Present Means of Official Control over Purity of Food in relation to Arsenic.

Under this heading the Commissioners summarise the effect of the evidence regarding the means of official control over the purity of food.

(1) *Control over the Manufacture of Food or of Food Ingredients.*—The existing Acts provide little, if any, official control over the proceedings of manufacturers of food or of food ingredients, and control can only be exercised when the manufacture of the food is completed and it is on sale to the public. The powers of the entry of Government officials into factories for specified purposes is discussed. With regard to dutiable articles, various powers of inspection or sampling are conferred upon Revenue officers. The object with which these powers have been granted has been the protection of the Revenue and not that of the public. Under the Customs and Revenue Act of 1888 the Treasury has power to prohibit the use of any substance or liquor of a noxious or detrimental nature in the manufacture or preparation for sale of any article of "excise." In October 1901 this power was used in respect of glucose and invert sugar containing arsenic. Since the issue of the order the Board of Inland Revenue has had numerous samples of various brewing materials examined, and in some instances brewers have been warned when malt or other ingredients were found to be seriously contaminated with arsenic. In the case of substances submitted for sanction as additions to beer, the Inland Revenue have the power of vetoing their use if they are considered undesirable or contaminated with arsenic. It follows, therefore, that so far as beer and dutiable articles are concerned the public can be protected from arsenical contamination.

The Commissioners point out that the evidence received from various official witnesses shows that the Sale of Food and Drugs Act, as at present interpreted and administered, is unsatisfactory for the purpose of protecting the consumer against arsenic or other deleterious substances in food for the following reasons:—

(1) *Prosecution of Retailer.*—In most cases prosecutions must be directed, not against the manufacturer, importer, or middleman, but against the retailer, who in the majority of cases has had nothing to do with the contamination, and is seldom in a position to ascertain that it exists. The retailer may be defended by the manufacturer, but the retailer is liable to be prejudiced in the eyes of his customer, and the evidence brought forward on this point shows that the authorities are often reluctant to institute proceedings in these circumstances against a person whom they do not regard as culpable. The question of warranty and its weak points is discussed.

The Food and Drugs Acts are generally intended to deal with certain well-known forms of fraudulent adulteration, and the officers who collect samples direct their attention to such cases. They have very little expert advice or direction which enables them to know what samples should be obtained as a control against substances injurious to health, or in what number they should be taken. Public analysts receive samples in order to report upon their "genuineness;" it is no part of their official duty to advise as to the nature and number of the samples which should be taken, and, usually, their authorities do not invite their co-operation in the matter.

The absence of official standards is referred to, and as mentioned before the Commissioners consider their imposition essential to the successful use of the Food and Drugs Acts, to prevent arsenical contamination.

PART 7.

Recommendations as to Improvements in Official Control over the Purity of Food.

The Commissioners consider that the control which can be at present exercised is unsatisfactory when applied to the prevention of risk of contamination of foods by arsenic; and, further, that serious defects exist in the machinery available to safeguard the public against the introduction of poisonous, deleterious, or valueless substances in general, into articles of food. In making the recommendations the Commissioners have regard to the broader issues concerned, and not merely to arsenic.

They point out:—

(1) The necessity for more extended administration by the Local Government Board. The work of local authorities should be co-ordinated, and they should have advice as to the way in which the Acts may best be applied to secure the purity of food. The Local Government Board should undertake further duties of supervision and watchfulness in relation to the purity of foods and the administration of the Acts bearing on the subject. The Board should also have the advice of a special officer with suitable scientific

knowledge, who should be in relation with the Government laboratory, and have adequate laboratory assistance.

(2) Necessity for official standards: board of reference.

The Local Government Board should be the authority to prescribe and from time to time vary standards for the purpose of the Sale of Foods and Drugs Acts. Similar recommendations were made by the Committee on Food Products Adulteration and the Committee on Preservatives and Colouring Matters in Foods. Like these committees the Commissioners advise that any action taken by the Local Government Board should be based on the scientific advice tendered by a board of reference. This board should not be administrative, but consultative. The standards for ingredients and substances used in the preparation of food is also dealt with, and there should be no difficulty in arriving at standards which will be of assistance to the manufacturer in preparing substances used in food preparation. The control over arsenical contamination recently exercised in breweries by the Board of Inland Revenue should be continued, and this control should facilitate the general adoption of official standards which may in future be prescribed in respect of arsenic in beer ingredients.

