete in the converter, and the mixture of iron and oxide of iron which is obtained is transferred to the electric furnace. Suitable precautions are taken to prevent the entrance of slag containing phosphorus, to the electric furnace, and the de-oxidation of the metal is then carried out in the presence of a basic slag, which removes the last traces of impurities, notably sulphur. A very pure form of iron is obtained, and into this may then be introduced manganese, silicon, tungsten, molybdenum, &c., so as to give the special properties of hysteresis and permeability. In this way the production of new qualities of metal, which may be usefully applied in magnetic and electrical apparatus, is rendered possible.
—B. N.

XII.—FATTY OILS, FATS, WAXES, AND SOAP.

Indian Oils; Characteristics of Certain ——. J. Lewkowitsch. Analyst, 1903, **28**, [333], 342—344.

Pongam Oil is obtained from the beans of the Pongam tree, *Pongamia glabra*, which grows in East India, where it is used as a lamp oil and medicinally. The author extracted from the seeds 33·7 per cent. of the oil by means of ether, and in the following tables compares the results given by this oil with those from a specimen obtained from India:—

——	Oil extracted in Laboratory.	Specimen of Indian Oil.
Specific gravity at 40° C. (water at 40° C. = 1)	0·9352	0·9240
Specific gravity at 15° C. (water at 15° C. = 1)	..	0·93693
Saponification value	178	183·1
Iodine value	94·0	89·4
Reichert-Meissl value	..	1·1
Unsaponifiable matter (per cent.)	9·22	6·96
Melting point of fatty acids (freed from unsaponifiable matter) (° C.)	44·4	..
Butyro-refractometer reading	78	70
Free fatty acids, as oleic acid, (per cent.)	3·05	0·5

Pongam oil is of a dirty yellow colour, and at 15° C. is of the consistency of butter. The author points out that it might be utilised in the soap and candle industries, since large supplies are available.

Margosa Oil (*Veepa Oil, Veppam Fat, Neem Oil*) is obtained from the seeds of *Melia azedarach*, a large tree found in most parts of India and Burmah. The specimen examined by the author was solid at the ordinary temperature, and gave the following results:—Sp. gr. at 40°/40° C., 0·9023; sp. gr. at 16°/16° C., 0·91423; saponification value, 196·9; iodine value, 69·6; Reichert-Meissl value, 1·1; butyro-refractometer reading, 52·0; and solidification point of fatty acids ("titre"), 42·0° C.

Ben Oil.—Owing to its low iodine value this oil is employed for lubricating delicate machinery, such as watch springs. A specimen of oil obtained from the Jamaica plant, *Moringa pterygosperma s. oleifera*, gave the following results:—Sp. gr. at 15°/15° C., 0·91267; iodine value, 72·2; iodine value of liquid fatty acids, 97·53; and butyro-refractometer reading, 50·0. Two specimens of ben oil, representing the solid and liquid portions obtained by filtration at 0° C., had the following characteristics:—

——	Specific Gravity at 15°/15° C.	Iodine Value.	Butyro-refractometer Reading.
Portion solid at 0° C.	0·91840	109·9	59·0
Portion freed from solid at 0° C.	0·91998	111·8	60·5

A commercial sample of ben oil had an iodine value of 112·6, and gave a reading of 59 in the butyro-refractometer. It was regarded by the author as a filtered oil.—C. A. M.

Linseed Oil; Composition of ——. W. Fahrion. Zeits. angew. Chem., 1903, **16**, [50], 1193—1201.

The author describes experiments to show that it is not possible to obtain satisfactory results in determining the solid fatty acids by precipitation with barium acetate from an alcoholic solution. The method originally proposed by him, based on the oxidation of the unsaturated fatty acids with alkaline potassium permanganate and insolubility of the oxidation products in petroleum spirit, is also shown to be only approximately correct, since the saturated fatty acids yield insoluble oxidation products (about 2 per cent.), whilst on the other hand the unsaturated fatty acids yield some products soluble in petroleum spirit. These two sources of error nearly compensate one another, and the fatty acids from linseed oil when thus examined were found to contain 8·2 per cent. of solid acids—a result judged to be slightly too high from the results calculated by other methods. The oxidation of oleic acid with alkaline potassium permanganate was found to be very incomplete, whereas the linolic, linolenic, and isolinolenic acids gave nearly quantitative results. The author confirms the conclusion of Hehner and Mitchell (this Journal, 1899, 77) that Hazura's linolenic hexabromide must have contained linolic tetrabromide. He agrees, however, with Hazura's melting point (177° C.), and attributes the higher figure found by Hehner and Mitchell to too rapid heating. The general conclusion drawn from all the experiments is that the specimen of linseed oil examined had the following probable composition:—Unsaponifiable matter, 0·8; palmitic and myristic acids, 8·0; oleic acid, 17·5; linolic acid, 26·0; linolenic acid, 10·0; isolinolenic acid, 33·5; and glycerol radical (C_3H_5), 4·2 per cent.—C. A. M.

Fatty Acids; Separation of Different ——. A. Partheil and F. Ferié. XXIII., page 37.

ENGLISH PATENT.

Fatty Acids or their Glycerides; Process for Converting Unsaturated ——, *into Saturated Compounds.* W. Normann, Herford, Westphalia, Germany. Eng. Pat. 1515, Jan. 21, 1903.

Hydrogen, or a gaseous mixture containing hydrogen, *e.g.*, water-gas, is brought into contact with unsaturated fatty acids or glycerides in the presence of a finely-divided metal, such as iron, cobalt, and especially nickel, to act as a catalysing agent. It is stated that oleic acid is thus completely converted into stearic acid, and that the fatty acids of tallow have their melting point raised by about 12° C. by the process. The temperature and quantity of nickel are immaterial, and only affect the duration of the process. —C. A. M.

FRENCH PATENT.

Fatty Acids; Process of Saponifying ——. Raison Sociale Gebrueder Haas. Fr. Pat. 333,974, July 18, 1903.

Claim is made for the use of atmospheric air in a special apparatus to replace the greater part of the steam hitherto used to expel the carbon dioxide formed in the process of saponifying fatty acids by means of alkali carbonates. —C. A. M.

XIII.—PIGMENTS, PAINTS; RESINS, VARNISHES; INDIA-RUBBER, Etc.

(*A.*)—PIGMENTS, PAINTS.

ENGLISH PATENTS.

Paint; Manufacture of White ——. R. Scholz, Cologne. Eng. Pat. 13,298, June 13, 1903.

Lead oxide (100 parts) and sodium chloride (20—40 parts) are triturated with water, and the product is washed if desired, treated with sulphuric acid until just acid (about 15 parts), and dried.—T. F. B.

Lithophone [*Lithopone*] *and Glauber Salt; Process of Making* ——. W. D. Gilman, Baltimore. Eng. Pat. 23,189, Oct. 26, 1903. Under Internat. Conv., Oct. 30, 1902.

See U.S. Pat. 732,732 of 1903; this Journal, 1903, 918. —T. F. B.

FRENCH PATENT.

White Lead; Manufacture of ——. J. H. Montgomery. Fr. Pat. 333,851, July 16, 1903.

Molten lead is blown into the lower part of a closed chamber by means of an injector, the air supply of which comes from a tube lying in the furnace that melts the metal. At the top of the chamber is a perforated pipe, whence fine streams of water fall upon the "atomised" lead. The material is constantly stirred up by a screw conveyor, which finally delivers the partially oxidised lead into an agitator placed underneath the chamber. From this agitator a pump raises the material to a revolving drum, where it is further submitted to the action of air under pressure. It next descends to a second agitator identical with the first, whence the same pump lifts it into a flat mill, where it is ground into the water present. From the mill the cream passes to a third agitator, the pump finally raising it to a second revolving drum, where it is treated with carbon dioxide under pressure. The plant is so arranged as to be driven from the one countershaft, and the connections are such that the whole series of operations can be repeated if necessary.—F. H. L.

FRENCH PATENTS.

Varnish; Manufacture of ——. [*Use of Naphthalene.*] A. Crebert. Fr. Pat. 334,107, July 24, 1903.

Certain proportions of naphthalene are added to the usual ingredients in making oil varnish, the natural low degree of solubility of the hydrocarbon being increased by mixing it first with the resin or resinous material. The advantages claimed on behalf of the naphthalene are that the varnish is paler and clearer, does not "skin," is cheap, carries a higher proportion of pigment if made into paint, and dries to a hard strong film. (See Eng. Pat. 16,933 of 1902; this Journal, 1903, 705.)—F. H. L.

Oils; Heating Drying ——, *for the Manufacture of Varnishes.* W. Leppert and M. Rogovin. Fr. Pat. 334,233, July 29, 1903.

See Eng. Pat. 17,035 of 1903; this Journal, 1903, 1250. —T. F. B.

(*C.*)—INDIA-RUBBER.

Caoutchouc from the Asclepias syriaca L. J. Marek. J. prakt. Chem., 1903, **68**, [10], 459—460.

The latex from the *Asclepias syriaca L.* yields a dry residue of about 17 per cent., 1½ per cent. being real rubber and about 8·3 per cent. substances soluble in boiling 98 per cent. alcohol. The latter may be divided into two groups—one slightly soluble in hot 95 per cent. alcohol, but practically insoluble in the cold; the other fairly soluble in both hot and cold 95 per cent alcohol. The first group is mainly a mixture of an acetic ester and a butyric ester corresponding to the rational formulæ $C_{30}H_{49}C_2H_3O_2$, $C_{29}H_{45}C_4H_7O_2$. The second group contains similar esters, but with fewer carbon atoms. The author has not yet been able to ascertain whether the alcohol components of these esters are true alcohols or phenols, but their behaviour with nitric acid and Liebermann's reagent point to aromatic hydroxides and phenols. Further study of this latex may throw some light on the formation and constitution o india-rubber, since the hydroxyl derivative of the radical $C_{30}H_{49}$ of the ester $C_{30}H_{49}.C_2H_3O_2$ possesses only the elements of one molecule of water over and above the constituents required by the empirical formula for caoutchouc.—J. K. B.

English Patents.

Rubber, Gums, and like Substances; Apparatus for and Art of Extracting ——. W. A. Lawrence, Brooklyn. Eng. Pat. 21,890, Oct. 12, 1903.

See U.S. Pats. 741,257 and 741,258; this Journal, 1903, 1200.—T. F. B.

Vulcanisation of Rubber Goods; Machines for ——. E. Frankenberg, Hanover, Germany. Eng. Pat. 22,826, Oct. 22, 1903.

The permeable casings fitted to "cold-curing" vulcanisers, and described in an earlier patent (Eng. Pat. 24,574 of 1902), are replaced by lightly hung valves or ventilating flaps opening inwards, which allow fumes to be removed freely from the vulcaniser by an exhaust, but stop their egress into the workroom should the exhaust break down from any cause.—R. L. J.

XIV.—TANNING; LEATHER, GLUE, SIZE.

Tanning Materials and Tanning Extracts; Determining the Weight-giving and Leather-forming Properties of ——. J. G. Parker. XXIII., page 37.

English Patent.

Grain Leather, and Process for its Production. S. E. Page, London. From the Universal Leather Co., New York, U.S.A. Eng. Pat. 22,872, Oct. 22, 1903.

"Flesh splits" are coated with a layer of pure rubber cement, dried, and then pressed. If desired the split may be previously dyed, or dye may be mixed with the cement. The superficial layers of the split are thus united with the body substance, forming a compact surface which admits of the process of graining, and behaves quite differently from a merely filled, flesh split surface. For some purposes a leather dust is lightly applied to the cemented surface.

—R. L. J.

French Patent.

Tanning by Use of Tawed Skins. L. R. A. Berthon and L. A. M. A. Berthon. Fr. Pat. 334,006, July 18, 1903.

Skins previously tawed with salt and alum may be placed in strong tanning liquor (vegetable) without risk of injury; the latter gradually displaces the salt and alum, and produces ordinary leather. The tawing liquor contains salt (10 per cent.), alum (1 to 2 per cent.), and sulphuric acid (1 to 2 per cent.) or an organic acid (5 per cent.) and may be made up from old tan liquor instead of fresh water. After tawing for from 12 to 48 hours the skins are dried in the air, worked on the beam, and placed for 8—15 days in strong tan liquor, to which may be added alkali acetates or sulphites, or soluble salts of barium, strontium, or calcium (5—10 per cent.) to decompose the alum which is otherwise eliminated somewhat slowly.—R. L. J.

XV.—MANURES, Etc.

Lime and Magnesia in Soils; Influence of the Relative Quantities of ——, *on the Growth of Plants.* O. Loew. Chem.-Zeit., 1903, **27**, [100], 1225.

The author, in reply to Gössel, who had criticised his statement that the maximum yield of a crop cannot be obtained if the soil contains an appreciably greater amount of magnesia than of lime, sums up the question as follows. Magnesium salts and calcined magnesia, when present even in moderate amount, act injuriously on plants. A moderate amount of lime is advantageous on many soils, but with an excess, the yield again decreases. Calcium salts counteract the injurious action of an excess of magnesia, and, if present in sufficient quantity, allow the magnesia to play its part as a plant foodstuff. The conclusion drawn from these facts that, with a certain ratio between the amounts of the lime and magnesia, the maximum yield is obtained, has been confirmed by experiments. In the case of most of the cereals the best ratio is $\frac{CaO}{MgO} = 1$, but in the case of other plants, especially of those bearing more leaves, the amount of lime should be from two to three times that of the magnesia.—A. S.

Potassium Salts, 40 per cent.; Value of ——, *compared with Kainite.* W. Schneidewind. Arb. d. Deut. Landw. Ges., 1903, [81]; Biedermann's Centr. Bl., 1903, [12], 803.

The new 40 per cent. "potassium salts" contains three and a half times as much potassium as kainite, and may therefore be employed with advantage in the case of soils which are injured, as regards their physical properties, by large amounts of soluble salts. At the same time the character of the crop has to be considered, since the different potassium manures act very differently on different crops.

—N. H. J. M.

Fertiliser rich in Nitrogen and Potash; Treatment of Vinasses of Molasses Distilleries to obtain a ——. G. Gimel. Bull. de l'Assoc. des Chim. de Sucr. et de Dist., 1903, **21**, [5], 510—513.

After the vinasse has been concentrated to 30°—35° B., it is distilled with quicklime and the ammonia, trimethylamine and a little methylamine, which volatilise are collected in hydrochloric acid. By evaporating the solution obtained, the mass is converted into a residue of ammonium chloride and methylammonium chloride, which is collected and afterwards liquefied. The residue from the distillation with lime, is treated with sulphuric acid until almost neutral, the precipitate filtered or "spun off," and the liquid concentrated to dryness. Glycerin will have been in great part destroyed by the lime. To the mineral matter which remains, the ammonium chloride should be added. The composition of the fertiliser is then: nitrogen (in the form of ammonia) 4·3, calcium sulphate 37, potassium sulphate 28, sodium sulphate 4, potassium chloride 12, water 4, and various 10 per cent.

—L. J. de W.

Tobacco; Manurial Experiments with ——. Max Lehmann. Landw. Versuchs-Stat., 1903, **58**, 439—470.

Whilst nitrogen is equally necessary to all parts of the plant, potassium seems to be chiefly of use to the leaves and roots, and phosphoric acid to the stems. Chili saltpetre proved to be the best nitrogenous manure, then ammonium sulphate and blood-meal. The latter seems to act favourably on the burning properties of the tobacco. Excessive manuring is to be avoided, as it increases the amount of water in the leaves, and promotes a relatively greater development of stems and roots. Chlorides and sulphates are unsuitable, as they decrease the burning properties. Potassium carbonate and "martellin" act favourably in this respect. Perchlorate does not act poisonously on tobacco when present in moderate quantity, but favours the development of the leaves, and especially the roots.

—N. H. J. M.

English Patent.

Distillery Refuse or Pot Ale; Treatment of ——. C. Day and E. W. Gaskell. Eng. Pats. 2519 and 2520, Feb. 3, 1903. XVII., page 32.

French Patent.

Soot; Process and Apparatus for its Recovery ——, *for Utilisation as a Manure.* H. Lamiche. Fr. Pat. 331,085, July 23, 1903.

The stack or chimney to a works is provided with a pipe entering below the damper, and continued externally with enlargements forming chambers, circular in horizontal section, merging above into a pipe which enters the stack at a higher level, so that the draught carrying the soot may be directed through the passage thus formed. Each chamber is fitted with a baffle-plate curved downwards, from which, and also from the sides of the chamber, the soot is continually removed by a revolving scraper. The soot thus detached mingles with powdered peat, introduced by a conveyor from a hopper at the side. Water-sprinklers are provided to form the soot and peat into a mud, which is discharged through a vertical pipe. A set of wings is kept rotating in the lower of the chambers or enlargements. The proportion of soot and peat in the manure obtained is regulated by adjusting the rate of feed of the latter.

—E. S.

XVI.—SUGAR, STARCH, GUM, Etc.

Crystal Sugar; Valuation of ——, for Working up into Refined. K. Wasilieff. Zeits. Ver. deutsch. Zuckerind., 1903, **53**, [574], 1157—1182.

In the first period of the refining (the crystallisation in the filling-house included) the colour of the syrup from crystals of medium quality with a content in reducing bodies corresponding to 0·02—0·25 per cent. of copper oxide increases seven to eight fold. The more strongly the crystals are coloured, the more does the colour of the syrup increase at the time of refining. The quantity of reducing substances increased fourfold. The products of decomposition of sugar must be dextro-rotatory, seeing that the purity-factor is increased. In the same period and under the same conditions, syrups prepared from crystals which had become moist and deteriorated, with reducing bodies equivalent to 0·57 per cent. of copper oxide, increase in colour twelvefold. As the purity-factor has diminished, the decomposition products of the sugar and the altered non-sugar must be lævo-rotatory. That the sugar which had become moist was itself colourless was no guarantee that the colour of the syrup would not increase during refining. No relation could be fixed between the colour of the original syrup and that after treatment in the refinery. A characteristic peculiarity of stored sugar which had become moist is the presence of reducing bodies, and the estimation of these on some strictly uniform plan is of prime importance. Crystals containing much reducing bodies must be regarded as abnormal. Since the non-sugar formed in crystal sugars that have become damp is optically inactive, a deduction should be made from the direct polarisation. The non-sugar formed, which undergoes further decomposition during refining, easily combines with the lime added to the cleare, and in this condition acts as a strong molasses-former. The action of the reducing bodies in damp crystals on the colour of the syrups and on the quality of the refined sugar is so great and so vital that it is difficult to fix the deduction to be made in this case.—L. J. de W.

Sugar Losses in the Refinery. E. von Lippman. Zeits. Ver. deutsch. Zuckerind., 1903, **53**, [574], 1131—1138.

In the complete working up of raw sugar into loaves, cubes, granulated, &c., and molasses, there are certain as yet unavoidable and not inconsiderable losses which do not occur in the mere centrifugalising or washing-up of raw sugar. The losses in total weight and as indicated by polarisation (or sugar content) do not coincide. Many of these losses are purely mechanical; the decomposition of sugar or chemical loss, attended by an increase in organic non-sugar, is ascribed by the author to changes during boiling and re-boiling. Twenty years ago the massecuite boiled amounted to five times the weight of raw sugar produced, now it ranges from 2 to 2½ times that weight. The question of high or low pressure steam for boiling is of relatively minor importance, the greater length of time at the lower temperature outweighs any advantage it might offer. A sugar of the following composition: polarisation 95·5, water 1·8, ash 1·0, organic non-sugar 1·7 per cent., would yield 90 per cent. of white sugar and 9 of molasses, the latter containing only 4·14 of sugar, 1·8 of water, 1·0 of ash, and 2·06 of organic non-sugar; a loss therefore of 1 per cent. of weight, 1·36 of sugar, and a gain of 0·36 of organic non-sugar. As in a refinery working without char, experience shows the loss to be only 0·25 per cent., there is left 1·36 — 0·25 = 1·11 due to chemical changes, of which (regarding the organic non-sugar produced as equal to its own weight merely of sugar) 1·11 — 0·36 = 0·75 per cent. so-called "non-demonstrable" loss. The destruction of sugar during boiling is not confined to its conversion into stable bodies which remain in the syrup, but the non-sugars first formed are further changed into volatile products, which pass over into the water of condensation, and consist of furfural, furfuran derivatives, acetone, and formic and acetic acids. During the boiling of concentrated solutions of sugar the formation of invert sugar is not to be expected, but of products of overheating, characterised, as Herzfeld has pointed out in refinery products, by increasing differences between the results given by direct polarisation and the Clerget inversion method, and not to be explained by the presence of lævo-rotatory invert sugar, but by dextro-rotatory bodies of a nature between sugar and caramel. In the boiling of after products it sometimes happens that an increase in the destruction of sugar is accompanied by a decrease in the reducing power.—L. J. de W.

Sugar; Chemical Nature of the Bodies Produced by Overheating ——. F. Stolle. Zeits. Ver. deutsch. Zuckerind., 1903, **53**, [574], 1138—1149.

Following Wasilieff (this Journal, 1903, 38) the author gives the results of analyses of the clairce and massecuites which were obtained by working exclusively pure white Russian sugar, without the smallest addition of after products or sweet waters. The raw sugar used polarised 99·75 per cent. It was melted and heated to 90° C., and passed over char at 69°—70° Brix. Thus far the slight increase in reducing power lay within experimental errors, and a slight purification had taken place. The massecuite of the first product, which was neutral, showed an increase in reducing power and in organic non-sugar at the expense of the polarisation. The destruction of sugar continued at an increasing rate in the second, third, and fourth products. The difference between direct polarisation and the sugar by the Clerget inversion method increased at each boiling, although the after products were boiled at a lower temperature. The nature of the products of decomposition cannot be determined with certainty, but it is clear that not only dextrose and levulose but also dextrins are formed. At every boiling there is also a caramelisation which is independent of the acidity or alkalinity of the syrup and increases with the temperature. This caramelisation is of influence on the colour, but its influence is usually considerably overestimated. Very little real caramel is formed, but many colouring matters, erroneously regarded as caramel, are produced by the action of lime on the non-sugars. Pellet is of the same opinion, seeing that most (beetroot) molasses contain no reducing bodies, whilst caramel reduces copper solution. Little caramel is contained in refinery molasses. Caramel is not precipitated by lead acetate solution made alkaline with a fixed alkali, but only by ammoniacal lead acetate; the colouring matter of molasses, however, is almost completely precipitated by ordinary lead acetate, while the caramel remains and exerts its reducing power. Caramelan in solutions of 0·1 to 1 per cent. strength, when boiled for two minutes with copper solutions, show a reducing capacity which is a constant, and which rises in exact proportion to the concentration. The ratio of reduced copper to caramelan is 1 : 3·33. The reducing power increases with the duration of heating. It is thus of influence in the determination of invert sugar. By the hydrolysis of caramelan with 3 per cent. sulphuric acid, a hexose, levulinic acid and humin bodies are formed. The hexose closely resembles dextrose, but differs in its osazone, and in the products formed when its calcium salts are oxidised with bromine.—L. J. de W.

Beetroot Juice; Determination of the Purity of ——. P. Herrmann. Bull. de l'Assoc. des Chim. de Suer. et de Dist., 1903, **21**, [5], 528—532. (See this Journal, 1901, 843.)

From tests made by the author at the Dormagen sugar works during seven weeks of work in 1901—2, determining three times each shift the purity of an average sample of the chips by Krause's method and, at the same intervals, the purity of the diffusion juice, he concludes that the determination of the purity of the juice is of the highest interest for the due appreciation of proposed processes for the extraction of the juice as well as for experiments on manuring, cultivating, and for the selection of seed. The method of pressing is to be absolutely rejected for this purpose. The method of digestion proposed by Krause gives, when the conditions are maintained uniform, sufficiently regular values for the quotient of purity. The quotients of purity found by Krause's method correspond relatively to the quotients of purity of the juice contained in the beetroot. The method answers therefore to all that can be required of a process for the determination of the purity of the beetroot. For the uniform execution of the method it is recommended that coarse raspings be used: the temperature of digestion should be 90° C., and the digestion should be continued for 30 minutes.—L. J. de W.

Fertiliser Rich in Nitrogen and Potash; Treatment of Vinasses of Molasses Distilleries to obtain ——. G. Gimel. XV., page 27.

Pineapples; Quantity of Sugar admissible in Imported Preserved ——. H. W. Wiley. *Composition of Fresh and Preserved Pineapples.* L. S. Munson and L. M. Tolman. XVIII. A., page 33.

English Patents.

Sugar Juice; Treatment of ——. H. Winter, Charlottenburg, Germany. Eng. Pat. 26,570, Dec. 2, 1902.

The object of this process is the manufacture of first quality sugar and waste molasses only. The vacuum pan, of large capacity, is fitted with an agitating device consisting of two perforated tubular rings situated near the bottom. One of the rings has small perforations through which air, steam, water, or juice can be admitted at will, whilst the other has larger perforations for the admission of syrups or molasses. Near the pan are situated two clarifiers heated by steam, from which hot syrup is drawn for regulating the purity of the masseeuite towards the end of the boiling. The masseeuite is discharged from the pan in such a condition that its final mother syrup has a purity quotient below 40. It is cooled to a temperature of 35°—45° C. in crystallising vessels provided with stirrers. From these the masseeuite is pumped into a special form of malaxeur, in which it is diluted with final molasses to a workable consistency. Finally the sugar is separated in centrifugals, specially constructed so that the impure molasses may be collected separately from the purer washings, which latter are returned to the syrup tanks.—J. F. B.

Sugar; Apparatus for Whitening ——, *in Centrifugal Machines by means of Steam.* G. Deutsch, Vienna. Eng. Pat 28,186, Dec. 20, 1902.

Steam supplied by the main is separated into wet steam and water, which are fed into the casing of the centrifugal for diluting the molasses and syrups, and into dry steam, which, before entering the basket or drum, is wire-drawn in order to superheat it. The dry steam renders the molasses more fluid by warming rather than by diluting it and thus less sugar is dissolved. The combined steam drier and wire-drawing valve consists of an annular chamber containing a helical or screw-thread shaped partition, designed to admit steam at the top and to eject water at the bottom, while the lower portion of its inner side is provided with holes for the admission of steam to the central chamber, these apertures, or others at the top end of the central chamber, being adapted to be narrowed by means of adjustable slide-valves. The tubular steam-spraying nozzle has a widened end portion with a conically turned-out edge in the shape of a valve seat, and a valve having its tubular stem adjustably screwed into the nozzle behind the widened end portion. Steam passes through apertures in the tubular valve stem into the widened end of the nozzle and thence through the narrow slot between the valve and its seat.—L. J. de W.

Sugar; Manufacture of ——. J. Krivanek, Kiew, Russia. Eng. Pat. 18,044, Aug. 20, 1903.

The specification relates to a process for making sugar in slabs, strips, or blocks. The masseeuite is filled *in vacuo* into the moulds and the syrup contained in the mass is completely driven off with moistened and filtered air, before the addition of better syrup is begun. The apparatus consists of several chambers or compartments arranged in such a manner that the free inner chamber of the mould is hermetically insulated from that of the cleansing apparatus, and can be placed in communication in a suitable manner with the device for the moistening and filtration of the air, and also when required, with the corresponding cleare-collecting vessel. Means are also provided by which the filling of the masseeuite or filling mass into the mould is effected *in vacuo.*—T. H. P.

Soluble Starch; Process for Making ——. W. P. Thompson, Liverpool, from O. Bredt and Co., Unterbarmen, Germany. Eng. Pat. 22,370, Oct. 16, 1903.

This process consists in treating starch, or starch-containing materials of all kinds, in neutral, alkaline, or sulphuric acid solution, and preferably at a high temperature, with more permanganate than is necessary for oxidising the extractive impurities present, the action being continued until all the starch is converted into the soluble form. Starch thus treated may replace dextrin, gelatin, glue, gum, and the like.—T. H. P.

United States Patents.

Glucose; Process of Making ——. L. Roth, Kauth, Germany, Assignor to W. R. Gentzen, Gühlichen, Germany. U.S. Pat. 745,675, Dec. 1, 1903.

Claim is made for a process consisting in subjecting the cellulosic material under exclusion of air in a closed vessel to ozonised oxygen under pressure and afterwards adding sulphuric acid and maintaining the pressure in the vessel. —T. H. P.

Sugar; Process of Making ——. J. O. Schweitzer, Paris. U.S. Pat. 746,177, Dec. 8, 1903.

See Eng. Pat. 16,614 of 1901; this Journal, 1902, 1033. —T. F. B.

French Patents.

Cane Sugar; Production from Beet Sugar of Products Resembling ——. H. Winter. Fr. Pat. 333,813, July 13, 1903.

The pleasant flavour of unrefined cane sugar has been found to be due to residues of the products formed by the action of the lime used in manufacture upon the invert sugar or other hexoses. In order to imitate this flavour in the case of beet sugars, purified beet sugar crystals are "clayed" with a thin layer of a syrup which contains, in addition to saccharose and invert sugar, products formed by the action of alkalis upon invert sugar or other hexose under the influence of heat. In preparing these products it is preferable to employ caustic alkalis, but any substance with an alkaline reaction may be used; the decomposition is not carried so far as to produce caramel.—J. F. B.

Concentrators [for Saccharine Liquids, &c.]. F. Meyer. Fr. Pat. 334,241, July 29, 1903.

See Eng. Pat. 19,962 of 1903; this Journal, 1903, 1301. T. F. B.

Starch; Manufacture of Soluble ——. W. Wotherspoon. Fr. Pat. 334,154, July 27, 1903.

Starch is heated for a sufficient length of time with a mono-carboxylated organic acid, *e.g.*, acetic, formic, or lactic acid, preferably under conditions which do not cause the gelatinisation of the granules. For instance, dried starch is treated with glacial acetic acid to the extent of from 10 to 50 per cent. of its weight, the mixture is heated with agitation in a closed steam-jacketed converter until the starch is soluble in hot water. If an aqueous acid be employed, an inert dehydrating agent may be used, such as alcohol or brine, to prevent the gelatinisation of the starch. The acid is recovered by distillation or other means.—J. F. B.

XVII.—BREWING, WINES, SPIRITS, Etc.

Yeast; Contribution to the Study of ——. J. J. van Hest. Zeits. ges. Brauw., 1903, **26**, [43], 701—706.

Absorption of Nitrogen Compounds by Yeast Cells.—The author's experiments with top-fermentation yeast show that good pitching yeast does not absorb any nitrogen compounds immediately after it has been mixed with wort, nor does it increase the percentage of nitrogen in the wort. On the other hand, inferior yeast, or such as has been improperly washed, will absorb nitrogen compounds as soon as it is brought into contact with wort, and bad or enfeebled yeast (the latter containing numerous dead cells) increases the nitrogen content of the wort, this result being specially noticeable in yeast that has been killed by artificial means.

Enzyme Action without Reproduction.—Up to a certain point this action is found to proceed without any cell reproduction; moreover, it is independent of the temperature. Weak yeast pitched and allowed to ferment at low temperatures, dies, and the contents of the dead cells are dissolved by the wort, wherein they give rise to a considerable loss of extract, the amount of zymase then coming into action being probably much greater than in cases in which the cells remain alive. In one case an addition of 1·2 per cent. of yeast to the wort reduced the extract in the latter from 10·9 to 6·0 per cent. Balling, without any cell reproduction being noticeable. In other experiments, wort of a gravity of 10·7 per cent. Balling was pitched with 0·5 per cent. of wet yeast, at an initial temperature of 11° C., and the gravity was tested daily. At the same time a portion of the wort was drawn off every day for a week, bottled, stored for 10 days at 0·5° C., and the gravity determined after filtration. The results are given in the following table:—

	From the Fermenting Vessel.		From the Bottles.		Loss of Extract without Growth	
—	Temp. °C.	% B.	Temp. °C.	% B.	Temp. °C.	% B.
Initial	10·0	10·7	..	..	..	..
After 1 day ...	10·4	10·0	0·5	9·5	..	0·5
„ 2 days...	10·9	9·1	0·5	7·8	..	1·3
„ 3 „ ...	12·1	7·0	0·5	5·6	..	1·4
„ 4 „ ...	13·7	4·4	0·5	3·9	..	0·5
„ 5 „ ...	13·6	3·4	0·5	3·1	..	0·3
„ 6 „ ...	11·7	3·0	0·5	3·0	..	0·0
„ 7 „ ...	9·8	3·0	0·5	3·0	..	0·0
		(7·7)				(4·0)

This procedure was varied in another instance by bottling two samples of the fermenting wort on the third day, cooling one to 0·5° C. and the other to 5·5° C., and storing them for six days. The second bottle was then cooled to 0·5° C., and the examination gave the following results:—

	From the Fermenting Vessel.		From the Bottles.		Loss of Extract without Growth.	
—	Temp. °C.	% B.	Temp. °C.	% B.	Temp. °C.	% B.
Initial	8·5	10·7	..	..	..	..
After 3 days..	9·9	7·8	0·5	7·8	5·5	7·8
„ 6 „ ..	11·8	3·5	0·5	6·8	5·5	5·9
„ 7 „ ..	10·7	3·2	0·5	..	5·5	..
„ 10 „ ..	..	..	0·5	6·1	5·5	5·3
„ 13 „ ..	..	..	0·6	5·8	0·5	5·0

The ready-formed zymase thus produced a loss of 2·0 and 2·8 per cent. of extract respectively. This is considered to indicate the possibility of arresting fermentation at any desired attenuation, and thus produce beer with a high percentage of extract and little alcohol. The amount of zymase ready formed in 1 litre of normal yeast cells is sufficient to ferment 870 grms. of sugar. —C. S.

Accumulation of Zymase in Colonies of Top-fermentation Yeast.—That yeast grown under conditions favouring reproduction, but in presence of very little sugar (*e.g.*, as colonies on malt gelatin plates), does ferment the sugar and liberate carbon dioxide, can be demonstrated by the colour change produced in gelatin stained with blue litmus and superimposed on the culture. Similar colonies transferred to a solution containing 2·2 per cent. of saccharose, and stored at 17·5 C., were found to have fermented 2 per cent. of the sugar in three days; and in another case a 10 per cent. solution of saccharose was completely fermented in five days. These experiments show that yeast cells cultivated on wort-gelatin plates develop zymase, which is then accumulated in considerable quantities. Even when grown on meat-gelatin plates, and under very unfavourable conditions, the cells begin to ferment when introduced into a medium containing sugar. The deduction from these phenomena is that the formation of zymase bears no relation to the amount consumed, but occurs to a definite extent under certain conditions of environment.—C. S.

Yeast; Treatment of Top-Fermentation ——. J. J. van Hest. Zeits. ges. Brauw., 1903, **26**, [47], 787—788.

Theoretically, the best way to separate the yeast from the barm is by leaving it to settle down, but it was customary to aid and accelerate the operation by washing. In attempting to ascertain how much water may be safely employed, so as not to weaken the yeast by extracting its nitrogenous constituents, the author examined a number of samples of the beer that separates from the barm, and found them to contain on the average 75 grms. of nitrogen per hectolitre. He concludes that so long as the total liquid in contact with the cells contains ¾ per cent. or more of dissolved matter, there is no danger of lixiviation. The importance of using sterilised water for washing yeast was shown by experiments which proved that the voluminous flakes of yeast carry down with them practically all the bacteria present in the water. Further experiments on the prolonged washing of yeast, under conditions precluding the reproduction of the yeast and any bacteria present, showed that between 20 per cent. and 30 per cent. of nitrogenous compounds can be extracted from the yeast in this way. In practice the amount of water generally used is too small to cause any injury by such extraction; but the point is one that should be borne in mind, and particular attention should be bestowed on the freedom of the washing water from bacteria.—C. S.

Pitching Yeast; Determination of the Number of Cells per Litre in Top-fermentation ——. J. J. van Hest. Woch. f. Brau., 1903, **20**, [51], 614—617.

In German top-fermentation breweries the surface yeast is skimmed off and collected in a tub for subsequent use as pitching yeast. Sometimes the frothy yeast is washed with water and allowed to settle, the supernatant water being decanted off. The concentration of this sedimentary pitching yeast is liable to fluctuations of about 100 per cent., which may have a disastrous effect upon fermentations which are pitched with a constant volume of the yeast. The author finds the most rapid practical method for determining the concentration of the yeast to be as follows:—100 c.c. of the pitching yeast are placed in a conical cotton bag, the weight of which is known. The yeast is drained until all the water has run off clear, the bag is then whirled in a centrifugal machine for 20 minutes at a speed of 180 revolutions per minute and then weighed again. The "centrifugal yeast" is thus obtained in a form containing 25 per cent. of dry substance, with a maximum error of only 5 per cent., and the weight of "centrifugal yeast" per litre of pitching yeast is thus found. "Centrifugal yeast" contains on an average 0·7 billion cells per 100 grms. By daily determinations, for several months, of the quantity of "centrifugal yeast" obtained per litre of pitching yeast in practice, the author has defined an average concentration which he takes as the normal standard. One litre of standard yeast contains 600 grms. of excess water and 400 grms. of "centrifugal yeast," containing 100 grms. of dry substance, sp. gr. 1·371, with 47·13 per cent. of albuminoids. Volumetrically, 1 litre contains 600 c.c. of excess water, 371·4 c.c. of "centrifugal yeast," and 28·6 c.c. of carbon dioxide, including 71·4 c.c. of dry substance. In short, 1 litre contains 900 grms. of water and 100 grms. of dry yeast, equal to 3 billion cells. The quantity of any pitching yeast required for pitching the wort at constant proportions may be calculated from the equation :—$G = \frac{400}{d} m \times hl$, where G = the volume (in litres) of pitching yeast required, 400 = the weight of "centrifugal yeast" in a litre of standard pitching yeast, d = the weight of "centrifugal yeast" found in a litre of the pitching yeast to be used, m = the standard proportion of pitching, *i.e.*, the volume (in litres) of standard pitching yeast which it is desired to add per hectolitre of wort, and hl = the volume of wort in hectolitres.—J. F. B.

Yeast ; Behaviour of ——, in Mineral Nutritive Solutions. A. Kossowicz. Zeits. landw. Vers. Wes Öst., **6**, 731—737. Chem. Centr., 1903, **2**, [23], 1286. (See also this Journal, 1903, 374.)

The results of further experiments confirm Wildier's view that the activity of yeast in nutritive media is dependent upon the presence of certain organic compounds, besides sugar and mineral constituents (nitrogen in the form of ammonium compounds). In ordinary nutritive solutions containing sugar, pure yeast cultures when present in very small quantities do not multiply. With somewhat larger quantities (more than 100 cells) of yeast, owing evidently to the organic matter which is simultaneously introduced into the solution, reproduction occurs, but only to a slight extent, and no perceptible fermentation is induced. Large quantities (one million cells) of yeast both multiply and bring about fermentation. Experiments made to ascertain the influence of calcium and iron compounds on the propagation of yeast and on fermentation, showed that calcium in the form of phosphate and chloride has a favourable influence. Iron in the form of sulphate, and to a less extent, in the form of chloride, has also a favourable effect, but not so considerable as that of calcium.—A. S.

Enzymes, especially Lactase ; Sensitiveness of ——, to Alcohol and Acids. T. Bokorny. Milch-Zeit., **32**, 641—642. Chem. Centr., 1903, **2**, [24], 1334.

Zymase was quickly destroyed by absolute alcohol, and was rendered less active by the action of 10 per cent. alcohol after one week. Invertase of yeast was not destroyed in 20 days by the action of absolute alcohol; maltase was less resistant, but appeared to differ in its behaviour according to the kind of yeast by which it was secreted. Lactase was not affected, with regard to its action on lactose, by 10 per cent. alcohol. The fermenting power of pressed yeast was destroyed in 26 hours by 0·5 per cent. sulphuric acid, in five days by 0·1 per cent. acid, but not completely even in six days by 0·02 per cent. acid. By 0·5 per cent. lactic acid the fermenting power was considerably diminished in four days. Lactase is not affected by lactic acid even at a concentration of 1·6 per cent.—A. S.

Amylo-Coagulase. A. Boidin. Comptes rend., 1903, **137**, [24], 1080—1082.

This coagulase exists not only in the grains of cereals (Wolf and Fernbach, this Journal, 1903, 1302), but also in cultures of saccharifying moulds. Its action effects the precipitation, along with starch, of some of the diastase present. The diastatic activity of the solution diminishes in consequence, though the diastase continues to manifest part of its activity even after precipitation. Some of the diastase also precipitates on the matters left insoluble at the end of the fermentation; after thorough washing and centrifugal dryings, these insoluble substances still produce sugar from Lintner's soluble starch. The coagulation of starch by amylo-coagulase is quite a different phenomenon from the precipitation (called by Maquenne the reversion) of starch solutions sometimes observed, which is due to traces of alkali.—J. T. D.

Barley ; Judging Malting ——, by Analysis. C. J. Lintner. Zeits. ges. Brauw., 1903, **26**, [45], 729—734.

So far as the moisture content is concerned, the maximum limit should be fixed at 15 per cent., and any excess should form the basis of a reduction in the price. The system of valuation recommended by Haase, in which the percentage of albuminoid or protein is taken as the basis, with 10 per cent. as the standard, and 11 per cent. as the extreme maximum permissible, appears to give the most satisfactory results. Bauer has traced a fairly definite relation between the percentages of albuminoid and extract present in barleys, 9—10 per cent. of the former corresponding to 78·7 per cent. of the latter; 11 per cent. to 77·4 per cent.; 11—1 per cent. to 76·1 per cent.; and over 12 per cent. to 74·4 per cent. of extract. The separation of the barley into three grades by means of Steinecker sieves, with meshes of 2·8, 2·5, and 2 mm. aperture respectively, is also of assistance. The proportions of the three grades should be 85—90 per cent., 10—15 per cent., and 3 per cent. respectively. —C. S.

Malt ; Relations between the Protein Content and the Yield of Extract of ——. H. Hanow and D. Neumann. Woch. f. Brau., 1903, **20**, [50], 601—602.

In the following table are collected the average results found for the percentage of protein and the percentage of extract (in fine meal) in 203 samples of malt, the colour of which varied only within narrow limits :—

Number of Samples.	Protein. Per Cent. on Dry Substance.	Extract in Fine Meal according to Balling. Per Cent. on Dry Substance.
45	Below 9	78·7
71	9—10	77·8
64	10—11	76·9
20	11—12	76·5
3	Above 12 (maximum 12·7)	74·7

This table shows clearly the general decrease of the extract content with increase of the protein, although many of the samples showed considerable deviations from the average values. The question whether the same relation holds good between the protein percentage of barley and the extract of the malt prepared from it is to be answered in the affirmative, with a few reservations. A series of comparative determinations showed that in most cases the protein percentages of barley and malt are practically identical. In certain cases, however, notable differences may occur, owing either to abnormal qualities of the barley or to special methods of treatment. If in the malting of normal barley a strong rootlet development be allowed, the respiration and consequent loss of extract is curtailed, and a malt relatively poor in protein will result. If, on the other hand, the rootlet development be restricted, the consumption of proteids will be small and the malt will be rich in protein; the same result will follow if the loss of starch be increased by extra respiration and a converse result if the respiration be curtailed. Good brewing barley, being poor in protein, does not tend to get too hot during malting, and the husks being thin, the grain on the couches lies solid and conducts away the heat well, consequently the malt is poor in protein and rich in extract. Coarse-hulled barley lies more loosely on the couch, thus admitting air, which brings about a greater loss of extract by respiration. Bad barley, being both rich in protein and coarse-hulled, gets hot on the floor and lies loosely, involving greater aëration and loss of extract.—J. F. B.

Currant Wine "Disease"; Fermentation of Citric Acid as the Cause of a ——. W. Seifert. Zeits. landw. Vers. Wes. Öst., **6**, 738—747. Chem. Centr., 1903, **2**, [2], 1286.

The disease in question manifested itself, after the completion of fermentation, in a diminution of acidity and production of turbidity, whilst the wine acquired a harsh taste. The scum of such diseased wines contained, besides yeast, numerous rod bacteria. Fermentation experiments with this scum showed that it caused the conversion of malic acid into lactic acid and the decomposition of citric acid into carbon dioxide, acetic acid and alcohol, and the author concluded that the "disease" was caused by the bacteria, which decompose the citric acid. He recommends that the wine, after fermentation, be rapidly clarified and then subjected to a slight "sulphuring" in order to prevent the development of the bacteria. Micro-organisms capable of fermenting citric acid also occur in grape wines. —A. S.

Silesian Potato; Difficult Fermentation of the ——.

Zeits. Spiritusind., 1903, **26**, [50], 530.

Babucke states that the Silesian potato is largely cultivated in his district and is readily saleable for food purposes. It is planted at the beginning of April in order that it may have sufficient time to ripen. This year's crop had an average starch content of 22·3 per cent.; the sweet worts at an initial density of 26° Balling were fermented by yeast of Race xii. only down to 3° Balling. This was not the fault of the yeast, since wort of 24° Balling from "Ceres" potatoes was attenuated down to 1°—1·5° by the same yeast. Consequently the Silesian potato is regarded as specifically difficult to ferment. Brademann has employed the Silesian potato for many years, and has never found that it gave poorer attenuations than other varieties. Being a slow ripener, it must be planted early in April, and not in June as is sometimes done. The potatoes then are harvested fully ripe, provided the development of the tubers be not stopped by the premature death of the green portions. Potatoes harvested under those conditions, whether Silesian or other varieties, always yield very viscous mashes and contain a notable proportion of unfermentable matters. Viscous mashes are unsuitable both for the production of alcohol and for the propagation of culture yeast. Frank has had considerable experience with Silesian potatoes from various soils and has always found them satisfactory both with yeasts of Race ii. and Race xii. He finds that Race ii. is more adapted for the fermentation of concentrated mashes than Race xii., and yields more alcohol per volume of mash tun. Klix states that the Silesian potato is preferred on account of its large crop and good keeping qualities; he has experienced no difficulty in attenuating down to 0·5° Balling. The potatoes should be steamed slowly at three atmospheres pressure and blown off at 2·5 atmospheres; the mashes are then fluid and pale-coloured, but under higher pressures and with rapid steaming, brown, viscous mashes are produced which attenuate badly. —J. F. B.

"Montanin," a new Disinfectant.

English Patents.

Beer Wort; Continuous Process and Apparatus for Purifying ——.

E. Hoffmann. Pfeddersheim-Worms, Germany. Eng. Pat. 1073, Jan 15, 1903.

The beer mash or wort is charged in consecutive order into an endless series of filtering cells, draining off by suction the filtered wort, and removing the residue or husks from each cell before it is again charged with mash or wort of first brewing. The apparatus comprises a circular tank divided into a series of cells by radial partitions, the tank being revolved beneath a wort supply pipe and also beneath another supply pipe preferably arranged diametrically opposite the first and formed as a sparge pipe. The latter delivers wort of second mash. Each cell is provided with a perforated bottom and filtering medium and with means for drawing off the filtered liquor. There is a funnel-like discharge chamber beneath the cells leading to discharge pipes dipping into a common tank, and float valves in the chamber to permit normal discharge but automatically to prevent the pipes becoming empty, in order to ensure a suction on the filtering cells. The cells are each fitted with a hinged filtering bottom plate to facilitate discharge of the exhausted husks. —L. J. de W.

Alcoholic Beverages and the like; New Process for Producing ——.

E. Nowak, Lhotka, Austria. Eng. Pat. 22,542, Oct. 19, 1903.

Starch or starchy materials, previously alkalised, are converted by a separate roasting process into a sort of dextrin. This is then saccharified by boiling with dilute sulphuric acid; the liquid is neutralised by lime or chalk, filtered, purified, and either fermented direct for the manufacture of alcohol or concentrated to a syrup for addition to beer wort, wine must, or the like.—J. F. B.

Distillery Refuse or Pot Ale; Treatment of ——.

C. Day and E. W. Gaskell, Glasgow. Eng. Pat. 2519, Feb. 3, 1903.

The refuse or pot ale is concentrated by evaporation and the concentrated fluid is calcined in a rotary furnace. The product can be used as a manure.—J. F. B.

Distillery Refuse and other Materials of a Hygroscopic Character; Treatment of ——.

C. Day and E. W. Gaskell, Glasgow. Eng. Pat. 2520, Feb. 3, 1903.

The dried or partially dried products or hygroscopic materials are mixed in a pulveriser with kieselguhr. —J. F. B.

French Patent.

Alcoholic Liquors; Process of Purifying Raw ——.

L. S. Highton. Fr. Pat. 328,082, Sept. 13, 1902.

See U.S. Pat. 736,098 of 1903; this Journal, 1903, 1010. —T. F. B.

Saké Beer; Process for Production of ——.

G. Jacquemin. Fr. Pat. 333,833, July 15, 1903.

Rice is saccharified and fermented by means of a symbiotic mixture of pure cultivations of the best selected Japanese "koji" and a champagne yeast of the finest vintage. The propagating apparatus consists of three closed vessels of different sizes in duplicate. The vessels are approximately similar in design, and are provided with agitators, steam and sterilised air supplies, thermometers, aseptic sampling cocks, water pipes, and outlet valves. The yeast is propagated in the smallest pair of vessels, of about 60 litres capacity each, being cultivated in saccharified rice wort obtained from a previous operation. The "koji" is propagated in the second pair of vessels, of about 200 litres capacity. The contents of the yeast and koji vessels, when ready, are mixed together in one of the largest pair of vessels, each holding about 500 litres; in this the two organisms enter into a symbiotic process, and develop a ferment suitable for starting the main saccharification and fermentation. This is effected by discharging the contents of the large vessel into one of a series of wooden tuns, provided with an agitator and cooling worm. This tun is charged with a mash of boiled rice at a concentration of about "10 kilos. per 100 litres"; the capacity of the tun is about 100 hectolitres. The preparation of the ferments requires about 30 hours, and the main fermentation, at a temperature not exceeding 25° C., is complete in about six days; sufficient tuns are provided to make the process continuous. The saké is finally filtered, pasteurised, and bottled.—J. F. B.

Brewing Process for Malt, Separated into Grist, Flour, and Hulls.

R. Kubessa. Fr. Pat. 333,939, July 9, 1903.

See Eng. Pat. 15,935 of 1903; this Journal, 1903, 1144 —T. F. B.

Vinegar from Skim Milk; Manufacture of ——.

A. Barbier. Fr. Pat. 334,071, July 23, 1903.

A sufficient quantity of sugar is dissolved in the skim milk to bring the density up to 1·075. The lactic acid is then neutralised by chalk, and the liquid is pitched with yeast to induce alcoholic fermentation. The fermented liquid, which contains about 10 per cent. of alcohol, is then infected with *Mycoderma aceti*, and is acetified in the same manner as wine vinegar. The vinegar is finally clarified and decolorised by powdered wood charcoal.—J. F. B.

XVIII.—FOODS; SANITATION; WATER PURIFICATION, & DISINFECTANTS.

(A.)—FOODS.

Phosphorus in Certain Food Materials and Animal By-Products; Status of ——, with Special Reference to the Presence of Inorganic Forms. E. B. Hart and W. H. Andrews. Amer. Chem. J., 1903, **30**, [6], 470—485.

It is generally believed that part of the phosphorus in plant substances exists in the form of inorganic compounds, such as calcium, magnesium, and potassium phosphates, and the authors tried to work out a method for separating and quantitatively determining this portion of the phosphorus in vegetable and animal feeding stuffs. The following method gave the best results, but the latter were too high, owing to hydrolysis of the organic compounds containing phosphorus. Five grms. of the material were shaken vigorously for 15 minutes with 125 c.c. of 0·2 per cent. hydrochloric acid, the mixture was filtered, and the residue washed with water till 500 c.c. of the solution had been collected. 200 c.c. of this solution were neutralised with ammonia, 10 grms. of ammonium nitrate added, followed, after heating to 65° C., by 2 c.c. of nitric acid of sp. gr. 1·2, and 25 c.c. of neutral ammonium molybdate solution. The magnesium pyrophosphate obtained from the precipitate in the usual manner was dissolved in nitric acid and the phosphorus again precipitated. From the results obtained it is concluded that commercial feeding stuffs of vegetable origin (oats, wheat, malt sprouts, brewers' grains, linseed meal, &c.), do not contain appreciable quantities of phosphorus in inorganic combination. Animal feeding stuffs (liver meal, dried blood) are also practically free from inorganic phosphorus, except in the case of commercial meat meal, which contains an amount varying with the proportion of bone present. During the germination of grains (oats, maize, wheat), proteolysis of nucleoproteids, with formation of more soluble nucleins and nucleic acids, takes place, but not a transformation of organic phosphorus into inorganic.—A. S.

Pineapples; Quantity of Sugar admissible in Imported Preserved ——. H. W. Wiley. *Composition of Fresh and Preserved Pineapples.* L. S. Munson and L. M. Tolman. Bull. de l'Assoc. des Chim. de Sucr. et de Dist., 1903, **21**, [5], 524—526.

Munson and Tolman analysed 38 samples of fresh pineapples, of which 21 were from Florida, 10 from Cuba, 4 from Porto Rico, 2 from the Bahamas, and 1 from Jamaica; 16 preserved pineapples purchased by the Consul-General of Singapore, of which 10 were in juice pressed from pineapples without sugar, 6 in juice with added sugar, and 2 samples from Nassau; 42 commercial samples of preserved pineapples from Singapore, the Straits Settlements, and the Bahamas. Some of the results obtained are shown in the following table:—

——	Fresh Pineapples.			Preserved Pineapples.											
				Without added Sugar.			With addition of Sugar.			Singapore and Straits Settlements.			Bahamas.		
	Minimum.	Maximum.	Average.	Minimum.	Maximum.	Average.	Minimum.	Maximum.	Average.	Minimum.	Maximum.	Average.	Minimum.	Maximum.	Average.

Reducing sugar	1·76	9·75	3·91	5·44	10·96	8·00	7·51	15·39	11·63	7·05	15·18	9·91	5·55	12·84	7·96
Cane sugar	2·98	10·18	7·59	1·85	6·64	5·40	2·28	8·82	5·14	4·34	16·48	7·77	0·53	9·05	2·78
Total sugar, as invert	8·20	15·28	11·90	8·55	14·89	11·59	16·70	17·93	17·11	14·55	25·10	18·04	6·33	22·37	9·98

Although there are great differences in the sugar content, there is about twice as much cane sugar as reducing sugar. Pineapples preserved without the addition of sugar are generally preserved in 30 per cent. of their juice. These naturally contain less insoluble matter, more reducing bodies, and much less cane sugar. Those from the Straits Settlements and Singapore must have had sugar added, those from the Bahamas only partly so. Wiley concludes that for levying duty, all those that contain as a maximum 14 per cent. of total sugar in each tin, and 13 per cent. as average of the cargo, should be considered as preserved in their juice without addition of sugar; those with more should be regarded as preserved with addition of sugar.
—L. J. de W.

Wheat Flour; Determination of Other Flours in —— G. Volpino. XXIII., page 37.

English Patent.

Tea, Nourishing and Digestible; Method of Rendering ——. International Plasmon, Ltd., London. From S. M. Bergheim, Paris. Eng. Pat. 26,254, Nov. 28, 1902.

Tea leaves are damped and incorporated with from 5 to 20 per cent. of dry powdered casein. The mixture is then dried. Infusions of the tea so treated contain a certain amount of casein, and are to a large extent freed from tannin. (See also Eng. Pat. 11,948, 1900; this Journal, 1900, 842.)—W. P. S.

(B.)—SANITATION; WATER PURIFICATION.

Air in the House of Commons; Chemical Analysis of the ——. W. J. Atkinson Butterfield. J. of Hygiene, 3, [4], 1903, 486—497.

The author made a number of analyses of the air in the Debating Chamber of the House of Commons, for the information of the Select Committee first appointed in April 1902. The report of the Committee was presented to the House on July 28th last, and is published by H.M.'s Stationery Office (No. 283). The following were the results obtained:—

——	Volumes of Carbon Dioxide in 10,000 volumes of Air.		
	Max.	Min.	Mean.
Air supplied to the chamber	3·74	3·14	3·37
Air at breathing level in the body of the chamber	5·23	3·35	4·59
Outgoing air from about 6 ins. below the ceiling of the chamber	5·60	4·82	5·27

Water; Sterilisation of Potable ——, by means of Chlorine and Bromine Compounds. F. Ballner. Arch. f. Hyg., 1903, **48**, 140. Biochem. Centralbl., 1903, **2**, [4], 134.

Schuder has shown that the sterility of water is not proved by the examination of a small aliquot portion, but that it is necessary to examine the whole quantity. Subjected to this stringent test Schumburg's bromine method has not proved satisfactory, and unfavourable results have also been obtained in Hünermann's sodium hypochlorite method. A critical examination of Engel's chloride of lime method applied to water infected with different pathogenic micro-organisms has shown that the prescribed quantity of reagent (150 mgrms. per litre = 30 mgrms. of chlorine in a 20 per cent. solution) is quite insufficient to effect sterilisation in 30 minutes, and that the time must be increased to an hour, or the chloride of lime to 0·45 grm. per litre for sterilisation in 10 minutes. On the other hand, increasing the amount of chlorine to even 50 mgrms. per litre gives an unpleasant alkaline taste to the water. Hence the author concludes that this method is only available in cases where a longer period of sterilisation (two to three hours) is possible.—C. A. M.

Sterilisation by Boiling under Reduced Pressure.
Schut, jun. XXIV., page 39.

English Patents.

Town Refuse; Methods of Destroying ——, by Burning, and the Utilisation of certain valuable Ingredients thereof. W. Naylor, Preston. Eng. Pat. 26,201, Nov. 28, 1902.

The refuse is mixed with alkali or lime and heated in a closed oven by means of the hot gases from the destructor furnace. The liberated ammonia is collected in the usual manner, the residue being discharged into the furnace. When lime has been added to the refuse, the furnace clinker produced may be ground for use as a building cement. (See also Eng. Pat. 17,650, 1902; this Journal, 1903, 865.)—W. P. S.

Water; Purification of ——. M. Otto, Paris. Eng. Pat. 12,522, June 2, 1903.

The water is subjected to the action of an electric current in tanks containing a mass of iron cuttings, the latter forming a positive electrode. The ferrous salts produced are then oxidised by suitably aerating the water, and the precipitate of organic matter and ferric hydroxide is removed by filtration.—W. P. S.

French Patent.

Ammonia from Town Effluents; Continuous Process and Apparatus for Recovering the ——. R. Schilling and C. Kremer. Fr. Pat. 333,819, July 13, 1903.

—T. F. B.

(*C.*)—DISINFECTANTS.

"*Montanin,*" *a New Disinfectant.* P. Lindner and P. Matthes. Zeits. Spiritusind., 1903, **26**, [52], 545—546.

"Montanin" is obtained from by-products of the pottery industry; it is a nearly colourless, odourless liquid, the principal active constituent of which is hydrofluosilicic acid. "Montanin" is said to be poisonous only in relatively large doses, and is practically without action on brewery and distillery metals, such as copper and tin. A 25 per cent. solution disintegrates beer-scale almost immediately; a 50 per cent. solution has no solvent action on tun-lacquer. A 2 per cent. solution of "montanin" prevents the growth of micro-organisms, and in many cases even a 1 per cent. is sufficient. Exposure of the vegetative growths of various cloudy-beer sediments to a 1 per cent. solution of "montanin" for ten minutes at the ordinary temperature prevented all growth when the material was subsequently transferred to sterile wort. Two coats of a 20 per cent. solution on walls and casks preserved them free from mould for six months under very severe conditions.
—J. F. B.

English Patent.

Resinous Product [Disinfectant] or Class of Product from Wood Tar; Manufacture of a ——. K. A. Lingner, Dresden. Eng. Pat. 2377, Jan. 31, 1903.

See Fr. Pat. 329,971 of 1903; this Journal, 1903, 1014.

XIX.—PAPER, PASTEBOARD, Etc.

Cardboard for Printing; Manufacture of Wood-free ——. C. B. Wochenbl f. Papierfabr., 1903, **34**, [50], 3706—3709.

High-class printing cardboard is generally made at a weight of 200—300 grms. per sq. metre. It is a matter of the first importance to avoid beating the pulp too "wet"; long, "wet" stuff gives strength, but uneven structure and surface, whilst short stuff causes brittleness. The best stock is prepared from a mixture of long and short pulps, beaten separately. The long pulp, which is to impart strength and flexibility, should be prepared from cotton rags or a soft form of wood cellulose, such as soda or sulphate wood pulp; ordinary sulphite pulp is too harsh, and beats "wet." In order to obtain length of fibre without "wetness," the beater must not be charged very thickly, and a further addition of soda pulp should be made a couple of hours before discharging. The short pulp is used for filling and closing up the sheet; it assists the felting, and imparts a uniform structure and surface. This pulp should be composed of straw and aspen wood-pulp, together with a little broken paper of strong quality. Paper of this thickness can only be made satisfactorily on a machine with an extra long wire, since the water must leave the pulp only slowly if a sheet of good texture be desired. On no account should the deficiencies of a short wire be counteracted by beating the pulp. By causing the water to run off too quickly, the use of steam always affects the structure, since the stuff must be very concentrated in order to get the weight of fibre through the gates of the machine, and if the water leaves too freely, the distributing action of the shake cannot come into play. With a long wire, only the slightest warming is necessary; the concentrated and moderately "wet" pulp flows in a thick even stream, regulated preferably by three gates, and is properly felted by means of a long and steady shake. The even distribution of the short fibres on the upper surface of the sheet gives a smoothness equal to that imparted by the wire to the lower surface. The web should be as moist as possible as it passes beneath the dandy rolls, two of which should be provided, whilst a third pair of press-rolls is advantageous as regards the subsequent drying. The first few drying cylinders must be only slightly heated, since rapid drying roughens the surface. The paper must lie for a few days with 6—7 per cent. of moisture before calendering.—J. F. B.

Animal Sizing. C. Hofmann. Papier-Zeit., 1903, **28**, [101], 3643.

In England and America animal sizing has always held its own for the better class of rag papers; in recent years, moreover, there has been a growing tendency to produce imitations of such writing papers by the animal sizing of paper prepared from sulphite wood-pulp and straw. Very fair writing papers are made with about 70 per cent. of sulphite wood pulp and 30 per cent. of straw pulp, only the thinnest sorts containing an addition of 10—20 per cent. of linen rags. Such papers are always half-sized in the engine with rosin, being subsequently passed through a dilute solution of animal size, and air-dried on the well-known form of drying machine; the shrinkage by this method of drying amounts to 1—1·5 per cent. The winding up and calendering of these papers requires the greatest care, since, if the paper be the least bit too dry, wrinkles are produced, whilst imperfect drying causes soft sizing. The temperature and hygrometric state of the air in the rooms where the paper is dried must be capable of constant observation and regulation, and the state of the weather has a considerable influence. A few of the older mills still prepare their own size from bones or hides, but the majority purchase the commercial glue pieces. A dark-coloured animal size has a far greater effect upon the colour of the paper than a dark-coloured rosin. As a rule, the stock solution of size is made up with 6—7 per cent. of glue, whilst 1 per cent. of soap and 1—3 per cent, of alum are subsequently added; the usual temperature of the size-bath is 35°—36° C. The temperature and concentration of the size must, however, be carefully regulated according to the thickness and nature of the paper. An excess of alum affects the colour of the paper and makes it brittle, but this tendency can to a certain extent be corrected by the addition of soap. The practice of half-sizing with rosin is being largely extended, even to the finest rag papers, since the advantages of both types of size are thus secured, and a distinct improvement in the colour of the paper, as compared with full animal sizing, is obtained.—J. F. B.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

Esterifications by Means of Sulphuric Acid. H. Meyer. Monatsh. f. Chem., 1903, **24**, [10], 840—843.

The author describes a method for the esterification of organic acids, as follows:—The finely powdered organic acid is warmed with 5 to 10 times its weight of concentrated pure sulphuric acid and to the cooled solution a slight excess over the equivalent quantity of methyl alcohol is added, the vigorous action which ensues being assisted by stirring. After cooling, the mixture is neutralised by pouring on to crystallised sodium carbonate, and, since neutralisation takes place without rise of temperature, a solvent such as ether or chloroform may be mixed with the soda in order to dissolve the ester, which is subsequently separated and purified. The method gives almost quantitative yields in many cases, and has been applied to acids of the pyridine, fatty, and aromatic series. There are certain cases in which esterification does not occur, owing to the inhibitive action of substituent groups in certain positions preventing the formation of the acylsulphuric acids, which is regarded as the intermediate step in the process; *p*-hydroxybenzoic acid and terephthalic acid are instances of such exceptions.—J. F. B.

Phosphoric Acid and Glycerol; Esterification of ——. P. Carré. Comptes rend., 1903, **137**, [24], 1070—1073.

When phosphoric acid and glycerol are allowed to react on each other, esterification proceeds further according as the temperature is higher and the pressure lower. In the vacuum of the mercury-pump and at a temperature of 115° C., the two are practically completely esterified when mixed in equimolecular proportions. In the industrial preparation of glycerophosphoric acid, some of the di-ester is, no doubt, always formed. No inquiries seem to have been made as to how this behaves when the acid is converted into glycerophosphates, but no doubt its existence accounts for some of the great discrepancies which have occurred in the analysis of glycerophosphates.—J. T. D.

English Patents.

Dimethyl- and Diethylamido-Antipyrin; Manufacture of ——. W. Majert, Berlin. Eng. Pat. 26,353, Nov. 29, 1902.

Amino-antypyrine hydrochloride (1 mol.) is heated with chloro- or bromo-acetic (or propionic) acid ($2\frac{1}{2}$ mols.) and sodium carbonate ($3\frac{1}{2}$ mols.) to 120°—130° C., until evolution of carbon dioxide ceases; the dicarboxylic acid [$C_{11}H_{11}N_2ON:(CH_2COOH)_2$] thus obtained is heated with 3—4 mols. of 10 per cent. sulphuric acid, in an autoclave, to 150°—160° C., for 4—5 hours; on addition of caustic soda, dimethyl- (or diethyl-) amino-antipyrine (1 phenyl-2.3-dimethyl-4-dimethylamino-5-pyrazolone) is obtained. —T. F. B.

Ortho- and Paratoluene Sulphamide; Separating ——. R. Barge, Stassfurt, and L. Givaudan, Geneva. Eng. Pat. 848, Jan. 13, 1903.

The separation of *o*- from *p*-toluene sulphamide is effected by fractional precipitation of a solution of the alkali salts by means of a normal magnesium or ammonium salt, the former giving a precipitate of the magnesium salts of the sulphamide, and the latter giving the free sulphamide, ammonia being liberated; in each case the *o*-compound is rather less soluble than the *p*-compound; thus, by adding a solution of 35 kilos. of ammonium chloride in 80—90 litres of water to a solution of 200 kilos. of the mixed sulphamides in 235 kilos. of sodium hydroxide solution of 23° B., a precipitate (about 110 kilos.) of *o*-toluene sulphamide is obtained; the remainder of the *o*-compound and part of the *p*-compound are precipitated by the addition of 10 kilos. of ammonium chloride to the filtrate, the resulting precipitate being again dissolved in alkali and treated as above.—T. F. B.

Toluene Sulphonic Chloride. R. Barge, Stassfurt, Germany, and L. Givaudin, Geneva. Eng. Pat. 1877, Jan. 26, 1903.

It has been found that when toluene is treated with a mixture of chlorosulphonic acid and sulphuric acid, quite as high a yield of the mixed *o*- and *p*-toluene sulphonic chlorides is obtained as when practically pure chlorosulphonic acid is employed. This enables the sulphonic chlorides to be prepared by the treatment of toluene with a mixture obtained by saturating fuming sulphuric acid, containing about 60 per cent. of the anhydride, with dry gaseous hydrochloric acid.—J. F. B.

Chemical Composition of the Series of Phenols [*Cetyl Guaiacyl*], *By-Products, and Process for making same.* L. H. Cress, Fremont, Ohio. Eng. Pat. 16,349, July 24, 1903.

See U.S. Pat. 736,061 of 1903; this Journal, 1903, 1013. The product is purified either by a "sweating" process or by means of pressure, at about 20° C., the cetyl guaiacyl, $C_{23}H_{40}O_2$, having a lower melting point than the impurities in it. The glycerin liquors, which contain alkali palmitate, are heated with ferric chloride, the "palmitate of iron peroxide" which separates being suitable for medical purposes. The cetyl-guaiacyl is abbreviated as "cetiacol" or "palmiacol."—T. F. B.

United States Patent.

Dialkyl-barbituric Acids; Process of Preparing ——. M. Engelmann, Elberfield, Assignor to Farbenfabr. of Elberfeld Co., New York. U.S. Pat. 744,732, Nov. 24, 1903.

5-Dialkyl-4-imino-2.6-dioxypyrimidine, prepared by condensing urea with dialkyl cyano-acetic esters by means of alkali alcoholates, is treated with saponifying agents, *e.g.*, hot sulphuric acid, whereby ammonia is split off and dialkyl barbituric acids remain.—T. F. B.

French Patent.

Radio-active Metallic Coating; Process for Depositing a ——, *on Articles.* R. Sthamer and R. Kasch. Fr. Pat. 328,096, Oct. 6, 1902.

Photographic Developers; Manufacture of ——, by means of Alkali Salts of Glycocoll or its Derivatives which have an Alkyl Radicle attached to the Nitrogen. Cie. Paris. Coul. d'Aniline. Fr. Pat. 328,093, Sept. 24, 1902.

See Eng. Pat. 20,377 of 1902; this Journal, 1903, 380.
—T. F. B.

Photographic Toning by Utilising the Action of Stannic Salts on Photographic Images in Presence of Gold (or Platinum) Chloride, either alone or in conjunction with Gallic Acid. M. Stoicescou. Fr. Pat. 333,637, June 6, 1903

A variety of tones may be obtained on gelatino-chloride or other "printing-out" papers by means of stannic and gold salts, with or without an organic reducing agent, such as gallic acid; the tones depend on the state of division of the gold deposited, and also on the extent of reduction of the gold oxide, the deposit also containing tin peroxide. A suitable method consists in using a solution containing stannic chloride, 3,200 grms.; citric (or tartaric) acid, 32 grms.; soda crystals (or sodium borate), 640 grms.; ammonium (or sodium or magnesium) chloride, 280 grms.; and water, 10 litres: for warm tones, 5 c.c. of this solution are added to 2—5 c.c. of a 1 per cent. gold chloride solution, and 100 c.c. of water, with 20—30 grms. of sodium chloride; the duration of toning may be from 2 to 45 seconds, the tone only appearing during fixation (in sodium thiosulphate, 1 part; sodium chloride, 1 part; water, 5 parts); for tones ranging from rose and violet to blue and indigo, the bath may consist of the concentrated solution, 5 c.c.; 1 per cent. gold chloride solution, 10—20 c.c.; 0·8 per cent. gallic acid solution, 3 c.c.; water, 100 c.c.; toning requires from 5—60 minutes, according to the tone desired; fixation has a considerable effect on the tone obtained, which is rose with short treatment, and varies from rose to blue as the duration is increased. Immersion of the finished print in mercuric chloride solution gives a brilliant red, which, however, is unstable in damp air. Platinum may replace the gold in this process, but brown shades are always obtained, the deposit consisting of platinum and tin peroxide. The gallic acid may be made into small tabloids, containing gallic acid, 0·1—0·3 grm.; potassium hydrogen oxalate, 0·25 grm.; borax, 0·25 grm., worked up with gum arabic, &c.—T. F. B.

XXII.—EXPLOSIVES, MATCHES, Etc.

Nitrocellulose; Study of ——. I. C. Haeussermann. Ber., 1903, **36**, 3956.

The author has previously shown that the distillate obtained when collodion cotton is boiled with caustic soda solution yields iodoform when treated with alkali and iodine dissolved in potassium iodide solution. He has since found that guncotton and nitrated sulphite cellulose behave in a similar manner, and that the caustic soda solution may be replaced by a solution of calcium, barium, or strontium hydroxide, or of an alkali carbonate. The author previously considered the volatile decomposition product to be acetone, but further examination indicates that it is of an aldehydic nature, although the amount obtained up to the present has been too small to allow of the isolation of the substance in a pure condition.—A. S.

Phosphorus; Investigations on ——. R. Schenck. VII., page 17.

English Patent.

Fireworks; Manufacture of ——. S. Salas, Barcelona. Eng. Pat. 8163, April 8, 1903.

See Fr. Pat. 329,636 of 1903; this Journal, 1903, 1064.
—T. F. B.

French Patent.

Matches, Readily Inflammable; Manufacture of ——. Chem. Fabr. Griesheim-Elektron. Fr. Pat. 333,816, July 13, 1903.

Suboxide of phosphorus, made, for example, by passing air into a slightly warm solution of yellow phosphorus in carbon tetrachloride, is substituted for phosphorus in match-head compositions.—W. G. M.

XXIII.—ANALYTICAL CHEMISTRY.

INORGANIC—QUANTITATIVE.

Alkali Bromates; Reduction of ——, by Hydrazine- and Hydroxylamine Sulphates. M. Schlotter. Zeits. anorg. Chem., **37**, 164—171; Chem. Centr., 1903, **2**, [22], 1255.

Alkali bromates in aqueous solution, when treated with hydrazine- or hydroxylamine sulphate, are reduced to bromides, with evolution of nitrogen, and, in the case of hydroxylamine sulphate, of oxygen also. The reactions may be expressed by the equations—

$$2NaBrO_3 + 3NH_2.NH_2 = 2NaBr + 6H_2O + 6N.$$
$$2NaBrO_3 + 6NH_2OH = 2NaBr + 9H_2O + 6N + 3O.$$

The reactions may be used for the determination of bromates. The aqueous solution of the bromate is treated with the necessary quantity of hydrazine- or hydroxylamine sulphate, the mixture warmed, and the bromine precipitated as silver bromide by silver nitrate in presence of nitric acid.—A. S.

Bone Ash [Cupels; Bumping of ——]. A. T. Firth. J. Chem., Metall., and Mining Soc. of S. Africa, 1903, **4**, [4], 176.

"Bumping" of bone-ash cupels appears to be due, not to the carbon dioxide produced by oxidation of the carbon remaining in the bone ash, but to the carbon dioxide evolved from the calcium carbonate present, since cupels made from bone ash containing 7·93 per cent. of calcium carbonate "bumped" badly, whereas cupels made from the same sample, after treatment with dilute hydrochloric acid, showed no tendency to "bump."—T. F. B.

Phosphorus in Certain Food Materials and Animal By-Products; Status of ——, with Special Reference to the Presence of Inorganic Forms. E. B. Hart and W. H. Andrews. XVIII. A., page 33.

ORGANIC—QUALITATIVE.

Hydroxylamine; New Reaction of ——. L. J. Simon. Comptes rend., 1903, **137**, [23], 986—987.

On adding to a dilute solution of hydroxylamine a few drops of a very dilute solution of sodium nitroprusside and a faint excess of alkali, and heating the mixture gradually to the boiling point, the liquid loses its yellow tint, and finally assumes a fine cherry-red colour, which changes to a bright rose on dilution of the solution. The reaction is very sensitive, a visible coloration being obtained with a solution of 1 part of hydroxylamine hydrochloride in 1,000,000 of water. The colour is only transitory, and disappears more or less rapidly according to its intensity. All the salts of hydroxylamine yield this reaction, which is, however, not given by oximes, whether aldehydic or ketonic, aliphatic or aromatic.—T. H. P.

"Arrhenal" [Sodium Methyl Arsenate] in Marsh's Apparatus; Behaviour of ——. D. Vitali. Boll. Chim. farmac., 1903, **42**, 643; Chem.-Zeit., 1903, **27**, [99] Rep. 311. (See this Journal, 1902, 874.)

Whilst cacodylic acid, according to Knoblauch, produces a white odorous vapour in the Marsh's apparatus, and this vapour (provided that no platinic chloride is used) gives an arsenic ring in the heated tube, arrhenal produces no vapour, but (unless platinic chloride be present) shows the black ring in the tube. The author indicates the following points of dissimilarity between cacodylic acid and arrhenal.

With Bougault's reagent (2 grms. of sodium peroxide, 1 c.c of water, and 20 c.c. of hydrochloric acid of sp. gr. 1·07), arrhenal, in the cold, gives at first a white turbidity, which then becomes red, and finally yellowish; on heating, the mixture first becomes grey and turbid, and then deposits a brown powder. Under the same conditions cacodylic acid remains at first unchanged in the cold, but becomes milky after half an hour, and after 12—18 hours covers the glass tube with a yellowish deposit, at the same time evolving a strongly irritating smell. On warming, the mixture at once becomes turbid, and gives out white irritating vapours and forms a red-brown sublimate. With Bettendorf's reagent (a concentrated solution of stannous chloride in fuming hydrochloric acid), cacodylic acid, when warmed, evolves white vapours and the objectionable smell of cacodyl, but does not become coloured; arrhenal, on the contrary, gives out no fumes or smell; on prolonged warming it forms a white sublimate, which later assumes a lemon-yellow hue.—W. G. M.

Spike Oil; Adulterated ——. E. J. Parry and C. T. Bennett. Chem. and Druggist, 1903, **63**, [1247], 1011.

The authors have recently met with numerous specimens of adulterated spike oil, which yielded figures for sp. gr., optical rotation, and solubility within the limits given by most authorities; the usual adulterants were turpentine, oil of rosemary of the commonest quality, and safrol. The optical rotation of spike oil is usually given as up to + 7°, but the authors find that + 4° is the usual upper limit, and that samples with a rotation of over + 5° are very frequently adulterated. With regard to solubility in alcohol, oils containing 25 per cent. of certain adulterants will pass the ordinary test. The authors recommend the use, for the solubility test, of six volumes of 65 per cent. alcohol, by which means additions of 5—10 per cent. of most adulterants can be detected. It is also advisable to determine the percentages of esters and of alcohols, and to fractionate the oil and examine the various fractions.
—A. S.

ORGANIC—QUANTITATIVE.

Indigo; Manufacture [and Determination] of ——. L. Bréaudat. IV., page .

Fatty Acids; Separation of Different ——. A. Partheil and F. Ferié. Archiv der Pharm., 1903, **241**, [7—8], 545—570.

In the separation of palmitic and stearic acids from oleic acid by treatment of the lead salts with benzene (this Journal, 1898, 804), insoluble double salts containing oleic acid are formed. To obviate this the author has tried experiments with monovalent metals, of which lithium has proved the most satisfactory. On adding lithium acetate to a hot alcoholic solution of the fatty acids, the lithium salts of stearic and palmitic acids are precipitated, whilst the oleic acid salt remains in solution. Lauric acid also remains in solution, whilst myristic acid is partially precipitated. The following table gives the solubility of the different lithium salts in water and in alcohol of specific gravity 0·797. In each case the figures represent the numbers of litres required to dissolve the molecular weight in grms. of the respective salts:—

Salt.	Water.		Alcohol. sp. gr. 0·797.	
	At 18° C.	At 25° C.	At 18° C.	At 25° C.
	Litres.	Litres.	Litres.	Litres.
Lithium stearate (290·38 grms.)	2903·5	2642·0	708·3	545·6
Lithium palmitate (262·38 grms.)	2388·0	1476·2	329·5	271·5
Lithium myristate (234·31 grms.)	1003·4	1001·4	127·4	110·5
Lithium laurate (206·27 grms.)..	130·5	119·5	49·3	46·62
Lithium oleate (228·37 grms.)...	427·8	218·4	31·74	28·57

The following method, based on these results, was eventually adopted for the separation of the acids:—0·25 grm. of different pure fatty acids was dissolved in 50 c.c. of absolute alcohol, and the solution neutralised with alcoholic potassium hydroxide solution and diluted with 50 c.c. of water. It was then treated with an excess of a 10 per cent. solution of lithium acetate in 50 per cent. alcohol, and the precipitate collected, washed with 50 per cent. alcohol, dried and weighed. In this way the following results were obtained:—Lithium stearate, 0·2495 grm. (theory, 0·2552 grm.); lithium palmitate, 0·2525 grm. (theory, 0·2558 grm.); lithium myristate, 0·2347 grm. (theory, 0·2565 grm.). No trace of precipitate was obtained from lauric or oleic acids. Hence the author concludes that it is thus possible to separate stearic and palmitic acid quantitatively and myristic acid nearly quantitatively from lauric and oleic acid. On the other hand, oleic acid can be separated from myristic and lauric acids by means of Farnsteiner's method (*loc. cit.*), for although mixed lead salts are precipitated from benzene solutions containing stearic, palmitic, and oleic acids, the lead salts of lauric and myristic acids under the same conditions are obtained free from oleate. Experiments are cited to prove that this is also the case when a mixture of the five acids is present.

Separation of Oleic Acid from More Unsaturated Acids.—In Schüler's method of extracting the barium salts with ether, it is shown that it is essential that the ether should contain water, since the dry barium salts of acids of the linolic and linolenic series are hardly soluble in anhydrous ether. The fatty acids recovered from the benzene solution in Farnsteiner's method of separating oleic from lauric and myristic acids should be dissolved in alcohol, neutralised with potassium hydroxide, and treated with a 10 per cent. alcoholic solution of barium acetate, and the dried barium salts extracted with ether containing water. For calculating the amount of stearic acid in the lithium precipitates, the author converts them into barium salts, and obtains the molecular equivalent of the fatty acids from the amount of barium present. Analyses of various fats by these combined methods are given in detail. In the case of butter the author confirms the statement of previous observers that not much stearic acid is present. One sample examined gave the following results:—Stearic acid, 6·54; palmitic acid, 17·95; myristic acid, 10·65; lauric acid, 17·08; and unsaturated acids (including 5·40 per cent. of highly unsaturated acids), 30·08 per cent.—C. A. M.

Tanning Materials and Tanning Extracts: Determining the Weight-giving and Leather-forming Properties of ——. J. G. Parker. Collegium, 1903, [88], 363—364.

Ten grms. of pure dry hide-powder, free from cellulose, are drummed in a churn of about 2 litres capacity with 150 c.c. of distilled water for about half an hour. A liquor of the material under examination is made up, containing about 8 per cent. of tannin (determined by the I.A.L.T.C. method) and is diluted so that when 350 c.c. are diluted by the 150 c.c. of water in the churn, the total amount of tannin in the churn will be exactly 5 per cent. This liquor (350 c.c.) is added 50 c.c. at a time, and the churn revolved for 30 minutes after each addition, and for one hour after the whole has been introduced. The tanned hide powder is placed on a filter funnel plugged with cotton wool, using the filtrate for washing purposes, is pressed down tightly, and allowed to drip for 24 hours and then weighed. A portion (10 grms.) is dried to determine the moisture, and from the dry weight the amount of combined and uncombined tannin in the whole is calculated. Another portion (20 grms.) is placed on a plugged filter as before and washed with one litre of water. When dried, the amount of chemically and physically combined tannin is calculated. The yield of washed leather and of unwashed leather thus give respectively the strictly combined tannin and the combined plus uncombined tannin. Estimation of the hide substance in the washed and unwashed leathers confirm these weight results to the second decimal place.—R. L. J.

Wheat Flour; Determination of other Flours in ——. G. Volpino. Zeits. Unters. Nahr.- u. Genussm., 1903, **6**, 1089—1095.

If a mixture of wheat flour with rye, barley, maize, or rice flour be made into a dough, and the latter be well washed in a stream of water, a mass of gluten is obtained which in weight is approximately proportional to the amount of wheat flour present. For instance, 30 grms. of wheat flour yielded about 8 grms. of gluten. When mixed with 50 per cent. of other flour, 30 grms. of the mixture gave from 4 to 5 grms. of gluten. The admixture of other flours to wheat flour may also be determined by forming 30 grms. of the sample into a dough with a little water, kneading the lump of dough with the hands under a stream of water and collecting the wash-water in a basin. The latter is passed through a piece of linen to collect any particles of gluten, and the solution is then filtered through an asbestos filter. The residue on the filter is dried at 100° C., and the nitrogen determined in it by Kjeldahl's method. The amount of nitrogen found multiplied by six gives the quantity of proteid matter. Pure wheat flour does not contain more than 0·2 per cent. of insoluble proteids other than gluten, whilst barley, maize, rice, and rye meals yield about 6 per cent.—W. P. S.

Morphine in Opium and Tincture of Opium; Determination of ——. E. Dowzard. Pharm. J., 1903, **71**, [3400], 909.

Morphine in Opium.—8 grms. of opium are treated in a flask fitted with a rubber stopper, with 100 c.c. of water, and the closed flask is heated for about one hour at 80°—90° C., with frequent shaking. After cooling, 3 grms. of slaked lime are added, the flask again closed and allowed to stand, with frequent shaking, for 1—2 hours. The mixture is then filtered through a plaited filter and 51·6 c.c. of the filtrate (= 4 grms. of opium) are treated in a flask, with 50 c.c. of 90 per cent. alcohol, 30 c.c. of ether, and 2 grms. of ammonium chloride. The flask is closed with a cork, shaken for 30 minutes, allowed to stand for 12 hours, again shaken for a few minutes, and the contents poured on to a filter. The aqueous liquid runs through, leaving the morphine attached to the filter, whilst the ether is left perfectly clear and can be completely removed with a pipette. Water saturated with morphine is used for rinsing out the flask and for washing the filter until the filtrate is free from chlorine. The filter is finally washed with about 10 c.c. of distilled water, allowed to drain, and about 15 c.c. of ether poured over the edges of the paper. After a few minutes the ether is removed with a pipette, the filter exposed to the air for half an hour, the paper and contents transferred to a beaker and rubbed to a pulp with 20 c.c. of N/10 sulphuric acid, and the excess of acid titrated with N/10 caustic soda solution, using methyl orange as indicator. Each c.c. of acid consumed is equivalent to 0·0283 grm. of anhydrous morphine; 0·05 grm. is added to the weight of morphine found, as directed in the B.P.

Morphine in Tincture of Opium.—In the B.P. method 80 c.c. of tincture and 3 grms. of slaked lime are used, and the mixture is made up to 85 c.c., whereas, according to the author, it should only be made up to 81·9 c.c. (1·44 c.c. for the lime and about 0·46 c.c. for the extractive matter carried down by the lime). The following method is recommended:—100 c.c. of the tincture are evaporated to about 30 c.c., cooled, the liquid mixed to a smooth paste with 3 grms. of slaked lime and made up to 100 c.c. with water, adding, if necessary, one or two drops of ether to remove froth. Two c.c. of water are then added, the whole allowed to stand for one hour with frequent agitation, filtered, and 50 c.c. of the filtrate (= 50 cc. of tincture) treated as described above.—A. S.

XXIV.—SCIENTIFIC & TECHNICAL NOTES.

Ethyl Alcohol; Hydrates of ——. E. Varenne and L. Godefroy. Comptes rend., 1903, **137**, [23], 993—996.

By means of a special form of constant pressure capillary viscosimeter, known as the "chrono-stiliscope," the authors have determined the viscosities of alcohol containing from 0 to 95 per cent. by volume of water. The curve connecting the time of flow with the percentage of alcohol present is an ellipsoid, showing various irregularities corresponding with definite hydrates. The latter contain, for every molecule of alcohol, 2/3, 2, 3, 6, and 22 molecules respectively of water. The method employed by the authors can be generally applied, for example, to the study of velocities of dissociation or esterification, molecular weight measurements, and so on.—T. H. P.

Fermentative Enzymes, Isolated from the Cells of the Higher Animals. J. Stoklasa and F. Cerny. Ber., 1903, **36**, [16], 4058—4069.

The fermentative enzymes, mention of which has previously been made in this Journal, 1903, 374 and 813, may be extracted from the animal organs in the following manner:—The organs, as soon as they are removed from the body, are pounded to a pulp; about 2—3 kilos. of this are mixed with a small quantity of sterilised, sharp-edged sand, together with ice. The mixture is triturated mechanically, in portions of 300 grms. each, until microscopic examination shows that the cells are completely disintegrated. The juice is then immediately expressed from the pulp by means of a pressure of 350 atmospheres. The fresh juice, when mixed with glucose or cane sugar at a concentration of 10—15 per cent., sets up a slight glycolytic action, but alcoholic fermentation is never observed. The fermentative enzymes of the juice are completely destroyed after 12 hours at 35° C. by the proteolytic enzyme and the action of bacteria. The property of setting up alcoholic fermentation is only possessed by the enzymic preparations, precipitated from the fresh juice. These precipitates are obtained as follows:—To 300 c.c. of the clear juice are added 350—500 c.c. of alcohol, and then, immediately afterwards, 300—500 c.c. of ether. The precipitate is allowed to settle in tall glass cylinders, the bulk of the liquid is then poured off and replaced by a volume of ether equal to that of the alcohol-ether mixture originally employed. The supernatant liquid is again rapidly siphoned off, and the precipitate is at once drained on the filter-pump, dried *in vacuo* at a temperature of 25°—30° C., and the horn-like product obtained, ground to a fine powder. The activity of the preparation entirely depends on the rapidity of the manipulation; the whole period of contact with alcohol and ether must not exceed a few minutes. The precipitated enzymes appeared to be of two kinds; those preparations obtained from juice expressed at less than 200 atmospheres have a low activity, and only set up a slight alcoholic fermentation after about 12 hours, whereas those obtained from juices expressed at 250—300 atmospheres are very active. The enzymes extracted from the muscles, liver, and lungs of cattle, if prepared under the most favourable conditions, will start alcoholic fermentations in solutions of hexoses and disaccharides (10—15 per cent.) almost immediately. Fermentation generally reaches its maximum point after 6 or 8 hours at 37° C., the froth rising to a height of some centimetres; the action is entirely ended after 60 hours. The dried preparations may be heated for 4—6 hours at 100° C., and still retain a certain amount of activity, but they lose almost all their fermentative power when kept for a fortnight at the ordinary temperature. The authors have performed a considerable number of experiments to prove that the fermentative properties of these preparations are truly enzymic, and not due to the activity of bacteria or other organisms. All quantitative experiments must, however, be conducted under perfectly aseptic conditions, with due regard to the fact that bacteria develop very readily in the solutions, with the production of carbon dioxide. If the enzymes be added to solutions in which fermentation does not readily take place, their activity will be completely destroyed by that of bacteria after 36 hours. For these reasons it is always advisable to perform experiments in the presence of an antiseptic such as thymol or toluene whenever possible. Tables are given showing the quantitative results of fermentation experiments with glucose, fructose, rhamnose, saccharose, lactose, and starch. It is noted in the case of glucose that the quantity of glucose consumed is greater than that corresponding with the quantities of alcohol and carbon dioxide produced, in spite of the total absence of bacteria; this fact has been accounted for by the observation that lactic acid is one of the products of the activity of the enzymes in solutions of glucose.—J. F. B.

Sterilisation by Boiling under Reduced Pressure. Schut, jan Zeits. f. Hyg., 1903, **44**, [2]. Biochem. Centralbl., 1903, **2**, [2—3], 95.

The author's experiments showed that heating a liquid to a particular temperature had less bactericidal effect than reducing the pressure so that boiling occurred at that temperature. By boiling a liquid under reduced pressure, bacteria were destroyed within the physiological limits of temperature, the rate of destruction increasing with the rise of temperature, at first rapidly and then more slowly. Saturated steam was found to be more effective at all temperatures than mere boiling. In practice, saturated steam at 90° C. was as effective as that at 100° C.

—C. A. M.

Sugars; Multirotation of ——. E. Roux. Ann. Chim. Phys., **30**, [7], 422—432; Chem. Centr., 1903, **2**, [22], 1242.

The aldoses can exist in three tautomeric modifications, α, β, and γ. In aqueous solution both the α-modification with high and the γ-modification with low optical rotation are converted into the β-modification with medium rotation. The author studied the course of this transformation at 18° C. in the case of the α- and γ-glucoses and lactoses. In 5 per cent. aqueous solution, the following values were obtained for $[\alpha]_D$: α-glucose, + 109·1°; γ-glucose, + 19·8°; α-lactose, + 83·16°; γ-lactose, + 35·17°. The rates of transformation of the α- and γ-modifications into the β-form are approximately the same. With a mixture of 36·73 per cent. of α-glucose and 63·27 per cent. of γ-glucose, a condition of equilibrium is attained; such a mixture has, in a 6 per cent. aqueous solution, a constant optical rotation, which is the same as that of β-glucose, namely, + 52·6°.

—A. S.

New Books.

West Indian Bulletin. The Journal of the Imperial Agricultural Department for the West Indies. Vol. IV., No. 3, 1903. Local Agents: Messrs. Bowen and Sons, Bridgetown, Barbadoes. London Agents: Messrs. Dulau and Co., 37, Soho Square, London, W. 1903. Price 6*d*.

This pamphlet-volume contains 92 pages, is of 8vo size and fully illustrated. The matter is subdivided and classified in the following groups:—I. Cotton Cultivation in the United States. II. Origin and Distribution of Sea Island Cotton. III. Varieties thereof. IV. Improvement of Sea Island Cotton by Seed Selection. V. Its Cultivation. VI Cotton Cultivation in the West Indies. VII. The Agricultural Chemistry of Cotton. VIII. Fungoid Diseases of Cotton. IX. Insect Pests of Cotton.

The Grant and Validity of British Patents for Inventions. By James Roberts, M.A., LL.B. John Murray, 50a, Albemarle Street, London. 1903. Price 25*s*. net.

Large 8vo volume, containing preface, table of contents, and tables of Cases and of Statutes and Rules. The text fills 609 pages, and there follows an alphabetical index. The matter is illustrated both with diagrams and engravings representing apparatus and plant, and is preceded by an alphabetised List of Abbreviations, a Table of Cases, also alphabetised, and a Table of Statutes and Rules. The matter is arranged in three principal parts. I. General Principles. II. Abstracts of Leading and Illustrative Cases, with Notes. III. Statutes and Rules, in so far as they bear on the Grant of Patents. Under these as principal heads the following are sub-headings:—I. (i.) Limits of Manufacture in Patent Law. (ii.) Inventions in Relation to the History and Development of the Arts. (iii.) Persons to whom Patents may be granted. (iv.) Conditions on which Patents are granted. (v.) Construction of Specifications. (vi.) Procedure to obtain a Patent. (vii.) Opposition to Grants and Appeals. (viii.) Amendment of Specifications, &c. II. Ninety-three cases referred to and given, dating from 1785 to 1903. III. Patents, Designs, and Trade Marks Act, 1883. Arrangement of Sections. Part I. Preliminary. Part II. Patents. Parts. III. and IV. Designs and Trade Marks. Part V. General. Patents, Designs, and Trade Marks (Amendment) Act, 1885. Patents Act, 1886. Patents, Designs, and Trade Marks Act, 1888. The Patents Act, 1901. The Patents Act, 1902. The Patents Rules, 1903. Law Officers' Rules. Admiralty and War Office Memoranda. The International Convention for Protection of Industrial Property. Instructions to Applicants for Patents.

Trade Report.

PARA (BRAZIL); TRADE OF ——, FOR 1902.

Foreign Office Annual Series, No. 3107, *Dec.* 1903.

British writing paper is very little known here, except by name. A fair demand for the durable kinds suitable for notarial documents would spring up if the matter were properly pushed. Many varieties of excellent paper bearing British watermarks exist, but they come from the United States, Germany, France and Italy. It is high time that the genuine article should reap some of the benefit of its good reputation. The Portland cement that comes here is another article that is British only in name. It comes from various countries, but the bulk originates from the banks of the Elbe. British barrels used to be too large, inconvenient to handle, and liable to break in transit and expose the contents to damage by water. British exporters were recommended to reduce the size, but the advice was not acted upon. German cement is put up in barrels of more suitable size, containing 120 kilos. There is a good demand for patent medicines and compressed drugs, &c., in the interior, among the people who are engaged in forest industries.

SCIENTIFIC APPARATUS: U.S. CUSTOMS DECISION.

Nov. 1903.

The Board of General Appraisers held the following to be free of duty when imported for educational institutions:—Evaporating dishes, combustion boats, Sartorius balances and weights, Royal Berlin crucibles, charcoal blocks, fine chemicals.—R. W. M.

II.—FUEL, GAS, AND LIGHT.

SHALE OIL FOR GAS WORKS: ARGENTINE REPUBLIC CUSTOMS DECISION.

Boletin Oficial, Oct. 26, 1903; *Bd. of Trade J., Dec.* 17, 1903.

A Presidential Decree assimilates for Customs purposes, shale oil, imported by gas companies for the purpose of improving the illuminating power of water gas or coal gas, to carbon bisulphide, which is free of duty under No. 3,147 of the tariff.

ANTHRACITE COAL BRICKS: U.S. CUSTOMS DECISION.

Nov. 24, 1903.

The Board of General Appraisers held that bricks of anthracite coal, cemented together with a small amount of coal tar, were dutiable at 20 per cent. *ad valorem*, as "manufactured articles unenumerated," under section 6 of the Tariff Act, and not free of duty under the Act of Congress of January 15, 1903, removing the duty on all coal for one year.—R. W. M.

III.—TAR PRODUCTS, PETROLEUM, Etc.

PARAFFIN: U.S. CUSTOMS DECISION.

Nov. 10, 1903.

A decision was rendered which is of importance in its effect on importations of petroleum into the United States. Paragraph 626 of the present Tariff Act contains a proviso as follows:—

"That if there be imported into the United States crude petroleum, or the products of crude petroleum produced in any country which imposes a duty on petroleum or its products exported from the United States, there shall in such cases be levied, paid, and collected a duty upon said crude petroleum or its products so imported equal to the duty imposed by such country."

In the cases under consideration, the paraffin was produced from Russian petroleum in Germany, which country imposes a duty on petroleum and its products. The Board held, following a previous decision, that the application of the German rate was erroneous, and sustained the claim of the importers that the Russian rate should have been imposed, and further stated that the Russian rate should be levied when importations were made from countries like Great Britain and Belgium, which imposed no duty on the American product, whenever Russian petroleum was used to produce the paraffin. The Board further held that, in cases where the origin of the crude petroleum was not known, the Collector of Customs was justified in levying the highest rate imposed by any country on petroleum and its products, such rate, however, being subject to change on the importer producing evidence of the origin of the crude oil used.—R. W. M.

CARBOLINEUM: U.S. CUSTOMS DECISION.

Nov. 12, 1903.

The Board held that carbolineum was dutiable at 20 per cent. *ad valorem* as a "preparation of coal tar, not a colour or dye," under paragraph 15 of the Tariff Act, overruling the claim of the importer at New Orleans that it was free of duty under paragraph 524, which provides for various products of coal tar, such as dead or creosote oil, naphthalene, &c.—R. W. M.

VIII.—GLASS, POTTERY, AND ENAMELS.

LEAD POISONING IN THE POTTERIES.

Pharm J., Dec. 26, 1903.

Having considered the award of Lord James and the special rules proposed to be issued under it (see this Journal, 1903, 1374), the Joint Committee of Allied Pottery Manufacturers has resolved to issue a circular stating that it is felt that everything possible has been done to convince Lord James that no such rules as proposed were either necessary or reasonable, and expressing regret that he had seen fit to issue an award which will be very difficult to carry out, and might probably be objected to on legal grounds. The Committee, however, recommends that manufacturers should, unless there are special circumstances in individual cases, which render such rules absolutely impossible, take no exception to them, but continue to work loyally for the reduction of cases of plumbism. At the same time, the committee feels it necessary to again place on record the opinion that the compensation scheme will, for some time at all events, have the effect of increasing the number of reported cases.

X.—METALLURGY.

MAGNETIC IRON SAND IN JAVA.

U.S. Cons. Reps., No. 1825, *Dec.* 14, 1903.

In the neighbourhood of the town of Tjilatjap, on the coast of the island of Java, extensive deposits of magnetic iron sand have been found. The deposits begin opposite the island of Noesa Kembangan, and extend about 29 miles to the east, along the coast line. The sand lies on the surface, and is said to contain in some places as much as 80 per cent. of iron. Samples taken in different parts give a very good result when smelted. Some time ago an English company, with a Hollander at its head, acquired the right of exploiting these deposits, which have been known since 1854.

PLATINUM WIRE: U.S. CUSTOMS DECISION.

Dec. 12, 1903.

The Board held that the provisions of paragraph 642 of the free list of the tariff, providing for the free entry of "platinum, unmanufactured, and vases, retorts and other apparatus, vessels and parts thereof composed of platinum, for chemical use," did not include platinum wire, and affirmed the assessment of duty at 45 per cent. *ad valorem*, under paragraph 193.—R. W. M.

TIN SCRAP: U.S. CUSTOMS DECISION.

Nov. 21, 1903.

Irregularly-shaped pieces of tinplate, unfit for manufacture into other articles, and used only for detinning by electrolytic processes, were held by the Board of General Appraisers to be dutiable at 10 per cent. *ad valorem* as "waste not specially provided for," under paragraph 463 of the Tariff Act, and not at $1\frac{1}{2}$ cents per lb. as "tinplate," under paragraph 134.—R. W. M.

XI.—ELECTRO-CHEMISTRY, Etc.

ELECTRIC ACCUMULATORS; MANUFACTURE OF ——.

Statutory Rules and Orders, No. 1004, *Nov.* 21, 1903.

The draft regulations for the manufacture of electric accumulators (this Journal, 1903, 1029—1030) announced as to come into force on Oct. 1, 1903, have been adopted by the Secretary of State, and came into force on Jan. 1, 1904.

XII.—FATS, FATTY OILS, Etc.

OLIVE OIL PRODUCTION IN AUSTRIA.

Bd. of Trade J., Dec. 17, 1903.

Olive oil production in Dalmatia and Istria shows during the last few years a sensible diminution. During the last three years an annual average of 5,362 tons was produced, as against an annual average of 10,194 tons produced during the nine preceding years. The oil is produced in the proportion of four-fifths by Dalmatia and one-fifth by Istria. The consumption of olive oil in Austria-Hungary during the 10 years 1892—1901 shows an average of 13,056 tons. The limited consumption of olive oil for domestic purposes in the monarchy is accounted for (1) by the very extended use, especially in Hungary, of animal fat (lard, grease, &c.), butter, margarine, goose fat, &c.; (2) by the large consumption of cotton-seed oil; (3) by the addition of sesamé oil with olive oil, which increases every day. The greatest consumption of olive oil is in Austria, as Hungary only consumes annually about 2,500 tons.

YELLOW HARD GREASE: U.S. CUSTOMS DECISION.

Dec. 1903.

A hard grease, obtained by washing the residue of the distillation of wool grease, and which is in substance wool grease, was held to be dutiable at $\frac{1}{2}$ cent per lb. as "wool grease," under paragraph 279 of the Tariff Act. The Board had previously held similar merchandise to be free of duty as "sod oil," under paragraph 568, which opinion was affirmed by the United States Circuit Court. On further appeal the United States Circuit Court of Appeals held as above stated, reversing both the lower Court and the Board. The above decision of the Board follows the decision of the higher Court.—R. W. M.

CHINESE WOOD OIL [TUNG OIL]:
U.S. CUSTOMS DECISION.

Nov. 14, 1903.

Following a decision of the United States Court reversing a decision of the Board, the Board of General Appraisers held that Chinese wood oil obtained from the kernels of various species of Aleurites is free of duty as "nut oil" under paragraph 626 of the present Tariff Act. A decision of the Board had also held that Jatropha nuts, from which an oil is obtained, are in fact nuts, hence the oil is a "nut oil."—R. W. M.

XIII. A.—PIGMENTS, PAINTS, Etc.

HEMATITE ORE PIGMENT: U.S. TREASURY DEPARTMENT.

Dec. 1903.

In a recent suit in the Circuit Court it was decided that certain soft hematite was dutiable at 40 cents per ton as an iron ore under paragraph 121 of the Tariff Act. The Treasury Department, however, holds that it is a "crude pigment," and has directed that future importations be classified at 30 per cent. *ad valorem* under paragraph 58, with the view of bringing the matter again before the courts for decision.—R. W. M.

XIV.—TANNING; LEATHER; GLUE, Etc.

SUMACH TRADE OF SICILY.

Bd. of Trade J., Dec. 17, 1903.

The new season's harvest of sumach is estimated to be about a third less than that of last year. "Stinco"

(*Pistacio lentiscus*), imported from Tunis, is scarce, owing to its being exported direct to France to tanners who have been employing it instead of sumach, the price of which had risen excessively.

XV.—MANURES, Etc.

PHOSPHATE ROCK IN TUNIS; DISCOVERIES OF ——.

Eng. and Mining J., Dec. 17, 1903.

A Belgian company, which has been exploring the district of Uarfa-Tarf, about 50 km. west of Gafsa, reports the discovery of an important deposit of phosphate rock. Six seams in all were found, of which three, having a total thickness of nearly 5 m., were of sufficiently high grade to warrant their exploitation. Analyses give an average of 63 per cent. calcium phosphate, with from 14 to 20 per cent. calcium carbonate and 1·5 per cent. of alumina. The deposits occur near the base of the Tertiary formation.

XVI.—SUGAR, STARCH, Etc.

BEET-SUGAR PRODUCTION AND CONSUMPTION.

U.S. Cons. Reps., No. 1825, *Dec.* 14, 1903.

Under date of October 27, 1903, United States Consul Walter Schumann, of Mainz, Germany, transmits the following estimated beet-sugar production of Europe, as compiled by the International Association for Sugar Statistics:—

Country.	Plants in operation.	Production.	
		1903-4.	1902-3.
	No.	Met. tons.	Met. tons.
Germany	384	1,803,160	1,750,670
Austria	215	1,116,500	1,050,960
France	296	757,000	823,600
Belgium	100	215,300	200,000
Holland	29	129,300	102,300
Russia	275	1,103,000	1,169,600
Sweden	16	110,795	73,400
Denmark	7	51,800	37,067
Total	1,322	5,286,855	5,207,537

World's Sugar Production and Consumption.

A pamphlet recently published by Sir Neville Lubbock gives the following statistics of the world's production and consumption of sugar, beet and cane:—

Production.