The Commissioners advise the following amendment of the Sale of Food and Drugs Act:—

If, in a prosecution instituted under the Sale of Food and Drugs Acts, it is alleged by defendant A that the article was sold in the condition in which it was supplied to him by B (*e.g.*, the manufacturer, importer, or giver of warranty), or that the contamination is due to an ingredient supplied by C, it should be possible for A to attach B (or C, as the case may be) to the prosecution. The same principle should apply to the person thus associated in the defence if he in his turn alleges that a third party is responsible, by breach of warranty or otherwise, for the adulteration or contamination of the final product.

If the whole facts are thus brought before the court at one hearing, responsibility can be properly brought home to the real offender in a way not at present possible. In making this recommendation the Commissioners had in mind the precedents which are afforded by section 12 of the Truck Act, 1887, and by section 141 of the Factory and Workshop Act, 1901.

A memorandum is appended by Dr. Thorpe to the effect that instead of creating a permanent committee of scientific men, it would be preferable to follow the procedure of the Board of Agriculture, and to entrust the consideration of the propriety of fixing a standard to specially constituted committees on which manufacturers and technical experts in the trade concerned were represented.

Discussion.

Dr. Thorpe said the paper Mr. Baker had brought forward was a very condensed and admirably succinct account of a lengthy and protracted enquiry, and he should have been pleased to have had the opportunity of listening to what gentlemen present might have to say respecting the findings of the Commission, after which he might have been in a position, possibly, to throw some light upon the points which might be raised, or to give further information.

The Chairman said they would be glad to hear Dr Thorpe again later on if necessary.

Dr. Thorpe said the first point that occurred to him was the position which the electrolytic method had been placed in by the Government Laboratory as being what Mr. Baker had called the *de facto* official method. It was not the intention of the Departmental Committee appointed by the Board of Inland Revenue to put the electrolytic method in any superior position to the zinc and acid method, but it was the fact that it had become the method in vogue at the Government Laboratory. But that in no true sense constituted it the official method. He should think it convenient that, should any judicial proceedings arise in connection with the determination of the amount of arsenic in a material, the amount should be assessed by the electrolytic method. There were a number of reasons which had led them at the Government Laboratory to prefer the electrolytic to the zinc and acid method. He need hardly remind those who had had to make determinations of the amount of arsenic in articles of food or other articles that the difficulties which attended the use of zinc were very considerable, when minimal quantities of arsenic had to determined, as was the case in the great majority of cases. The zinc and acid method laboured under the theoretical disadvantage that if the zinc was in the ideal condition—an absolutely pure zinc—it was useless for the purpose, because it would not generate hydrogen, and therefore would not make arseniuretted hydrogen. There must be a certain quantity of associated metal with the zinc before it would do its work. They were thus placed in a dilemma. If the zinc were absolutely pure, it would be inoperative; but if, on the other hand, it contained certain associated metals it would in the case of some of them also be inoperative. For it was found that if zinc contained any considerable quantity of iron, although it generated hydrogen with remarkable facility, yet, when arsenic was added to that zinc very little was obtained in the form of arseniuretted hydrogen. For some reason, which was not wholly explained, the presence of the associated iron tended to retain the arsenic and prevent its evolution as arseniuretted hydrogen. Therefore, some metal must be present, but care should be taken what that particular metal was which set up the galvanic action on which the evolution of the hydrogen depended. He need hardly say that it was not always practically possible to secure that happy condition of things, namely, a sample of zinc which might be operative, and which should be at the same time sensitive and sufficiently free from arsenic to be used. It was that fact which caused the difficulty, and although they made every effort to get all the samples they could, they were constantly met with the eccentricities arising from the zinc used, and that being so they were obliged to rely on a method which did away with the zinc altogether. In the Government Laboratory they were in the fortunate position, as were many others in large towns, of having a ready supply of current available, and it was very easy to reduce the intensity to manageable proportions suitable for the generation of hydrogen, and therefore to the formation of arseniuretted hydrogen. It was really by *force majeure* that they were driven to the adoption of the electrolytic method, and being so driven, they gradually worked out the principles of that method in the form in which the Departmental Committee eventually presented the matter to the Commissioners. At the same time they fully recognised, as Mr. Baker had pointed out, that there must be innumerable cases in which it was not possible for operators to avail themselves readily of the electric current (and the adoption of secondary batteries was a very troublesome procedure), and for that reason they did their best to make the zinc and acid method, as far as they could, a practical method. He might say, in this connection, that from careful experiments by some of his assistants, he was convinced that when they did get that comparatively rare thing, the proper kind of zinc, the results of the tests, the character and intensity of the mirrors obtained by the zinc and acid method, substantially agreed with the results obtained by the electrolytic method. At the same time, on account of the difficulties which attached to the zinc method, he thought it would very considerably clog judicial proceedings if one had to go into Court with a method which was liable to so many doubts and open to so many points of attack, and therefore he thought on the whole it was preferable to confine themselves to a method, when there was an issue of a judicial character, in which those difficulties were obviated. Certainly for the general purpose of working, for the brewer or the maltster he was sure that the public was efficiently protected by the intelligent use of the zinc and acid method. As Mr. Baker had said, it was the fact that brewing sugars at the present day were practically free from arsenic. He did not wish to claim any special credit for the action of the Inland Revenue, but there was no doubt that the efforts of the authorities to carry out the intention of the Commissioners had very largely resulted—of course, with the intelligent co-operation of the manufacturers themselves—in getting to this very happy consummation. He might remind them that all the makers of brewing sugars in this country were now under Excise supervision. There was a permanent Revenue