Country.	1901 2	1902-3.
	Tons.	Tons.
Europe (beet), except Russia	5,722,000	4,390,000
Russia (beet)	1,090,000	1,215,000
British colonies	545,500	513,000
Egypt	96,000	90,000
India	3,000,000	3,000,000
United States, Cuba, Porto Rico, Manila, and Hawaii	1,804,500	1,920,000
Peru, Argentine Republic, Dominican Republic, Mexico, and Brazil	738,500	582,500
Java	767,000	842,500
French colonies	119,000	104,000
Total	13,882,500	12,657,000

Consumption.

Of the foregoing India and Russia will consume their own product; the United States will consume its own product and that of Cuba, Porto Rico, Manila, and Hawaii; Europe will consume 2,656,000 tons and 2,750,000 tons of its own beet-sugar production for the years given. This leaves available for the United Kingdom and other countries the following amounts.

Product of—	1901-2.	1902-3.
	Tons.	Tons.
Europe (beet)	3,066,000	1,640,000
British colonies	545,500	513,000
Egypt	96,000	90,000
Peru, Argentine Republic, Dominican Republic, Mexico, and Brazil	738,500	582,500
Java	767,000	842,500
French colonies	110,000	104,000
Total	5,323,000	3,772,000

BEET-SUGAR FACTORY IN TURKESTAN.

U.S. Cons. Reps., No. 1826, *Dec.* 15, 1903.

Near Taschkent, the capital of the district of Turkestan, a beet-sugar factory is expected to be in working order in September, 1904. Its annual output is estimated at about 5,000 metric tons, about one-fifth of the total consumption of sugar in Russian Central Asia. The beetroot is said to contain in Turkestan about 2 per cent. more sugar than in European Russia, so that it is very likely the sugar industry in those parts will develop favourably and quickly.

COUNTERVAILING DUTIES ON SUGAR FROM BRITISH POSSESSIONS.

Bd. of Trade J., Dec. 17, 1903.

A Note from the Belgian Government announced the decision arrived at by the Permanent Sugar Commission at Brussels with regard to the countervailing duties to be applied to sugars imported into the territories of the States parties to the International Sugar Convention from the undermentioned British Colonies. In accordance with the declaration made by H.M. Government on the ratification of the Convention, there will be no penalisation of sugars imported into the United Kingdom from any British Possessions; and it is not obligatory upon the other States parties to the Convention to apply these countervailing duties until an appreciable amount of sugar is actually imported into their respective territories from the Colonies concerned. The rates of duty in question are as follows:—

	Per 100 kilos.	
	Frs.	Cts.
Canada:		
On refined sugar	3	63
South African Customs Union:—		
On raw sugar	2	05
On refined sugar	3	89
Commonwealth of Australia:—		
On raw sugar	0	94
On refined sugar	5	62

XVII.—BREWING, WINES, SPIRITS, Etc.

DENATURED ALCOHOL IN ITALY.

Chem. and Druggist, Dec. 19, 1903.

The manufacturers of sulphuric ether in Italy are allowed to use denatured alcohol, subject to conditions to be imposed by the Minister of Finance. Varnish manufacturers will enjoy similar rights.

XIX.—PAPER, PASTEBOARD, Etc.

CELLULOID ARTICLES; DUTY ON ——: U.S. CUSTOMS DECISION.

Dec. 2, 1903.

The Board of General Appraisers held that, in assessing duty on articles composed in part and in chief value of celluloid, the whole weight of the articles, and not that of the celluloid alone, should be taken.—R. W. M.

XX.—FINE CHEMICALS, Etc.

ESSENCE OF ROSEWOOD IN FRENCH GUIANA.

Foreign Office Annual Series, No. 3106, *Dec.* 1903.

Essence of rosewood is produced from the rosewood (*Licaria Guianensis*). The wood itself was formerly shipped to France, but two factories have recently been established to extract the essence, which is now shipped to France in carboys. The wood is sold in the local market at 80 fr. (3*l*. 4*s*.) per ton. The average product of 1 ton of wood is 22½ lb. of essence, the price in France being about 10*s*. per pound.

Salol and Phenacetin: U.S. Customs Decision.

Dec. 1903.

Salol, phenacetin and other medicinal preparations were assessed for duty at 55 cents per pound, under paragraph 67 of the Tariff Act, as "medicinal preparations in the preparation of which alcohol had been used." The importers endeavoured to show that alcohol was not necessary for their manufacture. The Board held this evidence to be insufficient and affirmed the assessment of duty.—R. W. M.

Chloral Hydrate and Salol: U.S. Customs Decision.

The United States Circuit Court of Appeals has rendered a decision regarding the dutiable character of salol and chloral hydrate which has an important bearing on the imports into the United States of medicinal preparations in the manufacture of which alcohol is used. The Court held that if alcohol is used in any way, and even if it is broken up or removed, the finished product is subject to a duty of 55 cents per pound under paragraph 67. In order to be dutiable at 25 per cent. *ad valorem* under paragraph 68, evidence must be submitted showing that alcohol was used at no stage of the process. This decision reverses numerous decisions of lower courts.—R. W. M.

Patent List.

N.B.—In these lists, [A.] means "Application for Patent," and [C.S.], "Complete Specification Accepted."

Where a Complete Specification accompanies an Application, an asterisk is affixed. The dates given are (i) in the case of Applications for Patents, the dates of application, and (ii) in the case of Complete Specifications Accepted, those of the Official Journals in which acceptances of the Complete Specifications are advertised.

Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

I.—PLANT, APPARATUS, AND MACHINERY.

JOURNAL OF THE Society of Chemical Industry.

A RECORD
FOR ALL INTERESTED IN CHEMICAL AND ALLIED MANUFACTURES.
ISSUED TWICE A MONTH.

No. 2.—Vol. XXIII. JANUARY 30, 1904. No. 2.—Vol. XXIII.

Subscription of Members 25/- per annum;
Entrance Fee 21/-;
Election by the Council.

Price to Non-Members 36/- per annum;
To Members 25/- per Set of extra or back numbers.
Single copies (Members and Subscribers only),
1882—1901, 2/6 each; 1902 *et seq.*, 1/9 each.

The Society of Chemical Industry.

Past Presidents:

Sir Henry E. Roscoe, B.A., D.C.L., LL.D., Ph.D., F.R.S.	1881—1882.
Sir Frederick A. Abel, Bart., K.C.B., G.C.V.O., D.C.L., D.Sc., F.R.S.	1882—1883.
Walter Weldon, F.R.S.	1883—1884.
W. H. Perkin, LL.D., Ph.D., F.R.S.	1884—1885.
E. K. Muspratt	1885—1886.
David Howard	1886—1887.
James Dewar, M.A., LL.D., F.R.S.	1887—1888.
Ludwig Mond, Ph.D., F.R.S.	1888—1889.
Sir Lowthian Bell, Bart., F.R.S.	1889—1890.
E. Rider Cook	1890—1891.
J. Emerson Reynolds, M.D., F.R.S.	1891—1892.
Sir John Evans, K.C.B., D.C.L., LL.D., Sc.D., F.R.S.	1892—1893.
E. C. C. Stanford	1893—1894.
T. E. Thorpe, C.B., LL.D., Sc.D., Ph.D., F.R.S.	1894—1895.
Thomas Tyrer	1895—1896.
Edward Schunck, Ph.D., F.R.S.	1896—1897.
F. Clowes, D.Sc.	1897—1898.
George Beilby	1898—1899.
C. F. Chandler, D.Sc., M.D., Ph.D., LL.D.	1899—1900.
Jos. W. Swan, D.Sc., M.A., F.R.S.	1900—1901.
Ivan Levinstein	1901—1903.

COUNCIL FOR YEAR ENDING JULY 1904.

President: Sir W. Ramsay, K.C.B., D.Sc., LL.D., F.R.S.

Vice-Presidents:

Prof. P. Phillips Bedson.
Prof. Marston T. Bogert.
E. Carey.
Dr. John Clark.
E. Grant Hooper.
Ivan Levinstein.
Dr. R. Messel.
W. H. Nichols.
Dr. F. B. Power.
Prof. H. R. Procter.
Dr. Jos. W. Swan, F.R.S.
Thos. Tyrer.

Ordinary Members of Council:

Dr. Edw. Divers, F.R.S.
Dr. J. Grossmann.
H. Hemingway.
Prof. W. R. E. Hodgkinson, Ph.D
David Howard.
Dr. J. Lewkowitsch.
N. H. Martin.
Max Muspratt.
B. E. R. Newlands.
Prof. W. J. Pope, F.R.S.
Frank Scudder.
Dr. W. S. Squire.

Sectional Chairmen and Secretaries.

Prof. W. R. Lang.	CANADIAN.	Alfred Burton.
F. H. Tate.	LIVERPOOL.	W. R. Hardwick.
Walter F. Reid.	LONDON.	Julian L. Baker.
J. Carter Bell.	MANCHESTER.	Julius Hübner.
Dr. J. T. Dunn.	NEWCASTLE.	F. C. Garrett.
Dr. V. Coblentz.	NEW YORK.	Dr. H. Schweitzer.
J. T. Wood.	NOTTINGHAM.	S. R. Trotman.
T. L. Patterson.	SCOTTISH.	Dr. Thos. Gray.
Prof. A. Liversidge.	SYDNEY, N.S.W.	T. U. Walton.
Jas. E. Bedford.	YORKSHIRE.	Thos. Fairley.

Honorary Treasurer:
Samuel Hall, East London Soap Works, Bow, E.

Honorary Foreign Secretary:
Dr. Ludwig Mond, F.R.S.

General Secretary: Charles G. Cresswell.

Offices: Palace Chambers, 9, Bridge Street, Westminster, S.W.
Telegraphic Address: 59, Palatable, London.

THE JOURNAL.

Publication Committee:

The President.

A. H. Allen.
G. Beilby.
J. Carter Bell.
Joseph Bernays, M.I.C.E.
H. Brunner.
Edw. Divers, M.D., D.Sc., F.R.S.
Sir John Evans, K.C.B., F.R.S.
T. Fairley.
Prof. A. G. Green.
Samuel Hall.
Otto Hehner.
John Heron.
D. B. Hewitt, M.D.
Prof. W. R. E. Hodgkinson, Ph.D.
E. Grant Hooper.
David Howard.
Julius Hübner.
Prof. A. K. Huntington.
Wm. Kellner, Ph.D.
Charles A. Kohn, M.Sc., Ph.D.
Ivan Levinstein.
J. Lewkowitsch, Ph.D.
A. R. Ling.
W. Macnab.
N. H. Martin.
B. E. R. Newlands.
John Pattinson.
F. B. Power, Ph.D.
Prof. H. R. Procter.
Boverton Redwood, D.Sc.
Walter F. Reid.
John Spiller.
W. S. Squire, Ph.D.
L. T. Thorne, Ph.D.
Thomas Tyrer.

Editor:

Watson Smith, 34, Upper Park Road, Haverstock Hill, N.W.

Assisted by the following Staff of Abstractors:

Robt. Adams	I.
L. Archbutt	I., XII.
J. L. Baker	XVI., XVII.
H. Ballantyne	II., XII.
D. Bendix	III.
E. Bentz	IV., V., VI.
J. O. Braithwaite	XX.
J. F. Briggs	XVI., XVII., XIX., XX.
J. K. Burbridge	XIII. C.
T. F. Burton, B.Sc.	Patent List.
J. H. Collins	X.
J. T. Dunn, D.Sc.	VII., X.
Ernest Feilmann, B.Sc., Ph.D.	IV., V., XX.
Leo F. Guttmann, Ph.D.	I., II.
Walter C. Hancock, B.A.	II., VIII., IX.
R. L. Jenks	XIII. C., XIV., XIX.
F. H. Leeds	II., III., XIII., XXI.
A. G. Levy, B.Sc.	VIII., IX.
G. W. MacDonald, M.Sc.	XXII.
W. G. McMillan	X., XI., XIV., XXII.
N. H. J. Miller, Ph.D.	XV.
C. A. Mitchell, B.A.	XII., XXII.
R. W. Moore	Trade Report.
Barker North	V., XI.
J. G. Parker, Ph.D.	XIV.
T. H. Pope	XVI., XX., XXI.
F. W. Renaut	Index.
Chas. Salter	II., III., XVI., XVII.
M. J. Salter	XIII.
A. Shonk	Gen. Chem.
W. P. Skertchley	XII., XVIII.
E. Sonstadt	III., VII., X., XV.
A. B. Steven, B.Sc.	IV., V.
E. Howard Tripp, Ph.D.	III., VII., XVI.
Charles T. Tyrer	XX.
L. J. de Whalley, B.Sc.	XVI.

Canadian Section.

Chairman: W. R. Lang.

Vice-Chairmen: G. P. Girdwood. F. J. Smale.

Committee:

G. W. Campbell Arnott.
J. Watson Bain.
Hugo Carlsson.
Thos. Davies.
W. Hodgson Ellis.
W. L. Goodwin.
Edgar B. Kenrick.
Thos. MacFarlane.
W. Lash Miller.
Jas. P. Murray.
J. M. Sparrow.
M. J. Taylor.
Harold Van der Linde.

Hon. Treasurer: M. J. Taylor, 77, Front Street East, Toronto.

Hon. Local Secretary:
Alfred Burton, 42, Front Street West, Toronto.

Liverpool Section.

Chairman: F. H. Tate.

Vice-Chairman: C. Longuet Higgins.

Committee:

Percy Bateson.
J. Campbell Brown.
G. C. Clayton.
A. Foden.
G. Watson Gray.
Max Muspratt.
E. L. Peck.
Julius Raschen.
Alf. Smetham.
H. B. Stocks.
J. W. Towers.

Hon. Treasurer: W. P. Thompson.

Hon. Local Secretary:
W. R. Hardwick, 13, Batavia Buildings, Hackins Hey, Liverpool.

London Section.

Chairman: Walter F. Reid.

Vice-Chairman: A. Gordon Salamon.

Committee:

J. N. Connah.
E. Divers.
Bernard Dyer.
M. O. Forster.
R. J. Friswell.
Oscar Guttmann.
Otto Hehner.
J. T. Hewitt.
J. Lewkowitsch.
A. R. Ling.
A. Gordon Salamon.
W. S. Squire.
F. Napier Sutton.
L. T. Thorne.
Thos. Tyrer.

Hon. Local Secretary:
Julian L. Baker, 7, Addison Road, Bedford Park, W.

SESSION 1903—1904.

Monday, Feb. 1. Mr. Julian L. Baker. "A *Résumé* of the Report, Minutes of Evidence, and Appendices of the Royal Commission on Arsenical Poisoning."

Manchester Section.

Chairman: J. Carter Bell.

Vice-Chairman: G. H. Bailey.

Committee:

J. Allan.
R. Clayton.
G. J. Fowler.
H. Grimshaw.
B. Hart.
W. E. Kay.
H. Levinstein.
K. Markel.
W. J. Pope.
F. Scudder.
T. Stenhouse.
H. L. Terry.

Hon. Local Secretary:
Julius Hübner, 24, Delaunay's Road, Crumpsall, Manchester.

SESSION 1903—1904.

Friday, Feb. 5. Mr. Julius Hubner and Prof. W. J. Pope, F.R.S. "The Lustre, the Tinctorial Properties, and the Structural Alterations which result from treating Cotton with Mercerising and other Liquids."

Newcastle Section.

Chairman: J. T. Dunn.

Vice-Chairman: W. L. Rennoldson.

Committee:

A. Allhusen.
P. P. Bedson.
H. S. Collins.
T. W. Hogg.
H. Louis.
N. H. Martin.
John Pattinson.
W. W. Proctor.
Harry Smith.
A. Spiller.
J. E. Stead.
C. E. Stuart.

Hon. Local Secretary and Treasurer:
F. C. Garrett, Durham College of Science, Newcastle-on-Tyne.

SESSION 1903—1904.

Thursday, Feb. 4.—Mr. George Sisson. "Some Notes on the Uses of Liquid Carbon Dioxide."

New York Section.

Chairman: V. Coblentz.

Vice-Chairman: Russell W. Moore.

Committee:

Capt. H. C. Aspinwall.
L. Baekeland.
Prof. C. F. Chandler.
G. Drobegg.
W. F. Fuerst.
E. J. Lederle.
Dr. Wm. McMurtrie.
Wm. H. Nichols.
T. J. Parker.
Clifford Richardson.
W. J. Schieffelin.
G. C. Stone.
D. Woodman.

Hon. Treasurer: R. C. Woodcock.

Hon. Local Secretary:
H. Schweitzer, 40, Stone Street, New York, U.S.A.

Nottingham Section.

Chairman: J. T. Wood.

Vice-Chairman: S. F. Burford.

Committee:

L. Archbutt.
F. J. R. Carulla.
R. M. Caven.
F. Stanley Kipping.
G. D. Lander.
H. B. Mayfield.
J. O'Sullivan.
J. M. C. Paton.
A. L. Stern.
G. J. Ward.
J. White.

Hon. Treasurer: S. J. Pentecost.

Hon. Local Secretary:
S. R. Trotman, King's Walk Chambers, Parliament Street, Nottingham.

Scottish Section.

Chairman: T. L. Patterson.

Vice-Chairman: D. J. Playfair.

Committee:

H. Bumby.
D. B. Dott.
Thos. Ewan.
J. Arnold Fleming.
W. Frew.
G. H. Gemmell.
Jas. Hendrick.
Jas. Hope.
H. Ingle.
D. S. Jerdan.
W. G. Johnston.
J. Falconer King.
J. G. F. Lowson.
J. S. Macarthur.
J. McCulloch.
M. A. Parker.

Hon. Secretary and Treasurer:
Thomas Gray, c/o Gourlay and Deas, 180, Hope Street, Glasgow.

Sydney, N.S.W., Section.

Chairman: A. Liversidge.

Committee:

W. A. Dixon.
J. F. Elliott.
F. B. Guthrie.
L. Meggitt.
J. Morison.
A. A. Ramsay.
J. A. Schofield.
R. Greig Smith.
H. G. Smith.
T. Steel.

Hon. Local Secretary:
T. U. Walton, Colonial Sugar Co., O'Connell Street, Sydney, N.S.W

Yorkshire Section.

Chairman: Jas. E. Bedford.

Vice-Chairman: G. W. Slatter.

Committee:

C. S. Bedford.
E. A. Brotherton.
John W. Cobb.
W. M. Gardner.
A. J. Murphy.
H. R. Procter.
F. W. Richardson.
Geo. Ward.
H. A. Watson.
Thorp Whitaker.
J. B. Wilkinson.

Hon. Local Secretary and Treasurer
T. Fairley, 17, East Parade, Leeds.

Notices.

ANNUAL GENERAL MEETING, NEW YORK, 1904.

The Annual General Meeting will be held in New York City on Thursday, Sept. 8th, and following days. Members who contemplate attending are requested to communicate with the General Secretary as soon as possible, in order that suitable travelling arrangements may be made. A programme appears in this issue of the Journal.

COMMUNICATIONS.

Authors of communications read before the Society, or any of its Local Sections, are requested to take notice that under Rule 43 of the Bye-laws the Society has the right of priority of publication for three months of all such papers. Infringement of this Bye-law renders papers liable to be rejected by the Publication Committee, or ordered to be abstracted for the Journal, in which case no reprints can be furnished to the author.

List of Members Elected

22nd JANUARY 1904.

Booth, N. P., Analytical Laboratory, Cadbury Bros., Ltd., Bournville, near Birmingham, Analytical Chemist.

Brading, R. W., Casella, Sandal Road, New Malden, Surrey, Builder.

Buchanan, E. F., 712, Payne Avenue, Akron, Ohio, U.S.A., Chemist.

Cirkel, Fritz, 80, Stanley Street, Montreal, P.Q., Canada, Mining Engineer.

Costobadie, H. A., Overdale, Mottram-in-Longdendale, near Manchester, Calico Printer.

Cramer, A., jun., Cramer and King Co., Paterson, N.J., U.S.A., Chemist.

Dale, G., Waverley Terrace, Hood Lane, Warrington, Technical Chemist.

Dick, W. D., 46, Primrose Hill Road, South Hampstead, N.W., Analytical Chemist.

Dreyfus, Dr. L. A., c/o The Muralo Co., New Brighton, S.I., N.Y., U.S.A., Chemist.

Fitch, A. J., 19, Grange Road, Canonbury, N., Brewer's Chemist.

Fleurent, Dr. E., 5, Villa du Chateau, Bois Colombes (Seine), France, Professor of Chemistry.

Hammond, H. S., Government Laboratory, Kingston, Jamaica, West Indies, Analyst.

Harley, B., 12, Russell Street, Falkirk, N.B., Analytical Chemist.

Hawthorn, J. H., Municipal Technical School, Leicester, Head Master.

Hornsey, J. W., 914, New England Building, Cleveland, Ohio, U.S.A., Chemical Engineer.

Howard, T., Hibernia House, Hibernia Road, Hounslow, London, Chemist.

Irlam, H. A., 34, East Street, Faversham, Kent, Chemist.

Johnson, F. M. G., 286, Peel Street, Montreal, P.Q., Canada, Chemist.

Kawai, I., 54, Shidamachi Shirokane, Shiba, Tokyo, Japan, Chemist.

Koch, J. A., Bluff and Pride Streets, Pittsburg, Pa., U.S.A., Chemist.

Koebig, Dr. J., Koebig and Fosdick, 828, E. Third Street, Los Angeles, Cal., U.S.A., Chemical Engineer.

Kyle, J., Canada Paint Co., Ltd., 572, William Street, Montreal, Canada, Analytical Chemist.

Lewis, E. W., c/o Associated Portland Cement Manufacturers (1900), Ltd., White's Branch, Swanscombe, Kent, Works Chemist.

Link, J., 92, Harrow Road, Leytonstone, N.E., Chemical Manufacturer.

Livermore, W. D., Washington Mill, Lawrence, Mass., U.S.A., Chemist.

Loomis, Dr. H., 58, West 10th Street, New York City, U.S.A.

MacKechnie, R. D., Chas. Tennant and Co., Ltd., Carnoustie, Forfarshire, Chemist.

Maréchal, H., Eugene Maréchal et fils, Vénissieur (Rhone), France, Oilcloth Manufacturer.

Mitsugi, R., Naoki Match Manufactory, Aratamachi, Kobe, Japan, Chemist.

Nichols, C. W., 406, Clinton Avenue, Brooklyn, N.Y., U.S.A., Manufacturing Chemist.

Packard, C. T., Millbank, Bramford, near Ipswich, Manager of Chemical Works.

Parker, G. H., c/o Messrs. Haddock, Parker, and Co., 14, Chapel Street, Liverpool, Chemical Broker.

Phillips, V. C., Haselmere, Morris Avenue, Manor Park, E., Chemist.

Ratcliffe, C. F., Tar Works, Pontefract Road, Leeds, Tar Distiller.

Riley, W. A., Brunswick Lodge, Newmarket Road, Norwich, Brewer.

Roeber, Dr. E. F., 114, Liberty Street, New York City, U.S.A., Editor of "Electrochemical Industry."

Rose, J., 121, Lovely Lane, Warrington, Technical Chemist.

Rowling, S. R., 1, Beechwood, Kendal, Westmoreland, Analyst.

Shepherd, A. B., Wood Nook, Cookridge, near Leeds, Analytical Chemist.

Short, A., Choppington, Morpeth, Works Chemist.

Skirrow, Dr. F. W., c/o The Manchester Oxide Co., Canal Street, Miles Platting, Manchester, Research Chemist.

Smith, A. E., c/o Mount Hope Finishing Co., North Dighton, Mass., U.S.A., Superintendent.

Smith, H., 83, Brownlow Road, Horwich, Bolton-le-Moors, Lancashire, Analytical Chemist.

Stephen, A. E., 23, Victoria Street, Ashfield, Sydney, New South Wales, Analytical Chemist.

Stevens, E. B., 688, 7th Street, Buffalo, N.Y., U.S.A., Treasurer and Chemist.

Stieglitz, J., University of Chicago, Chicago, Ill., U.S.A., Associate Professor of Chemistry.

Tyler, C. R., 421, West 57th Street, New York City, U.S.A., Analytical Chemist.

Uyeda, T., Takasago, Harima, Japan, Chemist.

Williams, H. L., P.O. Box 410, Bristol, Tennessee, U.S.A., Manufacturer of Barium Salts.

Young, J. H., c/o The Cassel Gold Extracting Co., Ltd., Shuna Street, Maryhill, Glasgow, Technical Chemist.

Zieme, C. H., c/o Incandescent and Chemical Co., Youngstown, Ohio, U.S.A., Chemist.

Changes of Address.

When notifying new addresses, members are requested to write them distinctly, and state whether they are temporary or permanent. Multiplication of addresses is also to be avoided as tending to create confusion. When sending subscriptions, the use of the form attached to the application helps in the verification of addresses, on which the safe delivery of the Journal depends.

Annandale, Jas. H.; all communications to Polton Paper Works, Midlothian.

Bennie, P. McN.; all communications to P.O. Box 118, Niagara Falls, N.Y., U.S.A.

Bierwirth, L. W., l/o Pompton Lakes; Dover, N.J., U.S.A.

Bourcoud, A. E.; all communications to Comp. General de Productos Quimicos del Aboño, Gijon, Spain.

Bradford, Henry, l/o "Aberfeldy"; Southampton House, Southwick, near Brighton.

Cady, W. B., l/o Cement City; c/o Wabash Portland Cement Co., Stroh, Ind., U.S.A.

Cooper, W. R., l/o Upper Tulse Hill; 113, Tulse Hill, London, S.W.

Crosskey, A. N., l/o Llanelly; c/o Dr. Crosskey, Lewes, Sussex; and communications temporarily to Cotswold Sanatorium, near Stroud, Gloucestershire.

Dickenson, E. N., l/o Wall Street; 141, Broadway, New York City, U.S.A.

Eastick, Chas. E.; all communications to 7, King Edward Street, Whitechapel, E.

Elmore, A. Stanley; communications to 4, Broad Street Place, E.C.; Journals as before.

Emery, A. L., l/o Palo Alto; 83-85, New Montgomery Street, San Francisco, Cal., U.S.A.

Evershed, F.; all communications to Atlas Works, Hackney Wick, N.E.

Fitzgerald, F. A. J.; all communications to P.O. Box 118, Niagara Falls, N.Y., U.S.A.

Fleming, J. Arnold; Journals to Britannia Pottery, 136, Glebe Street, Glasgow.

Fraser, Robt. A., l/o Bootle; The Serpentine S., Blundellsands, near Liverpool.

Gaskell, Holbrook, jun., l/o Liverpool; Erindale, Frodsham, Cheshire.

Gaskell, Holbrook, III., l/o Liverpool; Erindale, Frodsham, Cheshire.

Gill, J. Arthur, l/o Stratford; 10, Manor Road, Rusthall, Tunbridge Wells.

Haigh, Dr. Lagnel, l/o Bayonne City; 33, Norwood Avenue, Summitt, N.J., U.S.A.

Harman, E. A.; all communications to Gas Works, Huddersfield.

Hawdon, H. S.; all communications to Harton Road, Westoe, South Shields.

Hellier, E. A., l/o Hull; Avonside Varnish Works, Bristol.

Hemingway, Henry; Journals to Baglan Lodge, Briton Ferry, South Wales; communications as before.

Hibbard, P. L., l/o North 41st Court; 2657, North 42nd Court, Chicago, Ill., U.S.A.

Hislop, G. R., (subscriptions) Greenhill House, Underwood Road, and (Journals) Gas Works, Paisley.

Johnston, W. G.; all communications to Anchor Chemical Works, 1095, Garngad Road, Glasgow.

Jonker, H., Czn., l/o Rotterdam; Hotel zum Weiszen Ross, Worth a/S., Germany.

Laurence, Jas., l/o Wall Street; Box 707, Joplin, Mo., U.S.A.

Levinstein, Ivan, (subscriptions) 21, Minshull Street, Manchester, and (Journals) Hawkesmoor, Fallowfield, Manchester.

Lindmueller, Chas., l/o Columbus; c/o Ohio Farmers' Fertilizer Co., 882, Prospect Street, Cleveland, Ohio, U.S.A.

Longstaff, J. P., l/o Heriot Watt College; Chemical Department, The University, Edinburgh.

Macfarlane, Thos.; all communications to 317, Queen Street, Ottawa, Canada.

Milroy, And., l/o Glasgow; House Hill Muir, Nitshill, N.B.

Nact, Dr. E. E., l/o Moss Side; 26, Stanley Road, Whalley Range, Manchester.

Neumann, Dr. Max, l/o Engelufer; Hohenstaufenstrasse 32, Berlin W. 30, Germany.

Paul, Jas. H., l/o Charlton; 19, Glenluce Road, Blackheath, S.E.

Pitman J. R., l/o Pompton Lakes; c/o Laflin and Rand Powder Co., Haskell, N.J., U.S.A.

Richardson, F. W.; Journals to Oak Lea, Menston, Yorks.

Rothwell, C. F. Seymour, l/o Manchester; Film and Paper Factory, Mobberley, Cheshire.

Schultze, Wm., l/o 102; 194, Academy Street, Jersey City Heights, N.J., U.S.A.

Seymour-Jones, A.; all communications to Pendower, Wrexham.

Simpson, W. S., l/o Enfield; 17, Lakeside Road, Palmer's Green, N.

Smith, H. Procter, l/o Coatbridge; "Gorphwysfa," Shotton, Flintshire.

Smythe, Dr. J. S.; communications to Rantallard, Lance Lane, Wavertree, Liverpool; Journals as before.

Spence, J. Davidson; communications to 39, Mincing Lane, E.C.

Steel, R. E.; all communications to 38, East Park Parade, Northampton.

Stevens, M. White, l/o Plymouth; H.M. Patent Office, Chancery Lane, W.C.

Stoddart, F. W.; all communications to Western Counties Laboratory, College Green, Bristol.

Sundstrom, K. J., l/o Trenton; Sibley, Mich., U.S.A.

Sutherst, Dr. W. F., l/o Wembley; Brimsdown Lead Co., Ponders End, N.

Swinburne, Geo.; subscriptions c/o Jno. Coates and Co., Suffolk House, Laurence Pountney Hill, E.C.; Journals as before.

Tatlock, R. R.; all communications to 156, Bath Street, Glasgow.

Thomson, Jno., l/o Malauney; Overlee, Alexandria, N.B.

Umney, Charles; Journals to 81, Lawrie Park Road, Sydenham, S.E.

Walton, T. U.; Journals (temporary) to 65, Union Street, Greenock, N.B.

Wielandt, Dr. W., l/o Berlin; Maltkestrasse 8^1, Magdeburg, Germany.

Death.

Johnstone, Jas., Shawfield Works, Rutherglen, Glasgow. Jan. 10.

London Section.

Meeting held at Burlington House, on January 4th, 1904.

MR. WALTER F. REID IN THE CHAIR.

THE DEFECTS OF UNCARBURETTED WATER-GAS AS FUEL FOR LABORATORY USE.

BY MASUME CHIKASHIGE, D.Sc., F.C.S., AND HITOSHI MATSUMOTO.

To those who have to find the gas-fuel for their laboratories, water-gas will commend itself by the little room taken up by the apparatus for making it, and by the relative simplicity of its manufacture and purification owing to the fact that very little tar is produced. They will also take into account the smallness of the disadvantage of interrupting the manufacture when necessary, and of thus working the process intermittently. Governed by such considerations as these, we have for several years endeavoured to make use of water-gas in Bunsen burners for ordinary purposes in our laboratories. Having become convinced of its unfitness for this purpose, we offer an account of our experience for the information of those who, like ourselves, have to provide their own gas supply, and also for the information of others who, though more fortunate, may yet find interest in the problem of the utilisation of water-gas.

The Gas used.—The gas which we made and used was analysed from time to time. Its average composition is as follows:—

	Per Cent.
Hydrogen	48·8
Methane	0·8
Carbon monoxide	33·1
Carbon dioxide with some hydrogen sulphide	8·5
Nitrogen	8·5
Oxygen	0·3

The gas was purified only to the extent deemed sufficient, and was supplied under a pressure of 5 cm. of water. The plant being set up very near to the laboratory, the iron main-pipe was very short, and tarring the inside of it was therefore neglected. Iron will consequently have been taken up in minute quantity by the carbon monoxide in the passing gas, and been present in it as iron carbonyl.

The Burning of Water-Gas.—With the Bunsen burner ready to hand as the nearly universal laboratory gas-burner, we always used it for burning the water-gas, although the composition of this gas and its smokeless flame make the air-ways of a Bunsen burner almost useless. The admission of some air with the gas may perhaps raise its temperature a little, but for most purposes this is already too high, as will be shown presently. A problem, however, can be solved by the air-fed flame, of which the solution is not only of practical importance in connection with the use of the water-gas flame, but also of general interest in the study of hydrocarbon flames. It is that of determining the order followed in the combustion of this mixture of water-gas and air, to find out whether the hydrogen and carbon monoxide burn together or one before the other. Now, as water-gas, when fed with air, burns with a flame having the usual two cones, which can be separated in the Smithells and Ingle apparatus, it becomes easy to get the answer to this question. The experiment was accordingly made, and gave the results shown in the following table, together with those obtained with coal-gas by Smithells and Ingle :—

Partly burnt Gas.	Water-gas.	Coal-gas (S. and I.).
	Vol. per Cent.	Vol. per Cent.
Water	17·0	14·9
Hydrogen	20·0	10·9
Methane	0·3	trace
Carbon dioxide	8·8	3·8
Carbon monoxide	19·5	10·2
Oxygen	0·1	..
Nitrogen	34·3	60·3

The numbers given by the water-gas show that about one volume of air had been mixed with two volumes of the gas, that being as much as could well be employed without risk of explosion. In Smithells and Ingle's experiments with coal-gas, nearly ten times as much air was used (9·6 to 2), but this difference is a matter of course and necessity. Two points of interest in the comparison are (1) that in each case the volume of the remaining hydrogen is about equal to that of the carbon monoxide ; and (2) that the concentration of these gases is only half as great in the partly burnt coal-gas as it is in the partly burnt water-gas. Coming now to the problem to solve which the experiment with water-gas was undertaken, it will be seen that the result establishes the fact that the hydrogen burns before the carbon monoxide mixed with it. From this it follows that the inner cone of the flame of water-gas and air is that of burning hydrogen, and that in the outer cone of this flame, and also in that of hydrocarbon flames, the carbon monoxide must be the last constituent to burn.

Relative Value of the Water-Gas Flame.—We began this paper by stating some points in the manufacture of water-gas, which seem to commend its employment in some circumstances in the laboratory. But, as yet, we have made no reference to the advantages of using water-gas which are offered by the properties of its flame. Its advantageous properties when burning are, however, so well known that we need not dwell upon them, and we shall, therefore, only now refer to them in order to point out some drawbacks which attend them. One advantage is that the flame needs no air draught to render it smokeless, and to raise its temperature. Here, however, we often feel the want of the power to at once reproduce the luminous smoky-flame of coal-gas, as when we have to anneal glass just worked in it. Another advantage of this flame over that of coal-gas, is afforded by its particularly high reducing power. Against this may be placed the comparative difficulty of using it for oxidising purposes. Only the outermost region and quite the tip of the visible flame can be thus used, whereas the Bunsen coal-gas flame acts oxidisingly to a considerable depth from its tip and surface. The reason for this difference may be found in the fact that, for fear of its flame passing down the tube, water-gas can be mixed with so little air from below that the gas in the interior of the flame suffers very little combustion there. That, just as in a luminous coal-gas flame, the temperature inside the flame is much the lowest, can be easily demonstrated by holding a glass rod or a wooden splint across it. One more property possessed by the flame to its advantage is its high temperature. There is no ordinary gas-flame that equals it in this respect. In it comparatively thick copper wire and sheet, and even thin platinum wire, are easily melted, and hard glass easily worked. Yet it is just this property of specially high temperature which, along with the presence of so much carbon monoxide, makes its use often unsatisfactory, if not impracticable, for the ordinary work of the laboratory. This objection to the use of water-gas will now be illustrated.

Insufficient Volume of the Flame.—With an equal flow of gas, the volume of the water-gas flame is much smaller than that of the coal-gas Bunsen flame. The reason of this lies largely in the fact that there is so much more to burn in the coal-gas, and that its methane in burning to what is the analogue of water-gas, namely, carbon monoxide and hydrogen, or these two and water, besides the nitrogen of the consumed air, yields several times its volume of this combustible mixture. This fact of the small volume of the flame of water-gas seriously increases the necessary consumption of the gas. For when vessels of some size have to be heated, as is so often the case, the desirability of applying the heat over a wide extent of their surface can only be met by using a large enough flame, quite apart from any consideration of its temperature. In order to bring up the volume of the water-gas flame to that of the non-luminous coal-gas flame, it becomes necessary to increase the flow of the water-gas to about two and a half times as much. To give particulars : in an ordinary small Bunsen, such as we made use of, with its air holes closed, and with a pressure on the gas (after passing through the meter) of 3 cm. of water, 120 litres (nearly $4\frac{1}{4}$ cb. ft.) of gas will be consumed per hour, and the length of the flame will be only 7 cm. or so ; to get the usual Bunsen flame, that is, one about 15 cm. long, the aperture of the gas-nozzle must be enlarged until more than 300 litres ($10\frac{2}{3}$ cb. ft.) of the gas pass per hour. It will be evident that the much greater volume of water-gas required to give Bunsen flames of the ordinary size and also the effect of this requirement upon the capacity of the gas-plant show greatly to the disadvantage of water-gas when comparing it with coal gas, which, even in equal volumes, has much greater heat-giving power than water-gas. It must be remembered that in the routine of a teaching laboratory much gas is burnt to waste, since everywhere the flame must be at hand even though not in use, because to that extent the relative heating power of the flame becomes a secondary point.

Copper Air-baths and Water-baths Rapidly Destroyed by the Flame.—Owing to the high temperature of the water-gas flame, a strip of sheet-copper of considerable thickness not only melts in the flame, but burns away quickly with bright scintillations when held in the outer part of it. The edges of the flame have also a strongly oxidising action upon the bottoms of air-baths and water-baths and cause a constant stripping off of scales of black oxide. In addition to this injury, these vessels suffer gradual destruction from the sulphur and the dust usually present in the gas, a point to be returned to later on. It becomes almost necessary therefore, to replace copper water-baths by others of cast iron, and to fit the copper air-baths with cast-iron bottoms, both of which stand fairly well.

Nickel and Platinum Vessels also Rapidly Destroyed.—Not only is copper so readily corroded, but rapid destruction of nickel and platinum vessels is caused by the flame. In the case of these metals it is probably much less the high temperature of the flame than the presence in it of so large a proportion of carbon monoxide, that accounts for its injurious action upon them. We have had the bottom of a new nickel crucible burnt completely off in one operation, the metal being carbonised into a very brittle black substance. In what was perhaps the earliest attempt to construct an incandescence gas-mantle, Gillard found, in 1848, that a cage of platinum wire network suspended in a water-gas flame was soon corroded and then no longer incandesced brightly. In accordance with this observation, we have found that the bottoms of platinum dishes and crucibles get rapidly damaged by the flame, the metal becoming quite brittle with a very white crystalline-looking surface. After continued use, a crucible of this metal has broken apart spontaneously, the metal when struck yielding no more sound than a piece of lead. The experiment was made of heating a capsule formed out of platinum foil for many hours in the water-gas flame. One effect was a distinct though slight increase of weight. The metal became somewhat coated over by the heating, but this deposit was wiped off each time before weighing the capsule.

	Weight. Grms.
Before heating	4·7661
After 7 hours	4·7664
" 5 " more	4·7666
" 10 " "	4·7672

There was, therefore, a uniform increase of 1·1 part in 4,766 parts. The increase in weight may have been due to the fixation of carbon or of iron. As to the carbon, it is to be remembered that Langer and V. Meyer, in 1885, in their "Pyrochemical Researches," found carbon monoxide to suffer partial decomposition at 1,690° C. into carbon and carbon dioxide. Not only is this the case, but we have found that carbon monoxide, hydrogen, and methane, mixed in the proportions occurring in water-gas, will sometimes deposit soot on the bottom of a porcelain crucible, although the flame is perfectly "non-luminous." With regard to the iron, it is now an established fact that water-gas which has passed some distance through bare iron pipes contains iron carbonyl in the vaporous state, and iron carbide or iron oxide may be deposited from this on the platinum, or the platinum may take up iron. A platinum crucible which has been heated for a long time by water-gas will be found to yield traces of iron when treated with fusing acid potassium sulphate.

Porcelain Crucibles unavailable for Use with the Flame in Quantitative Analysis.—A deposit, such as forms on the bottom of a platinum crucible, is also left upon the bottoms of porcelain crucibles heated in the water-gas flame, but in this case much of it is firmly adherent to the porcelain and cannot be wiped off. As a consequence, the tare of the crucible is so changed as to seriously complicate the usual weighings, and indeed to render accurate weighing impossible. The film thus formed is sometimes brown and then consists of iron oxides, silica, &c., but sometimes it is black and is composed almost entirely of carbon and reduced iron, combined or not as carbide. The bottoms of three porcelain boats were kept for several days in the water-gas flame and became covered with this black deposit. After the increase in their weight had been ascertained, they were heated in a current of purified oxygen in a tube connected with a weighing tube containing crushed potassium hydroxide. The increase in weight of the latter being attributed wholly to carbon dioxide, and the oxidised residue on the boats being assumed to be all ferric oxide, the black deposit proved to be a compound or mixture of iron and carbon, approximately expressed by FeC_2:—Deposit, 0·0097 grm.; carbon dioxide, 0·0117 grm. = carbon, 0·0032 grm.; ferric oxide, 0·0100 grm. = iron, 0·0070 grm. Carbon, 31·9 per cent.; iron, 68·6 per cent. Theory for FeC_2: carbon, 30 per cent.; iron, 70 per cent. The slight error in excess may perhaps have been due to the presence of a little hydrogen, miscalculated as carbon.

Deposition of a Dirty Pale-blue Coating on Copper Vessels.—The action of the water-gas flame upon the bottoms of copper vessels heated in it has already been noticed, where the flame touches the copper, copper oxide is produced and scales off. But, besides this, all the copper above the edge of the flame that comes in contact with the hot products of combustion gets coated with a dirty bluish-white deposit, which easily detaches itself from the copper. It consists of nearly anhydrous copper sulphate, with a little ferric oxide and traces of silica, magnesia, lime, &c. Now, such a deposit is known to be also produced by burning coal-gas, though to a much smaller extent, and in calling attention to this and other objections to the use of water-gas, we do not mean to convey the notion that there is any absolute difference between the burning of water-gas and the burning of coal-gas, but to point out the much greater prominence of objectionable characters in the case of the former. Killing, in 1900, examined a similar whitish deposit on the copper ceiling protectors suspended over incandescence coal-gas burners, and found it to consist largely of copper sulphate, with other matter derived from the dust of the air and from the mantles. In the case of water gas, particularly when used fresh from the generators, the impurities of the copper sulphate come largely from the fine dust in the gas, as well as from iron carbonyl and silicon hydride. When the gas has not stood for some hours over water, its flame is often tinged reddish.

Poisonous Character of Water-Gas.—The danger to health and life of the unrecognised escape of water-gas into the laboratory is well known. But even during the burning of the gas there may be danger. Lewes has pointed out that carbon monoxide in small quantities occurs among the gases from the flame of coal-gas and air of a Bunsen burner under a copper vessel, and Thorpe has recently determined its amount to be 0·022 vol. from 6 vols. of coal-gas. We have made some experiments with water-gas burnt under a sand-tray and with a little air entering the Bunsen, so as to form an inner cone in the flame. We worked according to Thorpe's method. For these experiments the water-gas was freed from hydrogen sulphide by passing it through a solution of lead acetate containing acetic acid, and was burnt at the rate of 170 litres (6 cb. ft.) per hour. When fully burnt, 100 vols. of the gas may be assumed to give 41 vols. of carbon dioxide. The carbon monoxide escaping from the flame was found to vary greatly in quantity according to the position of the sand-tray in the flame, as the following cases show:—(1) With the tray some distance above the point of the inner cone, two experiments gave respectively 0·0010 grm. carbon monoxide to 0·1922 grm. carbon dioxide, and 0·0009 grm. to 0·1844 grm. The mean of these results comes out as 0·32 vol. carbon monoxide from every 100 vols. of gas burnt. (2) When, on the other hand, the tray was placed below the point of the inner cone at about two-thirds of its height, there was a much greater escape of carbon monoxide. In this case, three experiments gave respectively 0·0028 grm. carbon monoxide to 0·1795 grm. carbon dioxide, 0·0028 grm. to 0·2149 grm., and 0·0032 grm. to 0·2241 grm. Calculation from these numbers brings out the mean escape of carbon monoxide as 0·9 vol. to every 100 vols. of water-gas. (3) Lastly, by working, as Lewes did, with the tray at the point of the inner cone, the three results obtained were 0·0016 grm. monoxide to 0·2170 grm. dioxide, 0·0015 grm. to 0·2009 grm., and 0·0015 grm. to 0·1907 grm., making a mean of 0·48 vol. of carbon monoxide to every 100 vols. of water-gas used. The grand mean of these results is that 0·57 vol. of carbon monoxide escapes unburnt in the consumption of 100 vols. of water-gas in the usual ways as described. This contrasts very unfavourably with Thorpe's result with coal-gas, since 0·032 vol. from every 6 vols. of coal-gas burnt represents 0·37 per cent. Further, where work is done, as it usually is, with Bunsen flames of equal heights, when over 300 litres per hour of water-gas are burnt against 170 litres (6 cb. ft.) of coal-gas, the former contaminates the air with carbon monoxide nearly three times more than coal-gas, namely, to the extent of 1 vol. of carbon monoxide in place of the 0·37 vol. from coal-gas. The effect, therefore, is that where in a laboratory 30 coal-gas burners may be kept going without detriment to health, hardly 11 water-gas burners can be used with impunity. For the reasons set forth in what precedes, we have been induced to give up the use of water-gas as a substitute for coal-gas in the laboratory.

DISCUSSION.

Mr. DAVID HOWARD said the question of the use of water-gas or producer-gas, or other gases of that nature, was an increasingly important one. On a large scale it had worked most successfully, but there was a wide sphere for its application to the use of comparatively small flames, small compared to that of a regenerator furnace, but larger than a Bunsen flame. The question that required elucidation was whether a small gas furnace could be worked better with coal-gas, which was effective but expensive, or with producer-gas which had disadvantages, but which was cheaper. He was inclined to think that water-gas might be used for laboratory purposes, in conjunction with the ordinary Argand burner, and a metal tube. With coal gas heat was wasted by the use of an excess of air to prevent smoke, but with water-gas this objection did not obtain.

Mr. Gordon Salamon asked whether, in the burning of ordinary coal gas, mixed with a certain proportion of water-gas as was now the custom, the organic compounds of sulphur present in the gas were capable of exerting a deleterious influence on the platinum. It appeared to him that where gas companies were not subject to the sulphur clauses the amount of organic sulphur introduced would be quite sufficient to cause that question to be worthy of consideration. Having regard to the results now before them he would like to ask if they would be modified in their effect by admixture with oil-gas as was the custom in connection with gas works, also if such a mixture on combustion would yield the same *pari passu* results as were recorded in the tables.

Mr. Arthur Marshall said it had been pointed out that water-gas was now being mixed with the coal-gas supplied by the gas companies in increasing quantities, and it was a serious question as to whether carbon monoxide was given off when gas was burnt in an ordinary batswing burner, since most people, when burning gas for illuminating purposes, kept all the doors and windows shut, consequently the atmosphere contained all the products of combustion.

Mr. G. C. Jones said he had no experience of the use of water-gas in the laboratory, though he had some with regard to generator-gas of about half the strength, which, however, was a hopeless fuel for the laboratory. To make any effective use of it, gas-pipes double the usual diameter, unwieldy rubber tubing, and specially constructed burners were necessary. Moreover, high temperatures were unattainable.

The Chairman said he was sure the Society would authorise Dr. Divers, to whom they were much indebted for having read this paper before them, to convey their thanks to the authors.

Dr. Divers said he should inform the authors of Mr. Howard's suggestion to replace the Bunsen by Argand burners, which he himself believed would meet some of the difficulties in using water-gas. On the point raised by Mr. Gordon Salamon as to the effect upon the combustion of the sulphur compounds in coal-gas by the admixture of water-gas, he could supply no information. He believed that in America water-gas, mixed with hydrocarbons, had not been found to be so objectionable a fuel as water-gas alone had proved. As to the danger of contaminating the air with carbon monoxide during combustion of water-gas or coal-gas, that could only occur to a recognisable extent when vessels or other bodies in the flame prevented complete combustion.

Newcastle Section.

Meeting held on Monday, January 18th, 1904.

DR. J. T. DUNN IN THE CHAIR.

A special meeting was held at the College of Science, when the President of the Society gave a discourse on "Radium and the Inactive Gases of the Atmosphere."

Mr. N. H. Martin moved a vote of thanks to the President for his visit and for the lecture he had delivered.

Mr. John Pattinson seconded the resolution, which was carried by acclamation.

Afterwards the members of the Section dined together, the President being the guest of the evening.

Nottingham Section.

ERRATA.

EXAMINATION OF METHODS EMPLOYED IN ESTIMATING THE TOTAL ACIDITY OF GASES ESCAPING FROM THE CHAMBER PROCESS FOR THE MANUFACTURE OF SULPHURIC ACID.

BY H. J. WATSON.

Discussion (this Journal, 1904, 6—7).

Page 7, col. 1, line 31 from bottom, for "qrs." read "grs."

Delete lines 26 to 24 from bottom, and substitute:—"This escape was a small one, and although water, or water *plus* H_2O_2, gave practically the same result, they might not have done so if the escape had been high."

Page 7, col. 2, line 41, for "The chambers were 100 feet in length and 30 feet high" read "the chambers were 105 feet long, 25 feet wide, and 20 feet high."

Patent Specifications may be obtained by post by remitting as follows:—

English.—8*d.* each, to the Comptroller of the Patent Office, C. N. Dalton, Esq., Southampton Buildings, Chancery Lane, London, W.C.

United States.—1*s.* each, to the Secretary of the Society.

French.—1 fr. 25 c. each, to Belin et Cie., 56, Rue des Francs-Bourgeois, Paris (3ᵉ).

I.—PLANT, APPARATUS, AND MACHINERY.

English Patents.

Disseminating Gases in a Finely-divided State in Liquids; Method of and Apparatus for ——, for Effecting Intimate Contact with the Liquid or with Matters Suspended therein. H. Nordtmeyer, Celle, Hanover. Eng. Pat. 3619, Feb. 16, 1903.

The gases are forced under pressure into the liquid through porous substances, such as sandstone, burnt clay, kieselguhr, &c., so as to obtain, by the formation of extremely fine bubbles, a rapid and perfect absorption of the gas by the liquid, and an increased chemical or mechanical action of the gas on substances suspended or dissolved in the liquid.—R. A.

Separators; Centrifugal Liquid ——. G. T. Renuerfelt, New York. Eng. Pat. 23,843, Nov. 3, 1903.

See U.S. Pat. 744,938 of 1903; this Journal, 1903, 1361.
—T. F. B.

Washing $\frac{\text{and}}{\text{or}}$ Cooling Towers. A. B. Duff, Pittsburgh, Pa. Eng. Pat. 24,262, Nov. 9, 1903.

The invention relates to washing- or cooling-towers for gases, air, &c. The gas or air and the liquid are passed in opposite directions through separately supported sections of packing material alternating with mixing spaces, so that the fluids are thoroughly intermixed in each of the spaces, and then redistributed to the succeeding sections of packing material. This invention also provides means for preventing collapse of the packing and renders it possible to remove such packing in sections or parts, one part being removed without interfering with the others.—R. A.

United States Patents.

Furnace. J. D. Swindell, Assignor to the American Furnace and Machine Co., Pittsburg, Pa., U.S.A. U.S. Pat. 747,020, Dec. 15, 1903.

The furnace contains a fire-box and bridge-wall, which has a vertical duct opening at its upper end into the fire-box, and communicating at its lower end with an air-duct in the base of the furnace, which opens into the air at the back of the furnace. An arch, overhanging the fire-box, projects from the bridge-wall and over the upper end of the vertical duct in it. The front wall of the furnace contains a chamber, opposite the upper end of the bridge-wall, communicating with the upper part of the fire-box. Air-ducts, opening in the back wall of the furnace, are arranged backwards and forwards in the wall of the furnace, and communicate with the chamber in the front wall.
—W. C. H.

Product for Prevention of Furring in Boilers. P. Bez, Léran, France. U.S. Pat. 748,341, Dec. 29, 1903.

See Eng. Pat. 14,789 of 1902; this Journal, 1903, 942.

II.—FUEL, GAS, AND LIGHT.

Spirit versus Petroleum for Lighting Purposes [in Russia]. M. Glasenapp. Rigasche Ind.-Zeit., 1903, 28, 250; Chem.-Zeit., 1903, 27, [103], Rep. 330.

The author found, by comparative tests with the Pittner petroleum incandescence burner, the Denayrouze spirit incandescence burner, and ordinary petroleum lamps, that for the same illuminating power, the spirit incandescence burner is about 1½ times, and the ordinary petroleum lamp from 2½ to 3 times, dearer than the petroleum incandescence burner.—A. S.

English Patents.

Binding Compound [for Briquettes, &c.]; Chemical ——, and Process of Manufacture thereof. J. Mellinger, Baltimore, U.S.A. Eng. Pat. 22,441, Oct. 17, 1903.

A solution of calcined sodium carbonate is mixed with slaked lime; the liquid is evaporated, infusorial earth is added, and the whole fused. The melt, after cooling, is lixiviated with cold water, and the filtered liquid is evaporated until it has the sp. gr. 1·25. It is then ready for use as a binder with coal-dust and the like.—H. B.

Gas Generating Apparatus; Improved ——. A. E. Kiderlen, Amsterdam. Eng. Pat. 23,751, Nov. 2, 1903. Under Internat. Conv., Jan. 3, 1903.

A gas generator, acting by suction and attached to a gas motor, is provided with a water vaporiser consisting of a cylindrical, vertical air-tight jacket, through the axial line of which passes a pipe, leading the gas from the generator to the purifying column. Surrounding this pipe is a helicoidal wing, on to which boiling water is discharged at each suction of the motor, saturating a certain quantity of air, sucked in simultaneously, which then enters the generator. The gas, on its way from the vaporiser to the purifying column, imparts its heat to the water which is to enter the vaporiser, and is freed from dust by contact with water in hydraulic joints in the pipes. The amount of water and air fed to the generator is thus regulated automatically according to the work done by the motor. For small apparatus the vaporiser may be arranged horizontally, to work with water at constant level.—H. B.

French Patents.

Briquettes containing Binding Material Soluble in Water; Process of Hardening ——. Soc. Auguste Petit et Cie. Fr. Pat. 334,301, July 31, 1903.

Mixtures of binding materials soluble in water and the materials forming the base of the briquettes, or the finished briquettes made with these constituents, are exposed to a dry heat of not less than 150° C., whereby the binding materials are said to be rendered insoluble in water.
—W. C. H.

Liquid and Bituminous Combustibles; Process and Furnace for the Conversion of ——, into Coke. P. Höring and A. Mjöen. Fr. Pat. 334,448, Aug. 6, 1903.

The gasification of such combustibles as peat, brown coal, &c., is effected by utilising, for the conversion of the body into coke, the aqueous vapours produced by the drying of the materials treated, and introducing these vapours into the zone in which gas is produced, by means of an aspirating or similar device. The process can be carried out in a furnace provided with channels which pass from the coldest zone, in which the materials are dried, to the reducing zone of the furnace, or to another furnace. The furnace may consist of two parts, separated by sliding doors; in the upper section the drying takes place, and in the other the conversion of the materials into coke. Also the furnace may consist of a single chamber into the lowest part of which extends a pipe connected to an aspirator, whereby the vapours produced during the drying process are sucked down into the zone of fuel in which the conversion into coke occurs. Round the bottom portion of the furnace, vessels containing water are arranged, in which steam is produced by the heat derived from the mass of incandescent coke, the steam being led into the reducing zone of this or another furnace.—W. C. H.

Gas; Process and Apparatus for Manufacturing ——. G. Westinghouse. Fr. Pat. 334,776, Aug. 22, 1903.

See U.S. Pats. 742,411 and 742,412 of 1903; this Journal, 1903, 1287.—T. F. B.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM AND MINERAL WAXES.

Petroleum Products; Definitions of Nomenclature of ——. Petr. Rev. and Mining News, 1903, **9**, [251], 526.

The following classification of petroleum products, to which the Russian Excise authorities have decided to adhere, has been drawn up by the Baku Section of the Russian Technical Society at the instance of the Department of Trade and Manufactures :—

A. *Crude Oil.*—The natural product before refining. If the flashing point (open test) be above 70° C., the product is classified with residuals in group E.

B. *Light Products of Distillation.*—(1) Petroleum ether, rigoline, sherwood oil: sp. gr. not exceeding 0·700 and distilling completely up to 80° C.; (2) Light benzine: sp. gr. 0·700—0·717, not more than 5 per cent. left on distillation at 100° C.; (3) Heavy benzine: sp. gr. 0·717—0·730, not more than 5 per cent. of residue above 100° C.; (4) Ligroïn: sp. gr. 0·730—0·750; (5) "Putz" oil (cleansing oil): sp. gr. 0·750—0·770.

C. *Illuminating Oils.*—(1) Meteor: sp. gr. 0·806—0·810, flashing point not below 28° C. by Abel-Pensky test, colour, "1—2 marks"; (2) Testefas: sp. gr. 0·820—0·823, flashing point not below 38° C., colour, "1—2 marks"; (3) Kerosene: sp. gr. 0·815—0·826, flashing point not below 28° C., colour, "$2\frac{1}{2}$ marks"; (4) Astraline: sp. gr. 0·832—0·835, flashing point 40°—45° C., colour, "$2\frac{1}{2}$ marks"; (5) Pyronaphtha: sp. gr. 0·855—0·865, flashing point not below 98° C. by the Martens-Pensky test, colour, "discoloured"; (6) Gas oil: sp. gr. 0·865—0·885, flashing point (Martens-Pensky) not below 93° C.; (7) Light Solar oil: sp. gr. 0·878—0·885, flashing point (Martens-Pensky) 125° C.

D. *Lubricating Oils.*—(1) Vaseline oil: sp. gr. 0·885—0·895; flashing point (Martens-Pensky), 135°—185° C.; viscosity (Engler) at 50° C., 2 min. 4 sec.—2 min. 9 sec.; (2) Spindle oil: sp. gr. 0·895—0·900; flashing point, 150° C.; (3) Machine oil: sp. gr. 0·905—0·911; flashing point, 185°—215° C.; viscosity, 6—7·5 min.; freezing point, −10° C.; (4) Cylinder oil: sp. gr. 0·911—0·920; flashing point, 210°—245° C.; viscosity, 12·5 min.; freezing point, 5° C.; (5) Viscosine (valvoline): sp. gr. 0·925—0·935; flashing point, 290°—310° C.; viscosity at 100° C., 5 min.; (6) Residuals for manufacture of lubricating oils: sp. gr. 0·908—0·916; flashing point, 160° C.; viscosity at 50° C., 6—10 min.

E. *Fuel Oil.*—Mazout, residuals, lake oil: sp. gr. 0·895—0·935; flashing point (open test), not below 70° C.

F. *Goudron*: sp. gr. not below 0·935; flashing point, not below 270° C.—A. S.

Petroleum from Saghalien. Klei. Westnik shirow. weschtsch., 1903, **4**, 264; Chem.-Zeit., 1903, **27**, [103], Rep. 331.

Petroleum obtained at a depth of 34 fathoms at Bojatassin yielded hardly any benzine, 28 per cent. of kerosene, 16 per cent. of "pyronaphtha," 44 per cent. of "mineral oil" (lubricating oil), and 12 per cent. of residue.—A. S.

Vaselines; Artificial ——, *and Vaseline Oils.* J. Girard. J. de Pétrole, 1903, **3**, [20], 619—620.

Artificial vaselines are prepared by dissolving paraffin scale in hot vaseline oil or heavy petroleum oil (sp. gr. 0·850—0·860), the solvent being first deodorised and decolorised. One method of effecting this purification consists in agitating the oil with about 6 per cent. of zinc chloride for an hour, this being repeated three or four times and followed by washing with 60—80 per cent. of water. A quicker process, but one confessed as dangerous for the workpeople, consists in the use of concentrated sulphuric acid and potassium permanganate; this operation does not always succeed. For deodorising only, Henry recommends treating the oil with 20 per cent. of water, $1\frac{1}{2}$ per cent. of lead oxide, and 9 per cent. of potassium hydroxide (the potassium hydroxide may be more cheaply replaced by a larger quantity of anhydrous sodium carbonate), the whole being agitated for an hour, after which the oil is decanted. The oils most suitable for the purpose in view are those rich in paraffin. The most suitable proportions for pharmaceutical vaselines are 40 per cent. of paraffin scale (m. pt. 50°—54° C.) and 60 per cent. of heavy oil, any larger percentage of the former giving products too consistent for the manufacture of pomades and ointments. The European oils best adapted for artificial vaseline are those of Galicia and Roumania, the distillates furnished between 300° and 400° C. by Campeni-Parjol oil containing 18 per cent. of paraffin, and those from Tetscan, Moineshti, Campina, and Predeal oils over 12 per cent. of paraffin.

United States Patents.

Oils or Distillates; Process of Desulphurising ——. O. P. Amend, New York, Assignor to J. H. Macy, Boonton, N.J. U.S. Pat. 747,347, Dec. 22, 1903.

The acids are removed from "oil or distillates" by treatment with alkali, after which the oil is agitated with a solution of alkali and excess of a soluble copper salt, separated, and washed, first with sulphuric acid and then with water.—T. F. B.

Oils or Distillates; Process of Desulphurising ——. O. P. Amend, New York, Assignor to J. H. Macy, Boonton, N.J. U.S. Pat. 747,348, Dec. 22, 1903.

Sulphuretted hydrogen is removed from the oil by washing and then blowing steam or air, or both; the oil is then treated successively with a solution of a soluble copper salt and with a solution of a soluble carbonate. This may be followed by treatment with ferrous sulphate solution.

—T. F. B.

French Patents.

Asphalt; Artificial ——. J. A. Soriano. Addition, dated Aug. 3, 1903, to Fr. Pat. 332,051, May 13, 1903. (See this Journal, 1903, 1196.)

The bitumen composition claimed in the principal patent is mixed with "any alkaline earth compound, natural or artificial," instead of, or in addition to, the millstone grit.

—T. F. B.

Tar Containing Water; Process of Treating ——. L. Scholvien. Fr. Pat. 334,472, Aug. 7, 1903.

Tar is dehydrated by treatment with lime or with calcined calcium sulphate. When thus treated it is said to give finer pitch. The drying agent used is dehydrated by calcining.

—T. F. B.

Phenols from Mineral Tar; Separation of the ——, *by means of Lime.* Chem. Fabr. Ladenburg, G. m. b. H. Fr. Pat. 334,525, Aug. 8, 1903.

Calcium forms two salts with phenols, the normal, $Ca(OR)_2$, and the basic, $Ca(OR)OH$. The former are unstable at temperatures above 70° C., decomposing into phenols and the basic salts; hence, if tar oils or crude phenols be agitated with excess of milk of lime, filtered, and allowed to stand, the aqueous solution, after distillation under reduced pressure at 60°—65° C., to remove hydrocarbons, contains the normal calcium salts of the phenols. This solution may either be acidified and distilled in the usual way, or it may be distilled without acidification, and preferably by the aid of steam, at the ordinary pressure, whereby one-half of the phenols present distil over; the residue contains the other half in the form of the basic calcium salts, and is mixed with a further quantity of the tar oils or crude phenols, and the process repeated.

—T. F. B.

Sulphur; Process and Apparatus for the Extraction of——, by Continuous Working. E. L. Lalbin. Addition, of Aug. 5, 1903, to Fr. Pat. 333,094, of June 12, 1903. VII., page 62.

IV.—COLOURING MATTERS AND DYESTUFFS.

Colouring Matters; Notes on some Natural ——. A. G. Perkin and E. Phipps. Proc. Chem. Soc., 1903, **19**, [273], 284.

The flowers of the *Prunus spinosa* contain both quercetin and kampherol, whereas in the violet (*viola odorata*) and white clover (*trifolium repens*) quercetin alone has been detected. From the Japanese dyestuff "Fukugi" (botanical origin unknown), a new colouring matter, $C_{17}H_{12}O_6$, has been isolated, forming yellow, prismatic needles (m. pt. 288°—290°), the general properties of which indicate that it is closely allied to luteolin. On bromination, it yields the compound $C_{17}H_{10}O_6Br_2$ (yellow needles, m. pt. 280°), and, when fused with caustic alkali, phloroglucinol and protocatechuic acid are obtained.

Aniline; Action of Carbonic Acid on Solutions of ——, in presence of Nitrites. L. Meunier. Comptes rend., 1903, **137**, [26], 1264—1266.

When carbon dioxide is passed into an aqueous solution containing two molecules of aniline to every molecule of sodium nitrite, practically the whole of the aniline is converted into diazoaminobenzene. If silver nitrite be substituted for the sodium salt, diazoaminobenzene is also formed, but is at once converted into the silver derivative, $C_6H_5.N_2.NAg.C_6H_5$. The precipitation of diazoaminobenzene observed by Niementowski and Roszkowski when sodium nitrite and aniline are mixed in dilute aqueous solution, is really due to carbon dioxide, and does not occur when recently boiled water is used. The sodium derivative of diazoaminobenzene is not formed in aqueous solution; when prepared by reacting with sodium on diazoaminobenzene in ethereal solution, it is readily hydrolysed by contact with moisture.—J. T. D.

Chloranil; Improved Method of Preparation of ——. O. N. Witt and S. Toeche-Mittler. Ber., 1903, **36**, [17], 4390—4392.

p-Nitraniline is converted into 1.2.6.4-dichloro-*p*-nitraniline by adding to its solution in warm concentrated hydrochloric acid a warm solution of the theoretical amount of potassium chlorate. The yield is 87 per cent. of the theoretical amount, and a pure product is obtained by one recrystallisation from glacial acetic acid or acetic acid and alcohol. This product is reduced by means of granulated tin and concentrated hydrochloric acid to 2.6-dichloro-*p*-phenylenediamine, the solution of which is further treated, without previous isolation of the base, by adding potassium chlorate crystals in excess to the strongly acid, boiling solution. Chloranil is thus obtained of melting point 268°—270° C., and by recrystallising once from toluene a pure product melting at 285°—286° C. is isolated. Yields of 90 per cent. of the theoretical amount were obtained.

—E. F.

Triphenylmethane Dyestuffs from Bromomagnesiumdimethylaniline; Preparation of ——. P. Ehrlich and F. Sachs. Ber., 1903, **36**, [17], 4296—4299.

Amino derivatives of phenylmagnesium halides have not hitherto been obtained. The authors find that they can obtain dimethylaminophenylmagnesium bromide by acting on magnesium powder with an ethereal solution of ethyl bromide for a few minutes, pouring off the liquid, and then adding an ethereal solution of bromo-dimethylaniline. The resulting solution of dimethylaminophenylmagnesium bromide yields, with an ethereal solution of Michler's ketone, a yellow-brown precipitate which, on acidification with acetic acid, forms hexamethyltriaminotriphenylcarbinol (Methyl Violet). With benzophenone, dimethylaminotriphenylcarbinol is formed in an analogous manner, and is orange-red in acetic acid solution. From two molecules of dimethylaminophenylmagnesium bromide and one molecule of the ester of an aromatic acid, such as ethyl benzoate or ethyl naphthoate, Malachite Green or its homologues are obtained. With one molecule of dimethylaminobenzaldehyde there is formed, after acidification with acetic acid, the blue hydrol of Michler's ketone, $[(CH_3)_2N.C_6H_4]_2.CH.OH$. With benzophenone derivatives which contain the ketonic group in a closed ring, such as xanthone, fluorenone, or acridone, the compound reacts either feebly or not at all. Thus the sulphone of Michler's ketone whilst reacting readily with phenylmagnesium bromide to form a very similar dyestuff to Malachite Green, reacts with dimethylaminophenylmagnesium bromide with much greater difficulty.

Diphenylnaphthylmethane Dyestuffs [Triphenylmethane Dyestuffs]; Manufacture of ——. R. B. Ransford, Upper Norwood. From L. Cassella and Co., Frankfort-on-Main. Eng. Pat. 2694, Feb. 4, 1903.

See Fr. Pat. 328,878 of 1903; this Journal, 1903, 992.

—T. F. B.

Orthoamidophenolsulpho Acid; Manufacture of Derivatives of ——, and of Colouring Matters therefrom. R. B. Ransford, London. From L. Cassella and Co., Frankfurt a/Main. Eng. Pat. 3182, Feb. 10, 1903.

On dissolving acetyl-*p*-aminophenol in sulphuric acid, a monosulphonic acid is formed, with the sulpho group in the ortho position to the hydroxyl. On nitration of this acid, a nitro group enters into the remaining ortho position. The nitro acid can be reduced to the amino acid. The acetyldiaminophenolsulphonic acid can be diazotised and combined with amines and phenols to form dyestuffs. With β-naphthol a dyestuff is obtained dyeing wool in an acid bath a dull claret; this becomes an intense blue-black on after-chroming. Other phenols give similar dyestuffs. These dyestuffs dye very level, and are fast to light and milling.—A. B. S.

Polyazo Bodies and Dyestuffs [Azo Dyestuffs]; Manufacture of ——. R. B. Ransford. From L. Cassella and Co., Frankfurt a/M., Germany. Eng. Pat. 3654, Feb. 16, 1903.

β-Naphthylaminedisulphonic acid [2·4·8] is diazotised, and combined with α-naphthylamine. The resulting compound is diazotised, combined with Cleve's α-naphthylaminesulphonic acid [1.6 and 1.7], rediazotised, and combined with phenolic or amino compounds. The 2.3.6- and 2·5·7 aminonaphtholsulphonic acids, 1.6.3-dihydroxynaphthalenesulphonic acid, *p*-xylidine, and *m*-amino-*p*-cresol ether are especially valuable as final components. The dyestuffs are distinguished by clearness of shade and extreme fastness to light. Those formed with bodies of the naphthalene group dye cotton very fast blue shades; whilst those formed with bases of the benzene group dye directly dull violet shades which turn to deep blue shades, fast to washing and to light on diazotising on the fibre and developing with β-naphthol.—E. F.

Nitroalphylacidylaminonaphtholdisulphonic Acids, Nitroalphylaminoacidylaminonaphtholdisulphonic Acids, Aminoalphylacidylaminonaphtholdisulphonic Acids, and Aminoalphylaminoacidylaminonaphtholdisulphonic Acids, and New Azo Dyestuffs therefrom; Manufacture of New ——. O. Imray. From the Society of Chemical Industry, Basle, Switzerland. Eng. Pat. 24,936, Nov. 16, 1903.

Nitroalphylacidylaminonaphtholdisulphonic acids or nitroalphylaminoacidylaminonaphtholdisulphonic acids are prepared by the interaction through condensation, of a nitro-alphyl acid chloride, a nitroalphyl isocyanate, or a nitroalphyl isothiocyanate with 2.5.1.7-aminonaphtholdisulphonic acid. The acids thus prepared, by means of reducing agents, can be reduced to the corresponding amino compounds. Aminoalphylacidylaminonaphtholdisulphonic acids derived from 2.5.1.7-aminonaphtholdisulphonic acid may also be obtained by saponification of their acetyl derivatives. These latter are obtained by the action of acetylaminoalphyl acid chlorides on 2.5.1.7-aminonaphtholdisulphonic acid. By coupling any of these new acids with an aromatic diazo compound, new dyestuffs are obtained. New dyestuffs are also obtained by eliminating the acetyl group from acetylated dyestuffs obtained by the above method, and also by diazotising, directly or on the fibre an aminated dyestuff obtained by the above methods and combining with an amine or a phenol. These dyestuffs are scarcely distinguishable in shade from those obtained in an analogous manner from 2.5.7-aminonaphtholmonosulphonic acid (see Eng. Pat. 13,778, 1902; this Journal, 1902, 1274; also U.S. Pat. 724,078, 1903; this Journal, 1903, 548), but are more soluble, of equal affinity for cotton, and equally fast to washing. They dye in red shades, which are intensified by diazotisation and development with β-naphthol.—E. F.

United States Patents.

Acridine Dye, and Process of Making same. C. L. Müller, Assignor to Badische Anilin und Soda Fabrik, Ludwigshafen a/Rhein, Germany. U.S. Pat. 746,981, Dec. 15, 1903.

Dyestuffs dyeing tannin-mordanted cotton in orange or orange-yellow shades are obtained by heating an aminoacridine or acridine-yellow compound with glycerin.

Sulphurised Derivative of m-Toluylene Diamine, New, and Sulphurised Dyestuffs [Sulphide Dyestuffs] directly Dyeing Cotton Yellow, derived therefrom; Production of ——. Manuf. Lyonnaise de Mats. Colorantes. First Addition, dated Aug. 4, 1903, to Fr. Pat. 321,122 of May 14, 1902 (this Journal, 1903, 141).

To the melt of *m*-toluylene diamine with sulphur described in the original patent, a primary amine, especially benzidine or tolidine, is added. This addition has the effect of rendering the shades obtained from the final products brighter.—E. F.

Sulphurised Dyestuffs [Sulphide Dyestuffs]; Production of Orange-Brown ——. Manuf. Lyonnaise de Mats. Colorantes. First Addition, dated Aug. 4, 1903, to Fr. Pat. 321,183 of May 15, 1902 (this Journal, 1903, 141).

To the melt of *m*-toluylene diamine with sulphur described in the original patent, a primary amine, especially benzidine or tolidine, is added. This addition has the effect of rendering the shades obtained with the final products brighter.—E. F.

Nitroanthraquinonesulphonic Acids; Preparation of New ——. Soc. Anon. des Prods. F. Bayer and Co. Fr. Pat. 334,576, Aug. 11, 1903.

Anthraquinone-α-sulphonic acid is treated with nitrating agents, such as a mixture of nitric and sulphuric acids. A mixture of 1.5- and 1.8-nitroanthraquinonesulphonic acids is so obtained. These are readily separated, as they differ greatly in solubility.—E. F.

[Azo] Dyestuffs; Process for the Manufacture of [Black] Mordant ——. K. Oehler. Fr. Pat. 334,702, Aug. 18, 1903.

See U.S. Pats. 740,767 and 740,768 of 1903; this Journal, 1903, 1191.—T. F. B.

V.—PREPARING, BLEACHING, DYEING, PRINTING, AND FINISHING TEXTILES, YARNS, AND FIBRES.

Cotton; Weakening of ——, *by the Action of Malt.* A. Scheurer. Bull. Soc. Indust. de Mulhouse, 1903, **73**, 320.

By treating cotton in four successive baths, each containing 12·5 grms. of malt to a litre of water, the duration of each treatment being two hours, and the temperature 60° C., the strength of the cotton is reduced 7 per cent.

Increasing the number of baths to eight, or lowering the temperature to 40° C., makes no appreciable difference in the result.—R. S.

Dyeing Processes [Mordanting]; Contribution to the Knowledge of ——. P. Heermann. Färber-Zeit., 1903, **14**, [9], 142—145; [18], 335—339; [19], 350—352.

Influence of Temperature on Absorption of Metallic Oxide Mordants by Silk (see this Journal, 1903, 623).—Silk was mordanted for six hours at temperatures ranging from 0° to 30° C., at intervals of 5°, with tin, iron, chromium, and aluminium mordants (52°, 52°, 32°, and 15° Tw. respectively). At temperatures between 0° and 5° C., iron and chromium mordants were absorbed with great difficulty; tin mordants slightly more easily. With iron and tin mordants, the temperature has practically no effect on the amount absorbed by boiled-off silk, but the amount absorbed by raw silk, increases considerably with the temperature, reaching a maximum at 30° C. Chromium mordants act in just the reverse manner, *viz.*, the temperature has no effect on mordanting raw silk, but boiled-off silk absorbs more of the mordant as the temperature rises; with aluminium mordants, raw and boiled-off silks absorb increasing quantities up to 20° C., when a maximum is reached. The following table gives a *résumé* of the results obtained:—

Mordant.	Silk.	Temperature at which Maximum Increase of Weight occurs.	Temperature at which Minimum Increase of Weight occurs.	Increase per Cent. of Maximum Increase at Temperatures						
				0° C.	5° C.	10° C.	15° C.	20° C.	25° C.	30° C.

Influence of Concentration of Solutions on the Absorption of Mordants.—Silk was mordanted in solutions the strengths of which varied, at intervals of 5° B., between 5 and 50° B. The results showed that the concentrated baths did not in all cases give more mordanting action than the more dilute solutions; thus, tin and iron mordants, when concentrated, have little mordanting action on silk, but corrode it strongly; the latter action decreases and the former increases as more dilute solutions are used, until, when the maximum mordanting action is obtained, corrosion ceases; at greater dilutions the mordanting action of tin and iron gradually decreases. Chromium mordants give increased mordanting action as the concentration increases, whereas aluminium mordants act in exactly the reverse manner, having, apparently, greater mordanting power in dilute solutions. The following table summarises the results of these experiments:—

Mordant.	Silk.	Concentration for Maximum Increase in Weight.	Concentration for Minimum Increase in Weight.	Increase per Cent. of Maximum Increase at Concentration

—T. F. B.

Mordanting** Wool with Aluminium Sulphate and Lactic **Acid. F. Düring. Bull. Soc. Ind. de Mulhouse, 1903, **73,** 322.

In a sealed note, dated July 26, 1901, the author states that if the tartaric or oxalic acid used as an auxiliary mordant in the presence of aluminium salts be replaced by lactic acid, and alizarin colours be used in dyeing, more beautiful and faster shades can be obtained than by the methods now used. A very full alizarin red is obtained when the wool is mordanted with 5 per cent. of aluminium sulphate and 5 per cent. of lactic acid. It is also noticed that the wool is attacked less and does not shrink so much as when treated with tartaric or oxalic acid. The same differences are noticed on dyeing in one bath, *i.e.*, in a bath containing aluminium sulphate, lactic acid, and the alizarin dyestuff.—R. S.

Mordanting** Wool with Aluminium Sulphate and Lactic **Acid. A. Abt. Bull. Soc. Ind. de Mulhouse, 1903, **73,** 323.

The author found that patterns which had been mordanted with 5 per cent. of aluminium sulphate and 5 per cent. of tartaric, oxalic, and lactic acid respectively, then dyed with 6 per cent. of alizarin red, were very different. The wool mordanted with the aid of lactic acid gave a beautiful bright Ponceau red, which was very fast to milling. The tartaric acid gave the next best result, and the oxalic acid the worst. The shades obtained by these two latter were a dirty yellowish Bordeaux, which on milling changed to bluish Bordeaux. On dyeing and mordanting in the same bath similar results are obtained, but the shades are lighter. When equivalent proportions of the three acids are used, there is hardly any difference in the shades produced, although that obtained by lactic acid is always brighter and faster to milling. No difference was found in the feel or strength of the wool either after mordanting or dyeing. Although lactic acid shows the advantages over tartaric or oxalic acid claimed by Düring, its much greater cost is the reason why it is only of practical value when importance is attached to the great fastness to milling which goods dyed with its aid possess.—R. S.

White Discharge on Paranitraniline Red. C. Kurz. Soc. Ind. de Mulhouse, Nov. 11, 1903.

The author employs the following mixture for discharging Paranitraniline Red:—370 parts of gum senegal solution, 400 parts of "solid hydrosulphite," 150 parts of 40 per cent. formaldehyde, and 80 parts of glycerin. The material is steamed for from four to eight minutes.—R. S.

Discharges and Reserves from the Derivatives of Hydrosulphurous Acid. E. Zundel. Soc. Ind. de Mulhouse, Nov. 11, 1903.

The author describes the uses and formation of discharges formed by the condensation of hydrosulphites with formaldehyde. Formaldehyde-sodium hydrosulphite is obtained by the direct addition of formaldehyde of 40 per cent. strength, to sodium hydrosulphite precipitated from its solution by sodium chloride. It crystallises in white needles. The zinc salt is formed in the same way, also by boiling a mixture of formaldehyde-bisulphite with zinc powder and acetic acid, or by adding formaldehyde to the product formed by the action of zinc on a solution of sodium bisulphite of 35°. These new formaldehyde-hydrosulphites are remarkable for their great stability; they only show their reducing action on steaming. The zinc compound is much more stable than the sodium salt, and requires a longer steaming to decompose it, but on adding a sodium salt, such as the chloride, it decomposes quite as easily on steaming as the sodium compound, double decomposition taking place and formaldehyde-sodium hydrosulphite and zinc chloride being formed.—R. S.

English Patents.

Skein-holding Device. F. Benzinger, Hudson, N.J., and L. Freund, New York, U.S.A. Eng. Pat. 22,899, Oct. 22, 1903. Under Internat. Conv., Oct. 23, 1902.

The specification describes a device for holding skeins of thread, furnished with clips so that single threads can be withdrawn without disturbing the remainder.—A. B. S.

Liquid under Pressure; Method of Circulating or Applying ——, Applicable for the Leaching or Extraction of Mineral or Organic Substances, the Extraction of Fatty or Greasy Substances, the Dyeing and other Treatment of Textile Materials, and to other Useful Purposes, and Means or Apparatus for the Application of the said Method. J. P. L. Dumons, Roubaix, France. Eng. Pat. 26,963, Dec. 6, 1902.

See Fr. Pat. 322,172 of 1902; this Journal, 1903, 295.
—T. F. B.

Dyeing Textile Material on Bobbins; Apparatus for——. A. Marshall and The Times Coloured Spinning Co., Ltd., Heap Bridge, near Bury. Eng. Pat. 24,327, Nov. 10, 1903.

The open ends of the perforated bobbins are fitted into holes in a plate or partition. A bar is fixed parallel to this plate at the other end of the bobbins. There is a hole in this bar opposite the end of each bobbin and through such holes pass screws which hold the free ends of the bobbins firmly. By loosening the special screw any special bobbin can be removed without altering the remainder. The liquid is circulated as usual.—A. B. S.

Designs on Warp Yarns; Process and Apparatus for Impressing ——. A. Hofmann, Gothenburg, Sweden. Eng. Pat. 24,387, Nov. 10, 1903.

The coloured pattern is transferred in a working stroke (*i.e.*, at each working movement) by means of movable pressing or printing devices independent of each other, which move into position and print the surface in a desired number of colours. Each roller is arranged in its own dye-tank, is brought periodically into position, either by hand or automatically (for instance, by a Jacquard machine) and is carried in a suspended oscillating lever worked by a catch. The dye-tank and roller are mounted in a travelling carriage which oscillates backwards and forwards.
—E. F.

United States Patent.

Printing [with] Sulphide Dyestuffs; Process of ——. E. Bourcart, Mülhausen, Assignor to Fab. Prod. Chim. de Thann et de Mulhouse. U.S. Pat. 747,295, Dec. 15, 1903.

See Fr. Pat. 319,504 of 1902; this Journal, 1903, 25.
—T. F. B.

French Patents.

Silk, Artificial; Apparatus for Manufacture of ——. E. Thiele. Fr. Pat. 334,507, Aug. 8, 1903.

The apparatus consists of a funnel-shaped receptacle connected at its smaller end by means of a flexible joint with a long pipe. The silk composition is forced out of a jet into the narrow part of the funnel and passes down the long tube in contact with the precipitating liquid which is run into the funnel at the top and passes down the long tube. As the silk emerges from the tube it is wound on reels as required.—A. B. S.

Dyeing, Bleaching, Mordanting, Washing, or Drying Fabrics, &c.; Apparatus for ——. F. Cleff. Fr. Pat. 334,300, July 31, 1903.

See Eng. Pat. 16,549 of 1903; this Journal, 1903, 1345.
—T. F. B.

Rice-Flour; Treatment of ——, for Use in "Finishing" Yarns and Textiles. Soc. Anon. des Rizeries Françaises. Fr. Pat. 334,369, Aug. 1, 1903.

Rice-flour under ordinary conditions does not give a stiff "finishing" paste on account of the "caseinous" gluten which surrounds the rice-starch granules, and prevents them from swelling sufficiently. This action of the gluten may be removed in one of three ways:—(1) The flour may be boiled with about 2 per cent. of caustic soda together with a quantity of boric acid sufficient to produce sodium triborate; the flour, soda, and boric acid should be mixed together in the dry state. (2) The flour may be mixed in the dry state with powdered sodium thiosulphate which gelatinises but does not dissolve the gluten when the mixture is boiled. (3) The flour may be sprayed with a solution of an organic acid, such as lactic acid, before boiling the paste.—J. F. B.

VI.—COLOURING WOOD, PAPER, LEATHER, Etc.

French Patent.

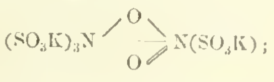
Depositing Silver or other Metals on Paper, Leather, &c.; Process for ——. Soc Nürnberger-Folienpapier-Fabrik, F. Pauli and Co. Fr. Pat. 334,549, Aug. 11, 1903.

A deposit of silver or of other metal is formed on a carefully polished glass plate, by reducing a silver solution or by any other suitable method. The metallic layer is washed and dried and then coated with a warm solution of gelatin or gum. After two or three minutes the sheet of paper, leather, or other material is laid on this and well rolled and dried. During drying the gelatin adheres to the paper or leather, and when the paper is stripped off, it brings the metallic layer with it. The metallic surface is covered with a transparent varnish to preserve it.—A. B. S.

VII.—ACIDS, ALKALIS, AND SALTS.

Peroxylaminesulphonates and Hydroxylaminesulphonates (Sulphazilates and Metasulphazilates). T. Haga. Proc. Chem. Soc., 1903, **19**, [273], 281—282. See also Carpenter and Linder, this Journal, 1902, 1493—1494. Compare also this Journal, 1903, 6—7.

By oxidising potassium hydroxylaminedisulphonate, Fremy obtained the salts which he called sulphazilate and metasulphazilate. Claus re-named the former "oxysulphazotate," and formulated its constitution as—



the latter he called "trioxyazoate," giving it the formula $O : N(SO_3K)_3,H_2O$. Raschig changed these formulæ into

and $(SO_3K)_3N < \substack{O\\O} > N(SO_3K)_3,2H_2O$;

whilst Hantzsch and Semple have re-named the sulphazilate "nitroxydisulphonate" with the formula, $O.N:(SO_3K)_2$, and have gone back to Claus's formula for the metasulphazilate. The author has found that (1) potassium sulphazilate interacts with normal potassium sulphite—

$$(SO_3K)_2NO.ON(SO_3K)_2 + K.SO_3K =$$
$$(SO_3K)_2NOK + (SO_3K)ON(SO_3K)_2,$$

to form normal potassium hydroxylaminedisulphonate, and potassium metasulphazilate; (2) the sulphazilate decomposes spontaneously into the metasulphazilate, hydroxylaminedisulphonate, and much nitrous acid, the last being preserved as nitrite when potassium hydroxide is present: $2(SO_3K)_4N_2O_2 + H_2O = 2(SO_3K)_3NO + (SO_3K)_2NOH + NO_2H$; (3) potassium metasulphazilate is decomposed quantitatively into sulphate and normal aminedisulphonate (iminosulphate) by sodium amalgam or by the zinc-copper couple, $KO.SO_2.O.N(SO_3K)_2 + 2Na = KO.SO_2.ONa + NaN(SO_3K)_2$; and (4) the ultimate products of its hydrolysis, when heated with hydrochloric acid, are hydroxylamine and sulphuric acid. The molecular magnitude of sodium hydroxylaminetrisulphonate and also of the 2/3-normal sodium hydroxylaminedisulphonate, as determined by Loewenherz's method, is in each case that which contains only one atom of nitrogen. The constitution of the sulphazilates is therefore that expressed by the name, potassium peroxylaminesulphonate, and the formula, $(SO_3K)_2NO.ON(SO_3K)_2$, and of the metasulphazilates that expressed by the name and formula, potassium hydroxylaminetrisulphonate, $(SO_3K)_2N.O.(SO_3K)$. The sulphazilates are oxime peroxides or peroximes, being produced by oxidising hydroxylaminedisulphonates with a variety of reagents (including ozone), even in the cold; they behave as oxidising agents, becoming again reduced to hydroxylaminedisulphonates, $2(SO_3K)_2NOH \rightleftarrows [(SO_3K)_2NO]_2$. A metasulphazilate is the only known case of a triacylated hydroxylamine. Having, as a hydroxylaminetrisulphonate, one of its sulphonate radicles in union with oxygen, it is clearly one-third sulphatic, yet without being actually a sulphate. It is a mixed oxide or anhydride of two acid salts, one being the acid sulphate and the other the 2/3-normal hydroxylaminedisulphonate—

$$(SO_3K)O\boxed{H + HO}N(SO_3K)_2.$$

The inorganic mixed anhydride most closely analogous to a hydroxylaminetrisulphonate is Pelouze's salt, potassium hyponitrososulphate, $(SO_3K).O.(N_2OK)$, the two salts agreeing in being stable in presence of caustic alkali and in not yielding barium sulphate with a soluble barium salt, whilst giving rise to a sulphate with sodium amalgam or zinc. To understand this behaviour, it is only necessary to assume that the metasulphazilate ionises into three metallic kations and a complex trivalent anion which includes within itself the sulphate radicle. Dunstan and Goulding have shown that zinc and acid reduce trialkylhydroxylamines to trialkyloxamines, so that if, as has hitherto been supposed, metasulphazilates were oxamines, they should reduce to aminetrisulphonates (nitrilosulphates), and not to aminedisulphonates and sulphates. The author concludes that the nitrogen of the sulphazilates and metasulphazilates is exclusively tri- and not quinquevalent, as suggested by the earlier investigators of these salts. There is so much difference between the properties of a peroxylaminesulphonate and those of the bluish-violet substance produced by the action of sulphur dioxide on a solution of nitrososulphuric acid in sulphuric acid that it is improbable that Sabatier's suggestion will prove correct as to the latter compound being the acid of Fremy's bluish-violet salt (this Journal, 1896, 622). Potassium hydroxylaminetrisulphonate is shown to have 3/2 mols. of water of crystallisation, whereas Claus, who stated that the salt contained 1 mol. of water, was perhaps unaware that some of its water of crystallisation becomes fixed by hydrolysis during the drying. Sodium, ammonium, and hydroxy-lead hydroxylaminetrisulphonates have been prepared for the first time.

Peroxylaminesulphonic Acid. E. Divers. Proc. Chem. Soc., 1903, **19**, [273], 283. Also Sabatier, this Journal, 1896, 622.

In support of Sabatier's assumption that the bluish-violet colour caused by the action of sulphur dioxide on sulphuric acid containing nitrososulphuric acid is due to the formation of the unknown acid of Fremy's bluish-violet potassium salt (sulphazilate or peroxylaminesulphonate), it is pointed out that the difference in properties observed by Haga (preceding note) is hardly greater than that between the behaviour of nitrous acid in the respective forms of nitrosulphuric acid and potassium nitrite. Sabatier's observations are shown to be quite consistent with the view that the acid is peroxylaminesulphonic acid, that is, a peroxide and a compound of trivalent nitrogen.

Nitric Peroxide; Constitution of ——. E. Divers. Proc. Chem. Soc., 1903, **19**, [271], 280—284.

Haga's examination of Fremy's *sulphazilate* has established the fact that it is *peroxylaminesulphonate*, a trivalent nitrogen compound and a peroxide. It is a sulphonated nitric peroxide, as suggested by Hantzsch and Semple, and when decomposed by water, gives a complex anhydrosulphate (hydroxylaminetrisulphonate) on the one hand, and, on the other, nitrous acid and sulphonated nitrous acid (hydroxylaminedisulphonate), equivalent respectively to the nitric and nitrous acids which are yielded by nitric peroxide. Dinitric peroxide is therefore a true peroxide, *nitrosyl peroxide*, $(NO)_2O_2$. Mononitric peroxide must be regarded as $O:N.O$, formulated with a univalent oxygen atom, and not with its nitrogen atom in the quadrivalent condition, $O:N:O$, as suggested by Piloty and Schwerin (Ber., 1901, **34**, 1884 and 2354); for it seems appropriate to consider the constitution of the two forms of nitric peroxide to be the same, the only difference being the presence in the one form of the bivalent double atom of oxygen, and in the other form of a single univalent oxygen atom. A true peroxide is correctly defined as a compound in which some or all of the oxygen is exerting on the rest of the compound only half its usual valency. Piloty and Schwerin's *porphyrexide*, $(C_5H_9N_3):NO$ (*loc. cit.*), is to be regarded as being such a peroxide.

Alkali-Metal Carbonates; Dissociation of ——. P. Lebeau. Comptes rend., 1903, **137**, [26], 1255—1257.

All the alkali-metal carbonates are dissociated when heated *in vacuo* at temperatures above 800° C. (the dissociation-pressure rises in the case of sodium carbonate from 2 mm. at 800° to 41 mm. at 1,200° C.). The oxides formed are volatile at the temperature used, and thus a volatilisation of the carbonate may be said to occur. Grouping the alkali-metals into the divisions: (1) lithium and sodium; (2) potassium, rubidium and cæsium; the more readily dissociable carbonate in the first group has the lower atomic weight, whilst those in the second group have the higher atomic weights.—J. T. D.

Potassium Chloride; Treatment of "Hartsalz" and Mixed Crude Potassium Salts for ——. C. Bauer. Chem.-Zeit., 1903, **27**, [104], 1268—1270.

The process of extraction of potassium chloride requires modification according to the nature of the raw material. A works which had been using a mixture of carnallite, sylvine, and "Hartsalz" of variable composition (see I., below), was compelled, through failure of this raw material, to work upon, first, "Hartsalz" (see II.), and later upon a mixture of salts (see III.); both of these supplies containing much more magnesium sulphate and less magnesium chloride than the original supply.

——	I.	II	III.
KCl	12—14	16	15—17
$MgSO_4.H_2O$	2—18	56	21—26
$MgCl_2$	0—8	..	4—6
NaCl	60—70	47	40—52

When these were submitted to the usual process (solution in mother liquor from a former operation by blowing in steam, settlement, and crystallisation) the crystallised potassium chloride contained less than 80 per cent. of potassium chloride, and lixiviation of it was necessary. The liquors from this, and the condensed steam, increased the bulk of the mother liquors used for extracting the raw material to such an extent that frequent evaporation was necessary. It was found, however, that when the raw material was more finely broken up (no pieces larger than a walnut), heated with the solvent by means of a steam coil, and brought thoroughly into contact with the solvent by mechanical agitation, much better results were obtained. The solvent used at first was a saturated solution of common salt, afterwards the mother liquors from the crystallisation, deficiencies being made up by addition of saturated common salt solution and lixiviation liquors from the preparation of 98 per cent. potassium chloride. The heating and agitation were kept up till the liquid had a sp. gr. of 1·3; then the contents were allowed to settle, the liquid poured off and allowed to crystallise, and the undissolved residue removed and thoroughly drained. The residue, about 80 per cent. of the original material, contained not more than 3·3 per cent. of potassium chloride, and about 7 per cent. of moisture. The crystals tested 83—85 per cent. of potassium chloride. This method was found applicable, not only to "Hartsalz" alone, but to various mixtures of crude salts; but when the magnesium chloride content of these mixtures reaches or exceeds 6 per cent., it becomes practicable to work them after the manner of carnallite. The mode of heating by means of steam coils allows much closer control over the composition of the liquors than the open steam method, and avoids the necessity of evaporating surplus liquor. In spite of the high kieserite content of the "Hartsalz" worked, there was no formation of potassium magnesium sulphate; nor was the same substance produced in the form of fine mud, when extracting the salts with magnesium chloride liquor, as was always the case when heating by open steam.—J. T. D.

Barium Nitrite; Preparation of ——. O. N. Witt and K. Ludwig. Ber., 1903, **36**, [17], 4384—4389.

Barium nitrite cannot be prepared from the nitrate like the alkali nitrites, as it decomposes at too low a temperature; and the only preparation which has come into commerce is made from sodium nitrite by converting it first into silver nitrite and then decomposing this by barium chloride, and is thus expensive. Matuschek attempted to prepare it, at the suggestion of one of the authors, as potassium nitrite is made from sodium nitrite, by direct decomposition of sodium nitrite and barium chloride; but the sodium chloride which falls from the hot liquid, when the exact molecular proportions for complete exchange are used, contains in admixture quite half of the barium chloride originally used. This the authors have found to be due to the "salting out" of barium chloride by the sodium chloride and barium nitrite formed, each containing an ion in common with the barium chloride. Accordingly, by using two molecules of sodium nitrite to one of barium chloride, they have succeeded in "salting out" completely the sodium chloride by means of the excess of sodium nitrite (which has no ion in common with the barium chloride, and hence does not affect it), and crystallising out practically all the barium nitrite on cooling. The process is conducted as follows:—360 grms. of 96 per cent. sodium nitrite and 610 grms. of barium chloride are intimately mixed, while 360 grms. of the nitrite are dissolved in a litre of boiling water. The mixed salts are run into the boiling liquid, and the reaction is completed almost at once. The liquid is filtered by suction in a steam-jacketed funnel, and the filtrate on cooling deposits good crystals of barium nitrite. These are separated centrifugally from the mother liquor, which is again ready, when boiled, to take another charge of the mixed salts, and thus to circulate continually, with only the additions needed to make up the inevitable mechanical loss. The nitrite is twice crystallised, 1 kilo. being dissolved each time in 300 c.c. of water, and the resulting crystals separated from the mother liquors by means of the centrifugal machine. The yield of nitrite in the first operation varies from 280—300 grms. (theory 292); and the ultimate yield of twice crystallised, chlorine-free salt is about 85 per cent. of the theoretical. The mechanical losses would be relatively less if the process were worked on a larger scale. The salt, and its solutions, are quite stable under 115° C., and it can thus be used for the direct preparation of solutions of determinate strength. If used for diazotising amines in sulphuric acid solution, no inorganic salt is left in the filtered solution of the diazo compound; and the salt also forms a starting point for the preparation of other nitrites, by double decomposition with the metallic sulphates.—J. T. D.

Fluorides; Preparation of Anhydrous Crystallised ——. Defacqz. Comptes rend., 1903, **137**, [26], 1251—1253.

Manganese fluoride (Moissan and Venturi, this Journal, 1900, 569) is heated to fusion with 10 times its weight of calcium chloride for two hours at 1000°—1200° C.; the cold product is broken up and extracted first with cold water, later with water acidulated with hydrochloric acid, the latter solvent being finally boiled. A white residue remains, in well-formed cubes, having the composition CaF_2. If the fusion be effected at 800°—1000° C., the crystals formed will be of octohedral form. If the crystals be heated in fused manganous chloride or alkali chloride, or if the mixture made for their preparation contain a large proportion of manganous fluoride (and hence a large proportion of manganous chloride when the reaction has proceeded some way), calcium fluochloride $CaClF$ is formed. The author has prepared by a similar process the fluorides of barium, strontium, magnesium, and lithium.—J. T. D.

Copper: Cause of the Non-precipitation of ——, *by Hydrogen Sulphide, from Potassium Cyanide Solution.* F. P. Treadwell and C. v. Girsewald. Zeits. anorg. Chem., 1904, **38**, [1], 92—100.

The fact that copper is not precipitated by hydrogen sulphide from potassium cyanide solution has been ascribed to the formation of the complex salts, $K_6Cu_2(CN)_8$ and $K_2Cu_2(CN_4)$ respectively. The authors find, however, that whilst concentrated solutions of the former salt are not precipitated by hydrogen sulphide, solutions of the latter salt are. It was also found that an ammoniacal solution of copper containing enough potassium cyanide for the formation of the salt $K_3(NH_4)Cu_2(CN)_6$, is not precipitated by hydrogen sulphide. The authors conclude that the non-precipitation of copper from potassium cyanide solutions is due to the formation of the complex ions $[Cu_2(CN)_8]$ and probably, also $[Cu_2(CN]_6]$.—A. S.

English Patent.

Lime Waste of Alkali Works and Lime Sulphate Waste; Utilisation of ——. H. Oliver and W. Bevan, New Ferry, Chester. Eng. Pat. 9412, April 25, 1903.

The waste lime material is suspended in water, run off from the grit, allowed to settle, dried and caked in kilns. The cakes are ground up, usually with oyster shells or the like, and the powder is wetted with solution of a magnesium salt, and magnesia may be added. Some fine fibrous material or insoluble organic powder is introduced, and the mixture is moulded into blocks adapted to various purposes. Colouring materials may also be added, either disseminated in the mixture or as a transfer.—E. S.

United States Patents.

Hydrocyanic Acid and Cyanide Salts therefrom; Process of Making ——. J. H. Paul, Charlton. U.S. Pat. 746,876, Dec. 15, 1903.

Alkali Cyanides; Manufacturing ——. P. Danckwardt, Deadwood, S.D. U.S. Pat. 746,795, Dec. 15, 1903.

A nitride and a carbide of an alkaline earth metal are heated with a salt of an alkali metal in an atmosphere of nitrogen, and the fusion is continued after addition of a mixture of an alkali metal salt and a carbide of an alkaline earth metal. The furnace shown is of the electric type.
—E. S.

Alkali Cyanide and Alkali Metal; Process of Simultaneously Producing ——. P. Danckwardt, Deadwood, S.D. U.S. Pat. 746,796, Dec. 15, 1903.

An alkali nitrite, another alkali salt, and a carbide of an alkaline earth metal are heated together with "exclusion of air," or, as expressed in another claim, an alkali nitrite is heated in the presence of nascent carbon or "carbon about to be produced," and of a nascent alkali metal, with exclusion of air.—E. S.

Sulphate of Barium and Chloride of Zinc; Process of Obtaining ——. W. D. Gilman, Roland Park, Md. U.S. Pat. 746,954, Dec. 15, 1903.

Solutions of barium sulphide and of zinc chloride are mixed; the barium chloride solution thus formed is separated from the precipitate, and is mixed with an aqueous solution of zinc sulphate. The barium sulphate thus thrown down is separated from the solution of zinc chloride, from which solution the zinc chloride is recovered.—E. S.

Chromates [*Bichromates*] *of the Alkaline Metals; Process of Making* ——. F. M. and D. D. Spence, A. Shearer, and J. J. Craig, Assignors to Peter Spence and Sons, Ltd., Manchester. U.S. Pat. 747,255, Dec. 15, 1903.

Sulphur; Process and Apparatus for the Extraction of ——, *by Continuous Working.* E. L. Lalbin. First Addition, dated Aug. 5, 1903, to Fr. Pat. 333,094 of June 12, 1903. See this Journal, 1903, 1292.

Earths, and especially organic matters, containing sulphur, such as tar or woody matters, are charged by aid of a screw conveyor, operating in a hopper into the top of a vertical retort, wider at the base than above, and heated from an adjoining furnace through surrounding flues. A branch from the lower part of the retort, first curved and then horizontal, traverses the furnace above the fireplace, and has entrance into a condenser for sulphur, provided with an exit tube for uncondensable gases. Arrangements are made for blowing into the retort a measurable quantity of compressed air, in order to oxidise gases which might otherwise form explosive mixtures. The spent material is discharged from the bottom of the retort by the operation of a screw. The apparatus may be adapted to the production of sulphur dioxide.—E. S.

VIII.—GLASS, POTTERY, ENAMELS.

Glass Metal; Melting of ——, *for Plate Glass.* H. Knoblauch. Sprechsaal, 1903, **36**, [50], 1881—1882; [51], 1915—1917.

An ordinary charge of "metal" for plate glass consists of: sand, 165 parts; sodium sulphate, 80; calcspar, 50; and anthracite, 4·1—4·2 parts; and these 300 parts will furnish 100 parts of glass containing 72·4 per cent. of silica, 15·3 per cent. of sodium oxide, and 12·2 per cent. of lime. In the furnace, the sodium sulphate melts first, dissolving the lime and afterwards the sand. At the same time the carbon reduces the sulphate to sulphite, with liberation of carbon monoxide, and the calcium carbonate parts with a portion of its carbon dioxide, whilst the silica displaces sulphur dioxide from the sodium sulphite; and this liberation of gases sets the mass in ebullition. Owing to the varying action of the heating gases, which also contain reducing carbon, it is impossible to obtain a uniform result in all cases from a constant proportion of carbon in the metal. When the total carbon is too small, the liberation of gas is diminished and sandiver is formed, the sand and lime also sintering to form incrustations. In such event, the smelter must immediately throw in more carbon, in small quantities at a time, and break up the crust by means of an iron crutch; if this be neglected, the resulting glass will be full of unmelted ingredients. If, on the other hand, there is an excess of carbon, a reddish-brown scum will form on the charge, and the pots will be liable to boil over unless the defect be remedied by throwing in more sodium sulphate and stirring the mass. In the absence of this treatment the glass will be coloured yellow-green to brown-red by excessive reduction of sodium sulphate to sulphide, and its plasticity will also be lowered. In the event of the charge consisting of small quantities of residual metal and a large quantity of cullet, unmelted inclusions may be formed, and there is also a risk of inclusions of sandiver should this latter substance be in a reduced state when fresh portions of metal are added to fill up the pots during the melting process. This may be obviated by providing an oxidising atmosphere in the furnace while the pots are being filled up. In the clarifying stage the sandiver must be eliminated by either skimming or reduction, the latter being preferable as not entailing any prejudicial lowering of temperature. The mass is then clarified by introducing a wet block of wood on the end of an iron rod, the violent liberation of gas thereupon ensuing causing the expulsion of any pre-existing gas bubbles. Arsenic produces the same effect, but has now passed almost entirely out of use. This clearing process must be repeated at intervals of an hour, for if delayed until the glass has become too fluid, the charge is liable to froth over. The final stage of melting is attended with difficulty, owing to the risk of pots giving way under the softening effect of the heat—which is near the melting-point of the pot material—and the weight of the contents. Finally, to impart to the charge the consistence necessary for plate glass, it must be left to cool for several hours, the gas being turned off, the ports opened, and the chimney draught through the furnace reversed every quarter of an hour.—C. S.

Porcelain Glazes; New Yellow ——, *for Strong Fire.* T. Hertwig. Sprechsaal, 1903, **36**, [49], 1845—1846.

On porcelain body rich in alkali (composition, 40 parts of clay substance, 25 of quartz, the quartz and part of the felspar being introduced from Thuringian alkaline sand, and 25 of felspar; to this different quantities of glaze material are added, and the mixture not too finely ground), the author obtained a series of brilliant colours with compounds of tungsten and molybdenum, these furnishing yellow and orange shades in presence of manganese in the reducing fire. At high temperatures manganese peroxide appears to yield oxygen to tungsten, the yellow being shaded from ivory to reddish-yellow orange by the manganese coloration. Natural calcium tungstate is also stained ochre-yellow. A 10 per cent. solution of molybdenum phosphate gave sulphur-yellow on the glaze being fired on a biscuit painted with concentrated manganese chloride. Other molybdenum compounds furnished the well-known Roerstrand black (molybdenum protoxide), the contours shading off into grey-white by oxidation. Colloidal tungstic acid (from the sodium salt) and its compounds give sulphur-yellow, which is converted into a whole range of tones, from ivory to orange-yellow, on refiring after the application of concentrated manganese nitrate or chloride. Alkali tungstates, supersaturated with any acid except nitric, and reduced by metallic zinc, furnish a blue precipitate of tungsten tungstate, which dissolves to an intense blue solution in phosphoric acid. Ammonium tungstate, when heated until the liberation of ammonia ceases, furnishes ammonium metatungstate, which can be used as a glaze pigment; and crystallisable metatungstates, suitable for the same purpose, can be obtained by treating solutions of nitrates or chlorides of alkaline earths or metals with tungstic acid, or by treating alkali tungstates with phosphoric acid. The metatungstates crystallise out, and are soluble in water. Double salts, also suitable for pigments, can be prepared by treating alkali metatungstates with barium chloride, and the resulting barium salt with metallic sulphates. Cadmium borotungstate, when treated with a large quantity of concentrated manganese nitrate solution and sodium metatungstate, followed by gradual additions of water, slowly furnishes a wine-red liquid, which gives an ivory underglaze colour when fired. This, however, converts into brown the subsequently applied glaze pigments, especially iron-red. Orange tones were found to fail unless fired immediately after application, owing to absorption by the porous biscuit.—C. S.

English Patents.

Waste Heat from Reheating Furnaces, known as "Glowry Holes," Used in Glass Works; Means for Utilising ——, and Means for further Effecting Economy in the Use of such Furnaces and for Reducing the Quantity of Smoke Escaping therefrom. G. R. Ridsdale, Walsall. Eng. Pat. 8789, April 18, 1903.

The waste heat of the products of combustion of the reheating furnaces, or the "glowry holes," is utilised to heat the muffles or ovens, known as "lears," in which the manufactured articles are annealed. For this purpose a flue runs from the crown of the "glowry hole" to that part of the "lear" where the grate is usually placed. Further, air flues are formed in the thickness of the two side walls and in the back wall of the heating chamber of a "glowry hole." Air from the atmosphere passes through these flues and mixes with the combustible gases inside, a higher temperature and more perfect combustion being consequently obtained. These air flues may be controlled by dampers.—A. G. L.

Glass; Manufacture of Plates or Sheets of ——, and Apparatus to be Employed in such Manufacture. J. Hirst, Vineland, N.J. Eng. Pat. 21,782, Oct. 9, 1903.

The glass is poured on to a mould table or bed having a perfectly level surface, preferably highly polished. This table may be heated before placing the glass on it. After the glass has been placed on the table, an air-tight cover is caused to descend on it so as to enclose that part of the top of the table which contains the glass. This cover carries a roller, which is caused to traverse the table one or more times, thereby causing the glass to spread out into a sheet of predetermined thickness, the thickness being best regulated by having a recess in the table, the depth of the recess determining the thickness. The whole operation is carried out under air-pressure, which is increased at the end of the rolling to the highest possible point. True smooth surfaces are thus obtained, which require no subsequent grinding or polishing.—A. G. L.

French Patents.

Ceramic Articles; Composition for ——. C. Robin. Fr. Pat. 334,490, Aug. 7, 1903.

The composition is formed either of one or of several clays, the silica in the mixture amounting to 65 to 75 per cent., and being five to six times the alumina. A suitable mixture consists of 69 per cent. of silica, 11·5 of alumina, 1·5 of ferric oxide, 4·5 of lime, 1·5 of magnesia, and 12 of water, carbon dioxide, and organic matter.—A. G. L.

Enamelling; Process and Apparatus for ——. J. C. Reed, U.S.A. Fr. Pat. 334,506, Aug. 8, 1903.

The metal object to be enamelled—as a bath pan, for instance—is transferred from the furnace to a metal receptacle having a movable bottom, and a closely-fitting cover, carrying the mechanism for feeding and distributing the enamel, and protected on all sides from heat radiation by asbestos packing or the like. A predetermined quantity of the enamel is placed in a hopper, and, by mechanism operated by an electric motor, is fed regularly into a vertical pipe descending a certain distance into the pan to be enamelled, where, by rapid rotation and the action of distributing wings, the enamel is dispersed centrifugally, and also falls about in such manner as to cover the internal surface of the pan uniformly. It is a feature of the invention that the object to be enamelled is maintained immovable, whilst the enamel is mechanically supplied, within a space closed from the air, and so protected against loss of heat that the enamelling is effected at a single process without the necessity for re-heating.—E. S.

IX.—BUILDING MATERIALS, CLAYS, MORTARS AND CEMENTS.

Lime Sandstone; Manufacture of ——. H. Schön. Chem. Ind., 1903, **26**, [24], 621—624.

According to the author, the method in which the lime is slaked in the same vessel in which the moulded blocks of artificial stone are hardened has proved to be the most economical, and it is now in use in 50 factories. The lime is placed in iron chests, which are arranged along the bottom of the cylindrical hardening chamber, and the trolleys bearing the moulded and pressed blocks of stone are wheeled in over them. The hardening is effected by steam under pressure and, by slaking the lime in the hardening chamber, a considerable saving of steam is attained. For example, in two comparative tests the eight lime-chests were each filled in one case, with 3 cwt. of slaked lime, and in the other with 3 cwt. of quicklime. Eight trolleys, containing altogether 6,400 moulded blocks of stone, were then placed above the lime in each hardening chamber. The two chambers were then heated up to 8 atmospheres of steam pressure. The chamber containing the slaked lime was heated entirely by means of steam from a boiler, and the desired pressure was attained in 2 hours 15 minutes. In the other case, by adding 120 litres of water to each of the lime-chests, the heat generated raised the pressure in 3 minutes by 2 atmospheres, and then on introducing steam from the boiler, the pressure of 8 atmospheres was attained in 1 hour 12 minutes. The saving of coal amounted to 0·7 cwt. per 1,000 blocks of stone.—A. S.

Lime-Sandstone Brick; Lime in the Manufacture of ——. S. V. Peppel. Thonind.-Zeit., 1903, **27**, [146], 2204—2205.

Practical experience has shown that 5—10 per cent. of lime is sufficient to furnish a good lime-sand brick, though the researches of Glasenapp demonstrated that, in the case of fine sand, a larger proportion of soluble silica could be obtained by increasing the amount of lime to 10—20 per cent., and more especially by raising the steam pressure in the hardening vessel. The study of the influence of the amount of lime on the crushing and tensile strength of the bricks has been resumed with varying proportions of coarse and fine sand and different kinds of lime (slaked under pressure). The sample blocks were moulded under a pressure of 700 kilos. per sq. cm., and hardened by 10 hours' exposure to a steam pressure of 11 atmospheres. With 3 parts of coarse and 2 parts of fine sand, and 5 per cent. of dolomite lime; the crushing strength of the blocks was 259 kilos. per sq. cm., increasing to 391 with 10 per cent. of dolomite lime. In the latter case the strength was found to be nearly doubled (529 kilos.) by congelation, owing, it is assumed, to the combination of free lime with carbon dioxide absorbed by the water. In other tests with the same proportions of sand, but with white lime, 5 per cent. of the latter gave a crushing strength of 184 kilos., which was not increased more than three-fold (491 kilos.) by raising the proportion of lime to 40 per cent. The conclusion drawn from these two sets is that the increased strength resulting from higher percentages of lime is not commensurate with the greater cost, and that for practical purposes not more than 10 per cent. of lime should be employed. The question of hydraulic lime *versus* white lime was also investigated, one sample being prepared from limestone containing 85 per cent. of calcium carbonate with traces of magnesium carbonate, and the other from dolomite composed of 42—44 per cent. of magnesium carbonate and 56—58 per cent. of calcium carbonate. The bricks were made of mixtures consisting of 2 parts of coarse sand, 1 of fine sand, and 10 per cent. of lime; they were subjected to a moulding pressure of 1,950 kilos. per sq. cm., and hardened under a pressure of 11 atmospheres for 4—14 hours. The crushing strength averaged 544 kilos.

with the grey lime, but only 364 kilos. with the dolomite lime, probably owing to the inferior cementing power of magnesium silicate—an idea that seems to be confirmed by the higher faculty for absorbing water. Finally, the substitution of kaolin for fine sand in the mixture diminished the crushing strength by about one-half, from which the author concludes that high-pressure steam is non-essential to develop the properties of hydraulic lime, whereas moisture is indispensable. He also considers that storage in water will improve the crushing strength of lime-sand brick, an opinion that has been confirmed by experiments at Charlottenburg. On the same subject, Zapf has reported a case where a mixture containing a lime with 84 per cent. of calcium oxide furnished better brick than lime with 97 per cent. of calcium oxide under the same conditions of hardening (10 hours), though on doubling the time of hardening these results were reversed. The more rapid hardening of the 84 per cent. lime is attributed by Cramer to its hydraulic properties, the calcium silicate binding the mass even before it is hardened, whilst the increased crushing strength imparted by hardening is due to the conversion of the still free lime into silicate during the process.—C. S.

Firebrick; Bauxite in the Manufacture of ——.
Thonind.-Zeit., 1903, 27, [140], 2132—2134.

The best variety of bauxite for the manufacture of firebrick for blast furnaces is said to be one approximating in composition to natural clay, with a slight preponderance of alumina to raise the fusing point and so retard combination of the silica and alumina. If, however, the proportion of alumina be excessive, the product is brittle, shrinks unduly, and is susceptible to the action of acid slags. A sample of bauxite, containing 49 per cent. of alumina, 28 per cent. of silica, and 18 per cent. of water, has been favourably reported on by Seger and Cramer, who state that the tendency to shrink is almost counteracted by the appreciable quantity of silica present, and that the substance belongs to the highest class of fireproof materials. It is less affected by strongly basic slags than are the best basic firebricks, and though attacked by slags of analogous composition, the resulting superficial vitrification forms a protecting layer, which advances as the outer portion is gradually fused away in the blast furnace, and therefore prolongs the life of the lining. The fusing point is No. 37 Seger cone, and after the first baking the bricks retain their volume. On the other hand, a bauxite richer in alumina and poorer in silica is preferable for firebrick exposed to the action of basic slags and high dry heat, *e.g.*, forced-draught furnaces, coal-dust firing, steam-raising on torpedo boats, &c. A typical specimen of this class contained 21·2 per cent. of silica, 74·78 per cent. of alumina, and 3·83 per cent. of iron oxide. This fused at Seger cone No. 39, ceased to shrink after the first baking, and resisted the attacks of highly basic slags. When bauxite is used as an adjunct in firebrick, it should first be fired at a high temperature, then finely ground and intimately mixed with the clay bind before the fireclay is added. This is the only way in which the added alumina can be caused to discharge its true function of increasing the fusing point of the mass, adding the bauxite in granules merely resulting in the gradual disintegration of the whole. C. S.

Portland Cement; Constitution of ——. W. Richter.
Thonind.-Zeit., 1903, 27, [120], 1862—1864.

To ascertain the reliability of the hypothesis that the absence of colour reaction between finely-ground Portland cement and phenolphthalein is due to the presumably free lime present being in the crystalline form, the author prepared specimens of crystalline lime by the calcination of anhydrous calcium nitrate. The product, when mixed with water, sets like cement and stands the boiling test well, but gives the colour reaction with phenolphthalein in an anhydrous solvent. This result, he considers, proves that no free lime is present in cement, calcium aluminate being also precluded for the same reason; the probability is that the aluminate is present solely in the form of neutral silico-aluminate. In preparing a synthetic Portland cement, successful results were obtained by fusing equal quantities of anhydrous calcium nitrate and amorphous calcium carbonate with silica, in the proportion $SiO_2:3CaO$, for three hours at white heat, then pulverising the mass and repeating the operation. At the end of eight hours' calcination, the negative result of the phenolphthalein test showed that the whole of the lime had entered into combination. The product formed a sintered mass, which stood the boiling test, and, when triturated with water, set gradually without any increase of temperature. This trisilicate being very unstable had to be stored out of contact with atmospheric moisture. When treated with 95 per cent. alcohol it suffered dissociation in 2—3 hours, and then gave a colour reaction with phenolphthalein. Bicalcium silicate was prepared in a similar manner, and found to be fairly indifferent to alcohol containing up to 50 per cent. of water, the dissociation being very gradual. Its setting properties are inferior, and the cubes soften on boiling. Prolonged incineration of the bisilicate with 1 mol. of calcium nitrate gave a well-sintered, homogeneous product, more indifferent to strong alcohol than the amorphous form, and behaving like well-made clinker. No decidedly crystalline structure could, however, be detected by the unaided eye. From the behaviour of bicalcium silicate in presence of water and lime water respectively, the author confirms the view that the hydration of the trisilicate proceeds in two stages, the first consisting in the formation of bisilicate and calcium hydroxide, the reaction between these in presence of water then resulting in the formation of the monosilicate and the hydroxide. No success attended attempts to combine more than 3 mols. of lime with 1 mol. of silica, even by prolonged exposure to white heat in presence of merely a slight excess of lime.—C. S.

English Patents.

Wood; Impregnation of ——. J. Wetter, London. From O. Heise, Berlin. Eng. Pat. 4435, Feb. 25, 1903.

Paving Material or Asphalt, Filling-up Cement, Waterproofing Material and Paint. W. P. Thompson, Liverpool. Eng. Pat. 24,807, Nov. 12, 1902.

The paving material is made by adding to melted pitch equal parts of burgy (the fine sand of glass works), fine field-sand or sea-sand, coarse-grained sea-sand, and as much fine and coarse gravel or broken macadam as can be added without taking away too much from the plasticity of the material. The burgy used, should pass through a 150-mesh sieve; it may be replaced by equally fine sand obtained by crushing gold ores. If the sand contain no bases, a little lime may be added to combine with the tar acids. The finished composition contains only 10 per cent. of pitch. For use as a waterproofing material, *e.g.*, for foundations, the coarse gravel or macadam is omitted. For ornamental purposes an intensely hard composition is obtained by adding gum, lac, or resin to the pitch.

—A. G. L.

Fire-Bricks, Crucibles, Retorts and other Refractory Articles; Process for Manufacturing ——. J. Bach, Riga, Russia. Eng. Pat. 24,041, Nov. 5, 1903.

Chrome-iron ore is purified by washing from the easily fusible admixtures it may contain. It is then powdered, mixed with powdered fireclay to which aluminium hydroxide has been added and burnt. A substance rich in carbon, such as sugar, resin, or coal, is preferably added in small quantity to the mixture before burning. The hydrated alumina may be replaced by the hydroxides of other highly refractory oxides.—A. G. L.

X.—METALLURGY.

Mercury Mines of Idria, Austria. T. L. Genter. Eng. and Mining J., 1903, **76**, [25], 923.

The mercury deposits of Idria are the second largest in the world, and have been worked for over 400 years. The chief ore is cinnabar, but metallic mercury is also occasionally met with. The gangue is generally composed of quartz, calcite, and dolomite, together with barite and an asphaltic mineral called "idrialite." The ores are classified as follows:—(1) "Steel ore" (Stahlerz) is found partly crystalline and partly amorphous. It contains 75 per cent. of mercury, but has been scarce during the past few years. (2) "Liver ore" (Lebererz) is amorphous and liver-coloured; it is generally found in wedge form in the steel ore: it contains 30 per cent. of mercury. (3) "Brick ore" (Ziegelerz) is sandy, bright red in colour, and sprinkled with crystals of cinnabar; it contains 50 per cent. of mercury. (4) "Coral ore" (Korallenerz) is a dark bituminous dolomite, sandstone or slate, containing petrified matter of unknown origin, resembling coral; it contains 6—7 per cent. of mercury. At the present time there are about 1,200 men and boys employed in the mines and mills, and there are six shafts, two drain tunnels, and about 20 miles of workings in operation. There are 12 levels in the mines, the deepest being about 1,100 ft. The main shaft is completely enclosed in masonry and Portland cement. The annual output of ore is about 800,000 metric tons, yielding more than 500 tons of mercury. The ores, after being sorted and crushed, are roasted in muffle furnaces, and the mercury is condensed in large U-shaped earthenware receptacles, on the bottom of which it separates as a slimy black mass or "stupp." This is treated in centrifugal machines called "presses" and the dirt, &c. separated is again roasted. The mercury is placed for shipment in heavy cast-iron vessels, with screw tops, called "arrobas;" each arroba holds about 25 lb. of mercury. It is estimated that the deposits will last for another 40 or 50 years at the present rate of extraction.—A. S.

English Patents.

Metals: Purifying and Separating ——. W. S. Simpson, London. Eng. Pat. 28,938, Dec. 31, 1902.

To facilitate the decarburisation and purification of iron for steel-making, &c., the metal is run into a receptacle lined with a refractory and non-conducting material, which vessel is subjected to repeated concussions, as by dropping many times upon a solid foundation from a height of about 12 in. The same process is used generally with metals while in a molten state, to eliminate metallic oxides and other impurities, and to separate metals of varying densities.—E. S.

Furnaces for Roasting Pyrites and other Substances. F. Benker, Clichy, and E. Hartmann, Wiesbaden. Eng. Pat. 260, Jan. 5, 1903.

Steel; Manufacture of Open-Hearth ——. B. Talbot, Pencoyd, Pa. U.S. Pat. 747,661, Dec. 22, 1903.

See Eng. Pat. 22,408 of 1900; this Journal, 1901, 1118. —T. F. B.

Steel; Manufacture of ——. B. Talbot, Harrogate, Assignor to Continuous Metal Refining Co., Philadelphia. U.S. Pat. 747,662, Dec. 22, 1903.

A charge of molten iron, prepared by heating iron oxide with pig-iron in such a way as to reduce the quantity of silicon present without much affecting the percentage of carbon, is introduced into an oxidised steel bath, covered with a layer of oxidising basic slag; the carbon of the iron and the oxygen of the steel combine to form carbon monoxide, which heats the charge by its combustion.—T. F. B.

Metal Compounds; Method of Converting ——. J. W. MacDonald, Pittsburg, Pa., Assignor to U.S. Sulphide Smelting Furnace Co., Toledo, Ohio. U.S. Pat. 746,721, Dec. 15, 1903.

In smelting ores, an elongated solid body of fluxing material is introduced through a vertical sustaining channel, with its lower portion immersed in the molten compounds within the area of their highest degree of oxidation. The fluxing body sinks by gravity to the bottom of the bath, and as it dissolves, fresh quantities are automatically supplied from the superincumbent portions.—E. S.

Copper Ores; Process of Smelting ——. R. H. Aiken, Winthrop Harbor, Ill. U.S. Pat. 746,773, Dec. 15, 1903.

A mixture of sulphide copper ores with silica and suitable fluxes, but without carbonaceous fuel, is introduced into a furnace, and a blast of air is passed into the charge at the upper zone of action, chiefly to oxidise the iron sulphides present; and simultaneously a separate blast of a mixture of air and of a liquid fuel is passed into the lower zone of action, whereby a melting temperature is maintained by which the iron oxide formed as described combines with the silica of the charge to form a slag, whilst the copper sulphide fuses to form a matte.—E. S.

Zinc; Process of Recovering ——, *from Sulphide Ores.* P. Danckwardt, Deadwood, S.D. U.S. Pat. 746,798, Dec. 15, 1903.

Ore containing zinc or other valuable metals is mixed with a salt of an alkali metal, a metal carbide or carbide-forming material in excess, and with suitable fluxes, and the mixture is heated electrically under a heavy cover of carbon, so that in the gases evolved carbon monoxide, and not carbon dioxide, may occur. The zinc vapours are condensed, and the molten charge is withdrawn from the furnace. After settling of the matte and metals, the slag is lixiviated, and the alkali sulphide solution obtained is treated with carbon dioxide, and the hydrogen sulphide evolved is collected and utilised, and alkali carbonate is crystallised from the concentrated solution.—E. S.

Smelting [Sulphide] Ores. J. W. MacDonald, Pittsburg, Pa., Assignor to U.S. Sulphide Smelting Furnace Co., Toledo, Ohio. U.S. Pat. 746,970, Dec. 15, 1903.

The raw sulphide ore is heaped up conically on a furnace hearth, with the inclined sides exposed, and is sufficiently heated to commence the burning of the sulphur. Several streams of hot air are caused to impinge upon the base of the heap, so that the flames rise along and fuse the exposed surface. As the molten product is drawn off, fresh portions of raw ore are fed upon the surface of the heap.—E. S.

Aluminium; Soldering Flux for ——. C. Ellis and O. J. Flanigan, Boston, Mass. U.S. Pat. 746,802, Dec. 15, 1903.

The soldering flux consists of a salt of a metal the heat of formation of which is less than that of the corresponding salt of aluminium, incorporated with a reducing vehicle. For example, silver chloride, incorporated with an organic reducing vehicle, such as an oil, may constitute such a flux. See also U.S. Pat. 717,833 of 1903; this Journal, 1903, 147.—E. S.

Crucible-Furnace. J. D. Swindell, Assignor to the American Furnace and Machine Co., Pittsburg, Pa., U.S.A. U.S. Pat. 747,019, Dec. 15, 1903.

The combustion chamber has a conical opening in its roof, the wider portion of the cone being towards the inside of the chamber. The bottom of the chamber can be raised or lowered, for example, by hydraulic machinery, and is conical in shape, the wider portion also pointing towards the inside of the chamber, and provided with a bevelled edge, which fits into the conical portion of the opening in the roof, when the bottom is raised. When the bottom is raised to be in contact with the roof, a flange on the lower side of the bottom closes the floor of the combustion chamber. Gas flues in the side walls of the combustion chamber are closed when the bottom of the chamber is raised to be in contact with the opening in the roof. This opening is provided with a movable cover. By the use of this furnace, crucibles can be raised by the moveable bottom, through the opening in the roof of the combustion chamber, which, together with the gas inlets, is simultaneously closed, top and bottom, to prevent the escape of furnace gases.—W. C. H.

French Patents.

Steel; Manufacture of ——, *and Treatment of the Mattes of Copper, Nickel, &c.* Cie. du Réacteur Métallurgique. Fr. Pat. 334,454, Aug. 6, 1903.

The metal to be converted into steel, or the mattes of copper, nickel, &c., are melted in a suitable converter, and jets, of air only, or of air charged with vapour, or oxides, silica, chalk, fluorides, carbon, carbides, hydrocarbons, chlorides, &c., are injected simultaneously upon and below the surface of the bath, or only upon or below, according to circumstances. Converters and subsidiary apparatus are shown adapted to the material under treatment.—E. S.

Iron and Other Metals; Reduction of Ores of ——. C. S. Bradley. Fr. Pat. 334,785, Aug. 22, 1903.

See Eng. Pat. 17,434 of 1903; this Journal, 1903, 1198. —T. F. B.

Metallic Compounds having as Principal Constituent Partially or Wholly Decarbonised Iron. S. Parfitt. Fr. Pat. 334,959, Sept. 1, 1903.

See Eng. Pat. 2612 of 1903; this Journal, 1904, 22. —T. F. B.

Ores and Products Containing Vanadium, Molybdenum, Titanium, or Tungsten; Treating ——. H. L. Herrenschmidt. Fr. Pat. 334,333, June 27, 1903.

The object of the invention is to obtain from ores of vanadium, vanadic acid or a vanadate, and alloys of vanadium with other metals, such as nickel, iron, or copper, the processes described being also applicable to obtaining corresponding products from ore of molybdenum, titanium, and tungsten. Solution of crude sodium vanadate, obtained from the ores by known processes, is concentrated and crystallised with addition of vanadic acid, resulting from a prior fractional precipitation of part of the liquor, by vanadium sulphate, or of an acid, or of a metallic salt. The same process is applied to obtaining a vanadate of nickel, iron or copper from the original solution after purification. These vanadates may be heated with carbon to obtain the corresponding alloys. Compare Fr. Pat. 328,421 of 1903, and Addition to the same; this Journal, 1903, 953 and 1198.—E. S.

French Patents.

Aluminium Alloy; Manufacturing ——. L. Trézel, P. V. G. Coppée, and A. J. De Monthy. Fr. Pat. 334,343, Aug. 3, 1903.

A preparatory "rich" alloy is obtained by fusion at a very high temperature (about 2,000 C.) of approximately equal parts of ferro-silicon and of cobalt, with two parts of aluminium, and variable smaller proportions of silver and of silica. This "rich" alloy is melted with aluminium at a comparatively low temperature, to form an alloy for which special characteristics are claimed; *viz.*, that it may be soldered and braized, &c.—E. S.

Minerals; Process and Apparatus for the Separation of ——, and for the Extraction of Mattes. G. A. Goyder and E. Laughton. Fr. Pat. 334,443, Aug. 6, 1903.

See Eng. Pat. 16,839 of 1903; this J., 1903, 1133.
—T. F. B.

Ores; Furnace for Treating ——. I. Santilippo, Italy. Fr. Pat. 334,444, Aug. 6, 1903.

The furnace, which is especially intended for the treatment of sulphide ores, or for refining sulphur, has as its essential characteristics, two compartments, one above the other, filled with hollow pillars extending to the roof, and perforated laterally to admit free passage of gases, the ore being fed from above. The arrangements are modified in various respects according to the use to which the furnace is put.—E. S.

Tinning and Soldering; Composition for Use in ——. K. Küppers. Fr. Pat. 334,491, Aug. 7, 1903.

The composition is made by mixing 9·5 parts of zinc chloride, 8 parts of ammonium chloride, and 5 parts of zinc oxide, with some water. The mixture is preferably dried at from 140° to 300° C., and then allowed to solidify.
—E. S.

Etching [Designs on] Metals. J. A. Dejey. Fr. Pat. 334,499, Aug. 8, 1903.

The design having been copied on to the roller or plate to be engraved, and a reserve of lead electrically deposited, the ink is dissolved off by turpentine or the like, and the plate is ready for etching by acids or liquors that do not attack lead, but only the design on the copper surface which is laid bare; ferric chloride or chromic acid solution may be thus used for instance. When it is desired to etch very deeply, the plate may be cleaned, and the etching already obtained covered with a varnish, and then a thick reserve of lead deposited and the process continued as before. Fr. Pat. 301,227, 1901, is referred to. See Addition to Fr. Pat. 301,054, 1901; this Journal, 1902, 51.—E. S.

Dust Floating in Roasting Furnaces having Superposed Hearths; Process and Arrangement [of Apparatus] to Prevent the Formation of ——. W. Kauffmann. Fr. Pat. 334,528, Aug. 10, 1903.

The invention consists in arrangements whereby the ore, in its descent from hearth to hearth, of a horizontal roasting furnace, is delivered without encounter of uprushing gases, for which passage is automatically made through independent openings, and the formation of floating dust is thus prevented. The passages for the gases are successively opened and closed by means of plates connected to the mechanism for discharging the ore from hearth to hearth, but in no case is rush of gases possible through an opening which is discharging ore.—E. S.

Waste [or Dust] of White or Pure Pyrites; Treating ——, with view to Recovery of the Iron. H. Sölbiský. Fr. Pat. 334,623, Aug. 14, 1903.

Waste pyrites, or furnace dust, the latter after separation of non-magnetic bodies, is heated sufficiently to "volatilise" sulphur and zinc, and is subsequently more strongly heated in air, to form zinc sulphate, which decomposes into sulphur dioxide, oxygen, and zinc oxide. The complete extraction of the sulphur and zinc is stated to be facilitated by using a mixture of products. It is also stated that the reduction of iron oxide by fusion with pyrites containing copper or nickel, may be effected by heating the mixture of them sufficiently; and that thus molten iron, or an alloy of iron with such metals, is obtained.—E. S.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

(*A.*)—ELECTRO-CHEMISTRY.

English Patents.

Water and other Liquids; Apparatus for Purification of —— [by Electrolysis]. W. B. Hardy, London. Eng. Pat. 25,041, Nov. 14, 1902.

The electrolytic tank is made in the form of a metal pipe, lined with two longitudinal slabs of wood opposite to each other, and with longitudinal staves with radial meeting edges for supporting the two slabs in position. The latter have longitudinal grooves into which slide aluminium plates, acting as electrodes, alternate ones as anodes and cathodes. The anode plates overlap the cathode plates at one end and the cathode plates overlap at the other, the overlapping portions being secured together by a threaded bar, provided with nuts on opposite sides of the plates for clamping them. The liquid is thus made to circulate in a sinuous course over the plates. The ends of the tank are secured to, and closed by, metal heads lined with slate, the latter fitting within the tank so as to abut against the wooden lining, and the slate is provided with grooves for supporting the electrodes and with openings for the terminals which are connected to the threaded bars. The liquid enters under pressure at one end and passes out in a pure state at the opposite end; but in the entrance pipe is placed a liquid motor of the blade type, attached to a governor and actuating a switch in such a way that a resistance is introduced into the circuit when the speed of the liquid is low, and cut out when the flow is fast, the circuit being broken when the flow ceases. This is accomplished by the centrifugal balls acting on a lever, so as to bring a contact point, attached to the lever, down on to a contact point attached to the electrodes through a resistance; or, if the speed is greater, so as to bring the contact point still lower on to a third contact point in direct connection with the electrodes, and thus cut out the resistance. When the flow ceases the balls drop and the contact points are separated, thus breaking the circuit.
—B. N.

Agitating the [Fused] Contents of Electrolytic Cells; An Improved Method and Apparatus for ——, or Effecting Systematic Transference of Portions of the Contents from one Cell to Another. E. A. Ashcroft, Runcorn. Eng. Pat. 12,083, May 27, 1903.

A pot electromagnet, with concentric poles, is arranged concentrically beneath the bath of fused material (*e.g.*, sodium chloride), and this sets up a violent swirl of the contents of the vessel, the magnet being so placed that the lines of magnetic force cut the lines of current flow more or less at right angles, and lie in planes at right angles to the direction of the required motion. Two vessels may be arranged in this way, with connecting tangential tubes, the second vessel containing fused caustic soda, with a sodium-lead alloy as the anode and a central nickel cathode. By using a horse-shoe magnet, with one pole vertically below each vessel, the swirls in the two vessels may be produced in the same direction and some of the intermediate electrode (sodium-lead alloy) will be transferred from one vessel to the other. Instead of the tangential passages, the two vessels may be placed side by side, with an opening near the bottom for connecting the cells, and in which is placed a baffle plate for directing the contents of one vessel into the other; or a passage may lead from the centre of the first to the periphery of the second cell, and another passage from the periphery of the first to the centre of the second, the increased pressure at the periphery of each vessel producing circulation.—B. N.

Insulating Materials, and Artificial Substitutes for Ebonite and the like. O. D. Lucas, London. Eng. Pat. 2695, Feb. 4, 1903.

Three classes of materials are used, a cheap earthy substance of a fibrous nature, such as peat, for the base, a binding material, such as China- or other clay, chalk, or powdered talc, and cementing materials, such as india-rubber and shellac or colloids like gelatin and glue. If rubber be used, sulphur is added in the proportions required, according to hardness desired and in the case of colloids, bichromate of potash or tannin is added to render them insoluble. The process is carried out by grinding the substances of the first and second classes, first alone and then together, and finally stirring them into a solution of the substance of the third class in a suitable solvent. The resulting material is granular when rubber or shellac is used: it is reground to a fine powder and is capable of being solidified under heat and pressure into a solid compact mass, having high insulating properties. The product from colloids is plastic or gelatinous when cold. It must be dried by the gentle application of heat or some other suitable method. It has a high specific resistance, is capable of taking a high polish, and can be moulded into any form and turned in a lathe.

—J. K. B.

French Patents.

Caustic Soda Solutions, Caustic Soda, Chlorine and its Derivatives; Method of Obtaining Strong ——, by Electrolysis of Sodium Chloride. R. Eserive de Romani. Fr. Pat. 334,332, June 25, 1903.

The conversion of the sodium amalgam, by means of water, into caustic soda and mercury is conducted in a separate cell from that in which the amalgam is produced by the electrolysis of sodium chloride. The former cell is at a higher level than the latter, and a pipe leading from the bottom of the electrolytic tank to the upper part of the other is provided with a valve which automatically passes the amalgam but excludes the solution. This is effected by using a ball-and-socket valve, of which the ball has a specific gravity lower than that of mercury but higher than that of the solution.—W. G. M.

Water; Process of Electrolysing ——. W. F. M. McCarty and W. S. Beebe. Fr. Pat. 334,543, Aug. 10, 1903.

See Eng. Pat. 17,399 of 1903; this Journal, 1904, 18.

—T. F. B.

Electrodes for Electrolysis. J. Hargreaves. Fr. Pat. 335,010, Sept. 2, 1903.

See Eng. Pat. 19,368 of 1902; this Journal, 1903, 1135.

—T. F. B.

(*B.*)—ELECTRO-METALLURGY.

United States Patent.

Metals; Separating ——, from Matte or Ore. P. Danckwardt, Deadwood, S.D. U.S. Pat. 746,797, Dec. 15, 1903.

Valuable metals are separated from metal sulphides and arsenides containing iron sulphide, by mixing the matte or ore with carbide-forming materials, and heating the mixture in an electric furnace to produce a carbide which will reduce the valuable metals to the metallic state, without reduction of the iron sulphide present.—E. S.

French Patent.

Alloy of Iron, Silicon, and Manganese; Process of Manufacturing a Triple ——, in an Electric Furnace. C. A. Keller. Fr. Pat. 334,504, Aug. 8, 1903.

An alloy containing iron, silicon, and manganese, in variable proportions, is produced by heating in an electric furnace, restricted to a tension of about 30 volts, a mixture of ferrosilicon, silica, and a manganese ore, with sufficient carbon to effect the reduction of the silica and of the ore. One application of the alloy is as a final addition to baths of molten steel.—E. S.

XII.—FATTY OILS, FATS, WAXES, AND SOAP.

Esters of [Fatty] Acids of High Molecular Weight; Preparation of Pure ——. F. Krafft. Ber., 1903, **36**, [17], 4339—4344.

The author has found that products purified by distillation in the vacuum of the cathode light have sharper boiling points than those prepared by the usual methods. The ethyl esters of stearic, palmitic, myristic, and lauric acids were prepared, and found to be readily volatile. Glycol esters of fatty acids were obtained by heating ethylene chloride for 10 hours at 180° C. with the respective potassium soaps dried at 140° C. The products of the reaction were extracted with ether, and the extracted substance dried and rectified under a pressure of 15 mm. in very shallow vessels (about 20 mm.). The white transparent crystalline masses yielded brilliant plates when crystallised from hot alcohol. On heating the potassium soaps for 12—15 hours with an excess of ethylene chloride or bromide, the respective chloro-ethyl- and bromo-ethyl-esters were obtained. Pure monoglycerides were prepared by heating monochlorhydrin with the dried potassium soaps in a sealed tube in which the air had been replaced by carbon dioxide. *Monobenzoin* ($C_3H_7O_2.CO_2.C_6H_5$) separated by rectification *in vacuo*, boiled at 124° C., and solidified, on cooling, to a crystalline mass melting at 36° C. *Monolaurin* ($C_3H_7O_2.CO_2.C_{11}H_{23}$) was prepared in the same way, the tube being heated for six hours at 180° C. The ethereal extract of the products of the reaction were dried under a pressure of 15 mm., and then *in vacuo* at 80° C., and rectified in the full green cathode light. The monolaurin distilled at 142° C. *in vacuo*, and solidified to a transparent, crystalline, non-hygroscopic mass, melting at 59° C. *Monomyristin* distilled at 162° C. *in vacuo*, and melted at about 68° C. *Monopalmitin* (m. pt. 72° C.), was prepared by heating two parts of potassium palmitate with 0·8 part of α-monochlorhydrin as described above. The ethereal extract was purified by crystallisation from ethyl and butyl alcohols, and the last traces of di- and tri-palmitin removed by means of hot benzene. *Monostearin* prepared in the same way melted at 78° C. *Mono-oleïn* ($C_3H_7O_2.CO_2.C_{17}H_{33}$) was fractionally precipitated by adding water to an alcoholic solution of the products of the reaction, and dried on a porous tile *in vacuo*. It formed white crystals melting at 35° C. The monoglycerides of fatty acids are converted into triglycerides when shaken and heated with benzoyl chloride and sodium hydroxide solution; for instance, *dibenzoyl monopalmitin*, $C_3H_5(CO_2.C_{16}H_{31})(CO_2.C_6H_5)_2$, melting at 69° C., and the corresponding compound of monomyristin (m. pt. 65° C.) were thus prepared. Both distilled without decomposition *in vacuo*. Crude fats were also fractionated in the same way. The solid fat separated by means of alcohol from laurel oil distilled at 250° to 275° C. *in vacuo* yielding trilaurin; trimyristin was also separated from muscat butter in the same way.—C. A. M.

Seeds of the Para Rubber Tree (Hevea Brasiliensis); Commercial Utilisation of the ——. Bull. of the Imperial Inst. (Suppl. to Board of Trade J.), 1903, [4], 156—159.

The seeds (husk and kernel ground together) when extracted with light petroleum, furnished 20 per cent. of oil, whilst the kernels, which constitute about 50 per cent. by weight of the seeds, yielded 42·3 per cent. of oil. The chief point of difference between the oils from the whole seeds and from the kernels is the presence in the former of a very small amount of a solid fat having a high saponification value and a low iodine value. The oil possesses drying properties: it gives a clear transparent film on exposure to the air, and could probably be used as a substitute for linseed oil. The oil prepared from the kernels had the following characters:—sp. gr. at 15° C., 0·9302; acid value, 10·7; free fatty acids (as oleic acid), 5·4 per cent.; saponification value, 206·1; iodine value, 128·3. A specimen of oil extracted from Para rubber seed meal was found to contain 65·6 per cent. of free fatty acids (as oleic acid). This large proportion of free acid, which is due to the decomposition of the neutral oil in the crushed seed by the action of a hydrolytic enzyme, renders the meal unfit for use as a fodder. The residual cake obtained after expressing the oil from the decorticated seeds could, however, be used as a cattle food. It contains:—moisture, 13·36; ash, 5·19; proteids, 26·81; fibre, 5·00; fat, 6·00; and carbohydrates, 43·64 per cent. Para-rubber seed oil has been valued at about 20*l.* per ton. It is not advisable to import the whole seeds, but the decorticated seeds, which are valued at 10*l.* to 12*l.* per ton. The "seed cake" would be of about the same value as linseed cake, *viz.*, 5*l.* 15*s.* to 6*l.* 15*s.* per ton.—A. S.

English Patents.

Fatty Matters from Bones and other Materials; Extraction of ——. W. R. Smith, Chester, and E. G. Scott, London. Eng. Pat. 3150, Feb. 10, 1903.

The material is placed in a chamber above a source of steam-heat (claim being made for "tubes held in tube plates and externally heated by steam"), whilst the solvent is introduced from above and falls through it. The solvent is vaporised by the heat and rising through the material is condensed and extracts more fat, until eventually, when the material becomes hot, the solvent is recovered by means of a condenser. The solution of the fat is conducted into a vessel, where the solvent is evaporated by means of tubes externally heated by steam, the process being accelerated by the introduction of live steam.—C. A. M.

Oils and Fatty Matters; Purifying and Deodorising ——. C. Godard, Termonde, Belgium. Eng. Pat. 22,085, Oct. 13, 1903. Under Internat. Conv., Oct. 16, 1902.

The oils are mixed with sodium silicate, the soap separated, and the neutralised oils deodorised by means of steam in a fine state of division. A special apparatus is claimed for the latter process.—C. A. M.

Oils and Fatty Matters; Decolorising ——. C. Godard, Termonde, Belgium. Eng. Pat. 22,086, Oct. 13, 1903. Under Internat. Conv., Oct. 28, 1902.

In order to prevent oxidation of oils during agitation with decolorising reagents, claim is made for carrying out the process *in vacuo*, and also for special apparatus for the purpose.—C. A. M.

United States Patent.

Seeds; Process of Eliminating Solvents from ——. M. Swenson, Madison, Wis., U.S.A. U.S. Pat. 747,267, Dec. 15, 1903.

The liquid solvent is expelled by the introduction of hot vaporised solvent, the residual seed being dried in the process. The vapour is itself removed from the seed by means of a high vacuum, and a current of hot air finally passed through.—C. A. M.

Oils or Distillates; Process of Desulphurising ——. O. P. Amend, Assignor to J. H. Macey. U.S. Pats. 747,347 and 747,348, Dec. 2, 1903. III., page 55.

French Patents.

Fatty Acids from their Esters; Process of Extracting ——. Vereinigte Chemische Werke Gesellschaft. Fr. Pat. 328,101, Oct. 9, 1902.

Claim is made for the use of vegetable ferments on an emulsion of the fat in presence of acids or acid salts. (See Eng. Pat. 22,111 of 1902; this Journal, 1903, 428.) —C. A. M.

Cacao Butter; Impt. of ——. G. Muller. Fr. Pat. 334,366, July 25, 1903.

This process, which is stated to render cacao butter soft and pliable, consists of heating the fat with water and sodium bicarbonate, then cooling it with constant agitation until it congeals, after which it is left for 24 hours, and is finally subjected to a process of pressing and kneading until supple. Claim is also made for a product thus prepared from a mixture of butter and cacao butter.—C. A. M.

XIII.—PIGMENTS, PAINTS; RESINS, VARNISHES; INDIA-RUBBER, Etc.

(*A.*)—PIGMENTS, PAINTS.

English Patents.

Paving Material or Asphalt, Filling-up Cement, Waterproofing Material and Paint. W. P. Thompson. Eng. Pat. 24,807, Nov. 12, 1902. IX., page 64.

Ultramarine; Manufacture of ——. C. F. Cross, London. Eng. Pat. 3171, Feb. 10, 1903.

A charcoal, rich in silica, such as charcoal from the husks of rice, is substituted either partly or entirely for the coal and kieselguhr, used in the ordinary mixtures for making ultramarine.—J. K. B.

French Patents.

Cement with Zinc Basis for Hot Joints. Bonneville & Co. Addition, dated July 8, 1903, to Fr. Pat. 332,789, June 4, 1903.

In cases where the presence of oxide of lead or its other compounds are either desirable or not objectionable, they may be added to the cement made with finely divided metallic zinc as described in the previous patent in this Journal, 1903, 1357.—M. J. S.

White Paint; Manufacture of a ——. J. E. Kollinger. Fr. Pat. 328,111. Oct. 23, 1903.

Limestone is saturated with petroleum oil, which is then set on fire. The resulting lime is submitted to the same operation a second time, and is then ground with a suitable paint vehicle. The second calcination is stated to improve the opacity of the product. The paints dry rapidly without the addition of a siccative, and acquire a hard surface which is highly resistant to atmospheric influences.— —M. J. S.

Pigments; Processes of Making ——. W. J. Armbruster and J. Morton. Fr. Pat. 334,649, Aug. 17, 1903.

See U.S. Pat. 737,056 of 1903; this Journal, 1903, 1055. —T. F. B.

Pigment, and Process of Manufacturing same. W. J. Armbruster and J. Morton. Fr. Pat. 334,650, Aug. 17, 1903.

See U.S. Pat. 737,055 of 1903; this Journal, 1903, 1055. —T. F. B.

(*B.*)—RESINS, VARNISHES.

United States Patent.

Turpentine Still. W. H. Krug, New York, Assignor to Standard Turpentine Co., Raleigh, N.C. U.S. Pat. 746,850, Dec. 15, 1903.

The still is provided with two delivery pipes, one of which is fitted with an automatic valve controlled by the internal pressure of the still, and the other with a valve operated by hand. The delivery pipes lead to separate condensers. —M. J. S.

French Patents.

Varnish; Process of Manufacturing ——, *by Direct Solution of Gums Without Previous Fusion.* A. Tixier and L. Rambaud. Fr. Pat. 334,430, Aug. 5, 1903.

"Terpineol ($C_{10}H_{16}O$)," obtained by treating oil of turpentine with dilute nitric acid, forms a very energetic solvent for gums in their natural state. The terpineol may be prepared by digesting at 15°—20° C. with acid of 20° B., until the oil of turpentine has been wholly converted into crystallised terpine, which is then washed and converted into terpineol by the action of highly dilute sulphuric acid, or by digesting at 60°—70° C., washing, and distilling by steam. The latter process is the more rapid, but the product is less pure. The commercially pure terpineol has a density of 0·940, and a refractive index higher than 1·478 at 20°. Varnishes may be prepared by dissolving unfused gums in this liquid, or in a mixture of it with oil of turpentine, benzene, or alcohol. To use it in the preparation of oil varnishes, it is desirable to add a fatty acid which is soluble in the oil, since such a mixture does not precipitate the gum from its terpineol solution, as a neutral oil would do if added in too large a proportion.—M. J. S.

Linoleum consisting of Two or More Layers; Process of Manufacturing ——. The Bremer Linoleum Werke Delmenhorst Co. Fr. Pat. 334,635, Aug. 11, 1903.

The mode of manufacture claimed consists in presenting the two or more compositions which are to form the respective layers to simultaneous compression between rollers. The mixtures are kept separate in the charging hopper by partitions which extend nearly to the zone where the compression takes place.—M. J. S.

(C.)—INDIA-RUBBER.

India-Rubber; Chemistry of ——. E. Marckwald and F. Frank. Gummi-Zeit., 1903, **18**, [13], 251—253.

It seems likely that the quantity *x* in the empirical formula $(C_{10}H_{16})x$ will be replaced by 10, for whilst the analysis of the most highly vulcanised product possible gives the formula $(C_{10}H_{16}S_2Cl_2)x$. Weber gives $(C_{10}H_{16})_{10}S_2Cl_2$ as the lowest vulcanisation product containing no free polyprene. In soft rubber Weber found sulphur corresponding to the formula $C_{100}H_{160}S$, and for hard rubber, obtained by mixing equal quantities of sulphur and rubber and vulcanising for eight hours at 140° C., he was unable to get a higher product than represented by the formula $(C_{10}H_{16}S_2)x$. It is evident that the combined sulphur cannot be removed from the rubber molecule without breaking up the latter, so that the so-called regeneration of india-rubber resolves itself into a physical manipulation of the old rubber merely, no real chemical alteration taking place.—J. K. B.

India-Rubber; Action of Metals on ——. C. O. Weber. Gummi-Zeit., 1903, **18**, [13], 255.

Unvulcanised rubber is rarely used in contact with metallic surfaces, but vulcanised rubber, on the other hand, is used for covering metals for very many purposes. It is found that the more readily the metal combines with sulphur the firmer is the combination between the rubber and the metal. This appears to be due to the fact that at the vulcanisation temperatures, certain metallic sulphides actually combine with rubber in a manner not yet fully understood. Arsenic, antimony, lead, copper, and silver act very energetically; tin, zinc, iron, and aluminium much less so; whilst gold and platinum are quite inert. Practical use of this property is made in the manufacture of cables, where the tinned copper wires are always used, wires thus coated resisting action of the sulphur. On the other hand, comparatively inert metals, such as iron and steel, may be coated with antimony or copper when it is desired to obtain the firmest possible adhesion.—J. K. B.

Sulphur for Vulcanising India-Rubber; Properties of ——. C. O. Weber. India-Rubber Journal, 1904, **27**, [1], 21 and 30.

Attention is drawn to the necessity of the sulphur used being free from acidity, especially when used for making pure rubber goods, which contain no fillers likely to neutralise the free acid. The sulphur should be stored in a cool place in order to avoid oxidation as much as possible. The presence of lime in a mixing is not a guarantee of its freedom from any free acid, as perfect admixture is impossible on mixing rolls. The author recommends grinding 2 to 3 per cent. of lime into the sulphur in a ball grinding machine. Such a mixture is peculiarly successful as a vulcanising agent.—J. K. B.

Rubber; Collection and Preparation of Different Sorts of Congo ——. E. de Wildeman. Gummi-Zeit., 1903, **18**, [14], 281.

The rubber called "tjibola" is yielded by a creeper, the bark of which contains a sticky product, which can only be separated by beating. By the beating process the natives eventually obtain rubber flakes about 3—4 mm. thick and 30—40 mm. wide. These are cut into strips and formed into balls, five of which are stuck together by dipping in hot water. A creeper 2 *m.* long yields 30 to 40 balls of rubber weighing about 275 grms., and this small yield represents a whole day's labour. Such rubber loses in drying before export only about 10 per cent. of its weight. Kanianga rubber is obtained from young creepers of the same species by cutting. A longitudinal and transverse cut is made in the bark, and the latex allowed to run down a stick or down the arm or breast of the native, the heat of the body coagulating it thoroughly. Rubber so prepared is of the best quality, practically free from impurities, for it runs fast and coagulates. Creepers yielding a slow-running latex are cut, five or six at a time, in the morning, and the rubber, which slowly gathers at the wounds, collected in the afternoon or next morning. The rubber obtained is of a good quality, but contains particles of bark enclosed. The yield is 15 to 20 balls, weighing about 150 grms. in all; the rubber loses 20 to 30 per cent. in weight in the store. Black rubber, or "tjikala," is white inside, excepting when the balls are very small, and the black colour is due to surface oxidation. It is obtained by cutting a creeper about 2 m. long, in a longitudinal direction only, commencing about ½ m. from the ground. The free-flowing latex is collected in a vessel, and poured into hot water in order to coagulate it. The rubber balls floating on the surface are caught between large leaves, and the water separated by trampling under foot. The resulting thin rubber cakes are cut into strips, formed into balls, and dried on hurdles. A creeper yields 70 to 100 balls of tjikala. Bakuba caoutchouc, called Suma, is obtained from the same creeper as kanianga. The balls are formed by pressing together the product obtained by boiling the half-run latex with water.—J. K. B.

Rubber Resources of the Soudan. Bull. of the Imperial Inst. (Suppl. to Board of Trade J.), 1903, [4], 168.

The rubber-yielding creeper, *Landolphia owariensis*, Beauv., var. *tomentella*, occurs abundantly all over the Bahr-el-Ghazal province; it is known to the natives of the various tribes as "Ndala," "Odiloh," "Ngeleh," and "Atilob." Specimens of the rubber made up in two forms, *viz.*, balls and cylindrical rolls, have been examined, with the following results:—

	Moisture.	Caoutchouc.	Resin.	Dirt and Insoluble Matter.	Ash (included in Dirt).
	Per Cent.	Per Cent.	Per Cent.	Per Cent.	Per Cent.
Balls	15·7	71·5	7·3	5·5	1·19
Rolls	17·8	69·5	7·4	5·3	1·16

The rubber, which was contaminated with a small amount of extraneous vegetable matter, was not sticky; it was rather hard in the mass, but small pieces exhibited very good elasticity and tenacity. It is valued at about 3*s.* 6*d.* per lb. By a decree issued by the Soudan Government on May 1, 1903, the rubber forests throughout the Soudan, with the exception of those in Kordofan, have been placed under official management, in order to prevent the destruction of the trees through reckless methods of collecting the rubber.—A. S.

Castilloa and Funtumia Rubbers; Experimental Cultivation of ——, *in Trinidad.* Bull. of the Imperial Inst. (Suppl. to Board of Trade J.), 1903, [4], 160—167.

Specimens of rubber from the various rubber-yielding trees cultivated in Trinidad were examined with a view to ascertaining the influence of the age of the tree and the method of treating the latex on the quality of the rubber obtained.

Castilloa Rubber.—The view held by previous investigators that trees of *Castilloa elastica* only yield rubber of good quality after they have attained the age of eight years is confirmed. In all the specimens examined, the proportion of resin was much higher than that hitherto recorded for this variety of rubber. The method of preparation had little influence on the composition of the rubber, except that specimens obtained by "creaming" the latex, *i.e.*, diluting it with a large volume of water and allowing to stand for 12 hours, before coagulating the rubber by the addition of alcohol, contained much less foreign matter than specimens obtained by the direct addition of alcohol to the latex, or by exposing the latter to the air. The two specimens of Castilloa rubber which alone were of commercial value, were obtained from trees 12 years old and upwards, and had the following composition:—Moisture, 15·2, 2·2; caoutchouc, 70·1, 69·1; resin, 11·7, 8·2; dirt, 3·0, 0·5; ash (included in dirt), 0·79, 0·25 per cent.; they were valued at 2*s*. 4*d*. and 2*s*. 9*d*. per lb. respectively. A specimen of Castilloa rubber prepared by Weber's method of adding formaldehyde to the "creamed" latex (this Journal, 1902, 1461) had practically the same composition and value as the second of the two specimens described above, but was much lighter in colour.

Funtumia Rubber.—The rubber from *Funtumia elastica* is much superior to that from *F. africana*. Two specimens of rubber from trees of *F. elastica*, 4½ years old, the first having been prepared by addition of alcohol to the latex, and the second by heating the latex, had the following composition:—Moisture, 29·5, 21·2; caoutchouc, 60·2, 68·5; resin, 7·9, 7·9; dirt, 2·4, 2·4; ash (included in dirt), 1·37, 2·08 per cent.; they were valued at 2*s*. 6*d*. and 2*s*. 2*d*. per lb respectively. The specimen prepared by heating contained a considerable amount of uncoagulated latex.—A. S.

XIV.—TANNING; LEATHER, GLUE, SIZE.

Myrobalan Extracts; Behaviour of ——, when kept under Various Conditions. J. Paessler. Collegium, 1903, **2**, [89], 369—373. From Deutsche Gerber-Zeit., 1903.

If weak myrobalan liquors, of a strength very slightly above that employed in analysis, are allowed to stand, they show an even more serious loss of tannin than was observed in the case of strong myrobalan liquors (see Youl and Griffith, this Journal, 1901, 428—429). Two liquors, of about 0·5 per cent. tannin strength, lost in the course of five days 11·8 per cent. and 21·8 per cent. respectively of the original amount of tannin, whilst this loss became 27·5 per cent. and 32·7 per cent. respectively in a total period of 15 days. In view of its commercial importance the behaviour of strong liquid extracts was examined in the following manner:—A newly made extract was analysed, and four quantities of 1 litre each measured off into stoppered flasks. Of these, two were kept in the laboratory and two in a cool cellar, one of each pair being treated by addition of 1 per cent. of salicylic acid. Analyses were made of each after periods of 25, 50, 100, 220, and 420 days, and the final results are shown in the adjacent table.

Table showing Alteration in a Myrobalan Extract (25° B.) when kept for 420 Days.

—	Original condition.	Kept in Laboratory. Un-treated.	Kept in Laboratory. 1 per Cent. of Salicylic Acid added.	Kept in Cool Cellar. Un-treated.	Kept in Cool Cellar. 1 per Cent. of Salicylic Acid added.
	Per Cent.	Per Cent.	Per Cent.	Per Cent.	Per Cent.
Tannin........	22·1	20·1	19·8	21·7	21·9
Non-tannin ...	13·7	12·3	12·4	12·8	12·7
Insoluble matter	3·2	7·2	8·3	5·7	5·5
Water.........	61·0	60·5	59·5	59·8	59·9

Thus, whilst myrobalan liquors may deposit 25—30 per cent. of their available tannin in the course of 15 days liquid extracts such as the above lose barely 5 per cent. in the course of a year. It further appears (1) that salicylic acid has practically no effect, and (2) liquid extracts should be stored in a cool cellar to reduce the loss caused by deposition to a minimum.—R. L. J.

Tannin Analysis; Improved Apparatus for ——. R. A. Earp. XXIII., page 77.

English Patents.

Titanium Solutions and the Manufacture of Leather; Impts. relating to ——. C. Dreher, Freiburg, Germany. Eng. Pat. 27597, Dec. 15, 1902.

Tanning liquors are prepared by dissolving titanic acid in a carboxylic acid of the fatty series, or in other acids, in the presence of compounds containing several hydroxyl groups in the fatty residue, and adding alkalis or alkali carbonates until the liquor is neutral or alkaline, after which the liquor is acidified. Alternatively the titanic acid may be at once dissolved in alkali in the presence of the fatty acids (or salt) or hydroxyl compounds. These liquors may be used (1) in conjunction with vegetable tannins or mordant dyestuffs, (2) in acid, alkaline, or neutral condition, and (3) in any desired order or combination.—R. L. J.

XV.—MANURES, Etc.

Potassium Compounds; Soluble ——, in the Soil, and their Utilisation by Plants. T. Schloesing, jun. Comptes rend., 1903, **137**, [26], 1206—1209.

Maize was grown in pots of different soils, alongside each pot being a comparison pot of the same soil, kept in the same state of humidity, but with no plant growing in it. At the end of the period of growth, 100 grms. of each soil were exhausted of soluble matters by slow continuous percolation with water (containing calcium nitrate to coagulate the albuminous portions and secure a clear percolate). Each successive 7 litres of percolate were evaporated in platinum, and the potassium determined. When the amount in each of the two members of a comparison pair (which in the first washings was greater in the virgin soil) was the same, the washing was discontinued, and the total amount of potassium compounds in the two cases compared. The results were as follows:—

—	Soil from Boulogne. Un-cult.	Soil from Boulogne. Cult.	Soil from Galande. Un-cult.	Soil from Galande. Cult.	Soil from Joinville. Un-cult.	Soil from Joinville. Cult.	Soil from Neauphle. Un-cult.	Soil from Neauphle. Cult.
	Mgrms.		Mgrms.		Mgrms.		Mgrms.	
Soluble potassium oxide per kilo. of dry soil.	443	325	178	103	233	133	283	160
	Grms.		Grms.		Grms.		Grms.	
Difference for the 36 kilos. in each pot.	4·2		2·3		3·6		4·4	
Total potassium oxide in the plants.	5·7		2·3		4·1		5·2	

It appears, then, that the plants draw the greater part, if not the whole, of the potassium compounds which they contain, from the potassium salts dissolved in the water of the soil, and not by direct action of the roots on the solid substances. The author has already shown that the same thing occurs in the case of phosphoric acid.—J. T. D.

Sugar Canes grown on Heavy Clay Lands; Influence of Manures on ——. Report on the Agricultural Work in the Botanic Gardens and the Government Laboratory of British Guiana for 1902-3.

By the addition of nitrogen, in the form of ammonium sulphate, sodium nitrate, raw guano, or dried blood, increased yields of the cane are obtained. Ammonium sulphate and sodium nitrate, when used so as to supply not more than 10 lb. of nitrogen per acre, are of about equal value, but, when used in excess of this proportion, ammonium sulphate gives much better results, the best result appearing to arise from dressings of 2 to 3 cwt. of the salt per acre. Increased yields of cane are also obtained by the use of lime dressings.—T. F. B.

Sewage; Agricultural Value of City —— in India. J. W. Leather. Agric. Ledger, 1903, 37—49.

Analyses of sewage purified by the septic tank process at Manjri and Poona showed that a daily application of 1,000 galls. per acre for nine months would supply 308—423 lb. of nitrogen, 229—219 lb. of phosphoric acid, and 224—350 lb. of potash respectively. The amounts of these constituents contained in a sugar-cane crop were found to be:—Nitrogen, 131; phosphoric acid, 81; and potash, 358 lb. per acre; and these numbers do not represent the amounts permanently removed from the soil, since the ash constituents of the dry leaves and the crushed cane (which are used as fuel in the boiling process) may be returned to the land. The green tops are, moreover, fed to the cattle on the spot, and the manure applied to the soil. —N. H. J. M.

Sewage; Field Experiments with —— on the Bombay Farms. J. W. Mollison. Agric. Ledger, 1903, 50—54.

The experiments were undertaken by the Bombay Agricultural Department, to ascertain the value of purified sewage as manure for sugar-cane and various other crops. Two sets of experiments were made, one in which the effluent from the septic tank was passed through contact beds, and one in which the effluent flowed direct from the tank to the fields. In both cases the water was clear, and had little or no perceptible odour. The purified sewage cannot be applied continuously during the whole period of growth. Some of the more sensitive seedlings might probably with advantage be irrigated with canal water during the first period of growth. Then, again, it is unlikely that the sewage can be applied during the ripening period; in the case of sugar cane, results were obtained which point to the conclusion that the application of the effluent should be discontinued two or three months before the crop reaches maturity. "Lodging" may, however, be avoided, even with the heaviest crops, by adopting the Mauritius system of planting two sets in deep pits about 2·5 ft. apart. It is anticipated that the effluent will furnish remunerative results with sugar-cane, yams, onions, turmeric, surans, sweet potatoes, guinea grass, lucerne, and various sorghums. Very heavy crops of guinea grass, maize, lucerne, and sorghums were obtained at Poona.—N. H. J. M.

Sugar Filling Masses; Column-shaped Crystallisation Vessels for ——. R. Fölsche, Halle a S., and F. Nowak, Roswadze, Germany. Eng. Pat. 23,692, Nov. 2, 1903.

In this type of crystallisation vessel the hot masseeuite is charged into the top of a long, vertical cylindrical vessel, in which it is cooled and crystallised, a similar quantity being withdrawn from the bottom. The general defect of the system lies in the fact that the circumferential portions of the masseeuite cool much faster than the central portions, so that there remains a core of hot, partially crystallised masseeuite. This is remedied by providing stirring arms in the vessels, furnished with inclined blades, scoops, tubes, or inverted cones, or any device which causes a gradual transference of the masseeuite from the circumference to the centre, and *vice versâ*, during the period of cooling. The columns may also be partitioned off into separate chambers, with inlets and outlets on opposite sides of the axis. —J. F. B.

United States Patents.

Sugar Cane; Process of Treating ——. M. Weinrich, Yonkers, N.Y. U.S. Pat. 747,520, Dec. 22, 1903.

The juice of the sugar cane is defecated before the cane reaches the mill. The cane is first shredded into fine fibres, and then steeped in a boiling solution of lime, into which is introduced sufficient lime to neutralise the acidity of the juice; the treated mass is finally delivered to the ordinary cane mill.—J. F. B.

Sugar; Process of Extracting ——. L. Naudet, Paris. U.S. Pat. 746,734, Dec. 15, 1903.

The cold saccharine material is first mashed with sugar juice "at a temperature below that required to effect osmosis"; the mashed material is then subjected to the action of a "circulating body of hot sugar juice," having a density equal to or greater than the juice contained in the cellules of the material to be acted on, until its temperature reaches 77° C. The cell containing the heated material is then coupled up with the other cells of the battery in such a manner that it forms the last member of the series. The enriched heating juice is mixed with the weaker juices obtained from the battery, and the juice from the battery is passed through that cell of the series "which is, at the time, richest in sugar."—J. F. B.

Sugar Juice; Method of Continuous Carbonation of ——. L. Naudet, Paris. U.S. Pat. 746,735, Dec. 15, 1903.

A certain amount of sugar juice of definite alkalinity and a certain amount of carbon dioxide are introduced into a treating vessel, and the relative proportions of such introduced bodies are subsequently varied in accordance with the variations in the alkalinity of the carbonated juice flowing from the vessel, as determined by changes in the initially determined carbonation level.—J. F. B.

Sugar; Apparatus for Extracting ——. L. Naudet, Paris. U.S. Pat. 746,736, Dec. 15, 1903.

This specification relates to the apparatus, battery-cells connections, pumps and tanks, for working the process described in U.S. Pat. 746,734 (above); it includes a compensating vessel for mixing the juices to equalise the gravities.—J. F. B.

Sugar; Process of Purifying ——. C. A. Spreckels and C. A. Kern, New York, Assignors to Federal Sugar Refining Co., Jersey City. U.S. Pat. 716,891, Dec. 15, 1903.

French Patent.

Beet Chips and other Moist or Wet Substances; Mechanical Drying of ——. J. C. F. Lateulle. Fr. Pat. 334,411. Aug. 1, 1903.

The chips are dried by a current of heated air drawn through the apparatus. This consists of a casing and a cylindrical rotary strainer provided with short radial wings on its inner periphery. The chips are fed upon a wire cloth table, which may be travelling or fixed. If travelling, the wire table is placed in a horizontal position diametrically throughout the length of the cylinder, and is given an endless motion transversely to the axis. If fixed, the table is situated at an angle to the horizontal, so that the chips will run down it by gravity. In either case the chips are transferred from one side of the table to the other, and they are then given a slight forward motion by means of a screw. Arrived at the other side of the table the chips are caught by the radial wings of the rotary screen, and returned to the side whence they started, at a point nearer the discharge end.—J. F. B.

XVII.—BREWING, WINES, SPIRITS, Etc.

Yeast Crop; Determination of the ——, from the Nitrogenous Assimilation by the Yeast, and the Relation between Alcohol Production and Nitrogenous Assimilation. J. J. van Hest. Woch. f. Brau., 1904, **21**, [1]. 1—3.

The researches of Delbrück and Grimmer have shown that the loss of nitrogen sustained by the wort is a direct measure of the multiplication of the yeast. The author has confirmed this fact by comparing the results of nitrogen determinations before and after primary fermentation (six days) with those afforded by enumeration and filtration. On the large scale, the increase of the yeast cannot be determined by direct methods, owing to the impossibility of obtaining average samples of the yeast mixture. But if the nitrogen in the [filtered] wort be determined before and after primary fermentation, the yeast crop can be calculated. A litre of standard pitching yeast (see this Journal, 1904, 30) contains 7·541 grms. of nitrogen and about three billion cells. If a = the grms. of nitrogen abstracted from the wort per hectolitre, and if b = the grms. of nitrogen in the volume of standard pitching yeast sown per hectolitre, then the yeast crop [pitching yeast + increase] = $\frac{a + b}{7·541}$ litres of standard yeast per hectolitre. Two series of experiments are recorded, one series with yeast in good condition and another with yeast of poor quality. The average temperatures of fermentation were between 8·5° and 12·5° C.; determinations were made, after three days and after six days, of the alcohol produced and the nitrogen abstracted from the wort. The following are average values:—

——	Good Series.	Poor Series.
Attenuation after three days.........	2·4° Balling	2·5° Balling
" " six "	5·85° "	5·9° "
Assimilation of nitrogen in three days.	76 per cent. of total.	21 per cent. of total.
Yeast crop [standard] calculated from the nitrogen assimilated.	2·5 litres	1·9 litres
Increase calculated from the nitrogen assimilated.	5·3 times	3·5 times

It will be noticed that in spite of the great difference in the behaviour of the yeast as regards assimilation, the attenuations are practially the same in both series. In the good series, which may be regarded as representing normal fermentations, the production of alcohol varies inversely as the assimilation of nitrogen, thus:—

——	First Three Days.	Second Three Days.
Production of alcohol, per cent. of total	40	60
Assimilation of nitrogen, per cent. of total................................	76	24

Whilst the yeast is growing and multiplying, the production of alcohol is small, but when its biological work is nearing completion its physiological work becomes more active. Experiments on the effect of varying the proportion of pitching yeast showed that the yeast crop was unaffected even when the proportion of pitching yeast was doubled.
—J. F. B.

Pitching Yeast; Determination of the Number of Wild Yeast Cells in ——, by Drying with Calcium Chloride. C. Bergsten. Woch. f. Brau., 1904, **21**, [1], 8—9.

The following method is offered as an alternative to that proposed by Lindner (this Journal, 1903, 1018):—One grm. of yeast is carefully spread by a platinum needle, with aseptic precautions, on the bottom of a Petri dish. The yeast is then covered with freshly-ignited powdered calcium chloride and thoroughly mixed up by means of a sterilised pestle; the mixture is covered with a further layer of calcium chloride, closed up, and placed in the desiccator for half an hour. At the end of that time the mixture is dissolved in 100 c.c. of sterilised water, 1 c.c. of the solution is diluted with 9 c.c. of sterile wort, and 1 c.c. of this mixture, equal to 1 mgrm. of the yeast, is used for counting the number of wild yeast growths in drop-preparations or for infecting gelatin plate-cultures. If the operation has been properly performed, only wild yeast cells will have survived. Commenting on the above proposal, Lindner points out that it depends, like so many others (action of chemicals, high temperatures, &c.), upon the time of exposure. Different varieties of culture yeasts and wild yeasts will have different powers of resistance to the action of the calcium chloride. It would always be necessary, before applying the method, to determine the time of action suitable for the variety of pitching yeast under examination, and there must always be some varieties of wild yeasts which will succumb before all the culture yeast cells have been killed.—J. F. B.

Barleys Rich in Protein. Wielding. Woch. f. Brau., 1904, **21**, [1], 12—13.

Discussing the question of judging the protein content of a barley from its outward appearance, the author gives a table of analytical results and descriptions of outward appearance. From this table and from the author's experience, it would follow that the small-corned, plump barleys, with thin, finely-wrinkled husks, have the lowest amount of protein, and yield the highest proportions of extract; in such barleys the judgment of an expert buyer is not often at fault. But in the case of large-corned, elongated barleys with medium or coarse-fibred husks, it is shown that the amount of protein may vary between 9·81 and 15·67 per cent., and the expert maltster can rarely estimate it until he comes to malt the barley. With barley rich in protein, a satisfactory malt is only obtained by ensuring a long development both of rootlet and acrospire. Malting should only be attempted in cold weather, and the temperature in the couches should never exceed 20° C. The author has experienced difficulties in the malting of Saale and Thuringian barleys containing over 11 per cent. of protein, owing to their tendency to get hot. But with most foreign barleys no difficulties have been met with from this tendency, and a case is quoted of a Russian barley with 14·36 per cent. of protein which malted perfectly well, yielding a malt with 75·5 per cent. of extract on dry substance. On the other hand an Anatolian barley containing only 9·81 per cent. of protein yielded a malt with only 74·5 per cent. of extract. Differences like these may occur with barleys of the same origin, and are only to be attributed to qualitative differences in the nature of the protein, depending on soil and nutrition. The relations between the soluble and the insoluble proteids no doubt play a part in the behaviour of the barley, and they certainly affect the stability of the beer. Malts with a high protein content have the advantage over those poor in protein in that they favour the production of full-bodied beers with good "head"-retaining properties. The desire for barleys with low protein content may be pushed too far, and the fact that the effect of a high proportion of protein on the stability of the beer can be avoided by suitable malting is recognised by certain brewers for export, who buy barleys containing up to 12 per cent. of protein.—J. F. B.

Cider Making; Report on Investigations on ——. F. J. Lloyd. Board of Agriculture and Fisheries, 1903, 129 pp.; price 8*d*.

These investigations were made on behalf of the Bath and West and Southern Counties Society from 1893 to

1902. When the apples are ready, they should be cleansed or washed before crushing. The crushed pulp is called "pomace"; this is wrapped in cloths to form "cheeses," which are then pressed. The crushing and pressing apparatus have a great effect on the yield of juice; the improved English presses yield about 71·8 per cent. of juice from the apples. The Continental presses yield much less, but there the maceration of the pressed pulp with water is practised for a second yield of juice. The "pomace" should be pressed soon after crushing, since exposure to air darkens the colour. The only way by which the pressed "pomace," containing 18 per cent. of sugar, can be profitably utilised is by maceration with warm or cold water, equal to half the quantity of original juice, for 24 hours, the strength being made up with sugar to produce "small cider"; this, however, is inferior, and deficient in tannin. The juice is fermented by the yeasts present on the skins of the apples; the amount of sugar which should be present when the fermentation is checked depends on the kind of cider it is desired to make; the lees play no useful part in the production of quality. Filtration of the fresh juice being impracticable, it is clarified by running from the press into "keeves," which are upright tuns with loose covers. At a temperature of 50°—52° F. a "heady" fermentation is here conducted, which carries the suspended matter to the top in the form of a compact "head," which is skimmed off two or three times. Other portions of the suspended matter settle to the bottom, and when this violent fermentation has subsided, the partially clarified juice is carefully racked off into the fermentation casks; at this stage it contains less than 1 per cent. of absolute alcohol. During fermentation the bunghole of the cask should be closed by a "water-seal," whereby the evolution of gas can be observed; frequent hydrometer readings should also be taken. The speed of fermentation should preferably be slow, and if it shows a tendency to be too rapid, it must be checked by racking the cider off into fresh casks when necessary. The contents of the several casks having been brought to approximately the same stage simultaneously by judicious racking, the cider should be made up to a standard quality by blending, according to the results of chemical analysis. Any general departure from the standard strength will preferably have been corrected previous to fermentation by the addition of cane sugar or "small cider" to the juice in the fermentation casks. After blending, the cider should be racked once again before filtration. When the cider contains at least 4 per cent. of alcohol (*i.e.*, about 8 per cent. proof spirit), it is filtered clear and further alcoholic fermentation is checked. Tables are given by which the percentage of sugar and alcohol can be determined from the original and present gravities. From the filter, the cider is passed direct to the storage casks, which should lie on their sides, tightly bunged. After this stage all contact with air must be strictly avoided, and the cider should be drawn from the storage casks when required, only under a pressure of carbon dioxide. The future development of the industry undoubtedly lies in the direction of bottled cider. The bottles should be filled straight from the filter when the cider is perfectly clear; the gravity must not exceed 1·025, and the alcohol must amount to at least 4 per cent.; a slight sediment forms during the process of ripening. Three brands of cider should be manufactured: (*a*) "extra dry," which requires much care and skill, and is consequently expensive; this contains not more than 2 per cent. of sugar; (*b*) "dry," containing less than 4 per cent. of sugar; and (*c*) "sweet," containing more than 4 per cent. of sugar. The "dry" variety promises the greatest development and keeps well, provided acetification be prevented by rigid exclusion of air.—J. F. B.

FRENCH PATENT.

Yeast; Preservation of ——. The Granular Yeast Co., Ltd. Fr. Pat. 334,480, Aug. 7, 1903.

THE yeast is washed, if necessary, and then filter-pressed; the cakes are crumbled up and spread upon open-work trays, which are arranged on waggons. The waggons are placed in a drying chamber, through which dry filtered air, heated to a suitable temperature, is driven or aspirated.
—J. F. B.

XVIII.—FOODS; SANITATION; WATER PURIFICATION, & DISINFECTANTS.

(*A.*)—FOODS.

Milk; Preservation of ——, by Hydrogen Peroxide. A. Renard. Monit. Scient., 1904, **18**, [745], 39.

THE author first proposed, in 1898, the use of hydrogen peroxide for the preservation of milk. If an amount of hydrogen peroxide not exceeding 2 per cent. of a 12-volume solution be added to milk, it is completely decomposed into water and oxygen in from six to eight hours. With larger additions, the decomposition proceeds more slowly, and with 5 per cent. of a 12-volume solution, a small quantity remains undecomposed even after several days. The rate of decomposition of the hydrogen peroxide varies with different kinds of milk, but, within certain limits, *e.g.*, between + 5 and + 30° C., is not affected by change of temperature. Milk is not sterilised by treatment with a small quantity of hydrogen peroxide, but after such treatment, it can be kept for a much longer time than ordinary milk without undergoing alteration. For example, at 11° C., a sample of milk turned sour after 24 hours; milk with 1 per cent. of 12-volume hydrogen peroxide, after 80 hours; with 2 per cent., after 90 hours; and with 3 per cent., after 95 hours; at 20° C., the corresponding figures were 13, 24, 26, and 32 hours. It is best to add the hydrogen peroxide immediately after milking, and then allow the milk to stand in a cool place for 6—8 hours, till the hydrogen peroxide is completely decomposed; the taste and odour of the milk are not altered. Tests as to the use of milk which had been treated with 1·5 per cent. of 12-volume hydrogen peroxide, for feeding infants, are stated to have given satisfactory results.

Water and other Liquids; Apparatus for the Purification of —— [by Electrolysis]. W. B. Hardy. Eng. Pat. 25,041, Nov. 14, 1902. XI. A., page 67.

Production of Lime Water and the like; Processes and Devices for the ——, and for the Purification of Water. H. Reisert, Cologne, Germany. Eng. Pat. 967, Jan. 14, 1903.

THE water or other liquid is caused to pass intermittently, from below upwards, through the quicklime, &c., under such pressure as to raise the whole mass of the material under operation. During the intervals of rest between the periods of liquid supply, the water becomes saturated, and clarifies by the settling of the solid materials. The quicklime, &c., is preferably in the form of a powder, and may be supported on a layer of gravel or similar material. Lime water formed in this manner may be employed, in the same apparatus, for the purification of water.—R. A.

Viscose; Manufacture of Threads of ——. Soc. Franç. de la Viscose. Fr. Pat. 334,515, Aug. 8, 1903.

Soluble sulphides are removed from crude viscose by passing it through a solution of a salt of a metal which forms an insoluble sulphide, *e.g.*, a 10 per cent. solution of ferrous sulphate.—T. F. B.

Cellulose Xanthate; Purification of ——, *for the Preparation of Viscose.* Soc. Franc. de la Viscose. Fr. Pat. 334,636, Aug. 14, 1903.

Crude cellulose xanthate is completely coagulated by heating to 45°—50° C. (a process which only requires a few hours), and treated with some salt solution which will remove the impurities without rendering the viscose insoluble in caustic soda; solutions of sodium chloride, aluminium sulphate, alum, sodium bicarbonate, &c., are suitable. The purified viscose is finally dissolved in an alkali solution.—T. F. B.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

Solanin and Convallamarin; Sugar Components of ——. E. Votoček and R. Vondráček. Ber., 1903, **36**, [17], 4372—4373.

Referring to the note by Zeisel and Wittmann (this Journal, 1903, 1305), in which it is stated that the glucoside solanin contains another sugar besides glucose, the authors remark that they pointed out this fact a year ago. The same is also the case with the glucoside convallamarin. The products of hydrolysis of these two glucosides contain, besides *d*-glucose, a second hexose, which yields a methylphenylhydrazone melting at 187° C. It has now been found that, when this hydrazone is decomposed by benzaldehyde, *d* galactose is formed, and this sugar is therefore the second hexose in question. The melting point of galactose methylphenylhydrazone has been wrongly recorded by Lobry de Bruyn and A. van Eckenstein as 180° C.—J. F. B.

Cotarnine; Application of Grignard's Reaction to the Study of ——. M. Freund. XXIV., page 78.

Citronella Oil; Adulterated ——. E. J. Parry and C. T. Bennett. Chem. and Druggist, 1903, **63**, [1248], 1061.

A sample of a shipment of citronella oil recently imported was found by the authors to be adulterated with alcohol. The alcohol, which was present to the extent of 20 per cent., had probably been added to make an adulterated oil capable of passing the so-called Schimmel test. The oil had the following characters:—Sp. gr., 0·899; optical rotation, −12°; refractive index, 1·4578; geraniol content, 50 per cent.—A. S.

Citronella Oil; Determination of the Adulterant in ——. M. K. Bamber. XXIII., page 77.

Terpene; A New —— [*from Russian Terpentine*]. Zelinsky and Alexandroff. J. Russ. phys.-chem. Ges., **34**, 848.

The authors have isolated from Russian turpentine a pinene having the following characters:—Sp. gr., 0·8688; m. pt., 16° C.; b.p., 158·5°—159° C.; refractive index, 1·4700; optical rotation, −70° to −75°. It forms a hydrochloride melting at 121° C., but does not give a crystalline compound with nitrosyl chloride.—A. S.

Camphor Industry of Formosa; The ——. A. F. Collins. Scientif. American Suppl., 1903, **56**, [1455], 23,319.

Since the establishment of the monopoly by the Japanese Government, the old, crude methods have been replaced by more modern ones. The camphor wood is steamed in roughly-built furnaces and the camphor is condensed in cooled wooden vessels, and freed from most of the oil by draining, crude or "grade B" camphor being thus obtained. For the production of refined or "grade A" camphor, the crude material is heated in large iron retorts, through which a current of air is passed. For the first 48 hours, only sufficient heat is applied to drive off the water and oil. The retorts are then connected to a condensing chamber, the roof of which is cooled by running water, and are heated to a higher temperature in order to volatilise the camphor. The camphor obtained (flowers of camphor) is formed into blocks in wooden moulds and pressed first by steam power and finally by a very high hydraulic pressure. (See also this Journal, 1899, 799, 872; 1900, 482, 799, 945; 1901, 1261; 1902, 802; 1903, 892, 1032, 1317).—A. S.

Camphor; Artificial ——. A. F. Collins. Scientif. American, 1903, **89**, [21], 368.

The author gives a description of a process, which, it is stated, is being worked on a commercial scale at Port Chester, near New York, for the manufacture of camphor from oil of turpentine. By heating turpentine with anhydrous oxalic acid, two new compounds, pinyl oxalate and pinyl formate, are said to be formed, which, when subjected to steam distillation in the presence of alkali, yield camphor and borneol respectively. The mixture of turpentine and oxalic acid is heated in steam-jacketed tanks, and when the reaction is complete, the liquid mass is pumped into stills, alkali is added, and the mixture is distilled by the aid of live steam. From the distillate a mixture of camphor and borneol is recovered by fractional distillation. The crude product is filter-pressed, washed free from all traces of oil, and treated with an oxidising agent to convert the borneol into camphor. The crude camphor is centrifugalised and then purified by sublimation. The yield of camphor is stated to be from 25 to 30 per cent. of the weight of the turpentine. (See also Eng. Pat. 14,754 of 1900, and addition to Fr. Pat. 303,812; this Journal, 1901, 67; 1902, 1469; also 1901, 604.)—A. S.

Camphoric Acid and Dehydrocamphoric Acid; Synthesis of ——. G. Komppa. XXIV., page 78.

Vanillin; Oxidation of ——, *by the Oxidising Ferment of a Fungus or of Gum Arabic.* R. Lerat. J. Pharm. Chim., 1904, **19**, [1], 10—14.

On oxidising vanillin with a fungus extract or with gum arabic solution, dehydrovanillin was obtained, identical with that obtained by Tiemann by oxidising vanillin with ferric chloride (see this Journal, 1886, 252).—T. F. B.

—T. F. B.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Photographic Processes; Theory of —— G. Jaeger. Akad. Wiss. Wien. Sitz. Ber., 1902, **111**, 1132—1143.

According to the author, if a dilute developer be used and the time of development be not too long, the degree of blackening is proportional to the concentration of the developer; to the amount of "active" silver bromide, *i.e.*, silver bromide which by the action of the light has become capable of being reduced; and to the time of development. When the development is prolonged, the degree of blackening tends to become proportional to the square root of the amount of active silver bromide. The active silver bromide can be completely reduced only by the use of concentrated developers.—A. S.

English Patents.

Photographic Pictures in Natural Colours; Production of ——. J. Szczepanik, Vienna. Eng. Pat. 3196, Feb. 10, 1903.

Three monochrome ("three colour") diapositives are printed, without filters, on films of transparent material, coloured with the corresponding dyestuffs, which must be sensitive to light; the three monochrome prints are superposed in register and fastened together in the usual way; or the monochrome diapositive, *e.g.*, for red, is printed on a celluloid film coloured red, the remaining dyestuff is fixed and the film varnished, and a second film coloured yellow is applied, and printed on, in register, through the diapositive for yellow, and so on.—T. F. B.

Developing Photographic Pictures [with m-Amino-o-Hydroxybenzylsulphonic Acid]. H. E. Newton, London. From the Farbenfabr. vorm. F. Bayer & Co., Elberfeld. Eng. Pat. 3546, Feb. 14, 1903.

See U.S. Pat. 729,054 of 1903; this Journal, 1903, 881.

XXIII.—ANALYTICAL CHEMISTRY.

INORGANIC—QUANTITATIVE.

Chlorine, Bromine or Iodine in Organic Compounds; Rapid Method of Determining either ——, by means of Sodium Peroxide. H. H. Pringsheim. Ber., 1903, **36**, [17], 4244—4246.

The substance is mixed with 16—18 times its weight of sodium peroxide, according as the carbon and hydrogen it contains, amount to 50—75 or to over 75 per cent. of its weight. Substances poorer in carbon and hydrogen are mixed with sufficient sugar or naphthalene to bring up the percentage to above 50, and the mixture is then mixed with the sodium peroxide. The mixture is placed in a cylindrical flat-bottomed iron crucible, about 2·5 cm. in diameter and 3 cm. high, furnished with a flat lid through which a hole is drilled. The crucible is now set in a porcelain basin filled with water up to within 2 or 3 mm. of the upper edge of the crucible, and the mixture fired by pushing a glowing iron wire through the hole in the lid. After combustion the crucible is turned on its side in the water, the lid also immersed, the basin quickly covered with a clock-glass, and the whole warmed till no more bubbles of oxygen come off, and solution is practically complete. The crucible and lid are removed and rinsed, the liquid is filtered, and the filtrate poured into excess of sulphurous acid, so as to reduce any oxyhalogen compounds. To the liquid (now about 500 c.c.) nitric acid is added, and enough silver nitrate to precipitate the halogen; the whole is warmed for some time on the water-bath, the precipitate filtered off, washed, dried, and weighed. Accurate results have been obtained with a great variety of halogen compounds. This iron crucible method is also suitable for the determination of sulphur in organic compounds as described by von Konek. (Zeits. angew. Chem., **16**, 516; also this Journal, 1903, 381.)
—J. T. D.

Silver Cyanide and Silver Chloride; Separation and Determination of ——. R. H. A. Plimmer. Proc. Chem. Soc., 1903, **19**, [273], 285.

Freshly precipitated silver cyanide, although insoluble in cold dilute nitric acid, readily dissolves in the boiling acid, evolving the theoretical quantity of hydrogen cyanide, so that the gas, when passed into silver nitrate solution, produces an amount of silver cyanide equal in weight to the sample originally employed. In this way silver cyanide may be quantitatively separated from silver chloride. When the cyanide has been dried at 100° C., the hard lumps produced offer a greater resistance to the solvent, and if the boiling be prolonged, the acid, on becoming more concentrated, oxidises a small proportion of the hydrogen cyanide.

Arsenious Iodide; Determination of ——. W. Duncan. Pharm. J., 1904, **72**, [3402], 8.

The method proposed depends upon the titration, with iodine solution, of the arsenious oxide produced by the hydrolysis of arsenious iodide in alkaline solution. A weighed quantity of the arsenious iodide is dissolved in sodium or potassium bicarbonate solution, and the liquid titrated with N/10 iodine solution, 1 c.c. of which corresponds to 0·02261 grm. of arsenious iodide. The author states that the variable composition of commercial arsenious iodide is chiefly caused by undue exposure to light and moist air. The anhydrous salt crystallised from boiling carbon bisulphide, keeps fairly well, if protected from moisture. —A. S.

ORGANIC—QUANTITATIVE.

Hydroxyl Radicles; Determination of ——. H. Hibbert and J. J. Sudborough. Proc. Chem. Soc., 1903, **19**, [273], 285.

In attempting to determine hydroxyl groups by Tschugaeff's method (this Journal, 1902, 1859), the authors have not succeeded in obtaining satisfactory results, owing to the following causes:—(1) Moisture gradually penetrates through the india-rubber, even although this is coated with collodion. (2) The vapour pressure of ether varies so enormously with slight alterations of temperature. (3) Grignard's magnesium methyl iodide solution slowly absorbs atmospheric oxygen. The following method is free from the foregoing objections; dry amyl ether is used as the medium, instead of ordinary ether, and the operation is carried out in an ordinary bottle provided with a double-bored india-rubber stopper, so that the bottle may be attached to (1) a Lunge's nitrometer filled with dry mercury, (2) a glass tube provided with a stopcock, so that the air in the apparatus may be replaced by dry nitrogen. The amyl ether solution of the hydroxyl compound is placed in the bottle and a solution of Grignard's magnesium methyl iodide in the same solvent is introduced in a small tube; when a constant temperature has been attained, the two solutions are mixed. Satisfactory results have been obtained with α- and β-naphthols, resorcinol, o-nitrophenol, acetoxime, deoxybenzoin, and chloral hydrate. Quinol gives somewhat low results, probably owing to the fact that it is only sparingly soluble in amyl ether.

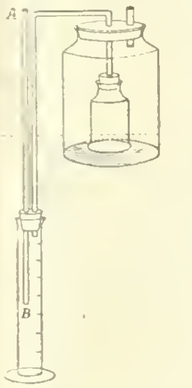
p-Nitrotoluene in Crude Nitrotoluene; Volumetric Method for the Determination of ——. B. Glasmann. Ber., 1903, **36**, [17], 4260—4261.

Ten c.c. of the oil are reduced by warming with 20 grms. of water, 20 grms. of iron filings, and 1 grm. of hydrochloric acid of sp. gr. 1·19 for six hours. 0·2 to 0·3 grm. of the resulting toluidine mixture is dissolved in 80 c.c. of ether and the p-toluidine precipitated with 25 c.c. of a 5 per cent. ethereal solution of oxalic acid. The precipitate of p-toluidine oxalate is washed with ether, dissolved in warm water, and titrated with N/10 sodium hydroxide solution, using phenolphthalein as indicator. —E. F.

Citric Acid; Determination of ——, *by the Lime Method.* O. v. Spindler. Chem.-Zeit., 1903, **27**, [103], 1263.

According to text-books, tricalcium citrate, when converted from the amorphous into the crystalline condition, becomes practically insoluble in water, and a method for the quantitative determination of citric acid has been based upon this statement. The author finds, however, that the precipitation of crystalline tricalcium citrate by boiling, even in concentrated solutions, and in presence of ammonium chloride, is not quantitative, and consequently the lime method for the determination of citric acid is quite unreliable, the amount of precipitate obtained being dependent upon the volume of the solution. Crystalline tricalcium citrate, $Ca_3(C_6H_5O_7)_2 + 4H_2O$, loses part of its water of crystallisation slowly even at 100° C. Tricalcium citrate obtained by neutralising citric acid with calcium hydroxide, always contains somewhat more calcium than the theoretical amount.—A. S.

Tannin Analysis; Improved Apparatus for ——. R. A. Earp. Leather Trades Rev., 1903, [921], 791.



The adjoining sketch illustrates a device for use in connection with the hide-powder filter which permits of any desired exact quantity of the detannised solution being collected automatically. The tube A B, open at both ends, is about 15 ins. long, according to the length of the siphon arm, and slides in the tightly fitting rubber stopper as shown, whilst the cork in the upper vessel fits loosely. To collect 30 c.c., the end B of this tube is adjusted to the level of the 30 c.c. mark in the graduated cylinder, and filtration is started by gentle suction at A. When 30 c.c. have come over, the tube A B simply fills up to the level of the liquid in the upper vessel, and filtration then stops. In a similar manner 50—55 c.c. (for evaporation) may be collected and stopped automatically by adjusting B to the corresponding mark on the cylinder. (See also Leather Trades J., Dec. 9. 1903, 860.)—R. L. J.

Hydroxylamine; Determination of ——. H. O. Jones and F. W. Carpenter. Proc. Camb. Phil. Soc., **12**, [3], 218.

According to the authors, the ordinary methods for the determination of hydroxylamine are inaccurate in presence of metallic salts and carbon dioxide. Reliable results can, however, be rapidly obtained by means of the method devised by Wood and Berry for the determination of reducing sugars (this Journal, 1903, 886). 10—20 c.c. of a solution of hydroxylamine or of one of its salts (containing not more than 0·5 per cent. of hydroxylamine) are run, with stirring, into 30 c.c. of a boiling Fehling solution, or a solution of copper carbonate in potassium bicarbonate. The mixture is heated to boiling, the cuprous oxide immediately filtered off, washed, dissolved in ferric sulphate solution in an atmosphere of carbon dioxide, and the ferrous sulphate produced titrated with permanganate solution. 4 mols. of potassium permanganate are equivalent to 10 mols. of hydroxylamine, the reduction of the copper proceeding according to the equation $2NH_2OH + 4CuO = N_2O + 2Cu_2O + 3H_2O$. Metallic salts, alcohol, and ketoximes do not interfere with the method.—A. S.

Citronella Oil; Determination of the Adulterant in ——. M. K. Bamber. Proc. Chem. Soc., 1903, **19**, [273], 292.

A mixture of 2 c.c. of pure cocoanut oil free from acid and 2 c.c. of the citronella oil under examination is shaken for one minute with 20 c.c. of 83 per cent. alcohol (sp. gr. 0·8273 at 30° C.) in the graduated tube (see figure), this vessel being then rotated in a centrifugal machine for 0·5 to 1·0 minute. The volume of cocoanut oil, which now contains the impurity originally present in the citronella oil, is ascertained, and this reading minus 2 c.c. represents the volume of the adulterant. For example, 2·45 c.c. of residual oil represent 0·45 c.c. of impurity in the 2 c.c. of citronella oil, or an adulteration of 22·5 per cent. A standard oil should be tested occasionally against the unknown samples in order to eliminate errors arising from the use of alcohol of different strengths. In this way, the adulterant is separated and estimated in three or four minutes, the test being conducted at 29°—30° C.

Caffeine and Theobromine [in Cocoa]; Determination of ——. J. Fromme. Apoth.-Zeit., **18**, 68. Pharm. J., 1903, **71**, [3401], 948.

The author finds that the best results are obtained by Welman's method (this Journal, 1902, 1476). He recommends, however, that the cocoa be boiled with water acidulated with sulphuric acid (3 grms. of dilute acid to 200 grms. of water) in order to convert the starch into sugar, and that, after boiling with magnesia in the usual manner and filtering, an aliquot part of the filtrate be taken, so as to avoid the tedious washing of the powder.—A. S.

XXIV.—SCIENTIFIC & TECHNICAL NOTES.

Stannimethane; Preparation of the Tetra-alkyl Derivatives of ——. W. J. Pope and S. J. Peachey. Proc. Chem. Soc., **19**, [273], 290.

Tetraethylstannimethane, $Sn(C_2H_5)_4$, is prepared by adding stannic chloride (1 mol.), dissolved in light petroleum, to the ethereal solution of magnesium ethyl bromide (4·5 mols.), washing with dilute acetic acid, and distilling the ethereal solution; it boils at 180°—181° C. under 758 mm. pressure.

Dimethyldiethylstannimethane, $Sn(CH_3)_2(C_2H_5)_2$, may be prepared either by the action of magnesium methyl iodide on diethylstannimethylene chloride, bromide, or iodide, or by that of magnesium ethyl bromide on dimethylstannimethylene chloride, bromide, or iodide in ethereal solution. After treating with water and distilling the ethereal solution, the substance is obtained as a colourless liquid identical with that prepared by Frankland's method.

Trimethylethylstannimethane, $Sn(CH_3)_3C_2H_5$, is obtained by treating trimethylstannimethyl bromide or iodide with the calculated quantity of magnesium ethyl bromide in ethereal solution, washing with dilute acetic acid, and fractionally distilling the ethereal solution; it boils at 107°—108° under 758 mm. pressure.

Trimethylpropylstannimethane is similarly prepared by the action of magnesium propyl bromide or iodide on trimethylstannimethyl bromide, and forms a colourless liquid boiling at 129° C. under 761 mm. pressure. Triethylpropylstannimethane, $Sn(C_2H_5)_3C_3H_7$, from triethylstannimethyl bromide, boils at 195° under 764 mm. pressure.

Dimethylethylpropylstannimethane—

$$Sn(CH_3)_2(C_2H_5)(C_3H_7),$$

prepared by the action of propyl magnesium bromide or iodide on dimethylethylstannimethyl bromide, boils at 153° under 762 mm. pressure.

Methylethyldipropylstannimethane, obtained from methylethylstannimethylene iodide and magnesium propyl bromide, is a colourless liquid boiling at 183°—184° C. under 758 mm. pressure.

Tetraphenylstannimethane, $Sn(C_6H_5)_4$, is conveniently prepared by the action of stannic chloride on magnesium phenyl bromide.

Saccharose; Combination of ——, with Metallic Salts. D. Gauthier. Comptes rend., 1903, **137**, [26], 1259—1261.

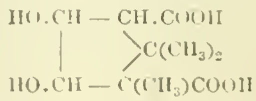
Saccharose forms compounds with potassium iodide, lithium chloride, bromide, and iodide, of the formula $C_{12}H_{22}O_{11}.MR.2H_2O$, with calcium bromide and iodide, of the formula $C_{12}H_{22}O_{11}.CaR_2.3H_2O$, with strontium chloride and bromide of similar formula, and with barium chloride, bromide, and iodide of formula $2C_{12}H_{22}O_{11}.BaR_2$. The characters of these compounds are now being studied.
—J. T. D.

Cotarnine; Application of Grignard's Reaction to the Study of ——. M. Freund. Ber., 1903, **36**, [17], 4357—4259.

Whilst hydrocotarnine is a very stable body, certain of its substitution derivatives, such as cyanohydrocotarnine and ethoxyhydrocotarnine, are very readily converted by dilute hydrochloric acid into cotarnine hydrochloride and hydrocyanic acid and alcohol respectively. Narcotine, which is a substitution derivative of hydrocotarnine of the same type (the α-position), is stable towards hydrochloric acid, and it is probable that bases generally, which are derived from hydrocotarnine by the substitution of a hydrocarbon radical in that position, are also unaffected by hydrogen ions. Such bases can easily be prepared by Grignard's reaction, and the author has obtained α-methylhydrocotarnine by the action of magnesium-methyl iodide. This base is a thick fluid sparingly soluble in water and readily soluble in ether, and several crystalline salts of it are described.—J. F. B.

Camphoric Acid and Dehydrocamphoric Acid; Synthesis of ——. G. Komppa. Ber., 1903, **36**, [17], 4332-4335.

Diketo-apocamphoric ester, obtained by condensing oxalic ester with β-β-dimethylglutaric ester (Ber., 1901, 2472), on methylation, gave a methyl derivative, which, on reduction with sodium amalgam, gave dihydroxycamphoric acid—



$$\begin{array}{l} HO.CH - CH.COOH \\ \quad | \qquad\qquad \rangle C(CH_3)_2 \\ HO.CH - C(CH_3)COOH \end{array}$$

On heating this latter with hydriodic acid and amorphous phosphorus, a dehydrocamphoric acid was obtained, which combined with hydrobromic acid to a bromocamphoric acid; this, on reduction with zinc dust and glacial acetic acid, gave an oily product, consisting of a mixture of *cis*- and *trans*-camphoric acids. The *cis*-acid was converted into its anhydride by means of acetyl chloride, the *trans*-acid, which remains unchanged, being removed by washing with sodium hydroxide solution. The camphoric anhydride thus obtained proved to be identical with the natural product; the identity was further established by conversion into the acid, which was identical with *i*-camphoric acid. This synthesis conclusively establishes Bredt's formula for camphor, since camphoric anhydride can be converted into camphor (see this Journal, 1896, 372).—T. F. B.

Prizes.

Alcohol, Denaturing; Prize for the Best Method of ——.

Bd. of Trade J, *Jan.* 7, 1904.

With regard to the prize of 50,000 roubles (5,300*l.*) offered by the Russian Ministry of Finance for the discovery of the best method of denaturing alcohol (this Journal, 1903, 1109), an Official Notice (in French) issued by the Russian Ministry of Finance with regard to this competition may be seen on application at the Commercial Intelligence Branch of the Board of Trade, 50, Parliament Street, S.W.

New Book.

Rubber, Gutta-percha, and Balata. By Franz Clouth. English Translation, with Additions and Emendations by the Author. Maclaren and Sons, 37 and 38, Shoe Lane, E.C. London, 1903. Price 12*s.* 6*d.* net. D. van Nostrand Company, Murray and Vesey Streets, New York, U.S.A.

8vo volume containing prefaces to English and German editions, table of contents, list of botanical illustrations, and text, filling 212 pages. These pages are illustrated with 30 engravings and a map. The treatment of the subject may be gathered from the following abstract of the contents:—Indiarubber: I. Historical. II Natural History. Indiarubber Plants. Climatic Conditions. Cultivation. III. Production of Raw Rubber. IV. Commercial Points. V. Chemical and Physical Properties of Raw Rubber. VI. Production of Soft Rubber Goods. VII. Vulcanisation. VIII. Chemical and Physical Properties of Vulcanised Soft Rubber. IX. Hard Rubber ("Ebonite."). X. Regenerated and Artificial Rubber. Gutta-percha: I. Historical. II. Natural History. Gutta Plants, &c. Climatic Conditions. Cultivation. III. Production of Raw Gutta-percha.

IV. Commercial Points. V. Chemical and Physical Properties. VI. Production and Employment of Gutta-percha Goods. BALATA: Historical. Geographical Distribution. Methods of Production. Commercial Points. Characteristics. Physical and Chemical Properties. Employment of Balata Goods. Survey of the Principal Products made of India-rubber, Gutta-percha, and Balata.

Trade Report.

I.—GENERAL.

FOREIGN TRADE OF THE UNITED KINGDOM IN 1903.

Bd. of Trade J., Jan. 14, 1904.

The following table shows the foreign trade of Great Britain in certain articles during 1903, with corresponding figures for 1901 and 1902:—

Article.	Imports.			Exports.		
	1901.	1902.	1903.	1901.	1902.	1903.
	£	£	£	£	£	£
Coal, coke and patent fuel	22,223	4,101	3,987	30,334,748	27,581,136	27,262,779
Iron ore, scrap iron and steel	4,672,336	5,091,972	4,888,702	284,944	336,763	455,220
Other metallic ores	5,709,062	5,414,737	5,924,657	55,074	68,469	134,844
Oil-seeds, nuts, oils, fats, and gums	23,208,132	25,234,400	24,163,925	2,815,043	3,132,895	2,976,743
Hides and undressed skins	8,001,576	8,019,045	7,382,588	330,361	375,931	1,279,331
Materials for paper-making	3,453,306	3,386,773	3,430,997	382,670	379,037	409,647
Chemicals, drugs, dyes and colours	9,060,580	9,026,584	8,846,688	10,963,497	11,559,057	12,079,554
Earthenware and glass	4,528,499	4,678,473	4,780,700	3,049,952	2,997,529	3,278,797
Paper	4,342,234	4,537,674	4,843,682	1,668,577	1,672,704	1,797,861

WEIGHTS; NEW BRITISH STANDARD OF ——.

U.S. Cons. Reps., No. 1836, *Dec.* 28, 1903.

The Board of Trade, under a special Order in Council, will sanction the use of a weight of 50 lb., in addition to the present standards of 112 lb. and 56 lb. The 50 lb. is by this action made a legal standard of weight.

II.—FUEL, GAS, AND LIGHT.

CARBON; RETORT ——: U.S. CUSTOMS DECISION.

Dec. 17, 1903.

The residuum of carbon which accumulates on the inner side of gas retorts when the gas is made from bituminous coal was held by the Board of General Appraisers to be dutiable at 20 per cent. *ad valorem,* under paragraph 415 of the present Tariff Act. An analysis showed the substance to contain 92·66 per cent of fixed carbon, and it was assessed for duty under paragraph 97 at 25 per cent. *ad valorem,* as an "article composed of carbon." The Board held that it was similar to coke and reversed the action of the Customs authorities.—R. W. M.

VII.—ACIDS, ALKALIS, Etc.

AMMONIUM SULPHATE STATISTICS.

Bradbury and Hirsch, Jan. 1904.

The estimated production of ammonia calculated into sulphate (including that used in the ammonia-soda and other chemical processes) from all sources in the United Kingdom, during 1903, is shown in the following table, together with the corresponding figures for the three preceding years:—

——	1900.	1901.	1902.	1903.
	Tons.	Tons.	Tons.	Tons.
Gas works	142,000	143,000	150,000	152,000
Iron	17,000	16,500	18,500	18,000
Shale	37,000	40,000	37,000	37,500
Coke and carbonizing works and producer gas.	17,000	18,000	23,500	26,500
	213,000	217,500	229,000	234,000

Of the total production in 1903, England contributed 154,500 tons; Scotland, 77,000 tons; Ireland, 2,500 tons.

NITRATE OF SODA STATISTICS.

W. Montgomery & Co., Dec. 31, 1903. *Shipments, Consumption, Stocks, and Prices from* 1901 *to* 1903.

——	1901.	1902.	1903.
	Tons.	Tons.	Tons.
Shipments from South American Ports to all parts for the six months ended 31st December	683,000	765,000	874,000
Shipments from South American Ports for the 12 months ended 31st December	1,238,000	1,360,000	1,424,000
Afloat for Europe on 31st December	374,000	374,000	478,000
Stocks in United Kingdom ports:—	25,000	26,000	23,000
Stocks in Continental ports on 31st December	218,000	237,000	132,000
Consumption in United Kingdom for the six months ended 31st December	35,000	35,000	33,000
Consumption on Continent for the six months ended 31st December	229,000	249,000	263,000
Consumption in United Kingdom for the 12 months ended 31st December	118,000	111,000	110,000
Consumption on Continent for the 12 months ended 31st December	1,036,000	917,000	1,017,000
Consumption in United States for the 12 months ended 31st December	192,000	214,000	265,000
Consumption in other Countries for the 12 months ended 31st December	18,000	17,000	20,000
Consumption of the World for the 12 months ended 31st December	1,364,000	1,259,000	1,412,000
Visible supply on 31st December (including the quantity afloat for Europe and Stocks in United Kingdom and Continent)	617,000	660,000	633,000
Price on 31st December per Cwt.	*9s. 6d.*	*9s. 1½d.*	*9s. 7½d.*

COAL TAR AND AMMONIA PRODUCTION OF THE UNITED STATES IN 1902.

U.S. Geological Survey; through Chem. Trade J., Jan. 9, 1904.