Officer attached to them, and by direction of the Commissioners of Inland Revenue it was one of the duties of that officer from time to time to take samples of their products, every month he believed, and to forward those samples to the Government Laboratory for the purpose of being tested as to their freedom from arsenic. Thus they were in a position to warn the makers if there was any contravention of the intention of the Commissioners as to purity in this respect. Having now made very many hundreds of estimations of arsenic in these materials, he could assure them that probably there was no common articles of food so free from arsenic as these particular materials. He regretted to say, however, that that was not quite the case with regard to malt. Immediately after the arsenic scare a very considerable quantity of malt was withdrawn from the market, as it was found to be arsenicated, and it was practically an unsaleable article, and for some time after the Commission commenced its enquiry malts were of a very high degree of purity. Whether the idea of arsenic and the constant talk about it bred a sort of familiarity which led to contempt he did not know, but he was sorry to say that it was the fact that within a comparatively recent time the general character of the malts which had come into consumption was not by any means so high as regarding freedom from arsenic, as it was immediately subsequent to the so-called arsenic scare. At the same time he did not wish to be an alarmist in this matter. The amounts he found were not very large—nothing approximating to what the condition of things was before, and certainly not so large as they found in the samples of malt to which reference had been made. Still he now did occasionally meet with samples which were distinctly beyond the limit of 1/100th grain per 1 lb. as prescribed by the Commissioners. Mr. Baker had said he thought the Commission, perhaps, was not fully informed as to the amount of arsenic which might occur in hops, and he could corroborate him to this extent, that within the last two or three days he had had samples of hops through his hands which certainly contravened the limit of 1/100th grain of arsenic per 1lb. Even now there were certain materials occasionally used by brewers—things which were ancillary, he might say, to the operations of the brewer, not exactly part and parcel of his every day work—where apparently sufficient care was not taken to exclude, as it easily might be excluded, even small quantities of arsenic. He had a particular article in his mind which was used to a limited extent by brewers which contained as much as two grains of arsenic to the 1lb. That showed an amount of culpable carelessness on the part of somebody which ought not to be tolerated.

Mr. A. Gordon Salamon desired to add his tribute to the praise already accorded to Mr. Baker for his *résumé* of what he thought they would all describe as a masterly document. He might be permitted as one who was concerned at the time of this outbreak in attempting rapidly to quell it, to say a few words respecting the use of the test which the Manchester Committee felt was the right one to adopt in the midst of that terrible calamity. He asked permission because that test had certainly at the time of the outbreak come in for an undue share of criticism. He was glad to say the Royal Commission in their Report had fully justified the use of the test under the conditions mentioned, and he was also glad to think that Mr. Baker had, that evening, endorsed the conclusions of the Commission. The position of the Manchester Committee was this: The Marsh-Berzelius test had not been then elaborated as it was to-day, and they found themselves in the midst of a calamitous outbreak of poisoning, and they had to stop its spread if possible. They were called upon to make thousands of rapid tests on barrels of beer very often isolated as single barrels in small public-houses. These beers had to be tested not for traces of arsenic, but for the amounts which the medical men who formed part of the Committee deemed to be poisonous quantities. Traces had obviously to be relegated to the Marsh-Berzelius test, and of that they were well aware when making the investigation. Looking back, and recognising as he did and had done ever since, the superiority of the Marsh-Berzelius method as a test when properly equipped and carried out, he still thought that if any one of those who had criticised that process were to go to Manchester under similar circumstances they would revert to the Reinsch test recommended under the conditions then existing. The result of the whole investigation by the Commission had come to this, that the two chief causes of food contamination by arsenic consisted in sulphuric acid and in fuel. He could have wished, although he knew he should not have the sympathy of sulphuric acid manufacturers, that having regard to what he had seen and to his experience quite recently—having regard to accidents which might occur through mis-direction or by non-direction—that the Royal Commission had seen its way to insist that all sulphuric acid manufactured from pyrites should be de-arsenicated. It was not a very great additional expense, and it would certainly minimise the risk of accidental contamination against which no legislation could provide. One could say to-day that the precautions which had been taken by the Inland Revenue had certainly given them sugars, which he could with confidence state might be regarded as free from arsenical contamination. He did not think at the present there was any danger in that respect other than danger due to accident or design.

With respect to fuel, the conditions were different. When they adopted the Reinsch test at Manchester they had no idea that malt was apt to be contaminated with such notable traces of arsenic as were subsequently discovered. Therefore they devised conditions for the use of the Reinsch test, which would deal with the quantity which would in effect prevent poisonous beer going to the public. They soon found, however, that the conditions prescribed were too rigid to pass beers as arsenic free, and they subsequently altered that test and made it into one which would pass a mere trace, but which at the same time would reveal the presence of any injurious quantity of arsenic. In the case of the Halifax malt to which allusion had been made in which the Reinsch test was applied, it would be found that the first prescribed method was adopted and not the second. They had discovered that these traces of arsenic came from malt and that their presence should be prevented. No doubt the bulk of the arsenical contamination of malt came, in the Yorkshire and Lancashire district certainly, from the use of gas coke, and as Dr. Thorpe had pointed out, since gas coke was wholly discontinued the malt became of exceptional purity. The cause of the contamination of some of the malt of to-day he thought was not far too seek. Maltsters had been loyally working to produce a malt free from arsenic, and the brewers on their side had spared no pains in insisting that they should have such deliveries. That had meant that maltsters had been advised to give up using coke, and in fact every fuel but anthracite. Thus there was an increased demand for anthracite used for malting purposes. His experience was that anthracite fuel as now employed showed a distinct increase in the traces of arsenic it contained. That was probably due to a larger consumption, and to the difficulty of sorting the quality, in the manner Dr. Thorpe had pointed out as being a necessity. He did not say that the exercise of greater care on the part of the suppliers of anthracite would not prevent this, but there was no doubt a tendency for maltsters to be lulled into security when they were using anthracite, and to think that they were more free from any possibility of trouble. Such was not the case, for he had come across numerous samples of anthracite containing very appreciable amounts of arsenic by way of traces. He had come across some which showed as much as 1/20th grn. to the 1 lb., and sometimes some kinds of anthracite in which a considerable proportion of it was in the volatile and not in the fixed condition. Again he had met with specimens from deliveries in which one could see cretaceous lines running through it, and if one split them and pulled off the scales, they were found to be highly arsenical. It was extremely necessary, therefore, that the utmost care should be taken in the selection of anthracite, and that the maltsters should devise some form of test, or some form of treatment which would prevent the possibility of these traces of arsenic from anthracite getting into the malt.

Mr. A. R. Ling said he also must congratulate Mr. Baker on the very clear and lucid way in which he had presented this very important report. It was very satisfactory to him to find that the Commission through Dr. McGowan's work substantially corroborated what he found in the case of malting fuel. He believed his own analyses were low, as he had not removed the iron as Dr. McGowan had done in the solution in which the arsenic estimation was performed. They had to thank Dr. McGowan for the very exhaustive data which he furnished to the Commission, which from the chemical point of view constituted, perhaps, one of the best features in the report. He thought that Mr. Baker's suggestion that sulphur exercised a reducing effect on arsenic and caused it to be volatile was no doubt correct, and he could corroborate the fact that hops were far more frequently found contaminated with arsenic than had been generally supposed. He himself had quite recently found commonly such amounts as 1/100th grain per 1 lb., and that day he had examined a sample of hop which contained 1/40th grain. Of course, he knew hops were very much more frequently sulphured on the kiln than malt, and probably that was the reason of their contamination.