In 1898 the 433 companies from which returns were received produced about 4,023,000 galls. of tar and 7,152,600 lb. of ammonium sulphate. The figures are approximations, although believed to be fairly accurate, and are estimated on a basis of 10 galls. of tar and 20 lb. of ammonium sulphate to the ton of coal carbonised. Including the output of tar and ammonium sulphate from retort-oven coke plants in 1898, the total production in that year (reducing the ammonia liquor reported to its equivalent in sulphate) was as follows:—ammonium sulphate, 31,102,296 lb.; tar, 28,407,798 galls. In 1902, the production of ammonia, reduced to its equivalent in sulphate, was 68,248,686 lb., and the production of tar 53,171,733 galls., an increase of more than 100 per cent. in the case of sulphate and of nearly that percentage in the case of tar. The aggregate value of all the products obtained from the distillation of coal in gas works or retort ovens in 1902 was 43,869,440 dols. About two-thirds of this amount, or 29,342,881 dols., was represented by the value of the gas produced. The value of the coke produced was 11,267,608, while the tar was worth, at the works, 1,873,966 dols. Most of the ammonia produced was sold in the form of ammoniacal liquor, which varied widely in the strength of the solution. This strength of solution ranged from 1·72 to 35·83 oz. of of ammonia per gallon. The total quantity of ammoniacal liquor sold was 49,490,609 galls., containing 14,683,374 lb. of ammonia, and was worth, at the works, 1,065,300 dols. In addition to this, there was an actual production of 11,276,502 lb. of sulphate, which sold for 319,685 dols.

The total production of tar from gasworks and bye-product ovens in 1902 amounted to 53,171,733 galls., valued at 1,873,966 dols., or 3·524 cents per gallon. In 1898, the production from gasworks alone was 24,384,798 galls., worth 902,400 dols., or 3·7 cents per gallon. The price in 1902 varied from 2·7 cents in Alabama to 10 cents in Oregon. The lowest price reported in 1898 was 2·23 cents in Indiana, and the highest price was 10·17 cents in Montana and New Mexico. From this it will be seen that, on the whole, the value of the tar produced has not changed materially since 1898.

The largest production of tar in 1902 was in Massachusetts, with New York second, Ohio third, and Pennsylvania fourth. In 1898, New York held first place, with Pennsylvania, Ohio, and Massachusetts following in the order named.

Of the 533 companies from which reports were received in 1902, there were only 106 which reported the recovery of ammonia, either in the form of ammoniacal liquor or as sulphate. These 106 companies reported a total production of 49,490,609 galls. of ammonical liquor, which sold for 1,065,300 dols., and 11,276,502 lb. of sulphate, which sold for 319,685 dols., a total value for the ammonia sold of 1,384,985 dols. The total quantity of coal carbonised or coked at the works operated by the companies in 1902 was 4,077,478 short tons. The companies which produced ammoniacal liquor used 3,436,312 tons of coal, and 641,166 tons were carbonised by the companies selling their ammonia as sulphate. From this it appears that the average yield per short ton of coal carbonised was 14·4 galls. of liquor and 17·6 lb. of sulphate.

In the report on this subject covering the year 1898, the total amount of ammoniacal liquor sold by 70 establishments from which returns were received was reported at 25,749,792 galls., which sold for 248,148 dols. This production, reduced to its equivalent in ammonium sulphate, is estimated to have been 23,949,696 lb. The sulphate equivalent of the 49,490,609 galls. of liquor sold in 1902 was 56,972,184 lb., which, added to the 11,276,503 lb. of sulphate separately reported, would be equal to a total production of 68,248,686 lb. of sulphate in 1902. Comparatively little progress in the manufacture of chemical products from coal tar has been made in the United States. Although over 50,000,000 galls. of coal tar are produced annually, the principal uses made thereof are in the manufacture of roofing paper, the creosoting of lumber, and for the preparation of street-paving material. The coal tar produced in 1902 was worth, at first hand, 1,873,966 dols. In the fiscal year ended June 30, 1902, the coal-tar products imported into the United States were worth, at points of shipment, 7,494,340 dols. The duty paid on these imports amounted to 1,594,799 dols., making the total cost, exclusive of freight, other expenses, and jobbers' profits, 9,089,139 dols. In the fiscal year ended June 30, 1903, the value of these imports was 7,690,895 dols.; duty, 1,692,145 dols.; total, 9,383,333 dols. A conservative estimate would place the total value of these products in the wholesale markets of this country at 12,000,000 dols., in both 1902 and 1903. The following figures show the value of the coal-tar products imported into the United States in the fiscal year 1903:—Salicylic acid, 19,012 dols.; colours or dyes, natural and artificial, 660,464 dols.; aniline salts, 789,553 dols.; coal-tar colours or dyes not specially provided for, 5,252,611 dols.; coal-tar preparations, not colours or dyes, 544,176 dols.; coal-tar products, not medicinal and not dyes (benzol, toluol, &c.), 425,019 dols.; total, 7,690,885 dols.

SULPHUR PRODUCTION OF SICILY IN 1902.

Eng. and Mining J., Dec. 24, 12, 1903.

The official returns of sulphur mining in Sicily in 1902, which have just been published, show that the production was 510,332 metric tons, as compared with 537,615 tons in 1901. At the close of the year there were 1,119 mines, of which 750 were actively operated, or 16 less than in the previous year. The number of labourers employed in the mines was 32,045, and in the refining works 5,744. The statistics show that the decline in the quantity of sulphur obtained from kilns (*calcaroni*), which has been noted in previous years, continued in 1902, and there was a corresponding increase in the output of the works employing other methods of extraction.

PHOSPHATE DEPOSITS IN SOUTH AUSTRALIA.

Bd. of Trade J., Dec. 31, 1903.

The *Queensland Government Mining Journal* states that another deposit of phosphate has been found on Yorke Peninsula, South Australia. The Government geologist of the State reports that it is similar in mode of occurrence to the deposits of Clinton, Bright, and Belvidere. Trenches have been made in two principal places, at a distance of about 100 yards apart, which have exposed boulders and lumps of phosphate rock, associated with argilaceous, arenaceous, and calcareous beds.

Samples taken from the workings showed on analysis tricalcic phosphate, 82·95 per cent., 74·8 per cent., 72·36 per cent., and 70·07 per cent. At the north end of the section samples, consisting of basic phosphate of alumina, with limestones, clay, &c., on analysis returned from 13 to 22·4 per cent. of phosphoric acid. The Cambrian limestone is exposed in several detached areas over this and the adjoining hundreds as far south as Curramulka, and it is in the vicinity of these outcrops that phosphate rock deposits are most likely to be found.

X.—*METALLURGY.*

MINING INDUSTRY OF BELGIUM IN 1902.

Eng. and Mining J., Dec. 24, 1903.

The output of the principal minerals other than coal in 1902 is shown below, the values being converted into English currency on the basis of 25 fr. to 1*l.*:—

——	Metric Tons.	Value.
		£
Barytes	33,000	9,220
Iron ore	156,580	27,190
Lead ore	164	514
Manganese ore	14,440	7,092
Marble	15,490	101,700
Phosphatic chalk	*315,200	56,584
Phosphate rock	135,850	59,568
Slate	37,120	53,666
Zinc ore	3,852	7,621

* Cubic metres.

As compared with the production in the previous year, the table shows a marked falling off in the output of iron and zinc ores and a slight gain in slate, manganese ore, and barytes.

The output of coal in 1902 showed an increase of 664,060 tons, or 3 per cent., but it was still about 600,000 tons less than the total recorded in 1900. The mines of the Liège basin contributed the greater part of the increment. The number of mines in operation was 119, giving employment to 134,889 workmen. The output was :—

——	Metric Tons.	Value.
		£
Coal	2,877,470	12,081,116
Coke	22,048,070	1,182,312

The production of spelter amounted to 124,780 tons, showing a decrease of 2,390 tons, or 3 per cent., as compared with 1901. There were nine sheet-zinc works in operation, and the output was 37,070 tons. The production of lead was 73,357 tons, against 61,900 tons in the previous year.

COBALT-NICKEL ARSENIDES AND SILVER IN ONTARIO.

W. G. Miller. Eng. and Mining J., 1903, 76, [24], 888.

Deposits of cobalt-nickel-arsenic and silver ores have been recently discovered in the northern part of Ontario, five miles south of Haileybury, a village on the Ontario side of the northern part of Lake Temiscaming. Four veins have been located, of which three are rich in native silver. In vein No. 1, the ore consists chiefly of niccolite ($NiAs$) and smaltite ($CoAs_2$), together with chloanthite ($NiAs_2$), dyscrasite (antimonial silver), and much native silver. In vein No. 2, the ore is chiefly smaltite and niccolite; no silver has been detected. The ore in vein No. 3 is similar to that in vein No. 1. Vein No. 4 is very clearly defined, but is considerably decomposed. Weathered specimens of the ore were found to be rich in native silver and also to contain cobalt bloom. The unaltered ore probably consisted of smaltite and niccolite, in addition to the silver. It is probable that the Haileybury deposits can be worked profitably for cobalt, nickel, arsenic, and silver, but the proportion of nickel does not appear to be sufficient to interfere materially with the lower-grade but larger deposits at Sudbury.—A. S.

XIII. C.—INDIA-RUBBER, Etc.

RUBBER INDUSTRY OF BRAZIL.

U.S. Cons. Reps., Dec. 1903.

The rubber crop of 1901–2 was the largest ever produced —29,998 tons. That of the season just closed was 29,890 tons, a decrease of only 108 tons. Of last season's crop, Europe took 15,261 tons, and the United States 14,566 tons, an increase in shipments to the United States over the previous year of 510 tons, while the shipments to Europe fell off correspondingly.

The product was shipped as follows :—

From	To Europe.	To United States.
	Lb.	Lb.
Manaos	16,619,381	18,425,657
Para	13,422,609	13,686,142
Iquitos	3,578,739	..
Serpa	22,583	..
Total	33,643,312	32,111,799

The stock on hand on June 30th was 129 tons. During the past year prices ruled fairly firm, at good figures. The exceedingly high prices which prevailed formerly may never be restored, but producers as well as dealers find there is still a very handsome profit for them, once they have accommodated themselves to the new and more healthy conditions.

XVI.—SUGAR, STARCH, Etc.

MOLASSES : ENTRY OF ——, INTO CANADA.

Bd. of Trade J., Jan. 7, 1904.

A Customs Memorandum (No. 1,254 B) relates to the duty payable on molasses imported into the Dominion of Canada, which is as follows :—"In view of the frequent importations of molasses found to contain an admixture of glucose, it is ordered that ¾ cent. per lb. duty be collected on molasses entered at Customs in Canada, and claimed to test not less than 35° pending test by polariscope at the Customs Department at Ottawa—subject, however, to refund of duty if the molasses be subsequently found entitled to entry under Tariff item 441. In the case, however, of molasses imported direct to a Canadian port from the West Indies or Guiana, the collector may allow delivery on payment of duty under Tariff item 441, upon importers undertaking to amend the entry when so required, if the Collector deems it advisable to do so after examination of the importation." The text of Tariff item No. 441 referred to is as follows :—Molasses produced in the process of the manufacture of cane sugar from the juice of the cane without any admixture with any other ingredient, when imported in the original package in which it was placed at the point of production, and not afterwards subjected to any process of treating or mixing, the package in which imported, when of wood, to be free :—(*a*) Testing by the polariscope, 40° or over, 1¾ cents per gall. (*b*) When testing by the polariscope less than 40° and not less than 35°, 1¾ cents per gall., with an additional duty of 1 cent per gall. for each degree or fraction of a degree less than 40°.

XVII.—BREWING, WINES, SPIRITS, Etc.

METHYLATED SPIRITS ; NEW CUSTOMS REGULATIONS RESPECTING ——, IN ORANGE RIVER COLONY.

Bd. of Trade J., Jan. 7, 1904.

The following is a copy of a Government Notice (No. 687 of 1903), issued at Bloemfontein on the 24th Nov. 1903 :—

"Be it hereby made known to all whom it may concern, under and by virtue of Article XVIII. of the Customs Union Convention and Article 18 of Law 34 of 1903, that His Excellency the Governor has been pleased to make the following Additional Customs Regulation, *viz.* :—

"Article 35.—Methylated spirits or alcohol imported from oversea solely for manufacturing or scientific purposes within the borders of this Colony shall be classified under Clause V. of the Customs Union Tariff, and be liable to the general *ad valorem* rate of 10 per cent., subject to the provisions of Article III. of the Customs Union Convention, provided :

"That such spirit or alcohol be imported under a certificate signed by the Collector of Customs or his representative, setting forth that such spirit or alcohol will be used exclusively for the purposes above specified ; and that on arrival of the spirit at its destination a sample will be submitted to the Collector of Customs for the purpose of being tested or that such spirit or alcohol be imported into this Colony under bond in terms of Article 11 of Law 34 of 1903, and Articles 12 to 24 of the Customs Regulations."

XX.—FINE CHEMICALS, Etc.

ALCOHOLIC TOILET ARTICLE : U.S. CUSTOMS DECISION.

Dec. 1903.

A preparation marked "Langbein's Eau de Quinine" or "Langbein's Chinawasser" was decided by the Board of General Appraisers to be dutiable at 60 cents per lb. and 45 per cent. *ad valorem* as an "alcoholic toilet preparation," under paragraph 2 of the present tariff. The importer claimed it to be dutiable as an "alcoholic medicinal preparation," under paragraph 67, at 55 cents per lb. Following a previous decision, the Board overruled this claim and decided as above.—R. W. M.

Patent List.

N.B.—In these lists, [A.] means "Application for Patent," and [C.S.], "Complete Specification Accepted."

Where a Complete Specification accompanies an Application, an asterisk is affixed. The dates given are (i) in the case of Applications for Patents, the dates of application, and (ii) in the case of Complete Specifications Accepted, those of the Official Journals in which acceptances of the Complete Specifications are advertised.

Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

Notices.

ANNUAL GENERAL MEETING, NEW YORK, 1904.

The Annual General Meeting will be held in New York City on Thursday, Sept. 8th, and following days. Members who contemplate attending are requested to communicate with the General Secretary as soon as possible, in order that suitable travelling arrangements may be made. A programme appears in the Jan. 30 issue of the Journal.

COMMUNICATIONS.

Authors of communications read before the Society, or any of its Local Sections, are requested to take notice that under Rule 43 of the Bye-laws the Society has the right of priority of publication for three months of all such papers. Infringement of this Bye-law renders papers liable to be rejected by the Publication Committee, or ordered to be abstracted for the Journal, in which case no reprints can be furnished to the author.

Changes of Address.

When notifying new addresses, members are requested to write them distinctly, and state whether they are temporary or permanent. Multiplication of addresses is also to be avoided as tending to create confusion. When sending subscriptions, the use of the form attached to the application helps in the verification of addresses, on which the safe delivery of the Journal depends.

Alexander, W. T.; all communications to Crummock, Eccles, Lancs.

Bamford, Harry, l/o Farcliffe Place; 70, Duckworth Terrace, Bradford.

Barnett, Robt. E., (Journals) 9, Virginia Road, and (communications) Leeds Technical College, Cookridge Street, Leeds.

Baur, Jacob, l/o Illinois Street; 67, Wells Street, Chicago, Ill., U.S.A.

Boyd, Pythagoras, l/o 6; 17, Union Street, North Adams, Mass., U.S.A.

Brearley, Harry, l/o Sheffield; Salamander Stahlwerke, Jaegel, Riga, Russia.

Chem. Centralblatt, l/o Leipzig; Dr. A. Hesse, Sigismundstr. 4, Berlin, W., 10.

Clarke, R. W.; Journals to Clinical Research Association, Ltd., 1, Southwark Street, S.E.

Cohn, Sigmund, l/o Frankfort Street; 13, Dutch Street, New York City, U.S.A.

Collingridge, Frank, l/o Barnet; 4, Wyndham Road, Edgbaston, Birmingham.

Cownley, A. J.; all communications to 225, Barry Road, Dulwich, S.E.

Dvorkovitz, Dr. P.; all communications to 26, Bevis Marks, London, E.C.

Elmore, A. Stanley; all communications to 4, Broad Street Place, E.C.

Fahrig, Dr. Ernst, l/o South 4th Street; 3642, York Road, Philadelphia, Pa., U.S.A.

Francis, W. H.; Journals to Cleveland, Thornton Road, Clapham Park, S.W.

Grandage, H., l/o Bradford; c/o Flax Pilp, Ltd., 25, Billiter Street, E.C.

Guest, Hon. Lionel G.; all communications to 205, St. James Street, Montreal, Canada.

Harrison, Wm. H.; all communications to 29, Avenue Crescent, Harehill's Lane, Leeds.

Hatfield, Jno. A., l/o Wednesbury; c/o Messrs. J. Lysaght, Ltd., Orb Iron Works, Newport, Mon.

Hawkins, Henry, l/o Oakland; American Powder Mills, 233, State Street, Boston, Mass., U.S.A.

Henshaw, Sam, l/o Tunstall; Glenthorn, Wolstanton, Stoke-on-Trent.

Hicks, Edwin F., l/o Pittsburg; 94, Hamilton Place, New York City, U.S.A.

Hurry, E. H., l/o Bethlehem; Room 122, 1, Broadway, New York City, U.S.A.

Johnson, Jesse F., l/o Beloeil; 58, Metcalfe Street, Montreal, Canada.

Joslin, Omar T.; Journals to 3223, Springrove Avenue, Cincinnati, Ohio, U.S.A.

Kelsey, Jas. W., l/o Blackill; c/o Pharmacie Swann, 12, Rue Castiglione, Paris.

Kingdon, Holman, l/o 9; 27, Grappenhall Road, Stockton Heath, Warrington.

Labonde, Dr. Leon, l/o Rochester; 172, South Main Street, Albion, Orleans Co., N.Y., U.S.A.

Langmuir, F. Leighton, l/o Toronto; Beau Séjour, Freiburg i/B., Germany.

Lewis, Fred. H., l/o Craigsville; Fordwick, Va., U.S.A.

Lomas, T.; all communications to 5, Esmond (*not* Osmond) Gardens, Bedford Park, W.

Luxmoore, Dr. C. M., l/o Reading College; University College, Reading.

McMaster, Daniel, l/o London; c/o Oxford Paper Co., Rumford Falls, Maine, U.S.A.

Mann, Harold H., l/o York; Indian Tea Association, Royal Exchange Building, Calcutta, India.

Mann, Jas. S., l/o Barking Road; 97, Greengate Street, Plaistow, E.

Mannhardt, Hans, l/o State Street; 1641, Melrose Street, Chicago, Ill., U.S.A.

Masury, Fred. L. M., l/o New York City; Sharon, Pa., U.S.A.

Mende, A. P., l/o West 14th Street; 120, Liberty Street, New York City, U.S.A.

Merritt, Wm. G., l/o Canton Avenue; 643, Second Avenue, Detroit, Mich., U.S.A.

Munton, Fred. T., l/o Winsford; Beaconsfield, Western Road, Runcorn, Cheshire.

Nash, A. Douglas, l/o Corona; 221, Broadway, Flushing, N.Y., U.S.A.

Page, Ralph H., l/o Detroit; retain Journals.

Pough, Francis H., l/o Brooklyn; c/o T. & S. C. White Co., 28, Burling Slip, New York City, U.S.A.

Riley, Fred., l/o India Street; 43, Grampian Way, Savin Hill, Boston, Mass., U.S.A.

Robertshaw, C. D., l/o W. Hampstead; c/o Chas. Price and Co., Oilworks, Belvedere, Kent.

Rogerson, J. W., l/o Orpington; 5, Ashley Gardens, London, S.W.

Sanderson, Jno., l/o Belsize Park; c/o B. S. Cohen, Ltd., 15, Clerkenwell Close, E.C.

Sayer, Harry, l/o Loftus; 82, Victoria Street, London, S.W.

Sharwood, W. J., l/o Montana; 2119, Durant Avenue, Berkeley, Cal., U.S.A.

Shearer, Arthur, l/o Manchester; 43, Derby Road, Burton-on-Trent.

Shepherd, A. B., l/o Leeds; c/o British Oil and Cake Mills, Ltd., 151, Cleveland Street, Hull.

Smith, F. Gurney, l/o Brook Green; 19, Queen Street, Perth (temporary).

Stead, J. Christopher, l/o Leytonstone; 1, Finsbury Circus, E.C., Technical Chemist.

Turnbull, G. W., l/o The Haws; 2, Haws Hill, Carnforth, Lancs.

Van Zwaluwenburg, Jas. G., l/o Box 69; 607, East Ruby Avenue, Argentine, Kas., U.S.A.

Warden, Jno. B., l/o Glasgow; P.O. Box 701, Deadwood, S. Dak., U.S.A.

Wilkins, A. D., l/o Allegheny; P.O. Box 34, Elizabeth, Pa., U.S.A.

Williams, Walter S.; all communications to Arnold Print Works, North Adams, Mass., U.S.A.

Wrampelmeier, T. J., 1/o Wilmington, Del.; E.I. du Pont de Nemours Powder Co., 39, Victoria Street, Westminster, S.W.

ERRATUM.

The announcement of the death of Mr. Jas. Johnstone, of Rutherglen (this J., Jan. 30, p. 50), happily turns out to be unfounded. The gentleman who died was not a member of this Society.

Canadian Section.

Meeting held in McGill College, December 22nd, 1903.

PROF. W. R. LANG IN THE CHAIR.

Dr. G. P. Girdwood (Vice-Chairman) read an interesting paper on Chemical Education, after which a discussion on the subject took place, the speakers being Mr. Thomas Macfarlane, Dominion Analyst, Ottawa, Prof. Walker, Lieut.-Col. Burland, and the Chairman. The Chairman also addressed the meeting, tracing the formation of the Section and explaining the objects of the Society.

Manchester Section.

Meeting held on Friday, January 8th, 1904.

MR. J. CARTER BELL IN THE CHAIR.

PREPARATION AND COMPRESSION OF PURE GASES FOR EXPERIMENTAL WORK.

BY R. S. HUTTON AND J. E. PETAVEL.

Introduction.—Having been engaged for some time past on experimental research dealing with the effect of high gaseous pressures upon electric furnace reactions, the necessity arose of preparing, compressing, and storing several gases which were either not available commercially, or which could not thus be obtained in the desired state of purity. Although a very great deal of information had been published relating to the production of the various gases in sufficient quantities for ordinary laboratory experiments, such methods cannot be easily applied when the required scale of working is considerably larger. On the other hand, the commercial manufacture in some cases has been most carefully worked out, but the plant required is too large and costly to be practical for temporary use. The object of the present paper is to describe how, with little more than such apparatus as should be available in any chemical laboratory, the preparation of a number of gases can be carried out at a trifling cost and with due consideration as to their purity. It will be noticed that the equipment is so devised as to be available for use in the different cases with but little modification. Those who look for any novelty in the principles of the methods adopted will, we fear, be disappointed; we venture, however, to think that to the increasing number of workers, who either for commercial or scientific purposes require, like ourselves, pure gases in considerable quantities, the information which we offer will be of some value. The apparatus has been devised for gas generation and purification at a rate of about 1 litre per second (130 cb. ft. per hour). Hydrogen, nitrogen, carbon monoxide, and ethylene are dealt with in detail. Apart from the information which we have been able to obtain by direct experiment, references are given to several of the more important published accounts dealing with the manufacture on the full commercial scale. For some chemical purposes, the gases would be passed straight from the generator for use in the chemical process for which they were required; on the other hand, it is frequently necessary for convenience to store the gas for subsequent use; in fact, where the experiments are at all general in character, it is advisable to have a stock of different gases constantly available. This involves the erection of compressing and storing plant even where high pressure *per se* does not play a part in the work. Our account, therefore, includes a description of a small plant which we have found satisfactory for these purposes.

Hydrogen: Commercial Manufacture and Applications.—Hydrogen is at present principally employed for inflating military balloons, autogenous welding, and lead-burning (Zeits. f. Elektrochem., 1895, 2, 204), and is manufactured in considerable quantities for these purposes. The older and purely chemical methods of generation based on the action of acids or steam on metals are being to a large extent displaced, where a continuous supply is required, by electrolytic processes, the working cost of the latter being considerably lower. Suitable electrolytic cells can now be installed at a reasonable expense. The plant for the chemical manufacture by the action of acids on metals is of two principal types. The first, a development of the ordinary laboratory "Kipp," will be described later. The second type is designed to give for a limited time a very

large quantity of gas, and in principle consists in employing a tall cylindrical receiver filled with metal turnings or granulated metal, the outflow of gas being regulated by the amount of acid which is allowed to flow into the top of the cylinder, the spent acid being run off at the bottom. This latter method is of the two, by far the more important for large-scale working, such as for inflating balloons. In this case some 10,000 cb. ft. of gas may be required to fill a single balloon, an operation which has to be effected within a short space of time. The process has also been employed for many years at the Royal Institution for the manufacture of hydrogen in connection with the liquefaction experiments, and at a more recent date by Morris W. Travers at University College, London (Phil. Mag., 1901, [6], **1**, 411). A plant on these lines has been recently constructed by Messrs. Lennox, Benton, and Reynolds, Ltd., capable of delivering some 800 cb. ft. of hydrogen per hour. The receiver is a copper cylinder about 6 ft. high and 1 foot diameter, and contains a charge of 4 cwts. of granulated zinc. As will be seen by the diagram, Fig. 1, the actual generator is mounted in the centre between two washing towers, each 8 ft. high. The three cylindrical towers, which are open at the bottom, are supported in a cast-iron tank, which forms a water seal and collects the spent acid. The towers are surmounted by two superimposed tanks, the lower one containing a lead coil immersed in water to act as cooling chamber, the upper one, lead-lined, acting as acid reservoir. A spray of water keeps the flints in the two washing towers moist. The rate of flow of the acid is observed through a sight feed. An apparatus of a similar type, the design of Ch. Renard, has been adopted by the French army for field use. The employment of zinc has, however, the serious disadvantage that the gas often contains sufficient arsenic to be dangerous if dealt with in any quantity.* Moreover, the gas generated by the action of acids on ordinary spelter or metallic iron is liable to be considerably more dense than pure hydrogen. (W. Dürer, Zeits. f. Elektrochem., 1901, **8**, 2.) Of other chemical processes, the heating of zinc-dust and soda-lime briquettes is employed in the German army in a portable equipment for balloon inflation, whilst the reaction between heated iron and steam has recently been applied by the Industrial Engineering Co., who regenerate the iron with producer-gas, and have thus brought this method into a convenient and practical form. The electrolytic manufacture of hydrogen is coming much to the front; in this case, whereas the first cost is relatively high, the working expenses, whenever the plant can be run continuously, are generally lower than for the chemical method. Numerous types of plant have been designed, the principal requirements being a low working voltage and the effectual separation of the hydrogen and oxygen; the latter, particularly where the gases have to be compressed, being of the utmost importance from the point of view of safety. The electrolytic methods will be found described in monographs by Victor Engelhardt and P. Schoop [V. Engelhardt, Die Elektrolyse des Wassers (Halle: W. Knapp, 1902); P. Schoop, Die Industrielle Elektrolyse des Wassers (Stuttgart: F. Enke, 1901)]; suffice it to say that in principle they can be grouped under three types:—

(1) The Schmidt and Ch. Renard systems employ iron electrodes in alkaline solution, the electrodes being separated by diaphragms of asbestos.

(2) The Schoop system, in which each cylindrical electrode is surrounded by tubular diaphragms, has the advantage of absolute safety from any danger of admixture of the gases, but involves some loss of power through additional resistance. In this case lead electrodes are employed in an acid electrolyte.

(3) The Garuti, Siemens Bros., and Schuckert plants employ metallic diaphragms and generally work with alkaline electrolytes.

At the present time almost all the European military authorities have adopted one or other of these electrolytic plants for balloon purposes, but in Germany the Government makes use largely of the waste hydrogen evolved in the electrolytic alkali industry, an example which will, no doubt, be widely followed in the future, when it is considered that, even at a moderate estimate, some 240,000 cb. ft. of hydrogen are going to waste daily in this way (*cf.* Zeits. f. Elektrochem., 1895, **2**, 290). At least three large installations (Buffa, Bull. de l'Assoc. des Ing. Electr. (Liège), 1900, **11**, 305), those at Brussels, Lucerne, and Rome, exist on the continent for putting on the market compressed hydrogen obtained by the Garuti process, a notable economy resulting from the fact that the oxygen, which is also compressed, finds a still more ready sale. A complete consideration of the question of cost would carry us too far, but full details will be found in the monographs referred to. Suffice it to say that, with spelter at 21*l.* a ton, a cost of at least some 35*s.* is incurred in zinc alone per 1,000 cb. ft. of hydrogen obtained, whereas by several of the electrolytic processes the same amount of hydrogen can be obtained for 157 kilowatt hours, which, even at 1*d.* per unit, a high estimate for power generation when used continuously, only amounts to 13*s.* 1*d.* It should be borne in mind that the oxygen produced simultaneously is also of considerable commercial value. Thus where an uninterrupted supply of gas is required throughout the entire year the electrolytic methods offer considerable advantages. Owing, however, to the much smaller capital outlay, the older chemical process is preferable when the hydrogen is required occasionally only, but in large quantities. Several years ago Dewar showed, as a lecture experiment, how coal-gas could be freed from methane and other hydrocarbons by cooling it to a sufficiently low temperature. Recently d'Arsonval (Ann. Chim. et Phys., 1902, [7], **26**, 446) has proposed this as a method of obtaining hydrogen; the process has, however, not yet proved of any commercial value.

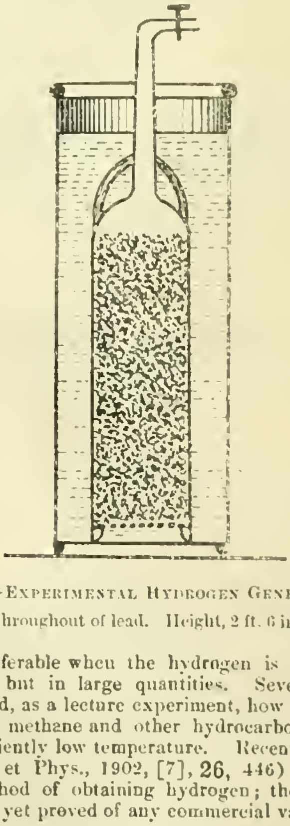

FIG. 2.—EXPERIMENTAL HYDROGEN GENERATOR.

Constructed throughout of lead. Height, 2 ft. 6 ins.; diam., 1 ft.

Experimental Plant.—In considering the type of apparatus suitable for experimental work, it must be borne in mind that the plant should be capable of producing gas at a comparatively high rate, at least for a limited number of hours. As will be more fully explained in describing the compressing plant, it is advisable to make the gas in sufficient quantities to supply the pump at its normal rate of working, which in our case was 100 to 130 cb. ft. per hour Under all conditions where the cost of a large capacity gasometer is not prohibitive, it would doubtless be mor

---

* Numerous attempts have been made to remove the arsenic from the gas, amongst which passage through a heated tube or a solution of a permanganate should be mentioned. Recently Ch. Renard has carried out some experiments on the use of liquid air for condensing the arseniuretted hydrogen in connection with the aeronautical department of the French army. It is found that cooling to −110° C. is essential for complete elimination of the arsenic. (C. R., 1903, **136**, 1317.)

convenient to generate the gas slowly and continuously, and then compress it, whenever the gasometer was filled. With such an arrangement it would have been more convenient even in the laboratory to use the electrolytic process. Preliminary experiments made in this direction showed that a satisfactory electrolytic cell could be easily and cheaply fitted up. This was effected by lining the sides of an ordinary stoneware mixing-pan with sheet lead, and using as a cathode a spiral coil of lead tube, covered with an inverted bell jar. From the top of this the gas is drawn off. To equip a plant to make gas at the rate mentioned above was, however, too costly for a temporary outfit. The preparation from Brunner-Mond zinc and 20 per cent. arsenic-free sulphuric acid was therefore resorted to, spelter of this quality being found to give gas of high purity. Sufficiently finely granulated zinc can be obtained by pouring the molten metal into water from a height of about three feet. Three lead generators were used of the ordinary type employed for lead-burning as shown in Fig. 2. These were arranged in parallel, and so connected that, whilst two were in actual use, the third was cut off, to allow the gas to displace the partially spent acid, after which it was reconnected and one of the others turned off. By working in this manner, the required rate of generation could be maintained. The gas was found to need no purification, but was led, through two towers containing solid caustic soda, direct to the gasometer and compressor. Analysis proved the purity to be 99·8 per cent. hydrogen.

Nitrogen: Commercial Manufacture and Applications.—Already at the present time nitrogen is coming into use in several of the cyanide processes, an application which will doubtless increase largely so soon as a satisfactory and economical method of generation has been devised. For, despite the apparent simplicity of the process, no very economical method of effecting the separation from the oxygen of the air is available. The older method of passing air over heated iron or copper is chiefly employed technically. In those cases where a large supply of nitrogen is needed, it would be advisable to carefully consider the employment of the waste gases from gas engines and sulphuric acid plants, which are available in quantity and contain a much reduced percentage of oxygen. It must also be borne in mind that similar gases are passed to waste in the course of manufacture of oxygen by Brin's process; whilst, provided any of the proposed methods of extraction of oxygen from liquid air by fractional distillation become of permanent commercial value, they will prove of direct assistance for the problem under consideration. As will be seen below, pure nitrogen can be prepared at moderate cost by an adaptation of the Harcourt method (Lupton, Chem. News, 1876, **33**, 90; R. Marston, Eng. Pat. 19,074 of 1900), consisting in burning out the oxygen of the air by the hydrogen contained in ammonia. Finally, the laboratory process of generation from ammonium nitrite (K. T. Fischer and H. Alt, Ann. der Phys., 1902, [4], **9**, 1149; von Knorre, Chem. Ind., 1902, **25**, 531 and 550) is out of question for large scale working, owing to the prohibitive cost of material. At the recent International Chemical Congress, R. Knietsch (Chem.-Zeit., 1903, [48], 586) proposed passing air and excess of hydrogen over warmed platinised asbestos; and at the same meeting a few details were given of the process of Messrs. Elkan, of Berlin, who supply the compressed gas in cylinders.

Experimental Plant.—From preliminary trials the Harcourt method seemed to be the only one which could be fitted up in a limited space with ordinary apparatus and suitable to produce gas at a moderate cost. The plant is shown in Fig. 3. An iron gas-pipe about 5 feet long and 2 inches internal diameter was filled with copper turnings, connections being made at one end for the introduction of air, supplied by a blower, and of the required quantity of ammonia liquor; at the other end to condensing, washing, and drying plant, and through these to the compressor. The method works without the slightest difficulty provided that the rate of admission of air and ammonia is properly regulated. From the preliminary experiments it was found that unless the ammonia is always in considerable excess of that required theoretically, oxides of nitrogen are produced

which cannot easily be removed. When gas containing such impurities is compressed serious corrosion of the valves and cylinders of the pump occurs. On the other hand, if the excess of ammonia is not removed, similar difficulties are met with. The method of working actually adopted was to admit approximately twice the theoretical amount of ammonia, and by passing a fairly rapid current of water through the washer J, such part of the ammonia as was not condensed in H was efficiently removed, the last traces of ammonia being held back by the sulphuric acid in L. To regulate the quantity of ammonia necessary, a rate gauge A was inserted in the air-supply pipe. This gauge was of a very simple construction, and consisted of a constriction in the supply tube, each side of the constriction being connected to one limb of a U-tube containing water, the difference in heights of which indicated the rate of flow of the gas. The instrument is calibrated, once for all, by taking observations with an ordinary gas meter or gasometer. The scale of the readings depends, of course, simply on the size of the constriction. As an example, one of these gauges, having a constriction of about ⅛-inch bore, gave about 40 cms. difference of level for a rate of 60 cb. ft. per hour. Knowing in this way the rate of flow of the air, the admission of ammonia liquor was regulated by means of the graduated tube so as to supply about twice the theoretical amount. The method by which this was performed will be quite clear from the diagram. The gas obtained was entirely free from oxygen and oxides of nitrogen, but contained about 4 per cent. hydrogen. This could, of course, be easily eliminated by passing through an additional tube of heated copper oxide, but for most purposes the presence of hydrogen would be of no disadvantage. For the guidance of any one employing the method in this form, we might state that in one operation some 200 cb. ft. were compressed, about 9 litres of 0·880 ammonia being passed through the apparatus; the flow of gas was regulated from time to time so as to supply the pump continuously at its normal rate of working. The cost of the ammonia for 1,000 cb. ft. of nitrogen would be about 17s. 6d., or half this amount if the excess of ammonia is efficiently recovered.

Carbon Monoxide: Experimental Plant.—For most chemical processes pure carbon monoxide is rarely required, some form of producer- or water-gas being generally employed. Where, however, the pure gas is a necessity, the manufacture of formates by the recent synthetical Goldschmidt process renders it possible to obtain it at a reasonable cost and in an extremely simple manner. The actual apparatus used is shown in diagram (Fig. 4), and consists of a bolt head E (9 litres) half filled with sulphuric acid (sp. gr. 1·73). The heating was performed, either by an electric resistance furnace as represented, or by an ordinary gas furnace; the former is preferable, when working with combustible gases, where electric current is available. An electric furnace of the kind can be built up temporarily at trifling cost. The outer walls are constructed of loose firebricks; the electrodes consist of two flat pieces of boiler plate, the space between which is filled with ground coke. An electric current passing through the coke heats this up to any desired temperature. In the present case the iron plates were each 11 ins. square, the distance between them being 14 ins.; the layer of coke G, about 40 lb., being 7 ins. deep. This gave a resistance when cold of 13 ohms and about 1·5 ohms when heated up to the working temperature. When generating gas at full rate, over 4 k.w. are required to maintain the temperature. The reservoir B contains a supply of technical 90 per cent. formic acid, from which the carbon monoxide is generated. This reservoir is kept slightly above atmospheric pressure by being connected to a supply of compressed air, thus enabling the acid to be easily forced over. The formic acid is delivered below the surface of the boiling sulphuric acid in the bolt head, the flow being regulated by the cock *d*. The temperature, which, when the formic acid is added, of course tends to fall, is maintained throughout the run at about 150° to 170° C. In this way, with a limited amount of sulphuric acid the process can be run continuously. The gas is purified in the apparatus shown in Fig. 3, the only modification being that the bottle L is in this case filled with 20 per cent. caustic soda solution, and a similar solution is also allowed to drip into the quartz tower K (Fig. 3), from the supply bottle H (Fig. 4). Nearly the full theoretical yield of gas is obtained, about 133 lb. of 90 per cent. formic acid being required per 1,000 cb. ft., costing 50s. The purity of the gas thus prepared was over 99 per cent.

Ethylene: Experimental Plant.—Up to recent years ethylene has been used in considerable quantities in connection with the production of liquid air; the apparatus which we have already described for carbon monoxide can, without modification, be employed for this preparation. There is not, however, the same latitude with regard to temperature and rate of production as in the former case. It is essential that the sulphuric acid should be kept between 160° and 165° C., since, even at a few degrees above this, carbonisation commences, accompanied by production of sulphurous acid and carbon monoxide; at a temperature below 160° C. the yield falls very rapidly, almost all the alcohol being transformed into ether. The sulphuric acid used in the bolt-head should be of such dilution as to boil at 160° C. Methylated spirit is admitted through a perforated lead tube (see Fig. 4). At first scarcely any ethylene is evolved, but as part of the water in the acid becomes displaced by the alcohol, the temperature being kept constant, the rate of production gradually increases, and, after about half an hour, becomes fairly steady. A constant evolution of gas can be maintained under these conditions for any length of time, but the flow of gas is only about one-tenth of what the same sized apparatus would produce in the case of carbon monoxide. The yield obtained was not much more than half the theoretical. An addition of ferrous sulphate to the sulphuric acid has been proposed by R. N. Lennox as ensuring against carbonisation and evolution of sulphurous acid. This addition seems to be a considerable improvement on the original process. The acid mixture is made with concentrated sulphuric acid (sp. gr. 1·84) and sufficient saturated ferrous sulphate solution to bring the boiling point down to 160° C.

Another method proposed by Newth (G. S. Newth, J. Chem. Soc., 1901, **79**, 915), which consists in employing syrupy phosphoric acid in place of sulphuric acid, was tried in the same apparatus. The temperature should be kept between 200° and 220° C.; there is no carbonisation, but a considerable amount of ether is collected. The yield in this case was even lower than with the sulphuric acid method, but the process can be worked quite continuously, and the quantity of phosphoric acid required is not large.

Notes on Various other Gases.—The foregoing pages deal with the preparation of such gases as cannot easily be obtained commercially. With regard to many other gases similar methods could of course be adopted, but producing them on the scale with which we have been dealing would hardly repay the trouble involved, in those cases where they are already on the market. Further, for such gases as sulphurous acid, chlorine, and ammonia, a special pump would be necessary; and even before oxygen could be compressed, much time would have to be spent in carefully removing all traces of organic matter from the pump cylinders, connections, and gauges.

Oxygen, nitrous oxide, carbonic acid, sulphurous acid, and ammonia can readily be obtained from the various companies in this country who make a speciality of their manufacture. Where a compressed gas is not required, oxygen in a similar way to acetylene can be produced by the action of water on one of its solid compounds. A French company has recently put on the market a mixture of sodium peroxide and bleaching powder, under the name of "Oxylith," which yields oxygen of satisfactory purity. The cost of the gas produced by this method (5*s*. 9*d*. per 20 cb. ft.) would, however, be prohibitive where a large quantity is required. So far as acetylene is concerned, it will be recalled that, as a result of the exhaustive investigations which followed on numerous and disastrous accidents, Berthelot and Vieille showed that it is highly dangerous to compress this gas above four atmospheres. The gas, however, can now be stored in cylinders, filled with some porous material saturated with acetone, this liquid absorbing about 24 times its own volume of gas per atmosphere pressure (A. Janet, Génie Civil, 1903, **43**, 180). In Germany (O. N. Witt, Die Chemische Industrie des deutschen Reiches im Beginne des 20 Jahrhunderts, pp. 100—105) considerable use has been made in recent years of liquid chlorine, which is produced by several companies, and notably by the Badische Anilin Company, and can be obtained retail (*e.g.*, Kahlbaum, Berlin) for 1*s*. 6*d*. per lb. in bombs of 20 lb. or over. Methyl chloride (2*s*. per lb., Douane, Paris), phosgene (Kahlbaum, 6*s*. per lb.), and ethyl chloride (2*s*. per lb.) can all be obtained commercially, and find uses particularly in the colour industries and for refrigeration.

Compression and Storage of Gases.—The portion of the subject which we have to deal with now is of rather a special nature. Much of the information given below will be well known to those few who have been connected with commercial gas-compression plants; but now that pumps can be obtained at a moderate cost and of sufficiently simple construction to give no trouble for continuous working, there is no reason why the great convenience of storing gas in the compressed state should not be more generally made use of. For work of this kind, the smallest convenient plant comprises:—

(1) A compressor capable of dealing with 60 to 130 cb. ft per hour, and of working up to 120 or 200 atmospheres.

(2) A small gas-holder (10 to 20 cb. ft. capacity), which is used, not to store the gas, but to act as an equaliser between the pump and generating apparatus. It being assumed that, wherever possible, the gas is made and pumped at the same rate.

(3) A stock of weldless steel gas cylinders.

As a general guidance with regard to cost, the price of the compressor may range from 60*l*. to 100*l*., and the gasometer from 10*l*. to 20*l*. For most purposes it is convenient not to exceed the commercial pressure of 120 atmospheres. For this pressure, gas cylinders, ready fitted with valves, can be obtained at about 1*s*. per cubic foot of gas stored, when purchased in small quantities; or at half this price when bought on a larger scale. For higher pressures, the cylinders have to be made to order, and are correspondingly more expensive. Another 10*l*. to 20*l*. should be allowed for the purchase of two or three pressure-gauges, a dozen cone connections, eight or ten high-pressure valves, and the capillary copper tubing which serves to conduct the gas from the compressor into the receivers. Weldless copper tubing of $\frac{1}{8}$ in. bore and $\frac{1}{4}$ in. external diameter is both strong and large enough for this purpose, and can be readily obtained from any copper tube manufacturers. This size has the further advantage, when annealed, of being quite flexible, and can thus be bent, whenever used, to the most convenient shape. The ends of each length of such tubing are soldered into brass or gunmetal cones, as shown in Fig. 5. These are screwed to the cylinder or pump valves by a nut which surrounds them. In a plant of this kind it is advisable to keep to a standard size, "half-inch gas" being most convenient for this purpose.

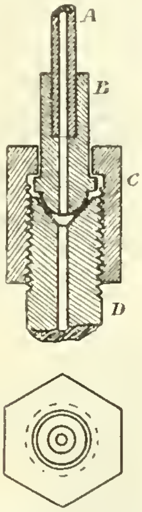

Fig. 5.—Cone Connections.

A. Flexible copper tubing. B. Cone.
C. Nut by which cone is pressed home: Screwed "½-in. gas."
D. Standard connection forming part of cylinders, valves, or compressor.

An ordinary air-pump is, of course, not suitable for dealing with combustible gases. The cylinders of the compressor should be entirely closed, the piston-rods passing through properly made stuffing-boxes. The smaller compressors are usually of the tandem two-stage type, the low-pressure cylinder compressing to about 7 atmospheres, the gas being then passed through a cooling coil into the high-pressure cylinder, which forces it up to the full pressure. The high-pressure cylinder delivers its gas, through another copper coil immersed in a cooling tank, into a small gas cylinder, which serves to separate the water used to lubricate the pump. At the bottom of this separator is a valve for withdrawing the water. If the pump is required to suck in its supply of gas under a partial vacuum, the low-pressure inlet valve should be arranged so as to be mechanically lifted at the top of each stroke. The water for lubricating the cylinders is fed through a sight feed, and for a compressor of the size we are dealing with, a single drop per two or three revolutions is an ample supply. The clearances should, in both cylinders, be about $\frac{1}{32}$ in., or at any rate not exceed $\frac{1}{16}$ in., in order that, at the highest working pressures, the pump may deliver its full volume, and not merely compress and expand the same gas.

The following precautions are of the highest importance from the point of view of safe and satisfactory performance:—

(1) The greatest care must be taken never to allow much more than the above-mentioned quantity of lubricating water to enter, as with such small clearances this water

carried into the high-pressure cylinder would be unable to pass through the narrow outlet valve and would burst the cover or bend the crank shaft.

(2) If the apparatus is to be used for air, or more especially for oxygen, it is of vital importance that no oil should be employed, either in the pump cylinders or in any of the valves, connections, or gauges. Many disastrous explosions have resulted from the neglect of these precautions. The water may, however, if desired, be replaced for lubrication by glycerine, which forms an excellent substitute for oil for this purpose.

(3) Each time before running the pump, it is advisable to turn it through one or two revolutions by hand to ensure that it is working freely. If the gas to be pumped is combustible, before connecting to the gas-holder the pump should be run for a minute or two with the inlet cock closed, and the end of the delivery pipe placed under water. In this case, if the stuffing boxes and connections are satisfactorily tight, the pump will be running under a vacuum and should deliver absolutely no gas.

(4) The purity of any combustible gas must of course be properly ascertained, as any admixture with air would lead to serious explosions.

(5) It is very advisable to adopt the excellent system, employed by all the gas-compressing companies, of distinguishing between combustible and non-combustible gases, by invariably storing the former in cylinders characterised by a bright red colour, and fitted with left-handed connections. Even where this is done it is advisable before connecting a partially filled cylinder with the pump to test its contents at a flame.

(6) All storage cylinders, connections, and other apparatus, with the exception of gauges, should be occasionally tested hydraulically to double the maximum working pressure.

T, T^1. Connecting and piston rods.

So far as the actual compressing is concerned, a clear idea will be obtained from the diagrammatic sketch (Fig. 6). The gas passes from the purifying apparatus shown in Fig. 3 to the gasometer A (Fig. 6), from which the two-stage compressor, driven by an electric motor, forces it into the water separator F. At its exit from this separator the gas is sufficiently dry for almost any purpose for which it may be required, since the percentage of aqueous vapour in a gas at 100 atmospheres is only 1/100 of its amount at ordinary pressure. When the gas is being made at the normal rate the valve *k* is kept open, the valve *m* closed, and the gas passed directly into a storage cylinder such as L or K, or, in the case of our own work, direct into the pressure furnace M. These were situated in the room on the next floor of the building to the compressor. A high pressure connection is also led direct to a duplicate gauge g_4, by which the pump pressure can be independently read. When necessary the gas can be blown off from the valves *q* on the upper floor, or *o* on the lower; *o* being connected to a pipe leading outside the building, for use with poisonous gases such as carbon monoxide. If, for any reason, the supply of gas fall below the normal rate, the valves *m* and *l* are partially opened, *n* being kept closed; a part of the gas delivered by the pump then returns to the gasometer, and is compressed again, thus avoiding the necessity of either stopping the pump or working it under a partial vacuum. When dealing with gases which can only be conveniently prepared at a very slow rate, it is of course necessary to give up any idea of continuous pumping. In these cases the gasometer is allowed to fill slowly; the pump is then started, and stopped a few minutes afterwards, so soon as all the gas has been pumped. The storage cylinder is thus filled step by step up to any desired pressure. It is not possible to restart the pump against a high pressure; the gas contained in the water separator F must therefore be blown off, and since, at a high pressure, the volume thus returned to so small a gasometer would take up a large part of its capacity, it is preferable to employ an auxiliary cylinder G, which takes the major part of the contents of F, the residue only being returned to the gasometer by the valves *k*, *m*, and *l*. The contents of G can be returned to the gasometer and pumped during the course of the next run through the valves *n* and *l*, *m* being kept closed. This last method of working is of course somewhat complicated, but has proved very useful in a few cases where it was practically impossible to produce the gas at the normal rate. For those purposes where it is required to study some chemical reaction or to purify a gas when under high pressure, a gas cylinder with a removable cover is employed. The ordinary cone joint as shown in Fig. 5 works satisfactorily to close the

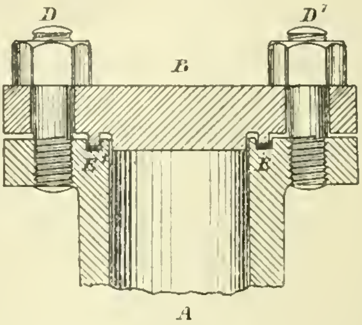

FIG. 7.—SPIGOT JOINT.

A. Cylinder containing solid reagent to dry or purify a gas under pressure, or react with it.
B. Cover.
D. and D^1. Bolts.
E. Spigot and spigot groove (about $\frac{1}{8}$ in. wide for 2-in. bore, rising to $\frac{1}{4}$ or $\frac{5}{16}$ in. for sizes up to 1 ft.).

The central part of the cover projects beyond the spigot, and is turned to nearly fit the bore of the cylinder. This acts as a guide when putting on the cover, and protects the spigot itself from injury when the cover is off.

opening of any tube up to one-inch bore. Above this size it is necessary to resort to some form of spigot joint, such as is shown in Fig. 7. One or two turns of lead wire about the same diameter as the groove are inserted in it, the ends of the lead being bevelled so as to overlap each other. The cover is then forced home by means of the bolts provided for the purpose, and, crushing the lead outwards and upwards, forms a gas-tight joint. When making such a joint for the first time, exceptional care must be taken that the nuts are pulled down evenly, as otherwise the cover may be strained or, being out of truth, the joint will not be gas-tight. When the cover has once been fitted correctly it can be removed and replaced some hundred times before it is necessary to add fresh lead packing. We have used joints of this kind up to a foot diameter, which have always worked satisfactorily. Above this diameter the weight of the cover and the size of bolts required become somewhat unmanageable when designed for pressures of 100 or 200 atmospheres.

Discussion.

Mr. **Wm. Thomson**: Mr. Hutton had stated that hydrogen prepared from zinc direct cost 35*s.* per 1000 cb. ft., and by the electrolytic method it cost 15*s.* He also referred to the process worked at the present time by the Industrial Engineering Company at Newton, near Hyde, but he (Mr. Thomson) did not think that Mr. Hutton had dwelt sufficiently upon the merits of that process as a comparatively large-scale laboratory method. It was one which could be easily carried out in the laboratory. Superheated steam was passed through iron turnings (heated to redness in a retort); the turnings became oxidised, liberating the hydrogen from the steam. Coal gas or producer gas could then be passed over the oxide of iron, which would liberate a large amount of heat from the combination of the oxygen of the oxide of iron with the hydrogen and carbon monoxide contained in the coal gas or producer gases. When the iron had become thoroughly deoxidised, superheated steam was again passed over the reduced iron, which decomposed the water, again producing oxide of iron and free hydrogen, which could be obtained almost chemically pure at a cost of about 1*s.* per 1,000 cb. ft.

Dr. **Markel** asked, in view of the large excess of ammonia, *viz.*, not less than 100 per cent., which Mr. Hutton found necessary to use when producing nitrogen by means of Harcourt's process, whether he had taken any precautions with regard to the elimination of the water vapour from the mixture of ammonia and air entering the combustion tube. It was well known that water vapour had of all gases the greatest protective influence on ammonia, and that, therefore, in the presence of water vapour a very much higher temperature was required to destroy ammonia by heat, or to burn it with air. Had Mr. Hutton taken this important protective property into account, and had he not found that when the water vapours were removed he could work with a very much smaller excess of ammonia, or a considerably lower temperature?

Mr. **Scudder** asked if the authors of the paper had made any observations on the effect of compressing and storing gases in steel cylinders. Reference had been made to the compression of carbonic oxide gas. Some years ago he (Mr. Scudder) had occasion to put down a plant for compressing water gas into steel cylinders, and he found that after the gas had been stored for a time it was found to be contaminated with iron carbonyl, which rendered the compressed gas useless for illuminating and experimental purposes. He should like to have the experiences of the authors of the paper as to any observed effects produced either by impurities in the gas or the effect of storage.

Mr. **Hutton**, in reply to Dr. Markel, said that they had always employed double the required amount of ammonia in order to ensure against the presence of oxides of nitrogen. Doubtless, a smaller excess would be sufficient, but they had not had time to study the reaction in detail, although this would doubtless give interesting results. It should be remembered that Ostwald's method of producing nitric acid consisted in passing air and small quantities of ammonia over various heated catalysing agents. In reply to Mr. Scudder, it was pointed out that the chief object of the work the authors were engaged in, was to study such reactions as were referred to in the question. It was, however, too early to deal with the results which have up to the present been obtained. So far as the action of carbon monoxide on the steel cylinders was concerned, other observers have noted the formation of iron carbonyl. The action does not, however, seem to be very rapid at ordinary temperatures. It has, however, caused trouble by deposition on the limes in lantern work even when compressed coal gas containing a small percentage of carbon monoxide is employed.

New York Section.

Meeting held at Chemists' Club, on Nov. 12th, 1903.

DR. VIRGIL COBLENTZ IN THE CHAIR.

MODERN SYNTHETIC MEDICINAL PRODUCTS.
PART II.

BY DR. VIRGIL COBLENTZ.

(See this Journal, 1898, 725.)

It was originally my purpose to continue the subject of my last annual address, devoted to the impurities of our medicinal chemicals and reagents. However, I have found this subject to be a very ungrateful one, for, in America, criticism I have had in this line seems to bear the type of resentment. The subject selected therefore is a continuation of my paper on Modern Synthetic Medicinal Products, presented to the Society in 1898. During the intervening five years many very important syntheses have been made in this direction, and much has been accomplished to still further elucidate the relationship between chemical structure and physiological action, which subject has been so ably and thoroughly treated in Fraenkel's "Die Arzneimittel Synthese" (Julius Springer, 1901).

Notable advances have been made among the alkaloids, as, for example, the synthesis of theophyllin (theocin), caffeine (from uric acid of guano), morphine derivatives (epiosin, heroin, dionin), eumydrin, and new quinine derivatives. Very interesting derivatives are to be found among the hypnotics, local anæsthetics, antiseptics, uric acid solvents, cacodylates, &c. Of interest to physiological chemists and indispensable to the invalid are the class of the patent foods. Unfortunately the writer is unable to give the patent numbers, owing to objections of many of the patentees. As an aid to those who may wish to secure further, more detailed information concerning any one of the products mentioned in the paper, the name of the manufacturer or patentee is given wherever possible.

Local Anæsthetics.

The search for local anæsthetics which offer, as cocaine substitutes, the advantages of stability (against hydrolysis) and lesser toxicity, has continued unabated. These are either derivatives of such basic groups as the eucaines, orthoforms, holocain, &c., or such phenols as the guaiacol derivatives, eugenol, &c. Directly related to cocaine, which is a derivative of the mother substance ecgonine, is *Tropacocaine Hydrochloride* (Merck). This is the hydrochloride of tropacocaine or benzoylpseudotropeine, $C_8H_{14}NO(C_7H_5O).HCl$, which forms white needles fusing at 271° C.

The *Eucaines* (E. Schering), derivatives of di- and tri-acetone-alkamine, which originated through the investigations of Ehrlich and Merling on the structure of cocaine, still retain their place. The investigations of Einhorn on the substituted amino derivatives of benzoic esters, demonstrated that they all possessed local anæsthetic properties[*] of greater or lesser intensity. Among these is Orthoform (Hoechster Farbwerke), *p*-amino-*m*-hydroxybenzoic acid methyl ester, $C_6H_3(COOCH_3)(NH_2)(OH)$, which has during recent years been replaced largely by the cheaper isomer *Orthoform New*, *m*-amino-*p*-hydroxybenzoic acid methyl ester, melting at 142° C.

Chloral-Orthoform New (Kalle & Co.) is a chloral-amino-hydroxybenzoic methyl ester, $C_6H_3(COOCH_3)(OH)N:CH.CCl_3$, prepared by interaction between molecular quantities of chloral and orthoform. More recently the orthoforms have had to give way to Ritsert's *Anæsthesin* (Hoechster Farbwerke) which is para-amino-benzoic acid ethyl ester, $C_6H_4(NH_2)CO.OC_2H_5$, fusing at 89·5° C. Besides being a local anæsthetic, this substance is valuable in hyperæsthesia of the stomach. A product of greater stability is *Subcutin*, *p*-phenol-sulphonate of anæsthesin, $HO.C_6H_4.SO_3H, NH_2.C_6H_4.COOC_2H_5$, a substance fusing at 195·6° C. Another derivative of this class prepared by Einhorn is *Nirvanin* (Hoechster Farbwerke), the hydrochloride of diethylglycocoll-*p*-amino-hydroxy-benzoic-methyl ester, which fuses at 185° C., $HCl(C_2H_5)_2N.CH_2.CO.NH.C_6H_4(OH).COOCH_3$. This substance produces complete and lasting anæsthesia when brought into contact with the nerve terminals through subcutaneous injection or open wounds. It is free from irritating action, and is especially adapted for Schleich's infiltrations in place of the ten times more toxic cocaine. Amino cinnamic ethyl ester, $C_6H_5CH:C(NH_2)COOC_2H_5$, has been introduced, with but little commercial success. The amino group, when in the para position to the hydroxyl group, produces a strong local anæsthetic action; this likewise exerts a toxic action in the circulatory system. Close proximity of the two groups accounts possibly for the comparative non-toxicity of the orthoforms and the absence of the hydroxyl group in anæsthesin. In nirvanin and subcutin the para amino groups, through substitution, have lost much of their toxic characters, which accords with the views of Oscar Loew (Natuerliches System der Giftwirkung) "that relative toxicity is determined by the degree of reactivity with the amino or aldehyde groups of the protoplasm." In these latter two compounds, the reactive amino group is rendered more resistive through the presence of these substituting groups. According to Ehrlich, the structure of the molecule must be such that it readily anchors with certain molecular groups of the protoplasm; also, this molecule must, in addition, contain the atomic complex with which it will exert its specific action in the protoplasm. For example, in cocaine the carrier of the anæsthetic action resides altogether in the benzoyl group, as may be noted in the loss of local anæsthetic action through the replacement by other acid radicles, while the balance of the molecular structuro is such that it anchors itself in the protoplasm.

Under the Holocain group is included a number of amidin and guanidin derivatives; the former may be considered to be derivatives of methylene-amino-phenol ethers of the general formula $CH_2 : N.C_6H_4.OR$. The older members of this group are *Holocaine* (Hoechster Farbwerke) *p*-diethoxyethenyl-diphenyl amidine, $C_2H_5OC_6H_4.NH.C(CH_3):N.C_6H_4.OC_2H_5$, which fuses at 121° C.; *Pyrocaine*, a guaiacol benzyl ester $CH_3O.C_6H_4.OCH_2.C_6H_5$; *Eugenol acetamide*, $CH_3.C_3H_5(OCH_3)OCH_2.CONH_2$, which fuses at 110° C.; and *Guaiacyl*, calcium orthoguaiacol sulphonate, $[C_6H_3(OH)(OCH_3)SO_3]_2Ca$. To these may be added *Methenyl-p-phenetidide*, $C_2H_5O.C_6H_4.NH.CH : NC_6H_4.OC_2H_5$, which fuses at 114° C., and its analogous *p*-anisidine base, fusing at 119° C., both of which are local anæsthetics. Of recent introduction, and belonging to the class of alkyl-oxyphenylguanidines, are the

Acoïns (V. Heyden Fabrik).—These are the hydrochlorides of the above-named derivatives, among which the Acoin C, di-*p*-anisyl-monophenetyl guanidine, has been proposed as a substitute for cocaine, possessing a minimum degree of toxicity and a greater degree of intensity of action. An objectionable feature is the necrosis following the hypodermic use of strong solutions. Its formula is $(CH_3O.C_6H_4NH)_2:C:NC_6H_4.OC_2H_5$.

Acetone Chloroform, otherwise known as *Aneson* and *Chloreton*, is a tertiary trichloro-isobutyl alcohol melting at 80° to 81° C., of the formula $(CH_3)_2C(OH).CCl_3.\frac{1}{2}H_2O$. A 2 per cent. solution of Aneson is equivalent in local anæsthetic activity to one of like strength of cocaine. This remedy is likewise employed as a hypnotic and sedative, also it will prevent nausea following anæsthesia. Chloretone appears in every respect to be a superior substitute for cocaine.

Nervocidin.—The active principle of the East Indian plant Gasu-Basu, which has found application as a dental local anæsthetic in 0·1 per cent. solutions, while anæsthesia of the cornea may be accomplished with a 0·01 solution.

Among those remedies which produce local anæsthesia by cold through rapid vaporisation, no new derivatives have been introduced. New in title are *Anestile* (Bengué), a mixture of ethyl and methyl chlorides, and *Narcotile*, a mixture of methyl and ethylene chlorides.

Synthetic Morphine Derivatives.

No department of chemical research has proved so alluring and yet so slowly productive of results as the chemical constitution of the vegetable alkaloids, and among these, in particular the alkaloid morphine. As soon as the structure of any one of these bases has been accurately established, it is only a matter of time until the pharmacologist and chemist are able, from a knowledge of the physiological action of various organic nuclei which enter into these compounds, to prepare derivatives of like or modified action. In the case of morphine it has been the constant effort of chemists to prepare a derivative which would be free from its objectionable secondary action. It is only very recently that any approach to this ideal has been accomplished.

The hydroxyl groups are intimately associated with the toxic action of morphine, which, through its narcotic characters, differs from all other opium alkaloids, its action being chiefly upon the nerve centres of the brain. Upon closing these OH groups by substituting one or both of the hydrogens by alkyl or acidyl radicals, the narcotic characters disappear, while, on the other hand, a spinal excitant (tetanic action) is developed, increasing with the number of alkyl radicals introduced. Thus, codeine produces, like morphine (but in lesser degree) narcosis, followed by an elevated reflex, which, if the dose be sufficiently large, develops tetanic convulsions. Other morphine esters, as codethyline, $C_{17}H_{17}ON(OH)(OC_2H_5)$, and thebaine, $C_{17}H_{15}(OCH_3)_2NO$, the latter of which is the most toxic alkaloid of opium, are characterised by their action on the spinal cord, the tetanic effects being identical to those produced by strychnine. This action increases with the number and molecular weight of the alkyl groups introduced; hence codethyline with its ethyl group is more intense in action than codeine, which contains but one methyl group. Among all possible derivatives, it is immaterial as to whether an acidyl or alkyl radical, aliphatic or aromatic, is introduced; there is practically no qualitative difference in action so long as the same hydrogen is replaced. The morphoxyacetic acid ($C_{17}H_{18}NO_3.CH_2COOH$), morphoxy propionic and butyric acids are pharmacologically inactive, where, on the other hand, the methyl and ethyl esters of these acid derivatives produce intense picrotoxin-like convulsions, the seat of action being the *crura cerebri*. In all instances the narcotic action of morphine is very much diminished, while the tetanic and also the action on the motor nerves is increased.

It is only during very recent years that any attempt toward producing morphine derivatives of the codeine type have been attempted. These substances, while less active for relieving pain, exert a sedative effect on the unstriped muscles of the bronchi, and reduce the disposition to cough; hence are of value in phthisis, bronchitis, asthma, &c. One of the first of this class of derivatives to appear, introduced by E. Merck, of Darmstadt, in 1896, was *Peronin*, the hydrochloride of benzylmorphine, $C_{17}H_{17}(OH)ON.O.CH_2.C_6H_5, HCl$. This narcotic was proposed as a substitute for codeine and

---

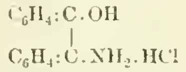
[*] Members of this class are the *o*- and *m*-methyl and ethyl esters of hydroxy- and dihydroxy-benzoic, salicylic, anisic, creosotic, protocatechuic and vanillic acids. Most of these possess objectionable irritating properties.

morphine in alleviating the cough in pulmonary tuberculosis, chronic bronchitis, and pertussis. This was followed by

Heroin (Elberfelder Co.).—The hydrochloride of the diacetic ester of morphine, $(CH_3COO)_2C_{17}H_{17}ON, HCl$. This preparation, which melts at 230° C., possesses a decided advantage in its ready solubility in water (1 in 2). Heroin, like others of this class, is valuable in affections of the respiratory passages. Stockmann and Dott prepared, in addition to the diacetyl morphine, the dipropionyl, dibutyryl, and divaleryl derivatives, the comparative action of which resulted to the advantage of the acetyl derivative. A later introduction and improvement over the older peronin was

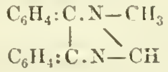
Dionine (E. Merck).—The hydrochloride of ethyl morphine $(HO.C_{17}H_{17}.NO.OC_2H_5.HCl)$. This compound, which fuses at 123° to 125°, appears to be a mild substitute for morphine, being equally available as an anodyne, hypnotic, and sedative.

As a result of the more recent investigations of Knorr and others, based on the breaking up of the ring structure of morphine, the presence of a phenanthrene and also an oxazine (morpholine) nucleus have been conclusively demonstrated. Assuming that either one of these nuclei might be responsible for the physiological action of morphine, E. Vahlen endeavoured to prepare a nitrogenated derivative of morpholine, in the hope of obtaining a therapeutically active body (Archiv f. exp. Path. u. Pharmak., **47**, 368). Such a compound he found in morphigenine hydrochloride—



$$\begin{array}{l} C_6H_4:C.OH \\ \qquad\quad | \\ C_6H_4:C.NH_2.HCl \end{array}$$

which he was able to obtain only in solution; this substance possess marked narcotic properties. Vahlen further prepared an amidazole derivative of morphigenine, to which he gave the name *Epiosin* (Dr. Heineman, Eberswalde). This new synthetic, which fuses at 195° C., is a methyl-diphenyleneamidazole of the structure—



Physiologically, epiosin possesses the anodyne and hypnotic action of morphine without any of its objectionable secondary effects. Clinical experiments are still in progress.

Alkaloids.

During the last five years much has been accomplished, not only in the isolation of many new plant principles, but also in the preparation of valuable derivatives of the well-known alkaloids. Only the more important members of the latter class are enumerated. The synthesis of theophyllin is mentioned elsewhere.

Eumydrin (Elberfelder Fabrik).—Atropine methyl nitrate is obtained either by the action of nitric acid on atropinium nitrate (or alkyl halides), or by treating atropine with alkyl nitrates, or atropinium alkyl sulphates (atropinium methyl sulphate, $[C_{17}H_{23}NO_3.CH_3]_2SO_4$) with the nitrates of such metals as form insoluble sulphates. This salt is without action on the central nervous system, and exhibits a less powerful effect on the pupil than atropine.

Lactyl Tropeïn, $C_8H_{14}NO.CO.CH(OH)CH_3$, accelerates the action of the heart.

Mydrol (Merck).—Iodo-methyl-phenyl-pyrazolone, a mydriatic.

Mydrin (Merck).—A combination of ephedrine and homatropine used as a mydriatic.

Quinine Derivatives.—Efforts in the preparation of new derivatives of quinine have been directed towards the production of insoluble tasteless products, free from the disagreeable secondary effects which usually accompany the use of the more common salts.

Aristochin (Elberfelder Fabrik).—A diquinine carbonic ester, $CO:(O.C_{20}H_{23}N_2O)_2$, which forms a tasteless powder fusing at 189° C. Of all the various quinine preparations this contains the largest percentage of alkaloid, namely, 96 per cent.

Euchinin (Zimmer, Frankfort).—Quinine ethyl carbonic ester, $C_2H_5O.CO.OC_{20}H_{23}N_2O$, forms tasteless needles fusing at 95° C. The inorganic soluble salts of euchinin possess the bitter taste of the alkaloids.

Quinine Chlorocarbonic Ester (Zimmer, Frankfurt), $Cl.CO.OC_{20}H_{23}N_2O_2$.—Tasteless crystals, fusing at 187° C.

Salochinin (Elberfeld Co.; also Zimmer Co.).—The quinine ester of salicylic acid. Insoluble crystals, which fuse at 130° C.

Rheumatin (Zimmer, Frankfurt).—Salicylate of salochinin. This fuses at 179° C.

Bromchinal (Zimmer, Frankfurt).—Quinine dibromosalicylate. Fuses at 198° C.

Chinaphtol (Merck).—Quinaphthol. β-naphthol monosulphonate of quinine. Fuses at 185°—186° C.

Quinine Lygosinate (Zimmer, Frankfurt).—Quinine di-*o*-cumaric ketone, $(C_{20}H_{23}N_2O_2)O.C_6H_4.CH:CH.CO.CH:CH.C_6H_4.O(C_{20}H_{23}N_2O_2)$. This salt is employed exclusively as an antiseptic. It fuses at 114° C.

Among the derivatives of minor importance are Acetyl quinine (m. pt. 108° C.), Ethyl quinine (m.pt. 116°—117° C.), Quinine acetylsalicylate, Quinine sulphoguaiacolate, Quinine sulphocreosotate, Quinine urethane, and Quinine carbamido dihydrochloride, $(C_{20}H_{24}N_2O_2)HCl + CO(NH_2)_2HCl + 5H_2O$; the latter three, because of ready solubility, are adapted for hypodermic use.

Hypnotics.

These may be divided into two classes, one in which the hypnotic action is largely dependent on the presence of alkyl radicles, while either an aldehyde or ketone group carries this effect in the other.

Under the former class very few synthetics of any importance have been introduced. That a firmly-linked ethoxyl group carries a definite narcotic effect is shown in the well-known ethoxy caffeine, tertiary-amyl alcohol, sulphonal, trional, and the analgesic phenacetin. Further experiments in this direction were made recently by Professors Emil Fischer and Merling in testing the hypnotic action of a series of compounds containing one or more ethyl groups linked to one and the same carbon, as is the case of tertiary amyl alcohol and trional. A series of such compounds have been discovered among the derivatives of urea, as, for example, diethyl acetyl urea, $(C_2H_5)_2N.CO.NHCOCH_3$, diethyl malonyl urea and the dipropyl malonyl urea. The second of these was selected for therapeutic use, and introduced under the title of

Veronal (E. Merck).—Diethyl malonyl urea, a crystalline powder which melts at 191° C.

The urethanes (carbamic acid esters) possess mild hypnotic action, increasing in activity with the molecular weight of the alcohol radical. Heretofore hypnotic action has been accomplished to a certain extent through the introduction of a substituted aldehyde, as in Uraline (Chloral Urethane) and Somnal (Uraline Alcoholate); however, such combinations are open to criticism, because of the objectionable action of the chloral. Recently an ideal and harmless hypnotic has been introduced, in which the methyl propyl carbinal group replaces the simple ethyl of urethane, the product being known commercially as

Hedonal (Elberfelder Fabrik).—Methyl propyl urethane, $NH_2CO.OCH(CH_3)C_3H_7$, an aromatic crystalline powder, which fuses at 76° C., and boils at 215° C.

Among the latest additions to a series of valuable valeric acid derivatives examined therapeutically by Drs. Liebrecht and Kionka are

Valyl (Hoechster Farbwerke).—A valeric acid diethyl amide, $C_4H_9.CO.N(C_2H_5)_2$, which boils at 210° C. This antispasmodic is useful in hysteria, neurosis, neurasthenia, &c.

Validol (Zimmer & Co.).—The mentholester of valeric acid $(C_{10}H_{19}O.CO.C_4H_9)$, which contains 30 per cent. of menthol.

Second Class.—The objectionable secondary action of chloral upon the heart and respiration, and the disagreeable burning produced in the stomach, which led to the introduction of various more stable combinations from which chloral is slowly eliminated, has not been altogether realised. Among such combinations were Chloral Formamide (Chloralamide), $CCl_3CH(OH)NH.CHO$; Chloralimide, $CCl_3.CH:NH$; Chloralose, Chlorosonin (chloral hydroxylamine), &c. More recently, a new combination of chloral with the hypnotic amylene hydrate (tertiary amyl alcohol) has been introduced under the title of

Dormiol (Chem. Fabrik "Rhenania"). — Amylene Chloral or Chloral dimethyl ethyl carbinol—

$$CCl_3.CH(OH)OC(CH_3)_2C_2H_5.$$

Although much slower in action, recent reports state that Dormiol is not much less toxic than chloral.

Isoprol.—A trichloroisopropyl alcohol, which fuses at 49° C.

In addition to the oximes of chloral (Acetaldoxime, Acetoxime, Camphoroxime, Benzaldoxime), A. C. Jensen (Frankfurt a/M.) introduced the

Chloral Acetophenone Oxime, $C_6H_5.C(CH_3):N.OCH.(OH)CCl_3$, fuses at 81° C.

To the limited number of ketones (the hypnotic properties of which are due to the carbonyl group), Propione (diethyl ketone) and Hypnone (acetophenone) have been added.

Hypno-acetin, the acetyl-*p*-amino phenol ether of acetophenone, $C_6H_5CO.CH_2O.C_6H_4.NHCOCH_3$, is obtained by condensing *p*-aceto-aminophenol with phenol and glacial acetic acid by aid of zinc chloride. This forms scales which fuse at 160° C.

Antipyretics.

Aniline Derivatives.—Safety in administration and freedom from secondary action, which accompany the use of the derivatives of the Pyrazolone and Phenetidine class have been the causes of the diversion from this once popular group of antipyretics. The few additions noted are special products.

Aniline Camphorate.—Used as an antispasmodic.

Sodium Acet-Sulphanilate (Hoffman, La Roche).—A rapid-acting antipyretic.

Anilipyrin. — Phenyldimethylpyrazolone acetanilide, made by fusing together antipyrine and acetanilide.

Aceto-Toluide (*Ortho*) (Merck) fuses at 107° C.

Para-phenetidine Derivatives.—On glancing over the additions to this group, it is evident that the list of organic acids which have been proposed in place of the acetyl groups of phenacetin has not yet been exhausted. Very evidently the attempt has been made to employ substituting groups which possess special medicinal properties as in the case of phenetidine agaricinate, valerydin, &c., adding otherwise to their value as antipyretics.

Agaric Acid Phenetidides (Riedel, Berlin).—These products represent a combination of the antihydrotic properties of agaric acid with the antipyretic action of the phenetidine nucleus, and are prepared by heating the components together at a temperature of from 140° to 160° C. Two products result, a monophenetidide, $C_{14}H_{27}(OH)(COOH)CO.NHC_6H_4.OC_2H_6$, which when anhydrous, fuses at 100° C., and a diphenetidide which fuses at 151° C.

Benzacetin.—Acet-amino-ethyl salicylic acid, $C_6H_3(OC_2H_5)(NH.COCH_3)COOH$. An acetylated amido-salicylic acid which fuses at 190° C.

Chinaphenin (*Quinaphenin*) (Zimmer, Frankfurt).—Quinine carbonate phenetidide, $(C_{20}H_{23}N_2O)O.CO.NH.C_6H_4.OC_2H_5$, obtained by the action of *p*-ethoxy-phenyl-carbamic chloride or *p*-ethoxyphenyl-isocyanate on quinine. The antipyretic properties of this compound combine those of the slowly acting quinine and more rapid phenacetin. Chinaphenin fuses at 186°—185° C.

Eupyrin (Zimmer, Frankfurt). — Para-phenetidine vanillin ethyl carbonate, $C_6H_4(OC_2H_5).N:CHC_6H_3(OCH_3)O.COOC_2H_5$. A non-toxic stimulating antipyretic for children. The fusing point is 87°—88° C.

Valerydin (*Sedatin*) (Erdmann, Leipzig).—Iso-valeryl para-phenetidine, $C_6H_4(OC_2H_5)NH.C_5H_9O$. A combined nervine and antipyretic.

Apolysin and Citrophen.—Anselmino (Ber. d. Deutsch. Phar. Gesellsch., 1903, 5), as a result of his investigations, claims that the usual accepted formulæ for these compounds are erroneous. Apolysin, formerly considered as a monophenetidine citrate, $C_3H_4.OH.(COOH)_2.CO.NH.C_6H_4.C_2H_5$, is, according to this author, a mono-phenetidide of aconitic acid $(C_6H_7O_6)NH.C_6H_4.O.C_2H_5$, while citrophen instead of being a citro triphenetidide, is in reality a monophenetidine citrate, fusing at 188° C.

Antipyrin Derivatives.—The camphorates (acid and neutral) of antipyrin and pyramidone (dimethyl amino antipyrin), serve as antihydrotic antipyretics, which are of special value in tuberculosis.

Acopyrin.—Acetopyrin (Heyden, Dresden).—An acetyl salicylate of antipyrin, which fuses at 61° C.

Pyrosol (Hofmann, Meerane i/S.).—A soluble salicyloacetate of antipyrin, which fuses at 150° C. $(C_9H_8O_5.C_{11}H_{10}N_2O)$.

Thiopyrin and Selenopyrin.—These are prepared by interaction between potassium hydrosulphide, also potassium selenide and the so-called antipyrin chloride (chloromethylate of 1 phenyl, 3 methyl, 5 chloropyrazole). The thiopyrin $(C_{10}H_{12}N_2S)$ fuses at 166° C.

Kryogenin.—Metabenzamido-semicarbazide—

$$C_6H_4(CO.NH_2)(NH.NH.CO.NH_2).$$

Acetyl Ethyl Phenyl Hydrazin.—An ethyl derivative of pyrodine (hydracetin).

Neurodin (Merck).—Acetyl *p*-hydroxy-phenyl urethane, $C_6H_4(OCOCH_3)NH.COOC_2H_5$, fuses at 87° C.

Antiseptics.

The majority of the synthetics introduced during the past five years belong under this class. However, comparatively few of these have found a permanent place in *materia medica*.

1. *Derivatives of the Amines:* — *Iodoformin* (Marquardt).—Hexamethylene tetramine-iodoform, $CHI_3(CH_2)_6N_4$. This compound, which fuses at 178° C., breaks up in presence of the wound secretions, with liberation of iodoform.

Iodoformal (Marquart).—Iodoformin ethyl iodide forms yellow needles, which fuse at 128° C. (German Patent 87,812.)

Iodoformogen (Knoll and Co.).—Iodoformin albumin. A readily sterilized preparation containing 10 per cent. iodoform. (German Patent, 95,580.)

Kresamin (Schering); Cresamin; Tricresolamin. An ethylene diamine cresol.

2. *Formaldehyde Combinations.*—These represent combinations of formic aldehyde with various antiseptics, from which the former is slowly eliminated when in contact with a wound.

Kreoform (Henning, Berlin).—A condensation product of creosote and formaldehyde.

Forman (Lingner, Dresden). — Chloromethyl menthylether, $C_{10}H_{19}O.CH_2Cl$, a chlorinated methyl ether of menthol prepared by the action of formaldehyde on menthol in presence of gaseous hydrochloric acid. This compound boils at 160° (16 mm.), and decomposes by the moisture of the air into formaldehyde, menthol, and hydrochloric acid.

Thymyloform (Henning, Berlin) *Thymoform.*—A condensation product of thymol and formaldehyde—

$$[C_6H_3(CH_3)(C_3H_7)O]_2CH_2.$$

Iodothymoform is an iodised thymoloform, which fuses above 150° C.

Naphthoformin (Henning, Berlin).—A condensation product of α- or β-napthol and formaldehyde.

Polyformin, soluble (Henning, Berlin).—A di-resorcinol-hexamethylene tetramine $[C_6H_4(OH)_2]_2.(CH_2)_6N_4$.

Polyformin, insoluble (Henning, Berlin).—On dissolving polyhydric benzenes or phenols with a condensed benzene nucleus in an aqueous solution of formaldehyde and adding excess of ammonia, insoluble compounds of high formaldehyde content are obtained, of which this polyformin is a representative.

Galloformin (Henning, Berlin).—A hexamethylene tetramine gallic acid, $C_6H_2(OH)_3COOH.(CH_2)_6N_4$. Similar to this are *Resorcinol Formin* and *Pyrogallol Formin.*

3. Aromatic Derivatives: (*a*) *Phenols: Antinosin* (Rhenania Fabrik).—Nosophen sodium or tetra-iodo-phenol phthalein sodium, $C_6H_4.COO.C.(C_6H_2I_2ONa)_2$.

Egols.—The mercury salts of *o*-nitro phenol (cresol or thymol) *p*-sulphonic acid. These are distinguished by prefixes Phen-egol, Cres-egol and Thym-egol.

Eosolates (Lehmann, Berlin).—The salts of the sulphonic acid derivatives of alipathic creosote esters (trisulphoacetyl creosote). (German Patent 94,078.) Calcium eosolate, $(C_9H_7S_3O_{12})_2Ca_3$; Silver eosolate, $C_6H(OCH_3)(OCOCH_3)(SO_3)_3Ag_3$; Quinine eosolate, $(C_{20}H_{21}N_2O_2)_3C_9H_7S_3O_{12}$.

Iodozols (Voswinkel, Berlin).—Various salts of di-iodo-phenol sulphonic acid.

Euresol (Knoll and Co.) — Monoacetyi resorcinol, $C_6H_4(OH)OCOCH_3$, which boils at 283° C.

Eunol (Henning, Berlin).—A condensation product of the naphthols and eucalyptol.

Ready saponifiable esters of pyrogallol and chrysarobin:—

Eugallol (Knoll and Co.).—Monoacetyl pyrogallol.

Lenigallol (Knoll and Co.)—Triacetyl pyrogallol, $C_6H_3(OCOCH_3)_3$.

Saligallol (Knoll and Co.).—Pyrogallol disalicylic ester.

Eurobin (Knoll and Co.).—Triacetyl chrysarobin.

Lenirobin (Knoll and Co.).—Tetracetyl chrysarobin.

Iodo-eugenal.—A compound analogous to aristol (di-thymol di-iodide) melting at 78° C.

Di-Fluor Diphenyl (Valentiner and Schwartz), $FC_6H_4—C_6H_4F$, obtained by the action of hydrogen fluoride on benzidine. It fuses at 87° C.

(*b*) *Aromatic Aids: Peruscabin* (A.-G. f. Anilinf.).—Benzoic benzyl ester. This along with cinnamein, styracin, and cinnamic acid. is the most active constituent of Peru balsam. Peruscabin boils at 173° C. (9 mm.)

Lygosins (Zimmer and Co.).—These are the sodium and quinine salts of di-ortho-hydroxycinnamic ketone obtained through the interaction between salicylic aldehyde and acetone in presence of sodium hydroxid. This ketone, of the formula $CO:(CH:CH.C_6H_4.ONa)_2$, fuses at 114° C.

Salibromin.—Dibromo-salicylic acid.

Epicarin (Elberfelder Fabriken).—β-hydroxy-naphthyl *o*-hydroxy-*m*-toluic acid, $C_6H_3(OH).CH_2(C_{10}H_{16}OH)COOH$. This belongs to a new group of creosotic acid derivatives in which a hydrogen of the methyl group of creosotic acid is replaced by a phenol rest, epicarin being the β-naphthol derivative. This fuses at 199° C., and is specially employed in scabies and various skin diseases.

Thymotal.—Thymol carbonate, thymol urethane (v. Heyden). Thymotal, which fuses at 49° C., splits up in the intestines, liberating thymol, which serves to destroy intestinal parasites.

Acetozone, Benzosone (Parke, Davis and Co.).—$C_6H_5CO.O.O.COCH_3$, benzoyl acetyl peroxide, which fuses at 40° to 41° C. In aqueous solution, owing to its ready hydrolysation, acetozone acts as a powerful oxidising agent.

Benzoyl Peroxid (Dr. Hellin, St. Petersburg).—This substance, which fuses at 103·5° C., is employed likewise as an oxidising agent.

Hetocresol (Kalle and Co.).—Cinnamic acid meta cresol, $C_6H_5CH:CH.COOC_6H_4CH_3$, fusing at 65° C. (German Patent No. 99,567.)

Hetol (Kalle and Co.).—Sodium cinnamate; both this and hetocresol are employed intravenously in treatment of tuberculosis.

(*c*) *Quinoline Derivatives: Vioform, Nioform* (Basel Fabrik).—Iodochlorohydroxyquinoline.

Quinosol (Fritzsche, Hamburg).—Hydroxyquinoline alum, hydroxyquinoline potassium sulphate $2(C_9H_6NOH)H_2SO_4 + K_2SO_4$.

Sulphurated Tarry Products.—The popularity of ichthyol, as well as the lapse of its patents, has led to the introduction of several products of similar composition. The Ichthyol Company has introduced some valuable combinations of ichthyol.

Ichthargan (Ichthyol Co.).—Silver ichthyol sulphonate, 30 per cent. silver.

Ichthermol (Ichthyol Co.).—Mercury ichthyol sulphonate, 24 per cent. mercury.

Ichthoform (Ichthyol Co.).—Ichthyol formaldehyde.

Ichthalbin (Knoll and Co.).—An ichthyol albumin analogous to tannalbin (tannin albuminate). An agreeable ichthyol substitute for internal use. (English Patent No. 11,344).

Petrosulfol (Hell and Co.).—Obtained by sulphonating a highly sulphurated Tyrolese bituminous oil and neutralising with ammonia.

Thiogenol (Hoffmann La Roche).—A 33 per cent., solution of the sodium salt of a sulphonated sulphur oil.

Sphagnol, Corbaoel.—A product of the dry distillation of turf. This contains anthracene, benzene, phenol, and cresols.

Gabamiol.—A sulphurated oil obtained from the natural shale of Herat.

Isarol (Ges. Basel).—A product identical with ichthyol, containing 8·5 to 9·5 per cent. of sulphur.

Ichthydrin.—Apparently a side product in the preparation of ichthyol.

Illyrin.—A product similar to ichthyol.

(*d*) *Miscellaneous Organics: Fluoroform Solution* (Valentine, Leipzig).—A saturated solution (28 per cent.) of fluoroform (CHF_3) in water.

Solvosal Salts (Helfenberg, Dresden).—The potassium and lithium salts of salol-o-phosphinic acid, *e.g.*, $C_6H_5O.CO.C_6H_4O.PO.(OH)OK$. This splits up into salicylic acid, salol, and a phosphate.

Toluidine Blue.—The soluble salt of a dimethyl toluthionine and zinc chloride, $C_{15}H_{16}N_3SCl.ZnCl_2$. A substitute for Methylene Blue in ophthalmology.

Acetyl Leuko-Methylene Blue (Hoechster Farbwerke). A product of the reduction of methylene blue.

4. *Organic Compounds of Bismuth.*—Recent years have added quite a formidable list of new bismuth combinations. Only the more important of these are given, among which are some valuable additions to antiseptic surgery, as, for example, airol, iodogallicin, and xeroform.

Bismuth Sulphophenate.

Bismuth Albuminate (Merck), 9 per cent. bismuth.

Dibismuth Mono-Iodo-Methylene-di-Cresotinate.

Bismuthose (Kalle and Co.).—A bismuth albumin compound, containing 22 per cent. of bismuth. (This Journal, 1902, 1244.)

Bismuth-oxy-iodo-Agaricinate.

Crurin (Kalle and Co.).—Quinoline bismuth sulfocyanide $(C_9H_7N.HSCN)_2Bi(SCN)_3$.

Hetaform.—Bismuth cinnamate, $Bi(C_9H_7O_2)_3.Bi_2O_3$.

Airol (Hoffmann, La Roche).—Bismuth oxy-iodo gallate, obtained by action of hydriodic acid on bismuth subgallate. It contains 20 per cent. of iodine, $IBiO_2.C_6H_2(OH)COO.C_6H_2(COOH)O_2BiOH$. Airol is the most important addition to this group. (German Patents 80,399 and 82,593.)

Ibit (Gesellsch. Basel).—Bismuth oxy-iodo tannate, a preparation closely related to airol, $C_6H_2(OH)_2(COOH)O.CO.C_6H_2(OH)O_2BiI$.

Iodogallicin (Sandoz and Co., Basel).—Bismuth oxy-iodid-methyl gallol obtained through action of bismuth oxyiodid on gallacin (gallic acid methyl ester)—

$$C_6H_2(COOCH_3)(OH)_2.OBi(OH)I.$$

This contains 23·6 per cent. of iodine, and 38·4 per cent. of bismuth.

Hæmostatin or *Zeroform* (V. Heyden).—Bismuth tri-bromo-phenate $(C_6H_2Br_3O)_2.BiOH + Bi_2O_3$. This preparation, which contains about 60 per cent. of Bi_2O_3, serves not only as an antiseptic, but also as a hæmostatic.

Bismutan (Mindes, Zürich).—A bismuth resorcinol tannate.

The Silver Antiseptics.—Although one of the standard remedies for the treatment of inflammation of the mucous membranes, silver nitrate possesses an irritating and often caustic action, which has greatly restricted its field of application. Aside from this, it has only a limited penetrating power, due to the fact that it is precipitated by albumin and sodium chloride, two of the ordinary constituents of the secretions and tissues. This is a serious disadvantage, since many of the conditions in which it is employed are due to micro-organisms, which are found not only in the superficial, but also in the deeper portions of the mucous membranes, and hence cannot be reached by solutions of this chemical, owing to the formation of an insoluble silver albuminate in the upper layers. The recognition of these drawbacks is responsible for the host of substitutes for silver nitrate which have been introduced in recent years. Most of these represent combinations of various percentages of metallic silver with different proteids. They are all said to be less irritating than the nitrate, and unaffected by either albumin or sodium chloride.

I. *Organic Combinations: Albargin* (Hoechster Farbwerke).—A gelatose silver containing 15 per cent. of the metal, which is prepared by mixing a neutral solution of glucose with silver salts, and precipitating with alcohol. Neither hydrogen sulphide, nor boiling with alkalis, produces any reaction, while chlorides produce only opalescence.

Argentol (F. Fritzsche, Hamburg).—An oxyquinoline sulphonate of silver ($C_9H_5N.OH.SO_3Ag$), containing 32 per cent. of the metal.

Argyrol (Drs. Barnes and Hille).—A non-irritating silver vitellin, which contains 30 per cent. of silver.

Argonin (Hoechster Farbwerke).—A casein-silver compound, which contains 10 per cent. of metallic silver. This yields very stable aqueous solutions.

Largin (Merck).—Protalbinsilver containing in the air dry condition 11 per cent. of the metal.

Nargol (Parke, Davis, and Co.).—A nucleide of silver containing 10 per cent. of the metal.

Protargol (Elberfelder Fabriken).—A silver proteid preparation, containing about 8 per cent. of silver in a fixed combination. Not precipitated by albumin, chlorides, or alkalis; it possesses great penetrating properties.

Ichthargan (Ichthyol Gessells.).—A silver ichthyol sulphonate. Contains 15 per cent. of sulphur and 30 per cent. of silver.

Argentamine (Schering, Berlin).—A solution of one part of silver phosphate and one part of ethylene diamine in 10 parts of water: 10 parts correspond to one part of silver nitrate.

Silberol.—Silver sulphophenate (1.4) obtained by action of a solution of phenol sulphonic acid on silver carbonate.

Itrol and Actol (v. Heyden).—Citrate and lactate of silver.

II. *Inorganic Combinations: Tachiol.*—Silver fluoride. It is claimed that this destroys pathogenic organisms in solutions of 1 to 200,000.

Collargol (v. Heyden).—Collodal silver which contains 90 per cent. of the pure metal. The preparation is completely soluble in water, is employed locally subcutaneously and in ointment form. According to Henriot (Chem. Zeit., 1903, 686) collargol is not an allotropic form of silver, but the alkali salt of collargolic acid prepared from Paal's lysalbate of silver. Collodal silver prepared by different methods deports itself differently.

7. *Mercurial Antiseptics.*—The value of mercurials in the treatment of syphilis and also as antiseptics has brought forward a variety of combinations, some of which, because of their ready solubility, freedom from irritation, and slow elimination from the system, are especially adapted for subcutaneous and instramuscular injection. While others represent antiseptics equal in value to sublimate yet free from its objectionable action on steel instruments.

Hyrgol or Colloidal Mercury (v. Heyden).—The solution of the commercial product deposits on standing a slight insoluble residue; this is objectionable because of variations in strength. This solution is free from irritating action; the metal is precipitated by acids, bases and salts of the heavy metals. Hyrgol is valuable for preparing various pharmaceutical preparations of mercury.

Mercurol (Parke, Davis, and Co.).—A nucleide of mercury, which contains 10 per cent. of the metal. It is not affected by albumin or alkalis, and is free from irritant action.

Mercuriol. — An aluminium-magnesium amalgam of Swedish origin.

An almost innumerable list of salts of mercury representing combinations with all the various aliphatic and aromatic acids, phenols, &c., have been already introduced; among the more important are—

Mercuric Formamide. — The hydrogen of the amino group in formamide, being replaced by mercury ($(H.CO.NH)_2Hg$.

Mercury Phenolates. — The mono-phenol derivative, $(C_6H_5O)_2Hg + H_2O$, which is quite unstable in the organism, is a valuable mercurial, while the diphenyl mercury is very poisonous, because of its stable character and cumulative action. Similar to these are the dimethyl and diethyl mercury $(CH_3)_2Hg$ or $(C_2H_5)_2Hg$, which, according to Hepp (Fraenkel, Arzneimittel, p. 464), ar very stable in the organism, producing at first the effect of the pure salt, which is followed later by symptoms of serious mercurial poisoning. Such salts as the oxycyanate, $HgO.Hg(CNO)_2$, vanillate, benzoate, tribromophenolacetate, phenylacetate, &c., have received but little attention. When employed hypodermically, these salts accumulate locally and frequently produce mercurial poisoning. Far more successful are the soluble non-irritating—

Mercuric Succinimide, $[C_2H_4(CO)_2N]_2Hg$ (Mering).

Mercuric Asparaginate, $C_2H_3O.OC(NH_2)CO(NH_2)_2Hg$ (Ludwig).

Mercuric Amino Propionate (Alaninate) $[CH_3.CH(NH_2)COO]_2Hg$.

Hydrargyrol.—Mercuric para phenol sulphonate.

Hermophenyl.—Mercuric sodium phenol disulphonate.

Asterol (Hoffmann, La Roche).—A double salt of *p*-phenol sulphonate of mercury and ammonium tartrate $[C_6H_4(OH)SO_3]_2Hg, 4C_4H_4O_6(NH_4)_2 + 8H_2O$.

Phenegol.—Mercuro-potassium salt of nitro-phenol *p*-sulphonate. The nitrated derivatives of phenol *p*-sulphonic acid unite readily with mercury; such compounds are termed Egols, as phenegol, cresegol, thymegol, &c. $[C_6H_3(NO_2)(SO_3K)O]_2Hg$.

Apallagin.—The mercury salt of nosophen (tetraiodophenolphthalein. For subcutaneous use the albumin derivatives of mercury, like those of silver, have evidently attained greater success. Upon adding an aqueous solution of mercuric chloride to one of a casein alkali salt, followed by alcohol, a casein-mercury is precipitated. A preparation of this nature, containing 7 per cent. of mercury, soluble in water upon the addition of a trace of ammonia, which is unaffected either by hydrogen sulphide or by the alkali sulphides, is prepared by the Hoechster Fabrik.

Sublamin (Schering).—Mercuric sulphate ethylene diamine, $HgSO_4(C_2H_8N_2)_2 + 2H_2O$. This double salt, which contains 43 per cent. of mercury, possesses the advantages of sublimate with ready solubility, freedom from irritation, penetration and failure to coagulate albumin.

8. *Guaiacol and Creosote Derivatives.*—The favourable action of creosote and guaiacol as internal antiseptics in the treatment of phthisis has led to a more extended search for new combinations free from taste, caustic and toxic action, which frequently accompany the administration of large doses of these chemicals. As is well known, the toxicity of the dihydroxybenzenes depends on the presence of free hydroxyl groups, reaching a maximum of convulsive action in pyrocatechol; if both of the hydroxyl groups are methylated as in veratol, the compound becomes three times less toxic than guaiacol; however, at the same time a material loss in intensity of action is experienced, which accounts for the preference given to guaiacol over veratrol. This same observation explains the relative non-toxic character of anisol and phenetol when compared to phenol, also the loss of narcotic action to morphine.

The number of esters of guaiacol, as the benzoate, cinnamate, carbonate, salicylate, &c., has not been increased materially, because the list of available organic acids has been practically exhausted. In other directions, however, advantages have been gained in the preparation of condensation products and more complex derivatives.

Guainform or Geoform (Henning, Berlin).—Methylene di-guaiacol, a condensation product of formaldehyde and guaiacol, $CH_2[C_6H_3(OH)OCH_3]_2$.

Guaialin.—The benzoic ester of methylene di-guaiacol.

Pulmoform (Zimmer, Frankfort).—Methylene guaiacol.

Pneumin (Dr. Speir, Berlin).—Methylene creosote.

Guaiacol Ethylenate (Merck). — $(CH_3O.C_6H_4O)_2C_2H_4$, fuses at 138° C.

Eugoform (Gustrow Fabrik).—An acetylated methylene diguaiacol, which is employed chiefly externally as a local anæsthetic and antiseptic.

Guaiasanol (Hoechtser Fabrik).—The hydrochloride of diethyl glycocoll guaiacol, fusing at 184° C., $CH_3O.C_6H_4.O.CO.CH_2.N(C_2H_5)_2HCl$.

Guaiacol Piperidine (Guaiaperol. Guaiaperon).—This fuses at 80° C. $C_5H_{11}NH.C_6H_4(OH)OCH_3$.

Guaiamar (Endemann). — Guaiacol ·glycocoll ester, $C_6H_4(OCH_3)OC_3H_7O_2$, fuses at 75° C.

Oresol (Dr. Knapp, Basel).—Glycerin mono-guaiacol ether.

Guaethol (Kalle and Co.).—Aethacol · Ajacol ; Thanatol. The mono-ethyl ether of guaiacol, which fuses at 26° C. and boils at 209°—210° C. Various other esters, such as the benzoate, butyrate, salicylate, &c., have been prepared.

Guaiachinol.—Dibromo-guaiacol of quinine—

$$C_6H_2Br_2(OCH_3)OH.C_{20}H_{24}N_2O_2.$$

Guacamphol (Henning, Berlin).—Guaiacol camphoric acid ester, $C_8H_{14}(COO.C_6H_4O.CH_3)_2$.

Guaiacetin (Majert, Berlin).—Guacetin. Phenoxyacetate of sodium, $C_6H_4(OH).OCH_2.COONa$. Fuses at 130—131° C.

Guatannin (A. Nissel, Benthen o. S.).—Guaiacol tannocinnamate. More popular among the inorganic combinations of guaiacol and creosote are—

Thiocol (Hoffmann, La Roche).—Guaiacol potassium orthosulphonate, $C_6H_3(OH).(OCH_3).SO_3K$.

Guaiacyl.—Guaiacol calcium ortho sulphonate—

$$[C_6H_3(OH).(OCH_3)SO_3]_2Ca.$$

This salt possesses local anæsthetic properties.

Cacodyliacol (Merck).—Guaiacol cacodylate—

$$As(CH_3)_2O_2C_6H_4OCH_3.$$

Phosot is Creosote phosphate, *Taphosot* is the tannophosphate and *Tannosal* is the tannic acid ester of this.

9. *Miscellaneous Inorganic Salts : Alkasal or Alkasol.*—An aluminium potassium salicylate.

Alkasal (Athenstaedt).—An aluminium potassium acetate, $Al(OH)_2(CH_3CO)_5K$. Ger. Pat. 78,903.

Aluminium Caseinate.—An intestinal astringent obtained by the addition of basic aluminium acetate to a sterilised milk free from albumin.

Aluminium Boroformate.—$Al_2O_3.H_3BO_3.H.COOH + 5H_2O$. Prepared by precipitating a solution of potash alum with a solution of borax. After washing the aluminium borate, it is dissolved in a solution of formic acid and the product crystallised.

Borogen (Bender and Hobein, Munich).—Boric acid ethyl ester. $B(O.C_2H_5)_3$ which is employed as antispetic in diseases of the air passages. In contact with moisture this ester splits up into its components.

Borol is a preservative made by fusing boric acid and sodium bisulphate.

Calcinol.—Calcium iodate, $Ca(IO_3)_2 + 6H_2O$.

Cupriaseptol.—Cupric meta phenolsulphonic acid—

$$[C_6H_4(OH)SO_3]_2Cu + 5H_2O.$$

Cupratin.—A copper albumin compound.

Cuprol.—A copper nucleinate. (See nucleinic acid compounds.)

Antigermin (Elberfelder Fabriken).—The copper salt of a feeble organic acid. When treated with hot water an insoluble basic salt separates.

Didymium Chloride (Zimmer, Frankfort) ($Di_2Cl_6.12H_2O$). In solutions of from 1/500 to 1/2000 grms. a very active disinfectant and preservative. Didymium salicylate, otherwise known as *Dymal*, is employed externally as an antiseptic dusting powder.

Fluorides.—Aluminium fluoride, $Al_2F_6 + 18H_2O$.

Chrysolein (Sodium Fluoride) has been employed as a preservative for foods ; for example, 0·5 per cent. is added to butter, and, before consumption, is removed by washing ; 0·3 per cent. is sufficient to preserve milk almost indefinitely. It is claimed that this salt is non-toxic internally. Ammonium and sodium silico fluorides, *e.g.* ($2NaF.SiF_4$) are employed largely as antiseptic inhalants.

Peroxides.—The peroxides of the alkaline earths have received some attention during recent years because of their antifermentive as well as their antiseptic properties. Among these are Calcium peroxide (*Gorit*), $CaO_2 + 4H_2O$; Magnesium Peroxide (*Biogen*), MgO_2; and Zinc Peroxide (*Dermogen*).

Vanadic Acid.—The various salts of meta vanadic acid possess a local stimulating action on the stomach, hence are of value as appetizers in debilitating diseases. They do not possess any cumulative action as in certain arsenicals. Larger doses of these salts paralyse the heart and respiratory centre.

Intestinal Antiseptics.

Investigation during recent years have conclusively demonstrated that thorough intestinal asepsis through the agency of this class of derivatives is not attainable, theoretical possibilities have not been borne out in practice. According to Schottelius (Münch. Med. Wochenschr., 1898, 35) there is no remedy which is capable of hemming bacterial action in all accessible portions of the intestinal tract without simultaneously exerting a destructive action upon the cell. Substances which possess in general superior antiseptic properties and have shown themselves to be useful in disinfection of the stomach, utterly fail to hem fermentation in the intestinal canal. As has been repeatedly pointed out, this is due to the alkalinity of the intestinal secretions which renders the antiseptic useless. Again other members of this group are so readily soluble in alkaline media that they are removed by absorption in the upper intestinal canal, as, for example, preparations of cresol, phenol thymol, &c. The third class of antiseptics which are best adapted for intestinal disinfection are the condensation products, which, because of their insolubility, reach the lower intestines, yet many of these fail in their object owing to the slowness of their decomposition. Of this class, the condensation products of tannin and gallic acid are still in favour.

Resaldol (Elberfelder Fabriken), $C_{20}H_{11}O_5\ (COCH_3)_2$.—The acetyl derivative of the condensation product of chloromethyl salicylic aldehyde and resorcinol.

Tannopin or Tannon (Elberfelder Fabriken).—$(CH_2)_6N_4.(C_{14}H_{10}O_9)_3$ Hexamethylene tetramine tannin. A condensation product of tannin and urotropin which contains 87 per cent. of the former and 13 per cent. of urotropin.

Tannoform (Merck).—Methylene ditannin. A condensation product of tannin and formaldehyde, which fuses at 230° C.

Tanocol (A.-G. f. Anilinfabr., Berlin).—A tannate of gelatin.

Tannosal, Kreosal.—The tannic acid ester of creosote.

Tannalbin (Knoll & Co.)—Tannin albuminate.

Tannogen (Elberfelder Fabriken). — Diacetyl tannin. $C_{14}H_8(CH_3CO)_2O_9$.

Tannin Albuminate (Merck).

Tannocasum (Romijn).—Produced by the action of formaldehyde on casein tannate.

Tannochrom (Hell & Co.).—A chrom tannin containing resorcinol.

Glutannol (Hundhausen in Hamm).—A combination of tannin and vegetable fibrin like tannalbin.

Protan (Mulford, Philadelphia).—Tannin nucleo-proteid.

Honthin (Hell & Co.).—Keratinized albumin tennate.

Gallogen (Heinemann, Eberwald). Egallic acid. This is pure egallic acid prepared by a patented process from the divi-divi pods ; the relationship of this product to tannin and gallic acid may be seen from the following :—

$$\begin{array}{ccc} & \longrightarrow -2H_2O-H_2 \longrightarrow & \\ 2C_7H_6O_5 & & C_{14}H_6O_8 \\ \text{Gallic acid.} & & \text{Egallic acid.} \\ & \longrightarrow -H_2O: \longrightarrow & C_{14}H_{10}O_9 \\ & & \text{Tannin.} \end{array}$$

Tribenzoyl Gallic Acid.