Mr. Grant Hooper said that after the remarks already made he need say nothing with reference to the analytical results which had been brought out by the Commission. But there was one point which had not been touched upon so far in the discussion, and that had reference to the condition of the malt actually in use at the present moment. He must say he was much struck by the fact that in the evidence given before the Commission the malting witnesses, who came specially to deal with the question of the preparation of the malt, were one and all agreed upon the fact that satisfactory malt could not be prepared without the direct action of the kiln fumes upon the grain. Again and again the Commission were told that whilst it was quite possible to dry malt, it was impossible to cure malt without the direct application of these fumes from the fire. Believing there were many practical men present he ventured to put it to them, whether that opinion was an altogether sound one, whether there was not something of a tradition which might be usefully questioned when they were face to face with the fact which Dr. Thorpe had mentioned, that malt was still found containing arsenic in quantities which occasionally approached a dangerous limit. Sugars had been brought to a degree of purity which rendered them entirely satisfactory from this point of view. Was it not a question for the practical men in the industry to consider whether the production of malt could not be made equally safe. Some years ago an endeavour was made to interest the brewing trade in the preparation for brewing purposes of unmalted grain which should have something of that empyreumatic flavour characteristic of malt, and a patent was taken out for a plant more especially designed for the treatment of barley. This torrified barley was produced by passing the grain through something which approached the character of a coffee-roasting machine, with this difference, that the cylinder instead of being open from end to end was so divided that the grain passing in at one end travelled continuously through and round the cylinder, and when it reached the other end it had been exposed to a high temperature sufficiently long to completely dry the grain and give it a certain toasted character, whilst at the same time the grain was so distended that it exhibited something of the light porous character of malt. He did not know whether this patent was still in existence, but he would ask whether, in connection with that invention or some similar application of the idea, there was not a possibility of producing a satisfactory malt which yet should not have been directly exposed to the fumes of a kiln fire.

Mr. R. J. Friswell said the few words he had to say were practically historical. There was an "arsenic scare" in the year 1869, at which time he was a student at the Royal College of Chemistry. The Royal Commission on the Pollution of Rivers had discovered arsenic in sewage, and Dr. Frankland set Mr. Adrian Brown and himself to work to discover the source of this arsenic. This resulted in the preparation of a number of standard mirrors, and a few days ago he discovered an old note-book containing 46 determinations of arsenic made by himself, and also a number of researches on the sensitiveness of the tests. From this note-book he was able to recover the standard mirrors which they then used, and he found that the lowest standard was $\frac{1}{100}$th mgm., and they went up 2, 4, 6, 8, 10, 15, 20, and 30 hundredths. They had to draw out the tubes in which these mirrors were made from large pieces of combustion tubing. They were sealed up in hydrogen, because they found that they were volatile and disappeared. The result of the matter was to discover arsenic in a great number of substances—in nearly all soda ashes, caustic soda, in some soaps, and generally they traced the arsenic back through sulphuric acid to the pyrites used in producing it. Then another series of experiments was conducted with London soot and London air. He had no record of those, but he believed a certain amount of arsenic was detected in 25 cubic feet of air drawn from the space over the lecture theatre of the old College of Chemistry in Oxford Street. He had one record of the soot taken off the roof, but the note-book stated there was no arsenic in that. The result of the whole series of investigations was to show that the arsenic found in sewage products was traceable back to pyrites, partly through alkalis, soap, and products in which sulphuric acid was used at some stage of the manufacture, and partly through the coal brasses, as he believed that soot was found to be arsenical, though he did not examine any, and the only sample of roof-sweepings examined contained none. He might call Dr. Thorpe's attention to the fact that a large quantity of sweetstuff was made of maize which was burst by roasting over small coke fires. It was afterwards coated with sugar, and he would suggest that it should be examined for arsenic.