Pyridine Tannate.

Uric Acid Solvents.

Treatment of uric acid diathesis is usually directed either toward securing a diminution in the formation of uric acid in the organism, or the employment of a preparation which is intended to exert a solvent action on the uric acid already deposited in the tissues.

Weiss, of Basel (Berliner Klin. Wochenschr., 1899, 14), proposed (as one of the first-named group) the use of quinic acid, $C_6H_7(OH)(COOH)$, which, through reduction in the system to benzoic acid, combines with glycocoll to benzoyl glycocoll, the salts of which are far more soluble than those of uric acid. Based on the evidence that quinic acid reduces the formation of uric acid, various combinations of this with uric acid solvents, more particularly the substituted diamines, have been introduced, namely :—

Sidonal and New Sidonal (Verein Chem. Werke, Charlottenburg).—The quinate of piperazine or its derivatives, as lysidine (dimethylpiperazin). As a cheaper substitute for sidonal, the lactone of quinic acid was introduced in 1901. This is converted in the system into quinic acid, which in the nascent state is far more active.

Urol (Schnetz, Gummersbach, Rhein). Urea quinate, $C_7H_{12}O_6$, $2CO(NH_2)_2$. This salt fuses at 106° C. Ger. Pat. 124,426.

Quinotropin (Schering, Berlin).—Urotropine quinate $(CH_2)_6N_4.C_7H_{12}O_6$. This preparation is known as quinotropin I, and contains 73 per cent. of quinine and 27 per cent. of urotropin. Quintropin II contains 80 per cent. of the alkaloid and 20 per cent of the amine. Another preparation of identical composition is quinoformin (Adrien and Trillet, Paris).

Urosin Cryst (Urnmer, Frankfort) Lithium quinate.

Urotropin, *Formin*, *Aminoform* (Schering, Berlin), or *Uritone* (Parke, Davis & Co.) otherwise known as hexamethylene tetramine $(CH_2)_6N_4$. This old and well tried agent, which has a well established reputation as an antiseptic in the treatment of diseases of the urinary passages, also in allaying intestinal putrefaction, has been tested by G. Markmann (Zeitschr. f. angew. Microscopie, IX. 4) as a preservative agent. A 0·1 per cent. solution in milk preserved it for two days under adverse conditions. Meat containing 0·2 per cent. showed no signs of change after twenty-four hours. The mixture employed consisted of urotropin, 20 parts; sodium chloride, 170 parts; potassium nitrate, 3 parts; and sugar, 7 parts.

Based on the fact that the aliphatic organic acids diminish the quantity of uric acid formed, increasing in efficiency with carbon content, we find citric acid employed in the more recent combinations with urotropin.

Urotropin "New" (Schering, Berlin).—The anhydro methylene citrate of urotropin which splits off formaldehyde more readily in the urine than urotropin.

Helmitol (Elberfelder Fabriken).—Hexamethylene tetramine-anhydromethylene citrate—

$$(HO.CO.CH_2)_2CO:(CH_2)_2:O.(CH_2)_6N_4.$$

Citarin (Elberfelder Fabriken).—Anhydro methylene citrate of sodium. This compound liberates formaldehyde in the blood forming staple combinations with the uric acid, preventing thereby the uratic concretions in the joints and renal tubules—

$$(NaO.CO.CH_2)_2CO.<{}^{CH_2}_{CO}>O.$$

Galloformin (Henning, Berlin).—A compound of urotropin and gallic acid $C_6H_2(OH)_3COOH(CH_2)_6N_4$.

Saliformin (Merck) Urotropin salicylate.

Caffeine Derivatives.—The exciting action of caffeine on the central nervous system is governed by the presence or absence of certain molecular groups, thus di-methylxanthine (theobromine) exhibits the diuretic action of caffeine with but little effect on the nervous system. The objectionably slow action of this derivative was relieved by the preparation of soluble double salts with the benzoates and salicylates of the alkalis; more recent among this class are—

Agurin (Elberfelder Fabriken).—A sodio theobromine acetate, $C_7H_7N_4O_2Na + CH_3COONa$.

Uropherin (Merck).—U. Benzoate is a theobromine lithium-lithium benzoate $(LiC_7H_7N_4O_2 + LiC_6H_5CO_2)$. U. Salicylate is the corresponding double salt with salicyl acid.

Diuzazin.—A theobromine acetyl methylene disalicylate.

The introduction of the sulphonic acid group (as in the Symphorol) not only destroys the action of the caffeine upon the nervous system, but also its diuretic effect was so much diminished that but little could be expected in this direction.

According to the researches of Ach, the dimethylxanthines are the most active diuretics; among these are theobromine (3·7 dimethyl, 2·6 dioxypurin); theophylline (1·3 dimethyl, 2·6 dioxypurin); and paraxanthine (1·7 dimethyl, 2·6 dioxypurin); theobromine being the weakest, and paraxanthine and theophyllin the most active.

An example of the modern triumphs in synthetic chemistry is the synthesis of this latter purin derivative from urea, which has been introduced under the titles of

Theocin (Elberfelder Fabriken).—Theophyllin (m. pt. 268° C.) prepared by Traube's method (Berichte, 1900, **30**, 3053) from urea. The most powerful diuretic on the market.

Theophyllin (Boehringer und Sohn).—Prepared according to the German Patent 121,224 from uric acid (guano), by the action of acetic anhydride, converting the resulting 8-methylxanthine, after methylating, into a chlorine derivative, which, with water, breaks up into theophylline. A recent patent (No. 145,880) starts from synthetic caffeine (from guano), which, after chlorinating with a solution of chlorine in phosphorus oxychloride, yields 7·8-dichlorocaffeine; on further treatment with formaldehyde and hydrochloric acid, 1·3-dimethyl-8-chloroxanthine or chlorotheophylline results, which on reduction yields theophylline.

Santheose.—Theobromine of French origin Among the more recent interesting additions to this group is the

Caffeine Ethylene Diamine.—As shown by E. Fischer, the chlorine in chloro-caffeine is readily replaceable by amino groups. Besides amino caffeine, a number of substituted amino caffeines have been produced, and according as to whether one or both of the amino groups of ethylene diamine are linked, a caffeine ethylene diamine or a dicaffeine ethylene diamine results. It has been found that the former, which contains an unchanged amino group, is, in conjunction with its salts and acetyl derivates, a valuable diuretic.

The objectionable gastric disturbances which frequently accompany the use of salicylic acid or its salts, lead to the suggestion of a substitute in the old and well known glucoside salicin, which hydrolyses in the system into glucose and saligenin, $C_6H_4(OH)CH_2OH$. A condensation product of this saligenin and castania tannic acid (phlobaphene) has been introduced under the name of *Antiarthrin*. This castania-tannic acid is one of a class of tannins, which yield on hydrolysis a tannin phlobaphene instead of gallic acid.

Antirheumatics.

Ever since the introduction of salicylic acid as a remedy in the treatment of rheumatic affections, efforts have been directed towards the preparation of derivatives free from gastric irritation and tinnitis, which usually accompany the internal use of this acid and its inorganic salts. The depression of the heart, serious gastric disturbances and irritation of the kidneys, which clinical experiences have amply demonstrated as very frequently accompanying the use of the synthetic acid, have led many practitioners to resort to the acid prepared from natural sources, as the oils of birch and wintergreen, or these esters themselves, which, however, have been unpopular because of the very intense odour, causing in some instances severe headache, especially when employed externally. This disagreeable feature has been almost entirely eradicated in the following new esters :—

Mesotan (Elberfelder Fabr.).—Ericin. Salicylic methoxymethyl ester, $C_6H_4(OH)COOCH_2.OCH_3$, boils at 162° C., and is employed chiefly locally. It has a feeble aromatic odour.

Amylénol.—An unnecessary title for the old and well-known amyl ester of salicylic acid, $C_6H_1(OH)COOC_5H_{11}$, which boils at 270 C. This is employed externally and internally.

Glycosol (Merck).—Monosalicylic glycerol ester. This forms white crystals which fuse at 76° C. It is employed internally as well as externally.

Salacetol (Chem. Fabr. Ludwigshafen). — Salantol; Salicylacetol, an acetalkyl salicylic ester, $C_6H_4(OH)COOCH_2.CO.CH_3$, which fuses at 71° C. This preparation is also offered as an intestinal antiseptic.

Propionyl Salicylic Acid (Elberfelder Fabriken).—$C_6H_4(COOH)O.CO.C_2H_5$. A product of the action of propionic anhydride on salicylic acid, which fuses at 95° C.

Ulmarène.—A mixture of the salicylic esters of the higher aliphatic alcohols.

The most popular and successful of the salicylic acid derivatives introduced during recent years is

Aspirin (Elberfelder Fabriken).—Acetyl salicylic ester, $C_6H_4(COOH)O.COCH_3$. This product, which fuses at 135° C., passes unchanged into the intestinal tract, where it undergoes slow decomposition without producing any of the objectionable features of the free acid.

Methyl Aspirin, $C_6H_4(COOCH_3)O.COCH_3$, fuses at 48° C.

Rheumatin (Zimmer, Frankfort).—Salicylate of salicylic acid quinine ester, $C_6H_4(OH)CO.OC_{20}H_{23}N_2O$, $C_6H_4(OH)$ COOH. This forms tasteless white needles which fuse at 179° C., the preparation being free from gastric irritation.

Cordol.—Tribromo salol, $C_6H_4(OH)COO.C_6H_2Br_3$ fuses at 195° C.

Salcreol (Heyden, Dresden).—The salicylic acid ester of creosote, produced by the union of this acid with the active constituents of wood creosote.

Sodium p-Cresotinate, $C_6H_3(CH_3)(OH)COONa$. —Prepared similarly to salicylic acid by the action of carbon dioxide on *p*-cresol sodium.

Bromide and Iodide Substitutes.

Where it is desirable to subject the system for a considerable period of time to the action of these halides and to avoid the undesirable secondary effects such as usually accompany the use of the usual alkali salts, recourse may be had to such organic compounds of bromine and iodine as contain these elements in a loose state of combination, or those which readily split them off after digestion.

Bromalin (Merck).—Hexamethylene tetramine ethylbromide $C_6H_{12}N_4.C_2H_5Br$. While this preparation is less liable to produce bromine intoxication then the alkali bromides, yet it has not been successful because of its feeble action.

Bromocoll (A.-G. f. Anilinfab.).—A combination of bromine, tannin and gelatin obtained by precipitating a solution of brominetannin with gelatin. This contains 20 per cent. of bromine.

Bromipin and Iodipin (Merck).—These are bromo and iodo addition products of sesame oil which contain 10, 25, and $33\frac{1}{3}$ per cent. of either of the halogens. These preparations have been very successful therapeutically, being adopted for subcutaneous use as well as per os.

Bromolein.—A sterilized bromine addition product of the unsaturated fatty acids of almond oil which contains 20 per cent. of bromine.

Chloralacid (W. Gans).—This is stated to be a chlorinated albumin preparation containing 3 per cent. of halogen, obtained by the action of the gas on moist or dissolved albumins, peptones or albuminates.

Eigons (Helfenberg Act. Ges.)—Iodine and bromine derivatives of albumin which are of constant composition. α-eigon contains 20 per cent of iodine which is readily split off by acids or alkalies. β-eigon is an iodized peptone which is more readily assimilable than the α compound. The corresponding bromine compounds contain about 11 per cent. of this element.

Iodalbacid (W. Gans).—An iodo albumin preparation which contains 10 per cent. of iodine. While equal in activity to potassium iodide, it never produces the intoxication symptoms or other secondary effects peculiar to this salt.

Iodyloform (Kohlmeyer and Co., Berlin).—A combination of iodine and gelatin which readily splits off 10 per cent. of this halogen.

Iodolen (Kalle and Co.).—A combination of iodol and albumin; one preparation intended for external use contains 36 per cent. of iodol, while the other contains 10 per cent. of this antiseptic.

Lipbromol and Lipiodol.—Bromine and iodine derivatives of the poppy, nut or sesame oils, which contain $33\frac{1}{3}$ per cent. of the former and 40 per cent. of the latter

Tribromhydrin, $(C_3H_5Br_3)$, with *Tetra and Penta-Bromo-Acetone*, have proved likewise unsuccessful.

Inorganic Salts of Nucleinic Acids.—Nucleinic acid, a substance common to the blood corpuscules, organs, and vital tissues of the animal organism, has suggested itself as a means for the more ready and effectual administration of metals. The hypothesis that inorganic salts of the heavy metals pass into the blood only so far as they combine with the nucleinic acid, has been accepted as offering sufficient ground for the artificial preparation of such derivatives which would be more readily absorbed and utilised in the human organism. Aside from this, certain of these combinations are especially adapted for external use as antiseptics because of their penetrability, freedom from irritation, and decomposition by contact with albuminoids.

Thus combined, the metal deports itself quite differently from the other more common organic salts, in that the usual inorganic reagents fail to respond to any of the characteristic qualitative reactions. For example, copper nucleinate fails to turn blue upon the addition of ammonia water, nor does it react with hydrogen sulphide. The addition of chlorides fails to precipitate the silver from this combination.

Nucleinic acid may be obtained from the blood, salmon, sperm, and yeast; from the latter source the acid is prepared by extracting with an alkali, when, after acidifying with acetic acid, the albuminoids are coagulated by heating to 75° C.; from the filtrate the crude nuclein is precipitated by means of acidified alcohol. Purification is effected by careful oxidation with permanganate. The slightly alkaline nuclein solution is then brought into reaction with the salts of silver, mercury, iron, &c., and then precipitated through the addition of alcohol and a neutral salt.

In such combinations as the nucleinate or other albumin derivatives of the metals, the latter are retained in the albumin molecule in a masked (larvated) state beyond the reach of the usual inorganic reagents. In the case of the iron preparations we have a ready means of distinguishing this masked metal from that present in the form of the ordinary organic salts, as the peptonate, lactate, &c., in the well known Macallum's test. This consists in adding a few drops of a 1 per cent. solution of haematoxylin to the solution of the preparation, wherby a blue to blue-black coloration ensues if it belongs to the latter class.

Cuprol (Parke, Davis & Co.).—A compound of nuclein and copper which contains 6 per cent. of the metal.

Argyrol (Drs. Barnes and Hille).—A silver vitellin compound containing 30 per cent. of the metal.

Ferratogen (Baseler Fabrik).—An iron nuclein compound containing 1 per cent. of the metal.

Mercurol (Parke, Davis & Co.)—A mercury nucleinate containing 1 per cent. of the metal.

Nargol (Parke, Davis & Co.).—Nuclein silver which contains about 10 per cent. of silver.

Cacodylic Acid Derivatives (Arsycodyles).—During recent years considerable attention has been attracted to this class of arsenical derivatives, which have been introduced as relatively non-toxic substitutes for arsenous oxide or its older inorganic salts. As already noted, a material decrease in toxic action results through the introduction of alkyl groups in place of one or both hydroxyls in polyatomic phenols, as guaiacol and veratrol; this is particularly the case with the dimethyl arsenic acid or cacodylic acid, $(CH_3)_2As.O.OH$, and its salts. These combinations dissociate exceedingly slowly within the organism without exhibiting any symptoms of cumulative action. They have been employed with marked success in all diseases arising from disturbances in nutrition; also in tuberculosis, goitre, malarial cachexia, urinary diseases, &c.

Cacodylic Acid forms white soluble crystals fusing at 200° C. Among the salts of this acid are the cacodylates of mercury, magnesium, iron, strychnine, and guaiacol.

Arrhénal Arsynal, Stenosine, Sodiumarseno-methylate (Adrian & Cie., Paris).—This salt, of the formula $OAs(CH_3)O_2Na.5H_2O$, fuses between 130 – 140° C.

Triphenyl Arsine Oxychloride $(C_6H_5)_3As(OH)Cl$.—This preparation, which contains 20·9 per cent. of arsenic, is not broken up by the fungus *Penicillium brevicale*; hence, according to Kobert, is devoid of arsenical action, passing through the system in unchanged condition.

Glycero-arsenic Acid Salts.—These were introduced by Schlagdenhauffen and Pagel. $AsO(O_2\overset{II}{Me})O.C_3H_5(OH)_2 + 2H_2O$.

Atoxyl (Ver. Chem. Werke., Charlottenburg).—Meta-arsenic acid anilid $(C_6H_5NHAsO_2)$, which contains 37 7 per cent. of arsenic acid. Doses from 40 to 50 times greater than arsenous oxide are readily tolerated.

Histogénal.—A compound of nucleinic acid and methyl sodium arsenate.

Patent Foods.

By this term we refer to a class of solid food-products which have been prepared from various raw food-stuffs through the agency of chemical processes. Their purpose is to present readily assimilable and highly nutritious forms of food free from all unnecessary and useless ballast materials, such as are necessary in the treatment of diseases of the digestive organs or in cases where the healthy functions of these organs are impaired or still further as a prelude to solid food for patients convalescing from disease or surgical operations. According to the class or classes of food material represented and the condition in which they are present, these products may be divided into the following general classes:—

1*st. Soluble Predigested Foods of the Somatose Type.*—These consist chiefly of albumoses prepared from meat or other forms of albumin. In addition to their general nourishing properties these preparations are especially adapted in diseases of the alimentary canal because of their freedom from irritating effects and stimulating action on the appetite and general nourishment.

2*nd. Highly Concentrated Nutritious Foods:* (*a*) *Insoluble Foods of the Tropon Class.*—These are mixtures of carbohydrates and albuminoids of vegetable and animal origin.—(*b*) *Soluble Concentrated Albumins of the Casein Type.*

3*rd. Infant Foods.*—These consist of mixtures of albumin, carbohydrates and fats. The class of meat extractives which possess purely stimulating properties, and cannot be classed as foods, are omitted from this list.

Class I. Soluble Predigested Foods of Somatose Type.—The crude proteids employed in this class have undergone a preliminary artificial or natural digestion, either through the agency of animal or vegetable enzymes or organic or inorganic acids, or the agency of superheated steam under pressure or *in vacuo.* The products aimed at in most cases are either pure albumoses or mixtures of these with some peptone. The presence of much peptone is objectionable, because of the bitter taste imparted, as well as the tendency, in conjunction with atmid-albumose, to produce intestinal irritation causing diarrhœa. One of the first of this class to be introduced was—

Somatose (Elberfelder Fabriken).—This is an artificially digested meat albumin containing 51·6 per cent. of deutero and 13·4 per cent. of hetero albumoses, 5 per cent. of peptone, 11 per cent. of moisture, and 5 per cent. of nutrient inorganic salts. Iron Somatose is a similar preparation, containing 2 per cent. of iron in organic state of combination. Milk Somatose is a soluble nutrient prepared by the same digestive process from casein containing 5 per cent. of tannin.

Carnigen.—A soluble nutrient containing albumoses, which, according to Denayer, consists of 52·12 per cent. of albuminoids, 24 per cent. of meat extractive, 4 per cent. of meat salines, and 10 per cent. of water. The total nitrogen is 12·6 per cent., of which 8·7 per cent. consists of albuminoid nitrogen and 3·9 per cent. of extractive nitrogen.

Heyden's Nutrient (Nährstoff) (Chem. Farbik v. Heyden).—An albumose prepared from egg albumin containing 85·31 per cent. of proteids, 6 per cent. of inorganic salts, and 2·36 per cent. of water. This preparation is intended only as an addition to foods.

Mietose (Eiweiss und Fleisch Ext. Co., Altona, Hamburg).—A meat albumose preparation; an almost chemically pure albumose, which swells when in contact with water.

Fersan (Dr. H. Byk, Berlin).—A ferruginous paranucleo proteid, which contains 0·25 per cent. of phosphorus and 0·12 per cent. of iron in organic state of combination with 90 per cent. of albumin.

Alboferrin (Drs. Fritz and Sachsse, Vienna).—A ferro-phospho albumin preparation, containing 0·68 per cent. of iron, 0·32 per cent. of phosphorus, and 90·14 per cent. of albumin.

Triferrin (Knoll & Co., Ludwigshafen).—A ferric paranucleinate obtained by precipitating the phosphorus that has passed into solution during peptic digestion of casein by means of a ferric salt. It contains 22 per cent. of iron, 2·5 per cent. of phosphorus, and 9 per cent. of nitrogen.

Alcarnose (J. O. Riedel, Berlin).—An albumose preparation of mixed foods, containing 23·6 per cent. of albumoses, 55·3 per cent. of maltose, dextrin, and dextrose, 17·7 per cent. of emulsified fat, and 3·4 per cent. of nutrient salts. (Allegemein. Med. Cent. Zeit., 1899, 93).

Class II. Highly Nitrogenised Concentrated Foods. (a) *Soluble.*—Much attention has during recent years been attracted to the class of insoluble albumin preparations of the Tropon type, in which cheaper grades of raw albuminoid matter—as fish, refuse meat, dried blood, gluten, peas, lentils, and other vegetables—after treating with diluted acids, are deodorised and decolourised by means of such oxidising agents as hydrogen peroxide, or chlorine. This idea was originated by C. Cosineru, who in 1890 attempted to utilise blood albumin as a commercial nutrient by treating with alcohol containing a little acid, followed by chlorine, potassium permanganate, or hydrogen peroxide. At that time no market was found for this class of nutrients. During the last few years a demand has been created for a highly nourishing concentrated food within the financial reach of the masses, which has been met by members of this type.

Tropon (Tropon Werke, in Mülheim-on-Rhine.)—Proposed in 1890 by Prof. Finckler (Bonn), and prepared according to the patent, by removing from mixed albuminoid matter (1 part of animal to 2 parts of vegetable), such as fish, refuse meet, gluten, legumes &c., all gelatinous substances by extraction with boiling water, the insoluble residue is then treated with 10 per cent. of hydrogen peroxide and finally extracted with ether. All malodorous, coloured substances, bacteria, &c. are removed while the albumin molecule remains intact. Since 1893 the tropon patent has substituted nascent chlorine for hydrogen peroxide. Tropon contains 99 per cent. of pure albuminoid matter. A mixture of tropon with dextrinized flour is called Tropon-Sano. Iron Tropon contains 50 per cent. of Tropon and 2·5 per cent. of iron. The nutritive value of 1 pound of Tropon is stated to be equivalent to that of 5 pounds of beef.

Soson (Eiweiss und Fleisch Ext. Co., Altona, Hamburg)—An albuminoid nutrient, prepared from dried powdered meat in which boiling alcohol under pressure is employed for the extraction, in place of heating under ordinary conditions as recommended by Cosineru.

Carnigen.—An albumose diatetic containing 52 per cent. of albuminoids, 24 per cent. of meat extractive, 3·9 per cent. of salines and 9·9 per cent. of water. Of like nature are *Aliment Complet* (Groult), *Nutralbin* (Fletcher & Co.), a mixture of casein, meat fibrin, cacao and digestive ferments, and Oxine (Oxine Co., London), which is stated to be a "concentrated" food from flesh and vegetables.

Globon (Lilienfeld, Vienna).—Occupies an intermediate position between acid albumin and albumose, prepared by a process in which vegetables and animal paranucleins containing phosphorus and free alloxuric bases are subjected to a decomposition in which the paranucleinic acid becomes detached, while the albumin group remains (Lilienfeld). According to Kronfeld (Wiener Med. Wochenschr. 44·99). Globon is a product of the splitting up of casein. However the analysis of this food tallies closely with that of casein. A class of leaven extracts prepared after different patent processes, in which this waste material of the breweries has been utilized as a nutrient in view of its high content in nitrogenous matter and phosphates, is represented in the Belgian preparation called "Bois" (Eurostose) and the English "Carnos". These form agreeable tasting albumose products of the artificial yeast digestion.

Carnos.—Prepared according to the English patent. 284,348, of O. Overbeck, Grimsby, in which compressed yeast is boiled with water until its cell structure is completely destroyed, then, on cooling to 60° F., one-sixth to one-half part of germinating malt is added and digested for three hours at this temperature. Finally, the product is boiled for half-an-hour, adding sufficient milk of lime to neutralize and clear. The resulting fluid, which contains yeast cells and some malt, is filtered and concentrated.

Mutase (Chem. Fab., Weiler-ter-Meer, Uerdingen-on-Rhine).—A dextrinated meal prepared from leguminous plants and other vegetables by digestion with diluted acids or saline solutions. According to E. Koch (Merck's Report, 99—107) Mutase contains 60 per cent. of vegetable albumin, about 18 per cent. of nitrogenous extractive, 10 per cent. of saline matter, 10 per cent. of water, and 2 per cent. of phosphorous acid.

Sitogen (Sitogen Ext. Co., Loebau, Saxony).—A compound yeast extract which serves as a nutritive food, also as an addition to soups, according to Dr. Filsinger. Sitogen consists of 25·9 per cent. of water and 74·1 per cent. of dry extractive, of which 13·8 per cent. are inorganic salts, 11·84 per cent. of non-nitrogenous extractive, and 48·44 per cent. of nitrogenous matter. This latter contains 1·68 per cent. of albumoses, 0·12 per cent. of insoluble albuminates, 1·43 per cent. of ammonium salts, and 45·21 per cent. of meat bases.

Among preparations of exclusive vegetable origin are—

Plantose.—An aqueous extract of oil cakes resulting from the expression of rape-seed oil. The product contains 12 to 13 per cent. of nitrogen.

Roborat (H. Niemoelle., Gütersloh, Westf.)—A dextrinised albuminoid nutrient prepared from wheat, corn, and rice by precipitating the albuminoid matter from solution and drying. This preparation contains 10·6 per cent. of water, 79·2 per cent. crude proteids, 4·1 per cent. of ether extract, 4·4 per cent. of starch, 0·2 per cent. of fibre, 1·3 per cent. of ash, and 0·09 per cent. of lecithin phosphoric acid. Iron-, Kola-, Tannin and Creosote-Roborat are prepared.

Aleuromat (Niemoelier, Guetersloh).—A wheat gluten preparation containing 7·2 per cent. of moisture, 80·8 per cent. of crude proteids, 5·6 per cent. of ether extract, 6 per cent. of starch, 0·2 per cent. of fibre, 1·3 per cent. of ash, and 0·04 per cent. of lecithin phosphoric acid.

Energin.—A preparation consisting of the proteids or rice, prepared by treating the latter with alkalies and precipitating the dissolved proteid matter by neutralization with an acid. According to Wintgen dry energin contain, 92 per cent. of dry proteid substance, 5 per cent. of ether extractive, 0·74 per cent. of starch and 1·13 per cent. of ash.

Typical representatives of a class of prepared cereal foods are the American products, "*Force*" and "*Malta Vita*."

Force is prepared from carefully assorted and cleaned wheat, which is steeped in a malt wort for five to six hours at a temperature ranging from 55 to 65° C. The malt wort which is not absorbed is then drawn off, and the remaining soaked wheat is subjected to a process of steaming and cooking under pressure. This steamed or cooked whole wheat is then allowed to cool, dried, and sufficient salt added. After it is completely dried, the whole wheat is transferred to mechanical steel rollers, in which every individual grain is pressed so as to produce the flaky condition of the product. These flakes are then carried to an oven, in which they are toasted and roasted, so as to obtain the crispness, at the same time developing the aromatic bread flavour and producing partial conversion of the starch into dextrins. It is then directly transferred to packages, which are each filled automatically and also sealed and labelled by machine.

Malta-Vita is likewise made from whole wheat only. The difference in its method of preparation from the above seems to be that the grain is not steeped in malt extract, but after steaming and cooking a concentrated malt extract is added to the whole grains just before flaking. The product is then salted and toasted. The percentages of maltose, dextrins, and soluble carbohydrates present in the Malta-Vita exceed those of Force considerably.

Class II. (*B*) *Soluble Casein Derivatives.*—Salkowski was the first (1894) to call attention to casein as a nutritive, demonstrating its complete absorption in the intestinal canal and high nourishing qualities. Owing to the insolubility of casein, advantage is taken of its property of forming soluble salts with such alkalies as sodium bicarbonate and ammonia, also double salts with the phosphates, glycero-phosphates and citrates of sodium, potossium and calcium. The first of this class to be introduced was—

Eucasin (Magert and Ewers, Grunau, Berlin).—A casein-ammonia obtained by passing ammonia gas over dry and finely pulverised casein. 30—40 grms. of eucasin (which contains 95 per cent. of albuminoid matter) correspond to 24—32 grms. of albumin.

Nutrose (Hoechster Fabrik).—A casein-sodium which toward phenolphtalein is the acid sodium salt. According to Aufrecht, nutrose contains 65·2 per cent. of albumin, 10·5 per cent. of water, 4·15 per cent. of inorganic salts, and 20·15 per cent. of non-nitrogenous matter.

Plasmon (Plasmon Company of America).—The freshly precipitated casein of skimmed milk, after mixing with a just sufficient quantity of sodium bicarbonate, is kneaded and dried at 70 C. in an atmosphere of carbonic acid. Plasmon contains 10·7 per cent. of moisture, 7·2 per cent. of inorganics, 0·7 per cent. of milk fat, and 81·3 per cent. of protoids. The dry Plasmon contains about 90 per cent. of pure proteid.

Sanatogen (Bauer & Co., Berlin).—A glycero-phosphate of sodium casein which contains 95 per cent. of albumin, and 5 per cent. of sodium glycero-phosphate.

Calcium Caseinate (Gesellschft. diaetet. Prod., in Zürich).—A casein calcium-phosphate intended to compete with Bauer's Sanatogen. It possesses an objectionable odour.

Galactogen (Theile and Holzhausen, in Berleben).—A casein-alkali preparation.

Some casein preparations contain excessive quantities of alkali, which in view of the fact that they are taken in large doses extending over greater periods of time, are open to serious objections. In view of overcoming this objection Schering introduced—

Sanose (E. Schering, Berlin).—An albumin preparation containing casein 80 per cent., and albumose 20 per cent.

Tannocasum (G. Romijn).—A casein tannate obtained by dissolving 1 kilo of casein by aid of sodium carbonate in 10 litres of water, and after adding a solution of 700 grms. of tannin in 3 litres of water with 100 c.c. of formaldehyde, the mixture is supersaturated with dilute hydrochloric acid. The precipitate is collected, washed, and dried. This preparation is employed largely as an intestinal astringent.

Casumen (Protein).—An English preparation consisting of casein only.

Class III. Mixtures of albumin, fats, starches, and dextroses, popularly known as *Infant Foods.*—This class of foods is so well known that attention is called to only a few of the more important newer preparations as—

Odda (Schnelke and Mayer, Hamburg).—A new infant food prepared according to the directions of Prof. Mehring, chiefly distinguished by the replacement of the fat and difficult digestible casein of cow's milk, by the yolk of eggs and cacoa butter. This was suggested by the observation that the butter-fat of cow's milk contains about 10 per cent. of volatile fatty acids, while the fat of mother's milk contains only 1·5 per cent. The glycerides of these volatile fatty acids readily hydrolize in the stomach and the liberated acids cause irritation of the intestinal mucous surfaces. This preparation contains 14·5 per cent. of albumin, 6·5 per cent. of fat, 71·5 per cent. of carbohydrates, 0·4 per cent. of lecithin, 2·1 per cent. of inorganic salts, 1·1 per cent. of phosphoric acid and 5·4 per cent. of water.

Theinhardt's Hygiama.—A mixture of milk, flour, malt cocoa and sugar which contains 27 per cent. of albumin, 10 per cent. of fat, 60 per cent. of soluble carbohydrates, and 3·5 per cent of inorganic sults.

Eulactol (Nahrmittel Werke, Act.-gesellsch., Cologne).—A nutrient prepared from milk and vegetable albumin, containing albumin, fats, carbohydrates, and salts.

Enterorose (Gesellschaft für Diatetische Praeparate, Zuerich).—A preparation of vegetable albumin impregnated with an extract of beef and diastase. It contains 18 per cent. of vegetable albuminoids, 11 per cent. of fat, 3·8 per cent. of inorganic salts, and 59·5 per cent. of carbohydrates. The ratio between albumins, fat, and carbohydrates is the same in this preparation as in milk.

Belonging to the Theinhardt's type of food are the well known foods of Nestlé, Mellin, Horlick, and the Ideal. To the class of cereal foods belong the Imperial Granum, Ridge's Food, and Gerber's Food.

Tabular List of Manufacturing Firms.

A.-g. f. Anilinf. = Aktiengesellschaft für Anilinfabrikation, in Berlin.
Baseler Fab. = Baseler Chemische Fabrik, Basel.
Boehringer = C. F. Boehringer und Soehne, Fabrik chem. Producte, Waldhof b. Mannheim.
Chem. Fab., Ludwigshafen = Chemische Fabrik vormals Hoffmann, in Ludwigshafen.
Chem. Fab., Guestrow = Drs. Hillringhaus und Heilmann, Guestrow.
Erdmann, Leipzig = C. Erdmann, Leipzig, Lindenau.
Elberfelder Fabrik = Farbwerke vormals Fried. Bayer und Co., in Elberfeld.
Fritzsche, Hamburg = Fr. Fritzsche und Co., Hamburg.
Gans, W. = Pharmaceutische Institut, Ludwig Gans, Frankfurt a.-Main.
Henning, Berlin = Dr. G. F. Henning, Berlin, S.W., 48.
Hell and Co. = Hell und Co., Troppau, Silesia.
Heyden, Dresden = von Heyden, Chem. Fabrik, Dresden-, Radebeul.
Hoechster Fabrik = Farbwerke Meister, Lucius und Bruening, in Hoechst-on-Main.
Hoffmann, La Roche = F. Hoffmann, La Roche Co., Basel.
Helfenberg Akt.-gesell. = Chemische Fabrik, Helfenberg Aktiengesellschaft, in Helfenberg, Saxony.
Ichthyol Gesellsch. = Ichthyolgesellschaft, Hamburg.
Kalle and Co. = Kalle und Co., Biebrich-on-Rhine.
Knoll and Co. = Knoll und Co., Ludwigshafen-on-Rhine.
Lingner, Dresden = Lingner's Chem. Laboratorium, Dresden A.
Lehmann, Berlin = Berliner Capsule Fabrik, J. Lehmann, in Berlin.
Majert, Berlin = Majert und Ebers, Gruenau, Berlin.
Marquardt = Chemische Fabrik vormals M. Bevel, Bonn.
Merck = E. Merck, Darmstadt.
Moeller, Hamburg = Moeller und Linsert, Hamburg.
Rhenania Fabrik = Chemische Fabrik "Rhenania," Aachen.
Riedel = Chem. Fabrik J. D. Riedel, Berlin.
Schering, Berlin = Chemische Fabrik auf. Aktien vormals E. Schering, Berlin.
Schuetz, Gummersbach = Schuetz u. Dallmann, Gummersbach, Rheinland.
Valentiner, Leipzig = Valentiner u. Schwartz, Leipzig, Plagwitz.
Ver. Chem. Werke = Vereinigte Chemische Werke Aktiengesellschaft, in Charlottenburg, Berlin.
Zimmer, Frankfurt = Vereinigte Chininfabriken, Zimmer u. Co., Frankfurt-a.-Main.

RARE-EARTH MORDANTS.

BY CHAS. BASKERVILLE, PH.D., F.C.S., AND
T. B. FOUST, B.S.

During the progress of a number of investigations of the chemistry of the rare earths, we have sought incidentally to utilise the by-products obtained in the manufacture of the Welsbach mantles. On reviewing patent and other literature of the rare earths and mordants, no mention of a patent for the use of rare earths as mordants has been found, nor any record of work along this line, either in the United States, England, France, or Germany, with the exception of one paper by Prud'homme, who wrote on "Mordants in Dyeing and the Theory of Mendeleeff" (Chemical News, **63**, 193). This work in no way influenced what is herewith reported. After the completion of the work, Waegner and Mueller published an article upon "The Use of the Rare Earth Metals in Dyeing" (Zeits. f. Farben- u. Textil-Chem., 1903, **15**, 290; see this Journal, 1903, 946).

The compounds of the rare earths used were praseodymium hydroxide, neodymium, lanthanum and praseodymium acetates and a mixture of the sulphates of these elements, so-called "pink-salts." They showed no marked value, although in the majority of cases slight differences were produced, and in a few the variation was very marked. The rare earth compounds, under the conditions of our experiments, possess no very valuable properties as mordants, although from the facts observed, indications were had that a stricter adherence to the application of mordant dyes and the use of the oxidising agents would furnish a larger number of instances of notable change. The application to silk and wool was undertaken to supplement the work on cotton, and only such work as would furnish comparative results was deemed necessary. In some cases the salts used showed mordanting action, but the colours produced were not of a bright shade, and not always very fast to washing. The rare earths can have little practical application as mordants, for the following reasons:—(1) because they do not possess the mordanting action to a degree which would allow competition with known mordants; (2) because the supply is somewhat limited, and would not admit of extended use; (3) their cost, which, even in the event of the first and second considerations being favourable, would bar their practical use extensively. Therefore, it is only a matter of theoretical interest that we note this property of the rare earths.

As far as possible, uniform conditions were preserved throughout in the experiments, and, where no favourable results were obtained, the conditions were varied. All the cotton used was in the form of yarn made into small hanks, and was thoroughly "wetted out" by boiling in a 4 per cent. solution of sodium carbonate, bleached with chloride of lime and wetted before dyeing. The dye baths were made up in quantity, and divided into smaller portions for application to the various mordants. The heating was carried out on a large water bath, which would accommodate all the baths at once, and the washing after treatment was made as nearly the same for each dye as possible. Mordanting with acetates was carried out in a 10 per cent. solution of the salts after treatment with an acetic acid bath. The cotton was boiled for two hours in this bath, drained, squeezed out, and dried in an air oven at 80° C. until practically all the acetic acid was driven off. This was determined by the odour. The remaining acid was not neutralised, as it was found that a precipitate was formed when neutralisation was attempted with 1 per cent. soda solution. Hence the dyeing was performed in baths made slightly acid with acetic acid. Mordanting was also tried by allowing the cotton to remain over night in the mordant bath, squeezing out, passing through a 10 per cent. soda solution and dyeing. Precipitation took place in the carbonate solution, and no results of value were obtained. Cotton was mordanted with a mixture of the rare earth sulphates, neodymium, praseodymium and lanthanum sulphates, by entering it into a saturated solution of the salts, and boiling for an hour and a half. In some instances during this boiling the nona-hydrated sulphates separated. The skeins were well squeezed and allowed to drain. No perceptible difference was observed when the mordanting was accomplished by allowing the yarn to remain in a cold solution over night. Praseodymium hydroxide was also suspended in cold water in which the cotton was allowed to remain overnight. No effort to use nitrites was made.

For the use of basic dyes, the treatment with tannic acid in connection with the rare earth sulphates was tried. The cotton was entered cold in a solution of tannic acid, just sufficient of the solution being used to cover the cotton; the temperature was then raised to 40° C., and maintained for two hours. It was then worked for 30 minutes in a cold, saturated solution of the rare earth sulphates, squeezed out and dried.

Only the rare-earth sulphates were used to mordant wool. The wool, after being thoroughly wetted by boiling in water for one and a half hours, was placed in a lukewarm bath with a mordant to which a little sulphuric acid had been added. The temperature was gradually raised to 100° C. during one hour and boiled for one and a half hours longer; the wool was removed from the bath and allowed to drain over night.

Silk was entered into the mordant cold, and allowed to stand over night, removed, squeezed, and rinsed slightly to remove excess of nitrate and passed into the dye bath. In every case an unmordanted skein was dyed to furnish a basis of comparison. The results obtained were largely negative. The following dye-stuffs were used:—Bismarck Brown, Malachite Green, Methyl Violet, Chrysoidin, Tropæolin, Alizarin Blue, Alizarin, Logwood, Eosin, Fuchsin, Aniline Red, Aniline Blue, and Diamantgelb.

It may be well to call attention, briefly, to those samples which showed most marked differences from the unmordanted skeins, mentioning the dyestuff and mordant used.

Malachite Green with neodymium acetate.
Malachite Green with lanthanum acetate.
Malachite Green with tannin and sulphates.
Malachite Green with praseodymium hydroxide.
Malachite Green with rare earth sulphates.
Chrysoidin with tannin and sulphates.
Chrysoidin with praseodymium hydroxide.
Tropæolin with rare earth sulphates.
Tropæolin with praseodymium hydroxide.
Alizarin Blue with tannin and sulphates.
Alizarin Blue with rare earth sulphates.
Alizarin with rare earth sulphates.
Logwood with neodymium acetate.
Logwood with rare earth sulphates.

In spite of the obstacles in dyeing small quantities, namely, the difficulties of working to obtain even dyeing, heating the baths uniformly, &c., the results obtained show that the salts used have not been without effect upon the dyes.

We have to thank the Welsbach Incandescent Lighting Co., Gloucester City, N.J., for providing the materials used in the above research, and permission to publish the same.

Sydney, N.S.W., Section.

Meeting held at Sydney, on December 16th, 1903.

PROF. LIVERSIDGE, F.R.S., IN THE CHAIR.

THE BACTERIAL ORIGIN OF THE VEGETABLE GUMS.—PART I.

BY R. GREIG SMITH, D.SC.

The vegetable gums until about a year ago were supposed to be the products of certain trees in an unhealthy or pathological condition, and beyond that really nothing was known regarding their origin. It is true that it had been claimed that certain moulds induced the plant to secrete the gum, and that bacteria had been observed in the slime-flux of certain trees, such as the oak, but a definite relation between the gum and a causative agent had not been brought forward. In 1901, Marshal Ward (Disease in Plants, London), said "beyond the fact that *gummosis* (gum-flux) is a pathological phenomenon, we know very little of the disease."

I began my researches into the origin of the gums with the belief that bacteria were responsible for their production. Many facts connected with the gum and its distribution pointed to a mycological formation, and among the moulds, yeasts, and bacteria, the latter were the most promising gum producers. I have contributed several papers upon my investigations to the proceedings of the Linnean Society of New South Wales, and in this paper I propose to collect such data as would appeal to the chemist who might have more than a passive interest in an important industry, and to whom my original papers may not be accessible.

The research began with the examination of two trees, one of which, *Acacia penninervis*, exuded a pale yellow gum, partly soluble in water; the other, *Acacia binervata*, yielded a product which varied from colourless to dark brown, and was entirely soluble in water. From the bark of the latter, a bacterium which I have named *Bacterium acaciæ*, was obtained in pure culture, and from the former two bacteria were isolated. One of them was *Bacterium acaciæ*, the other was named *Bacterium metarabinum.*

Many gum bacteria when removed from their natural habitat do not form their typical products readily, and both of these bacteria come under this category. In the ordinary media of the bacteriological laboratory they grew easily enough, but the formation of gum was suggestive rather than actual. Still, although the yield was small, sufficient was obtained to show that the bacteria were really gum-formers. The most suitable medium was one containing saccharose, potato juice, and agar, and this produced a luxuriant crop of cells with a small quantity of slime. Acting upon an observation that the tissues of the tree, adjoining a wound through which the gum oozed, were acid and contained tannin, I added tannin to the medium. Instead of a thin watery growth of bacterial cells in the plate cultivations, there was produced a luxuriant thick slime, which could easily be removed from the agar surface. The ready removal of the slime is an important point, for it must be remembered that agar-agar is allied to the vegetable gums, inasmuch as it is a pararabin, and if the slime could not be easily taken off it might become contaminated with fragments of agar. I have grown many different gums on this or similar tannin agar, and also, for purposes of comparison, in fluids, and in no case have I found any difference between the gums obtained from the solid or from the fluid cultures. No constituent capable of being detected is removed with the slimes. As an example of the luxuriance of the slime growth, it may be mentioned that in some cases 5 grms. have been scraped from the surface of 20 c.c. of agar medium in an ordinary 9 cm. Petri-dish.

The raw bacterial product is not a gum. It is a slime and consists of gum, together with bacterial cells and albuminoids, the latter of which are undoubtedly responsible for giving the gum a slimy consistency. Before proceeding to obtain the gum, the slime was freed from sugars by repeatedly coagulating its aqueous suspension with alcohol. After a repeated coagulation the slime was generally found to be free from saccharose and reducing sugars. In the second or subsequent coagulation it was sometimes necessary to add a few drops of a 10 per cent. solution of potassium chloride when the slime showed signs of being "milked" by the alcohol. Having been so far purified, the slime was ready for the separation of the gum. This was effected by heating or digesting the watery slime in the autoclave at a pressure of three atmospheres for a quarter of an hour. In some cases a longer digestion was necessary, in others the addition of a drop or two of dilute sulphuric acid was beneficial. The treatment coagulated the albuminoids which carried down the bacterial cells, leaving the gum dissolved in the clear supernatant liquid. In a few cases when the solution was faintly opalescent, aluminium hydroxide effected a clarification. This method of digestion not only enables the majority of the bacterial gums to be obtained from their slimes, but it also converts many of the insoluble vegetable and bacterial gums into soluble modifications. These, however, generally revert to their former insoluble condition upon desiccation. I thought the process was new, but recently I have found that the method is used commercially for the solution of the metarabin gums of the cherry and other fruit trees. (Andés, Gummi arabicum und dessen Surrogate, Leipzig, 1896, 41).

The solution of the bacterial gum when evaporated to dryness gave a clear transparent and brittle gum like a similarly treated solution of arabin from gum Arabic. When the thick gum mucilage was tested dropwise upon glass, as recommended by Maben, it gave the general reactions of gum acacia. The arabin obtained from the gum of the tree from which the bacteria had been isolated gave the same reactions. The bacterial and the natural gums gave furfural upon distillation with hydrochloric acid and furnished crystalline plates of mucic acid upon oxidation with dilute nitric acid. The filtrates from the mucic acid contained oxalic acid. Thus the bacterial gum gave the same reactions and the same decomposition products as the natural gum.

The vegetable gums constantly vary in their optical activity, as shown by many writers, and in view of the different conditions surrounding the birth of the natural and of the laboratory gum it seemed to be extremely improbable that the rotation of the two gum acids would be the same; upon examination, the rotatory power was found to be widely different, that of the natural acids being practically zero ($[\alpha]_D = + 0°\cdot9$) while the bacterial gum acids were dextrorotatory ($[\alpha]_D = + 43°$).

Although the two gums have been shown to possess many chemical properties in common, there remained the question of the identity of the products of hydrolysis. In identifying the sugars obtained from all the bacterial gums which I have prepared I have trusted entirely to the recognition of the osazones. By doing so I have been enabled to work upon a comparatively small quantity, for although I have said that the growth of slime upon the tannin media was luxuriant, yet as it contains but from 3 to 4 per cent. of total solids, it is evident that much slime would require to be grown in order to obtain a quantity of arabin sufficient for the recognition of the sugars by other methods. The preliminary experiments in the hydrolysis and detection of the sugars were made upon the natural gum, and a scheme was gradually elaborated. In the few cases in which bacterial gums have been examined by other investigators there have been obtained osazones, the melting points of which gave no clue to their identity, or else the author has affirmed that he did not have enough material to justify the purification of the osazone. A method for the purification of the osazones of the bacterial gums was apparently wanted and my investigation showed that it could be easily done.

The gum after being freed from adhering sugars was hydrolysed by boiling with 5 per cent. sulphuric acid for about five hours. This treatment, as a rule, converted the gum completely into reducing sugars. The so-called fractional hydrolysis (*i.e.*, heating the gum with 2 per cent. acid on the water-bath for 15 minutes), did not recommend itself, for not only the arabinan, but the gum complex as a whole was hydrolysed. I found it much quicker to hydrolyse the gum completely and to separate the osazones afterwards. This saved the separation of the unaltered gum and the double preparation and separation of the osazones. The completion of the hydrolysis was made evident by the absence of matter precipitable by alcohol and by the presence of reducing sugars in a small abstracted and neutralised portion.

The hydrolysed solution was neutralised with barium carbonate, filtered, evaporated, clarified with aluminium hydroxide and warmed upon the water-bath. Two c.c. of a recently prepared solution of phenylhydrazine acetate (phenylhydrazine, 4 c.c.; glacial acetic acid, 4 c.c.; water, 2 c.c.) were added, and the beaker was kept in the steam for half-an-hour. It was then rapidly filtered through a hot wet filter in order to remove a tarry deposit. To the filtrate another two or more c.c. of phenylhydrazine acetate solution were added and the heating continued for another hour and filtered as before. The filtrate upon cooling deposited the osazones. The bulk of the black tarry impurity and unaltered base were removed by the filtrations and the remainder was in most cases eliminated by percolating the dry osazones with ether. With some galactan gums this impurity was not entirely extracted by this simple method. The osazones had either to be precipitated by cooling a hot saturated alcoholic solution when the quantity was large, or the osazones were successively extracted with ether and cold water when the quantity was small.

The separation of the purified osazones of arabinose and galactose was accomplished by taking advantage of the fact that arabinose is more soluble in hot water and in alcohol than galactose. The mixed osazones were either treated with hot water and then with hot solutions of alcohol of increasing strengths, or they were completely dissolved in hot concentrated alcohol which was slowly evaporated, hot water being added to maintain the original volume. Both methods were fractional, and galactosazone was obtained at one end and arabinosazone at the other. The intermediate fractions consisted of mixtures of the two. The end products were found to be pure by microscopical examination, and by their inability to be resolved into fractions with differing melting points. In the microscopical examination, oil globules and amorphous particles were sought for; the presence of these would show that the purification of the osazone had not been complete. The intermediate fractions were either treated as before or they were grouped together before treatment according to their respective melting points. With arabinosazone and galactosazone a little experience enabled the operation to be quickly performed.

In the case of another slime which hydrolysed to galactose and a glucose, much the same treatment was followed in separating the osazones. By the gradual addition of strong alcohol, the galactosazone dissolved, leaving the glucosazone. Again, by the complete solution in hot strong alcohol and gradual addition of water, the glucosazone was made to precipitate before the galactosazone. Both methods depended upon the relatively greater solubility of galactosazone and insolubility of glucosazone in alcohol.

To return to the gum of *Bact. acaciæ*, it was found that it hydrolysed to a mixture of arabinose and galactose. The natural gum of *Acacia binervata* also hydrolysed to these sugars in apparently the same proportions. It has, therefore, been shown that the bacterial gum and the natural gum were chemically identical, and as the organism was found in the tree and in the places from which the gum was exuding, and furthermore as the fresh gum contains myriads of dead bacteria, it is to *Bact. acaciæ* that the origin of the gum must be ascribed.

The natural gum of the other tree, *Acacia penninervis*, consisted of a mixture of arabin and metarabin, or cerasin. Metarabin swells with water, forming gelatinous lumps which may slowly dissolve, or may not, according to the age of the gum. It is dissolved in the sap of the plant, and becomes insoluble when the gum dries. As I have already mentioned *Bact. acaciæ*, the arabin former, and another, *Bact. metarabinum*, were isolated from the tissues of the plant. *Bact. metarabinum* grew as stiff cohesive colonies upon ordinary media; the wrinkled appearance and leathery consistency of the colonies suggested the presence of an insoluble gum. Upon saccharose-potato-agar it grew as a thick slime, which, while not so thin as the slime of *Bact. acaciæ*, was still capable of being easily removed from the surface of the medium. Upon digestion in the autoclave, the slime yielded a solution of a gum which behaved to reagents like arabin; when the digestion was conducted with care, the gum was converted into the insoluble form upon drying or by treatment with alcohol. In this condition it swelled with water, forming an unfilterable jelly. The dehydration had converted the gum into a substance like metarabin, and, like a typical metarabin, it was insoluble in dilute alkali. Boiling dilute sulphuric acid hydrolysed it to arabinose and galactose. The metarabin of the natural gum behaved in precisely the same way. Thus the bacterium undoubtedly produced a metarabin gum, and to its activity must be ascribed the formation of the metarabin portion of the natural gum.

Concurrent with the formation of gum in solutions of saccharose, there was a production of carbon dioxide, ethyl alcohol, and acids. The carbon dioxide was small in amount, and was detected by aspirating the air in closed culture flasks through baryta water. The alcohol was also small in amount, and was obtained upon distilling a fluid culture containing chalk, after saponification with barium hydroxide. The acids as formed in fluid cultures containing chalk were found to be *l*-lactic and acetic, with traces of succinic, lauric, oxalic, and formic. The ratio of non-volatile to volatile acids was roughly three to one.

The method which I have found most useful for the detection of the bacterial acids is as follows:—A 20 or 30 days' culture containing chalk is decanted, and the fluid is evaporated down to small volume. Both fluid and residual chalk, &c., are acidified with dilute sulphuric acid, cooled and filtered. The calcium sulphate residues are added together, drained by means of the filter-pump, washed with a small quantity of water, and dried in the air, or in an incubator. The fluid, together with the washings from the residues, are extracted in an ether extraction apparatus such as that of Schoorl (this Journal, 1900, 567).

The dried calcium sulphate is ground to a rough powder and extracted either within a perforated tube in the same apparatus or else in a Soxhlet apparatus. The ethereal solutions are slowly distilled and the ether recovered. The residual solutions are exposed to the air until the odour of ether disappears. Hot water is added, and the insoluble acids that separate are removed by filtration and examined. As a rule, the insoluble acids are chiefly obtained from the calcium sulphate residue. The filtrates from the insoluble acids are added together and distilled in a current of steam until all the volatile acids have passed over, or until the distillate has a constant acidity. The volatile acids are then divided. One portion is neutralised with sodium hydrate, evaporated to small volume, and treated with silver nitrate to precipitate the acetic acid; the filtrate from the silver acetate is placed under observation for the blackening caused by formate. A portion of the second half of the volatile acids is tested for formic acid with mercuric chloride. The remainder is treated with an excess of calcium carbonate, evaporated to dryness, and extracted with strong alcohol. The bulk of the acetate and formate remains undissolved, and much of the butyrate is dissolved and may be recognised by the odour of the ethyl ester. The non-volatile acids are evaporated to small volume and allowed to crystallise overnight. The crystals of succinic acid are filtered off and tested. The filtrate is treated with an excess of calcium acetate and warmed, when the tartrate, citrate, and oxalate that may precipitate are separated by filtration. For their identification, see Schoorl (*loc. cit.*). To the filtrate an excess of milk of lime is added, and the solution is filtered. The residue contains the remainder of the succinic acid. The filtrate is evaporated to dryness and extracted with hot 70 per cent. alcohol. The extract contains calcium lactate, which is allowed to crystallise out.

It is interesting to note that both *Bact. acaciæ* and *Bact. metarabinum* produced the same acids during the fermentation of saccharose. Morphologically, the bacteria are very similar, and had the gums had an equal solubility it is possible that the cultural character of the organisms would have been identical. So much was I impressed with the idea that the one was a modification of the other that I subcultivated both bacteria at 30° and at 17° for four months, to see if an approximation would ensue, but no change was observed. If they had originally been one organism, long cultivation under neutral conditions had so fixed the characters that they had become definite producers of arabin and metarabin respectively.

I had an opportunity of investigating the gum-flux of other trees. The first of these was the gum-flux of the vine. Some vines in certain low-lying portions of a vineyard showed an exudation of gum upon the ends of branches that had been pruned in the previous season. The gum had thus been exposed to the winter's rains, and upon being tested was found to consist of metarabin. From the gum-bearing branches, I separated *Bact. acaciæ* and *Bact. metarabinum*. Had freshly exuded gum been obtainable it doubtless would have been found to consist, like the gum of *Acacia penninervis*, of arabin and metarabin, the products of both bacteria.

A sample of plum gum consisted of arabin and metarabin. The soft and fresh gum yielded a culture of *Bact. acaciæ*. *Bact. metarabinum* was not obtained, but as the organism is, on account of the insoluble nature of its gum, easily crowded out of the culture plates by the more diffusible *Bact. acaciæ*, the failure to obtain it does not indicate that the metarabin was the product of the organism that was found.

Bact. acaciæ was also separated from the tissues of gum-bearing red cedar, *Cedrela Australis*, and from the unknown stock of a Japanese date plum.

Two interesting cases that I examined were the fruits of the peach and the almond, both of which were exuding gum from insect punctures and cracks. The fresh gum taken from cavities within the fruits contained a few cells of *Dematium pullulans* and practically no living bacteria, although the microscopical examination of stained films showed that the gum was really a gum matrix in which were imbedded immense numbers of badly staining (*i.e.*, dead) bacteria. The gum had not been formed in the fruit but had been forced into it by the sap pressure; its place of formation had been the stem and branches where the sap is less acid than in the growing fruit. The acidity kills the bacteria that accompany the gum, but has little effect upon adventitious yeast-like moulds, such as *Dematium*, which thus become the only living inhabitants of the gum. The arabin-former, *Bact. acaciæ*, was found in the branches attached to the fruit, where it had produced the soluble constituent of partially soluble gum.

Massee has recorded that *Dematium pullulans* caused a gum-flux of the plum, and as there was the possibility that a similar claim might be made for the races that I found in the peach and almond gums I investigated the slime produced by the peach-race in saccharose media. The slime yielded a gum which, while soluble in the fluid cultures, easily became altered to an insoluble modification, which was soluble in dilute acid and insoluble in dilute alkali. The gum was not hydrolysed by boiling 5 per cent. sulphuric acid, but concentrated acid converted it into a mixture of arabinose and galactose. The gum was therefore a pararabin.

Hot dilute hydrochloric acid was employed to extract the slime from cultures of *Dematium* grown upon solid media, and it dissolved not only the pararabin but also a carbohydrate from the nucleic acid of the mould. This substance was easily hydrolysed to a mixture of glucose and a galactose. That it was not a constituent of the true slime was shown by its absence in the filtered fluid cultures. As the almond gum did not contain pararabin and as its presence is unknown in peach gum, it is evident that *Dematium pullulans* played no part in the formation of these gums.

In these two fruits as well as in the red cedar, I found an organism *Bact. persicæ*, which produced a gum. This hydrolysed to a mixture of arabinose and galactose, the latter preponderating. It was rather an insoluble gum, but when dissolved in dilute acid it was not readily precipitated by the addition of alcohol. This suggested a means of determining whether or not the bacterium contributed towards the gum-flux of the trees in which it occurred. Almond gum was treated with water and the arabin removed. The insoluble but swollen residue was dissolved in the autoclave. The solution of the gum was acidified with hydrochloric acid and treated with alcohol. The filtrate from the precipitated metarabic acid was neutralised with sodium hydroxide, when a small quantity of a gum was precipitated. This was dissolved in the autoclave and tested. It gave the same reactions as the gum of *Bact. persicæ*, so that this organism had contributed its quota towards the gum which exuded from the almond and probably also from the peach and cedar.

The acids which the bacterium formed from saccharose consisted of lactic and butyric, with traces of succinic, formic and acetic. Ethyl alcohol and carbon dioxide were also produced. The only positive coagulating agents that could be depended upon in testing the gum were neutral and basic lead acetates, baryta water, milk of lime, and alcohol.

We have already seen that when *Dematium pullulans* produces a ropiness of fluids, the viscosity is due to the presence of pararabin. This member of the arabin group occurs naturally mixed with arabin as an exudate from a species of Sterculia. With the object of discovering a pararabin bacterium, I examined the gummy exudation from *Sterculia diversifolia*, and found therein the arabin bacterium, *Bact. acaciæ*, which explained the presence of arabin in the gum. Associated with it there was another bacterium which produced a gum upon or in media containing saccharose, dextrose, levulose, galactose, mannite, or glycerin. Three races of the bacterium were obtained; these differed slightly in their cultural characters and in their optimum temperatures. The gums produced by them also differed in some of their chemical reactions, but all were constant in giving curdy precipitates with alcohol, baryta water, basic lead acetate, and ferric chloride. Copper sulphate, followed by potassium hydroxide, gave a blue compound which coagulated upon heating, like arabin and many other gums.

The gum had been obtained from slime which had formed upon saccharose-potato-agar as well as in saccharose-asparagine fluid. Upon desiccation, such as by drying at 100°, the gum was converted into an insoluble modification, which swelled with water. Dilute acid dissolved it readily, while the swollen carbohydrate was contracted, but not dissolved, by dilute alkali. The gum was not attacked by boiling 5 per cent. sulphuric acid, but treatment with concentrated and then dilute acid converted it into a mixture of arabinose and galactose. Thus, the bacterial product had the same solubility, the same resistance to hydrolysis, and gave the same products of hydrolysis as pararabin, which it undoubtedly was. The gum of Sterculia is, therefore, the product of *Bact. acaciæ* and an organism which I have named *Bact. pararabinum*. Like the arabin and metarabin bacteria, *Bact. pararabinum* does not secrete invertase, and thus may be distinguished from many other slime-forming bacteria. The acids formed from saccharose consisted of succinic, lauric, butyric, acetic, and formic; the ratio of volatile to non-volatile acids was, roughly, 1 : 10. Ethyl alcohol and carbon dioxide were also produced.

In concluding the first part of this paper, I have shown that bacteria inhabiting the tissues of gum-bearing trees can form arabin, metarabin, pararabin, and other gums; and since we must admit that the natural gums of these trees were produced by the bacteria, we must also admit the probability of all other gums of an arabin nature being produced by bacteria. To put it shortly, the arabin gums are bacterial gums. The tree is, as it were, a laboratory in which certain constituents of the sap are converted by bacteria into gum which either flows out from cracks or wounds or is carried with the sap into the developing fruit. Although I have not examined every kind of tree affected with gum-flux or trees in other climates, yet it will be agreed that enough has been done to show that the vegetable gums are bacterial and not higher plant products, and that the differences in the nature of the gums are due to the fact that they are produced by different bacteria. Differences in the physical nature of the same gums, such as the varieties of gum arabic, soluble wattle gums, &c., are probably due to differences in the (climatic) temperature of formation and the nature of the sap. It is known that the gum of one season differs optically from that of another, and a difference in season would undoubtedly influence the activity of the bacteria in certain directions.

Every susceptible tree does not produce gum, but it could be made to do so by an artificial infection, either with pure bacteria or with the fresh juice from a selected and affected tree. Furthermore all the branches of a tree may not be producing gum, and in such cases an artificial infection would augment the yield. Thus the world's supply of gum might be materially increased if the native gatherers could be instructed in the principles of plant infection, *i.e.*, how to sow bacteria and reap gum.

Obituary.

HARRY GRIMSHAW,

MEMBER OF COMMITTEE OF THE MANCHESTER SECTION OF THE SOCIETY OF CHEMICAL INDUSTRY.

Harry Grimshaw was born at Cheetham Hill, Manchester, in 1851, and received his scientific education in Owens College, which he entered in 1869. He studied chemistry under Sir Henry Roscoe and Prof. Schorlemmer, gaining the Dalton Chemical Scholarship and other distinctions, and finally being elected a demonstrator and assistant lecturer in chemistry. Later he commenced as a chemical manufacturer at Clayton, near Manchester, in company with his younger brother, and was also on the directorates of the Recovered Rubber Works, Ltd., and the United Rubber Co., Ltd. Since the formation of the Society of Chemical Industry, he has been an active member, and more especially in connection with its Manchester Section. Some 11 or 12 years ago he assisted in the formation of the Chemical Section of the Manchester Chamber of Commerce, afterwards acting as hon. secretary of the Section. H. Grimshaw always took a great interest in local government and affairs, and in 1881 was elected a member of the Bradford (Manchester) Local Board and of the Bradford School Board, and became in 1897 a representative of Bradford in the Manchester City Council; he was also a member of the Mersey and Irwell Joint Committee. Mr. H. Grimshaw has been a magistrate since 1892, and by his death the City of Manchester will sustain a severe loss, and particularly the districts he represented, wherein he was ever zealous in promoting the interests of the poor. Amongst his original scientific work may be enumerated the following:—In 1873, an investigation on Ethyl-amyl, read before the Chemical Society, on which occasion the late Sir Edw. Frankland said that "students would do well to look upon it as a pattern for research work"; 1875, on a crystalline basic calcium chloride; 1877, on Di-isopentyl or Diamyl; and 1879, Analysis of the Water of Thirlmere (subsequently taken to supply the City of Manchester). He died somewhat suddenly on Jan. 29th.

WALTER GEORGE McMILLAN,

SECRETARY OF THE INSTITUTION OF ELECTRICAL ENGINEERS, &C.

W. G. McMillan was born in January 1861, and received his education in King's College School and then in King's College, where he gained the Daniell Research Scholarship in 1880. His special study was metallurgy, though his long course as a valued abstractor, since 1882, upon the staff of this Journal has amply demonstrated the fact that his knowledge of science was both well founded and thoroughly comprehensive. After leaving King's College he wisely worked for about a year with an accountant in order to obtain an acquaintance with business methods. Then returning to the College, he became private assistant to Prof. Huntington, and in 1883 was appointed Demonstrator in his Metallurgical Department. Here he remained till 1888, when he was appointed for five years under the Indian Government as chemist and metallurgist to the Cossipore Ordnance Factories near Calcutta. Immediately on his return to England he was elected Lecturer in Metallurgy at Mason's College, Birmingham, and held the position till 1897, when he was appointed Secretary of the Institution of Electrical Engineers. W. G. McMillan has written two articles on Electro-Chemistry and Electro-Metallurgy for the supplement of the "Encyclopædia Britannica," a "Treatise on Electro-Metallurgy," and a translation of Dr. Borchers' "Electro-Metallurgy" in 1897.

Whilst in India he was Examiner in Chemistry at the Calcutta University. He was also Vice-President of the South Staffordshire Institute of Iron and Steel Works Managers in 1897, and the Examiner in Electro-Metallurgy for the City and Guilds of London Institute at the time of his death.

After partial recovery from an attack of pleurisy, he suddenly suffered a relapse, and died on Sunday night, Jan 31.

Patent Specifications may be obtained by post by remitting as follows:—

English.—8*d*. each, to the Comptroller of the Patent Office, C. N. Dalton, Esq., Southampton Buildings, Chancery Lane, London, W.C.

United States.—1*s*. each, to the Secretary of the Society.

French.—1 fr. 25 c. each, to Belin et Cie., 56, Rue des Francs-Bourgeois, Paris (3^e^).

I.—PLANT, APPARATUS AND MACHINERY.

Reaction-Towers and the Regulation of Temperature in them. H. Rabe. Zeits. angew. Chem., 1903, **16**, [19], 437—444; and 1904, **17**, [1], 8—9.

The first part of the paper is a review of modern practice. The demands made on the filling material are discussed, and the extent to which different materials meet them. It is found that with suitable filling material it is advantageous to increase the area of the tower and lessen its height; but the greater the horizontal section of the tower the more difficult it becomes to secure uniform distribution of the absorbing liquid. The author describes a distributor of his own, the action of which will be clear from the figures. A is the tower, and B its cover. The liquid entering by the sloping tube enters the vessels D and F (Fig. 1), which divide it into a number of small streams. These streams fall into the compartments J (Fig. 2), which communicate with the delivery troughs forming the revolving arms H; and the size of each compartment is proportional to the length of the connected trough, and hence to the circumference of the circle over which the water flowing into the cell and out by the trough is distributed. The whole is driven by an external motor, and secures a very even distribution of the liquid. The abstraction from the reacting gases and liquid of the heat produced by their reaction has always been a desirable thing to accomplish, for rise of temperature usually means imperfect reaction, and hence necessitates increase of tower-capacity and of volume of liquid to be handled. It has, however, presented difficulties, for the walls of the tower abstract and dissipate but very little heat, and tubes, when introduced, have usually served to collect the liquid and destroy its even distribution in the portions of the tower below them. The author has devised two plans of effecting cooling, the one in stoneware, the other in lead. The stoneware device consists of a circular drum, illustrated by Figs. 3 and 4, which is built as a section of the tower. Vertical tubes pass through the upper and lower faces of the drum. The upper face of the drum is divided into sections by slightly raised ridges, each section containing one of the vertical tubes; and each tube is provided with a loose cap pierced with holes at the sides. The whole of the liquid passing down the tower thus comes

Fig. 1.

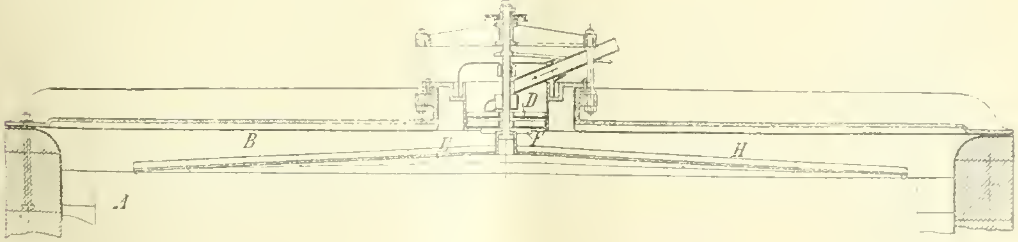

Fig. 2.

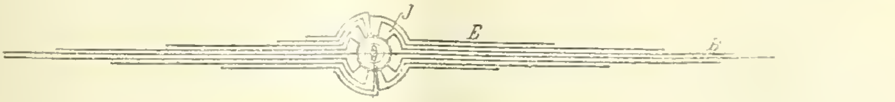

Fig. 3.

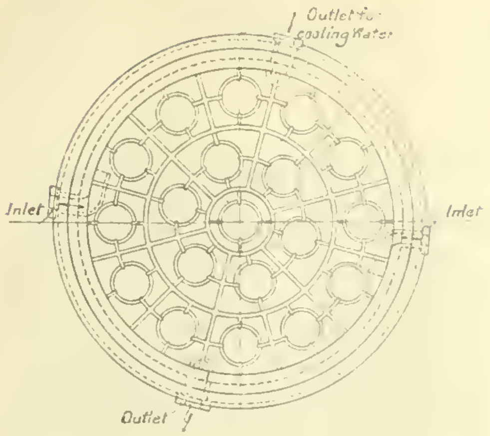

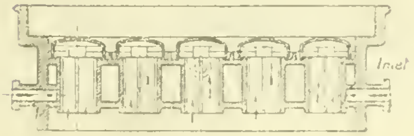

Fig. 4.

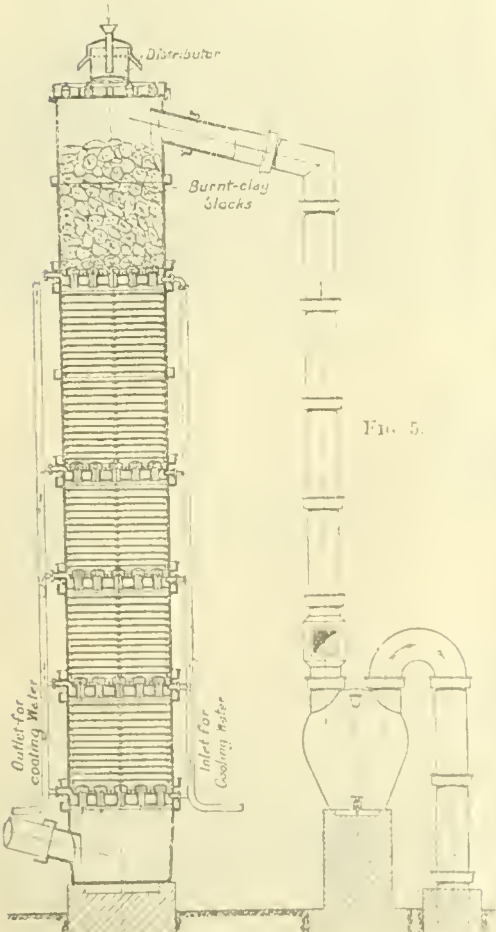

Fig. 5.

into contact with the stoneware drum, and the ridges and vertical tubes secure that the distribution of the liquid is not disturbed. Inflow and outflow tubes in the cylindrical sides of the drum are arranged for the passage of the cooling water. Any number of such drums can, of course, be intercalated throughout its height, as sections of the tower. The mode of doing so is indicated in Fig. 5. In the case of a leaden tower, horizontal leaden tubes, say 8 cm. diameter, are passed through the walls of the tower at regulated distances apart, say 18 cm., the whole set ending in a common reservoir at each end, so that a single inlet and outlet serve for the feed-water of the set. To secure even distribution of the fluid in the tower, each pipe is ribbed at intervals by bending round it strips of lead $\frac{1}{4}$ in. to $\frac{1}{3}$ in. square in section, and twisting and soldering the ends of each strip. In filling the tower, prisms of coke or other filling material are arranged so as to lead the liquid from any section of one tube to the corresponding section of the next. Soft lead can be used for these tubes if webs of ┬-section be passed through them to prevent sagging; and the weight of the tubes should be carried by an external framework, not by the lead of the tower. In an actual case, in which gases were to be dried in a tower 2·7 m. square and 8 m. high, by sulphuric acid of 1·7 sp. gr., both gas and acid entering at a temperature of 30° C., drying was very imperfect, because the heat of absorption raised the temperature to over 70° C. When, however, cooling tubes were introduced, the effluent gas was at 25° C., and well dried, though the amount of drying liquid had been reduced. Obviously, the subsequent removal of a given quantity of water in re-concentrating the used sulphuric acid is effected more economically from a small quantity of more dilute than from a large quantity of less dilute acid. The application of cooling tubes to the Gay-Lussac tower should effect a considerable economy, both in tower-space and in acid.—J. T. D.

English Patents.

Roller Crushing Mills ; Impts. in ——. The Edison Ore Milling Syndicate, Ltd., London. From T. A. Edison, Llewellyn Park, N.J. Eng. Pat. 2645, Feb. 4, 1903.

The crushing rolls consist of crushing plates attached to a roll centre or hub, made in two parts, which are secured together on opposite sides of an enlargement on the roll-shaft, so that movement along the shaft is prevented. One of the rolls may be laterally movable, and connected to its driving shaft by a non-circular "wobbler" or loose shaft. Details in the couplings connecting the rolls to the driving gear, and in the bearings and lubricating arrangements, are also claimed.—R. A.

Treatment of Animal, Vegetable, or Chemical Substances for the Purpose of Increasing their Solubility in Liquids. J. Maggi, Paris. Eng. Pat. 9002, April 21, 1903.

See Fr. Pat. 330,691 of 1903 ; this J., 1903, 1078.—T. F. B.

Preventing Explosions in Vessels Containing Inflammable Liquids ; Device for ——. R. Scheuffgen and Fabrik Explosionssicherer Gefässe G.m.b.H., Salzkotten, Westphalia. Eng. Pat. 25,547, Nov. 23, 1903.

The filling and discharge openings of the vessels are fitted with a number of perforated cylinders, one within another, and closed at the bottom, the perforations in the cylinders being displaced relatively to one another. The space between each pair of cylinders may be filled with fire-resisting material, such as asbestos, glass-wool, &c. (See also Eng. Pat. 2384 of 1901 ; this J., 1901, 974.)—R. A.

United States Patents.

Separator ; Centrifugal Liquid ——. A. B. Ayers, Lansing, Mich., Administrator of J. H. Ayers, deceased. U.S. Pat. 748,038, Dec. 29, 1903.

The separator is provided with a series of baffle-plates, of regular polygonal form, arranged in concentric order with chambers between the plates, and formed with horizontal slits or openings. The metal between the openings is bent at an angle to the plane of the plates, so that its lower edge extends outwards farther than its upper edge, thus causing a downward flow of the liquid passing through the openings. —R. A.

Vacuum Driers; Filling or Emptying Apparatus for ——. E. Passburg, Berlin. U.S. Pat. 748,411, Dec. 29, 1903. (See also Eng. Pats. 4126 of 1901 and 12,453 of 1902; this J., 1902, 458, and 1903, 708.)

The vacuum chamber is provided with automatic continuously-working filling and emptying devices, located respectively at the inlet and outlet of the chamber. Each of the devices consists of a number of pairs of suitable closing devices, with an intermediate chamber between each pair, and an air-sucking apparatus connected with each of these chambers.—R. A.

Drying Moist Material; Apparatus for ——. E. N. Trump, Syracuse, N.Y. U.S. Pat. 748,893, Jan. 5, 1904.

A closed system is formed through a series of chambers, one of which consists of a stack for the treatment of the material. The stack increases in cross-sectional area upwards, and is contracted at the top, the material to be treated being fed into it through suitable regulating means. The drying agent is forced upwards with a spiral motion through the stack, so that it not only holds the material under treatment in suspension, but also separates the finished from the unfinished material, this selective action being strengthened by the decreasing vertical velocity of the drying current, due to the construction of the stack. The finished material is received in a separating-chamber, from which the drying agent is returned to the stack. —R. A.

Treating Material; Process of ——. E. N. Trump, Syracuse, N.Y. U.S. Pat. 748,894, Jan. 5, 1904.

The claims relate mainly to the process carried on by the apparatus claimed in the preceding patent.—R. A.

[*Water*] *Distilling Apparatus.* Eva E. Stocker, Administratrix of J. Stocker, St. Louis, Mo., deceased. U.S. Pat. 748,564, Dec. 29, 1903.

This apparatus comprises a closed tank furnished with insulated walls, a condensing coil arranged within the tank and connected with the supply-pipe, a cooling tower within the coil, an evaporating chamber and a heating chamber located respectively at the top and the bottom of the tower, and a receiving tank beneath the coil. A communicating passage is provided between the heating and evaporating chambers, and a pipe leads from the top of the condensing coil to the heating-chamber.—R. A.

Filter-Press [*Pulp*]. E. B. Hack, Assignor to the American Filter Press Extraction Co., Denver, Colo. U.S. Pat. 749,140, Jan. 5, 1904.

The press is composed of distinct pulp-holding and filtering members, with a movable head or end, and tightening levers for acting on one of the head members. The members are provided with registering openings, forming longitudinal passages outside the pulp and filter chambers, each pulp-frame having a lateral channel for the introduction of pulp to the pulp-chambers. Provision is also made for the introduction of liquid and air, and for the discharge of the solutions after they have passed through the pulp. —R. A.

French Patent.

Distillation Apparatus. A. H. L. Gerhardt. Fr. Pat. 335,034, Sept. 4, 1903.

The apparatus is arranged for the continuous distillation of any liquid, such as benzol or water. Inside a vertical still is placed a steam heating-coil, provided with a drain pipe for the condensed water. The liquid to be distilled passes through a preheater, warmed by the hot vapours, and is admitted into the still through a pipe, the level being kept constant by means of a ball valve. The vapours generated, pass through the preheater, and are then condensed in a water-cooled spiral, and drawn off. A safety-valve—which may be of special design—is fixed to the preheater and if there is any sudden disengagement of gas from the crude preheated liquid, this gas is blown through a pipe into the still. At the same moment a ball valve closes the pipe admitting the crude liquid to the preheater, thus preventing the blown-off gas from again mixing with it. The apparatus is quite automatic in action.—L. F. G.

II.—FUEL, GAS, AND LIGHT.

Retort; Vertical [*Gas*] ——. W. King. J. Gas Lighting, 1904, **85**, [2122], 80—83.

In the Settle-Padfield experimental plant at Exeter, excellent results have been obtained from two and a half years' working of a vertical retort improvised out of old 16-in. circular retorts. The method of feeding is one of the most important features of the system. From the top of the retort rises a short 6-in. bored cylindrical tube, on which a conical hopper is fixed. A rod within the tube carries a fixed cone at the bottom and an adjustable one at the top, both having their apices pointing inwards. This constitutes the plunger, which works up and down smoothly within the tube, being actuated from above by a reversible worm and toothed-wheel gearing. The coal, in the form of slack, is fed into the conical hopper; and, as the plunger rises, the top cone rises from its seat and the coal drops into the annular space round the rod. On the descent of the plunger, when the lower cone passes the outlet of the cylinder, the charge slips into the retort, being directed towards the incandescent sides, and the gas is driven out rapidly. The charges are very small—about 6½ lb. at a time. During the charging there is no escape of flame and smoke. It is stated that no trouble is experienced from stoppage of the ascension pipe. From Somerset, Durham, and Yorkshire slacks, it is claimed, the yield of gas is over 13,000 cb. ft. per ton, against slightly over 10,000 cb. ft. with ordinary horizontal retorts; it is said that the tar is entirely got rid of, the large hard coke produced is more valuable than that obtained in horizontal retorts, and that the quality and quantity of the gas are well maintained hour by hour. A new bed of retorts has been constructed containing six circular retorts, three on each side, of 1 ft. 4 ins. top diameter, expanding to 1 ft. 9 ins. at the bottom. The vertical portion is 3½ ft. long, and the curved, inclined, discharge end is 4 ft. 9 ins. long. Ground space will be saved, as the charging is done mechanically from above, and drawing takes place by gravitation. It is calculated that the floor area required, in the case of 20-ft. horizontal retorts, is 103 sq. ft. per ton of coal carbonised, equal to 99 cb. ft. of gas per square foot, whereas the Exeter plant requires only 79 sq. ft. per ton, equal to 161 cb. ft. of gas per square foot. A definite opinion as to the capital cost and fuel account of the system is not yet justifiable; but it is urged that there will be savings in connection with stoking and drawing machinery and brickwork, and that not only is a lower temperature sufficient for carbonising by this system, but there is less brickwork and less coal to be heated up for a given yield of gas. The use of small coal or slack, instead of large coal, effects a large saving.—H. B.

Cyanogen; Recovery of ——, *by Bueb's Process at Hanover Gasworks.* Körting. J. f. Gasbeleuchtung, 1904, **47**, [3], 45—46.

At the Hanover gasworks, the gas, after removal of the tar and naphthalene, is passed through a standard washer having four chambers, the first three, which contain the absorbent liquor, being filled with wooden faggots, whilst the fourth is provided with rotating metallic discs, between which stirring chains are suspended. To prepare the washing liquor, a solution of ferrous sulphate, of 19°—20° B., is run into the fourth chamber, and the gas from the absorption chambers is passed through it until all the iron has been converted into sulphide. When cyanogen is found in the gas leaving the washer, the cyanogen mud from chamber 1 is pumped into a reservoir, the liquor from chamber 2 is pumped into chamber 1, that from 3 into 2, and the fresh sulphide liquor from 4 into 3. These changes are required every 18 to 24 hours. The cyanogen mud is

sold without further treatment; it contains about one-third of the ammonia in the coal. (See this J., 1903, 356.)
—H. B.

Sulphur in Coal and Coke; Rapid Method of Determining ——. J. D. Pennock and D. A. Morton. XXIII., page 131.

Mercury Vapour; Conductivity of —— [*Mercury Vapour Electric Lamp*]. P. C. Hewitt. XI. A., page 119.

ENGLISH PATENTS.

Briquettes; Manufacture of Fuel ——. M. Hecking, Dortmund, Germany. Eng. Pat. 1260, Feb. 23, 1903.

The binding material, preferably in a liquid state, is added to the fuel or combustibles "shortly before the completion of the heating in the heating apparatus." The apparatus suggested consists of a rotating cylinder, which can be heated, into one end of which the fuel is fed, and moves towards the discharging end by reason of the rotation, or by accessory mechanism. The binding material is supplied through a pipe, entering the discharge end of the cylinder, and is mixed with the combustible material by the rotation of the cylinder and its contents; the point at which the addition of the binding material takes place, depends upon the nature of the combustible, and the operation is not interrupted. Compare also Eng. Pat. 14,054, 1902; this Journal, 1902, 1126.—W. C. H.

Coke Ovens. F. J. Collin, Dortmund, Germany. Eng. Pat. 7487, March 31, 1903.

See Fr. Pat. 330,754 of 1903; this J., 1903, 1080.—T. F. B.

Gaseous Mixture which is as Dry as possible; Production, by means of Liquid Hydrocarbons, of a ——, *and Apparatus therefor.* L. Rüdemann, Paris. Eng. Pat. 23,166, Oct. 26, 1903.

The combustible gaseous mixture, derived from liquid hydrocarbons, is rendered as dry as possible, by removing all the moisture from the air required for the production of the mixture, before it enters the generator. The deposition of the moisture is effected by causing the air to flow over the exterior walls of the generator, for example, by enclosing this within a larger tube, and causing the air to pass through the latter, in the direction opposite to that taken by the hydrocarbon mixture. The air may also be supplied through a tube, provided with heat-conducting wings, placed in the upper part of the generator, where it is exposed to the reduced temperature, and also may be passed through chambers containing water-absorbing substances, such as "chloride of lime."—W. C. H.

Gas-Purifiers; Impts. in ——. R. Dempster and Sons, Ltd., and J. W. Broadhead, Elland, Yorkshire. Eng. Pat. 5910, March 14, 1903.

Gas purifiers are arranged in compact groups of four, in square or oblong formation, in such a manner as to leave a central space bounded by a portion of the inner wall of each purifier, this space containing the inlet and outlet valves and controlling gear of the purifiers.—H. B.

Electrodes for Arc Lamps; Manufacture of ——. A. Blondel, Paris. Eng. Pat. 23,262, Oct. 24, 1902.

Mineralised carbon electrodes are formed of carbon paste containing 10—70 per cent. of fluoride, oxide, carbide, or phosphate of calcium, to which is added from 3 to 25 per cent. of borate of barium, calcium, aluminium, or magnesium, with or without borates of alkali metals. By the use of the earthy borates, which is the main feature of the invention, it is claimed that irregularities in the light emission are prevented.—H. B.

UNITED STATES PATENT.

Gas [*Oil-Gas*]; *Apparatus for the Manufacture of* ——. R. Dempster, Marietta, Ohio. U.S. Pat. 748,933, Jan. 5, 1904.

See Eng. Pat. 16,764 of 1903; this J., 1904, 14.—T. F. B.

FRENCH PATENTS.

Agglutinant for Agglomerating Coal Dust; Manufacture of an ——. F. Hache. Fr. Pat. 334,782, Aug. 22, 1903.

According to this process, waste resinous products such as the heavy oils left in the distillation of tar, anthracene oils, petroleum, beech or oak tar, and resin, and similar hydrocarbons, are mixed and distilled. A composite oil is thus obtained, and an artificial resin, which may be mixed with coal dust and sold in the form of briquettes.
—L. F. G.

Briquettes; Manufacture of Coal ——. G. Quentin. Fr. Pat. 334,983, Sept. 1, 1903.

Coal dust is mixed with clay or loam in the proportion of 5 per cent. of clay to 94·5 per cent. of coal, and 0·5 per cent. of a strong glue or gum arabic solution in water, is added as an agglutinant. The briquettes are formed from the cold material.—L. F. G.

Briquettes; Manufacture of ——. (Mrs.) F. A. Merrill. Fr. Pat. 335,324, July 21, 1903.

See Eng. Pat. 16,127 of 1903; this J., 1903, 1079.—T. F. B.

Peat; Manufacture of Fuel from ——. J. B. Bessey. Fr. Pat. 335,097, Sept. 9, 1903. Under Internat. Conv., Sept. 9, 1902.

See Eng. Pat. 19,719 of 1902; this J., 1903, 943.—T. F. B.

Gas; Process and Apparatus for the Production of ——. H. S. Elworthy. Fr. Pat. 335,120, May 30, 1903. Under Internat. Conv., May 31, 1902.

See Eng. Pat. 12,461 of 1902; this J., 1903, 900.—T. F. B.

Alcohol; Carburisation of ——. F. Hache. Fr 334,783, Aug. 22, 1903.

Denatured alcohol is mixed with crude petroleum in about equal proportions by volume. The mixture is then distilled until the whole of the alcohol has passed over. The distillate is a homogeneous product, more luminous than pure alcohol, and does not produce noxious fumes nor greasy residues. The residues of distillation find a use in industry as agglutinants.—J. F. B.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM, AND MINERAL WAXES.

Petroleum; Canadian ——. Bull. of the Imperial Inst. (Suppl. to Board of Trade J.), 1903, [4], 183—187.

The principal source of Canadian petroleum is the province of Ontario. The crude petroleum is a heavy, dark brown oil, having a very unpleasant odour, owing to the presence of sulphur compounds. The sp. gr. generally ranges from 0·804 to 0·808. On distillation in the laboratory the oil yields:—Naphtha (sp. gr. 0·735), 12·5; lamp oil (sp. gr. 0·820), 35·8; lubricating oil, 43·7 and hard paraffin, 3·0 per cent. On the large scale, however, in 1899, the yields of the different products were stated to be:—Benzine and naphtha, 1·6; lamp oil, 38·7; paraffin and heavy oils, 25·3; waste, 34·4 per cent. A specimen of petroleum from Westmoreland County, New Brunswick, having the sp. gr. 0·857, yielded:—Light petroleum (naphtha), 5·6; kerosene (lamp oil), 28·3; heavy oils and solid hydrocarbons, 58·2; and water, 7·9 per cent.—A. S.

Petroleum and Asphalt in the Islands of Pedernales, Pesquero, and del Plata, Venezuela. Hirzel. Chem. Rev. Fett- u. Harz-Ind., 1903, **10**, [12], 275—277.

The occurrence of extensive deposits of asphalt and petroleum in the islands named, which are off the Venezuelan coast, near the mouths of the Orinoco, has already been reported by R. Zuber. In the north-western part of Pedernales, near the coast, is a large deposit of solid asphalt named "La Brea," 1,000 metres long and on the average 60 metres wide, in which are a large number of crater-like depressions, containing a thick liquid asphalt of sp. gr. 1·01, from which bubbles of gaseous hydrocarbons continually arise. Deposits of asphalt and petroleum have also been met with in other parts of the island. A specimen of the liquid "crater asphalt" yielded on distillation: water, 4·5; oil of sp. gr. 0·870, 6·5; oil of sp. gr. 0·950, 25·1; and solid "pure asphalt," 60·9 per cent. In the author's opinion, it is evident that this liquid asphalt and also the solid asphalt have been formed from petroleum. In the island of Pesquero, petroleum is found in the upper sandstone layer and rises to the surface of the earth through fissures and cracks. This oil has the sp. gr. 0·918 at 15° C., and yields about 30 per cent. of illuminating oil.—A. S.

Petroleum from Trinidad. Bull. of the Imperial Inst. (Suppl. to Board of Trade J.), 1903, [4], 177—180.

Two specimens of petroleum have been examined. The first (A) was obtained from a well sunk at Guayaguayare in 1902 to a depth of over 1,000 ft.; it had been kept for some months. It consisted of a thick dark brown oil of sp. gr. 0·920 at 20° C. and flashing point (Abel-Pensky test) 21·5° C. On distillation it yielded: light petroleum (up to 150° C.), 11·1; kerosene (150°—270° C.), 38·0; heavy oil, 43·0; and coke (by difference), 7·9 per cent. The second specimen (B) was obtained from a natural spring, and consisted of a thick oil of a dark brown colour and exhibiting distinct fluorescence; its sp. gr. was 0·8686 at 20° C. and its flashing point (Abel-Pensky test) 71·6° C. On distillation it yielded: light petroleum (up to 150° C.), 0·2; kerosene (150°—300° C.), 70·0; heavy oil, 27·4; coke (by difference), 2·4 per cent. Both samples are stated to represent valuable commercial products, A resembling Russian rather than American petroleum, whilst B is similar to Canadian oil in its small yield of light petroleum, but contains more kerosene than the latter.—A. S.

Pitch, Natural, or Manjak, from Trinidad. Bull. of the Imperial Inst. (Suppl. to the Board of Trade J.), 1903, [4], 180—182.

The sample of manjak consisted of lumps of a black, somewhat lustrous mineral, more friable than good bituminous coal, which it resembled in general appearance. It contained: fixed carbon, 55·15; soluble matter, 40·92; ash, 3·55; and moisture, 0·38 per cent. It became soft at 220° C. On extracting with acetone and subsequently with chloroform, the following results were obtained: Acetone extract ("petrolene"), 12·06; chloroform extract ("asphaltene"), 83·19; insoluble residue, 4·75 per cent. The manjak is not suitable for the manufacture of black varnish or of paving asphalt, owing to its melting point being high in consequence of its low content of "petrolene." It is probable, however, that this defect might be remedied by incorporating a certain proportion of petroleum residuum with the manjak. (See also this J., 1899, 127, 738.)—A. S.

United States Patent.

Dry Distillation of Organic Substances; Apparatus for the Continual Charring and ——. H. C. Aminoff, Domnarfoet, Sweden, Assignor to A. C. Mark, Gothenburg. U.S. Pat. 748,457, Dec. 29, 1903.

The substances to be distilled are caused to ascend a long, inclined chamber, into the lower end of which a current of hot "gases" is introduced; the products of distillation are collected at the upper end of the chamber.—T. F. B.

French Patent.

Anthracene; Process of Purifying Crude ——. L. Scholvien. Fr. Pat. 335,013, Sept. 3, 1903.

Crude anthracene is melted at as low a temperature as possible (about 100° C.), cooled gradually to 50° C., and the portion which has separated out removed from the liquid portion. By this means it is said that a 45 per cent. anthracene is easily obtained.—T. F. B.

IV.—COLOURING MATTERS AND DYESTUFFS.

United States Patents.

Anthraquinone Dye, Blue [Anthracene Dyestuff], and Process of Making Same. E. Hepp and C. Hartmann, Assignors to Farbwerke vorm. Meister, Lucius und Brüning, Höchst a. M., Germany. U.S. Pat. 748,375, Dec. 29, 1903.

Aminohydroxyanthraquinones are treated with halogens, the halogen derivatives are treated with aromatic amines, and the condensation products are converted into sulphonic acids by sulphonating agents. The products are easily soluble in water, and dye unmordanted and chrome-mordanted wool in fast blue shades. The product obtained from 1·5-aminohydroxyanthraquinone by means of bromine, aniline, and feebly-fuming sulphuric acid is especially claimed.—E. F.

[Azo] Dyestuff and Process of Making Same; Dark Blue Wool ——. M. Hoffmann, Frankfort, Assignor to Cassella Colour Co., New York. U.S. Pat. 749,195, Jan. 12, 1904.

See Eng. Pat. 3182 of 1903; this J., 1904, 56.—T. F. B.

French Patents.

Bases [p-Nitraniline]; Manufacture of Aromatic ——. The Clayton Aniline Co. Fr. Pat. 335,204, Aug. 10, 1903. Under Internat. Conv., Nov. 2, 1902.

See Eng. Pat. 24,869 of 1902; this J., 1903, 1125.—T. F. B.

Anthraquinone Derivatives [Anthracene Dyestuffs]; Preparation of New ——. Soc. Anon. F. Bayer et Cie. Fr. Pat. 334,658, Aug. 17, 1903.

Purpurin-α-sulphonic acid is obtained by treating anthraquinone-α-sulphonic acid (see Fr. Pat. 333,144; this J., 1903, 1290) with very strong fuming sulphuric acid, and then saponifying the sulphuric ether of purpurin-α-sulphonic acid so obtained. The product dyes wool mordanted with alum in red, and chrome-mordanted wool in bluish-red shades.—E. F.

Coloured Products [Indophenols] resulting from the Condensation of Nitrosohydroxy Derivatives with Aromatic Amines; Manufacture of ——, *and also of Leucoindophenols derived therefrom.* Soc. pour l'Ind. Chim. à Bâle. First Addition, dated Aug. 22, 1903, to Fr. Pat. 330,388 of March 18, 1903. (See Eng. Pat. 7025 of 1903; this J., 1903, 861.)

According to the original patent, aromatic amines with a free para position are condensed with nitrosophenols or quinone chlorimides in presence of sulphuric acid. The sulphuric acid may be replaced by other mineral acids. The amines may be replaced by their neutral or acid salts in presence of a dissolving or diluting agent. The nitrosophenols and quinone chlorimides may be replaced by oxidation products obtained from the corresponding aminophenols by treatment with peroxides or electrolytic oxygen. —E. F.

Lakes [from Azo Dyestuffs] Fast to Light; Preparation of Reddish-Blue ——. Cie. Paris. Coul. d'Aniline. Fr. Pat. 328,128, Oct. 31, 1902.

See Eng. Pat. 23,830 of 1902; this J., 1903, 1055.—T. F. B.

Azo Dyestuff; Process for Preparing a Red ——. Cie. Paris. Coul. d'Aniline. Fr. Pat. 328,131, Nov. 4, 1902.

See U.S. Pat. 733,280 of 1903; this J., 1903, 946.—T. F. B.

Azo Dyestuff; Process of Manufacturing a Violet ——. Cie. Paris. Coul. d'Aniline. Fr. Pat. 328,137, Nov. 5, 1902.

See U.S. Pat. 737,967 of 1903; this J., 1903, 1082.—T. F. B.

Indoxyl [Indigo Dyestuffs] and its Homologues, Manufacture of ——. Cie. Paris. de Coul. d'Aniline. 1st Addition, dated Aug. 24, 1903, to Fr. Pat. 317,121 of Dec. 1, 1901 (this Journal, 1902, 967).

According to the original patent, aromatic organic compounds) containing the group R.N.CH_2.CO—— are treated at a high temperature with inorganic substances capable of decomposing water. It is found that these inorganic substances may be replaced by the hydrides of the metals of the alkalis or alkaline earths.—E. F.

Indoxyl and its Derivatives [Indigo Dyestuffs]. Badische Anilin und Soda Fabrik. Fr. Pat. 328,148, Nov. 21, 1902.

See Eng. Pat. 26,372 of 1902; this J., 1903, 1289.—T. F. B.

V.—PREPARING, BLEACHING, DYEING, PRINTING, AND FINISHING TEXTILES, YARNS, AND FIBRES.

Caruá [Caroá] and Makimbeira Fibres from Brazil. Bull. of the Imperial Inst. (Suppl. to Board of Trade J.), 1903, [4], 170.

Caruá, or more correctly Caroá fibre is obtained from the plant *Neoglaziovia variegata*, Mex., of the pine-apple order, *Bromeliaceæ*, which is common in the northern parts of the State of Bahia. The specimen examined had been prepared in a crude way by natives; it consisted of a white, fairly strong fibre containing little or no ligno-cellulose; it was valued at 10*l.*—13*l.* per ton, whilst a specimen of hand-made rope, probably prepared from selected fibre, was valued at 25*l.* per ton. The specimen of the fibre, after being cleaned by hackling, gave the following results:—Moisture, 8·4; ash, 3·1; loss on hydrolysis (*a*), 25·6; loss on hydrolysis (*b*), 33·7; loss on acid purification, 15·3; "loss on mercerisation, 23·5"; gain on nitration, 17·3; cellulose, 69·8 per cent.; length of ultimate fibre, 2—5 mm, A consignment of dressed Caruá fibre recently realised 31*l.* per ton. Makimbeira fibre is obtained from a plant closely allied to Caruá. The specimen of fibre examined, which had been prepared by natives, was valued at 13*l.* to 20*l.* per ton; it was too small to allow of chemical examination.
—A. S.

Fibre of Cryptostegia Grandiflora, from Madras. Bull. o the Imperial Inst. (Suppl. to Board of Trade J.), 1903, [4], 172.

The specimen examined consisted of a nearly white, fine, strong fibre, with a staple of average length, 16—20 inches, and resembling that of *Marsdenia tenacissima* (see this Journal, 1903, 1192). The fibre contains little or no ligno-cellulose, and persistently resists the action of alkali. It gave the following results on examination:—Moisture, 7·9; ash, 0·95; loss on hydrolysis (*a*), 5·2; loss on hydrolysis (*b*), 9·8; "loss on mercerising, 4·3"; loss on acid purification, 1·2; gain on nitration, 49·0; cellulose, 92·0 per cent.; length of ultimate fibre, 10—60, average, about 30 mm. It was valued at about 30*l.* per ton.—A. S.

Albumins; Action of Nitrous Acid upon ——. A. Pellizza. Rev. Gén. des Mat. Col., 1904, **8**, [85], 5—6.

In view of the doubts which have been expressed as to the correctness of Prud'homme's view that the wool molecule contains NH or NH_2 groups, and also of the uncertainty existing as to the constitution of albumins, the author examined the behaviour of various albumins to nitrous acid. Both classes of albumins, namely (1) the albumins proper, that is, albumins, globulins, caseins, and nucleo-albumins, and (2) the transformation derivatives of these, the albumoses and peptones, in the absence of light, and in the cold, react with nitrous acid. The products are yellow-coloured substances, which, when purified by washing with water and dilute alkali or alkali acetate solution, and dried, are fairly stable in a vacuum. They are decomposed by light and heat, and easily by moisture. The products obtained from the albumins of the second class are moderately soluble in water and in acid solutions. Those derived from the albumins of the first class dissolve in solutions of alkalis, and in the presence of the latter, without necessarily entering into solution, react with phenols and aromatic amines, giving thus with phenol yellow, with the naphthols red, and with the aminophenols and aminonaphthols brown-coloured compounds. These are slowly decolorised by energetic reducing agents. The compounds derived from the naphthols and the peptic or tryptic transformation products of the albumins are yellow, soluble in water, and fairly easily dialysable. Albumins rendered insoluble by treatment with formaldehyde react with nitrous acid like the corresponding unchanged albumins. Similarly, the albumin-azo-naphthol compounds are rendered insoluble by the action of formaldehyde. These facts are not in accordance with Benedicenti's theory that the albumin molecule contains amino or imino groups, which are acted upon by formaldehyde. The action of the latter reagent may be shown by printing a cotton tissue prepared with sodium-β-naphtholate with the yellow "nitroso" derivative of blood albumin, admixed with a sufficient quantity of alkali, the deep rose colour-lake being soluble in water as thus produced, but being rendered fast to washing by treatment with formaldehyde. (See also this Journal, 1888, 841; 1897, 405; 1893, 312; and 1899, 1015 and 1016.)—E. B.

Mordanting Wool with Chromium; Relative Reducing Powers of Various Assistants employed in ——. E. Schnabel. Färber-Zeit., 1903, **14**, [24], 433—435.

The reducing powers of the chief assistants employed in mordanting wool with chromium, as measured by the amounts required, in the absence of the wool fibre and during $1\frac{1}{2}$ hours at 212° C., to reduce 1 grm. of potassium bichromate, (*p*) in the presence of an excess of, and (*a*) in the absence of sulphuric acid, are respectively as follows:—Lignorosin ("concentrated"), (*p*) 0·668 grm., (*a*) 1·942 grm.; lignorosin (60 per cent. of the strength of the concentrated quality), (*p*) 1·114 grm., (*a*) 3·236 grm.; lactolin, (*p*) 0·799 grm., (*a*) 1·305 grm.; tartar (100 per cent.), (*p*) 0·609 gm., (*a*) 1·342 grm.; vegetalin, (*p*) 2·488 grm., (*a*) 4·524 grm.; lactic acid, (*p*) 0·699 grm., (*a*) 1·031 grm. (See also this Journal, 1900, 659; 1902, 339, 612, 769, and 1132; 1903, 91.)—E. B.

Formic Acid in Dyeing with Acid Dyestuffs; Use of ——. A. G. Green and A. B. Steven. J. Soc. Dyers and Colourists, 1904, **20**, [1], 6—8.

In dyeing the wool in cotton and wool unions with acid dyestuffs, with addition of sulphuric acid to the dye-bath, there is danger of the cotton becoming tendered. To obviate this, acetic acid is frequently employed instead of sulphuric. It is found, however, that colours so dyed are not so fast to perspiration, hot water, &c., as those dyed with addition of sulphuric acid. If formic acid be used instead of acetic, the dye-baths are much better exhausted, and the colours produced are very much faster to hot water. The use of formic acid is quite practicable, as it can now be obtained at a price almost the same as that of an equivalent amount of acetic acid.—A. B. S.

Gallotannic Acid; Detection of ——, on the Fibre.
A. Menger. XXIII., page 135.

English Patent.

Printing Cotton or other Vegetable Fibre with Indigo in Combination with other [Mordant] Colouring Matters. J. Y. Johnson, London. From Badische Anilin und Sodafabr., Ludwigshafen. Eng. Pat. 6094, March 16, 1903.

See Fr. Pat. 330,159 of 1903; this J., 1903, 1084.—T. F. B.

United States Patent.

Transferring and Printing [Designs on Fabrics]. J. E. Hesse and M. Paraf-Javal, Paris, Assignors to J. Diederichs, Lyons. U.S. Pat. 748,604, Jan. 5, 1904.

See Eng. Pat. 17,872 of 1899; this J., 1900, 899.—T. F. B.

French Patents.

Dyeing Cotton in Ribbons; Machines for ——. D. Mattei. Fr. Pat. 334,681, Aug. 18, 1903.

Mechanical details are described of a machine for dyeing ribbons of loose cotton, in which all the operations, including the transference of the material from one portion of the apparatus to another, are carried out mechanically. Modified forms of soaking and dyeing troughs are also described. —T. F. B.

Dyeing by Means of Sulphide Dyestuffs; Process of ——. Soc. pour l'Ind. Chim. à Bâle. Fr. Pat. 334,797, Aug. 22, 1903.

The oxidation, and consequent inequality of dyeing, which occurs when working with dye-baths containing leucosulphide dyestuffs and alkali sulphide, can be prevented by the addition to the dye-bath of animal or vegetable oils or fats. For instance, 8 kilos. of olive oil may be added to a dye-bath containing 2,000 litres.—T. F. B.

Dyeing by Means of Sulphide Dyestuffs; Process of ——. Soc. pour l'Ind. Chim. à Bâle. First Addition, dated Aug. 28, 1903, to Fr. Pat. 334,797 of Aug. 22, 1903. (See preceding abstract.)

In place of using vegetable oils or fats in the dye-bath, mineral oils or fats, fatty or aromatic hydrocarbons, or solutions of fats or oils in mineral oils or hydrocarbons, may be used. These fatty substances are preferably added to the dyestuff before it is dissolved, thus preventing oxidation during the dissolving.—T. F. B.

Tissues; Process for Rendering —— Waterproof. T. Luthringer. First Addition, dated Aug. 14, 1903, to Fr. Pat. 321,480, May 5, 1902. (See this J., 1903, 296.)

A modification of the apparatus described in the principal patent consists in connecting the impregnating chamber with the drying chamber by means of a short passage, through which the wet fabric passes; the drying chamber contains two rows of rollers, placed on different levels, the fabric passing alternately over one of the upper and one of the lower rollers, thus presenting a large surface to the drying atmosphere, and thus also expediting the process. —T. F. B.

Waterproofing Fabrics; Process of ——. T. Luthringer. Second Addition, dated Aug. 22, 1903, to Fr. Pat. 321,480, May 5, 1902. (See this J., 1903, 296.)

The drying chamber contains a false bottom, on which rest lumps of ice, alone or with suitable acids or salts, thus ensuring condensation of the carbon bisulphide vapour. —T. F. B.

Embossed Designs on all Kinds of Fabric; Process of "Fixing" ——. L. J. Chischin. Fr. Pat. 335,238, Aug. 29, 1903.

Embossed designs are "fixed" in fabrics, by impregnation or coating with a thin layer of collodion; this has also the effect of waterproofing the fabric.—T. F. B.

VI.—COLOURING WOOD, PAPER, LEATHER, Etc.

French Patent.

Wood; Process for Rendering ——, *more suitable for Absorbing Colours.* J. von Brenner. Fr. Pat. 334,663 Aug. 17, 1903.

After a preliminary treatment with superheated steam, wood is subjected to the action of sulphuric acid of 10—20° B. under pressure, after which the acid in the wood is neutralised by treatment with dilute alkali, and the salt thus formed removed by washing. Wood prepared in this manner is said to be readily and evenly coloured by any process.—T. F. B.

VII.—ACIDS, ALKALIS, AND SALTS.

Lead Sulphate; Solubility of ——, *in Hydrochloric Acid Solution of Stannous Chloride.* A. van Raalte. Zeits. anal. Chem., 1904, **43**, [21], 36—38.

De Jong (this J., 1902, 1473) states that lead sulphate is soluble in hydrochloric acid solution of stannous chloride. The author repeated de Jong's experiments, and found that solution of the lead sulphate is effected, not by the stannous chloride, but by the hydrochloric acid.—J. T. D.

Arsenates; Preparation of ——, *from Arsenious Acid and Metallic Peroxides.* O. Schairer. Chem.-Zeit., 1904, **28**, [2], 15.

Sodium orthoarsenate is readily obtained by adding excess of sodium peroxide to an ice-cold saturated solution of arsenious acid, gently warming, concentrating, and crystallising out. *Lead orthoarsenate* is formed when a mixture of lead dioxide and arsenic trioxide is slowly brought to a red heat; the melt is powdered and repeatedly extracted with boiling water to remove arsenious acid. *Barium orthoarsenate* is similarly obtained from barium peroxide and arsenic trioxide, the reaction setting in, on gentle heating, with some violence. Calcium, strontium, and manganese gave unsatisfactory results.—W. A. C.

Reaction Towers and the Regulation of Temperature in them. H. Rabe. I., page 109.

Vanadic Acid; Colour Reactions of ——, *with Ethenol (Vinyl Alcohol).* C. Matignon. XXIII., page 131.

Hypochlorous Acid; New Method for the Detection and Determination of ——. E. Klimenko. XXIII., page 132.

Ammonia; Gasometric and Gravimetric Methods for Determining ——. E. Riegler. XXIII., page 132.

Sulphides, Thiosulphates, and Haloids: Determination of —— [*in Mixtures of the Same*]. W. Feld. XXIII., page 132.

Bleaching Powder; Method of Determining Available Chlorine in ——. J. Pontius. XXIII., page 133.

Manganese Peroxide; Titration of ——. L. Débourdeaux. XXIII., page 133.

Halogens; Determination of ——, *in Organic Compounds. Case of Chlorine and Bromine.* H. Baubigny and G. Chavanne. XXIII., page 136.

English Patent.

Graphitic Substance; Separation of ——, *from Associated Rocky Matter or Gangue.* C. Kendall, Upper Norwood. Eng. Pat. 1309, Jan. 19, 1903.

The crushed graphite-containing substance is mixed with oil (kerosene or paraffin) and water in a suitable mixer, *e.g.*, a vertical cylinder containing a number of perforated discs placed horizontally, from which the mixture emerges in the form of a thin sheet (preferably annularly and horizontally), and at a considerable velocity, into a vessel initially filled with water, or water and oil. This vessel is of such a shape that it enables the water and gangue to pass off at an outlet near the bottom, whilst the oil, together with the graphite, flows off near the top into a settling tank or into a second mixer similar to the first. From the settling tank the mixture passes to a filter-press, which retains the graphite, and in which it may be washed with water to remove adhering oil, which is used over again. The gangue may be re-treated in the same way.—A. G. L.

United States Patents.

Sulphate of Aluminium; Drying ——. R. S. Perry and H. G. Schanche, Philadelphia, Pa. U.S. Pat. 748,525, Dec. 29, 1903.

The aluminium sulphate to be dried is subjected to a temperature slightly lower than the initial melting point, and as this point rises, the temperature is proportionately increased. Practically, the temperature to which the aluminium sulphate is subjected is gradually raised from 227 to about 320° F.—E. S.

Hydroxides or Oxides of Metals; Production of ——, by Electrolysis. F. F. Hunt, Assignor to Maas and Waldstein. U.S. Pat. 748,609, Jan. 5, 1904. XI. A., page 119.

French Patents.

Phosphates; Process of Converting ——, into Dicalcium Phosphate, Hydrated Calcium Sulphate, and Carbon Dioxide. P. De Wilde. First Addition, dated Aug. 11, 1903, to Fr. Pat. 333,344 of June 24, 1903; this J., 1903, 1348.

The acid used in dissolving phosphates and regenerated, as described in the main patent, contains calcium sulphate in notable proportion. To remove this, the regenerated acid is treated with the necessary amount of a suitable barium salt, in strong solution or in powder. The barium sulphate formed quickly settles, and is separated for use as "blanc fixe," whilst the purified acid is fit for re-use in dissolving phosphates. (See also Eng. Pat. 14,194 of 1903; this J., 1903, 1085.)—E. S.

Chrome Ironstone; Process of Disaggregating ——, preliminary to the Preparation of Potassium Chromate. Chem. Fabr. Griesheim-Elektron. Fr. Pat. 334,713, Aug. 19, 1903.

Chrome ironstone in fine powder, mingled with a strong lye of potassium hydroxide, is heated, with abundant access of air, to 300°, rising to 500° C. The product is lixiviated with addition of lime, and the filtered solution is concentrated, to obtain solid potassium chromate, with recovery of the excess of the lye used. Compare Eng. Pats. 12,250 of 1901, and 5902 of 1903; this J., 1902, 548, and 1903, 950 respectively.—E. S.

Bichromates; Transformation of Chromates into ——, with Production of Alkali. Chem. Fabr. Griesheim Elektron. Fr. Pat. 334,685, Aug. 18, 1903. XI. A., page 119.

Copper Sulphate; Electrolytic Manufacture of ——. E. Lombard. Fr. Pat. 334,799, Aug. 27, 1903. XI. A., page 120.

Liquid Air; Manufacture of ——. J. Loumiet. First Addition, dated July 25, 1903, to Fr. Pat. 334,205, July 11, 1903. (See this J., 1904, 18.)

In the production of low temperatures, and especially in liquefying air, advantage is taken, in combination, of expansion of air at a moderately low temperature with external work; and of expansion, with or without external work, causing a further lowering of the temperature, down to that of liquid air. At least three expansion motors are used in series, these being connected by double serpentine tubes forming exchangers of temperature. A valve is interposed, as in the process described in the main patent, between the system of exchangers and motors, and the superposed bottles arranged for reception of the liquefied air.—E. S.

VIII.—GLASS, POTTERY, ENAMELS.

English Patent.

Enamelling; Methods of and Apparatus for ——. J. C. Reed, Allegheny, Pa. Eng. Pat. 16,883, Aug. 1, 1903.

See Fr. Pat. 334,506 of 1903; this J., 1904, 63.—T. F. B.

United States Patent.

Ornamented or Lettered [Glass] Articles; Manufacturing ——. R. K. Duncan, Washington, Pa., Assignor to Duncan Chemical Co., Pa. U.S. Pat 748,850, Jan. 5 1904.

A compound obtained from lead oxide and boric acid is fused to the heated glass article before annealing. The fusion may be effected by the heat of the hot glass itself.
—A. G. L.

IX.—BUILDING MATERIALS, CLAYS, MORTARS AND CEMENTS.

English Patents.

Building Blocks, Slabs, and the like; Composition of ——. R. McAlpine, Glasgow. Eng. Pat. 25,321, Nov. 20, 1903.

Lump or ground "steel slag" is mixed with Portland or other cement in a semi-liquid condition; clinker, gravel, or sand may also be added. The mixture is moulded and dried as usual.—A. G. L.

Slags; Process and Means for the Treatment of Blast-Furnace and other ——. [Cement Manufacture.] H. Passow, Hamburg. Eng. Pat 28,256, Dec. 22, 1903.

See Fr. Pat. 328,533 of 1903; this J., 1903, 999.—T. F. B.

United States Patents.

Waterproofing and Finishing the Surface of Stone, Brick, or other Analogous Porous Material. N. Farnham, Chicago, Ill. U.S. Pat. 748,595, Jan. 5, 1904.

The waterproofing agent is applied to the heated porous material, the excess then being removed by directing a blast of sand and air against the surface.—A. G. L.

Hydraulic Cement; Process of Manufacturing ——. J. Gresly, Liesberg, Switzerland. U.S. Pat. 748,912, Jan. 5, 1904.

See Addition, of Jan. 28, 1903, to Fr. Pat. 325,661 of 1902; this J., 1903, 998.—T. F. B.

French Patents.

Marble, Onyx, Calcareous Stones, Natural Earths, Raw or Burnt; Process of Colouring ——. A. Boyeux and A. Mora. Fr. Pat. 328,132, Nov. 5, 1902.

See Eng. Pat. 27,804 of 1902; this J., 1903, 698.—T. F. B.

Fireproof Wood. J. L. Ferrell. Fr. Pat. 335,054, Sept. 5, 1903.

A composition suitable for fireproofing wood is obtained by adding to a solution of sodium silicate of 45° to 50° B., sufficient of a sodium chloride solution of 24° B. to coagulate it; caustic soda solution of 26° B. is then added until the precipitate is entirely redissolved. The liquid is diluted to a strength of 20° B., and is then ready for use. In order to render it clearer, a little strong solution of sodium silicate may be added to it; on the other hand, it can be thickened by the addition of precipitated calcium carbonate or of powdered magnesite. Whey may also be added to render it more penetrating, and at the same time semi-opaque.—A. G. L.

Fireproof Wood. J. L. Ferrell. Fr. Pat. 335,055, Sept. 5, 1903.

Wood is treated with a solution containing 280 grms. of aluminium sulphate and 15 grms. of oxalic acid per litre. The presence of the oxalic acid enables the inferior qualities of aluminium sulphate to be used, which, otherwise, owing to their containing iron, would discolour the wood in a short time.—A. G. L.

Cement; Artificial ——. E. L. Candlot. Fr. Pat. 334,705, Aug. 19, 1903.

From 5 to 10 per cent. of calcium sulphate is added to a mixture of 25 to 30 per cent. of clay and 75 to 70 per cent. of calcium carbonate, and the whole burnt at a moderate temperature. The calcium sulphate may be replaced by other sulphates. The setting and hardening of the cement so obtained are claimed to be very regular.
—A. G. L.

Cement; Process of Manufacturing ——, from Blast-Furnace Slag. C. Canaris, jun. Fr. Pat. 335,233, Aug. 28, 1903.

See Eng. Pat. 18,623 of 1903; this J., 1903, 1293.—T. F. B.

X.—METALLURGY.

Limestone in the Cupola ; Effect of Addition of ——. F. Wüst. Stahl u. Eisen, 1904, **24**, [1], 28—32.

The amount of limestone added to the charge varies enormously in the practice of different foundries. The theory is that the limestone serves to form slag with the ash of the coke, and hence the amount used should depend on the amount of that ash and the composition of the limestone itself. The limestone, moreover, serves to remove in the slag some of the sulphur of the coke, which otherwise might find its way into the metal. No published researches on this point exist, and the author gives the following results obtained by A. Sulzer-Grossmann at Winterthür. Charges of 500 kilos. of mixed pig-iron and 30 kilos. of coke were used, with amounts of limestone varying in 11 experiments from 0 to 10 kilos. ; the whole amount of metal melted in each experiment varied from 15,000 to 20,000 kilos., and the conditions were as nearly as possible the same in all the experiments, save the amounts of limestone used.

Composition of the Iron.—The manganese and phosphorus were scarcely affected ; the silicon varied somewhat irregularly ; but the sulphur diminished from 0·13—0·16 per cent. with 0—1 kilo., to 0·085 per cent. with 8—9 kilos. of limestone.

Composition of the Slag.—As the limestone increased, the lime in the slag increased, though somewhat irregularly, the iron and manganese slowly diminished, and the alumina showed great irregularities, perhaps through irregular action on the furnace-lining. The silica also diminished as the limestone increased ; but though the diminution was considerable, it was not regular, occasional rises taking place ; and the sulphur varied in a manner showing no connection with the amount of lime, of silica, or of manganese ; possibly the sulphur in the slag depends on physical causes, such as temperature and the viscosity or mobility of the melted slag.

Losses in the Slag.—Increase of limestone causes an increase in the percentage of iron and of manganese lost in the slag, but hardly affects that of the silicon ; the total loss of all three rises from 0·8 to 1·6 per cent. (The figures are much lower than those usually quoted in the handbooks : 3 to 6 per cent.) If the iron in the coke-ash be taken into account, about 0·1 per cent. would be taken off these figures.

Mechanical Properties of the Metal.—The resistance to shock rises till the limestone is 20 per cent. on the coke (6 kilos.), and then remains stationary. The resistance to bending steadily rises as the limestone increases, to a maximum at 8 kilos. The tensile strength increases to a maximum with a limestone charge of 6 kilos., and is but little influenced by further increase in the limestone. The resistance to compression is hardly influenced at all.

—J. T. D.

Ferromanganese Production : Composition of Slags of ——. F. Wittmann. Stahl u. Eisen, 1904, **24**, [1], 14—16.

It is generally agreed that in making ferromanganese a basic slag should be aimed at, but to this term different meanings are attached. Stoïchiometrically the slag is more basic as the oxygen of the acid bears a smaller proportion to that of the bases, but here alumina is often left out of consideration, from doubt whether it should be considered an acid or a base. Platz considers a slag more basic as the sum of the silica and alumina bears a smaller proportion to the sum of the other bases, whilst the furnace foreman will regard a viscous slag of high-melting point as basic. In ferromanganese work, however, the melting point of the slag is of less importance than its capacity for dissolving manganese oxide. But as the amount of manganese in the slag depends chiefly on the amount of coke used (in using plenty of coke a highly silicious slag can be obtained containing very little manganese, whilst with little coke a highly basic slag can take up much, as in making spiegel), the examination of the results of analysis of slags can yield no useful result, unless all the samples proceed from similar conditions of working (amount of coke, blast temperature, shape of furnace, &c). The following analyses, from a single furnace at different periods during nine years, fulfil this requirement :—

11	12·17	30·91	8·23	0·59	45·62	2·03	..	0·63	1·26	1·54	1·09	1·23	47·70	80	Jan. 1894.

These results, it will be seen, are arranged in descending order of manganese-content. Whether we examine the ratio of basic oxygen to acid oxygen, or of bases other than alumina to silica and alumina, and whether we include the manganous oxide or leave it out, there is no connection between any set of these figures and the decrease in manganese ; but the total percentage of alkaline-earth oxides is obviously complementary to that of manganese oxide, while the other figures in the analysis show that the diminution in manganese with increase in alkaline-earth oxides is not due to simple dilution of the whole slag by these oxides. On plotting the results with percentages of alkaline-earth oxides as abscissæ, and of manganese oxide as ordinates, the decrease of the latter with increase of the former up to about 45 per cent. is clearly shown. Further increase of the alkaline-earth oxides has practically no effect.—J. T. D.

Quartz Milling ; Notes on the Common Practice of ——, *on the Rand.* W. Beaver. J. Chem., Met. and Min. Soc. of South Africa, Nov. 1903, 217.

Of a sample passing through a screen of 500 mesh which had been used 90 hours, 0·473 remained on a perfect [illegible] mesh ; from a broken screen just before changing, 1·2[illegible] per cent. remained on a 500 mesh, 0·533 per cent. on a 400, 0·109 per cent. on a 300, and 0·011 per cent. on a 200. Screens should be changed before reaching that stage. Great care should be taken in dressing the plates, as also while changing screens, to prevent amalgam getting into the tailings.—J. H. C.

Molybdenum Ores; Utilisation of ——. J. W. Wells. Bull. of the Imperial Inst. (Suppl. to Board of Trade J.), 1903, [4], 213.

The author's method for the concentration of molybdenum ores is based upon the fact that molybdenite, when passed between rolls, does not become pulverised, but forms flakes. A specimen of ore containing 50 per cent. of pyrrhotite, 10 per cent. of pyrites, and 6·5 per cent. of molybdenite, together with mica, quartz, &c., was passed between rolls and then screened, first through a sieve with a 0·2-in. mesh, and then through one with a 0·1-in. mesh. There remained on the first screen 1·4 per cent. and on the second 1·54 per cent. of the material treated, in the form of a concentrate containing about 55 per cent. of molybdenite and 45 per cent. of mica. This concentrate, when treated in a Wetherill magnetic separator, yielded an ore containing from 90 to 91 per cent. of molybdenite.—A. S.

Blast-Furnace Gas as the Sole Source of Power for a Modern Metallurgical Works. K. Gruber. Stahl u. Eisen, 1904, **24**, [1], 9–14; [2], 89–93.

After referring to the great progress which has already been made, especially in Germany, in the use of blast-furnace gas for heating and power purposes, the author states, as the result of a series of calculations, that not only can the whole of the power- and heating-gas required in a metallurgical works be obtained by the rational employment of furnace gases, but that there will still be an amount of gas in excess that can be applied to other industrial purposes.—A. S.

Tungsten in Tungsten Steel and Ferrotungsten; Determination of ——. E. Kuklin. XXIII., page 134.

Amalgams of Platinum; Behaviour of ——, towards Nitric Acid. N. Tarugi. XXIII., page 131.

English Patents.

Iron and Steel; Process of Treating ——, with Carbides. E. Engels, Düsseldorf, Germany. Eng. Pat. 25,932, Nov. 27, 1903.

Iron or steel in the solid (not molten) state, is treated with a carbide, such as silicon carbide, and a decomposable alkali salt, such as sodium sulphate, and reaction is induced by heating.—E. S.

Iron and Steel; Treatment of ——. C. Koller, Salgstarjan, Hungary. Eng. Pat. 28,178, Dec. 20, 1902.

Molten pig iron or steel is run into a lined vessel, mounted on a vertical shaft, to which rapid rotation is imparted by suitable machinery. The vessel is tightly covered. Under the centrifugal action, the oxides contained in the iron float to the surface of the fused mass, and may be removed as scum when the vessel is brought to rest.—E. S.

Iron, Steel, and their Alloys; Manufacture and Refining of ——. J. B. de Alzugaray, London. Eng. Pat. 1562, Jan. 22, 1903.

See Fr. Pat. 333,382 of 1903; this J., 1903, 1353.—T. F. B.

Iron and Steel; Production of ——. A. G. Bloxam, London. From La Soc. Electro - Métall. Française, Forges. Eng. Pat. 7027, March 26, 1903.

See Addition, of July 10, 1903, to Fr. Pat. 328,350 of 1903; this J., 1904, 25.—T. F. B.

Iron and Steel; Manufacture of Malleable ——, and Apparatus therefor. F. E. Young, Canton, Ohio. Eng. Pat. 8101, April 7, 1903.

See U.S. Pat. 724,770 of 1903; this J., 1903, 557.—T. F. B.

Refractory Ores [Lead-Zinc]; Treatment of ——. E. H. Miller, London. Eng. Pat. 20,465, Sept. 19, 1902.

The ore is made into dry blocks with stated proportions of silicious matter and pitch with or without lime, according to the silver contents; and the blocks are loosely packed in a furnace, to admit of air-spaces, and the layers are sprinkled with lime. The temperature is gradually raised until the reduced zinc distils over, and is collected. The lead and silver contents of the ore are found in the residue in the metallic state, and are recovered thence by melting out.—E. S.

Furnace or Kiln for Burning Ore Briquettes. G. Gröndal, Djursholm, Sweden. Eng. Pat. 23,764, Nov. 2, 1903.

The furnace is of the channel type, for receiving trucks carrying briquettes to be heated by gas, and consists of a compartment for preliminary heating, a cooling compartment, and a burning chamber of a somewhat greater height, situated between these compartments. There are channels in the walls and roof for passage of a part of the air for combustion, interconnected, and communicating with one or more openings in the wall of the gas inlet to the burning chamber. The compartment for preliminary heating is of greater height than the cooling compartment. See Fr. Pat. 330,763, 1903; this J. 1903, 1091.—E. S.

Ores; Separation of the Metallic Constituents of ——, from Gangue [by the Oil Process]. A. E. Cattermole, London. Eng. Pat. 26,295, Nov. 28, 1902.

The crushed ore is mixed with water, oil, and an emulsifying agent, such as soap, the proportion of oil used being only sufficient to produce granules with the metalliferous contents of the ore. Under these conditions, the oil-carrying particles sink, and are thus separable. The oil used, is recovered by the further use of an emulsifying agent, preferably with addition of a small proportion of a free alkali. When, as in many gold ores and slimes, the metalliferous particles are associated with much gangue, the desired agglomeration is facilitated by the introduction of coarser metalliferous matter, such as the coarser concentrates, which act as centres of granulation.
—E. S.

Ores: Classification of the Metallic Constituents of —— [by the Oil Process]. A. E. Cattermole, London. Eng. Pat. 26,296, Nov. 28, 1902.

After agglomeration of the metalliferous constituents of ores by oil, &c., as described in the preceding patent, advantage is taken of the varying affinity for oil of, for instance, particles of copper pyrites, galena, and blende, to effect a fractional separation by the use of successively stronger emulsifying or "breaking down" solutions, particulars of the adaptation of which to different conditions are given. An "up-current" or other separating device is used for removing the freed mineral from the more resisting granules (metalliferous), and a series of mechanical separators is used to recover the emulsion for subsequent application. The separated minerals may be drained, or treated in centrifugal apparatus, for closer recovery of the oil and other products.—E. S.

Zinc; Manufacture of ——. A. Kunze and K. Danziger, both of Kattowitz, Germany. Eng. Pat. 5016, March 4, 1903.

Blende zinc ores containing iron pyrites are moistened and exposed to the air for several weeks, with application of heat, which may be by means of underlying flues. Under these conditions, it is stated that the pyrites oxidises, and the oxidised products may be removed by washing, leaving the blende practically unaffected. Or, if the pyrites be not wholly oxidised, it becomes disintegrated and easily removable.—E. S.

United States Patents.

Case-Hardening Compound. J. Cadotte, Suncook, N.H. U.S. Pat. 748,842, Jan. 5, 1904.

The dry compound is composed of two parts each of "white calcined plaster" and of potassium ferrocyanide, with one part of lampblack, all by weight.—E. S.

Steel and Ingot Iron ; Manufacture of ——. B. Talbot, Leeds, England, and P. Gredt, Luxemburg, Germany, Assignors to the Continuous Metal Refining Co., Philadelphia, Pa. U.S. Pat. 749,115, Jan. 5, 1904.

The impure metal is blown in a converter, a portion of the charge is run off, and from the remainder of the charge the phosphorus is removed by lime and blowing ; the slag thus produced is then removed, oxides are added to the bath and a further charge of impure metal, when the combined charge is blown.—E. S.

Briquettes [from Fine Ores]. W. Huffelmann, Duisburg, Germany. U.S. Pat. 748,739, Jan. 5, 1904.

See Eng. Pat. 10,618 of 1903 ; this J., 1903, 1051.—T. F. B.

French Patents.

Cast Iron ; Refining ——, *by Pulverisation.* H. Harmet. Fr. Pat. 334,892, Aug. 28, 1903.

The molten iron to be refined is run into a basin lined with refractory material, and having, at the side and near the bottom, an outlet inclined slightly downwards, and wider at the inner end. The metal flows from this opening in a jet, encompassed by a blast of heated air from a tuyère the outlet of which forms an annular opening surrounding the sides of the passage for the metal, which is thus dispersed as a spray, assuming a conical shape, and "pulverised" into innumerable minute globules exposed to the action of the air. The metallic spray is projected into a suitably packed receptacle, at the bottom of which the purified iron or steel collects, and whence it may be tapped. —E. S.

Heavy Metals ; Process of Extracting ——, *by the Use of Chlorine [from Sulphide Ores, &c.].* Soc. Allgem. Elektro-Metallurg. Fr. Pat. 334,941, Aug. 31, 1903.

Finely-powdered ores or mattes containing sulphur are mixed with iron oxide and agitated in a solution of calcium chloride whilst chlorine is passed through. The sulphuric acid formed by oxidation of the sulphur is thus precipitated as calcium sulphate, with liberation of hydrochloric acid, which dissolves the iron oxide, forming ferric chloride. Air is blown through the solution in the presence of fresh ore or matte, whereby any ferrous chloride present is decomposed, with separation of ferrous hydroxide. Claim is also made for the recovery of the chlorine, which may be used to dissolve other portions of ore or metals.—E. S.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

(A.)—ELECTRO-CHEMISTRY.

Mercury Vapour ; Conductivity of —— *[Mercury Vapour Electric Lamp].* P. C. Hewitt. Electrician, 1904, 52, [1338], 447—449.

The author made a number of experiments on the conductivity of mercury vapour, taking precautions to obtain results not vitiated by effects due to the terminals or electrodes. The results obtained are given in a series of curve-diagrams, in which the influence of the density (pressure) of the vapour, the diameter of the lamp or tube containing the vapour, and the strength of the current, upon the drop in volts per unit length of the column of vapour is shown. It was found that the voltage required to maintain an electric current in mercury vapour is directly proportional to the density of the latter, and that it decreases as the diameter of the lamp increases. The resistance decreases with increase of current. The light-efficiency of mercury vapour varies with the density of the latter. On passing a current through the vapour at a very low density, practically no light is visible, but the light-efficiency increases with the density of the vapour up to a certain limit, after which it again decreases. If another gas is present with the mercury vapour, the current is usually selective, and gives the spectrum of mercury, but the resistance is materially altered. By the application of magnetic force transversely, the resistance is increased remarkably when the density of the vapour is low, but at higher densities the effect is not very marked. The author states that the relation of the conductivity of mercury vapour to the physical conditions under which the electric current through the vapour is maintained, appears to be, broadly speaking, generally true for all gases and vapours. (See U.S. Pats. 690,952 and 690,953 ; this J., 1902, 465, 466.) —A. S.

Alkaline-Earth Metals ; Electrolytic Separation of ——. A. Coehn and W. Kettembeil. XXIII., page 134.

English Patent.

Electrodes for Accumulators. A. Meygret, Paris. Eng. Pat. 1676, Jan. 23, 1903.

The electrode is composed of a series of small sheets of lead, lead and antimony, or other suitable metal or alloy, joined together at one extremity by means of a common support, either directly in the casting, or in the stamping out, or by soldering together. The electrode is covered with oxide of lead, dipped into tetra-acetate of cellulose, and then dried in the air. A protective and elastic envelope, not acted on by the electrolyte, is thus obtained, which is afterwards rendered porous by perforations made in the form of small holes or cuts.—B. N.

United States Patents.

Electrodes for Storage Batteries ; Method of Producing ——. F. A. Feldkamp, Newark, N.J., Assignor to Electra Manufacturing Co., New Jersey. U.S. Pat. 748,940, Jan. 5, 1904.

The electrode is produced by subjecting a porous material to the action of a salt or salts of lead, and then chemically reducing the same ; or a reducing agent in fine particles, such as zinc, may be incorporated with the porous material previously to subjecting to the action of the lead salt. The porous material may be carbonised, and may be applied to a conducting plate, for instance, by sewing it fast to the plate.—B. N.

Hydroxides and Oxides of Metals by Electrolysis ; Production of ——. F. F. Hunt, New Brighton, N.Y., Assignor to Maas and Waldstein, New York. U.S. Pat. 748,609, Jan. 5, 1904.

The electrodes are made from the metal the hydroxide or oxide of which is required, as, for instance, tin, each electrode being used as anode and cathode, alternately, at suitable intervals. The electrolyte consists of a solution of a salt of an alkali or alkaline earth, such as common salt, the acid radicle of which combines with the anode to form a soluble metallic salt, and the latter reacts with the alkali formed at the cathode, producing the desired hydroxide or oxide, and simultaneously re-forming the salt used as the electrolyte. —B. N.

Alkali Chlorides ; Apparatus for the Electrolytic Decomposition of ——. J. J. Rink, Elsinore, Denmark. U.S. Pat. 748,985, Jan. 5, 1904.

See Eng. Pat. 5718 of 1902 ; this J., 1902, 913.—T. F. B.

Manure ; [Electrical] Process of Manufacturing ——, *from Apatite.* W. Palmaer. U.S. Pat. 748,523, Dec. 29, 1903. XV., page 124.

French Patents.

Electrodes for Electrolysis ; Process of Manufacture of ——. Chem. Fabr. Griesheim-Elektron. Fr. Pat. 334,684, Aug. 18, 1903.

The residues from pyrites burners, or any other forms of oxide of iron in a sufficiently pure state, are melted in an electric furnace, whereby the substance is made into a good conductor. The melted mass is cooled in moulds of any required form.—B. N.

Bichromates, with Production of Alkali [Electrolytic] ; Process of Transformation of Chromates into ——. Chem. Fabr. Griesheim-Elektron. Fr. Pat. 334,685, Aug. 18, 1903.

This process is carried out electrolytically by placing a saturated solution of chromate in both the anode and cathode chambers, these being separated by a suitable diaphragm. An anode must be used which is not attacked, such as lead or platinum, and a cathode, such as iron, which will not reduce the chromate. The whole of the chromate is converted into bichromate, and the volume of the cathode chamber is such that the alkali has a strength of 100 grms. per litre when the conversion of chromate into bichromate is complete.—B. N.

Copper Sulphate ; Electrolytic Manufacture of ——. E. Lombard. Fr. Pat. 334,799, Aug. 27, 1903.

The invention relates to a process for the electrolytic manufacture of sulphate of copper, useful for replenishing the baths used in electrotyping. Electrodes of copper are used, the anode being placed in water acidulated with sulphuric acid, and the cathode in a porous vessel containing sulphuric acid or a saturated solution of a sulphate of a metal other than copper. Diffusion of the copper sulphate through the diaphragm towards the cathode is thus prevented. A special diaphragm may be used, consisting of two porous vessels, with an annular space between, filled with sulphuric acid of 53° B., the inner vessel containing dilute sulphuric acid and a copper cathode ; the two vessels, together with a copper anode, are immersed in water acidulated with sulphuric acid.
—B. N.

Amines, Fatty and Aromatic ; Process of Producing ——, by Electrolytic Reduction. P. Knudsen. Fr. Pat. 334,726, July 2, 1903.

Fatty and aromatic amines are produced by the electrolytic reduction of condensation products of aldehydes with ammonia or amines. *Ethylamine* is prepared by reducing ethylideneamine, obtained by the condensation of aldehyde-ammonia over sulphuric acid (Délépine) ; 30 grms. of ethylideneamine, mixed with 120 c.c. of sulphuric acid of 41° B., at a temperature below 0° C., is electrolysed, in the cathode compartment of a cell, with lead cathode, the anode being of lead in sulphuric acid contained in a porous vessel ; eight hours with a current of six ampères is sufficient, the temperature being kept below 10°—12° C. ; the ethylamine is obtained by distilling the product with excess of caustic soda. *Diethylamine* is prepared by electrolysing the sulphuric acid solution of the product of condensation of ethylamine and acetaldehyde. By subjecting to electrolysis the product of the action of methylamine on benzaldehyde, *methylbenzylamine* is obtained, while *methylaniline* is obtained by a similar treatment of anhydroformaldehyde-aniline.—T. F. B.

(*B.*)—ELECTRO-METALLURGY.

Gold and Silver ; Electrolytic Precipitation of —— , from Cyanide Solutions. E. M. Hamilton. J. Chem. Met. and Min. Soc. of South Africa, Nov. 1903, 209—216.

The cyanide plant at Minas Prietas, Sonora, Mexico, has a capacity of 9,000 tons per month, 40 per cent. slimes and 60 per cent. sands. Single treatment is adopted, using mechanical stirrers and centrifugal pumps for agitation. Each dwt. of gold obtained carries 1 oz. of silver with some copper. The precipitation plant consists of (6) boxes, 30 ft. long, 10 ft. wide, and 5 ft. deep, divided into 12 compartments, each having 18 anodes and 17 cathodes. The current is supplied by (2) Siemens-Halske dynamos having a capacity of 250 ampères and 30 volts, the current density being from 0·2—0·25 ampère per sq. ft. of anode surface. The anode is made of sheet lead coated with peroxide, and is not enclosed in any way. The precipitate is a fine slime, which readily falls to the bottom of the box ; the cathodes are of tin-plate. By the newest arrangement, they can be cleaned without removal. Both cathodes and anodes are practically indestructible. In a series of experiments made under varying working conditions to determine the current efficiency, using a current density of 0·3 ampère per sq. ft. for slime solutions and 0·55 ampère for sand solutions, the non-effective ampèrage varied from 86—95 per cent. of the total. The cyanide "regenerated" by the passage of the current amounted to 0·35 lb. for each ton of sand treated, and 0·94 lb. per ton of slimes, or an average of 0·58 lb. ; the theoretical quantity, supposing no water to be decomposed, is 0·93 lb. ; the cyanide consumption averaged 2·5—3·0 lb. per ton of ore. When ores are treated without previous amalgamation, the regeneration of cyanide is lessened. The gold precipitate contains much lime, and it is suggested that the addition of a little caustic potash to the solution, and the use of a current of lower density, would lessen this.—J. H. C.

XII.—FATTY OILS, FATS, WAXES, AND SOAP.

Fats and Waxes ; Vegetable ——, of Indo-China. M. Lemarié. Bull. of the Imperial Inst. (Suppl. to Board of Trade J.) 1903, [4], 206—212.

Dika Butter.—This fat, which is also known as "oba" or wild mango oil, is obtained from the seed-kernels of *Irvingia Barteri* by boiling them with water and then subjecting them to pressure : yield, 60—65 per cent. It is a white fat, with a sweet odour and pleasant taste ; on keeping, it becomes yellow and rancid ; it is readily saponified, and is used in the manufacture of candles, and as a substitute for cocoa-nut oil in the manufacture of marine soap. The fat has the following characters :—Sp. gr. at 15° C., 0·820(?) ; m. pt., 30°—32° C. ; saponification value, 173 ; iodine value, 30·9—31·3 ; free fatty acids, 4—10 per cent. It contains the glycerides of lauric, palmitic, and myristic acids.

Irvingia Butter.—This fat, known by the natives as "cây-cây," is obtained from the seed-kernels of *Irvingia malayana*, the candle-tree of Indo-China : yield, 52·0—56·7 per cent. It melts at 37·5°—38° C., and solidifies at 35·5°—36° C., and is completely saponified by alkalis, yielding a white nacreous soap which is readily soluble in alcohol.

Chinese Vegetable Tallow.—The seeds of *Sapium sebiferum*, known locally as "cây-sôi," consist of 60 per cent. of shell and 31 per cent. of kernels. From the shells, by heating with steam, 29·5 per cent. of "pi-yu," a white solid fat, is obtained having the sp. gr. 0·918 at 15° C., and m. pt. 44·5° C. From the kernels, by expression, is obtained 59·5 per cent. of "tsé-iéou," or "ting-yu," a liquid oil which possesses drying properties, and is used as an illuminant and in the manufacture of varnish. "Mou-iéou" is a mixture of "pi-yu" and "ting-yu" obtained from the whole seeds ; it has the sp. gr. 0·915 at 15° C., and m. pt. 35° C., and is slightly acid, owing to the presence of propionic acid. Both "mou-iéou" and "pi-yu" are sold as Chinese vegetable tallow—a product used in the manufacture of candles.

Chaulmoogra, or Gynocard Oil.—This oil is obtained from "krebao" seed, known by the Chinese as "ta-fung-tze," the product of one or more species of *Hydrocarpus* of the natural order *Bixineæ.* By expression the seeds yield 30 per cent. of oil, which melts at 17° C., whilst by extraction with ether, 50—52 per cent. of oil, melting at 14° C., is obtained. The freshly-prepared oil is white, odourless, and tasteless, but oil which has been kept, or which has been extracted from old seeds, has a light brown colour and an odour resembling that of bird-lime. The oil is used for medicinal purposes in Indo-China and Siam.

Japan Wax.—The most important sources of this product are *Rhus succedanea* and *R. vernicifera.* When the wax is prepared from the fruit by expression, the last traces left in the press residues are extracted by adding about 10 per cent. of oil of perilla, or "ye goma" (this J. 1903, 806), and again submitting the wax to pressure. The presence of the oil of perilla is the cause of the varying hardness of commercial Japan wax. The wax melts at 53°—54° C., and solidifies at 40·5°—41° C. The crude wax has the sp. gr. 1·006 ; the bleached wax, 0·97 —0·980 ; it consists chiefly of palmitin, together with small amounts of the glycerides of volatile fatty acids.

Fats derived from the Dipterocarpeæ.—Borneo tallow from the seed-kernels of *Shorea aptera* (Burk.) an *Isoptera borneensis* (Scheff.) contains about 95 per cen of saponifiable fats (stearin and olein) ; it is used by th natives for culinary purposes, in England as a lubrican and in Manila for the manufacture of candles. Piney o

Malabar tallow, from the seeds of *Vateria indica*, is tasteless and inodorous, and has a consistence between that of stearin and wax. It contains about 2 per cent. of a volatile oil, which can be extracted by alcohol; the tallow, after removal of this oil, consists of 75 per cent. of palmitin and 25 per cent. of olein. The tallow has the following characters:—Sp. gr. at 15° C., 0·915; m. pt., 40° C.; solidifying point, 30·5° C.; saponification value, 191·9; m. pt. of fatty acids, 57° C.; solidifying point of fatty acids, 55° C. Candles made of Piney tallow burn steadily and emit an agreeable aromatic odour.

Fats derived from the Lauraceæ.—"Lalreu" tallow, or "undung," is obtained from the seeds of *Tetranthera laurifolia*, Jacq. ("bói-lói"); it is used in the manufacture of candles. *T. citrata*, Nees., *T. glabraria*, Nees., and *T. Roxburghii*, Bl., yield similar products. "Vegetable butter" or the pulp of the "advocate pear," the fruit of *Persea gratissima*, yields on expression a large percentage of oil, which is used as an illuminant and for the manufacture of soap. "Tangkallah" fat is obtained from the seeds of *Cylicodaphne sebifera*, Bl.; yield, 40—45 per cent. It melts at 45° C., and contains 85 per cent. of laurostearin and 14 per cent. of olein. It is used in the manufacture of soap and candles. It is stated that the seeds produced annually by one tree yield sufficient fat for the manufacture of 500 candles.—A. S.

Plants which contain in their Seeds an Enzyme capable of Decomposing Fats into Glycerin and Fatty Acids. S. Fokin. J. russ. phys.-chem. Ges., **35**, 831—835. Chem. Centr., 1903, **2**, [26], 1451.

The author found that the most active seeds, superior even to castor-oil seeds, were those of *Chelidonium majus*; the seeds of *Taraxacum vulgare*, *Brunella vulgaris*, *Cynoglossom*, *Aquilegia vulgaris*, and *Aconitum Lycoctonum* had a distinctly weaker action. (See also this J., 1902, 1541; 1903, 67, 639, 873, 1094.)—A. S.

Lubricant; Process of Making ——. S. A. Smith, Providence, R.I., U.S.A. U.S. Pat. 748,317, Dec. 29, 1903.

A mixture of antimony trioxide and air-slaked lime is finely powdered and added to an oil of heavy gravity, the whole being subsequently mixed with an oil of lighter gravity.—C. A. M.

Fat-like Substance; Process of Making ——. O. Liebreich, Berlin. U.S. Pat. 748,511, Dec. 29, 1903.

See Ger. Pat. 136,917 of 1900; this J., 1903, 149.—C. A. M.

French Patent

Soap containing Lemon Juice. G. Giraudet and A. Neuberger. Fr. Pat. 334,916, Aug. 29, 1903.

Fresh filtered lemon juice is mixed with an alcoholic solution of oil of lemon and citric acid, and sufficient starch added to form a paste, which is dried and incorporated with ordinary soap in a suitable proportion. Claim is made for the use of starch as a vehicle for fruit juices and essential oils in general.—C. A. M.

XIII.—PIGMENTS, PAINTS; RESINS, VARNISHES; INDIA-RUBBER, Etc.

(*A.*)—PIGMENTS, PAINTS.

English Patent.

White Lead; Manufacture of ——. J. H. Montgomery, St. Louis. Eng. Pat. 15,742, July 16, 1903. Under Internat. Conv., July 19, 1902.

See Fr. Pat. 333,851 of 1903; this J., 1904, 26.—T. F. B.

United States Patent.

Protecting Ironwork: Material for ——, *and Method of Preparing the same.* W. O. Emery, Crawfordsville, Ind., U.S.A. U.S. Pat. 748,270, Dec. 29, 1903.

A clear, highly viscous material, consisting of calcium and sodium silicates and calcium aluminate, is prepared by fluxing at a white heat a mixture of quicklime, quartz, felspar, alumina, and sodium sulphate. This is powdered, and incorporated with melted asphalt.—M. J. S.

French Patents.

White Oil-Paint; New ——, *and Process of Making it.* Farbwerke W. A. Hospelt. Fr. Pat. 334,835, Aug. 25, 1903.

Lead oxychloride is produced by the trituration of lead oxide with sodium chloride or any other chloride. The mass is then treated with sulphuric acid until it exhibits a neutral or feebly acid reaction. The product is pressed and dried, and ground with oil and a siccative.—M. J. S.

White Lead and Zinc White; Substitute for ——. C. Gendre. Fr. Pat. 334,917, Aug. 29, 1903.

A mixture of randanite (fossil meal), barytes, and asbestos, is calcined and reduced to powder.—M. J. S.

Lithopone Resistant to Light and Atmospheric Influences; Process of Manufacturing ——. Chem. Fabr. Marienhütte. Fr. Pat. 334,944, Aug. 31, 1903.

The tendency of lithopone to darken on exposure to sunlight is found not to be exhibited by products from the manufacture of which chlorides have been entirely excluded. Crude zinc sulphate is therefore purified from iron and manganese by heating with a permanganate and an alkali, and the solution is further purified by treatment with zinc powder and copper sulphate, after which it is employed for the manufacture of lithopone in the usual manner.—M. J. S.

Pigment [Barium Sulphate and Zinc Sulphide]; Process of Making a ——. W. J. Armbruster and J. Morton. Fr. Pat. 335,115, Sept. 10, 1903.

See U.S. Pat. 740,072 of 1903; this J., 1903, 1200.—T. F. B.

Pigment [Barium Carbonate and Zinc Sulphide]; Process of Making a ——. W. J. Armbruster and J. Morton. Fr. Pat. 335,358, Sept. 10, 1903.

See U.S. Pat. 740,073 of 1903; this J., 1903, 1200.—T. F. B.

(*B.*)—RESINS, VARNISHES.

French Patents.

Linseed-Oil Varnish; Substitute for ——. M. S. Muller and C. Klee. Fr. Pat. 334,923, Aug. 29, 1903.

This varnish is especially intended for use with zinc white, to which it imparts a covering power rivalling that of white lead. Thirty-two parts of zinc white are incorporated with 1,000 parts of melted rosin, and the mixture is cooled and crushed. A separate mixture is made of 100,000 parts of petroleum oil (pétrole), 1,300 parts of lysol, 35 parts of nitrobenzene, and 4,000—5,000 parts of pure water. Then 460 parts of the first are heated with 455 parts of the second mixture, and the "acide d'abiétine," which rises to the surface, is removed by a perforated skimmer. Lastly, 100 parts of poppy-seed oil, or other drying oil, are added.—M. J. S.

Varnish; Coloured ——. L. Leroy and P. E. Leroy. Fr. Pat. 334,992, Sept. 2, 1903.

A SOLUBLE silicate is mixed with any pigment or colouring matter.—M. J. S.

Linoleum; Substitute for ——. E. V. Clausen. Fr. Pat. 335,243, Aug. 31, 1903. Under Internat. Conv., Oct. 22, 1902.

SEE Eng. Pat. 19,233 of 1903; this J. 1903, 1358.—T. F. B.

(C.)—INDIA-RUBBER.

Sulphur; Determination of ——, *by Eschka's Method* [*in Vulcanised Rubber*]. O. Pfeiffer. XXIII., page 132.

FRENCH PATENT.

Caoutchouc; Manufacture of Artificial ——. L. L. A. Seguin and J. F. G. de Roussy de Sales. Fr. Pat. 334,833, Aug. 25, 1903.

TAR, or any hydrocarbon containing the "isomers of caoutchouc," is acidified with an acid, such as boric or hydriodic, capable of "eliminating nitrogen" from it. The mixture is then seeded with "particles of caoutchouc" or "other appropriate ferment," and is maintained at 60° C. in an oxidising atmosphere free from nitrogen. After some time the whole mass will have become converted into "a viscous solution of caoutchouc" of an amber colour.
—M. J. S.

XIV.—TANNING; LEATHER, GLUE, SIZE.

Extraction of Tanning Materials; Influence of Chlorides and Sulphates present in Natural Waters upon the ——. E. Nihoul and L. van de Putte. Bull. de l'Assoc. belge des Chim., 1903, **17**, [10].

A CONTINUATION of previous work on the influence of various salts present in tannery water (see this Journal, 1901, 1005). A record is given of the results obtained by extracting oak-bark, pine-bark, and sumac with artificial hard waters in comparison with distilled water. The quantities of salts used were such as are to be found in natural waters, *viz.*, 0·005 grm., 0·050 grm., 0·150 grm., 0·400 grm., 0·500 grm., and 1·000 grm. of chlorine per 1000 as the sodium, magnesium and calcium compounds respectively, and 0·0309 grm., 0·0445 grm., 0·1056 grm., 0·2700 grm., and 0·3383 grm. of sulphuric acid (calculated as SO_3) per 1000 in combination with the same bases. In the adjoining table the results obtained with the smallest and greatest proportion of each salt on each material are given.

In many instances the smallest quantities of salts have little appreciable influence, whilst the largest quantities produce most marked effects, *e.g.*, of calcium chloride on oak and sumac (where 50 per cent. of the tannin disappears), and of magnesium chloride on the organic non-tannins of all three materials. The following are the more important conclusions to be drawn.

Influence of Chlorides.—Chlorides have a marked destructive effect on the tannin, and the losses observed with natural water may be almost completely ascribed to their influence. Thus a natural water containing 0·4655 grm. of chlorine per 1000, all as calcium chloride, caused a loss of 4·80 per cent. of tannin in the case of pine bark, whilst the artificial water, with 0·500 grm. of chlorine, lost 4·88 per cent. The influence upon extraction is of a double nature; part due to the base and part to the tanning matter. Oak tannin is wasted approximately in proportion to the concentration of the salt solution, and nearly the same is true of sumac, whilst pine bark shows great irregularities. As regards the destructive influence of the various chlorides, this in some instances appears to increase with the molecular weight of the salt used.

Influence of Sulphates.—Combined sulphuric acid has an even greater destructive influence than combined chlorine, pine bark and oak bark being more sensitive than sumac. The relation between the loss in tannin and the quantity of salt dissolved, whilst being of a similar character for each tanning material and each salt, shows greater variations than the analogous relation when chlorides are concerned.

These results further show that the evil effects of hard waters are not altogether avoided by chemical softening processes. Salts of sodium are not only not harmless, but in some cases, as in that of pine bark, produce more loss than the calcium or magnesium compounds, so that a naturally

---

* NOTE.—The chloride waters contained 0·005, 0·050, 0·150, 0·400, 0·500, and 1·000 grm. of chlorine per 1000. The sulphate waters contained 0·309, 0·0445, 0·156, 0·270, and 0·3383 grm. of SO_3 per 1000. The original tables give the results for all these waters to two places of decimals. In the above table only the first and last in each case are recorded to one decimal place.

The oak contained 10·5 per cent. water; the pine bark 12·5 per cent.; and the sumac 8·7 per cent.

soft water is of greater advantage than hitherto imagined. The column of figures showing the amount of mineral matter fixed by the hide, indicates an important interaction between the saline constituents and the tanning matters. Soluble molecular compounds are formed, capable of absorption by the hide substance, or, alternatively, the tannin combines with the salt base, and free acid is liberated. Both suppositions are possible, and the latter especially, in view of the distinct effect of sodium sulphate on pine-bark liquor. The practical conclusions of this are (*a*) that owing to this fixation of mineral matter the ash of leather will vary in amount according to the water used in manufacture, and analysts must allow a certain latitude in the matter; and (*b*) the discovery of sulphuric acid in leather when none has been employed in the manufacture can be explained by the presence of sulphates in the tannery water.—R. L. J.

Mangrove Bark as a Tanning Material. J. Paessler. Collegium, 1904, [91], 15—16.

Pieces of hide were tanned in mangrove bark liquors (*a* for about two weeks in liquors of 4° Bé. density. One half were then washed till the water was no longer coloured, and then air-dried, and analysed. The other half were (*b*) further tanned for six months in liquors strengthened up to 6° Bé., washed, dried, and analysed as before. Similar tests were made with an oak tannage, and the results calculated to 18 per cent. of moisture were as follows:—

——	Mangrove Bark. (*a*)	Mangrove Bark. (*b*)	Oak.
	Per Cent.	Per Cent.	Per Cent.
Water	18·0	18·0	18·0
Ash	0·2	0·2	0·7
Fat	0·4	0·6	0·7
Soluble constituents:—			
Tannin substance.......	5·1 } 5·5	4·3 } 4·8	3·4 } 6·0
Non-tannin substance...	0·4 }	0·5 }	2·6 }
Leather substance:—			
Tannin	32·2	32·4	30·2
Hide substance	43·7	44·0	44·[illegible]
	100·0	100·0	100·0
Total fixed tannin in the leather..................	37·3	36·7	33·6
Yields of leather per 100 parts of hide substance..........	228·9	227·3	225·0
Fixed tannin per 100 parts of hide substance	74·0	73·6	67·8

The leather was thus fully tanned in a fortnight, and the results are rather better with mangrove than with oak.

Sulphuric Acid in Leather; Determination of ——. M. C. Lamb and J. W. Lamb. XXIII., page 134.

English Patents.

Hides; Process and Compound for Unhairing ——. J. Mellinger, Baltimore, U.S.A. Eng. Pat. 22,442, Oct. 17, 1903.

Soda lye, containing 30·22 per cent. of caustic soda (100 lb.), soda lye as above but saturated with hydrogen sulphide (200 lb.), and commercial ammonium carbonate of the composition "$NH_4 + 20·3CO_2$" (100 lb.) are mixed, dissolved in warm water (500 gallons), heated to 60° F., and allowed to stand. The hides are soaked in cold water for 12 hours, suspended in the above liquor, and the loosened hair and epidermis is washed off in water. Heavy hides require immersion for 2—3 hours, and skins 10—30 minutes, according to substance.—R. L. J.

United States Patents.

Clarifying Liquors [Glue Solutions]; Method of ——. E. R. Hewitt, Garden City, N.Y., U.S.A. U.S. Pat. 748,865, Jan. 5, 1904.

Solutions, such as glue, which are slightly acid, are neutralised by addition of a suitable base so as to form a fine precipitate. Aqueous sulphurous acid and the lime salts of bones are then added, and the mixture is again neutralised so that a readily separable sludge is obtained.
—R. L. J.

Glue from Hides: Manufacture of ——. E. R. Hewitt, Garden City, N.Y., U.S.A. U.S. Pat. 748,866, Jan. 5, 1904.

The hides are treated with a cold aqueous solution of sulphurous acid containing calcium phosphate and calcium sulphite (*i.e.*, two acid salts which precipitate when neutralised), washed, dissolved in hot water, neutralised, and the precipitate is settled out. If necessary the hot neutral solution is further treated with a little of the original pickling solution and again neutralised to induce a second precipitation.—R. L. J.

Horn-like Material from Raw Skins; Process of Preparing ——. E. Jetter, Erfurt. U.S. Pat. 7[illegible],297, Jan. 12, 1904.

See Fr. Pat. 330,006 of 1903; this J., 1903, 1056.—T. F. B.

XV.—MANURES, Etc.

Flax Cultivation; Manurial Experiments in ——. Bull. of the Imperial Inst. (Suppl. to Bd. of Trade J.), 1903, [4], 188—200.

The results of the experiments, which extended over two seasons, are shown in the following table:—

Nature of Manure and Amount of Dressing per Acre.	Average yield of Retted Flax Straw per Acre.	Average yield of Scutched Flax per Acre.		Value of the Scutched Flax from 1 Acre.			Cost of Manure per Acre.		
1901.	Lb.	St.	lb.	£	*s.*	*d.*	£	*s.*	*d.*

* In the 1902 results the value of the tow is included in that of the scutched flax.

The most notable result is the effect of fertilisers containing potash in increasing the yield of flax fibre. Although with the other manures the average results were unsatisfactory, yet in individual cases the results were good.—A. S.

United States Patent.

Manure; [Electrical] Process of Manufacturing ——, *from Apatite.* W. Palmaer, Stockholm. U.S. Pat. 748,523, Dec. 29, 1903.

A solution containing sodium chlorate, or sodium perchlorate, or a mixture of these with foreign salts, is electrolysed, and the acid solution formed at the anode is used to act upon a mineral phosphate in a separate vessel. To the solution thus obtained, the alkaline solution formed at the cathode during the electrolysis is added, to precipitate dicalcium hydrogen phosphate. Compare U.S. Pat. 707,886, 1902; this Journal, 1902, 1189.—E. S.

XVI.—SUGAR, STARCH, GUM, Etc.

Sugar Cane; Deterioration of Cut ——. Bull. of the Imperial Inst. (Suppl. to Board of Trade J.), 1903, [4], 212.

Experiments have been made to determine the rapidity with which the sucrose in sugar canes is converted into invert sugar after the canes are cut. The results obtained with five varieties of sugar cane, *viz.*, "White Manilla," "Purple Cheribon," "Manila," "Dikchan," and "Rukhra," are shown in the following table, the figures being the per cent. of loss on the total sugar present:—

	Days after Cutting.			
	1.	2.	3.	4.
	Per Cent.	Per Cent.	Per Cent.	Per Cent.
Total loss of available sucrose	2·7	8·0	21·4	32·1
Daily loss of available sucrose	2·7	5·3	13·4	10·7

These results show that in the first two days the loss is relatively small, but after three days, more than one-fifth of the available sugar has disappeared. The conclusion is drawn that the canes should be received at the factory not later than 24—36 hours after cutting.—A. S.

Starch; Reversion and Coagulation of ——. L. Maquenne, A. Fernbach, and J. Wolff. Comptes rend., 1904, **138**, i, [1], 49—51.

Attention is called to the difference between the amylocellulose which is obtained on the spontaneous reversion of starch, and which can still be saccharified by diastase, and the coagulum formed by treating starch with a small quantity of malt extract; this coagulum is incapable of saccharification by diastase. Amylocellulose may be recognised by treating it for a short time with potassium hydroxide, then adding a slight excess of hydrochloric acid and a few drops of iodine solution, which gives a blue coloration. It is found that the formation of amylocellulose is much more rapid in the coagulum obtained by the action of amylo coagulase on starch paste heated at 120° C. for 15 minutes, or at 100° for 30 minutes, or liquefied by heating at 130° for 2 hours, than it is in the spontaneous reversion of the starch paste. If, however, the coagulum is examined immediately after its formation, very little amylocellulose is detected, but the amount increases, and may finally constitute as much as one half of the total coagulated matter.—T. H. P.

Fehling's Solution; Sodium Sulphide as an Indicator with —— *[Determination of Reducing Sugars].* L. Beulaggue. XXIII., page 137.

Nitrates in Liquids charged with Organic Matters [Beetroot Juices, &c.]; Determination of Traces of ——. A. Paguoul. XXIII., page 135.

United States Patent.

Saccharine Juices; Process of Defecating ——. W. C. Salisbury, Assignor to A. J. Kramper, both of Dakota, Neb. U. S. Pat. 748,313, Dec. 29, 1903.

Saccharine juices and syrups are clarified and bleached by treating them with powdered alum in the proportion of 1 oz. of alum to 100 galls. of juice, and then boiling the juice, with agitation, for about an hour, and skimming off the impurities separated by the action of the alum during boiling and agitation.—J. F. B.

Sugar; Process of Making ——. W. C. Salisbury, Assignor to A. J. Kramper, both of Dakota, Neb. U.S. Pat. 748,314, Dec. 29, 1903.

One hundred gallons of juice, prepared from saccharine substances, are treated, whilst boiling, with 1 oz. of powdered alum and ½ oz. of sodium bicarbonate (with or without the addition of 4 oz. of sugar for each gallon of juice). The juice is boiled, stirred, and skimmed for about one hour, the resulting syrup is then cooled slightly and 1 oz. of a "suitable extract" is added thereto.—J. F. B.

XVII.—BREWING, WINES, SPIRITS, Etc.

Fermentation; Theory of ——. *Nutrition of Yeast with Sugar.* A. Richter. Zeits. angew. Chem., 1904, **17**, [2], 55—56; from Centralbl. f. Bakt. u. Parasitenk., II., **11**, 438.

The author has previously shown that yeast is capable of decomposing all the sugar present in a liquid before it attacks the nitrogenous substances, provided that it is fed with very small quantities of pepsin at the same time. Further experiments show that in the development of yeast in a medium containing fermentable material, the latter is decomposed quite independently both of the decomposition of the nutrient solution and of the presence of other nutrient matter. The whole process is shown to be of an enzymic nature, thus confirming Buchner's theory.—T. H. P.

Fermented Liquids; Origin of the Amyl Alcohol in ——. B. Rayman and K. Kries. Woch. f. Brau., 1904, **21**, [2], 25—27.

In a series of investigations on the by-products of alcoholic fermentation (this Journal, 1896, 465), the authors determined that amyl alcohol was produced by pure-cultivated yeasts quite apart from any contamination with bacteria, but failed to establish the conditions necessary for its production. It has now been definitely ascertained that the formation of amyl alcohol by pure yeast is not attributable to the unfavourable physiological condition of the yeast cells. It has also been found that pure-cultivated distillery yeast produces no amyl alcohol in artificial glucose media, but that if barley malt worts be employed, amyl alcohol is found amongst the products of fermentation. It was consequently inferred that the amyl alcohol is not a product of the fermentation of hexoses, but of those carbohydrates of the wort which accompany the hexoses and which belong to the class of "furfuroids," prepared by Tollens by the acid hydrolysis of brewers' grains. A series of experiments was therefore made in which glucose solutions containing peptone and nutrient salts were fermented with pure cultures of *S. cerevisiæ L.*, due precautions being taken to exclude bacteria. Some of these fermentations were allowed to proceed for periods up to three years, and the products consequently contained ammonia, organic bases, and sulphur compounds. Apart from such decomposition products there were formed in most cases formic acid, valeric acid, acetaldehyde, ethyl alcohol, glycerin, and succinic acid, but never amyl alcohol. Beet-juice, fermented for 36 days, likewise yielded no amyl alcohol. On the other hand, a wort prepared from raw barley saccharified by malt, fermented for 11 months, and a wort prepared from brewers' grains by Tollens' method, and containing the "furfuroids," yielded acetaldehyde and ethyl alcohol together with large quantities of amyl alcohol.—J. F. B.

Dissimilar Fermentations in Tuns filled with Wort of the same Brewing. Vogel. Zeits. ges. Brauw., 1904, 27, [2], 23—24.

In large breweries the wort from a single brewing is frequently distributed between two or three fermentation tuns, and it is by no means rare to find that the different portions ferment in a totally different manner. The author enumerates some of the possible causes of such dissimilarities in fermentation. The position of the tuns may be such as to cause large variations in the temperatures of the wort fermenting in them; some tuns may be close to a door or ventilating shaft and thus be exposed to draughts, others may be close to a stove or heating arrangement and so become unevenly heated. The pitching yeast given to each tun may vary in consistency, and irregularities may occur in making up and measuring out the pitching yeast. A very frequent cause of dissimilar fermentation lies in variations of the quantity of absorbed oxygen in the wort. If a check occur on the cooler, the collecting tank of the latter becomes nearly empty, and the wort, as it is drawn off into the tuns, may form a vortex, sucking in bubbles of air; then, later, the collecting tank fills up again and the wort runs away without air. Also, if hose pipe be used for filling the tuns, it may sometimes dip to the bottom and at other times merely rest on the edge of the tun; it is generally advisable to fix a "swan's neck" pipe to the edge of the tun at a constant height and to attach the hose to this. Again, the pitching temperature in the different tuns may vary, owing to irregular control of the temperature of the wort as it leaves the cooler. Other irregularities of fermentation may be caused by some of the tuns being lacquered and others not; they may also depend on the shape of the tuns and the height to which they are filled. The last tun filled generally receives more than its share of cooler-dregs and rinsings of the plant; on the other hand, if the pipes, &c., be infected, most of the infecting growths will be washed through into the first tun filled, the second and third being only moderately contaminated.—J. F. B.

Brewing by the Infusion Method. P. Petit. Ann. de la Brasserie, 1903, 6, [24], 553—556.

To obtain a beer of low attenuation, which, when fined, will give a good secondary fermentation and satisfactory head without the necessity for added sugar, it is essential to retard saccharification by quickly raising the temperature of the mash to 65°—68° C. At the same time, in order to secure the solution of head-forming nitrogenous constituents, it is desirable to carry on the preliminary mashing in the machine at 40°—45° C. The author states that either of the following methods of mashing will give satisfactory results:—100 kilos. of malt are mashed in the machine with 150 litres of water at 65° C., and the mixture is run into the mash tun containing 130 litres of hot liquor "at 90° C." The temperature of the mash will be about 62° C., which is then raised to 73°—75° C. with boiling water. After a short rest the wort is drawn off and the grains are sparged. In the second method, 100 kilos. of malt are mashed with 100 litres of water in the machine, so as to attain a temperature of about 45° C. By introducing hot liquor above and below, the temperature is raised to 65°—68° C. in 10 minutes, and is then slowly brought up to 75° C., the mash being afterwards left for 10—15 minutes at about 68° C. By means of a steam coil in the mash tun, a saving may be effected in the quantity of hot water required for heating the mash. In such case, one-third of the thick mash from the machine (temperature 40° C.) may be run into the hot liquid in the mash tun, so as to obtain a temperature of 65° C. At the end of 10 minutes, steam is turned on, and the temperature raised to 90° C., whereupon the rest of the thick mash is added, reducing the temperature to 63° C., the whole being then slowly raised to 75° C. This arrangement also permits the use of raw grain, without any additional apparatus being required.—C. S.

Disinfection and Disinfectants in Brewing. H. Will. Zeits. ges. Brauw., 1903, 26, [51], 865—871; [52], 886—891.

Sodium Carbonate.—The chief value of sodium carbonate solution consists in its power of loosening and dissolving dried impurities. It should be used of 10 per cent. strength, boiling hot, and allowed to act on the vessels for at least half an hour and at a temperature not below 80° C.

Calcium Hydroxide (Slaked Lime).—The action is similar to that of sodium carbonate, but where contamination is more than moderate, the application of lime should be preceded by a thorough scrubbing. The effect will be greater if the dressing be prevented from drying too quickly. Quicklime has proved very useful when strewed on damp floors.

Bleaching Powder.—In the form of a solution containing 1 per cent. of active chlorine, this substance is useful for washing the walls and floors of fermenting cellars and malthouses, as well as fermenting vessels that have become mouldy owing to damp storage. There does not seem to be any risk of unfavourably affecting the taste or smell of the beer, provided the above concentration is not exceeded and the vessels, &c., are well washed afterwards.

Antiformin.—This preparation consists of sodium hypochlorite and caustic soda, the active ingredient being the chlorine, of which over 4 per cent. is liberated on treatment with hydrochloric acid. The author classes it among the best disinfectants available for brewery work. It rapidly softens organic impurities and facilitates their removal by scouring, in addition to its oxidising action, and it also dissolves incrustration. The germicidal power is high, and a 5 per cent. solution is sufficient for most purposes. It is used cold, and may be safely applied to varnished surfaces with a brush, provided care is taken to prevent prolonged contact.

Sulphur Dioxide.—Though good results are obtained with this gas, it cannot penetrate to a sufficient depth through a contaminating deposit of yeast to act effectually thereon.

Calcium Bisulphite.—The disagreeable effects of this disinfectant on the operator may be diminished by diluting the solution to a strength of 10 grms. of sulphur dioxide per litre (one part of the average commercial article to six parts of water). For destroying mould it is superior to bleaching powder, and it also keeps better than the latter.

Hydrofluoric Acid.—This is an excellent disinfectant, and is equal to antiformin in germicidal power. A 1 per cent. solution is sufficient, and this will not attack the varnish on vats. Its caustic action, however, even when in a very dilute condition, militates against its extensive use.

Ammonium Bifluoride.—A 5 per cent. solution forms a very strong germicide, and even one of 2 per cent. strength is powerful. It ranks next to antiformin, to which it is superior in retarding vegetation. The solution does not injure the skin, is inodorous, and does not liberate vapour. Hose pipes may be cleaned by scrubbing, followed by immersion for 12—24 hours in a 0·4 per cent. solution of this salt contained in a closed vessel. The treatment is repeated once a fortnight, and the old solution may be used for washing floors, flushing drains, &c. Vats and other vessels are scrubbed and then well brushed over with a 3 per cent. solution of the bifluoride, which is left to act for at least three hours. Wooden buckets, &c., must be used, since the 3 per cent. solution attacks metal.

Montanin (Hydrofluosilicic Acid).—A solution containing 1·5 per cent. of the acid ranks between microsol and antigermin as a germicide, and also retards vegetation. It does not attack varnish, and has little effect on the skin.

Microsol.—This preparation varies in properties, but seems to depend for its action mainly on the presence of copper sulphate. A 2 per cent. solution (in exceptional cases 3—4 per cent.) is suitable for washing the inside of storage casks. It may be also mixed with milk of lime for whitewashing.

Antinonnin (Potassium Orthodinitrocresol).—Damp walls may be made dry by applying a hot 1—2 per cent. solution of this preparation, after a good scrubbing with hot water, a second application being given in three days' time. When dry the wall is brushed over with white lime mixed with the same solution. The strength is doubled if large quantities of mould fungi are present.

Antigermin.—This preparation is a copper salt of a weak organic acid. It is said to be soluble in 200 parts of water, and is applied after mixing in hot water and stirring up the mixture. Its power of retarding vegetation is still greater than that of either antinonnin or microsol, and the low solubility prolongs the antiseptic action. Mixed with a 2 per cent. solution of lime and applied as a double or triple coating to walls, it dries them and eliminates mould fungi; but, like antinonnin, it cannot be used for utensils that are to come in contact with wort, beer, or yeast.

Formaldehyde.—In addition to its disinfectant properties formaldehyde constitutes the best deodoriser for fusty cellars. It has also been used for sterilising pure-culture yeast plant. One objection, however, to its employment is its injurious effect on the mucous membrane.—C. S.

Beer; Resin Turbidity in ——. H. Will. Zeits. ges. Brauw., 1904, 24, [3], 29—30.

Turbidity of beer due to resins is a very rare occurrence; it is generally attributed to the separation of resins extracted from the hops. The author, however, cannot admit that hop resins are present in the beer in such quantities as to cause a visible turbidity. The small quantity which fails to settle out with the yeast is found in the sediments from the lager casks. The author has recently examined a number of samples of beer, more or less turbid, and possessing a distinct flavour of pitch. The microscopic examination of these turbid samples showed that the turbidity was caused solely by the presence of globules of resin. On applying pressure to the cover-glass it was found that these globules varied in consistency, as if the resin were dissolved in some solvent in varying proportions. The globules were separated by centrifugalising some of the beer; they were then placed on a gypsum plate to remove most of the water, and moistened with a reagent composed of a mixture of 5 c.c. of acetic anhydride and one or two drops of concentrated sulphuric acid. A violet coloration was thus developed—a conclusive proof that the turbidity was caused, not by hop resins, but by rosin derived from the pitch lining of the casks. It is not yet clear how this pitch is absorbed by the beer, but it is very probably due to overheating when coating the casks, and the consequent formation of rosin oil, which appears as a bluish iridescent layer over the surface of the pitch after cooling. The microscopic appearance of the centrifugalised rosin particles may vary from characteristic globules, through intermediate forms, to roundish, indefinitely shaped particles, which tend to adhere in masses, and have a shrunken, honeycombed appearance, ranging from colourless to yellowish-brown.

Starch in Barley and Malt; Method for the Rapid Determination of ——. H. T. Brown and J. H. Millar. XXIII., page 137.

Tartaric Acid; Characteristic Reaction of Free ——. [*Detection of Tartaric Acid in Wines.*] D. Ganassini. XXIII., page 136.

English Patent.

Malt, Barley, and the like; Roasting ——, *for Colouring and Flavouring Stout and Ales.* G. Valentine, Dublin. Eng. Pat. 28,834, Dec. 31, 1902.

The grain is roasted in an hermetically closed, revolving cylinder, provided with an internal cylindrical water-condenser, and with a right- and left-handed screw for mixing. The vapours produced are condensed by the internal cold surface and reabsorbed by the grain, thereby swelling it and preventing carbonisation. The uncondensed gases are led away through a pipe, with a valve and universal joint, to receivers, where they can be measured and absorbed by a fresh charge of grain for subsequent roasting. If the water in the condenser be insufficient to control the temperature of the roasting grain, water may be admitted to the centre of the mass in the roaster. The roasting may safely be conducted at a temperature of 460° F.—J. F. B.

United States Patents.

Brewing; Process of ——. H. E. Frees, Assignor to Wahl and Henius, Chicago. U.S. Pat. 746,320, Dec. 8, 1903.

Claim is made, in brewing beer, for the process of removing from corn its soluble oil, consisting in mixing with the ground corn an alkaline earth (such as lime) and water, and cooking the mixture, thereby reducing the soluble-oil contents to an insoluble soap, mashing the cereal, drawing off the wort, and intercepting the soap in the grains from which the wort is separated.—T. H. P.

Brewers' Apparatus. A. L. Neubert and S. T. Wiedenbeck, Minneapolis, Minn. U.S. Pat. 749,087, Jan. 5, 1904.

The brewing vessel consists of a casing provided with a charging opening surrounded by an overflow flange; means are provided for admitting steam, air, and water to the top of the casing, and for admitting steam and air near the bottom of the casing, below a perforated false bottom. This false bottom is made up of sectors, and a series of agitator arms is carried by a vertical shaft in the casing, the lowermost arms being constructed to sweep the perforated plate and keep the holes clear. The discharge pipe from the bottom of the casing below the perforated plate is conducted upwards, and communicates by one branch with a cooler and by another branch with a strainer tub, which discharges into a "grant," which in its turn has a discharge pipe leading back into the opening in the top of the casing.—J. F. B.

XVIII.—FOODS; SANITATION; WATER PURIFICATION, & DISINFECTANTS.

(A.)—FOODS.

English Patent.

Vegetable Foodstuffs; Process for obtaining the Assimilable Phospho-organic Matter from ——. S. Posternak, Paris. Eng. Pat. 24,692, Nov. 13, 1903.

Instead of the mineral acids specified in Eng. Pat. 18,910 of 1902 (see Fr. Pat. 318,311; this Journal, 1902, 1464) the oil cake may be extracted by solutions of some of the more powerful organic acids, which dissolve insoluble alkaline-earth salts and react towards Congo red like mineral acids. The impure extracts or precipitates containing the phospho-organic compounds may be purified by the action of oxidising agents, such as permanganates, chlorine, &c., which have no action upon the compounds in question. The free phospho-organic acid may be extracted from aqueous solutions by a mixture of ether and alcohol, or it may be precipitated by means of a metallic or earthy base, the metal being subsequently precipitated by an acid with which it yields an insoluble salt. The free phospho-organic acid has a composition corresponding to the formula $C_2P_2H_8O_9$; it is tetrabasic, and is split up on heating with mineral acids at 130° C. into phosphoric acid and "inosite." Its salts and double salts are also claimed. —J. F. B.

United States Patents.

Synthetic-Milk Compound, and Process of Producing same. W. A. Hall. U.S. Pat. 746,502, Dec. 8, 1903.

The compound described consists of casein, an alkali (for instance, sodium bicarbonate), calcium chloride, and milk-sugar, with or without a butter-fat; the constituents are mixed together in various proportions.—T. H. P.

Yeast Extracts; Process of Preparing Alimentary ——. M. Elb, Dresden. U.S. Pat. 748,711, Jan. 5, 1904.

See Eng. Pat. 13,097 of 1901; this J., 1902, 924.—T. F. B.

French Patent.

Animal Blood; Desiccation of ——. G. Tauer. Fr. Pat. 334,902, Aug. 28, 1903.

Unclotted blood, or clotted blood suitably pulped, is treated with an oxide, hydroxide, or metallic salt, *e.g.*, with 1—3 per cent. of lime, so as to form a jelly. The albuminoids are then precipitated by acidulation with very dilute mineral acid, with agitation. The mass is then pressed and dried. If desired, the mixture may be heated before precipitation or pressing.—J. F. B.

(*B.*)—SANITATION; WATER PURIFICATION.

Water-Pipes; Peculiar Destruction of ——. M. Freund. Zeits. angew. Chem., 1904, **17**, [2], 45—48.

The author gives analyses of curious dark grey graphite-like masses formed in the walls of iron water-pipes situate near an electric tramway in Frankfort-on-the-Maine; the formation of these masses, which were soft enough to be scratched by the finger-nail and readily cut with a knife, proceeded from the exterior to the interior of the pipes, and it was found that they all lie on a straight line. The result of the analysis was as follows:—Free iron, 10·4; ferrous phosphate, $Fe_3P_2O_8$, 37·1; ferrous silicate, $FeSiO_3$, 44·0; and carbon, 8·1 per cent. Comparison of the material with the unaltered iron of the pipes shows that the phosphoric acid and silica have their origin in the phosphorus and silicon contained in the iron, and are not at all derived from the surrounding soil. That this substance is the result of an electrolytic action in presence of moist soil was shown experimentally.—T. H. P.

United States Patent.

Water; Apparatus for the Removal of Sulphuric Acid from ——. H. Reisert, Cologne, Germany. U.S. Pat. 748,308, Dec. 29, 1903.

A funnel-shaped vessel, constituting a "barium-carbonate bath," and contained within an outer vessel, is provided centrally with a tube admitting the water to be purified to near its bottom, whence it passes upwardly through filtering material at the top, and overflows into the containing vessel, which latter receives from an elevated reservoir a regulated supply of saturated lime water for the removal of calcium and magnesium bicarbonates from the water which flows into the vessel from the overflow described. (Compare U.S. Pat. 713,800, 1902; this J., 1902, 1550.)—E. S.

XIX.—PAPER, PASTEBOARD, Etc.

Tissue Paper; Sulphite Wood Pulp for ——. Wochenbl. f. Papierfabr., 1904, **35**, [3], 162—163.

The successful preparation of tissue paper from wood pulp depends mainly on the quality of the raw material. The only pulp suitable is a well-boiled, tough cellulose, free from splinters and resin, which has been so thoroughly washed that the lime and boiling liquor are completely removed. Pulp which still contains some of the boiling liquor makes satisfactory work on the machine almost impossible, owing to the sticking of the paper to the press-rolls. It is not essential for ordinary grades of tissue paper that the pulp should be of an easy bleaching variety, provided it be perfectly boiled and washed. Bad washing causes a slimy deposit to collect on the wire and felts, especially the top felt, thus preventing proper couching and pressing. Resin specks and splinters produce holes in the paper; it is also impossible to make a well-closed tissue paper with good "rattle" from brittle, badly boiled pulp. It is not possible to prepare the sulphite pulp to make papers corresponding with several different samples; if samples have to be worked to, other kinds of cellulose must be mixed in, in order to produce the desired variations. The better classes of tissue papers require an admixture of rag pulp.—J. F. B.

Cotton-Rag Paper; Knots in ——. P. Papier-Zeit., 1904, **29**, [6], 181.

Commenting on a sheet of unsized cotton-rag paper which contained a large number of knots, the writer remarks that the clotting of the pulp in this manner is caused by too violent agitation either in the stuff-chests or as it is fed on to the machine. With cotton pulps the circumferential speed of the stirrer in the stuff-chest must not exceed 1 metre in 6½ seconds. The stirrer must not present broad, flat surfaces to the pulp, but all its parts must be wedge-shaped, so as to cut through the stuff. The blades of the stirrer should be sloped off, so as to prevent the deposition of the fibres. Should the diameter of the chest be so large that the pulp is not properly kept in suspension at so low a speed, boards about 8 inches wide should be fixed to the stirrer-arms not quite horizontally, but with a slope to an angle of 40°. If this be not sufficient, stirrers with four arms should be provided. Similar knots may also be produced by the too violent action of the stirrer connected with the paper-machine for mixing the pulp with the "back-water." A few of the knots present in the paper in question were derived from the knotted stitches in the rags, which are not reduced in the beaters. These knots are only to be avoided by picking out the stitches from the rags, or, preferably, by using an efficient knotter with slits 0·3 mm. in width.—J. F. B.

Paper; Re-manufacture of Waste ——, in America. R. K. Wochenbl. f. Papierfabr., 1904, **35**, [2], 86—89.

The re-manufacture of waste paper has assumed enormous proportions in America, especially in the New England States. After a preliminary sorting and dusting, the paper is boiled with sodium carbonate solution. This treatment is distinctly better than those in which soap solutions, ready formed, are employed, since a direct reaction takes place between the soda and the saponifiable constituents of the printing ink. The lamp-black is thus set free and becomes incorporated with the soap solution at the moment of saponification. Thus emulsified, the carbon is easily removed in the subsequent washing process. The pulp is then bleached and a fine white "stuff" containing 8—10 per cent. of ash and possessing excellent paper-making properties results. This material is mixed with a small percentage of wood cellulose and the desired amount of loading. It runs on the machine with extreme ease and, considering its strength, at a high speed. The resulting paper possesses exceptional opacity and elasticity—properties which assure for it a large demand amongst the printers. Samples of this paper compared by the writer with paper prepared from new materials [poplar pulp] were pronounced to be better than the latter, both on account of the properties mentioned above and on account of its structure and surface. Most of the American magazines are stated to be printed on re-manufactured paper, and to this fact their well-known superiority is largely attributable. —J. F. B.

United States Patents.

Paper, and Process of Making same. E. H. Fowler and G. N. Hoover, Washington, D.C. U.S. Pat. 748,179, Dec. 29, 1903.

Paper is impregnated, either in the unfinished or finished state, with a solution of glycerin, alcohol, and water. —J. F. B.

Paper from Old Newspapers, Books, Magazines, &c.; Process of Making ——. W. B. Meixell and T. Holt, Sayre, Pa., Assignors to S. Thorp, Elmira, N.Y., and H. L. Towner and F. K. Stephens, Sayre, Pa. U.S. Pat. 748,968, Jan. 5, 1904.

Printed waste-paper is reduced to a pulp and treated, with or without heat, with a solution of a compound consisting of soda, margaric acid, oleic acid, water, and earthy matter. The pulp is finally washed to remove the carbon and colouring matters, and made into paper.—J. F. B.

Gelatinous Product, and Process of Producing same; Insoluble ——. H. V. Dunham, New York, Assignor to Casein Co. of America, New Jersey. U.S. Pat. 748,708, Jan. 5, 1904.

A substitute for albumin is made by adding 3 parts of hexamethylenetetramine to a solution of 17 parts of "ordinary dry commercial gelatinous substance" in 40 parts of water; the mixture is evaporated to dryness and the product subjected to the action of steam, at about 180° F., for about half an hour. Compare U.S. Pat. 695,198 of 1902; this Journal, 1902, 547.—T. F. B.

Casein-Cellulose Composition, and Process of Producing same. H. V. Dunham, New York, Assignor to Casein Co. of America, New Jersey. U.S. Pat. 748,709, Jan. 5, 1904.

A product resembling celluloid is obtained by mixing together solutions of casein and nitrocellulose in a common solvent, *e.g.*, glacial acetic acid; camphor, or other substance used in the manufacture of celluloid, may also be added to the mixture.—T. F. B.

French Patent.

Paper and Similar Substances; Treatment of ——, to Render them Tougher and more Impervious. Vellumoid Paper Co. Fr. Pat. 335,376, Sept. 18, 1903.

See U.S. Pat. 740,006 of 1903; this J., 1903, 1115.—T. F. B.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

Rare Earths; Bismuth as an Agent of Separation in the Series of ——. G. Urbain and H. Lacombe. Comptes rend., 1904, **138**, [2], 84—85. (See this J., 1903, 1365.)

The authors find that bismuth, in fractionating, lies between samarium and europium, and thus divides two series. Europium may be considered as the first member of the yttrium series. The authors have based a new method of separation on the following considerations: When a series of isomorphous salts gives uncrystallisable mother-liquors, the latter retain a quantity of crystallisable salt depending on the amount of uncrystallisable compounds they contain; and, similarly, a considerable amount of crystallisable salts will, in crystallising, take down with them a sensible amount of an uncrystallisable salt present in relatively small quantity, and still more of a very soluble crystallisable salt. Thus the uncrystallisable mother-liquors of the double magnesium nitrates retain a certain amount of gadolinium salts. By adding to these a quantity of bismuth magnesium nitrate and crystallising, the gadolinium compounds are partially removed with the bismuth salt, and can be completely removed by repetitions of the treatment. The separation of these salts from the bismuth is, of course, an easy and straightforward operation. A similar process serves to eliminate gadolinium from crude yttrium compounds in which it occurs in small amount.—J. T. D.

Silver, Colloïdal, Pure; Preparation and Properties of ——. A. Chassevant. Bull. Soc. Chim., 1904, **31**, [1], 11.

Colloïdal silver was prepared by the method of Schneider (Ber., 1890, **25**, 1281) by mixing 500 c.c. of 10 per cent. silver nitrate solution, with a solution composed of 500 c.c. of 30 per cent. ferrous sulphate solution and 1,700 c.c. of a solution containing 280 grms. of crystalline sodium citrate. The precipitate thus obtained was collected on the filter pump, re-dissolved in water, and precipitated with twice its volume of alcohol (95 per cent.), the bluish-black precipitate thus obtained being in the soloïd condition. It was filtered out by means of a Chamberland filter. The dry residue was then dissolved off by placing the cylinder in a test-tube containing water. The blocked cylinder appears to act as a dialyser. Solutions of pure colloidal silver have no tendency to precipitate in a geloïd state. Although, in the presence of the mother solution, the silver assumes the insoluble black geloïd form in a few hours, if it be purified from all electrolytic salts, it may be kept for several weeks in the soluble soloid condition. The presence of alcohol, however, retards the influence of the salts in this direction. Colloidal silver, after the addition of alcohol, may be kept for a considerable time, even in the presence of an excess of crystalloïds, without passing into the geloïd state, as it would quickly do in the absence of alcohol. This method of precipitation has been applied to the purification of colloidal silver, which, after two treatments, gave 96·59 per cent. of Ag. This purified product is precipitated in the geloid form by various electrolytes. If its solution be evaporated *in vacuo*, or if the deposit on the Chamberland cylinders be dried, ordinary metallic silver results. The aqueous solution of the soloid form is very stable, and the precipitate on the porcelain may even be preserved in strong alcohol; it is soluble in alcohol, but only in the presence of water, being insoluble in absolute alcohol. It is readily soluble in glycerin, sp. gr. 1·264, and forms organo-soloïds, as indicated by Schneider. After the addition of other colloid substances, such as gum, gelatin, or soda solution of acid-albumose, the mixture may be evaporated *in vacuo*, in the cold, without affecting the physical condition of the silver, which retains its colloidal state and its solubility in water.—J. O. B.

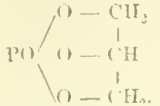
Collodion-Cotton of the German Pharmacopœia. C. Jene. Chem.-Zeit., 1904, **28**, [6], 61.

The author has determined the nitrogen-content of collodion-cotton prepared according to the German Pharmacopœia, and finds it to be on the average 11·9 per cent. The percentage composition of the acid mixture prescribed is 17·43 HNO_3.65·0 H_2SO_4, 17·57 H_2O. The spent acid contains 11·5—12·5 per cent. of HNO_3. The author has never been able, following the directions of the Pharmacopœia, to obtain a preparation completely soluble in a mixture of 1 part of alcohol and 7 parts of ether. As this appears to be the experience of others also, the author suggests that the Pharmacopœial directions should be revised.—J. T. D.

Phosphoric Esters of Glycerol. P. Carré. Comptes rend., 1904, **138**, i, [1], 47—49.

The di- and tri-phosphoric esters of glycerol are hydrolysed by cold water giving ordinary glycerophosphoric acid. The transformation is rapid in the case of the tri-ester but slow with the di-compound; boiling facilitates the reaction greatly but gives rise to a certain amount of free phosphoric acid. Pure glycerophosphoric acid may be obtained in solution by the action of hydrogen sulphide on the lead salt suspended in boiling water, but when the solution is evaporated in a vacuum over sulphuric acid, decomposition begins to take place when the liquid attains the composition, $2PO(OH)_2.OC_3H_5(OH)_2 + H_2O$. The unstable di-phosphoric ester formed by the fixation of two molecules of glycerol on one of phosphoric acid, has not been isolated.

The tri-ester can be readily isolated as a hard, spongy mass, which can be powdered and is insoluble in the ordinary solvents; it has the constitution—



—T. H. P.

Tannalbin; Official Method for the Preparation of and Tests for ——. Supplement to the Dutch Pharmacopœia: through Pharm. Centralhalle, 1903, **44**, [27], 413.

Twenty parts of egg albumin are dissolved in 200 parts of water and filtered; 13 parts of tannin are added to the filtrate; the precipitate formed is collected on a cloth, washed with 200 parts of water, pressed, dried at 30° C., and rubbed to powder. This powder is heated for six hours between 115—120° C. The following are the official tests for tannalbin:—1 grm. is digested at 40° C. for three hours with a solution of 0·25 grm. of pepsin in 100 c.c. of water and 1 c.c. of hydrochloric acid. The insoluble residue, after washing with water and drying, gives the weight A. Another 1 grm. of the tannalbin is similarly treated with a solution of 1·5 grm. of sodium carbonate in 100 c.c. of water; the insoluble residue is washed, dried, and weighed, as before, giving the weight B. The difference between the weights A and B should be not less than 0·2 grm. When reduced to ash, tannalbin should not give more than 1 per cent. of residue.—J. O. B.

Quinine Tannate (*Tasteless*). Supplement to the Dutch Pharmacopœia; through Pharm. Post, 1903, **36**, [41], 583.

Seven grms. of quinine sulphate are dissolved in 14 grms. of alcohol 95—96 per cent., by the heat of the waterbath, and a similar alcoholic solution of tannin, 24 grms., is added with constant stirring. The mixture is then warmed in a covered vessel until it becomes homogeneous. It is then poured into 200 c.c. of water. After occasional stirring, the mixture is allowed to stand for the precipitate to assume a pulverulent condition; it is then collected, pressed, dried at normal temperatures by exposure to air, powdered, and again dried at a temperature not exceeding 30° C. The resulting powder should contain 9·5 per cent. of quinine.—J. O. B.

Geum urbanum [*Wood Avens*]; *Essential Oil of* ——. E. Bourquelot and H. Hérissey. Soc. Pharm. de Paris; through J. Pharm. Chim., 1903, [6], **18**, 369.

The authors find that this essential oil, which was first recorded in 1818 by Tromsdorff, and its resemblance to clove oil indicated in 1844 by A. Buchner, does not occur in the fresh plant, but is developed by the hydrolysing action of a ferment on a glucoside. The fresh plant bruised and macerated for 12 hours in water, gives a small amount of essential oil with a clove-like odour and which contained eugenol. The alcoholic extract obtained by boiling the root with alcohol, of 95 per cent. strength, gives an odourless aqueous solution, which, however, developes a marked clove-like odour when treated with the specific ferment, the glucoside furnishing the oil being split up, so as to yield eugenol, whilst the optical rotation of the solution is deviated from the left to the right.—J. O. B.

French Patents.

Alkaloids from Liquid Vegetable Extracts; Apparatus for Extracting ——. E. Belot. Fr. Pat. 334,937, Aug. 31, 1903.

The apparatus in which the extraction takes place is a long horizontal vessel, divided by vertical walls into a number of compartments. The vegetable extract, *e.g.*, tobacco juice, containing the free alkaloid, is fed in at one corner of the vessel, whilst the non-miscible extracting medium, *e.g.* petroleum spirit, is fed in at the corner diagonally opposite. The two liquids are made to take a zigzag course horizontally through the compartments in counter-currents, whilst circulating pumps, attached to each compartment, withdraw liquor from the bottom, and deliver it again at the top, so that it flows down over zigzag screens arranged in each compartment. In this way a systematic extraction of the alkaloid is effected. The petroleum spirit, charged with alkaloid, is then passed into a separate vessel where it is agitated with dilute acid, and deprived of its alkaloid, the regenerated solvent being returned to the storage tank.

Soap containing Lemon Juice. G. Giraudet and A. Neuberger. Fr. Pat. 334,916, Aug. 29, 1903. XII., page 121.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

"Mariotype" and "Ozotype" Processes; Theory of the ——. T. Manly. Phot. J., 1903, **43**, 301.

It is a well-known fact that when a film of gelatin impregnated with potassium bichromate is exposed to light in a practically but not chemically dry state, the gelatin becomes insoluble in water. In the presence of organic matter, light reduces part of the $2CrO_3$ in the salt, yielding $Cr_2O_3 + O_3$. As the bichromate is always in excess, one or more molecules of chromic acid unite with the chromium oxide, forming $Cr_2O_3(CrO_3)n$; while the oxygen liberated combines with the gelatin. The author adduces analogical evidence to show that neither this oxygen, nor the CrO_3 attached to the Cr_2O_3, should play any part in rendering the gelatin insoluble; but that the nascent Cr_2O_3 forms a definite combination with the gelatin which is insoluble. This hypothesis renders it possible to understand the "continuating action of light." When a chemically damp bichromated gelatin plate has been exposed, there is an image composed of $Cr_2O_3CrO_3$ lying in a film containing excess of bichromate and sufficient moisture to make the CrO_3 soluble. This dissolved CrO_3 diffuses through the film, attacks the gelatin that is still soluble, tans it, is reduced to Cr_2O_3, and, as before, immediately withdraws a molecule of CrO_3 from the bichromate, which acts like its predecessor. Thus, where a primary image in chromium is produced, which is afterwards converted into the substance that forms the final print, it is of the utmost importance to preserve the CrO_3; but in ordinary "carbon printing," where the pigmented film holds the sensitive salt, the acid oxide in the complex $Cr_2O_3CrO_3$ is of little or no value. In the *Mariotype Process*, in which well-sized paper coated with bichromate (only) and dried, is exposed till a faint image is visible, and then brought into contact for some 10 hours with a film of bichromated "carbon tissue" which has not been insolated, the CrO_3, or the continuating action of light, is the chief factor concerned.

The Ozotype Process.—In this process also the CrO_3 is the principal reagent, but here it is utilised in making the finished picture, whereas in mariotype it simply starts the action. Neglecting preservatives, &c., the ozotype process is worked by applying a mixture of a manganous salt and a bichromate to paper, and exposing under a negative when dry. The effect of light is to produce $Cr_2O_3(CrO_3)n$ as before, together with manganous chromate (and potassium sulphate as by-product), and the result is that 2 molecules of CrO_3 are set free instead of one. When exposure is complete, the print is washed in such fashion that the CrO_3 is not removed, and it is then brought into close contact with a modified form of carbon tissue, which has been soaked in a weak solution of an acid and a reducing agent (*e.g.*, hydrochloric acid and ferrous sulphate, or acetic acid and quinol). During this operation the 2 molecules of CrO_3 are reduced to one of Cr_2O_3, the ferrous being oxidised to ferric sulphate, and the result is that two of the most energetic tanning agents known are produced in the film. If the quinol (hydroquinone) bath be employed, the acetic acid perhaps liberates the CrO_3, which then yields Cr_2O_3 and quinone, the latter having no action. This liquid is less rapid in its effect than the former, but it may be accelerated by the addition of copper sulphate, which presumably behaves as a catalyser. Mariotype, therefore, depends on the continuating action of light, the CrO_3 derived from the image being reduced by contact with the gelatin, a process which is slow and uncertain, requires the film to be kept moist, and involves the danger of all the bichromate being decomposed and all the gelatin (even in undesirable portions of the picture) becoming insoluble. In ozotype there is no continuation, for all the bichromate is washed away, and the CrO_3 is reduced by a specific reagent, which acts more quickly and satisfactorily. Most metallic chromates (except those of barium and lead) are soluble in bichromate solutions, and perhaps this is the reason why an organic film containing bichromate is insensitive when wet; for a solid and insoluble image of chromium chromate cannot be formed in a solution which dissolves it. Some authorities hold that because a solution of chromium chromate produced by boiling potassium bichromate with grape sugar has only a small effect in rendering gelatin insoluble, oxygen must play a part in the tanning operation; but when the chromate is produced in this manner, it probably consists of $Cr_2O_33CrO_3$, *i.e.*, it contains an excess of its acid constituent, which retards the tanning; while when it is formed by exposure to light it is very basic, *e.g.*, $3Cr_2O_32CrO_3$, and it is the basic radicle that converts the gelatin into an insoluble body.—F. H. L.

Emulsion [*for Process Work*]; *Collodion* ——. Von Hübl. Atel. des Photographen. Brit. J. Phot., 1904, **51**, [2281], 66—67.

The collodion emulsions generally used for process work are, as a rule, sensitized by means of silver salts which increase the colour-sensitising action of any dyestuff. The silver salts of the eosin group of dyestuffs have been employed for this purpose, either alone or in ammoniacal solution. Emulsions prepared in this way have, however, low sensitiveness. Another method consists in treating the plate with a solution of the dyestuff, and, just before exposure, immersing it in a dilute silver nitrate solution. These methods, however, all produce plates, which have a tendency to fog, on account of the presence of soluble silver compounds. The author points out that a dyestuff can only sensitize when it stains the silver bromide of the emulsion, and circumstances which increase or reduce the staining power of the dyestuff will raise or lower the colour-sensitising action. Soluble bromides reduce and finally destroy the staining power of dyestuffs, and consequently are to be avoided, but soluble chlorides have no harmful effects in this direction, therefore it appeared that an emulsion containing silver chloride and silver bromide, and made with a slight excess of chloride, would give satisfactory results. In presence of ammonia, fine-grained bromide emulsions are easily obtained; but, in presence of acids, coarse-grained silver bromide is formed. The following method of preparation was found to give an emulsion of very fine grain and fairly sensitive, containing excess of soluble chloride.—A solution of 50 grms. of silver nitrate in 50 c.c. of ammonia solution (sp. gr. 0·91) to which 100 c.c. of 95 per cent. alcohol has been added, is mixed in the dark with 700 c.c. of a 4 per cent. solution of "celloidin-collodion" in ether-alcohol (1:2). To this is added gradually a solution of 27 grms. of ammonium bromide in 40 c.c. of water, to which is added 100 c.c. of alcohol and 15 c.c. of a lithium chloride solution, made by dissolving 10 grms. of lithium chloride in 10 c.c. of water, adding 90 c.c. of alcohol and filtering. The emulsion is agitated thoroughly and allowed to stand for two or three hours, when it is precipitated by the gradual addition of 300 c.c. of water, with constant agitation, poured into 3 litres of water, and, when settled, washed by decantation, dried as far as possible, and dissolved in a mixture of 350—450 c.c. of alcohol and 400—550 c.c. of ether. The emulsion is about twice as sensitive as a wet collodion plate, and gives gradation similar to that obtained on platinotype paper. Addition of a soluble silver salt does not increase its sensitiveness. Addition of a chromate gives increased contrasts, but reduced sensitiveness. Staining with eosin, however, has the same effect on the contrasts without affecting the speed of the emulsion.

—T. F. B.

English Patent.

Photographic Pictures in Natural Colours; Means for and Method of Printing ——. E. W. Butler, London. Eng. Pat. 8260, April 9, 1903.

A gelatin film is stained with a suitable dyestuff and then sensitised with a soluble bichromate, printed on from a negative and developed in water. The dyestuff must not be affected by the sensitising agent, and must not be too soluble in water. For three-colour work, Fuchsin, Naphthol Yellow and Thion Blue are well suited. The positives may be made separately and then superimposed, or the first colour-positive may be coated with gelatin, stained with the second colour, sensitised and printed in the manner described, and the process repeated for the third colour-positive.—T. F. B.

French Patents.

Developing Photographic Plates and Papers in Daylight, dispensing with a Dark Lamp; Process for ——. Soc. Anon. Prod. Photographiques A. Lumière et ses fils. Fr. Pat. 334,915, Sept. 1, 1903.

Sodium sulphite is mixed with some substance which gives a coloured solution which will absorb actinic rays; this may either be a substance whose aqueous solution is a suitable colour, or one which gives a colour in presence of sodium sulphite. Thus, of the former, Tartrazine, aminoazobenzene, Croceïn Scarlet 3 B, &c. give suitably coloured solutions, but these all give more or less of a colour to the film or paper. Of the latter class of substance, however, picric acid and picrates give, in presence of sodium sulphite, orange-red solutions which absorb actinic rays; picrates, when used in this way, give no stain on the film. The method claimed may, thus, consist of substituting for the sodium sulphite in the developer a mixture of sodium sulphite, 2 parts, magnesium picrate, 1 part.

United States Patent.

Smokeless Powder Composition. H. Maxim, Brooklyn, U.S.A. U.S. Pat. 748,200, Dec. 29, 1903.

This process for making a smokeless powder composition consists in gelatinising soluble pyroxylin in a solvent which does not dissolve trinitrocellulose, adding a solution of the latter, and precipitating the same in the paste in the act of incorporating the two mixtures. The finished explosive should contain 75 per cent. of soluble nitrocellulose. (Compare Eng. Pat. 13,157 of 1903; this J., 1903, 963.)

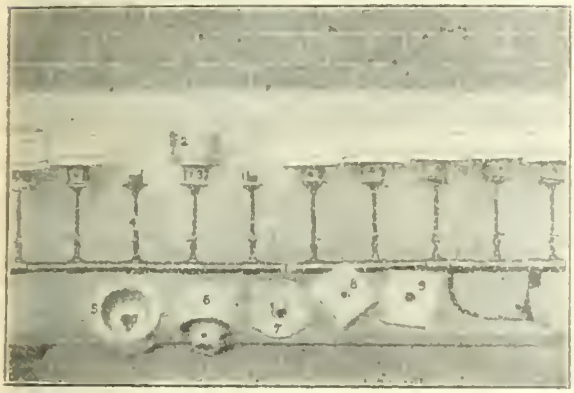
—G. W. McD.

XXIII.—ANALYTICAL CHEMISTRY.

APPARATUS, ETC.

Muffles of Graphite or Asbestos. J. M. Pickle and C. B. Williams. J. Amer. Chem. Soc., 1903, **25**, [12], 1277—1280.

Simple muffles for ash determinations, volatilisations, &c., can be readily constructed in the laboratory from asbestos board of about 0·6 c.m. in thickness. The piece cut to the right size is saturated with water, rolled around a cylinder of suitable size, and left to dry. The bottom, in which is a smaller cylinder (with a side hole) fitting on to an Argand burner, is then fixed in, and the whole muffle wired together. The accompanying figure shows a battery of such muffles fitted to Argand burners on the same gas supply-pipe; 7 represents a graphite lid with a small hole under the handle, and 8 and 9 top and bottom views of lids consisting of asbestos board, aluminium plate, and platinum riveted together. For long continued daily use these muffles are not sufficiently durable, nor are they so when constructed of copper coated inside and out with asbestos. When made of graphite, however, coated with asbestos, they have proved perfectly satisfactory in this respect.—C. A. M.



INORGANIC—QUALITATIVE.

Amalgams of Platinum; Behaviour of ——, towards Nitric Acid. N. Tarugi. Gaz. chim. ital., 33, [2], 171—186. Chem. Centr., 1903, **2**, [26], 1475.

According to the author, the process of Knoevenagel and Ebler (this J., 1902, 1296) is not only not an improvement on the ordinary analytical method, but it also opens the way to further sources of error. The separation of bismuth, platinum, and gold by the method cited is not complete. Further, by boiling for a short time, the arsenates are reduced to arsenites, and as such interfere with the reduction of the gold or platinum salts by the hydrazine. Another important source of error is to be found in the fact that when mercury is present, its power of forming amalgams must be taken into account. For instance, platinum behaves quite differently towards nitric acid according to whether mercury is present or not. From a mixture (or amalgam) containing 4·64 per cent. of platinum and 95·35 per cent. of mercury, 99·94 per cent. of the platinum is dissolved by nitric acid; from one containing 38·70 of platinum and 61·20 of mercury, only 29·9 per cent.; and from one containing 90·69 of platinum and 9·30 of mercury, only 4·7 per cent. On the other hand, from a mixture of 91·11 per cent. of mercury and 8·88 per cent. of platinum, 1 per cent. of the mercury is left undissolved by nitric acid; from one containing 62·13 of mercury and 37·86 of platinum, 11·87 per cent.; and from one containing 17·02 of mercury and 82·97 of platinum, as much as 99·5 per cent. Microscopic examination showed that the products obtained by the simultaneous reduction of platinum and mercury salts are amalgams. On the contrary, by the reduction of mixed gold and mercury salts by hydrazine, no amalgams are formed.—A. S.

Vanadic Acid; Colour-reactions of ——, with Ethenol (Vinyl Alcohol). C. Matignon. Comptes rend., 1904, **138**, [2], 82—84.

Ammonium *m*-vanadate solution gives with tannin a blue precipitate or coloration, according to the concentration of the solution. The colour can be detected in a solution containing 2 cb. mm. of vanadium pentoxide per litre. A similar coloration is given by gallic acid, pyrogallol, and (less sensitive) catechol, but not by quinol, resorcinol, phloroglucinol, nor guaiacol. In all cases, the colour vanishes on heating the liquid, and reappears on cooling. The addition of ether frequently, but not always, increases considerably the delicacy of the reaction with pyrogallol, and the author has traced this effect to the small amounts of ethenol contained in some, but not in all, commercial samples of ether. By partial evaporation of an "active" ether, thus concentrating the ethenol in the residue, the "activity" of the residue is raised, and the coloration is obtainable with a solution containing 0·02 cb. mm. of vanadium pentoxide per litre. An inactive ether can be rendered active by passing through it a current of ozonised oxygen, and then leaving it at rest for some months. Ferric salts and chromates, which also give colorations with the reagent, must be removed before testing for vanadates.—J. T. D.

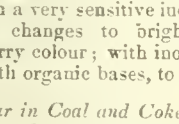
INORGANIC—QUANTITATIVE.

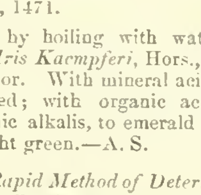
Extract from Iris Blossoms as an Indicator. A. Ossendowsky. J. russ. phys.-chem. Ges., **35**, 845—846. Chem. Centr., 1903, **2**, [26], 1471.

The violet solution obtained by boiling with water the blossoms of the Japanese iris, *Iris Kaempferi*, Hors., is said to form a very sensitive indicator. With mineral acids, the colour changes to bright red; with organic acids, to raspberry colour; with inorganic alkalis, to emerald green; and with organic bases, to bright green.—A. S.

Sulphur in Coal and Coke; Rapid Method of Determining ——. J. D. Pennock and D. A. Morton. J. Amer. Chem. Soc., 1903, **25**, [12], 1265—1269.

This method is essentially a combination of Sundstrom's process of oxidation with sodium peroxide (this J., 1903, 381) and of Andrews' volumetric method of determining sulphur. About 16 grms. of sodium peroxide and 0·7 grm. of coal (or 11·5 grms. of sodium peroxide, and 0·7 grm. of coke) are thoroughly mixed in the crucible by means of a spatula. The crucible (see figure) is made of soft steel, nickel plated, and has a small hole ($\frac{1}{4}$ in. diameter at top, and $\frac{3}{32}$ in. at the bottom) in the lid for the introduction of a hot wire. The thickness of the walls is $\frac{1}{32}$ in., and the capacity of the crucible about 40 c.c. A suitable stand can be made from a sheet of aluminium cut as shown by the heavy lines in the diagram, and the four points marked A, and the corners B, bent downwards. The covered crucible is placed on the stand in a 20-oz. beaker containing sufficient water to reach about half way up the outside of the crucible, and the contents ignited by the introduction of a red-hot iron wire through the hole. After about three minutes the stand is removed, and the crucible turned over into the water and subsequently washed out and withdrawn. The solution is acidified with hydrochloric acid and boiled, then treated with ammonia in slight excess, vigorously boiled for a minute, and mixed with 15 c.c. of barium chromate

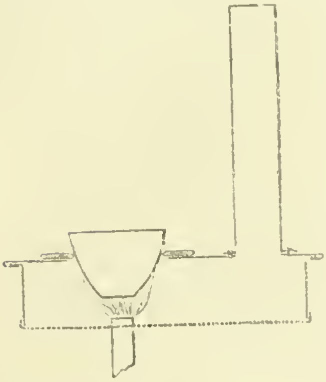




solution (prepared by dissolving 23 grms. of pure barium chromate in a mixture of 80 c.c. of strong hydrochloric acid and 920 c.c. of water). The boiling solution is then diluted to 200 c.c., a very slight excess of ammonia added, and the liquid again boiled for one or two minutes. The precipitated barium sulphate is then filtered off and washed twice with 20 to 30 c.c. of hot water. About 1 grm. of potassium iodide is added to the filtrate which is then cooled to 30° C. and titrated with N/10 sodium thiosulphate solution, the number of c.c. required multiplied by the factor 0·153 giving the required percentage of sulphur. The results obtained in more than 1,000 determinations by this method have shown that it is accurate to within a few hundredths of a per cent., whilst two or three complete determinations can be made in an hour. Typical results obtained by this and by Eschka's method (this J., 1891, 952, and 1893, 465) are given in the paper.—C. A. M.

Sulphur; Determination of ——, by Eschka's Method. O. Pfeiffer. Chem.-Zeit., 1904, **28**, [4], 38.

In order to obtain results by the Eschka method not vitiated by the presence of sulphur compounds in the products of combustion of coal gas, the author uses the device shown in the accompanying figure. It consists essentially of a box of thin sheet iron, open at the bottom, which is placed over the ring of a tripod. Two holes are provided for the insertion of the crucible and of a chimney respectively. An asbestos ring is placed round the crucible, and the joint is rendered air-tight by means of soluble glass (sodium silicate). In a blank experiment with this arrangement, in which a quantity of the Eschka oxidising mixture was heated in the crucible for eight hours, no sulphur was absorbed. The author has obtained good results with the Eschka method in the determination of the vulcanisation sulphur in india-rubber.—A. S.



Phosphoric Oxide; Calculation of Amount of ——, in Magnesium Pyrophosphate. T. Kämpfer. Zeits. anal. Chem., 1894, **43**, [1].

A 25 page supplement to this issue, giving the amount of phosphorus pentoxide corresponding to each 1/10 mgrm. of magnesium pyrophosphate, from 0·0001 grm. to 0·4000 grm. —J. T. D.

Hypochlorous Acid; New Method for the Detection and Determination of ——. E. Klimenko. Zeits. anal. Chem., 1903, **42**, 718—724.

As is well known, a solution of hypochlorous acid acidified with hydrochloric acid liberates iodine from potassium iodide, the amount of liberated iodine being proportional to the quantity of hypochlorous acid; the reaction is represented by the equation—$HClO + HCl + 2KI = H_2O + 2KCl + I_2$. If, however, potassium iodide be added to a solution of hypochlorous acid containing no hydrochloric acid, only one atom of iodine is liberated, that is, one-half the quantity. The addition of hydrochloric acid causes the other half to be set free. This fact forms the basis of the method described, the reaction being particularly useful for the determination of hypochlorous acid in solutions containing free chlorine. A known volume of the solution is treated with potassium iodide solution and the liberated iodine titrated with a standard solution of sodium thiosulphate. The quantity of the latter used gives the iodine set free by the chlorine and hypochlorous acid. The titrated solution is then acidified with hydrochloric acid, when a further amount of iodine is liberated corresponding to one-half the hypochlorous acid present. This is also titrated. The iodine due to chlorine may then be calculated from the two titrations. Should there be no further liberation of iodine on acidifying the solution after the first titration, no hypochlorous acid is present. The solution of potassium iodide employed should not be more than 8 per cent. in strength.—W. P. S.

Ammonia; Gasometric and Gravimetric Methods for Determining ——. E. Riegler. Zeits. anal. Chem., 1903, **42**, 677—686.

Both methods depend upon the fact that ammonia, or its salts, form ammonium tri-iodate when treated with excess of iodic acid. This tri-iodate is insoluble in dilute alcohol, the equation showing its formation being—$NH_4Cl + 3HIO_3 = NH_4.H_2(IO_3)_3 + HCl$. By acting on ammonium tri-iodate with hydrazine sulphate, nitrogen is liberated according to the equation—$2[NH_4.H_2(IO_3)_3] + 9N_2H_4.H_2SO_4 = (NH_4)_2SO_4 + 8H_2SO_4 + 6HI + 18H_2O + 9N_2$. The details of the gasometric method are as follows: 5 c.c. of a 20 per cent. iodic acid solution are placed in a small Erlenmeyer flask, 10 c.c. of the ammonia solution containing not more than 0·014 grm. of NH_3, are added, and finally 25 c.c. of 95 per cent. alcohol. The flask is closed, well shaken, and allowed to stand for one hour. The crystalline precipitate is then collected on a small filter and washed with 95 per cent. alcohol until free from iodic acid. The filter and its contents are now pressed between blotting-paper to remove most of the alcohol, and then transferred to the evolution flask of an apparatus where the treatment with hydrazine sulphate is carried out (see this J., 1902, 73). 50 c.c. of a 2 per cent. solution of the latter will be found sufficient. The volume of nitrogen liberated is read off and calculated to normal temperature and pressure. 1 c.c. of nitrogen at 0° C. and 760 m.m. pressure corresponds to 0·17 mgrm. of ammonia, or 1 mgrm. of nitrogen to 0·1351 mgrm. of ammonia. According to the gravimetric method, a quantity of iodic acid, corresponding to about 30 times the amount of ammonia to be determined, is dissolved in 15 c.c. of water, the ammonia solution is added and also 30 c.c. of 95 per cent. alcohol. After shaking, the mixture is allowed to stand for two hours in a closed flask. The precipitate is then collected on a tared filter, washed with 95 per cent. alcohol and dried in a desiccator over sulphuric acid. The weight of the precipitate obtained is multiplied by the factor 0·0314 to give the amount of ammonia in grms.—W. P. S.

Sulphides Thiosulphates and Haloids; Determination of ——, [in Mixtures of the same]. W. Feld. Zeits. anal. Chem., 1903, **42**, 708—711.

When only sulphides and haloids are present, a portion of the sample is distilled with the addition of magnesium sulphate in a current of carbon dioxide. A suitable apparatus is described in this J., 1903, 1186. The liberated hydrogen sulphide is collected as it distils over in a known quantity of standard iodine solution. The halogen salts remaining in the distillation flask are then precipitated with silver solution as usual. An alternative method is to precipitate both haloid and sulphide with an excess of standard silver solution, dilute to a known volume, and determine the excess of silver in the solution. The total precipitate is then distilled with hydrochloric acid and some sheet aluminium in a current of carbon dioxide, the hydrogen sulphide formed being collected in standard iodine solution. The difference between the total silver in the precipitate and the amount present as sulphide gives the quantity of silver combined with the haloids. Should the substance under examination contain sulphides, thiosulphates, and haloids, a portion is boiled with the addition of mercuric oxide. All the sulphur compounds are precipitated as mercuric sulphide. Alkaline solutions must be previously treated with magnesium sulphate and acid solutions with magnesium oxide. The mercuric sulphide is filtered off, and the haloids determined in the filtrate. A separate portion of the substance is taken for the determination of the sulphur compounds (see this J., 1903, 1186). If ammonium salts be present, a preliminary distillation with magnesium oxide is necessary before determining the haloids.—W. P. S.

Alkali Iodates and Chlorates; Reduction of ——, by Hydrazine Sulphate. M. Schlötter. Zeits. anorg. Chem., 1904, **38**, [2], 184—190.

Alkali iodates are rapidly and quantitatively reduced to iodides by the action of hydrazine sulphate. The reaction appears to proceed in two stages, represented by the equations—

$$5(N_2H_4.H_2SO_4) + 4HIO_3 =$$
$$5N_2 + 12H_2O + 5H_2SO_4 + 4I;$$

$$4I + NH_2.NH_2 = 4HI + N_2.$$

Alkali chlorates are also quantitatively reduced to chlorides by the action of hydrazine sulphate, but in this case, it is necessary to boil the mixed solutions for two to three hours. (See also this J., 1904, 36.)—A. S.

Bleaching Powder, Method of determining Available Chlorine in ——. J. Pontius. Chem.-Zeit., 1904, **28**, [6], 59—60.

Weigh off 7·1 grms. of bleach, triturate with water in the usual way, dilute to 1 litre, and use for titration 50 c.c. (= 0·355 grm.). Weigh or measure roughly 3 grms. of sodium bicarbonate into a flask, and pour upon it the measured volume of bleach solution from the pipette, so as to mix thoroughly. Add 1—2 c.c. of starch paste, and then from a burette run in N/10 potassium iodide solution, shaking well after each addition. The first portions of iodide produce a red-brown coloration, which rapidly disappears. As the titration approaches the end, the red-brown colour becomes more blue, and at the last each drop strikes a strong blue colour, which completely disappears on shaking. When the next drop fails to produce this coloration, but gives only a permanent faint light-blue tint, the titration is ended. The solution of the bleach, the decomposition by sodium bicarbonate, and the titration, are represented by the equations—

$$6CaOCl_2 = 3CaCl_2 + 3Ca(OCl)_2;$$

$$3CaCl_2 + 3Ca(OCl)_2 + 6NaHCO_3 =$$
$$6CaCO_3 + 6NaCl + 6HOCl;$$

$$6HOCl + 6NaHCO_3 + 2KI =$$
$$2KIO_3 + 6NaCl + 6CO_2 + 6H_2O;$$

so that one-sixth molecule ($\frac{166}{6} = 27 \cdot 667$ grms.) of potassium iodide is equivalent to one atom of chlorine. The suspended calcium carbonate does not interfere with the reaction. If pure potassium iodide is not at hand, from which an accurately decinormal solution can be prepared directly, the solution is best standardised by comparison with an accurate Penot solution on a sample of bleach. For rapid work, the titration can be carried out in the mortar, weighing off 1 grm. of the bleach, and using an empirical solution (7·7935 grm. per litre) of iodide, such that 1 c.c. = 0·01 grm. of chlorine. In this case, care must be taken that none of the pasty bleach sticks to the sides of the mortar, and thus fails to enter into reaction. The method is available for bleaching liquids; but if these contain alkali hydroxide or carbonate, boric acid must be added—an excess of this does no harm. The bleach solution has no action on the starch during the time occupied in the titration. The one necessary precaution is to have excess of sodium bicarbonate present.—J. T. D.

Manganese Peroxide; Titration of ——. L. Débourdeaux. Comptes rend., 1904, **138**, [2], 88—89.

The substance (0·75—1·0 grm.) is dissolved in 50 c.c. of a solution containing 40 grms. of crystallised oxalic acid and 120 c.c. of strong sulphuric acid in the litre, the flask being connected to a reflux condenser so as to avoid concentration when the liquid is heated. The resulting solution is diluted to 200 c.c., and 50 c.c. of the oxalic-sulphuric solution are also diluted to 200 c.c. The oxalic acid in 150 c.c. of each is determined by permanganate, and from the difference the amount of peroxide is calculated. In the remaining 50 c.c. of each, the free acid is titrated by standard ammonia solution, using fluoresceïn as an indicator. The difference gives the amount of acid (which can of course be calculated into hydrochloric acid) needed for solution. The process is rapid, and needs little continuous attention; the two determinations are made on one portion of the substance; carbonates do not interfere, and it suppresses errors occurring in the hydrochloric acid method, from the titration of the hydrochloric acid needed with the ammoniacal copper sulphate, from incomplete absorption of chlorine, and from free iodine arising from the decomposition of the potassium iodide. The oxalic-sulphuric solution containing manganese, prepared for the determination of nitric acid by the author's method (this J., 1903, 883) can be used for this titration also.—J. T. D.

Antimony and Tin; Separation of ——, by means of Oxalic Acid. F. Henz. Zeits. anorg. Chem., 37, 1. Analyst, 1904, **29**, [334], 13—14.

The author, having been unable to effect a complete separation of these metals by Clarke's method as modified by Rössing (Zeits. anal. Chem., **41**, 1), has devised the following method, in which hydrogen peroxide is employed for a preliminary oxidation:—The sulphide solution, containing not more than 0·3 grm. of the alloy, is mixed with 6 grms. of pure potassium hydroxide, and 3 grms. of tartaric acid, and decolorised by means of hydrogen peroxide solution (30 per cent.). The liquid is next boiled for a short time, allowed to cool slightly, and then treated with a hot solution of 15 grms. of oxalic acid. It is again boiled for 10 minutes, after which a current of hydrogen sulphide is introduced, the solution being kept boiling. Fifteen minutes after the first signs of precipitation of the antimony, the liquid, the volume of which is about 80 to 100 c.c., is diluted to 250 c.c. with boiling water. After 15 minutes longer the boiling is stopped, though the current of gas is still continued for 10 minutes more. The precipitate is now collected on a weighed Gooch's crucible, and washed with a boiling 1 per cent. solution of oxalic acid (twice) and then with very dilute boiling acetic acid, both solutions being also saturated with hydrogen sulphide. The Gooch's crucible is then placed in a tube, through which is drawn a current of dry carbon dioxide, the tube being meanwhile heated first at 100°—130° C. until the precipitate is dry, and then at 300° C. until it has been completely converted into the sulphide, Sb_2S_3. The heating is preferably done with the aid of a small drying oven, in which is placed the part of the tube containing the crucible. A perforated rubber cork was found the best means of closing the larger end of the tube, a Rose's crucible lid being used to protect it from radiant heat. The author has found this method more satisfactory than electrolytic methods or conversion of the sulphide into tetroxide. The tin in the filtrate is best determined electrolytically after concentration of the solution. Suitable conditions are:—Voltage, 2 to 3; amperage, 0·2 to 0·3; and temperature, 60° to 80° C. After 6 hours, 5 c.c. of sulphuric acid (1 : 1) are added, and the electrolysis continued for 18 hours longer. Under these conditions the tin is completely separated as an adherent deposit. In test experiments the results were slightly too low for tin, but were nearly theoretical in the case of antimony. When tin is obtained as a sulphide in an analysis, it may be dissolved by means of ammonium hydrogen oxalate and the solution electrolysed, a little dilute sulphuric acid being added after a few hours, as described above.
—C. A. M.

Aluminium; Application of the Reducing Power of ——, in Quantitative Analysis. N. Tarugi. Gazz. chim. ital., 1903, **33**, [2], 223. Chem.-Zeit., 1904, **28**, [3], Rep. 4.

If a piece of pure aluminium foil be introduced into a solution of silver nitrate acidified with sulphuric acid and the whole heated to boiling, the silver is quantitatively precipitated as metal in the course of two to three hours, and can be filtered off, washed, dried and, weighed. The precipitation of metallic copper from copper sulphate solution, under similar conditions, is not complete.—A. S.

Persulphate; Quantitative Separations by means of ——. G. v. Knorre. Zeits. anal. Chem., 1904, **43**, [1], 1—14. (See v. Knorre, this J., 1902, 72; 1903, 1104. Dittrich and Hassel, this J., 1902, 1414; 1903, 46, 230; Baubigny, this J., 1903, 45, 381, 823, 864.)

The author had previously found that manganese peroxide, precipitated by persulphate from manganese solutions containing other metals, always carried down with it small amounts of the oxides of these metals. Dittrich and Hassel, on the other hand, state that by taking certain precautions the precipitated manganese peroxide is obtained perfectly pure, and they recommend the method as a means of separating manganese from these other metals. The author has very carefully repeated Dittrich and Hassel's experiments, adhering rigidly to the detailed conditions described by them, and has found that in the case of every metal used (copper, zinc, calcium, nickel, magnesium), except chromium, some of the oxide was carried down with the manganese peroxide. Even when the precipitate was washed with boiling 2 per cent. nitric acid, the co-precipitated oxide was not removed. Moreover, the results were not worse when the author's method of precipitating (heating the cold mixture of test-liquid and persulphate on gauze over a flame, and boiling for 5 or 6 minutes) was used, than when Dittrich and Hassel's (heating up in a water-bath, and keeping there for 2—3 hours) was used. Baubigny, too, has found that alkalis, when their salts are present, go down with the peroxide; and he also finds precipitation to be complete after 20—25 minutes on the water-bath. In the case of chromium (as Salinger first proved, in work undertaken at the author's suggestion) the separation from manganese is perfect. When the mixed manganese and chromium salts are heated to boiling in acid solution with persulphate, the chromium is completely converted into chromic acid, and this, having no basic character, has no tendency to precipitate with the manganese peroxide; the chromic acid can be washed out completely by cold water. In a separation by this method the author found 0·6058 grm. instead of 0·6055 grm. of Mn_3O_4, and 0·2774 grm. instead of 0·2772 grm. of Cr_2O_3.—J. T. D.

Tungsten in Tungsten Steel and Ferrotungsten; Determination of ——. E. Kuklin. Stahl u. Eisen, 1904, **24**, [1], 27.

The method is based on the facts that metatungstic acid, liberated from tungstates by acids in presence of phosphoric acid, is reduced by zinc to tungsten dioxide, WO_2, which is then reconverted into WO_3 by permanganate. Two grams of steel are dissolved in one volume of sulphuric acid (sp. gr. 1·84), one volume of phosphoric acid (sp. gr. 1·70), and six volumes of water, adding from time to time 3 c.c. of permanganate solution, so as to maintain a rose-coloration in the liquid, and warming at the end to complete the solution. The cooled liquid is brought into a measuring flask, and half of it used for the titration. To this is added 200 c.c. of 1 : 3 sulphuric acid and 40 grms. of zinc turnings, and the solution is heated. When it is port wine coloured, it is allowed to cool in a stream of carbon dioxide, filtered to separate the excess of zinc, and titrated with permanganate. In the other half of the solution the iron is determined by Reinhardt's method, or by stannous chloride and iodide; and the difference between the two titrations gives the tungsten. Ferrotungsten (0·5 grm.) is heated in a platinum crucible with fused ammonium nitrate, the nitrate destroyed by heating, and the remaining oxides fused with potassium-sodium carbonate. The fused mass is dissolved in water, treated with the acid mixture as above, and titrated. Or the ferrotungsten may be fused with sodium bisulphate, the melt dissolved in water, sodium carbonate added, then the acid mixture as above, and the operation continued as for tungsten steel.—J. T. D.

Alkaline-Earth Metals; Electrolytic Separation of ——. A. Coehn and W. Kettembeil. Zeits. anorg. Chem., 1904, **38**, [2], 198—212.

The authors have previously shown (this Journal, 1901, 1221) that the E.M.F. required for the deposition of certain metals (zinc, cadmium, silver, copper, and iron) can be reduced by using a mercury cathode, with which the metal deposited forms an amalgam. They now find that by making use of this fact, the electrolytic separation of the alkaline-earth metals can be effected. Saturated solutions of barium, strontium, and calcium chlorides were electrolysed at 15°—18° C., in a glass dish, 6 cm. in diameter and 3 cm. high, using a mercury cathode with a surface of about 28 sq. cm., and a platinum wire spiral as anode. It was found that the E.M.F. at which amalgam was first formed was 0·2 volt lower in the case of barium than of strontium, and 0·25 volt lower in the case of strontium than of calcium. Electrolytic tests with solutions containing both barium and strontium chlorides gave the following results:—

E.M.F.	Time.	Barium present.	Barium found.	Difference.
Volts.	Mins.	Grms.	Grms.	Per Cent.
2·02—2·08	180	0·1362	0·1379	+ 1·25
2·00—2·14	250	0·1362	0·1362	± 0·0
2·00—1·90	225	0·2781	0·2782	+ 0·03
1·95	155	0·2781	0·2790	+ 0·3
1·75—1·85	180	0·2781	0·2788	+ 0·3

The method also gives satisfactory results for the separation of barium and calcium, and of strontium and calcium.
—A. S.

Soaps; Determination of Small Proportions of Sodium Hydroxide and Carbonate in ——. P. Heermann. Chem.-Zeit., 1904, **28**, [5], 53; [6], 60—61.

The best methods for determining sodium hydroxide are:—(1) Salt out the soap from dilute aqueous solution, filter, precipitate the carbonate from the filtrate by means of barium chloride, and titrate the hydroxide with acid and phenolphthaleïn. The large amount of sodium chloride present affects the titration, and needs a correction, which bears a serious proportion to the total amount of hydroxide present, and the indication is not very sharp. The barium chloride method is, however, better. (2) Dissolve 5—10 grms. of the soap in 250 c.c. of freshly boiled water, and add 10—15 c.c. of barium chloride solution (300 grms. per litre) which has been neutralised by addition of N/10 sodium hydroxide solution to incipient reddening of phenolphthaleïn. Warm till the precipitate of barium soap and barium carbonate collects together, collect it on the end of a rod, pour off the clear liquid, wash the precipitate on the rod and on the sides of the beaker a few times, and titrate the clear liquid at once. The titration is sharp, is not interfered with by the excess of barium chloride, and may be carried out with either sulphuric or hydrochloric acid. Sodium carbonate may be determined in either of two ways: (3) Determine the hydroxide as in (1) above; then repeat on another portion, not precipitating with barium chloride, but titrating the total alkali, using Methyl Orange as indicator. The difference between (3) and (1) represents the carbonate. (4) Dry the soap in shavings, dissolve in absolute alcohol, completely carbonate the alkali by passing carbon dioxide through the solution, filter, thoroughly wash the sodium carbonate on the filter with absolute alcohol, dissolve it in hot water, and titrate with acid and Methyl Orange. The difference between (4) and (2) gives the carbonate. This is the better method of the two. In the qualitative search for free alkali in soaps, mercuric chloride is in general (though not in the case of resin soaps) more sensitive than mercuric nitrate.—J. T. D.

Sulphuric Acid in Leather; Determination of ——. M. C. Lamb and J. W. Lamb. Leather Trades Rev., 1904, [930], 25—27.

The authors describe an indirect and volumetric method for the determination of free sulphuric acid in leather. Two similar quantities are oxidised, the free acid being previously fixed with a base in one portion only. The residues are dissolved, the sulphuric acid is precipitated as benzidine sulphate, and this is titrated with standard alkali, the difference in titre being a measure of the free acid in the leather.

(*a*) *Total Free and Combined Acid.*—The shredded leather (5 grms.) is dissolved in a flask on the water-bath by pure caustic soda solution (25 c.c. of 10 per cent. strength), and sufficient water to cover the material. The liquid is then made acid to phenolphthaleïn with strong hydrochloric acid (20—25 c.c.), filtered, and, with the washings, evaporated to dryness in a platinum dish. The contents are ignited, dissolved in a little weak hydrochloric acid (30 c.c. of normal solution), diluted, filtered if necessary, the filtrate treated with benzidine hydrochloride solution (see this

Journal, 1903, 883, 925, 1104), 200 c.c., and the mixture allowed to stand for 15—20 minutes. It is then filtered at the pump, on a porcelain disc, with two well-fitting papers, the flask being rinsed out by means of the filtrate, which should also be tested for complete precipitation. The precipitate is washed with 10 c.c. of water twice (the last should be neutral to litmus), and transferred, together with the filter paper, to a flask, and there broken down in water (50 c.c.) by violent agitation of the flask when stoppered. The contents are now titrated with N/10 caustic soda solution, using phenolphthalein as indicator, and when apparently just alkaline, heated to 50°—60° C.; the faint alkalinity is restored by further titration, and again after boiling, the total volume (*a*) of N/10 alkali being recorded.

(*b*) *Combined Acid only.*—Another portion of the leather (5 grms.) is gently coked in a platinum dish, the carbon is burnt off in a stream of oxygen gas at a minimum temperature to avoid loss of sulphates, and the residual ash is strongly ignited over the blow-pipe for five minutes. It is then dissolved in weak hydrochloric acid, the solution filtered, and the sulphuric acid determined as in *a*. If b = the number of c.c. of N/10 caustic soda solution required, then $(a - b) \times 0{\cdot}098$ = percentage amount of free sulphuric acid in the leather.

Preparation of Benzidine Hydrochloride.—Commercial benzidine (12·5 grms.) is ground up in a mortar with water (50 c.c.), transferred with hot water to a litre flask, and after addition of strong hydrochloric acid (15 c.c.) made up to the mark. This solution is filtered and diluted to 5 litres for use as reagent, of which 100 c.c. precipitates about 0·1 grm. of sulphuric acid, representing 2 per cent of acid in 5 grms. of leather.—R. L. J.

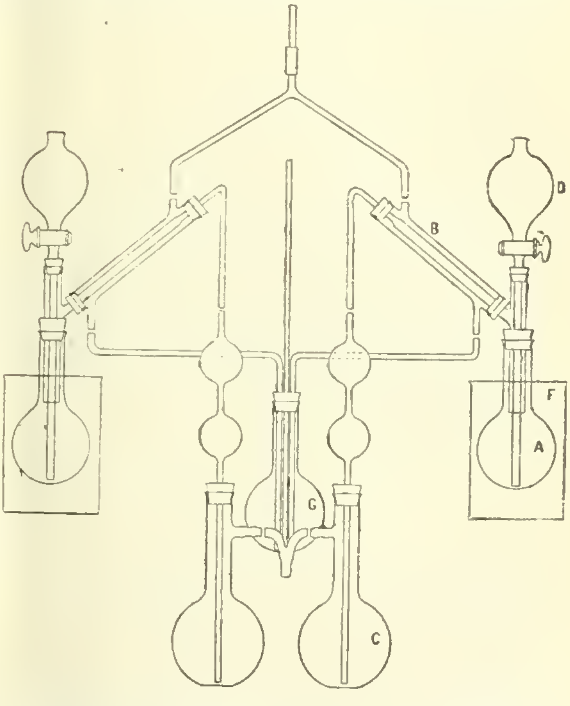
Nitrates; Determination of Traces of ——, in Liquids charged with Organic Matters. A. Pagnoul. Bull. de l'Assoc. des Chim. de Sucr. et de Dist., 1903, **21**, [6], 602—608.

The reagents required are: solution of basic lead acetate; animal charcoal in impalpable powder and absolutely freed from traces of nitrates by being heated in a closed platinum crucible to a red heat; an alkaline solution of potassium permanganate, made by dissolving in hot water 10 grms. of sodium hydroxide and 40 of permanganate, and making up to a litre; Grandval and Lajoux's reagent, obtained by dissolving in the cold 10 grms. of crystallised phenol in 70 c.c. of pure sulphuric acid. The comparison tint is prepared as follows:—A quantity of sodium nitrate solution, equal to 1 mgrm. of nitrogen, is introduced into a 100-c.c. flask and made up to the mark; 10 c.c. of this are evaporated to dryness in a porcelain dish and 15 drops of the phenol reagent stirred in, then ammonia added drop by drop until the yellow coloration due to ammonium picrate is persistent. This represents 1 mgrm. of nitric nitrogen per litre. Several solutions are prepared in sealed tubes for making comparisons. In making determinations in beetroot juice or pulp, lead acetate is added and the measured solution filtered. An aliquot portion is taken and boiled with the alkaline permanganate, which is added until a pink coloration remains, when a little animal charcoal is added. The cold colourless solution, now free from organic matter, is made up to a definite volume, filtered, and treated as when making the standards. With juice from a beetroot distillery the author found 27 mgrms. per 100 c.c., in fresh pulp 21, and in molasses 62 mgrms. Leaves of plants should be first dried at 100°—110° C. to separate the nitrates.—L. J. de W.

Ammonia and Asparagine; Determination of by the Sachsse-Schloesing-Longi Method. H. T. Brown and J. H. Millar. Trans. of the Guiness Research Lab., 1903, **1**, [1], 25—29.

The distillation of ammonia from solutions containing other nitrogenous matters capable of forming ammonia (*e.g.*, amides and amino acids) must be effected in presence of magnesia and at temperatures not exceeding 40° C., under reduced pressure. The authors have devised a modification of Longi's apparatus for conducting this distillation, whereby certain defects of the latter are corrected. The improved apparatus is shown in the figure, in duplicate form. A is a flask of about 600 c.c. capacity, having a wide glass tube passing through a caoutchouc plug. Above the plug a side-piece is fused into the tube, and continued so as to form the inner tube of an inclined reflux condenser, B. Its further end is then bent downwards and connected with a tube having two bulbs and dipping into a large flask, C, containing standard sulphuric acid. The neck of the flask C is connected with the water-pump. D is a tap-funnel for introducing the liquid into the distillation flask, and F is a water-bath, which maintains the desired temperature of distillation. The flask G belongs to a system which keeps the condenser B supplied with warm water at such a temperature that the inner tube is always kept dry, so that no condensation and return of ammonia can take place. Magnesia suspended in water is placed in the flask A, the liquid to be distilled is introduced by the funnel D and the pressure in the whole apparatus is reduced to 10 mm.; the contents of the flask can then be boiled to dryness, if desired, at a temperature of 35° C. In this apparatus, from pure ammonium chloride, ammonia corresponding to 99 per cent. of the salt was distilled. In a mixture of ammonium chloride, asparagine, and aspartic acid, the ammonium chloride found amounted to 96·5 per cent. of the quantity added. In the determination of asparagine, the amidic nitrogen must first be converted into ammonia by hydrolysis with acid. For this purpose it is preferable to boil the asparagine with hydrochloric acid (10 c.c. of strong acid diluted to 100 c.c.) for 2—6 hours. The results obtained on subsequent distillation with magnesia are constantly too low, and must be increased by 5 per cent. Alternatively, hydrolysis may be effected by boiling with 5 per cent. oxalic acid for 10 hours, in which case the results are to be increased by 10 per cent.

—J. F. B.



ORGANIC—QUALITATIVE.

Gallotannic Acid; Detection of ——, on the Fibre. A. Menger. Färber-Zeit., 1903, **14**, [24], 435—436.

A small portion of the textile material is boiled for a very short time with a 5—10 per cent. solution of caustic soda. The solution is divided into two parts, one of which is cooled, the other being again heated to boiling. The appearances of the two parts are then compared. In the absence of any dyestuff which may affect the result, the presence of gallotannic acid is indicated by the distinct reddish colour of that part of the solution which has been heated for a short time only, conjointly with the absence of colour from, or mere pale yellow colour of, that portion which has been heated for a longer time. Catechutannic acid gives with the alkali solution a reddish coloration, which is not altered by boiling.—E. B.

Sperm Oil; Examination of ——. L. M. Nash. Analyst, 1904, **29**, [334], 3—4.

The residue left on saponification of sperm oil is soluble in absolute alcohol, whereas mineral oils are practically insoluble. But since mineral oils are soluble in a mixture of ethyl alcohol and alcohols from sperm oil, the test affords no proof of the freedom of a sample of sperm oil from mineral oils. By substituting rectified spirit for absolute alcohol as the solvent, a much smaller proportion of mineral oil is dissolved, as is shown in the following results, obtained with a sample of American lubricating oil of sp. gr. 0·905 :—

Absolute Alcohol.	Sperm Alcohols added.	Temperature.	Mineral Oil dissolved by Absolute Alcohol.	Mineral Oil dissolved by Rectified Spirit (Sp. Gr. 0·845).
Volumes.	Volumes.	° F.	Volumes.	Volumes.
100	0	70	2	Trace

—C. A. M.

Linseed Oil from Boiled Oils; Differentiation of ——. J. Lewkowitsch. Analyst, 1904, **29**, [334], 2.

The author's experiments on the determination of the amount of insoluble bromides yielded by the glycerides (this Journal, 1899, 77; 1903, 595) have confirmed his conclusion that the test can be used to differentiate between drying oils and those boiled either with or without driers. He gives a table showing the yields of bromides, together with the specific gravities and iodine values of different specimens of oil, from which the following results are selected as typical :—

Oil.	Specific Gravity.	Iodine Value.	Insoluble Bromide.
			Per cent.
1. Linseed oil	0·9308	186·4	24·17
2. Pale boiled oil	0·9429	171·0	20·97
3. Double boiled oil	0·9449	169·96	13·03
4. Linseed oil heated to 600° F......	0·9354	176·3	8·44
5. Linseed oil blown at 120° C. for 10 hours.	0·9460	166·6	23·16
6. Ozonised oil	0·9310	180·1	36·26—36·34
7. "Thin" lithographic varnish	0·9691	125·3	2·09
8. "Medium" " "	0·9693	121·9	0·95
9. Burnt " "	..	102·69	None

The yields of bromide given by No. 6 (derived from Baltic oil) and some other linseed oils were remarkably high, as were also the iodine values of the fresh oils. In the author's opinion some of his experiments with good drying oils furnish additional evidence against the assumption that there is a direct ratio between the iodine value and oxygen absorption of oils.—C. A. M.

Cod-Liver Oil and its Adulterants; Tests for ——. E. H. Gane. Amer. Pharm. Assoc.; through Amer. J. Pharm., 1903, **75**, [9], 430.

The following tests are suggested as indicating a pure oil :—Half an ounce of the oil in a test-tube should remain perfectly clear when immersed in ice for two hours. One fluid drachm of the oil is saponified by boiling with alcoholic potash solution; the soap solution is diluted with 2 fluid ounces of water and heated to expel the alcohol. The fatty acids are then liberated by an excess of hydrochloric acid, and their odour noted. Twenty drops of the oil are placed in a watch glass, and 5 drops of strong nitric acid added. On well stirring together, the oil, if pure, gives a rose-red tint, changing, in half an hour, to lemon-yellow.—J. O. B.

Tartaric Acid; Characteristic Reaction of Free ——. D. Ganassini. Boll. Chim. Farm., **42**, 513—516. Chem. Centr., 1903, **2**, [26], 1476.

Free tartaric acid can be distinguished from formic, acetic, propionic, butyric, valeric, oxalic, succinic, malic and citric acids by the following reaction. The solution, free from mineral acids, is treated with a somewhat larger amount of minium, Pb_3O_4, than corresponds to the quantity of tartaric acid present, the mixture is heated to boiling for a short time, decanted or filtered, a small quantity of a 2 per cent. solution of potassium thiocyanate added to the clear liquid, the mixture heated to boiling and then allowed to stand, when even in the case of a 1 per cent. solution of tartaric acid, the liquid gradually darkens owing to the deposition of lead sulphide. The reaction can be used for the detection of tartaric acid in wines, a brownish-violet precipitate being produced.—A. S.

Tartaric Acid; Detection of ——, *in Citric Acid.* O. v. Spindler. Chem.-Zeit., 1904, **28**, [2], 15.

Denigès' reaction for citric acid (see this Journal, 1898, 802) is thus modified :—0·5 grm. of the acid is dissolved in 10 c.c. of water, 2 c.c. of mercuric sulphate solution (5 grms. of mercuric oxide, 20 c.c. of concentrated sulphuric acid, 80 c.c. of water) are added, and the whole is brought to boiling; 2 c.c. of a 0·5 per cent. solution of potassium bichromate are then added. On cooling, pure citric acid deposits a light yellow precipitate of varying composition; should tartaric acid be present, the liquid becomes dirty brown, carbon dioxide is evolved, and the filtrate has a green colour. The above method serves to detect 5 per cent. of tartaric acid with ease; if the quantity be less, it is well to carry out a blank test with pure citric acid.—W. A. C.

Formaldehyde; Reactions with ——. C. Goldschmidt. Chem.-Zeit., 1904, **28**, [6], 59.

Formaldehyde and dimethylaniline in alcoholic solution yield after standing for some days, laminae of tetramethyldiaminodiphenylmethane. Formaldehyde, methyldiphenylamine, and hydrochloric acid yield an anhydro-alcohol of high melting-point, insoluble in the usual solvents, which slowly turns blue in the air, and yields a blue resin on treatment with oxidising agents. Methyldiphenylamine and formaldehyde heated in alcoholic solution with a couple of drops of hydrochloric acid, yield an oil, which speedily solidifies; while when methylaniline is substituted for methyldiphenylamine a crystalline precipitate is formed, from which two substances can be separated, one soluble in alcohol, m. pt. 63° C., the other insoluble, m. pt. 180° C.
—J. T. D.

Quinine Sulphate; Detection of Allied Alkaloids in ——. Supplement to Dutch Pharmacopœia; through Pharm Post, 1903, **36**, [41], 583.

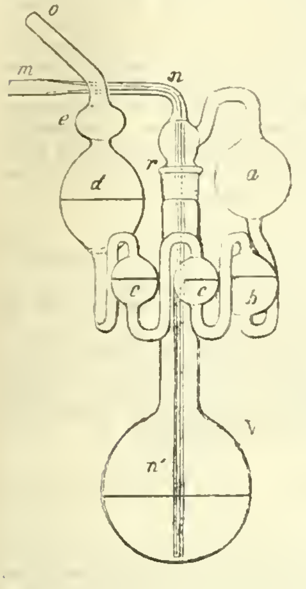
0·75 grm. of the salt, well dried at 100° C., is dissolved in 40 c.c. of boiling water with the aid of a trace of sulphuric acid, so that the solution barely changes the colour of red litmus paper. After adding 6 c.c. of a 10 per cent. solution of neutral potassium chromate and thoroughly cooling, the precipitate is filtered out through glass wool. The clear filtrate thus obtained should not give any opalescence or flocculent precipitate on the addition of 10 drops of caustic soda solution, even after standing for 24 hours.—J. O. B.

ORGANIC—QUANTITATIVE.

Halogens; Determination of ——, *in Organic Compounds.* H. Baubigny and G. Chavanne. Comptes rend., 1904, **138**, [2], 85—87.

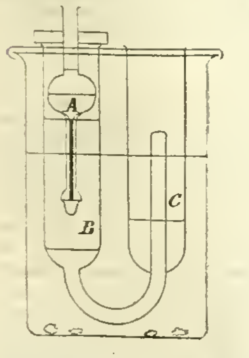
The authors have devised an apparatus for determining chlorine or bromine by their method (this J., 1903, 761) of combustion by sulphuric and chromic acids. The apparatus is shown in the figure; it is made of stout glass, and the tubes *m n* and *o c* touch, and can be tied together.

so that the whole apparatus may be shaken without fear of fracture. About 25 c.c. of alkaline solution of sodium sulphite are introduced into the bulbs through o, and the end m of $m\ n$ is closed by a cork. The sulphochromic mixture is poured into the flask, the substance in its little glass tube dropped in, and the flask at once closed by the stopper carrying the condensing bulbs. The flask is at first warmed or cooled according to the rapidity of the reaction; but action must never be allowed to become violent, and the combustion should last 30 or 40 minutes. Towards the end, the flask is heated in a paraffin bath, in which it is hung by a string, and the temperature is gradually raised to 135°—140° C. When action is over, air is blown through $m\ n\ n'$ till all chlorine or bromine is expelled from the flask; the condenser is removed, the tube $n\ n'$ washed with a jet of water, and the sulphite solution emptied through a and the stopper into a long-necked flask which has been brought up over the tube $n\ n'$ and the stopper. Two or three washings with 30 or 40 c.c. of water introduced by o serve to rinse the condenser thoroughly, and the chlorine or bromine in the liquid is then determined by any of the usual methods. Obviously, a separation of chlorine from bromine cannot be thus effected, though either or both of them can be separated from iodine.—J. T. D.



Soaps; Method of Grading ——, as to their Detergent Power. H. W. Hillyer. J. Amer. Chem. Soc., 1903, **25**, [12], 1256—1265.

In a previous communication (J. Amer. Chem. Soc., **25**, 511, 524) the author showed that when a solution of soap is allowed to fall in drops beneath the surface of an oil, the number of drops formed from a given volume of the solution depends on the amount of soap present, and is also a measure of the emulsifying (detergent) power of that solution. In the present paper he recommends this test as a means of forming some opinion as to the detergent properties of different soaps in hot or cold water. As a standard for the hot test, 1 grm. of neutral sodium palmitate (prepared from 36 c.c. of $N/10$ sodium hydroxide solution and 0·921 grm. of palmitic acid), is dissolved in 200 c.c. of hot water, and portions of 10, 20, 30, and 40 c.c. respectively of this solution diluted to 50 c.c. with boiling water, and tested in the apparatus. The essential part of the latter is a pipette, A, with capillary outlet of about 0·45 mm., opening from a flat horizontal surface of about 10 mm. in diameter. The pipette holds 5 c.c., and has a spherical body; the internal diameter of the stem is 3 mm. The receptacle for the oil may be a test tube, but it is preferable to use a vessel of the form, B, C, so as to obtain a more nearly constant pressure. It is immersed in a covered beaker containing water which is kept boiling. In using the apparatus, 2 or 3 c.c. of water are introduced into B, followed by 20 c.c. of kerosene, the pipette is rinsed out twice with the given soap solution, then filled, its point placed in the kerosene, and the number of drops formed in falling from the mark on the pipette counted. The numbers of drops given by each of the diluted boiling standard solutions, with the standard kerosene oil, are then plotted in a curve in which the ordinates represent percentages of the standard, and the abscissæ the numbers of drops corresponding to those percentages. Unknown samples of soap are tested in the same way, and the results referred to sodium palmitate as a standard. Thus, if 0·5 grm. of a commercial soap be dissolved in 100 c.c. of water, and the solution tested at the boiling point, it may be stated that the sample yields the same number of drops as a solution of sodium palmitate containing x per cent. of the standard, or that with hot water it has as great a detergent power as a soap containing x per cent. of sodium palmitate. In testing cold water soaps a solution of 1 grm. of sodium oleate in 200 parts of freshly-boiled distilled water is taken as the standard (= 100 per cent.). Fractional standards are prepared as before, each being diluted with cold freshly-boiled water, tested in the same way, as far as possible at a standard temperature, and the results plotted as a curve. In the actual test, 0·5 grm. of a sample of soap in shavings is mixed with 100 c.c. of freshly-boiled cold water, and allowed to stand over night, then filtered, and the filtrate stirred and tested as before. The hot test will give results concordant within 1 per cent. with successive samples, and much closer in duplicate determinations with the same sample, whilst the cold test gives figures, agreeing within 4 or 5 per cent. in the case of the most slimy products. A table of the results given by commercial soaps is shown, and it is pointed out that these confirm in some cases the relative values assigned by the makers to their products. The author considers that this method will afford the manufacturer a better means of judging a soap, and of determining the effect on its detergent power of variations in the composition.—C. A. M.



Fehling's Solution; Sodium Sulphide as an Indicator with ——[Determination of Reducing Sugars]. L. Beulaygue. Comptes rend., 1904, **138**, i, [1], 51—53.

Sodium sulphide (10 per cent. solution) serves as a very convenient indicator in the volumetric estimation of reducing sugars by means of Fehling's solution. The latter, mixed with double its volume of water, is heated to boiling in a porcelain dish and the sugar solution gradually run in from a burette. When the end point is approached, a drop of the liquid is removed from the dish by means of a glass rod and is placed on the upper surface of two filter papers, the first of which filters off the cuprous oxide so that only the clear liquid reaches the lower paper. The moistened part of the latter is then touched with a drop of the sodium sulphide solution, which gives a black spot if unreduced copper salt is still present. When very little of the copper remains unreduced, the coloration produced by the sulphide changes to brown, and at the end point it disappears altogether. This method of working is a very sensitive one, especially if the moist spot be viewed by transmitted light. In the preliminary determination of the strength of the Fehling's solution, it is also necessary to work in the way described above.—T. H. P.

Starch in Barley and Malt; Method for the Rapid Determination of ——. H. T. Brown and J. H. Millar. Trans. of the Guiness Research Lab., 1903, **1**, [1], 79—91.

The two methods hitherto available for the determination of starch in barley and malt, *viz.*, O'Sullivan's "maltose and dextrin" method and the method of fermentation, require several days. The authors have therefore devised the following rapid method, which is based on cupric reduction only, so that the tedious extraction of the optically active amylans, the weak point of the O'Sullivan method, can be dispensed with, since it has been proved that this class of bodies yields no reducing sugar on treatment with malt diastase. The grain is first ground to the finest possible powder in a Maerker mill, a weighed quantity of about 5 grms. is then placed in a paper extraction thimble. About 80 c.c. of alcohol, sp. gr. 0·920, are placed in the extraction flask, which is preferably made of copper, and conditions are thus established which ensure the continuous extraction of the meal by alcohol of 0·900 sp. gr. About 0·5 grm. of high-melting paraffin should be placed in the flask to prevent frothing. Extraction is conducted for three hours in the case of barley, and for nine hours in the case of malt, by which treatment all cupric-reducing bodies and all nitrogenous bodies soluble in alcohol are removed. The meal is then transferred to a beaker with about 100 c.c. of water and the mash is thoroughly boiled. After cooling to 57° C., 10 c.c. of an active malt-extract are added and conversion is allowed to proceed for one hour. The solution is boiled and filtered, the residue washed, and the filtrate diluted to 200 c.c. after cooling. The cupric-reducing power is then determined under the standard conditions laid down by Brown, Morris, and Millar (J. Chem. Soc., 1897, 94), and the maltose is calculated from Table XI. (*loc. cit.*, p. 100) after correction for the reducing power of the malt-extract. This method depends on the conversion of the starch to the point known as the "No. 8 equation" of Brown and Heron, according to which 84·4 parts of maltose correspond to 100 parts of starch. The attainment of this point depends, however, on the converting power of the malt-extract, and the factor is only accurate when the extract is prepared from a malt kiln-dried at 50°—52° C., and possessing a diastatic power of 80° on Lintner's scale. If the malt employed have a lower diastatic power the starch equivalent of the maltose produced at the final stage must be determined by a control experiment with pure starch.—J. F. B.

Formaldehyde; Determination of ——. C. Kippenberger. Zeits. anal. Chem., 1903, **42**, 686—696.

Attention is drawn to a series of errors in the method given in the German Pharmacopœia for the determination of formaldehyde. It is there directed to mix 5 c.c. of the formaldehyde solution with 20 c.c. of water and 10 c.c. of ammonia solution (German Pharm. strength), allow the mixture to stand in a closed vessel for one hour, then to add 20 c.c. of N/1 hydrochloric acid solution, and titrate the excess of acid with N/1 potassium hydroxide solution, using rosolic acid as indicator. The author shows that this indicator gives unreliable results should the ammonia solution contain carbonate, which is nearly always the case. Further, the hexamethylenetetramine formed is not a stable body. It undergoes partial decomposition in the presence of acids, neutralising a portion of the latter. Although it is also possible for this substance to be decomposed by alkalis, this does not come into consideration under the conditions of the above process. A sample of formaldehyde solution gave 36·74 per cent. of formaldehyde, using rosolic acid as indicator. With methyl orange, 28·46 per cent. was obtained, the latter figure closely agreeing with that obtained by a different method—conversion of the formaldehyde into trisulphomethylene.—W. P. S.

XXIV.—SCIENTIFIC & TECHNICAL NOTES.

Hydrogen Peroxide; Radio-activity of ——. O. Dony-Hénault. Bull. de l'Assoc. Belge des Chim., 1903, **17**, [10], 365—373.

Experiments were made to ascertain the relationship between the radio-activity of hydrogen peroxide, and its rate of dissociation into water and oxygen. The rate of dissociation diminishes when the temperature is lowered, and it was found that the radio-activity was also lowered, care being taken in all these experiments to keep the sensitised surface itself at a uniform temperature by means of melting ice. On the other hand acceleration or modification of the dissociation rate by means of catalytic agents such as mercury and platinum, or by chemical agents which affect the stability of hydrogen peroxide solutions, *e.g.*, sulphuric acid, alcohol, or alkalis, neither accelerate nor modify the intensity of radio-activity. The loss of radio-activity noticed when the temperature falls, can not therefore be explained by the diminished rate of dissociation. Contrary to the opinion of Graetz, the radiations of hydrogen peroxide cannot reproduce hydrogen peroxide from the vapours present in the atmosphere, so that the analogy with the Becquerel rays which ozonise oxygen is much weakened; whilst the influence of temperature on the two kinds of radiation points to an essential difference between them.—R. L. J.

Chemical Action of Light. G. Ciamician and P. Silber. Ber., 1903, **36**, [17], 4266—4272.

On allowing a shallow dish containing finely-powdered stilbene to remain for nearly a year in a dessicator, it was found that the walls of the latter, and more especially those parts of them subjected to direct sunlight, became covered with long, acicular crystals of benzoic acid; mixed with the acid was an amorphous, resinous substance, also occurring in the residual, unaltered stilbene. The authors explain this change as due to the desiccator not being quite closed and so allowing the entrance of oxygen which united with the stilbene giving a peroxide.—T. H. P.

Dinitrobenzylideneaniline; Action of Light on ——. F. Sachs and E. Sichel. Ber., 1904, **36**, [17], 4373—4377.

On subjecting a solution of 8 grms. of 2:4-dinitrobenzylidene-aniline in cold benzene, placed between the walls of a double-walled, sealed glass cylinder, for four weeks (in July) to the action of direct sunlight, it was found to yield: (1) 0·3 grm. of a substance separating from its nitrobenzene solution in pale yellow needles, and (2) about 3 grms. of *o*-benzeneazo-*p*-nitrobenzanilide $[(CO.NH.C_6H_5):(N:N.C_6H_5):(NO_2) = 1:2:4]$.—T. H. P.

Oxidation caused by Manganese; Influence of Albuminoïd Substances on ——. A. Trillat. Comptes rend., 1904, **138**, [2], 94—96.

If weak solution of albumin from white of egg be added to the gallic acid and alkaline manganese solution described in a previous paper (this Journal, 1903, 1371), the oxidising action on the gallic acid is greatly increased, especially in the early stages. Increase of albumin accelerates the action up to a certain point (about 0·1 per cent. of the whole). The effect of paralysing agents is very marked. Other albuminoids and colloids have given very variable results. Albumin tends to prevent the precipitation of manganese salts by an alkali, and as it has been found that the activity of certain soluble substances lessens as they approach their point of coagulation or separation, so possibly the retention of the manganese oxide in the colloidal condition accounts for the increased activity caused by the albumin. The association of metallic salt, base, and colloid, like albumin, is exactly what is found in nature.—J. T. D.

New Books.

A Systematic Survey of the Organic Colouring Matters. Founded on the German of Drs. G. Schultz and P. Julius. Second Edition, revised throughout and greatly enlarged. By Arthur G. Green, Professor of Tinctorial Chemistry at the Yorkshire College, Leeds, &c. Macmillan and Co., Ltd., London and New York. 1904. Price 21*s*.

Large 8vo, almost 4to, volume, containing preface and introduction, list of abbreviations, and tabulated subject-matter filling 269 pages. At the close are alphabetical indexes of "Raw and Intermediate Products" and of "Colouring Matters." Of the portion introductory to the tables (Raw Products, or Section I.), this is subdivided as follows:—(i.) Coal Tar. (ii.) Intermediate Products, consisting of Nitro Compounds; Sulphonic Acids of Hydrocarbons; Carboxylic Acids of Hydrocarbons; Primary Amines and their Sulphonic Carboxylic Acids; Secondary and Tertiary Amines and their Derivatives; Diamines and their Sulphonic Acids; Primary Amines and Diamines used in the Preparation of Substantive Cotton Colours; Phenols and their Sulphonic and Carboxylic Acids; Amidophenols and their Derivatives; Halogen Compounds; Aldehydes, Ketones and Quinones; Diazo and Azo Compounds; Compounds of the Fatty Series. Section II., Colouring

Matters. The tables, here extending from page 74 to 268, contain 711 dyestuffs, and these are treated under the following headings:—"Commercial Names"; "Scientific Names"; "Empirical Formulæ"; "Constitutional Formulæ"; "Methods of Preparation"; "Year of Discovery"; "Discoverer, Patents, Literature"; "Behaviour with Reagents. Shade and Dyeing Properties and Method of Employment." The work concludes with an Alphabetical Index to Section I. and also an Alphabetical Index to Section II.

Gas Undertakings. Return relating to all authorised Gas Undertakings in the United Kingdom other than those of Local Authorities, for the year ended the 31st December, 1902. 331. Eyre and Spottiswoode, London. Price 9*d.*

This is an annual return issued by the Board of Trade, containing statistics as to the operation of the various gas companies in the United Kingdom. The present return deals with 454 authorised undertakings, with a total authorised share capital of 74,319,363*l.*, and supplying 2,197,987 consumers. During the year ended 31st December 1902, the receipts of these companies amounted to 17,205,092*l.*, and their expenditure to 13,167,186*l.* 8,520,004 tons of coal were carbonised during the year, and 99,676,048 cb. ft. of gas made.

Gas Undertakings (Local Authorities). Returns relating to all authorised Gas Undertakings in the United Kingdom belonging to Local Authorities for the year ended the 25th March, 1903. 330. Eyre and Spottiswoode, London. Price 5½*d.*

This return shows that during the year ended the 25th March 1903, 256 local authorities were engaged in the manufacture of gas for lighting purposes, &c. The quantity of gas made in 1902-3 was 60,902,739 cb. ft., coal to the extent of 5,589,215 tons being used. The number of consumers supplied with gas was 1,970,738, and in addition, 294,828 public lamps were lighted by gas manufactured by local authorities.

Trade Report.

I.—GENERAL.

Preferential and Reciprocal Trade Act in New Zealand.

Bd. of Trade J., Jan. 14, 1904.

The "Preferential and Reciprocal Trade Act, 1903" (No. 78 of 1903) came into force on Nov. 16 last; it provides for the levying of duty on certain articles imported into New Zealand and not the produce or manufacture of some part of the British dominions, in addition to the ordinary tariff duties in force. The following are examples:—

Cement: an amount equal to the duty payable under the tariff. Candles; china, porcelain, &c; cream of tartar; earthenware, &c.; glass and glassware; various kinds of paper; plate and plated ware: an amount equal to one half the duty payable under the tariff. Printing paper:—a customs duty equal to 20 per cent. of the value for duty as defined by the "Customs Laws Consolidation Act, 1882."

American Chemical and Allied Mineral Trades in 1903.

Eng. and Mining J., Jan 7, 1904.

Cyanide.—Apart from a good home demand, a fair export trade was done with Mexico, South America, and Canada, at rather low prices. With a domestic production of about 2,500,000 lb., the United States imports annually between 3,000,000 lb. and 4,000,000 lb. from Great Britain and Germany. Market prices have felt the anxiety of foreign makers to unload heavy stocks accumulated in recent years. Importers at New York quoted 19·5 to 21 cents per lb., and probably took some large contracts at less, although there is a duty of 12·5 per cent. *ad valorem* on potassium cyanide and 25 per cent. on sodium cyanide.

Bleaching Powder.—Consumption has been large, notwithstanding labour troubles in certain important industries. The imports of foreign bleach into the United States in 1903, paying a duty of 0·02 cent per pound, amounted to 109,003,234 lb., of which Great Britain furnished 88,744,166 lb., or 81·4 per cent. Compared with 1902, the total imports show a decrease of 3,371,244 lb., or 3 per cent. Re-exports were 779,826 lb., as against 198,794 lb. in 1902, the difference indicating that the domestic production and quality of bleach is improving, particularly in the central west. Foreign prime bleach sold in New York in the early months of the year at 1·75 dols. per 100 lb., but in September free offerings of varied test brands were made as low as 85 cents. The extreme monthly average prices were 1·42 dols. in February, and 1·01 dols. in October, making 1·187 dols. for the year. Domestic prime bleach touched 1·25 dols. f.o.b. works in February, and 75 cents for off-test in May and later; the year's average was 1·107 dols. Contracts for 1904 delivery at seaboard have been taken at 1·25 dols. per 100 lb. for prime British and American, and 1·20 dols. for Continental brands. Lower grades have been booked at a discount.

Copper Sulphate.—There were imports of British blue vitriol in the face of a 0·5 cent per lb. duty, a loss of 62·8 per cent. to 8,355 long tons in domestic exports, and a further reduction of 20·5 per cent. to 17,309 tons in production, owing partly to the disastrous fire at the works of the Nichols Chemical Company. Better prices obtained in 1903, as a result of a higher market for copper and of the centralisation of the trade. The best prices were reported in February—May, 5·875 dols. per 100 lb. being touched in April; the lowest was 4·125 dols. in January. The extreme monthly average prices were 4·37 dols. in January, and 5·54 dols. in March, making 4·87 dols. for the year. Frequently the British article sold below the domestic, but on the whole both brands maintained a satisfactory level.

Arsenic.—The United States is the largest consumer in the world, importing annually fully 6,000,000 lb. of white arsenic, metallic arsenic, and arsenic sulphides from Europe and Canada. Recently importers booked contracts for white arsenic at an average of 2·975 cents per lb. for French, 3·125 cents for Spanish and German, and 3·25 cents for British, f.o.b. New York. In January there were sales as low as 2·75 cents to 3·125 cents, according to brand, and, summed up, the year's prices have been less than in 1902, owing to competition. Red arsenic, imported from Germany, was also weak, receding from 6·75 to 7 cents per lb., in January, to 6·375 to 6·50 cents later.

Sulphuric Acid.—The heavy consumption, especially by the fertiliser and petroleum industries, with the friendly relations among the larger eastern acid-makers, has resulted in satisfactory market prices. Contract deliveries in 1903 and 1904 in New York and vicinity have been quoted on the basis of 1·05 dols. per 100 lb. for 60° acid in carboys, and 18 dols. to 20 dols. per ton in bulk; 1·20 dols. per 100 lb. for 66° in carboys, and 21 dols. to 23 dols. per ton in bulk; and 13·50 dols. to 14·50 dols. per ton for bulk chamber, or 50° acid. In other parts of the country, especially in the central west, where acid is made chiefly as a by-product in treating zinc sulphide ores, lower prices have been received, but the eastern market is practically free from this competition.

Nitric Acid.—The continued strength in the raw material market is reflected in the prices for nitric acid, for this or next year, which are 4·37½ dols. per 100 lb. for 36° in carboys delivered in New York and vicinity, 4·75 dols. for 38°, 5 dols. for 40°, and 5·37½ dols. for 42°. Consumption is good.

Oxalic Acid.—Only occasionally was the market unsettled by a pressure to sell on the part of importers, and during the flurry quotations at New York dropped to 5 dols. to 5·12½ dols. per 100 lb. At other times the market was firm at 5·25 dols. to 5·50 dols. Contracts for 1904 delivery were booked in October and later at 5 dols. for German and British, and 5·25 dols. to 5·50 dols. for Norwegian. The annual imports into the United States are something between 5,678,000 and 5,700,000 pounds.

Hydrochloric Acid.—Buying by consumers has been about up to the average in the past year, and prices have been remunerative to the producer. The average quotations at New York for 1903 and 1904 deliveries are 1·50 dols. per 100 lb. for 18° acid, 1·60 dols. for 20°, and 1·75 dols. for 22°.

Sulphur and Pyrites.—The production of sulphur in the United States during 1903 is estimated at 13,500 short tons, valued at 262,175 dols., as compared with 8,336 short tons, valued at 220,560 dols. in 1902. The greater part of the output was obtained from the mines of the Union Sulphur Company, near Lake Charles, Calcasieu parish, La., the balance coming from the mines of the Utah Sulphur Company in Beaver county, Utah, and those of the Nevada Sulphur Company at Rabbit Hole Springs, near Humboldt county, Nev. Although the production of domestic sulphur in the United States has never exceeded 1 per cent. of the total consumption, it is noteworthy that the output from the domestic mines during 1903 is the largest ever recorded, which indicates that the development of this branch of the mineral industry is of good promise. During 1903 the total consumption in the United States of sulphur from domestic and foreign sources, together with the sulphur content of pyrites used for the manufacture of sulphuric acid (including both domestic and foreign product) aggregated 472,662 long tons as compared with 481,830 tons for 1902. The details of the supply are given in the subjoined table, the imports for December being estimated :

——	1902.	1903.
	Long Tons.	Long Tons.
Sulphur, domestic	7,443	12,054
Sulphur, foreign (net imports)	174,939	185,796
Sulphur content of domestic pyrites	102,689	88,636
Sulphur content of foreign pyrites	196,759	186,176
Total consumption	481,830	472,662

Prices have ruled high, and until the deposits in Mexico and Alaska, optioned to Americans, are developed actively the Anglo-Sicilian Sulphur Company, which controls 85 per cent. of the output in Sicily, will continue to dictate prices. New York importers booked shipping contracts for Sicilian sulphur at an average of 22·75 dols. per ton in January and 21·75 dols. in June, or 22·25 dols. for the year for best unmixed seconds, which is only 75 cents more than the average price in Sicily, plus the freight of 1·84 dols. per ton. Best thirds sold in New York in January at an average of 20·75 dols., and in November at 21·50 dols., making 21·20 dols. for the year, which is only 40 cents more than the Sicilian delivery price at Atlantic ports. Re-sales have been made on spot at higher prices, but taken as a whole the margin of profit for importers has been rather small. A 7 per cent. decrease in the demand for pyrites this year has naturally affected prices somewhat, but as sellers usually make long-time contracts with consumers the transient market is seldom disturbed. Ocean freight rates from Spain, averaging from 9*s.* 6*d.* to 12*s.* 6*d.* per ton also had some influence on the market, while the heavier imports of Pilley's Island pyrites attracted no little attention. Spanish pyrites, containing from 43 to 51 per cent. of sulphur, sold at 10 to 13·5 cents per unit for lump, and 9 to 11·5 cents for fines. Domestic ore, carrying from 42 to 44 per cent. of sulphur, brought an average of 5 dols. per ton for lump, and 10 cents per unit for fines, f.o.b. Atlantic coast mines.

Nitrate of Soda.—An increased consumption, higher market prices, comparatively lower ocean freight rates from South American ports, and the adjustment of the *quotas* of exports from Chile for the third year (April 1, 1903, to March 31, 1904), at 32,500,000 qtls. give hope for continued prosperity. Earnings of the *oficinas* are large, and it is also noteworthy that on the year's exports of 1,405,143 long tons the Chilian Government has collected about 17,823,640 dols., besides enriching its treasury from the sales of mineral-bearing land in Tarapaca and Toco.

Saltpetre.—The consumption in 1903 has been the largest recorded, imports into the United States amounting to 13,552,059 lb. Crude saltpetre sold in New York at 3·30 dols. to 3·75 dols. per 100 lb. for immediate delivery, and at 3·25 dols to 3·60 dols. for future shipment. The refined quality brought 4 dols. to 4·50 dols. per 100 pounds.

Zinc Oxide and White Lead.—Labour troubles in the building trades interfered somewhat with the domestic market and reacted on the production of white lead. A larger export trade encouraged the output of zinc white. American dry white lead sold in New York at 4·50 to 5·75 cents per lb., according to quality and time of delivery, while extra dry zinc oxide brought 4·375 to 4·75 cents. Foreign brands sold proportionately higher than the domestic, owing to the duty of 2·875 cents per lb. on white lead, 1 cent per lb. on dry zinc white, and 1·75 cents in oil.

Phosphates.—The production of all classes of phosphates in the United States in 1903, estimated below at 1,477,401 long tons, is somewhat less than the previous year, owing to a curtailed demand, as indicated by the shipments given.

——	Production.	Shipments.	
		Domestic.	Foreign.
Florida hard rock	488,750	1,000	466,819
Land pebble	285,188	149,008	153,563
Peace river	49,985	49,985	..
Total, Florida	773,923	199,993	620,382
Tennessee	422,889	313,008	117,387
South Carolina	280,789	218,227	40,929
Total, United States	1,477,601	731,228	778,698
Total, 1902	1,487,471	782,455	821,515

It is worthy of comment that, although 52·8 per cent. of the production was sent abroad, the proportion is less than 1902. Our best customers were Germany and Belgium for hard rock, and Italy, France, and Great Britain for land pebble. A surprising feature is the continued large imports of phosphates from Belgium and other countries, which in 1903 amounted to about 136,531 tons, and were used principally as "fillers" for artificial fertilisers.

British Guiana ; Trade of ——. (Year Ended 31st March, 1903.)

Bd. of Trade J., Jan. 28, 1904.

The following tables, showing the total value of the imports and exports of certain articles into and from British Guiana during the financial year ended 31st March last, as compared with the preceding year, are compiled from the report of the Comptroller of Customs at Georgetown on the Customs statistics of the Colony for the year 1902—1903:—

Imports.

——	Year ended 31st March	
	1902.	1903.
	Dols.	Dols.
Metals and metal manufactures (includes machinery, hardware, and cutlery)	761,000	656,000
Manures	445,000	528,000
Beverages (includes malt liquors, wines, and spirits)	178,000	181,000
Oils, petroleum and other	143,000	161,000
Coal and coke	125,000	111,000
Leather manufactures	122,000	139,000

Exports of Colonial Produce.

——	Year ended 31st March	
	1902.	1903.
	Dols.	Dols.
Sugar	4,983,000	5,002,000
Gold	1,788,000	1,790,000
Rum	772,000	651,000
Balata	144,000	195,000
Molasses	21,000	59,000

II.—FUEL, GAS, AND LIGHT.

Gas; Illuminating Power and Purity of ——. Committee of Enquiry.

Bd. of Trade J., Jan. 28, 1904.

The President of the Board of Trade has appointed the following gentlemen, *viz.*, the Lord Rayleigh, F.R.S. (Chairman): Sir Wm. de W. Abney, K.C.B., F.R.S.; Robert Farquharson, Esq., M.D., M.P.: William King, Esq.; and J. Fletcher Moulton, Esq., K.C., M.P., to be a Committee to enquire and report as to the statutory requirements relating to the illuminating power and purity of gas supplied by the Metropolitan Gas Companies, and as to the methods now adopted for testing the same, and whether any alteration is desirable in such requirements or methods, and, if so, whether any consequential alteration should be made in the standard price of gas.

Mr. Herbert C. Honey, of the Board of Trade, has been appointed Secretary to the Committee.

IV.—COLOURING MATTERS, Etc.

Alizarin Blue G. W.: U.S. Customs Decision.

Dec. 31, 1903.

Merchandise named as above, which on analysis was shown to be made from alizarin or anthracene, was decided by the Board of General Appraisers to be free of duty under paragraph 469 of the present Tariff Act, as a "dye derived from alizarin or anthracene."—R. W. M.

VII.—ACIDS, ALKALIS, Etc.

Bromine Production of U.S. in 1903.

J. Struthers. Eng. and Mining J., Jan. 7, 1904.

The production of bromine in the United States during 1903, including the quantity of bromine contained in potassium bromide, amounted to 603,500 lb., valued at 172,000 dols., as compared with 513,890 lb., valued at 128,472 dols., in 1902. The price of bromine during 1903 has been very erratic, beginning the year at 25 cents per lb., and going to as high as 40 cents for a few lots in July and August; toward the end of the year it has been quoted at 30 cents. The average for the entire year may be taken at 28·5 cents per lb. The world's production of bromine continues to be controlled by the associated American producers and by the Leopoldshall-Stassfurt Convention, the latter association continuing operative for several years to come. There has been very little, if any, change in the bromine industry in the United States during 1903. More than one-half of the total output was furnished by Michigan, which contributed approximately 270,000 lb. in the form of potassium bromide, and 56,500 lb. in the form of liquid bromine (total 326,500 lb.), as compared with the respective quantities of 165,000 and 61,462 lb. (total 226,462 lb.) for the year 1902.

Sulphur; Canadian ——.

Chem. and Druggist, Jan. 16, 1904.

It is reported that sulphur deposits have been discovered in the Steep Rock Lake district. The deposits of pyrites are said to carry from 40 to 45 per cent. of sulphur suitable for sulphuric acid manufacture.

X.—METALLURGY.

Kolar Gold Field, India.

A. M. Smith. Trans. Inst. of Min. and Met., Jan. 21, 1904.

The Kolar goldfield, though one of the smallest in the world, is one of the richest—if not the richest—in point of gold production. Up to September last it had yielded no less than 16 millions sterling in gold, of which 6 millions has been paid in dividends, while the annual output has now reached 2¼ millions. The industry gives employment to some 20,000 mining men, hundreds of whom are from this country. The two chief lodes or reefs on the Kolar goldfield are known as the Champion lode and the Oriental lode. These run parallel to one another, about 4,000 ft. apart, and both of them occur in the eastern half of the schistose belt. Profitable mining operations have hitherto been carried on only on the Champion lode, which is not auriferous, in a paying sense, throughout. Very rich patches occur in places, to which the name of "shoots" has been given. These shoots all crop out at the surface, and have a well-defined pitch to the north. As a rule, there are old native workings where the shoots crop out, and the old workers have gone down in some places as deep as 300 ft. Between the shoots there is much reef matter that does not pay to mine; hence the endeavour, on all the mines, to find the "shoots" of ore. As much as six millions sterling in gold has been taken out of a single "shoot." It is generally agreed (1) that the auriferous rocks form a narrow band, from 1 to 4 miles wide from east to west, and some 40 miles long; (2) that the auriferous rocks are bent into a synclinal fold, with a north and south axis; (3) that the auriferous quartz reefs occur about the middle of the schist band, and are parallel to the layers of the schist, and hence strike north and south; (4) that the Champion lode, which occurs on the east central portion of the belt, dips west at an angle of from 45° to 60°. As the Champion lode occurs about the middle of the schist band, and as its dip is coincident with the bedding of the schists (an angle of 45°), it is clear that it will not extend downwards in depth indefinitely.—J. H. C.

Mercury in 1903.

A. S. Pickering. Chem. and Druggist, Jan. 16, 1904.

The following tables show the business done in the United Kingdom in mercury during 1903 and past years:—

——	Imports.	Exports.	Highest. Price.	Lowest Price.
	Bottles.	Bottles.	£ s. d.	£ s. d.
1903	34,886	18,846	8 15 0	8 5 0
1902	33,192	19,519	8 17 6	8 14 6
1901	35,341	26,863	9 2 6	8 17 6
1900	32,725	25,869	9 12 6	9 2 6
1899	51,696	32,239	9 12 6	7 15 0
1898	54,563	34,014	7 15 0	6 16 0
1897	54,734	39,768	7 7 6	6 9 6
1896	47,159	35,211	7 6 0	6 5 6
1895	49,654	36,827	7 8 6	6 7 6
1894	51,251	43,598	6 14 0	5 7 0

It will be noted from the above figures that the exports are the lowest since 1894, but as a matter of fact they are the lowest for 23 years.

India; Minerals in ——.

Indian Geological Survey. Through Bd. of Trade J., Jan. 14, 1904.

Chromite.—Chrome-iron deposits were investigated in the Peshin and Zhob districts, Baluchistan. One of the most promising localities occurs about two miles east of Khanozai, in the Peshin district, where a vein-like mass about 400 feet long, with an average breadth of 5 feet, was investigated. The vein consists of almost pure ore of great richness. An analysis made in the laboratory of the Department gave over 54 per cent. of chromium sesquioxide, and some parts of the vein show an even higher percentage. The locality is connected by an excellent road with Khanai railway station, 17 miles distant.

Fire-clay.—The deposits noticed near Jowai, Assam, were, at the request of the Chief Commissioner, re-examined and sampled for testing. The tests showed that the material forms excellent fire-bricks, capable of standing a great heat.

Iron and Manganese.—In connection with the Dhar Forest Survey, the rich iron ore deposits received some attention, but it is stated that the main and, at present, insuperable difficulty in connection with the development of these ores on a large scale is the absence of mineral fuel. The manganese ores, which are also widely distributed in the same district, are to be the subject of a special report to the Dhar Durbar.

Lead.—A lode of galena discovered in Dargoti State was examined north-east of Simla; the opinion expressed, supported by assays, is that the ore-body is neither rich enough nor large enough for successful exploitation.

Petroleum.—Regarding the investigation of a possible oil field near Pakoku district, Upper Burma, northward, the report says:—"The structure is that of a productive oil field, and it is possible that a remunerative supply of oil could be obtained, although, owing to the formation, the oil will not be obtainable at the pressure which gives rise to the flowing wells of Yenangyat."

Mineral and Metal Production of the United States in 1903.

Eng. and Mining J., Jan. 7, 1904.

The following table gives the figures for the estimated production of minerals and metals in 1903 in the United States, with values; the figures for 1902 are added for comparison:—

	1902.			1903.		
		Value at Place of Production.			Value at Place of Production.

XII.—FATS, FATTY OILS, Etc.

Cod-Liver Oil; Norwegian ——.

U.S. Cons. Rep., No. 1843, Jan. 6, 1904.

The best Norwegian oil is extracted from the fat livers of the cod in the early part of the winter fisheries in the Lofoten Islands. The livers at this time—in January, February, and a part of March—are, as a rule, light-coloured, plump, and very rich in oil, which is extracted, after careful sorting of the livers, with simple machinery, by steam. The product is clear, nearly tasteless, and without smell. The islands present many advantages over other places for the production of pure oil. The average annual catch of cod in the islands is 30,000,000. Unlike other districts in the country, the cod at this time of the year is about the only kind of fish caught, so there is less opportunity for mixing the livers from cod with those from inferior fish, such as coalfish or pollock, ling, haddock, and others. Oil from these is darker, contains less fat, and its medicinal properties are of less value. The year 1903 was an exceptional one as regards the Norwegian winter cod fisheries. In ordinary years the shoals of fish arrive in the beginning of January, but this year no fish whatever appeared before the middle or first part of March, and they were then found to be in such poor condition that only a very insignificant quantity of oil was produced—only 3,000 barrels against 30,000 barrels in ordinary years. The quality of the 1903 output was also, as a rule, poor. It is estimated that in ordinary years the livers of 4,500 cod are required to produce a barrel of 30 galls., or 100 kilos., of medicinal oil, while 40,000 livers were required the present year (1903) to produce the same quantity. Prices for the best quality of medicinal oil f. o. b. Christiania have for the last three years been as follows:—In 1901, 56 kroner per barrel; 1902, 130 kroner per barrel; 1903, 400 kroner per barrel—all in wood-covered tin barrels of 30 gallons, price including barrel. Considerable apprehension is felt that the conditions ruling the Lofoten fisheries in 1903 will also make themselves felt in 1904. The first small shoals of winter cod arrive the latter part of December on the banks along the coast as far south as Bergen; the larger shoals arrive later. The Lofoten fisheries terminate in the latter part of April and the fish gradually work farther north and last appear in great numbers on the banks at Finmarken as late as June, after which they disappear till next season.

Cotton-Seed Oil Imports at Trieste.

Bd. of Trade J., Jan. 21, 1904.

The import of cotton-seed oil at Trieste during 1903 has been higher than the average of the last ten years. Prices varied: in July, from *2l.* 9*s.* 2*d.* to 2*l.* 10*s.*; and in December, from 2*l.* 2*s.* 10*d.* to 2*l.* 8*s.* 8*d.* per 100 kilos. The following table shows the quantity imported during the last two years :—

From—	1902.		1903.	
	Barrels.	Met. Tons.	Barrels.	Met. Tons.
England	11,987	2,258·1	12,764	2,424·9
America	39,093	7,427·4	64,869	12,324·9
Other countries	6,481	1,206·2	3,408	647·2
Total imported .	57,561	10,891·7	81,041	15,397·0

XIII. A.—PIGMENTS, PAINTS, Etc.

Hematite; Spanish ——, for the United States.

U.S. Cons. Reps., No. 1844, *Jan.* 7, 1904.

A vein of rich hematite ore, suitable for paint for ironwork, has been discovered near the city of Jaen, in Spain, and has been worked during the past year; much of the output has found ready sale in the United States. The mine is 100 miles from Malaga, but the ore is brought there by rail and prepared for shipment, both in its crude state and refined, at a plant on the outskirts of this city.

Enamel; White ——: U.S. Customs Decision.

Dec. 30, 1903.

A white paint consisting of zinc white, linseed oil, and varnish, variously described as enamel white, white bath enamel, and Japan white, was assessed for duty as "varnish," at 35 per cent. *ad valorem* under paragraph 53, and as "paint," at 30 per cent. *ad valorem* under paragraph 58 of the present Tariff Act. The importer claimed it to be dutiable at $1\frac{3}{4}$ cents per lb. under paragraph 57, as "white paint, ground in oil." A former decision of the Board of General Appraisers was against the importer, on the ground that the addition of varnish advanced the article beyond the condition of a pigment containing zinc ground in oil. On appeal to the Circuit Court, the action of the Board was reversed, and the claim of the importer sustained on the ground that the addition of varnish does not affect the character of the mixture as a paint. Following this decision, the Board decided that the article was properly dutiable at $1\frac{3}{4}$ cents per lb.—R. W. M.

XVI.—SUGAR, STARCH, Etc.

Sugar; Drawback on Certain Foreign ——, in the United Kingdom.

Bd. of Trade J., Jan. 21, 1904.

The Board of Customs have recently issued a general rder (No. 2 of 1904) directing that drawback is in future o be allowed on duty-paid foreign sugar which has underone a process of crushing and colouring in the United Kingdom. The conditions to be observed for obtaining this rawback are similar to those applicable in the case of astor and icing sugar (see this J., 1902, 438).

Saccharin and Analogous Products; Importation of ——, into Spain Prohibited.

Bd. of Trade J., Jan. 21, 1904.

A Spanish law dated 24th December, 1903, prohibits e importation, manufacture, and sale of saccharin and analogous products, and of alimentary substances, beverages, and all articles which contain saccharin and analogous products, as well as mixtures of glucose and sugar. An exception is made in the case of saccharin and similar products imported for medicinal purposes; such importations must, however, be effected through the Custom houses specially designated for the purpose.

XVII.—BREWING, WINES, SPIRITS, Etc.

Denatured Spirit in Germany; Retail Price of ——.

Zeits. Spiritusind., 1904, 27, [2], 9.

The *Centrale für Spiritusverwerthung* (this J., 1902, 513) has notified an increase of the price of denatured spirit, but it is stated that the rise is not of sufficient amount to interfere with the healthy development of the application of spirit to technical purposes. The use of spirit for illuminating purposes is still profitable, even with a wholesale price of 25 m. per hectolitre for 90 per cent., and of 28 m. per hectolitre for 95 per cent. denatured spirit. The application of denatured spirit to technical purposes will, however, be seriously retarded if, following the usual tendency, the retail price be increased to a greater extent than corresponds to the rise of the wholesale price, and individual distillers are urged to use their influence to prevent any such excessive rise of the retail price.—A. S.

XX.—FINE CHEMICALS, Etc.

Aceto-Salicylic Acid: Australian Customs Decision.

Dec. 12, 1903.

Aceto-salicylic acid ("aspirin") was decided to be free of duty as a "drug," and not subject to 20 per cent. *ad val.* import duty as a "substitute for salicylic acid."

Tincture of Cannabis Indica: U.S. Customs Decision.

An alcoholic tincture of *Cannabis indica* of the strength used by homœopathic physicians was decided by the Board of General Appraisers to be dutiable at 55 cents per lb. as a "medicinal preparation containing alcohol," under paragraph 57 of the present Tariff Act, and not at 60 cents per lb. and 45 per cent. *ad val.*, under paragraph 2, as an "alcoholic compound" as assessed for duty.—R. W. M.

Patent List.

N.B.—In these lists, [A.] means "Application for Patent," and [C.S.], "Complete Specification Accepted."

Where a Complete Specification accompanies an Application, an asterisk is affixed. The dates given are (i) in the case of Applications for Patents, the dates of application, and (ii) in the case of Complete Specifications Accepted, those of the Official Journals in which acceptances of the Complete Specifications are advertised.

Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

I.—PLANT, APPARATUS, AND MACHINERY.

[A.] 1694. Morgan Crucible Co., Ltd., and Fox. Muffles. Jan. 22.

„ 1695. Morgan Crucible Co., Ltd., and Fox. Manufacture of cupels. Jan. 22.

„ 1975. Voiry and Fresnaye. Process and apparatus for the distillation, separation, or extraction in a closed vessel of volatile liquids only, or such as are contained in non-volatile substances. [Fr. Appl., March 27, 1903.]* Jan. 26.

[A.] 1997. Tetlow. Separators. [U.S. Appl., March 9, 1903.]* Jan. 26.

„ 1999. Shaw. Apparatus for cooking, concentrating, and evaporating liquids. Jan. 26.

„ 2002. Hauberg. Centrifugal balancing separators. Jan. 26.

„ 2171. Cossor. Means for gauging the quantity or density of liquids contained in tanks. Jan. 28.

„ 2211. Lawrence. Construction of trays for filter-presses. Jan. 29.

C.S.] 2264 (1903). Thompson (Anderson). Presses. Feb. 3.

„ 7520 (1903). Haddan (Edson). Evaporating apparatus. Feb. 3.

„ 20,049 (1903). Howorth (Eyde and Birkeland). Method of producing powerful chemical reactions in gases or gas mixtures, and apparatus therefor. Feb. 3.

„ 23,230 (1903). Cummer. Method of and apparatus for filtering liquids. Jan. 27.

„ 24,415 (1903). Niclausse. Separating liquids of different density. Feb. 3.

„ 25,059 (1903). Haddan (Edson Reduction Machinery Co.). Drying apparatus. Jan. 27.

„ 28,022 (1903). Howorth (E. Bazzi and Co.). Emulsifying apparatus. Feb. 3.

II.—FUEL, GAS, AND LIGHT.

[A.] 1365. Talbot. Regenerative furnaces. Jan. 19.

„ 1393. Johnson (Deutsche Continental Gas Ges., and Bueb). Manufacture of coal-gas. Jan. 19.

„ 1591. Shiels. Production of combustible vapour or gas. Jan. 21.

„ 1628. Zohrab. Mode and apparatus for the production of dry peat and peat charcoal. Jan. 22.

„ 1676. Blondel. Processes of manufacturing electrodes for arc lamps. [Fr. Appl., Feb. 5, 1903.]* Jan. 22.

„ 1738. Whitfield. Process and apparatus for the manufacture of combustible gas from peat, &c. Jan. 23.

„ 1825. Everitt and Redman. Extraction of tar and other impurities from illuminating gas. Jan. 25.

„ 1887. Hoffman and Clark. Artificial fuel.* Jan. 25.

„ 2001. Duttenhofer. Manufacture of illuminating gas. Jan. 26.

„ 2199. Hollis and Bentley. Gas producers. Jan. 29.

„ 2240. Capitaine. Purifying the gas of gas producers.* Jan. 29.

„ 2268. MacGregor and Pearson. Apparatus for the manufacture of peat fuel. Jan. 29.

„ 2303. Johnson. Manufacture of air-gas. Jan. 30.

„ 2358. Peters. *See under* VII.

[C.S.] 4019 (1903). Banke and Fuchs. Process and apparatus for generating water-gas. Feb. 3.

„ 5496 (1903). Miess. Apparatus for the production of explosive mixtures by means of oil. Feb. 3.

„ 21,968 (1903). Höring and Mjöen. Method and apparatus for coking hydrous-bituminous combustibles. Feb. 3.

„ 23,583 (1903). Wigelius and Laurell. Production of gas for motive power and like purposes. Feb. 3.

„ 24,815 (1903). Maisch. Manufacture of incandescent mantles. Jan. 27.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM, AND MINERAL WAXES.

[A.] 1881. Schulze and Chem. Fabr. Ladenburg. Manufacture of *m*-cresol from crude cresol. Jan. 25.

„ 2102. Coulson. Method of solidifying tar. Jan. 25.

[C.S.] 4431 (1903). Adiassewich. Method of treating stale oil and similar substances. Jan. 27.

„ 13,185 (1903). Van Wirkner. Process for the manufacture of pitch. Jan. 27.

IV.—COLOURING MATTERS AND DYESTUFFS.

[A.] 1389. Newton (Bayer and Co.). Manufacture and production of new colour lakes. Jan. 19.

„ 1502. Rowland. Aniline dyeing compound.* Jan. 20.

„ 1581. Lake (Oehler). Manufacture of colouring matters. Jan. 21.

„ 2265. Newton (Bayer and Co.). Manufacture and production of a new azo colouring matter and of colour lakes therefrom. Jan. 29.

[C.S.] 5328 (1903). Bury and Gerland. Manufacture of soluble indigo. Jan. 27.

„ 7395 (1903). Johnson (Badische Anilin und Soda Fabr.). Purification of indigo. Jan. 27.

„ 27,630 (1903). Imray (Soc. Chem. Ind. in Basle). Manufacture of new substantive tetrazo dyestuffs. Feb. 3.

V.—PREPARING, BLEACHING, DYEING, PRINTING, AND FINISHING TEXTILES, YARNS, AND FIBRES.

[A.] 1285. Slacke and Courtney. Manufacture of waterproof paper or fabric. Jan. 18.

„ 1334. Pope, Hübner, and Brandt. Treating or finishing woven fabrics or paper to render embossing, moiré, or other effects produced thereon more permanent. Jan. 19.

„ 1646. Cuny-de-Pierron (Ulrich). Washing blue. Jan. 22.

„ 1840. Christiani. Colour printing. Jan. 25.

„ 1867. Johnson (Badische Anilin und Sodafabr.). Discharge of halogenated indigo colouring matters. Jan. 25.

„ 1930. Murray. Waterproofed textile fabrics and other materials, and methods and means employed in waterproofing them. Jan. 26.

„ 1935. Morton. Printed pile fabrics. Jan. 26.

„ 2027. Renard. Ornamenting fabrics. Jan. 27.

„ 2167. Castle. *See under* XIV.

[C.S.] 1407 (1903). Rudometoff. Multicolour printing mechanism. Jan. 27.

„ 1583 (1903). Rolffs. Polychrome printing on calico and other materials. Jan. 27.

„ 9724 (1903). Jardin. Process of bleaching flax, hemp, cotton, jute, ramie, straw, &c. Jan. 27.

„ 14,125 (1903). Dargue, Dargue, and Barker. Apparatus for dyeing, mordanting, or washing fibrous materials. Feb. 3.

„ 14,200 (1903). Rovira. Continuous bleaching apparatus. Jan. 27.

„ 22,697 (1903). Haddan (Oliva). *See under* XIV.

„ 27,426 (1903). Caffall. Process of treating surfaces for waterproofing and preservative purposes. Jan. 27.

VI.—COLOURING WOOD, PAPER, LEATHER, Etc

[A.] 2385. Epstein. Process of dyeing chrome-tanne leather. Jan. 30.

[C.S.] 5594 (1903). Lake (Chem.-Tech. Fabr. Dr. Alb. R. W. Brand and Co.). Process for colouring and hardening natural stone; applicable also to organic material, such as ivory or the like. Jan. 27.

VII.—ACIDS, ALKALIS, AND SALTS.

[A.] 1232. Fitton, Priestley, and Brook. Soda for washing and other domestic purposes. Jan. 18.

„ 1452. Grossmann. Method of manufacturing alkali nitrates. Jan. 20.

„ 1630. Macknight. Process of treating soot for the recovery of ammonia and other products, and apparatus used therein. Jan. 22.

„ 1684. Pearson. Process of fixing atmospheric nitrogen. Jan. 22.

„ 2284. Lake (Fallows). Production of phosphoric acid.* Jan. 29.

„ 2358. Peters. Process for utilising the waste ends of carbons from arc lamps.* Jan. 30.

[C.S.] 1755 (1903). Garroway. Manufacture of sulphuric anhydride. Feb. 3.

„ 4625 (1903). Gin. Manufacture of sulphate of copper. Jan. 27.

„ 24,639 (1903). Parkes. Production of Glauber salts, ferrous carbonate, ferrous hydrate, and ammonia from nitre cake. Feb. 3.

VIII.—GLASS, POTTERY, AND ENAMELS.

[A.] 1933. Marzin. Ceramic printing and the like. Jan. 26.

[C.S.] 4031 (1903). Shenstone. Furnaces for use in the manufacture of silica glass. Jan. 27.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

[A.] 1339. Reid. Construction of and method of firing kilns for use in firing bricks, tiles, pipes, and other earthenware goods. Jan. 19.

„ 1695. Morgan Crucible Co., Ltd., and Fox. *See under* I.

Notices.

INTERNAL TRANSPORT.

The question of internal transport has been engaging more and more attention in recent years, and the demand for greater facilities for cheap transport has taken the concrete form of efforts to improve our canal system. The subjoined report of a committee of the Society specially appointed to consider this subject, shows the actual incidence of railway freights, irrespective of distance, on the chemical industry. Other industries and interests might be dealt with in a similar manner, with a view to bringing the importance of this question under the notice of members of Parliament and His Majesty's Government.

REPORT OF THE SUB-COMMITTEE ON INTERNAL TRANSPORT.

This Committee was appointed to collect from Members of the Society information showing the incidence of railway freights upon the chemical and allied industries. Questions were sent out to all Members as follows:—

(1) What goods do you manufacture?

(2) What is the total amount paid by you directly or indirectly for carriage within Great Britain of your raw materials to your manufactory, expressed per ton of finished products?

(3) What is the average amount paid per ton of finished product for carriage within Great Britain to the consumer, the retailer, or to the port of shipment?

(4) What is the average sale price per ton of your finished products?

(5) Do you make any use of inland waterways; and, if so, for what proportion of your total carriage?

From these questions it was expected that the proportion of freight charge to the selling value of the goods would be established for the classes of goods in which the Society is interested, as well as the extent to which canals are utilized, and possibly the effect upon railway freights should the utilization of canals be further developed.

The total number of replies received was 72; of these 26 were practically useless, owing to insufficiency of the replies, 24 were from makers of heavy chemicals, 3 from paper makers, 2 from glass makers, 3 from glucose makers, 2 from bleachers and dyers, 3 from tanners, 9 miscellaneous.

The firms giving replies may be fairly taken as thoroughly representative of their respective trades. In a large number of cases, however, the inward freight calculated on the finished product is not given. In summarizing, therefore, it will be necessary to separate the complete from the partially complete returns, and in dealing with these two classes it will be advisable to divide them into (1) Heavy Chemicals, (2) Allied Industries; the latter including all the other classes of manufacture mentioned above. The summary consists of tables, in which are given (A) value of goods per ton, (B) percentage of freight on value of goods, (C) percentage utilization of canals, and are as follows:—

COMPLETE RETURNS.

(R.M.C. means "Raw Materials chiefly by canal.")

(1) *Heavy Chemicals.*

—	A.	B.	C.
	£ *s.* *d.*	Per Cent.	Per Cent.
1	39 0 0	2½	Nil
2	7 10 0	4	R.M.C.
3	15 0 0	5⅓	1
4	39 17 0	5·8	25
5	10 0 0	6½	49

12	10 0 0	15	Nil
13	8 0 0	25	"

RETURNS WHERE ONLY OUTWARD FREIGHT IS GIVEN.

(1) *Heavy Chemicals.*

1	20 0 0	2·2	R.M.C.
2	20 0 0	2½	Nil
3	60 0 0	3·3	"
4	6 0 0	5½	"
5	2 15 0	6	"
6	4 10 0	6	"
7	9 0 0	8	22
8	4 0 0	10½	R.M.C.
9	8 10 0	11½	Nil

(2) *Other Articles.*

1	180 0 0	1	Nil
2	10 15 0	3	"
3	26 0 0	4	"
4	10 10 0	7	40
5	20 0 0	7	40
6	1 13 0	15	Nil
7	5 6 9	23	"

As would naturally be expected, the burden of freight is highest on the cheaper articles, and the articles under the value of 5*l.* per ton bear a burden varying from 8½ per cent. to 23 per cent. of the value.

These totals are irrespective of distance, and, as we may fairly assume that each works has a certain amount of short distance trade where it has the advantage of position over competitors, it follows that, in the really competitive areas, the burden of freight exceeds the average figure, bringing the range of the figures where competition is keenest to from 15—30 per cent. As compared with cheap freights from continental ports, this is an extremely heavy burden, and a serious handicap to Lancashire manufacturers wishing to send goods to London or Newcastle, or to the two latter wishing to send goods to Lancashire.

No deductions can be drawn from the figures collected as to the effect of the utilisation of canals upon railway freights, but this may be due to the fact that a large proportion of the canals are in the hands of the railway companies.

Whether the railway companies can be expected to carry at appreciably lower rates is doubtful, but, as proved by the experience of Germany, Belgium, France, and the United States, heavy articles can be carried much more cheaply by canal, if the latter be only brought up to date.

The whole weight of the Society should be brought to bear on the subject, and similar bodies of manufacturers should be invited to investigate the incidence of railway freight in their trades.

To emphasize the importance of this question, it is worth noting that halving the burden of freights in competitive areas would afford relief to manufacturers of from 7½ to 15 per cent. of the selling price.

ANNUAL GENERAL MEETING, NEW YORK, 1904.

The Annual General Meeting will be held in New York City on Thursday, Sept. 8th, and following days. Members who contemplate attending are requested to communicate with the General Secretary as soon as possible, in order that suitable travelling arrangements may be made. A programme appears in the Jan. 30 issue of the Journal.

COMMUNICATIONS.

Authors of communications read before the Society, or any of its Local Sections, are requested to take notice that under Rule 43 of the Bye-laws the Society has the right of priority of publication for three months of all such papers. Infringement of this Bye-law renders papers liable to be rejected by the Publication Committee, or ordered to be abstracted for the Journal, in which case no reprints can be furnished to the author.

List of Members Elected

23rd FEBRUARY 1904.

Allen, T. E., c/o American Aristotype Co., Jamestown, N.Y., U.S.A., Chemist.

Alton, L. A., "Dungarvan," Putney Heath, S.W., Chemist.

Andrews, G. D., 7, Old Ford Road, London, N.E., Chemist.

Archdale, W., 21, Oldham Road, Miles Platting, Manchester, Manager of Chemical Works.

Baron, W. B., Manchester Steam Users' Association, 9, Mount Street, Manchester, Chemist.

Benn, R. H. D., 16, Springfield Avenue, Westmount, Montreal, Canada, Analytical Chemist.

Bowden, T., 201, Heights Lane, Rochdale, Dyer's Chemist.

Braman, W. W., State College, Pennsylvania, U.S.A., Assistant.

Coblentz, L., 122, Broderick Street, San Francisco, Cal., U.S.A., Chemist.

Cochran, C. B., 514, S. High Street, West Chester, Pa., U.S.A., Teacher of Chemistry.

Culmer, H. H., 6200, Madison Avenue, Chicago, Ill., U.S.A., Chemist and Tar Distiller.

Catts, Henry E., 55, Fulton Street, New York City, U.S.A., Technical Chemist.

Davidson, R., c/o Dalgety and Co., Ltd., 15, Bent Street, Sydney, N.S.W., Australia, Chemist.

Dubois, N. A., 407, Euclid Avenue, Syracuse, N.Y., U.S.A., Instructor in Chemistry.

Duncan, W. W., 406, Massachusetts Avenue, Boston, Mass., U.S.A., Chemist.

Finch, M. L., Vitriol and Chemical Works, Cattledown, Plymouth, Chairman of Directors.

Finn, C. P., Farnley Iron Works, Farnley, Leeds, Technical Chemist.

Glendinning, T. A., 31, Garthland Drive, Dennistoun, Glasgow, Brewery Chemist.

Gotthelf, A. H., Hastings on Hudson, N.Y., U.S.A., Chemist.

Gray, Jas., Box 5, Fordsburg, Johannesburg, Transvaal, Chemist.

Gresty, J. E., 135, Oxford Street, Manchester, Chemical Engineer.

Hadley, Geo., 58, Halesowen Street, Blackheath, Staffs., Spelter Works Manager.

Henshaw, P. B., 3, Dobbin Hill, Endcliffe, Sheffield, Steel Chemist.

Holden, N. N., c/o Messrs. Hardman and Holden, Miles Platting, Manchester, Manufacturing Chemist.

Holgate, Arthur, Rigby Street Mills, Liverpool, Corn Miller.

Hopewell, F., 86, Youville Square, Montreal, Canada, Manager.

Howell, W. L., c/o Appraiser's Office, Custom House, New Orleans, La., U.S.A., Chemist.

Huntzinger, A., 3, Egerton Road, Chorlton-cum-Hardy, near Manchester, Chemist and Colourist.

Johnston, Thomas J., 4, Garrioch Drive, Kelvinside North, Glasgow, Chemist.

Jordan, Stanley, 100, William Street, New York City, U.S.A., Importer of Chemicals.

Lancey, Darragh de, Great Barrington, Mass., U.S.A., Secretary and Assistant General Manager.

Lessing, Dr. Rudolf, The Gas Light and Coke Co., Ltd., Tar and Liquor Works, Beckton, E., Chemist.

Loveland, James W., 8, Kenwood Street, West Somerville, Mass., U.S.A., Superintendent of Soap Works.

Mackintosh, J. C., Canada Iron Furnace Co., Midland, Ontario, Canada, Chemist.

Merry, John B., Ashfield, Ash Lane, Hough Green, near Widnes, Works Chemist.

Moore, G. J., jun., c/o National Brewers' Academy, 39, South William Street, New York City, U.S.A., Analytical Chemist.

Morson, Thomas D., c/o T. Morson and Son, Summerfield Works, Ponder's End, N., Chemist.

Nicholson, Wilfred, Hunslet Chemical Works, Leeds, Chemical Manufacturer.

Norris, Cassius W., 612, Commerce Street, Milwaukee, Wis., U.S.A., Tannery Chemist.

Oberländer, Dr. Otto, 62, Delaunay's Road, Crumpsall, Manchester, Technical Chemist.

Owen, Halsall, Newholme, Latchford, Warrington, Engineer.

Perrott, Bert, County School, Neath, Glamorgan, Demonstrator in Chemistry.

Pickup, Edgar H., 348, Great Clowes Street, Higher Broughton, Manchester, Calico Printer.

Prichard, N. B., Capelton, Quebec, Canada, Chemical Engineer.

Rademacher, Dr. Ferdinand, Prag Carolinenthal, Austria, Chemical Manufacturer.

Ray, William, 65, Wellington Road, Fallowfield, Manchester, Colourist.

Rowley, E. W., Chemical Laboratory, Loco. Department, N.E.R., Gateshead-on-Tyne, Analytical Chemist.

Seligman, Richard, c/o Messrs. J. and W. Seligman, Mills Buildings, New York City, U.S.A., Chemist.

Skerten, William B., 25, Broad Street, New York City, U.S.A., Chemical Accountant.

Standfast, J. T., c/o Messrs. Burt, Boulton, and Heywood, Ltd., Selzaete, Belgium, Chemist.

Thurston, Azor, Grand Rapids, Ohio, U.S.A., Chemist.

Tickle, Thos., 83, Queen Street, Exeter, Analyst.

Trautwein, Alfred P., Carbondale, Pa., U.S.A., President.

Turner, Owen, Park Tower, Ipswich, Tanner and Currier.

Walther, Wm., Holzapfel's Compositions Co., Ltd., Heworth Shore, Felling-on-Tyne, Chemist and Works Manager.

Whatmough, Dr. William H., Woodleigh, Cheadle, Cheshire, Chemist.

Wieler, Eric E., 4, Palatine Road, Withington, Manchester, Chemical Merchant.

Wigg, Chas. E., Rockshaw, Merstham, Surrey, Electrical Engineer.

Williams, John T., Glenbrook Avenue, Stamford, Conn., U.S.A.

Williams, Naboth, 28, Rolleston Street, Warrington, Technical Chemist.

Woolcott, G. H., 26, Birdhurst Road, Croydon, Brewer's Chemist.

Changes of Address.

When notifying new addresses, members are requested to write them distinctly, and state whether they are temporary or permanent. Multiplication of addresses is also to be avoided as tending to create confusion. When sending subscriptions, the use of the form attached to the application helps in the verification of addresses, on which the safe delivery of the Journal depends.

Biggart, Wm. L ; all communications to Woodbine, Bridge of Weir, N.B.

Borland, C. R., l/o Oakland, N.J.; P.O. Box 24, Concord Junction, Mass., U.S.A., Powder Manufacturer.

Burls, H. T., l/o Lewisham; c/o H. S. King and Co., 65, Cornhill, London, E.C.

Burton, Alf.: all communications to 42, Front Street West, Toronto, Canada.

Campbell, And.; all communications to Burma Oil Works, Dunneedaw, Rangoon, Burma.

Church, E. D., jun., l/o 65; 63, Wall Street, New York City, U.S.A.

MR. WALTER F. REID IN THE CHAIR.

RAPID ESTIMATION OF MERCURY BY MEANS OF HYPOPHOSPHOROUS ACID.

BY B. F. HOWARD.

Introductory.—For some reason the estimation of mercury by methods of reduction has never replaced, or even competed with the well-established method of distillation. This may be partially accounted for by the highly unsatisfactory results which are often obtained by the use of certain reducing agents. Stannous chloride, for instance, is not at all a suitable reducing agent for the estimation of mercurial salts, as the reduction takes place very slowly and is apt to give variable results. Vanino and Freubert (Ber., 1897, **30**, 2808, and this J., 1898, 72) state that phosphorous acid after 12 hours' standing in the cold completely reduces mercuric chloride to calomel. Warming causes the formation of metallic mercury; in the presence of hydrogen peroxide, however, the precipitated calomel remains unchanged, and the reaction is complete in a few minutes. The calomel is filtered, washed and dried at 105° C. and weighed as such. In another paper (Ber., **30**, 2000; this J., 1897, 1043) the same authors state:—"If hypophosphorous acid be added to a solution of mercuric chloride in sufficient quantity, the whole of the mercury is rapidly precipitated as calomel. Should the acid be in excess, the metallic mercury is precipitated, but this can be prevented by the addition of hydrogen peroxide." J. R. Thompson (this J., 1897, 263) recommends the use of hypophosphorous acid in the following manner. The salt is dissolved in hydrochloric acid, and potassium hypophosphite is added, calomel being obtained and the mercury being estimated as such. He recommends this method for analysing ammonio-mercuric chloride, and quotes some results obtained from different samples of this salt. To most analysts who purpose using reduction methods for the estimation of mercury, it would seem more satisfactory to make use of a reducing agent which would readily reduce the mercury salt to the metallic state, so that it could be obtained as a metallic bead, and weighed as such, instead of being weighed as mercurous chloride, as the previously mentioned chemists suggest. Hypophosphorus acid when used in considerable excess will be found to answer this purpose very well. With the following common commercial salts of mercury it has been found to give a rapid reduction, and to enable the whole estimation to be performed in a period varying between 1 hour and $1\frac{1}{2}$ hours: calomel or mercurous chloride, corrosive sublimate or mercuric chloride, ammonio-mercuric chloride, $HgClNH_2$, mercuric nitrate and mercuric oxide. Its use could doubtless be successfully applied to most of the other well known salts of mercury. The process has proved especially useful when a rapid estimation is desired, for, as is well known, the distillation method cannot easily be carried out in less than three hours. This method may also be employed for determining the strength of solutions of mercuric chloride and nitrate of mercury. These can be estimated very rapidly, as the mercury is precipitated in metallic form on the addition of hypophosphorous acid to the solutions. This process compares favourably with the ordinary distillation method, for it has practically no sources of error which are not equally prominent in both methods. It cannot, however, be applied to the estimation of mercuric iodide.

Experimental.—The estimations using mercurous chloride were at first carried out in the following manner:—An amount between 0·75 and 1·5 grm. was weighed into a small porcelain dish, and hypophosphorous acid of sp. gr. 1·136, at the rate of 5 c.c. to 1 grm. of mercuric chloride run into the basin and stirred up with the salt. The dish was then warmed on a steam bath and the contents stirred gently. After five minutes the mercury was all deposited in a fine black powder; in 15 to 20 minutes the reduction was complete, and a clean globule of metallic mercury obtained. In the first series of experiments, this globule was washed free from acid with water, then with alcohol and ether, and, to complete drying, was placed on a steam bath in a previously weighed glass capsule, and afterwards weighed. The sample contained 0·078 per cent. of water. The theoretical percentage of mercury in mercurous chloride is 84·96, or, with 0·078 per cent. of water, 84·88 per cent.; the amount of mercury found by experiment was 83·24 and 83·32 per cent. The low results were due, no doubt, to the small floating particles of mercury being washed away, and to the volatisation of metallic mercury during the final drying. In order to remedy these defects, various modifications of procedure were tried, of which the following gave most satisfactory results.

A small filter-paper was washed with hypophosphorous acid, alcohol, and ether, dried in the oven, and weighed in a weighing bottle. This paper was then used to filter all the washings of the mercury globule, and was afterwards dried, returned to its weighing bottle, and re-weighed. In this way all the small floating particles of mercury were included in the total weight of mercury obtained. The globule, after being thoroughly washed with water, alcohol, and ether, was placed in its glass capsule in a desiccator before weighing, so that no loss could occur at this stage through volatisation.

The amount of hypophosphorous acid, sp. gr. 1·136, required for 1 grm. of the mercurous chloride was increased from 5 c.c. to 10 c.c. With the above modifications, fairly concordant results were obtained, five consecutive estimations of the same sample giving the following results :—

Expt. No.	Weight of Hg_2Cl_2 taken.	Percentage of Hg found.	Percentage of Water in Sample.	Theoretical Percentage of Hg.	Corrected for this Sample.
	Grms.				
7	0·9890	84·18	0·0784	84·96	84·88
8	1·2175	84·27	0·0784	84·96	84·88
9	1·0077	84·45	0·0784	84·96	84·88
10	1·1443	84·23	0·0784	84·96	84·88
11	0·9154	84·41	0·0784	84·96	84·88

The lowness of these results may be accounted for in two ways:—(1) The extremely volatile nature of the floating particles of freshly precipitated mercury at the temperature of the water bath. (2) The comparatively large quantity of the residual mercury which was in the form of a film on the tared filter paper. The average weight of film was 0·00352 grms., or about 0·4 per cent. of total mercury. In order to obviate these sources of error, the next series of experiments was conducted somewhat differently. A larger amount of the mercurous chloride was used for the estimation, but not so great an excess of hypophosphorous acid. It was found that the reduction was just as rapid, and the total amount of floating particles did not increase. The process was carried out in a lipped glass capsule of about 100 c.c. capacity. The washings were very carefully decanted off, so that all the particles of mercury remained behind in the basin. After washing with water, alcohol, and ether, the basin and its contents was placed in a desiccator for some hours and then weighed. It was found that no appreciable quantity of mercury was washed out, better results accordingly being obtained. Apparently the accuracy of these determinations depends largely on the quantity of the mercury salt used, for the greater the original weight the more the sources of error were reduced. Care must be exercised to wash out the excess of hypophosphorous acid before adding alcohol, for the acid contains traces of lime, which are precipitated by alcohol and remain with the mercury.

The following results were obtained with the above modifications :—

Expt. No.	Grms. of Hg_2Cl_2.	Grms. of Hg obtained.	Percentage of Hg found.	Theoretical Percentage of Hg, corrected for Moisture in Sample.
12	5·3343	4·5172	84·68	84·88
13	6·1481	5·2098	84·74	84·88
14	8·3474	7·0816	84·84	84·88

These figures show that the method is quite reliable for the estimation of calomel, provided that the following conditions are observed :—(1) At least 5 grms. of the salt should be used for the estimation. (2) The last traces of hypophosphorous acid should be washed completely away from the globule before alcohol is added. (3) The floating particles must be allowed to settle before the washings are decanted off.

Ammonio-Mercuric Chloride, $HgClNH_2$.—The reduction appeared to be just as rapid and easy as in the case of calomel. The blackening took place immediately on adding the acid, and metallic beads were obtained after about 15 minutes' warming on the water-bath. On experimenting with small quantities (1·6 to 2·5 grms.) low results were obtained. The following are three typical results obtained by using small quantities :—

Amount of $HgClNH_2$.	Weight of Hg.	Percentage of Hg.	Percentage of Hg in $HgClNH_2$.
Grms.			
1·5167	1·1705	77·17	79·68
2·0849	1·6082	77·14	
2·3289	1·8085	77·32	

This salt of mercury has invariably been found to give results from 1 per cent. to 2 per cent. lower than the calculated amount of mercury (compare J. R. Thompson, this J., 1897, 263). A further estimation, carried out with a larger quantity of this salt, confirmed the previous results. The discrepancy between the amount of mercury obtained by the analysis of this ammonio-mercuric chloride and that required by theory is fully accounted for by the presence of ammonium chloride, traces of this being found in all commercial samples of the salt.

Mercuric Nitrate (Impure).—The crude nitrate must be mixed with some cold water before adding the acid, and this should be diluted and added slowly in order to avoid the action taking place too violently. If the strong hypophosphorous acid is added direct to the nitrate, the reduction takes place with explosive violence, occasioning loss.

There is considerable variation in the results recorded in the following table, but this is due to the exceedingly variable composition of the mixture which was analysed. It will be observed that the results of the estimations of each sample agree fairly closely.

Sample.	Experiment.	Water used.	Hg obtained.	Hg.
		Grms.	Grms.	Per Cent.
A	1	12·9600	9·7588	75·3
	2	12·9600	10·0440	77·5
B	1	12·9600	11·1326	85·90
	2	12·9602	11·1261	85·85
C	1	12·9600	10·0369	77·6
	2	12·9600	10·0068	73·0

Mercuric Oxide, HgO.—Hypophosphorous acid may be used for the estimation of mercury in this salt. As in the case of the nitrate, the reduction is very rapid, in fact almost explosively so, consequently water must be added both to the oxide and to the acid before mixing them. A slight variation was made on the former procedure. All the washings from the mercury bead were kept in a beaker, and any mercury in suspension settled to the bottom. The supernatant liquor was decanted off and the residual mercury was washed and placed with the globule in the capsule dish.

Six consecutive estimations of a sample of commercial mercuric oxide gave the following results :—

Experiment No.	Grms. of HgO taken.	Grms. of Hg obtained.	Percentage of Hg in sample.
1	3·0724	2·8485	92·06
2	3·5356	3·2440	91·75
3	4·5272	4·1455	91·57
4	3·1886	2·9030	91·04
5	3·2678	2·9851	91·04
6	2·1202	1·9387	91·44

Mercuric Chloride.—The analysis of mercuric chloride by this method proved satisfactory. On the addition of the acid (in the proportion of 2 c.c. of acid to 1 grm. $HgCl_2$) a white flocculent precipitate of calomel is deposited, but on adding more water and stirring and warming this is rapidly reduced to metallic mercury, a clean globule being obtained in about 10 minutes.

The following results were obtained :—

Estimation. No.	Grms. of $HgCl_2$ used.	Grms. of Hg obtained.	Percentage of Hg found.
1	3·0439	2·2363	73·46
2	3·1983	2·3589	73·75
3	3·4822	2·5651	73·67
4	2·4703	1·8192	73·72
5	1·9548	1·4390	73·66
6	2·1792	1·6053	73·66

The calculated amount of mercury in mercuric chloride is 74·07 per cent.

The difference between the theoretical and experimental result may be attributed, as before, to the volatilisation of floating particles of freshly reduced mercury while in the water bath. This would, however, be a fair constant experimental error, and could be allowed for.

Mercuric Iodide. — The estimation of this salt by reduction methods is attended with considerable difficulty, owing to the formation of hydriodic acid, which, acting on the mercury, forms the soluble mercurous iodide and so prevents a complete reduction. Various modifications were tried, but this difficulty could not be altogether removed, and consequently unreliable results were obtained.

Experiment A.—2·1996 grms. of the salt were acted upon direct with 25 c.c. of the acid (sp. gr. 1·136), and, on warming, part of the mercury was deposited, *viz.*, 0·7848 grm. On adding water to the acid liquor and boiling, a further quantity of 0·202 grm. of mercury was precipitated. The total weight of mercury deposited was 0·9153 grm., equal to 41·62 per cent. The calculated yield is 44·12 per cent. of mercury.

Experiment B.—A smaller excess of acid was used, 3·2977 grms. being treated with 15 c.c. of the acid. The first deposit of mercury was 1·0830 grm., and the second 0·0871 grm. Total Hg = 1·1701 grm. = 35·5 per cent.

Experiment C.—The salt 0·9393 grm. of mercuric iodide was dissolved in potassium iodide and 30 c.c. of hypophosphorous acid added. Weight of mercury obtained = 0·2356 grm.; therefore percentage of Hg = 25·08 per cent.

Experiment D.—The salt was intimately mixed with zinc dust in a large excess; both were finely powdered together, stirred with water, and warmed on a water-bath. A zinc-mercury amalgam was readily formed under these conditions. This was washed with water to remove the soluble zinc iodide; the zinc was eliminated by warming with 50 per cent. sulphuric acid. Considerable difficulty was experienced in getting rid of the last traces of zinc, the operation requiring prolonged treatment with sulphuric acid for a period of several days. The mercury bead (which even then was not quite free from zinc) was washed with alcohol and ether, and weighed. Salt taken, 2·3708 grms.; Hg obtained, 1·2302 grm.; yield = 51·04 per cent. Hg.

Experiment E.—The salt was several times evaporated to dryness on a water bath in the presence of strong nitric acid, and the residue treated with hypophosphorous acid as before. Weight of salt, 2·0940 grms. Weight of mercury obtained, 0·7065 grms.; yield = 33·74 per cent. In this case the conversion of iodide into nitrate and the liberation of the iodine was not complete, and some of the iodine remaining behind as hydriodic acid or iodic acid, prevented the complete precipitation of the mercury.

In all these cases, the failure of the estimation may be attributed to the difficulty of removing all the iodine in the mercuric iodide. Unless a suitable "iodine carrier" can be found, the estimation of this salt by reduction methods is not possible.

The above results show that the method can be applied to the estimation of several salts of mercury for the purpose of rapid analysis. Rough commercial salts which contain unsoluble impurities, such as dirt, sand, &c., must be dissolved in hydrochloric acid and filtered before the mercury is reduced to the metallic state. This should always be done when the globule of mercury obtained by the direct action of hypophosphorous acid on the solid is not perfectly clean and bright. In this manner the method may be found applicable to the analysis of pure and impure salts of mercury.

Discussion.

Mr. Thomas Tyrer congratulated the author on his useful paper. The differences between the results by this method and theory were somewhat large, but it was not always possible to have close accuracy with that rapidity which was sometimes essential for rapid checking in manufacture. The author had demonstrated that, whatever the defects of the method, the results were comparable. Hundreds of analyses, by this method, had been made in his firm's laboratory, and the results were practically identical with Mr. Howard's, and, making the average allowance for each salt, accurate working figures were obtainable. He used the hypophosphorous acid method first, about 1893 or 1894, and he could not account for any discrepancies except on the ground of the volatility of mercury. He was somewhat surprised, on looking into an old edition of Fresenius, to find it stated that there was no danger from volatility, and yet results were given of some experiments which indicated that the volatility of mercury under some conditions was 0·0004. C. T. Bennett refers to this method in the Pharmaceutical Journal, [4], **11**, 575, with confirmatory results. With regard to the ammonio-chloride salt, its absorbent character should be remembered, and for close results the air-dried salt should be treated. In the assay of red iodide of mercury the copper method of the Pharmacopœia was almost as unreliable as the usual lime method. He never got anything like the theoretical 43·5 to 44·0 per cent. of mercury. Very disappointing results were obtained by the use of zinc, arising undoubtedly from the causes already referred to. Magnesium dust was suggested by his assistant, Mr. Gosling. The operative conditions were much the same as for zinc, with equal rapidity in operation. There was a more violent action at first, but, with obvious precautions, loss from that cause could be avoided. The results would compare well with theory, and were certainly more encouraging than with zinc dust. The results were 41·29, 41·8, 41·31, and 41·28 per cent., instead of 32 and 33 per cent. by the zinc method. It should, however, be stated that a trace of mercury was found in the supernatant liquid, but not enough to account for the whole deficiency. There was no danger of amalgamation. He agreed with the author as to the treatment by the hypophosphorous method of mixed mercurial residues containing sand and all sorts of substances, but he found that it was best to treat the whole together carefully and after washing on a tared filter, drying, and weighing, to heat in a crucible and volatilise the mercury.

Mr. D. A. Sutherland said he had analysed many hundreds of samples of mercury ores, and never took longer than 40 minutes, and often not more than 15. He had never made an estimation of mercuric chloride, mercurous chloride, or ammonial mercuric chloride in this way, but he had of mercuric oxide, and constantly of sulphide or cinnabar and other ores occasionally containing as much as 82 per cent. or nearly 90 per cent. of mercury. The process, although apparently not well known, was simple: it only required a special crucible lid of pure gold. One grm. of the ore to be analysed is weighed into an ordinary Berlin crucible and 5 grms. of litharge stirred in. A gold lid, so constructed that the central portion can hold water, is fitted to the crucible. The crucible is heated by a Bunsen burner, and the mercury volatilised on to the lid. In five or ten minutes the lid and adhering mercury can be weighed. He saw no reason why iodide of mercury should not be estimated in this way. If any sample presented special difficulty he should reduce the mercury to sulphide, or in some other way get it in a form in which it could be treated in a crucible.

Dr. L. F. Guttmann remarked that, with reference to the estimation of mercuric iodide, Mr. Howard said that he evaporated with nitric acid and obtained low results. He had found the same, and had attributed it to the volatility of the mercury salt.

Mr. D. A. Louis said the author had devised a very careful and accurate process for the estimation of mercury, which took some 48 hours. He had been in mercury mines, where he had estimated sulphides, chlorides, and other combinations of mercury, within a quarter of an hour or so. Although he regarded the use of the gold lid described by Mr. Sutherland as preferable, yet in its absence he had successfully used a sovereign for the purpose. The presence of organic matter did not affect the determinations. Even mercuric ointment could be easily estimated by the method.

Mr. W. T. Burgess cited the following proof of the volatility of mercury at the ordinary laboratory temperatures. For many years, where he was working with mercury he had some shelves on which chemicals were kept, and he noticed that, although they were several yards away from the mercury table, the stoppers and tops of bottles containing iodine, no matter how often they were cleaned, always had a thin coating of iodide of mercury on them. He could easily scrape off sufficient iodide to show the characteristic change of colour on heating.

Dr. Divers said that this determination of mercury as metal was a case well illustrating the advisability of seeking greater accuracy by working on larger quantities than usual when the doing so was not counter-indicated. Having had some experience in the collection of precipitated mercury for weighing, he could confirm the author's experience that loss of mercury in the finely-divided state was difficult to avoid, and that its amount depended upon the mode of working, and very little upon the quantity of mercury worked upon. He could recommend, for rapidity and simplicity, the washing of a globule of mercury upon a porous tile or a few layers of filter paper. The volatility of mercury with steam was such that any mercurous salt, soluble or insoluble, boiled with water gave off metallic mercury. A paper on this subject, by a Japanese chemist, Mr. Hada, had been published in the Journal of the Chemical Society for 1896. This chemist had also shown (J. Chem. Soc., 1895) that the first product of the action of a hypophosphite upon mercuric or mercurous nitrate in solution is to form a black double salt, mercurous nitrate hypophosphite, $HgH_2PO_2.HgNO_3.H_2O$. The speaker believed that the presence of any considerable quantity of acid other than hypophosphorous acid would prove to be undesirable by delaying reduction of the mercury, since that was markedly the case when the reducing agent was sulphur dioxide. Ammonio-mercuric chloride, or "white precipitate," would rarely give accurately the calculated percentage of mercury, since it is liable to contain a little additional ammonium chloride and also minute quantities of the half-hydrated dimercurammonium chloride, $2NHg_2Cl.H_2O$, described by André in 1889, and again by Prof. Ray, of Calcutta, in 1902. The failure to fully reduce mercuric iodide dissolved in potassium iodide may be attributed to the immediate reconversion of mercurous iodide into mercuric iodide by this salt, which would continuously undo the work of the hypophosphorous acid.

Mr. C. G. Cresswell asked what steps were taken to ascertain whether the mercurial salts contained the calculated percentages. It was quite possible that some of the results might be quite correct, although they did not agree with the calculated percentages, if the salts contained some unknown impurity.

Mr. B. F. Howard, in reply, said a number of suggestions and criticisms on this method had been made, and he thought he agreed with nearly all, and thanked the members for their various suggestions. There was no doubt using a lid or gold dish as suggested would answer in the case of these mercurial salts just as well as in ores containing mercury. As the amount of mercury obtained was very small, there was more possibility of error in the weighing. He failed to see why there should not be a great difference between the volatility of freshly precipitated floating particles of mercury and a homogeneous bead or globule of the same metal. He was obliged to Mr. Tyrer for his suggestion about the use of magnesium dust to make an amalgam; it would probably be a more convenient way than the zinc method. Washing on filter paper would undoubtedly be better than by decantation.

The Chairman said, with regard to the volatility of mercury, that it was considerable even below the boiling point of water; mercury was even volatile in the heat of the sun. They were much indebted to Mr. Howard for this interesting paper, which bore testimony to much careful research. If all manufacturers were to work out the details of their business in a similar manner they would have no need to fear foreign competition. He hoped this would not be the last paper which Mr. Howard would contribute to their proceedings.

THE DETERMINATION OF MOISTURE IN NITROGLYCERIN EXPLOSIVES.

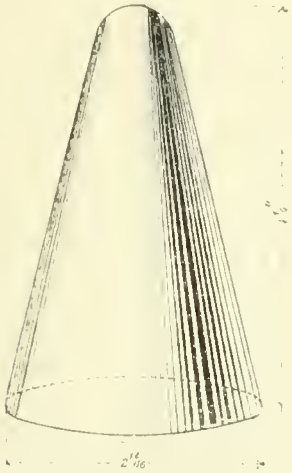
BY ARTHUR MARSHALL, F.I.C., F.C.S.

The difficulty in making this estimation is due to the fact that nitroglycerin is decidedly volatile at the temperatures required to drive off the moisture. At the same time, the determination is of great importance, especially in the case of propulsive explosives, such as cordite, because the velocity and pressure developed in the gun are affected by the amount of acetone and water left in the powder. Moreover, as nitroglycerin itself can only be estimated in the explosive by difference, it is impossible to ascertain the exact percentage present, unless all the other constituents, including moisture, can be accurately estimated. A method, in which the escape of the nitroglycerin is effectively prevented, was first devised by Mr. L. W. Dupré, when he was working at the Royal Gunpowder Factory, Waltham Abbey. In his method, which he published in the "Chemiker-Zeitung," 1901, 540, 2 grms. of the finely-ground sample were weighed on to a watch glass, which was then placed in an aluminium dish, and covered with a weighed glass cone 6 ins. high and $3\frac{1}{4}$ ins. in diameter at the bottom. The dish was placed over a hole in the top of a boiling water-bath, and was left there for an hour or until the weight was constant. The apparatus was then taken off the bath and allowed to cool in the air, after which the watch-glass and the cone were placed separately in dessicators, and finally weighed. The loss in weight was taken to accurately represent the moisture. The nitroglycerin driven off from the powder was entirely condensed again upon the glass cone, as was clearly shown by the fact that continued heating caused no further loss of weight.

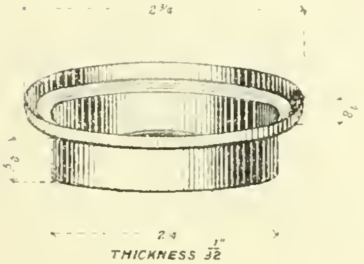
The most apparent objection to this method is that the weight of the apparatus, 50 or 60 grms., was out of all proportion to the loss of weight, which was frequently less than a milligramme. From variations in the atmospheric conditions the glass cone might gain or lose in weight to at least an equal extent.

The matter being in this state, acting under the directions of Major F. L. Nathan, R.A., Superintendent of the Royal Gunpowder Factory, I carried out a long series of experiments and determinations during the years 1901 and 1902, with the object of devising a better test to be applied not only to cordite having the composition then exclusively used (nitroglycerin, 58; guncotton, 37; mineral jelly, 5 parts).

but also to mixtures containing larger proportions of guncotton. It may appear an easy matter to devise a satisfactory test, but it was found that unless certain precautions were taken, the results obtained were inaccurate, and the sources of error in some cases were only discovered by series of estimations extending over months.



B



A

The form of apparatus that has finally been adopted is shown in the figure. It consists of an aluminium dish, A, having the dimensions shown, and the glass cone B, weighing not more than 30 grms. The cordite or other explosive is prepared in the manner laid down for the Abel heat test; that is to say, it is ground in a small mill, and that portion is selected which passes through a sieve having holes of the size of No. 8 wire gauge, but not through one with holes No. 14 wire gauge. Of this material 5 grms. are weighed into the aluminium dish A. This is covered with cone B, and the whole is accurately weighed, and is then placed upon a metal plate heated by steam from a water-bath. It is left upon the bath until all the moisture has been driven off, then it is allowed to cool for about half an hour in a desiccator and is weighed. The loss of weight gives accurately the moisture in the sample. For cordite of the original composition one hour's heating is sufficient to entirely drive off the moisture; for modified cordite, containing 65 per cent. of guncotton, two hours is enough provided that there be not more than 1·3 per cent. of moisture present. If the proportion of nitrocellulose be higher a longer heating is necessary. Table I. gives a few of the results that have been obtained.

A few words may be added regarding some of the details of the method. The aluminium dish must not be shallower than shown in the figure, for if the distance between the substance and the edge of the glass cone be less than half an inch, some nitroglycerin will be lost. Again, the sample must not be ground finer than as stated, else some of the moisture will be lost in the grinding and sieving operations, and the results will be too low. In order to be able to drive off all the moisture in the times mentioned, it is essential that the glass cone shall not fit too closely on to the aluminium dish, consequently the horizontal ledge round the top of the dish should be bent, so as to render it slightly untrue, and leave a clearance of about 0·02 in. in some places. If these few simple precautions be taken, the method will be found to be very accurate and expeditious and in all respects satisfactory. Duplicate determinations do not differ by more than 0·01 per cent.

TABLE I.

Explosive.	Composition.			Per Cent. Loss in		
	Nitroglycerin.	Nitrocellulose.	Mineral Jelly.	One Hour.	Two Hours.	Three Hours.
Cordite, Mark I.	58	37	5	0·18	0·19	..
				0·30	0·31	..
				0·21	0·21	..

Dynamite......	75	Kieselguhr 25	..	0·22	0·23	..

In conclusion, I have to thank Major Nathan for giving me permission to publish these results, and Dr. R. Robertson and the chemical staff of the Royal Gunpowder Factory for assistance given during the work.

The method has been officially adopted to govern the supply of "Cordite, M.D."

DISCUSSION.

Mr. OSCAR GUTTMANN said they had to thank the Government authorities, and especially Major Nathan, for the readiness with which they published some of their methods and results. He should not like to say anything offhand about a method which had been adopted officially as a standard for taking over deliveries of cordite, because it must be assumed that the authorities at Woolwich or Waltham Abbey would not have adopted it without most careful and searching examination; nevertheless he might be permitted to express a preliminary doubt as to its accuracy. He felt that doubt when Mr. L. W. Dupré published the method in the "Chemiker Zeitung," and it was not removed after Mr. Marshall's explanation. The reason was obvious, when Mr. Marshall told them the dimensions of the aluminium tray had to be absolutely the same, or the results would vary, and that the sample, when prepared for analysis, must pass through a standard sieve, because, if ground finer, low results might be obtained. In the case of cordite, they were testing a colloidal explosive which, in some cases, was as hard as wood, and in others as plastic as india-rubber, and yet by heating for two hours all the moisture was eliminated from grains of the large size stated. It had never been possible, by any means adopted in drying rooms, to remove only the moisture at a temperature, for example, of 40° C. When a material of this description was exposed to the temperature of boiling water, Mr. Marshall told them that all the nitroglycerin, as well as water and acetone, was driven off in the space of two hours. With the size of the grains between Nos. 8 and 14 wire gauge, this was, in his opinion, impossible. With regard to driving out the water through the fine aperture between the sides and the lid, and not allowing the nitroglycerin to escape, he again had some little doubt. He pointed out, about 26 years ago, that the volatility of nitroglycerin at the temperature of 40° C. was such that you lost 10 per cent. out of dynamite within a day. He failed to see why some nitroglycerin vapours should not pass out by way of the rim just as much as the water vapour. Until he had made further experiments with the test he would not express a definite opinion, but he thought he was justified in raising these doubts.

Mr. G. W. MACDONALD thought Mr. Guttmann had misunderstood what Mr. Marshall said with respect to driving out the nitroglycerin. He had carried out a great number of tests with this apparatus exactly of the same dimensions, from details kindly supplied by Major Nathan. The whole of the nitroglycerin was not driven off. About 0·36 per cent., after two hours, was condensed on the cone, and after about three hours, something like 0·6 per cent. In reply to the Chairman, Mr. Macdonald said he meant the percentage in the whole explosive calculated on the 5 grms. taken. If the explosive were removed from the aluminium tray, and the cone, containing the condensed nitroglycerin, replaced, and subjected to a further heating of three hours, no appreciable loss of condensed nitroglycerin could be observed.

Mr. Oscar Guttmann asked if Mr. Marshall or Mr. Macdonald could give some further explanation of the method employed, because at present he was not sure he understood what happened. Were they to understand that the nitroglycerin, acetone, and water were driven off, the water and acetone removed and the nitroglycerin condensed, or were they both got out of the substance, and the substance only weighed?

Mr. Stanley Fox said he was disappointed that no mention had been made of the test as applied to nitroglycerin blasting powders, *i.e.*, gelatines, gelignite, &c. With regard to the test described by the author, he had found it accurate, and the results were concordant. He regarded it as answering perfectly the purpose for which it was intended, *viz.*, of ensuring cordite to be free from volatile matter down to a certain standard limit, which limit had been most carefully determined by the authorities at Waltham Abbey and Woolwich, who had in view the effect of volatile matter on the ballistics of the powder and on its physical and chemical stability. The test was carried out in precisely the same way day after day, and in the same standard apparatus. He dissented from Mr. Guttmann that there was any discrepancy in the method of sifting and preparing the samples for testing, except that in the operation of grinding, when the energy of working the mill, being converted into heat, affected the moisture in cordite by eliminating a certain amount of the residual water and acetone. It was difficult to understand precisely where the water went. Undoubtedly nitroglycerin was condensed in the cone, but where did the water and acetone go? He did not believe for one moment that it escaped *in toto* underneath the glass. Whilst agreeing that the test was quite satisfactory for guidance in the factory, he still considered that, from a purely scientific point of view, it was open to improvement.

Dr. Robertson said this test had now been in use for a considerable time in his laboratory at the Royal Gunpowder Factory, and had given every satisfaction. He did not see much difficulty in the mechanism of the test. In the first place, there was a certain amount of confusion in the use of the term "moisture." Moisture in explosive work included much more than water. A better term would be "volatile matter." There was no difficulty in imagining that acetone vapour would escape between the glass cone and the aluminium dish. The water might escape in the same way, or, if it were condensed along with the nitroglycerin in the glass cone it would be removed when the cone was placed in the desiccator. The volatility of nitroglycerin was well known, as also was its easy condensability. If a large U-tube, containing 100 grms. of ground cordite, were placed in a boiling water bath, and a current of air passed through the tube and its contents, the nitroglycerin that was carried over was condensed at the point where the side tube of the U-tube passed over the water-bath. It was impossible to find, even at a very short distance from the U-tube, any considerable trace of nitroglycerin. This result led Mr. L. W. Dupre to devise the test of which the one under discussion is a modification. This experiment answered the question raised by Mr. Guttmann with regard to the possibility of the nitroglycerine vapour escaping between the cone and the dish, even if that were not already disposed of by the results given in the paper on the effect of the continued heating of powder in the apparatus described by the author.

Mr. H. A. Tauresen asked whether Mr. Marshall had tried drying carbonite containing as much as 4 or 5 per cent. of moisture; also whether, alluding to Mr. Guttmann's remarks, Mr. Guttmann could tell him of any better test than Dupré's for quick factory work.

The Chairman said that at first sight the apparatus appeared to him to be not altogether the most accurate method of getting rid of the moisture. He was not quite clear that he understood correctly how the moisture escaped.

Mr. de Mosenthal said he thought it was pretty clear that there were two kinds of evaporation, evaporation sideways and evaporation upwards. The former carried away the acetone and the nitroglycerin went upwards and settled in the cone. This was placed in the desiccator, and the moisture was consequently removed, so that nitroglycerin alone remained. That was how he understood it.

The Chairman said, he was glad Mr. de Mosenthal had given such an ingenious explanation, which, as he understood it, was that the different constituents in the explosive were, as it were, ear-marked and sent out in different directions as required. To sum it up, he understood the bulk of the moisture got out at the joint between the aluminium disc and the glass; in fact, the edges of the vessel were bent a little. He was inclined to think that that was not the most scientific way of going to work, but it might act in practice fairly well. It had been very well said when a method of this kind was designed for testing, uniformity of results was wanted by observers and workers in different places. A test might appear to be a little crude at first, and not designed on the most elaborate and scientific lines, yet possibly it would work well in practice, provided of course there were not sources of error in it, which would render it inapplicable for the purpose for which it was intended. He thought, in this case, there was one such source of error, because the very initial operation prescribed, rendered an accurate estimation of moisture absolutely impossible. If cordite of different diameters was ground in a mill, the very operation of grinding was a good method of drying it. If the percentage of moisture in the explosive as it was exploded in the gun or rifle was to be determined, the material must be taken as it was without any preliminary loss of the constituent, which was to be estimated. Another point which he could not quite understand, was why the nitroglycerin should all be condensed on the cone, and not the moisture. On looking at the apparatus, it was apparent that the nitroglycerin had not been equally condensed. Round the edges there were slight indications of air currents, and that might have affected the nitroglycerine percentage as well as the moisture. As he understood the operation, any nitroglycerin which had escaped would be considered as moisture. They all knew, as Mr. Guttmann had pointed out, that nitroglycerin was very volatile at the temperature employed in the analysis. It was quite clear there must be a loss of nitroglycerin, and he thought that should be estimated and allowed for.

The Chairman then proposed a vote of thanks to Mr. Marshall, and also to Major Nathan for allowing this paper to be read. It was one of considerable importance, and had given rise to a very interesting discussion. As there seemed to be a difference of opinion as to the accuracy of the method, and the way in which the action took place he hoped that further tests would be made, and they might, perhaps, have another communication on the subject.

Mr. Marshall, in reply, assured Mr. Guttmann that this method had been thoroughly tested, not only at Waltham Abbey by Dr. Robertson, by himself, and other chemists, but independently by Dr. Kellner at Woolwich, and Dr. Dupré in London, and they had found it very satisfactory. With regard to the standardisation of the apparatus, some of the dimensions were of great importance, but others were not of the same importance; in fact one could get identical results with apparatus varying very much from the particular one illustrated. There must, however, be at least half an inch between the powder and the edge of the glass, or the loss of nitroglycerin would become perceptible. There must also be a slight clearance at one or two points round the rim. Slight variations made no appreciable difference. The most important point raised, perhaps, was what happened to the nitroglycerin, and moisture. The Chairman said nitroglycerin was very volatile on the water-bath. He should not say it was very volatile; it was volatile, but only slightly as compared with other substances. Here were three substances—water, acetone, and nitroglycerin. No accurate determination had been made of the vapour pressure of nitroglycerin so far as he knew, but he thought he was not far out in saying that at 70° C., the actual temperature of the explosive inside the dish, the vapour tension of acetone was at least 1,000 times as great as that of nitroglycerin. Consequently the acetone and the water from the explosive in the dish would come away about 1,000 times as fast as the nitroglycerin. Of the small quantity of nitroglycerin that was given off practically the whole was deposited again upon the cool glass cone. Meanwhile the water and acetone gradually escaped under the edge of the cove. A slight interchange of air also went on between the outer atmosphere and the space inside the apparatus; this was sufficient to remove the moisture but not to carry off more than about 0·01 per cent. of nitroglycerin, as calculated on the weight of material taken. Some speakers had failed to see the necessity of grinding the sample to grains of a certain size. In the case of powders of large size they might in their undivided state be heated for weeks without giving up the whole of the acetone and water they contained. But if the sample were ground up it gave off its moisture at a temperature of 70° C., in an hour or two. The greater the proportion of nitroglycerin in the sample the more readily did the moisture come off. On the other hand the substance tended to lose these volatile products during the process of grinding. This loss would of course be much more considerable in the case of very finely divided material, than when it was in grains of appreciable size. It was, therefore, necessary to select by means of a set of sieves that portion, which was sufficiently finely divided to readily give off its moisture during the test, but not so fine as to lose an appreciable amount of moisture during the grinding. A considerable number of experiments had been carried out at Waltham Abbey, the results of which indicated, that if the operations were carried out as stated in the paper the loss of moisture from this cause was quite inconsiderable. He had not had any experience in the analysis of carbonite, but he had tested other explosives containing as much as 4 or 5 per cent. of moisture. The results were quite satisfactory, it was only necessary to prolong the heating somewhat. Some figures obtained with one or two different blasting explosives would be found in the paper. Mr. de Mosenthal's remarks were evidently not intended to be taken seriously.

ADDITIONAL NOTE BY MR. ARTHUR MARSHALL.

Because this test is simple and because the method of carrying it out has been carefully laid down, it has been supposed by some of the speakers in the discussion that it is only of an empirical nature and does not give the true moisture in a nitroglycerin explosive. In my endeavour to treat the matter in a thoroughly scientific manner I have perhaps led my hearers to suppose that there is considerable liability to error. This is not the case. Every analytical method is more or less inaccurate, but the one here described is not more so than at least nine-tenths of those upon which the analyst is in the habit of placing absolute reliance. For instance, in the determination of sulphuric acid by precipitation as barium sulphate, it is well known that there are many sources of error, yet the method is not regarded as "unscientific." This moisture estimation will compare favourably with the barium sulphate method as regards accuracy. The scientific method of treating an analytical process consists, not in shutting one's eyes to the possibilities of errors, but in thorough investigation of them, and careful avoidance of them based upon this investigation, and also, if possible, in comparison with standard methods. In the case of the test under consideration it is unfortunate that there is no reliable independent method with which the results can be compared. There is no other method known which yields even approximately accurate figures. It, therefore, only remains to examine carefully the various possible sources of error. This has been done very exhaustively.

Errors may be of two kinds, experimental and systematic. The former would cause the results of duplicate tests to differ one from another. That the method is not liable to inaccuracies of this kind may be clearly seen from Table II., in which are given the results of four determinations carried out upon the same sample.

TABLE II.

	Per Cent.	Per Cent.	Per Cent.	Per Cent.
Loss after two hours' heating.	1·26	1·26	1·28	1·28
Loss after three hours' heating.	1·29	1·28	1·29	1·29

In the case of another sample, determinations were made with varying quantities of powder. The following were the results:—

TABLE III.

Quantity taken.	Moisture found.
3 grammes	1·47 per cent.
4 "	1·49 "
5 "	1·47 "

Many similar series of figures might be cited.

If there be any error in the method it must therefore be a systematic one, that is an error which would make the results uniformly too high or too low. There are only three ways in which a systematic error can here occur: (1) there may be a loss of nitroglycerin or other matter during the course of the determination, (2) there may be some moisture remaining in the explosive at the end of the test, or (3) there may be a loss of moisture during the grinding and sifting. I will now proceed to show there is no appreciable error from any of these causes.

1. That the continuous loss of nitroglycerin is very minute is clearly shown by the fact that the diminution of weight after the first hour or two is extremely small, as may be seen from the figures quoted in Tables I., II., and III. This is brought out even more clearly in the following tests, in which the heating was continued up to 20 hours:—

TABLE IV.

	Per Cent.	Per Cent.
Loss in 2½ hours	1·43	1·49
" 4 "	1·47	1·49
" 20 "	1·55	1·61

These and many other results indicate that the loss of nitroglycerin is only about 0·006 per cent. per hour.

There remains, however, a bare possibility that in the early stages of the drying, the moisture and air expelled from the apparatus may carry away with them an appreciable quantity of nitroglycerin. If, now, it can be proved that a considerable percentage of moisture can be driven off from a sample of explosive under the conditions laid down, without diminishing the dry weight of the substance, it must be admitted that the accuracy of the method as regards this source of error is fully demonstrated. Three separate experiments were carried out on these lines. In the first case, 5 grms. of cordite, M.D., were weighed out, and the moisture was determined in the usual manner; then 0·04 grm. (0·8 per cent.) of a mixture of equal volumes of acetone and water was sprayed on to the explosive. The glass cone was then placed over the dish again, and the whole was heated on the water-bath as usual. After two hours' heating, it was found that the weight of the cordite was only 0·004 per cent. less than the previous dry weight. A further heating of one hour produced a loss of only 0·02 per cent. more.

The second experiment was similar, except that in this case 0·1 grm. (2 per cent.) of a mixture of two parts acetone to one part water was added in drops. The final weight, after four hours' heating, was 0·03 per cent. less than the original dry weight. In the third experiment, 5 per cent. of moisture was added, and here, again, there was no appreciable loss of nitroglycerin.

These results were entirely satisfactory, as they clearly showed that the moisture does not carry away with it a weighable quantity of nitroglycerin. On the contrary, the loss of weight was less than 0·01 per cent. per hour during the heating. In order, however, to place the matter upon a more scientific basis, the actual vapour tension of nitroglycerin was determined at 70° C., the temperature of the explosive in the moisture test apparatus. Some nitroglycerin was introduced into a small gas-washing bulb, which was immersed for about five hours in a water bath maintained at 70° C., whilst a known volume of air was bubbled slowly through. The exit tube of the bulb was connected with a piece of glass tubing, the upper part of which was cool enough to condense, practically, the whole of the nitroglycerin evaporated. Both this tube and the bulb were weighed before and after the experiment. It was found that the bulb had lost 0·0013 grm., whereas the tube had gained 0·0011 grm. The former figure is slightly too high, because the nitroglycerin towards the end of the time was beginning to decompose to a very slight extent. On the other hand, the latter figure must be somewhat too low, because, even at the lower temperature of the tube, nitroglycerin must still have a slight vapour tension. We may, therefore, take the quantity of nitroglycerin evaporated at 0·0012 grm. The volume of the air drawn through was 1,850 c.c., measured at 13·5° C. Calculating from the formula—

$$p = \frac{gT}{mv}$$

It is found that at 70° C. nitroglycerin has a vapour tension of 0·0051 cm. of mercury, that is to say, the volatility of nitroglycerin is almost exactly equal to that of mercury. In order to test the method and apparatus the vapour tension of mercury was at 70° C. determined in precisely the same manner. The quantity of air drawn through was 1450 c.c., measured at 18° C. The weight of mercury evaporated was 0·0009 grm. Hence the vapour tension is calculated to be 0·0056 cm., which figure agrees satisfactorily with that given by Ramsay and Young, 0·0052 cm. The vapour pressures of nitroglycerin and mercury being equal, and the molecular weights of the two vapours (227 and 200 respectively) being not very different, it necessarily follows that rules laid down for the prevention of loss of the one substance may be applied to the other. The vapour pressure of nitroglycerin being known it is possible to calculate the quantity that will be carried away by the moisture expelled in the test. The volume of the moisture from 5 grms. of cordite would seldom exceed 50 c.c. as measured in the gaseous state. This even if completely saturated with nitroglycerin would carry away less than 0·00004 grm. of it, or 0·0008 per cent. as calculated on the powder.

A rough estimate may also be made of the minimum volume of air that circulates between the interior of the moisture apparatus and outer space. The loss of nitroglycerin is usually 0·0002 to 0·0005 grm. per hour, whence it is calculated that in spite of the narrowness of the interval between the glass cone and the aluminium dish not less than 300 to 800 c.c. of air enter and leave during each hour of heating.

2. That none but the minutest trace of moisture remains in the explosives at the end of the test is sufficiently proved by the figures already quoted. It has been shown that the loss from the ground nitroglycerin explosive after the first two or three hours is very small and quite uniform. Everyone who has had any experience of the drying of collodial substances knows that they lose their moisture at first rapidly and then gradually more and more slowly until all the moisture has been expelled. There is no evidence of any diminishing loss of this kind after the first two or three hours. There are undoubtedly other explosives that would not be dried within the period mentioned, but nitroglycerin explosives fortunately give up their moisture with comparative ease.

3. Loss of moisture during grinding and sifting. In order to ascertain whether any appreciable error arises in these processes some cordite of small size was submitted to the test without preliminary grinding and parallel determinations were carried out with material prepared in the usual way. It was, of course, necessary to prolong the heating in order to drive the whole of the moisture out of the unground cords.

TABLE V.

—	Cordite, Mark I.		Cordite, M.D.	
	Ground.	Unground.	Ground.	Unground.
Loss in 2½ hours' heating....	0·24	0·17	..	..
„ 4 „ „	0·24	0·22	0·44	0·45
„ 5 „ „	0·26	0·23	0·45	0·47
„ after 16 additional hours in desiccator and 1½ hours further heating..	..	..	0·45	0·47

Another sample of the same cordite, M.D., gave the following results:—

TABLE VI.

—	Ground.	Unground.
Loss in 5 hours' heating	0·42	0·41
„ 6 „ „	0·44	0·42

With a cordite, M.D., containing a larger proportion of moisture, the results were equally satisfactory.

TABLE VII.

—	Ground.	Unground.
Loss in 5½ hours' heating	1·09	1·06
„ 6½ „ „	1·11	1·10
„ after 16 additional hours in desiccator.	1·12	1·11
„ „ 1 „ hour heating	1·13	1·12

It is quite evident from these figures that the loss of moisture during grinding and sifting is very minute.

All possible sources of error have now been examined experimentally, and in every case it has been shown that the inaccuracy does not exceed a few hundredths per cent. Any attempt to obtain a higher degree of accuracy than this must necessarily be in vain, as it is not possible to take a sample from a large batch of explosive, which shall represent the main bulk absolutely. However much care be exercised in the sampling the difference between duplicate samples will considerably exceed any possible error of this method of analysis.

The general accuracy of the test is further demonstrated by the fact, that the same results can be obtained with very different apparatus, provided of course that attention be paid to the few points mentioned in the paper. Some determinations were made using an ordinary glass funnel instead of the cone shown in the figure. The stem was plugged with glass wool and the funnel was inverted over the dish. Parallel determinations were also made using an aluminium dish half an inch larger in diameter than the one shown in the figure. This was covered also with a funnel of suitable size. The following figures were obtained with the three modifications of the apparatus:—

TABLE VIII.

—	Cone.	Funnel.	Large Dish and Funnel.
	Per Cent.	Per Cent.	Per Cent.
Moisture found	1·20 1·20	1·20 1·21	1·19 1·18

From the various figures which have been quoted it is perfectly evident that the method gives reliable and accurate result.

Meeting held at Burlington House, on Monday, February 1st, 1904.

MR. WALTER F. REID IN THE CHAIR.

A *RÉSUMÉ* OF THE REPORT, MINUTES OF EVIDENCE, AND APPENDICES OF THE ROYAL COMMISSION ON ARSENICAL POISONING.

BY JULIAN L. BAKER.

The final report of the Commission was published on December 3rd, 1903, and the two volumes of minutes of evidence and appendices on December 23rd, 1903. The publication is no ordinary blue book, for it contains many new experimental facts and data. Exhaustive investigations have been carried out by experienced physiologists on the different questions relating to the effect of arsenic on human beings and animals, and by chemists on the detection of arsenic in the various food and food materials. Analytical methods have been elaborated, which are now in daily use in many laboratories. The mass of data collected by the Commission, and the valuable conclusions deduced therefrom, may possibly be lost sight of by chemists and others when the immediate cause which led to the appointment of the Commission becomes a matter of history. Bearing this in mind, the London Committee felt that some steps should be taken to present the members of the Section and the Society with a condensed account of the chemical matters dealt with by the Commission. This is the more appropriate when it is borne in mind that a joint committee was appointed by the Society of Public Analysts and this Society to investigate the methods for the estimation of small quantities of arsenic. This Committee presented its report to the Commission, and the recommendations contained therein received the cordial appreciation of the Commissioners.

My endeavour will be to describe the ground covered by the report, my remarks for the most part being confined to the chemical and analytical matters submitted to the Commission. In a few cases I have ventured to submit criticisms.

PART I.

Observations regarding the Epidemic of Arsenical Poisoning in 1900, and the Medical and Public Health Aspects of the Evidence received regarding Arsenic in Beer and Food.

The epidemic of arsenical poisoning which occurred at the latter end of 1900, and which led to the appointment of the Royal Commission, was very soon traced to Bostock's brewing sugar. The total number of persons who suffered from the epidemic was over 6,000, and at least 70 fatal cases were attributed to poisoning by arsenic in beer. This does not represent the total number of fatal cases, for deaths occurring before the discovery of the cause of the outbreak were frequently certified as due to other diseases.

The evidence relating to the symptoms of poisoning due to arsenic in beer during the epidemic is very comprehensive, and the Commissioners point out that it should form valuable material for reference and comparison in future cases or future outbreaks, where the possibility of arsenical poisoning calls for consideration.

A considerable proportion of the beer brewed in some parts of the country before 1900 contained certain quantities of arsenic, which was no doubt derived from malt and from brewing sugar. The evidence shows that malt has been liable to arsenical contamination in much greater degree when the fuel used in the kiln has been gas coke than when other forms of malting fuel, such as oven coke or anthracite, have been employed. In the south of England the use of gas coke previous to 1901 had never been common, but in certain parts of the North and the Midlands, and in Manchester and Liverpool, gas coke was constantly employed at the maltings supplying various breweries. The greater prevalence of alcoholic neuritis among beer drinkers in Manchester and Liverpool before 1900, when compared, for example, with London and the South, is probably due to the degree to which the beer was contaminated by arsenic derived from malt.

In January and February 1902 an outbreak of arsenical poisoning occurred at Halifax, resulting in the death of three persons. Suspicion fell on the beer, and this when examined was found to contain 1/10th to 1/16th of a grain of arsenious acid per gallon. Careful inquiry revealed that the beers in question had been contaminated by arsenic derived from the malt used in their preparation. In nearly all cases there was evidence that the malt had been dried over local gas coke. This outbreak was highly instructive to the Commission, for all the Halifax cases were characterised by peripheral neuritis, which, taken by itself, was hardly to be distinguished from "alcoholic neuritis." The Halifax beers associated with the outbreak must have been typical in respect of arsenic of a large class of beers prepared before the 1900 epidemic from arsenical malt.

It was suggested by certain witnesses that the contaminated beer might contain some organic compound of arsenic with a toxic action differing from that of arsenious oxide. Although some witnesses expressed the opinion that such organic compounds were present, no direct evidence was brought forward bearing on this point.

The susceptibility of the individual to arsenic varies greatly, and this was very marked in the epidemic of 1900, for large numbers of people must have been drinking beer, much of which was contaminated by arsenic to a high degree, in considerable quantities over several months without any apparent bad result. In this connection the experiment carried out by Prof. Delepine on the effect of administering varying quantities of arsenic to rats are very interesting. He found that minute quantities of arsenic could be administered over comparatively long periods before detrimental results appeared, so long as the animal was well fed; whereas in rats under identical conditions, but on restricted diet, the deleterious effects of the arsenic were much sooner apparent. The association of arsenic and beer appeared to increase the resistance of the rats by improving nutrition.

The physical effect of arsenic on the human system was inquired into at considerable length, and the evidence showed the correctness of the generally accepted view that arsenic is a poison which, as a rule, is eliminated comparatively rapidly from the body. The clinical data obtained during the epidemic showed, however, that arsenic can only be termed a "non-cumulative" poison in a restricted and comparative sense. When small quantities of arsenic are taken over long periods, accumulation occurs in certain tissues. Many cases admitted to hospital in 1900 continued to show increasing signs of poisoning for weeks after beer had been discontinued.

Important observations have been made regarding the numerous ways in which arsenic may be eliminated from the body. Arsenic was detected in sweat, in the epidermic scales which are freely shed in the condition known as keratosis, in nails, and in hair. The fact of arsenic being excreted by hair attracted the attention of the Commission, for it was possible that the elimination of arsenic in this manner might prove important in instances (such as supposed alcoholic neuritis) where it was desirable to ascertain whether a patient had lately been taking arsenic, either as a contamination of food or beer, or medicinally. Samples of hair were obtained from patients who had taken arsenic in known amounts over known periods of time, together with suitable controls, and were submitted to analysis by Mr. R. F. Wood Smith. The method of analysis used was destruction of the organic matter of the hair, and estimation of arsenic in the inorganic residue by the Marsh-Berzelius process. About 2 grms. of the hair to be tested were weighed and transferred to a Jena flask of 250 c.c. capacity. Upon the hair were then poured about 30 c.c. of strong nitric acid and 4 c.c. of strong sulphuric acid. The contents of the flask were warmed, and when the first violence of the oxidation had subsided the temperature was raised and the liquor thoroughly boiled. After continued boiling the liquor darkens, more nitric acid is added, a point being finally arrived at when only clear sulphuric acid remains, containing all the arsenic present in the sample. The sulphuric acid is then diluted and evaporated down again to its original bulk, this operation being necessary to guard against the possibility of nitrogen compounds being present during the Marsh-Berzelius test. The liquid was then "Marshed" in the usual manner. A lengthy series of estimations were made, the results being very interesting. Out of 41 control cases, principally hospital and infirmary in-patients of both sexes, who had been taking no arsenic medicinally, the hair of 38 was either free from arsenic or showed no more than 1/150th gr. per lb. Samples of hair were obtained from the same cases after they had taken arsenic medicinally. The male patients who had been taking about 1/10th gr. of arsenic daily at the end of two months showed amounts of arsenic varying from 1/20th to 1/5th gr. per lb. in hair which had been grown during the interval. One case showed 1/50th gr. per lb. Male patients taking smaller amounts, 1/33rd and 1/22nd gr. of arsenic daily for two months, showed quantities of arsenic varying from 1/80th to 1/10th gr. per lb. in the recently grown hair.

With female patients considerable difficulty arose in obtaining samples which represented the hair which had grown during the period of arsenic taking, but the results, though less uniform than in the male cases, were similar in character. The result of testing hair of cases in which arsenic had been taken for less than five weeks were irregular, owing, no doubt, to the fact that the sample examined usually contained a proportion of hair which had grown before the administration of arsenic had began.

The Commissioners point out that the exclusion of small quantities of arsenic from food and drink is of considerable importance, and calls for more attention than it has hitherto received. The effects of very small quantities of arsenic administered over long periods along with food have not been fully studied; although evidence of marked toxicity may be absent, it is possible that the arsenic may have unrecognised effects on nutrition. Professor Delepine stated that continuous daily ingestion of 1/100th gr. of arsenic along with food may be prejudicial to the human subject.

Part 2.

The suggested Relation between the Disease "Beri-Beri" and Arsenical Poisoning.

Certain witnesses examined before the Commissioners had pointed out the similarity existing between the symptoms of the 1900 arsenic epidemic and those of "beri-beri," a disease mainly characterised by peripheral neuritis, which is met with in certain tropical countries and in parts connected with Eastern trade. This disease may be due to the presence in particular articles of diet of a poison which has a toxic action on nerve tissue, and it has been suggested that beri-beri may prove to be due to contamination of food by arsenic. This view was not, however, shared by the Commissioners.

Part 3.

Tests for Arsenic in Food and Substances used in the Preparation or Manufacture of Food.

At the time the first report of the Commission was published a considerable difference of opinion existed as to the relative value of different methods of estimating small quantities of arsenic in beer and other foods. Many instances occurred in which discordant results had been obtained when identical samples were examined by different chemists and by different methods. Since that date the Commission have been in receipt of various reports of work on the subject undertaken by many chemists. The substances examined comprised beer, malt, sugars, and various other foods and organic substances liable to contain arsenic, fuels, and chemical substances used in connection with food preparation.

A number of witnesses were examined by the Commission on this subject, and a condensed account of their investigations and conclusions is to be found in the final report of the Committee appointed by the Manchester Brewers' Association of May 11, 1901, and the report of the Joint Committee of the Societies of Public Analysts and Chemical Industry. This latter report was subsequently discussed at a joint meeting of the two societies. A Departmental Committee was appointed by the Board of Inland Revenue to prescribe tests for arsenic in beer and brewing materials. Their report was presented last April.

It will be well at this stage to consider these reports. The report of the Committee appointed by the Manchester Brewers' Association, dated May 11th, 1901, was of the nature of a preliminary investigation. The report of this Committee has been subjected to a certain amount of criticism, but the circumstances obtaining at that time should be borne in mind. The arsenic scare was at its height, and immediate measures had to be adopted by brewers and others to test materials and to satisfy the public that measures were being taken for their protection. Much divergence of opinion existed then as to the most satisfactory way of testing for small quantities of arsenic. The Marsh-Berzelius test was not elaborated to the extent that we now know it, and in view of the pressing necessity of a more or less rough discriminating test the Committee adopted the Reinsch test. The words of Mr. A. G. Salamon show clearly the way in which the Manchester Committee regarded the test (Q. 1525): "It was not a test which was meant to deal with minute traces, it was a test conceived after consultation with Prof. Delepine, Sir Lauder Brunton, Dr. Stevenson, and Dr. Luff, as to a means of preventing beer being sent out to the public, at a moment of crisis, which contained poisonous quantities of arsenic."

In the final report of this Committee it is pointed out that the first suspicion as to Bostock's sugar being the cause of the widespread poisoning dated from about November 21st, 1900, and its employment in or about Manchester was discontinued nine days later. The members of this Committee were soon confronted with the circumstance that arsenic continued to be found in small quantities in brewings both in Manchester and in other parts of the United Kingdom. This necessitated long and detailed investigation of the different materials used in brewing. It appeared that one-fifth of the samples of beers contained arsenic derived from sources other than Bostock's sugar. Glucose, invert sugar, with the exception of products made by Bostock, raw and purified sugars used in brewing, caramels, and malt adjuncts, were found to be quite free from arsenic. The samples of hops examined were free from arsenic but the possibility of minute quantities being present was foreseen. The Committee also established the fact that yeast absorbs arsenic. Arsenic was found in kilned or sweated barley, in malt, in malt culms, and kiln dust, in malting anthracite and coke. In concluding their report the Committee recommended that brewers should insist on a written guarantee of freedom from arsenic with all purchases of brewing materials of every kind, also that brewers should from time to time test the purity of their beer and brewing materials in respect of arsenic.

With regard to malt the Committee suggested that—

1. The maltster be required to give a guarantee to the brewer that he does not employ gas coke in the preparation of his malt.

2. That the malt culms be regularly tested for the presence of arsenic.

3. If the culms be found to contain noticeable quantities of arsenic, that the kiln dust be at once removed, and that the fuel employed be further examined for arsenic.

4. That wherever possible the best anthracite be employed for malting purposes.

The Committee further suggested a standard test for arsenic in beer. 200 c.c. of the suspected beer is submitted to the Reinsch test and when the presence of arsenic is ascertained the amount is estimated by the Marsh-Berzelius method.

A joint committee was appointed in March 1901 by the Societies of Public Analysts and Chemical Industry. This Committee made an extended investigation of the Marsh-

Berzelius method, and presented a report in June 1902 which was subsequently discussed at a joint meeting of the two societies. In this report the Committee recommend the Marsh Berzelius method and give detailed instructions for purifying the materials employed in the test and for carrying out the test under standard conditions. The Committee stated that organic materials, such as beer, yeast, &c., cannot be tested, when sulphuric acid is used without destruction of the organic matter, whilst as a rule they can be directly tested with hydrochloric acid. Directions are given for determining the amount of arsenic in malt, hops, sugar and other brewing materials with and without the destruction of organic matter. Two processes are available for destroying the organic matter: the acid method which involves treatment by nitric and sulphuric acid, and the basic method where the materials are mixed with pure lime or magnesia, dried, and incinerated. Ling and Newland's process (this Journal, 1901, 1008) is advised for estimating volatile and total arsenic in malting fuels. The Committee were satisfied that arsenic in both states of oxidation can be detected and estimated by the procedure described in their report. The Marsh-Berzelius test as recommended is extremely sensitive; with quantities of 20 grms. or 20 c.c. an indication of one part of arsenious acid in 7,000,000 is possible.

In January 1902 a Departmental Committee was appointed by the Board of Inland Revenue, in pursuance of the recommendation made by the Commissioners in their first report, to prescribe tests for arsenic in beer and brewing materials. The report was presented by Sir Henry Primrose in April 1903. This Committee, which comprised Messrs. Thorpe, Tilden, Dixon, Aldous and Pattinson gave their attention to the methods of detecting and estimating the amounts of arsenic in malt, malt substitutes, wort, hops and hop substitutes, beer, yeast, and yeast foods, chemicals, finings, and fuels. Of the various methods which have been suggested for the detection and estimation of relatively small quantities of arsenic which may be present in beer and the ingredients of beer, the Committee decided that the methods which are based upon the conversion of arsenic into arseniuretted hydrogen, and the subsequent deposition of the arsenic in the elementary form by heating the gas are to be preferred. The hydrogen may be generated either electrolytically or by the action of dilute hydrochloric acid upon zinc. The amount of arsenic deposited by heating the arseniuretted hydrogen is determined by comparison with deposits obtained in a similar manner from wort, beer, malt extracts, &c., containing known quantities of arsenic. The Committee adopted a modification of Bloxam's method (Quart. J. of the Chem. Soc., **13**, 1861, 12 and 338). As the process has already been described in this Journal (1903, 965), it will be unnecessary to again refer to it. Since the electrolytic method is now adopted at the Government laboratory in preference to the Marsh-Berzelius test it becomes *de facto* the official test and it will be well to briefly compare the relative advantages and disadvantages of the two methods.

The advantages of the electrolytic test are that—

1. It obviates the use of zinc.

2. It is simple in execution, is under perfect control, and may be carried out under such conditions that the results obtained by different operators are strictly comparable, inasmuch as with a current-strength of fair regularity the evolution of the gas is practically constant and uniform.

3. The whole of the solution to be tested for arsenic may be added to the apparatus at once, so that during the whole time of testing the arsenic is under the influence of the "nascent" hydrogen.

4. It has been established that such amounts of arsenic as are present in beer or its ingredients are evolved as arseniuretted hydrogen during the 30 minutes occupied by the test. The nature of the material associated with the arsenic is found to exercise no inhibiting effect on the formation and evolution of the arseniuretted hydrogen. Beer and aqueous extracts of malts and worts may be added directly to the electrolytic apparatus without previous destruction of the organic matter as required by the zinc and acid process.

5. The deposits obtained are more uniform in character than those furnished by the zinc and acid method, and admit therefore of more accurate quantitative comparison.

6. The process allows of the simultaneous execution of a number of estimations of arsenic, depending upon the arrangement of the rheostat.

The disadvantages of the methods are:—

1. The initial cost of the apparatus as compared with that employed in the zinc and acid method.

2. That it can only be applied when an electric current of sufficient intensity is available.

The main advantages of the Marsh-Berzelius method are that it is sufficiently delicate, is rapid and easy of execution, and that the apparatus and materials needed are comparatively inexpensive.

The disadvantages attending it are:—

1. That zinc very frequently contains small amounts of arsenic, and hence must be carefully tested before use. It has been established that the arsenic when present is not uniformly distributed throughout the metal, and hence different portions of zinc from the same granulation may contain arsenic in very different amounts. It has been further shown that small quantities of admixed metals, apparently iron in particular, tend to prevent the formation of arseniuretted hydrogen, and so prevent the detection of minute quantities of arsenic.

It is necessary, therefore, to ascertain not only that the zinc is free from arsenic, but that it will give rise to arseniuretted hydrogen when arsenic is usually brought in contact with it.

2. The character of the deposit of arsenic is influenced by the rate at which the hydrogen is evolved, and as this depends upon the "activity" of the zinc, which is not always under complete control, the deposits obtained by different operators, or with different specimens of zinc, are apt to show slight variations.

There can be no doubt that the electrolytic method possesses material advantages over the Marsh-Berzelius test, but it is unfortunate that the official process is only applicable when an electric current of sufficient intensity is available. That the necessity of electric current will bar the official test being used in a large number of laboratories and breweries is a matter of regret, for, in such an important matter as the rejection of a delivery of malt or other ingredients of beer, or prosecutions by a local authority, it is most desirable that the chemists concerned should use the official method. The disadvantages of the electrolytic method have been discussed to some extent among chemists, but I venture to think that many of the points raised against it owe their origin to difficulties attending the manipulation of a new and somewhat complicated piece of apparatus. The Marsh-Berzelius test, carried out under the conditions advised by the Joint Committee, will in all probability continue to be the one in common use for control of purity of products. The electrolytic method will be the final appeal for disputes between buyer and seller of brewing materials.

The Commissioners report at some length upon the Marsh-Berzelius test. After summing up the difficulties of the application of the method, they are of opinion that chemists appear to be in general agreement as to the conditions of the test. The Commissioners are obviously careful not to insist on any one of the many modifications of the method which have been brought before their notice, and they consider that any single detailed routine is not applicable to all cases.

The evidence offered by chemists satisfied the Commissioners that differences in quantities of arsenic as small as 0·002 of a milligram or 1/720 of a grain per lb. can be estimated, whilst it can be detected in amounts below 1/1000 grain per lb., or 1/300 grain per gallon. The important consideration of allowance for differences in personal judgement of the reading of the mirrors is referred to, and the evidence on this point of Messrs. Hehner, Chapman, Allen, McGowan, and Finlow is summed up in the statement, "that a difference in reading, corresponding to 0·002 milligram of arsenic, too much or too little, appears to be regarded as an outside limit. On 10 grms. of material this difference would be ± 1/720 grain per lb., or with 30 c.c. of liquid ± 1/360 grain per gallon.

A considerable amount of data has been brought forward on the preliminary treatment which should be applied to different substances, in order that the total arsenic they contain may be estimated by the Marsh-Berzelius method. In the earlier stage of the enquiry, somewhat contradictory opinions were expressed by different witnesses as to whether the organic matter should be destroyed, but as chemists gained experience in the Marsh-Berzelius method the view became general that destruction was advisable. There are, however, a few exceptions, such as, for example, unground malt. Destruction of organic matter is obviously necessary when the arsenic is in the form of an organic compound, or where it is intimately combined with organic matter such as hair, animal tissues, coal, colouring matters, &c.

The Commissioners advise that the organic matter should be destroyed in wort and beer when the Marsh-Berzelius method is used. Ling's method for the determination of volatile and fixed arsenic in fuel is referred to, and also the method described in the report of the Departmental Committee (substantially the same as that elaborated by Wood Smith, and Jenks, this Journal, 1901, 437), which consists of burning the fuel in a current of oxygen, collecting the arsenic which is volatilised in an absorption apparatus containing dilute sulphuric acid; and subsequently estimating the volatile arsenic obtained in this solution, and also the arsenic left behind in the ash. (This Journal, 1903, 964.)

The use of other methods for the detection and estimation of small quantities of arsenic is not advised, the Commissioners holding, that methods involving the comparison of mirrors have been developed to such a state of efficiency that they are now general. The use of the Reinsch test for the purpose of detecting small quantities of arsenic is condemned; the results may even be misleading, for one of the breweries of Halifax, which supplied arsenical beer in 1902, had their products systematically tested by the Reinsch method, and only negative results were reported.

Looking at the matter of the estimation of small quantities of arsenic broadly, the electrolytic method, when available, possesses the great advantage of removing all the drawbacks connected with impurities and sensitiveness of zinc. This is, undoubtedly, the weak point in the Marsh-Berzelius method, as hydrochloric and sulphuric acids may be obtained free of minute traces of arsenic; but with zinc it is different, and there are few of us who have not experienced trouble in this respect. Another and very important point in favour of the electrolytic method is that beer wort and certain other substances may be added directly to the apparatus without previous destruction of organic matter. This obviously tends to ultimate accuracy of results, for, however careful the chemist may be, the addition of materials to the substance to be tested and subsequent manipulation opens the door to the possibility of contamination, and, moreover, increases the time taken by the test.

PART 4.

Ways in which Foods are liable to become Contaminated by Arsenic.

Much evidence was submitted by witnesses as to the risks of arsenical contamination which arise in the manufacture of foods and substances used in the preparation of food. Mr. H. Hammond Smith instituted enquiries on behalf of the Commission from representative food manufacturers. Many of the samples which were collected were analysed by Dr. McGowan. The results are described in Appendices 24 and 25. Mr. H. Hammond Smith conducted a lengthy and valuable investigation under the following heads:—

The use in the preparation of sundry articles of food and drink of substances liable to contain arsenic, or liable to introduce arsenic into the finished product.

The precautions which have been and are now being taken by manufacturers and vendors of foods or drinks to avoid risk of arsenical contamination.

The approximate degree of contamination of various foods or drinks by arsenic, which might arise on the assumption that all precaution was neglected; and the quantities of arsenic which have been actually found to be present in samples of particular foods or drinks.

Space will not permit of an adequate abstract of [illegible] investigations, but the following summary comprises the principal points dealt with in his report:—

(1) *Glucose* is an important ingredient of numerous articles of food, particularly of table syrups, jams, marmalade, confectionery, and biscuits; also of sundry beverages, particularly brewed ginger beer and certain kinds of wine.

In most of these foods and drinks the proportion of glucose used may be considerable. Arsenical contamination of the glucose on the Bostock scale would involve serious contamination of the finished products. Use in these substances of glucose containing as much arsenic as has in exceptional instances been found in samples on the market in 1901–2, and not coming from Bostock's (*e.g.*, 1/25th to 1/10th grain of arsenic per lb.) would also in most instances involve a material degree of contamination of the finished product by arsenic.

Nearly all the glucoses used are of foreign, usually American, origin.

Food manufacturers using glucose differ very much in their method of taking precautions to secure that it is satisfactory as regards arsenic. At the works visited analytical control of greater or less stringency had been adopted since 1900 by certain firms; others, the majority, were content with guarantees given by the glucose manufacturer, middleman, or agent; others, again, had required no guarantee and had not tested their glucose for arsenic.

(2) In instances where *invert sugar* was used by cider makers, or by manufacturers of brewed "temperance beverages," it was either obtained from brewing sugar manufacturers taking precautions to exclude arsenic from their invert sugar, or it was prepared by the cider maker without the use of sulphuric or hydrochloric acid.

(3) The use of sulphuric acid in the preparation of "*golden syrup*" and *treacle* involves risk of contamination by arsenic if the precautions taken to secure a satisfactory acid are insufficient.

(4) The use of sulphuric acid to convert raw grain in *vinegar making* involves risk of serious contamination of the vinegar by arsenic in the absence of sufficient precautions. Care in this respect was taken by the two firms visited which manufactured vinegar in this way.

(5) Besides the foods above mentioned are a few others, in the preparation of which sulphuric or hydrochloric acid may be used. In the case of certain *meat extracts*, "peptones," the amount of hydrochloric acid employed is relatively minute. Direct addition of sulphuric acid to *vinegar* and *pickles* appears to be seldom practised. If a strongly arsenical acid were employed these substances might become contaminated by arsenic to a marked degree. The information thus far obtained does not suggest that the sophistication of *spirits* by mineral acids, if still practised, is common.

(6) Commercial *phosphoric* acid and commercial *phosphates*, such as are used in sugar refining and in baking powders, are liable to contain arsenic, but the quantity of arsenic which could be introduced in this way into finished products is in most instances small.

(7) *Tartaric and citric acids*, largely used for food purposes, particularly as ingredients of lemonade powders and the like, are liable to contain arsenic. The steps habitually taken by manufacturers of these acids in this country to secure freedom from lead also tend to make serious contamination by arsenic unlikely, and it is the custom of food manufacturers to demand that these acids should be satisfactory in regard to lead.

(8) The use of exceptionally large quantities of *boron preservatives* in articles such as milk, cream, and butter may involve the introduction of material quantities of arsenic into these substances.

(9) *Glycerin* has occasionally been found to contain large amounts of arsenic (*e.g.*, 2 to 4 grains per lb.); quantities of arsenic less than 1/13th grain arsenic per lb., if present, might not be detected by the tests prescribed for

glycerin in the British Pharmacopœia. Glycerin may be used in cakes to the amount of 1 per cent., and also an important ingredient of certain sweets and meat extracts.

Certain food manufacturers visited employed glycerin stated to conform to pharmacopœial tests; they had not, however, caused the glycerin supplied to be analysed for arsenic, and they did not recognise that arsenical glycerin might cause objectionable contamination of their products.

(10) Arsenic may be present in sundry "coal tar" *colouring matters* used in food. In the case of confectionery, it is usual for the confectioner to obtain colours with a guarantee from a responsible analyst that they were harmless for confectionery purposes, such guarantee being given with due regard to the quantity of the colour likely to enter into the finished product. Samples of Bole Armenia and other *mineral pigments* have been found to contain over 0·8 grain of arsenic to the lb.; these pigments are used in sausages, anchovy preparations, and the like, without any steps being taken to secure their wholesomeness.

(11) In one instance *sheep wool grease* sold as "cocoa butter," and employed in sugar refining, contained about 1/16 grain of arsenic per lb., probably derived from arsenical sheep dip.

(12) Samples of brown "*Demerara*" *sugar* coming from the West Indies in certain instances have been found to contain small amounts of arsenic, 1/300th to 1/50th grain per lb.

(13) The British manufacturers of *maltine and malt preparations* visited were in each instance taking precautions to secure that the malt used was satisfactory as regards arsenic. Foods manufactured in America, which consist largely of malt, are coming into extensive use in this country. In the absence of more exact information as to American systems of maltings, and of analyses on a comprehensive scale, it is not possible to decide whether these foods are subject to any material risk of arsenical contamination.

(14) A food preparation consisting mainly of brewers' *yeast*, "Carnos," has been found to contain 1/6th grain of arsenic per lb., notwithstanding the precautions against arsenic adopted in its manufacture.

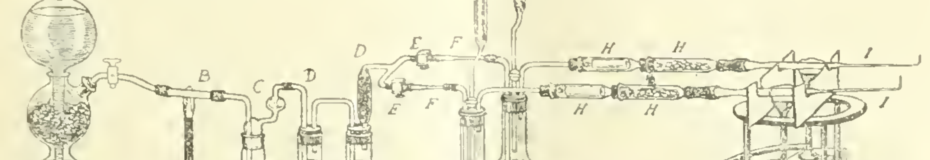
(15) *Chicory* may be dried by exposure of the roots to fumes of coke for several days. None of the few samples examined for arsenic has shown more than 1/100th grain of arsenic per lb. of chicory, but examination of a sufficient number of representative samples would be necessary before a satisfactory estimate of the degree of liability of chicory to contain arsenic can be obtained.

(16) *Hams, bloaters, coffee, lemon peel, &c.*, may be dried by exposure to the fumes of coke, but the degree to which these substances are likely to become contaminated by arsenic in this way is slight.

(17) Considerable daily doses of arsenic may be administered to *fowls* for several weeks or months without causing their flesh or livers to contain more than extremely minute quantities of arsenic.

It will be seen that the food and drink substances referred to in this report vary within wide limits in respect of their liability to contain arsenic. Of foods which are subject to risk of serious contamination the principal are those in which glucose is used, or which, like glucose, are prepared by the use of a relatively large quantity of sulphuric or hydrochloric acid. There can be no question of the necessity that stringent precautions as regards arsenic should be taken by manufacturers of foods of this class, and by persons using them in the preparation of other foods. In the case of certain other foods dealt with, the liability to contamination by arsenic is not so great, but it seems nevertheless important that precautions against arsenic should be taken by those manufacturing them; for example, foods made with glycerin; foods consisting largely of yeast; chicory; or West India sugars. In a third class of foods dealt with in the report, it may be urged that the liability to arsenical contamination, in the absence of all precaution, is so slight that there is no occasion at all for the question of arsenic to be considered by the manufacturer; or again, in the case of particular substances (anchovy sauce, for example), it may be claimed that precaution is unnecessary on account of the small quantities in which they are taken by the individual. But in the majority of cases it would seem a matter of little difficulty for the manufacturer of the substances here in question to secure that none of his ingredients, even if used in small amount, contains any noteworthy proportion of arsenic. A sugar refiner or mineral water maker, for example, might use phosphoric acid or phosphates containing relatively large amounts of arsenic without contaminating his finished product to a degree which could be considered objectionable. But as he can obtain these substances practically free from arsenic with little additional trouble or cost, it would seem more satisfactory that he should do so, and thus secure that his finished product was free from arsenic, in the sense that no arsenic would be detectable, by the Marsh-Berzelius test, in quantities of his product such as are usually taken for arsenic analysis; and if the small proportion of a given ingredient renders its content of arsenic of less moment to the consumer, it also renders insignificant the extra cost of arsenic-free material.

Dr. McGowan and Mr. R. S. Finlow examined most of the foods and materials used for the preparation of food collected by Mr. H. Hammond Smith for arsenical contamination. The results are contained in Appendix 25. The methods employed in the examination are described by Messrs. McGowan and Floris in Appendix 22. For the purification of hydrochloric acid Thomson's method (*British Food Journal*, October, 1902) was adopted, which consists of distilling hydrochloric acid of sp. gr. 1·1 with an excess of potassium dichromate. To work this process satisfactorily the acid in process of distillation must carry with it a continuous stream of chlorine. The bromine method put forward by the joint committee was not always successful in the hands of these chemists. A description is also given of the purification of sulphuric and nitric



A. Kipp apparatus.
B. Jena glass tube heated by Bunsen burner to effect partial purification of hydrogen from arseniuretted hydrogen.
C. Washing apparatus containing strong sulphuric acid.

G. Generating flasks connected to tubes packed with lead acetate paper and calcium chloride.

acids and other chemicals. The apparatus used for "Marshing" was a modification of that described by Scudder (Evidence, Vol. 1, Q. 4270).

The point which characterises this form of apparatus is that the greater part of the supply of hydrogen other than that required for the formation of arsenuretted hydrogen is derived from a source external to the "Marshing" flask. This is shown in Diagram 1. A disadvantage in the working of the apparatus appears to arise from a deposition of double mirrors, one in front of the other. When the standards are prepared in the same way as the mirrors in the actual determinations, the personal difference in reading the mirrors is practically negligible.

Method of Working the Apparatus.

The portion of the apparatus dealing with the purification of the Kipp hydrogen having been fitted up, and the hydrogen turned on, 3 grms. of zinc and about 30 c.c. of water are introduced into the generating flask. The complete apparatus, with the exception of the mirror tube, is now connected up, and the Kipp hydrogen allowed to flow through it for 10 minutes or so, at the rate of about four bubbles per second. The mirror tube is then attached, and the flow of hydrogen continued for another five minutes, after which the Bunsen burner under the mirror tube is lighted. If after a further period of 10 minutes the tube is still perfectly clean, the hydrogen is slowed down to the rate of about one bubble per second, the diluted acid (10 c.c. of 1 in 4 sulphuric acid, or 10 c.c. of hydrochloric acid of 1·1 sp. gr., as the case may be) run into the generating flask, and another "blank" of 10 minutes performed. Should there still be no sign of any deposit in the mirror tube, the solution to be tested is run into the generating flask, and the experiment continued for at least an hour longer, by which time the whole of the arsenic present will have been deposited in the mirror tube. The rate of flow of the Kipp hydrogen is now slightly quickened for a few minutes, and the mirror tube fused off and read against standards prepared in the same manner. The volume of liquid in the generating flask is always kept as uniform as possible, *i.e.*, at about 50 c.c., and if the flask should show any tendency to become warm it is immersed in cold water.

The materials examined were "Marshed" direct, or, after preliminary destruction of the organic matter by (1) the Fresenius-Babo method, with chlorate of potash and hydrochloric acid; (2) Gautier's method with nitric and sulphuric acids; (3) the Basic method of Ling and Newlands (*loc. cit.*).

The results are tabulated and particulars of each experiment recorded. The following substances were examined:—(1) Preparations of malt or food contained malt. Samples of "Carnos," which is a food prepared from yeast and extracted malt culms, contained quantities of arsenic varying from 1/6th to 1/25th grain per lb. (2) Meat and milk preparations were practically free. (3) Cereal preparations were free. (4) Demerara sugars. In one instance 1/400th grain per lb. was observed. (5) Prepared table salt; free. (6) Table syrups. A sample of Bostock's contained 1 gr. per lb. (7) Preservatives; a preparation known as Friziline contained 1/21th gr. per lb. (8) Baking powders; two samples contained 1/60th and 1/5th gr. per lb. respectively. (9) Powders for beverages containing citric or tartaric acid were free. (10) Gelatins; one sample contained 1/140th gr. per lb. (11) Vegetables; one sample of potato skins contained 1/353th gr. per lb. (12) A sweetening substance described as Porcherine contained 1/260th gr. per lb. (13) Liquorice; the samples examined contained amounts of arsenic varying between 1/130th and 1/780th gr. per lb. (14) Colouring matters; ten samples were examined; all contained arsenic in quantities varying between 1/130th and 9/10th gr. per lb. (15) Smoked and dried food. Of the 22 foods examined, comprising such foods as chicory, coffee, lemon peel, ham, bloaters, and smoked herrings, two were free of arsenic, the remainder contained from a trace to 1/140th gr. per lb. (16) Gooseberries watered with Paris green. The samples of fruit contained 1/20th to 1/60th gr. of arsenic per lb. (17) Fowls to which arsenic had been administered. The flesh and organs contained from 1/600th to 1/200th gr. per lb., the feathers from 1/5th to 2/5ths gr. per lb. (18) Cigarette papers with metalled tips. Seven samples contained from 1/200 to 4 gr. per lb. (19) Parchment paper manufactured with sulphuric acid used for wrapping food in was free. (20) Sulphuric acid. (*a*) Not dearsenicated contained $10\frac{1}{3}$ gr. per lb. (*b*) Dearsenicated, free. (21) A sample of water-softening powder contained 1/40th gr. per lb.

Arsenic was formerly used as an ingredient of the enamel of various cooking utensils, and an investigation carried out by Dr. McGowan in which he employed saucepans lined with a specially made enamel containing arsenic, shows that liquids boiled in such utensils may take up considerable quantities of arsenic. A number of specimens of saucepans and enamelled hollow-ware ordinarily met with did not contain arsenic as an ingredient of the enamel.

Principal Ingredients of Food, or Substances used in Food Preparation, which are liable to contain Arsenic.

Sulphuric Acid.—This is the most important of the substances to be considered, for it is used sometimes in large amounts in the preparation of a variety of foods. Most of the acid used in this country is obtained by roasting pyrites ores. Such ores contain large proportions of arsenic, and unless the acid is submitted to a dearsenication process it will be arsenical. The sulphuric acid (B.O V.) supplied in 1900 by Messrs. Nicholson and Sons to Messrs. Bostock and Co. was contaminated to an unusual extent, as much as 1·45 to 1·9 per cent. of arsenious acid being present. The evidence of many witnesses proved that dearsenicated acid can be easily produced. The difference in price between arsenical and non-arsenical sulphuric acid is so small that it can seldom be of material account to the food manufacturer. Sulphuric acid prepared from brimstone, recovered sulphur, and spent oxide, is not usually submitted to a dearsenication process, as the probability of arsenical contamination is remote. The Commissioners very properly point out that such acids should not be assumed without analysis to be free from arsenic.

Hydrochloric Acid.—Commercial acid frequently contains arsenic derived from the use of arsenical sulphuric acid in its manufacture. Hydrochloric acid is less easy to obtain free of arsenic than sulphuric acid. The liability of hydrochloric acid to be arsenical is small when the acid is obtained by "cylinder" or other processes in which care is taken to use sulphuric acid free of arsenic.

Glucose.—Solid and liquid glucose and invert sugar are liable to obtain arsenic derived from sulphuric or hydrochloric acid used in the conversion process. Bostock's glucose manufactured in 1900 contained as much as 3 grs. of arsenic per lb. Glucose manufacturers were well aware of the necessity of guarding against arsenic before the scare in 1900, and there appears to be no difficulty in producing glucose free from arsenic. It is striking that the material which was the direct cause of the outbreak of arsenical poisoning should, with the single exception of Bostock's preparation, be so generally free from arsenic.

Glycerin.—This substance, which is prepared by distillation of the crude glycerin derived from soapmakers' lyes, may contain considerable amounts of arsenic derived for the most part from hydrochloric acid used in the manufacture of the crude product.

The evidence of Messrs. Moore, Marshall, Campbell, Brown, and Fairley showed that glycerin supplied for pharmaceutical and domestic purposes is sometimes heavily contaminated with arsenic.

Cases were cited where samples of glycerin appeared to be free of arsenic by the Gutzeit test, as directed by the British Pharmacopœia, yet, when examined by the Marsh-Berzelius method, were found to contain appreciable quantities, in one instance as much as 1/13th gr. per lb. The sufficiency of the official test is now under the consideration of the Pharmacopœial Committee of the General Medical Council.

Caramel.—This material is used to colour and flavour a large number of foods, including beer. Considerable quantities of arsenic have been found in caramels, and its presence was probably due to impure alkaline carbonates used in the manufacture. Commercial caramel free from arsenic can be readily obtained.

It is striking to note how much the purity of these and other materials has improved in respect to arsenic since the outbreak of arsenical poisoning in 1900.

A very important section of the report has now to be considered, namely, the question of the contamination of malt by arsenic. This contamination was recognised after the cause of the 1900 epidemic had been ascertained. Beers brewed with an all malt grist were found to contain considerable quantities of arsenic, which was ultimately traced to the malt. This matter has received close attention at the hands of brewers and maltsters, and, from the evidence brought forward, the Commissioners say that it is now commercially practicable to produce malt which either may be considered free from arsenic, or in which the amount of arsenic is less than 1/250th grain per lb., and they further point out that most of the malt prepared during the past two years has been of this character.

The coal or coke used for drying and kilning malt always contains arsenic. When the fuel is burnt in an ordinary malt kiln part of the arsenic is volatilised, and much of the arsenious oxide which is formed becomes condensed in different parts of the kiln and in the malt. Part of the arsenic remains behind in the ash in combination (as arseniate) with basic matter contained in the fuel. Some of this ash, carried up by a strong draught, may become deposited in the malt, and so add to the quantity of arsenic which the latter contains.

The evidence of Mr. Ling in showing how malt may be contaminated with arsenic in a malt kiln and the distribution of such contamination is interesting, and also of importance, in view of the fact that there is little likelihood of any radical alterations being made in existing kilns. In such cases it is obvious that freedom from arsenic can only be attained by exercising strict supervision over the fuel used and the cleanliness of the maltings. Several witnesses showed that sweepings from the inner walls, girders, dispersing plates, and other parts of malt kilns have been found to contain large quantities of arsenic. The liability of malt to become arsenical is greatly increased when such dust is allowed to accumulate on any of these surfaces, either above or below the malt floor. It is most important that the interior of kilns should be thoroughly cleansed, not only at the beginning of the season but at frequent intervals during the season. So marked is the increase of small quantities of arsenic in malt towards the middle and end of the malting year that I have advised the maltings with which I am connected to thoroughly and frequently brush out the kilns, treat them with a lime wash, and leave them at least two days before firing again, so that the dust may settle. It has been amply proved that all malting fuel contains arsenic, and it would appear that as the season progresses the walls of the kiln do not absorb arsenic to the same extent as in the beginning of the season, so that more arsenic passes into the malt, and the successive products from such a kiln show increasing amounts of arsenic. As soon as a kiln is efficiently cleaned, and if the anthracite is of normal quality, the malts show no traces of arsenic.

The Commission discuss the question of drying and curing malt without access of the products of combustion, and point out that sufficient evidence has not been adduced in favour of the general belief that it is essential that the products of combustion should pass through the malt in order that it may possess a flavour which is necessary for beer. Methods of drying and curing malt without the presence of the fumes from the fire require to be tried on a considerable working scale at English maltings before sufficient experience can be gained of their advantages or disadvantages from the point of view of the cost involved, and of the extent to which they meet the requirements of the brewer and the demands of the public taste. With regard, however, to the absolute exclusion of arsenic and consequent freedom in the choice of fuel, the advantage is unquestionable. The Commissioners express the opinion that processes of malting without the products of combustion should in future receive careful consideration from brewers and maltsters who are about to erect new malt kilns.

As the Commissioners were clearly not warranted in suggesting that malt kilns should be structurally altered so that arsenical contamination could be avoided, suggestions were put forward whereby arsenic could be prevented from passing with the other products of combustion to the malt. These methods involved the treatment of fuel before firing or of passing the products of combustion through a suitable filtering medium. In the course of their examination Messrs. Ling and Beavan described in some detail processes for attaining this object. Mr. Ling described Mr. Newlands' (this Journal, 1901, 736) method, which consists in intimately mixing the fuel with milk of lime before putting on the kiln fire. Mr. Beavan (this Journal, 1902, 182, 268) described an arrangement by which lumps of limestone are placed at the outlet of the kiln furnace. He claims that the fumes from the fire in passing over the surfaces of heated lime lose practically all the arsenic they contain. Figures were given by these witnesses in support of their statements.

When the very varied construction of malt kilns is considered it is evident that some kilns have a greater risk of arsenical contamination than others. In old-fashioned kilns, which are still in use in some of our malting centres, the kiln floor is only a few feet above the fire. Arsenical contamination is easy to conceive in such cases. On the other hand, in recently constructed maltings the products of combustion have to pass up a long shaft and traverse baffle plates before they reach the malt, so that the arsenic in the fumes has a greater chance of being deposited. In daily practice it is usual to find that the proportion of traces of arsenic in malts is higher when they are cured in a low kiln.

Much has been said about removing arsenic by screening and brushing malt. All malt is screened before it leaves the maltings and again before it is ground in the brewery. By the process of screening the rootlets or culms are separated and a certain amount of arsenic which may have been deposited is removed. The evidence showed that the rootlets of malt contain more arsenic than the malt, and this is not to be wondered at when the bulky nature of the rootlet is considered. A number of determinations which have been made in my laboratory show that the culms or rootlets roughly contain twice as much arsenic as the malt itself. This point has been recognised by the Commission, for they advise that screening should be thoroughly carried out. The brushing of malt is also of value in removing a considerable proportion of arsenic from malt, especially when the brushing is repeated several times. Messrs. C. Brown and Stopes contend that the arsenic in a relatively high arsenical malt was completely removed after the malt had been brushed three times. Mr. T. Earp on the other hand said that arsenic cannot be altogether removed by brushing. Laboratory experience tends to support Mr. Earp's statement. Brushing will remove comparatively large quantities of arsenic from highly arsenical malts, but malts on the border line of danger, containing such quantities as 1/200th grain per lb. and less, appear to be unaffected or very slightly so. The completeness with which brushing removes the arsenic from malt no doubt depends upon the conditions under which contamination occurred. If malt is dried and cured with an arsenical fuel most of the arsenic is deposited on the outside of the corn, but owing to the porosity of the external covering of the malt, a portion of the arsenic is absorbed internally, and no amount of brushing will remove it.

The Commissioners consider that the brushing machinery which is in use at good maltings and breweries is capable of removing a considerable proportion of the arsenic from arsenical malt. It is however obviously preferable to take steps to prevent the access of arsenic to malt, rather than to rely on any subsequent process for removing arsenic after it is deposited on the grain.

Selection of Fuel.—This matter has been fully gone into by the Commission and the result of the inquiry should be of considerable value to colliery owners and masters.

Up to 1901 oven coke and gas coke were often the principal fuels used in Yorkshire and Midland maltings: this was doubtless partly due to the local abundance of coke and the remoteness of the anthracite collieries. When it was recognised that arsenical malts were generally those which had been dried over gas coke, whereas anthracite dried malts were usually free of arsenic, the use of coke was practically discontinued.

At the commencement of the enquiry few examinations of anthracite with regard to arsenic had been made, and satisfactory methods of estimating small quantities of arsenic in fuel were unknown. In Appendix 30 will be found a series of reports relating to arsenic in anthracite obtained from South Wales. Mr. Strahan of the Geological Survey investigated the appearance and geological correspondence of the seams of anthracite worked at various collieries visited in respect of the removal of the impurities from the coal which they supply to maltsters

From these collieries a large number of samples were carefully collected for the Commission by Mr. S. W. Price, and tested for arsenic by Dr. McGowan, by means of a method devised by himself and Mr. Floris. It is essentially a modification of Ling and Newlands' method (*loc. cit.*). It was found that the whole of the arsenic could not always be estimated when the residue after ignition with or without lime was dissolved in hydrochloric acid and "Marshed" directly. The "non-volatile" arsenic was in several cases in excess of the total arsenic, and this contradictory result was most marked when the residue was rich in iron, the latter thus appearing to be the disturbing factor in the analysis. To overcome this difficulty, these chemists devised the following process.

For the determination of "total arsenic" a weighed quantity of the finely powdered coal, from 1 to 10 grms., is mixed with 3 grms. of arsenic-free lime and ignited in a platinum basin at a bright red heat over a strong Bunsen flame, until the ash shows only the red-brown colour of oxide of iron and there are no obvious black specks left in it; this usually takes about three hours. After cooling, the residue is cautiously slaked with water and treated with about 5 c.c. of dilute arsenic-free nitric acid (1 in 10), dried on the water bath, and re-ignited for a short time to decompose any nitrate that has been formed. The entire mass is now dissolved in excess of arsenic-free hydrochloric acid (the excess amounting to about 10 c.c. of 20 per cent. acid) the solution diluted with water, and gently warmed for some time. It is then filtered, the iron and arsenic in the filtrate reduced with excess of aqueous sulphurous acid, and the excess of the latter evaporated or boiled off very gently. After this sulphuretted hydrogen is passed to saturation through the cold liquid, which has a volume of about 70 c.c., and is contained in a small conical flask of Jena glass of 100 c.c. capacity; the flask is then tightly corked, allowed to stand until the precipitate has settled, and if not still smelling strongly of sulphuretted hydrogen, it is re-saturated from time to time.

The precipitate is then filtered through asbestos in a small Gooch crucible, and washed first with sulphuretted hydrogen water until free from chlorides, and then in succession with alcohol, carbon bisulphide and alcohol again. The entire contents of the "Gooch" are now transferred to a small porcelain basin and extracted three times with about 5 c.c. of dilute aqueous ammonia (1 in 4), the extract being of course, filtered from the insoluble matter each time.

The entire filtrate and washings are then evaporated to dryness on the water-bath, and the residue so obtained treated three times with a very little concentrated arsenic-free nitric acid (about 1 c.c. at the time), the contents of the basin being brought down to dryness after each addition of acid. The last-mentioned residue is finally extracted three times with a few c.c.'s of dilute aqueous ammonium carbonate (1 in 10), the extract being if necessary filtered; the ammonia is then got rid of on the water bath and the arsenic in the liquid reduced with excess of aqueous sulphurous acid, the excess of the latter being evaporated off as before. This final solution is then made up to a given volume, and a suitable portion, usually one-half, is Marshed with 3 grms. of zinc and 2·5 c.c. of sulphuric acid (previously diluted), the total volume of liquid in the "Marshing" flask not exceeding, as a rule, 10 to 50 c.c.

Non-Volatile or "Fixed" Arsenic.

For the estimation of "non-volatile arsenic" an exactly similar procedure is adopted, excepting that the ignition is done without lime.

The sample was prepared for analysis in the following way:—

The entire sample was roughly broken with a hammer, mixed, and halved; one-half of this is again broken, mixed, and halved, and the process is again repeated a third time, Of this last sample one-half or one-quarter is broken up with a hammer between shafts of glazed brown paper on a wooden block, until no pieces are left of larger diameter than about ¼-inch; it is then carefully and successively mixed and halved until only about 50 grms. remain. From this final sample the amount required for the analysis is ground in Wedgwood mortars to an almost impalpable powder. The inside of the bottles in which the final sample is kept should be examined carefully, in order to ensure that there are no loosely adherent flakes of glass.

In August 1901 Mr. Hammond Smith visited four typical maltings, and found that the anthracite used was obtained from different collieries. He refers to the heating power and flavouring properties which appear to influence maltsters in the selection of particular collieries.

All anthracite supplied was understood to be hand-picked at the colliery in order to remove impurities, but impure coal and pyrites were sometimes met with in the fuel delivered. Two maltsters had caused some analyses of anthracite for arsenic to be made, but there had been no question at any of the maltings of purchasing anthracite under guarantee as to arsenic. No weight was attached by the maltsters to copies of analyses which they received from colliery companies showing that anthracite samples had been found free from arsenic.

From Mr. Strahan's report it appears that the great bulk of the anthracite used by English maltsters is derived from a limited portion of the South Wales coalfield contained in an area of 25 miles by 4. To the north it is limited by the outcrop of the coal measure; to the south, where the seams descend to a great depth, their limits have not been ascertained, but there is reason to believe that they gradually lose their anthracite character. Ten collieries were visited, and each supplied anthracite for malting purposes. Five seams were worked for malting, and the greater part of the coal is got from one seam which is generally known in the different collieries as the *Stanllyd*, the *Big*, or the *Nine-feet* vein. This seam is stated to be superior to the others in calorific power and purity. The seams crop up and are worked near the surface and at great depths below it; thus, the term "deep," which is applied to some of them in the trade, has therefore no significance.

Mr. Strahan shows in a series of tables the different seams met with at the several collieries visited, and the names under which they are known, also the distribution of visible yellow or black pyrites in the different seams. Another table describes the seams in detail and shows partings other than those of pyrites. In certain seams no visible iron pyrites occurs, in others it is visible in greater or less abundance. It occurs in lumps of thin impersistent bands and takes one or two forms, namely, that characteristic of yellow pyrites, or that of black material consisting largely of coal, but containing sulphide of iron in a form not distinguishable by the eye.

Seams of anthracite are usually "solid," consisting of coal from top to bottom without any partings of clay or stone. Certain seams have impurities other than pyrites which consist of impure coal and black stone.

The third point which Mr. Strahan investigated was the different methods in use of freeing anthracite from impurities. From a consideration of these it is plain that genuine efforts are made by the collieries to supply anthracite as pure as possible to the maltster.

The same method is in use at all the collieries, with slight differences in detail. The miner is supposed to pick out all visible pyrites, fragments of shale, &c.; but from the conditions under which he works he is unable to do so completely. The coal on reaching the top of the pit is tipped into an iron shoot, down which it passes with a rapidity which can generally be regulated. One or more men are stationed by the side of the shoot whose business it is to pick out pyrites or impure coal. The coal then passes over two or more screens, in the last of which the bars are placed at distances apart varying from two to eight inches at different collieries. The small coal falls through, and large lumps only pass on to the truck for the maltster. In this truck two or more men are stationed whose business it is to arrange the coal and throw out any impurities that have passed the men on the screens.

At all collieries it is stated that a special screen is kept for the malting coal, and that all screening is done in daylight. As a rule no alteration has been made in the system in consequence of the demand for arsenic-free fuel, but in one or two cases the picking is done more carefully than it used to be.

Large lumps of coal in which no pyrites is visible are not broken, it being considered that pyrites, if it existed in them, would always show itself on their surface. Lumps in which pyrites shows itself are broken, and the coal generally put back upon the screen.

All the impurities picked out are thrown on the rubbish heap, except a certain form of bright coal associated with pyrites, which is used locally as a house coal.

Samples of anthracite from the different collieries were collected by Mr. Price and examined by Dr. McGowan. The results are contained in a series of tables of which the following is a brief extract:—

(1) *Anthracite from Seams used for Malting.*—Twenty-two samples of this class were examined, each representing the whole thickness of a seam used for malting exclusive of visible impurities: 19 contained from 0—10 parts per million and 3 from 10—20 parts.

(2) *Anthracite as consigned to Maltsters.*—The 12 samples examined represented a large bulk which was indicated by the colliery proprietors as satisfactory malting anthracite. They contained from 0—10 parts of total arsenic per million. Mr. Ling stated in his evidence that he examined 21 samples, 17 of which contained from 0—10 parts, 3 from 10—20 parts, and 1, from 20—30 parts per million of total arsenic These figures are interesting when compared with the arsenic found in gas and oven coke.

——	—	Gas Coke.	Oven Coke.
0—10 parts per million { 0— 5 parts 0 5—10 ,, 5 }	5	0	5
10—20 ,, ,, ...	3	1	2
20—30 ,, ,, ...	4	4	0
30—40 ,, ,, ...	0	0	0
Over 40 ,, ,, ...	4	0	4
	16	5	11

Dr. McGowan, in 1903, analysed four samples of coke taken from a certain Yorkshire gas-works which formerly supplied maltsters, and other four samples of oven coke, taken from bulk at a Midland ironworks, with the following results:—

——	—	Gas Coke.	Oven Coke.
0—10 parts per million { 0— 5 parts 0 5—10 ,, 2 }	2	0	2
10—20 ,, ,, ...	1	0	1
20—30 ,, ,, ...	1	0	1
30—40 ,, ,, ...	1	1	0
Over 40 ,, ,, ...	3	3	0
	8	4	4

Taking into consideration the number and diverse origins of the various samples of "clean" anthracite examined for the Commission and the care taken to see that they were representative, it may be concluded that the results above summarised give a fair indication of the ordinary limits within which the small amounts of arsenic found in "clean" anthracite from South Wales collieries may vary. Some samples contain much more arsenic than others, but the variations are within much narrower limits than is the case with gas cokes or oven cokes of the kind which are, or have been, used habitually by maltsters It is evident that some oven cokes may contain quite small proportions of arsenic, and it is likely that many gas cokes would show much less arsenic than the Yorkshire samples above referred to. But it may be concluded the clean South Wales anthracites, as a class, are much purer as regards arsenic than either of these kinds of coke.

Impurities of Anthracite with respect to Arsenic:—

(*a*) Definite hard masses or nodules consisting of pyrites contained from 1,300 to 93 parts per million of total arsenic. Hard black nodules locally termed pyrites but showing no yellow pyrites contained comparatively small quantities of arsenic, varying from 2·5 to 10 parts of total arsenic per million.

(*b*) Granular black bands, which consist of black "pyrites" mixed with various amounts of coal, contained from 15·3 to 200 parts of total arsenic per million.

(*c*) Bands of impure coal consisting largely of shale. The samples examined contained from 6·4 to 2·80 parts of total arsenic per million.

(*d*) "Inferior coal" separated by partings from the rest of the thickness of the vein showed in most cases more arsenic than the better coal of the same vein.

The volatile arsenic was also estimated in all the samples examined; in anthracite, and also in coke, no constant ratio between fixed and volatile arsenic appears to exist. The proportion of arsenic volatilised under experimental conditions of combustion is less in cokes than in anthracites. It is pointed out that the evidence is not sufficient to determine the extent to which particular processes of estimating "volatile" arsenic in the laboratory can be relied upon to determine the proportion of arsenic which will become volatilised when the fuel is burnt, under varying conditions, on the fire of the malt kiln.

Dr. Buchanan discusses the bearing of the results on the selection of malting anthracite by colliery owners and by maltsters in the following terms:—

"The results show the extreme importance of careful exclusion, in the mine or on the surface, of all impurities which may be present in the veins worked for malting, and the need for constant supervision and watchfulness on the part of the colliery owner to ensure that his men carry this out properly and thoroughly, so that only 'clean' anthracite is supplied to maltsters. It is essential to remove not only nodules of pyrites, lumps in which pyrites and coal are mingled, and bands of slate or shale attached to or passing through lumps of coal, but also any obvious granular 'black' pyrites. In a seam where such granular black pyrites is present as a definite layer traversing the vein at a particular level, it can be more readily eliminated than where the pyritous portions are distributed irregularly throughout the vein. In one colliery a system exists by which all pieces of anthracite in which the band is represented are rejected.

"It is also essential that maltsters should systematically keep a strict watch on the anthracite supplied to them with the view of detecting and discarding impurities of the kinds above mentioned.

"It is important that 'clean' anthracite, as supplied to maltsters, should from time to time be sampled for the colliery owner, and that the quantity of arsenic contained in it should be estimated and compared with all available data. For this purpose a thorough and accurate method of obtaining a fair sample is essential. This point cannot be too strongly emphasised. The analyses desired are for the information and guidance of the colliery, and not for the purpose of obtaining a favourable report on specially selected samples for exhibition to maltsters.

"Where more than one seam of anthracite is worked at a colliery, advantage may be gained by analyses of the seams separately, together with associated impurities. For example, at a colliery four seams are worked for malting coal, the 'Big,' 'Green,' 'Gras Uchaf,' and 'Pump Quart' veins respectively. The samples from the last two, which are 'solid,' and have practically no impurities to be removed, and also the sample from the Big Vein, in which the impurities consist of large and easily-removed lumps of yellow pyrites, contained in each instance less arsenic than samples of 'clean' anthracite taken from the 'Green' Vein. This Green Vein also was found to have a band of impure top coal which showed 280 parts of arsenic per million. So far as arsenic is concerned, therefore, it would seem better not to work such a vein as the last-named for the supply of malting fuel.

"When colliery owners run short of malting anthracite, they occasionally fulfil their orders by arrangements with owners of other collieries, and this of course is the regular practice of agents and middlemen in similar circumstances. Where this is done it would seem important that the person or firm who has undertaken to supply the maltster should inform him that the source of supply has been changed, and should ascertain that the new supply is satisfactory as regards removal of impurities.

"The exceptional result obtained in the case of anthracite from a colliery outside the anthracite area shows that it is desirable that the maltster, besides taking steps to obtain a supply of anthracite that is 'clean' and apparently free from visible impurities, should also take the precaution of occasionally submitting samples to the analyst. This seems especially important when the supply is obtained from a new colliery, or when the maltster receives anthracite of a different character from that to which he has been accustomed."

In a short note which immediately follows this communication, my colleague, Mr. W. D. Dick, and myself have endeavoured to show that the practice of adding sulphur to the kiln fire may result in the malt becoming contaminated with arsenic. Experimental evidence is adduced proving that when arsenical fuels are burnt in presence of sulphur a considerable amount of the fixed arsenic is rendered volatile, due no doubt to the reducing action of the sulphur on the kiln fire.

The Commissioners report in the following terms on hops:—

"Hops are exposed to the products of combustion of fuel during their drying on the kiln, and it has also been suggested that they may become contaminated through the use of impure sulphur (on the kiln or as an insecticide) and possibly in other ways.

"It is the practice of hop dryers to employ anthracite, and not coke, for burning in the kiln, and if suitable care is exercised in the selection of fuel the risk of hops becoming contaminated is evidently small. The quantities of arsenic which have been reported to us as having been detected in hops have in all cases been minute."

I venture to think that the evidence offered to the Commission on this point was somewhat meagre. Thus Messrs. Niven, Salamon, and A. K. Miller, say that they found small quantities. Mr. Berry said that contamination was not possible in growing hops on a large scale, but admitted the risk if improper fuel were used. Mr. C. O. Sullivan admits the possibility, but points out that owing to the proportion of hops used the risk would be infinitesimal. Dr. Thorpe reported on seven samples; one was free from arsenic. The maximum amount found was 1/100th gr per lb. Mr. Thomson found 1/80th to 1/100th per lb. The expert Committee examined 11 samples of hops and found them free, but recognised that hops might contain arsenic.

My own experience has not been so fortunate, for in many instances I have found that hops sometimes contain relatively large quantities of arsenic. Of 12 samples examined in February 1901, four were free of arsenic, the remainder containing from 1/100th to 3/16th gr. per lb. of arsenious acid. Many samples now contain 1/50th to 1/100th gr. per lb. It is probable that many hops at present in use would be condemned by the Inland Revenue officials.

Finished Foods which are liable to Arsenical Contamination.—Since the 1900 epidemic close attention has been given by brewers to the exclusion of arsenic from glucose, invert sugar, malt, and other materials used in brewing. In spite of such precautions contaminated beer is occasionally met with, for example the Halifax case. Such instances may now, however, be considered unusual. The Commissioners are satisfied that most of the beer made in this country may be regarded as free from arsenic, and that where detected it is usually in minute amount. It has been agreed that it is commercially practicable to produce beer which uniformly shows less than 1/100th gr. of arsenic per gallon, and in which as a rule any arsenic present is in much smaller proportion than this.

Contamination of Cereals or Roots grown on Arsenical Soil.—This probability was investigated by Dr. J. A. Voelcker. Experiments were carried out in which barley and swedes were grown on plots which were manured with superphosphate containing no arsenic, with superphosphates containing various known proportions of arsenic, and left unmanured. The results were practically negative. Very small quantities of arsenic were found in the barley straw and leaves of the swedes, but no arsenic was detected in the grain or bulbs of the swedes. Mr. A. Angell failed to detect arsenic in the ripe grain or in the fruit or seed of any of the plants grown on soil containing arsenical superphosphate.

PART 5.

Precautions which should be taken by Manufacturers to exclude Arsenic from Foods.

The Commissioners state at some length what they consider the duty of the manufacturer of foods or food ingredients when liability to arsenical contamination arises. Thus, manufacturers of sulphuric acid, phosphoric acid, glycerin, glucose, invert sugar, caramel, and malt are advised to take steps to obtain uniformly degrees of purity which are at present commercially attainable, and that they should always be alive to improvements which tend to eliminate even traces of arsenic. Moreover, it is essential that manufacturers of the above substances and also of other ingredients of food which are liable to arsenical contamination should frequently test their products for arsenic, and should keep for their own guidance a systematic record of the results of the testing. It is advised that the estimations should be made by comparison of mirrors, obtained by the zinc and acid method, or electrolitically.

It is regarded as essential that any guarantee as to arsenic supplied by the manufacturer as an ingredient of food should be given with full knowledge of the amount of arsenic which, if present, would be detected by the tests which he employs, and of the significance in terms of approximate quantity of any minute proportions of arsenic which he cannot be certain of excluding by the precautions which he adopts. A manufacturer may give a guarantee as to freedom from arsenic, even if it contains a minute trace of arsenic (for example, 1/500 grain per lb. in glucose or malt), provided that he can state a definite proportion of arsenic which his product does not contain, and that he endeavours to keep out arsenic altogether irrespective of the guaranteed limit.

The Commissioners are of opinion that no substance should be used as an ingredient of food which contains more than 1/100 gr. per lb. of arsenic, or in the case of solution of 1/100 gr. per gal. In many cases, more particularly glucose and malt, much smaller quantities than these are now commercially attainable, and should be insisted on. This is one of the most important paragraphs in the report, for the manufacturer may reasonably conclude that the allowable limit of arsenical contamination in an ingredient of food is 1/100 gr. per lb. or gal. respectively. It was naturally foreseen that 1/100 gr. of arsenic per lb. could not be allowed in the case of glucose or malt, for this amount would mean considerably more than 1/100 gr. of arsenic per gal. in the beer. It is, perhaps, a little unfortunate that the last sentence in the paragraph referred to could not have been strengthened, and the fact emphasised that 1/100 gr. of arsenic in malt is not an allowable quantity.

The Commissioners regard it as important that guarantees as regards arsenic should not be given unless tests are applied systematically and with sufficient frequency. The giving of guarantees should not be allowed to degenerate into a perfunctory routine.

The Commissioners and many of the witnesses are of the strong opinion that the value of guarantees as to freedom of arsenic in ingredients of food and substances used in the preparation of food would be increased if such guarantees were given on a uniform basis with reference to official "standards" which should define for particular substances the amount of arsenic determined by a definite test which should be regarded as inadmissible. The Commissioners state that such standards are needed by manufacturers and the users of food ingredients.

The application of the Sale of Food and Drugs Act to prevention of the contamination of foods by deleterious substances is materially hindered by want of an official authority with the duty of dealing with the various medical, chemical, and technical questions involved. At the present time there is no authority to define impurities or adulterations which should be specifically looked for in the course of examination of particular foods submitted for analysis under these Acts, or to lay down official standards respecting the nature and extent of impurity or adulteration on a given food which, without question, should render its vendor or warrantor liable to proceedings under the Acts. In the case of foods liable to contain arsenic these drawbacks have been amply illustrated. The witnesses have been practically unanimous in urging on the Commission the need for such official standards, and their imposition is considered essential to the successful use of the Sale of Food and Drugs Act to prevent arsenical contamination. The powers of seizure given to the Medical Officer of Health or Inspector of Nuisances in districts where Part II. of the Public Health Amendment Act, 1890, has been adopted, is not capable of satisfactory application where the proof that the article is deleterious is dependent on chemical analysis, particularly as the official would have no power to lay an embargo on the sale of a suspected article pending its chemical examination. The Commission expresses the opinion that the powers which medical officers of health possess under the Public Health Acts to obtain the condemnation of unsound or unwholesome articles of food should be extended, and that they should be able, subject to proper restrictions, to lay an embargo on the sale of the suspected articles or on the use of the suspected ingredients pending their official examination.

It is advised that dealers or middlemen selling to food manufacturers should ascertain from the maker of the food ingredients that the article to be supplied is suitable for food purposes. Attention is also drawn to the too prevalent custom of selling chemical substances to food manufacturers under misleading or ambiguous trade names.

The Commissioners suggest that mineral and coal tar colour makers should prevent colours being supplied for food purposes, for, apart from the possibility of being contaminated with arsenic, they are generally used for undesirable purposes. The use of chloride of tin for producing a bloom on West Indian sugars is also condemned.

Finished Food liable to contain Arsenic.—The manufacturer who uses substances liable to contain arsenic in the preparation of the food which he supplies to the public can guard against arsenical contamination (1) by obtaining adequate assurance from the vendor that the ingredients which he purchases are satisfactory in respect of arsenic, and by taking care that their intended use for food purposes is known to the vendor; (2) by testing the ingredients which he purchases or prepares.

PART 6.