Mr. Thorne said he could endorse what Mr. Salamon said with regard to anthracite. He had had occasion recently to test different samples of malt made in the same kilns under similar conditions, except the coal used, and he found that although only different kinds of anthracite coal had been used, the malts varied very considerably in the arsenic contained in them. It never reached a serious amount, the maximum being 1/400th grn., but varied from about 1/1,000th up to about 1/400th grn. per lb. He would ask Dr. Thorpe whether he would correct one expression he had used, which he thought was taken in a little different meaning to what he intended. When he spoke of confining the standard to 1/100th grn. of arsenic per 1 lb. in malt, the speaker had noticed that that was a point which had been misunderstood in the report of the Commission, and had been misunderstood or overlooked in Professor Thorpe's evidence. A great many people had supposed that it authorised the assumption of safety if the arsenic in malt did not exceed 1/100th grn. per 1 lb. Of course, as Dr. Thorpe pointed out in his own evidence, if they had a malt containing that quantity, the beer produced from that malt might contain anything from, say, 1/80th grn. up even to 1/50th, or in strong beers to 1/30th, and would then be condemned by the Royal Commission limit. He quite agreed with what Dr. Thorpe said as to the relative positions of the electrolytic and Marsh-Berzelius methods. All who had used the Marsh-Berzelius method knew of the difficulties as to purity of materials, and those who had facilities for adopting the electrolytic method would certainly overcome those difficulties. But his experience in a very large number of determinations was, that if care were taken, the Marsh-Berzelius method was still a very reliable one, and by a slight modification of the method of purification of zinc by sodium, which Mr. Hehner first told them of, one was able to get a zinc which was very reliable indeed. If the purification were carried out at a low temperature and with precaution, to prevent too rapid oxidation, one could obtain a zinc which was sensitive, fairly easily attacked by acid, not giving a rush of gas but a regular and fair current, and yet free from arsenic.

Mr. Bryan Corcoran, with the reference to the question of arsenic in malt, said there were different sorts of malt kilns, and it is only necessary to know the kiln which actually made the malt to enable one to judge the quality of the malt itself. Some malt kilns do not properly dry with any amount of heat, while others dry at a very low temperature, and these points were very necessary to be known, as they regulate the deposition of the volatile substances.

With regard to the fumes of combustion not coming in contact with the goods, this could be done, but it was not so easy or so economical, and malt generally was not so satisfactory as when the fumes passed through it. He could show Mr. Hooper a torrefying machine in which all the starch cells were ruptured, so that barley weighing 50 lb. per bushel would come out weighing only 25 lb.; in other words, one bushel of barley is equivalent to two bushels of torrefied material.

Mr. **Berry** said that many imported German materials used in brewing were sometimes found to contain arsenic.

Dr. **Thorpe** said if he accurately appreciated the observation of Dr. Thorne it was that a limit of 1/100th grain per ton of malt amounted to much more than 1/100th grain per gallon of beer. That might or might not be the case. That assumption was based on the supposition that all the arsenic present in the malt got in the wort, and eventually into the beer, but all experience went to show that that did not necessarily follow. Practical experience had shown that a limit of 1/100th grain per 1 lb. of malt did tend to the production of beer with less than 1/100th grain per gallon. It was a fact that the greater portion of the arsenicated material from the malt was frequently in such a condition that it never went into solution at all. It was not all there as sublimated arsenious oxide, but a considerable fraction was there simply mechanically put on the malt by the fine particles of insoluble arseniates which were deposited on the grain.

Dr. **Buchanan** writes: "I hope the administrative side of the report will not be lost sight of by chemists, though perhaps questions that more particularly affect public analysts will hardly come under discussion much at your meeting. I feel that one of the chief lessons of the inquiry is that both manufacturers and chemists, and the chemists of public authorities, should be in much better and closer relations with processes of food manufacture than they are at present. They seem to me to be much too much treated as mere analysts, and to be called in at too late a stage. But I suppose this is an old complaint."

A letter was received from Mr. A. C. **Chapman** in which he says that so far as brewers and maltsters are concerned the limits suggested in the Report are fair, and will not press at all heavily on any man who exercises reasonable care and supervision over his materials and manufacturing operations. Owing to its extraordinary ramifications it is quite possible that cases may arise (although they must necessarily be few) which have not been brought before the notice of the Commissioners, and which are consequently not specifically dealt with in their Report. The recommendations contained in the final Report might therefore very seriously affect one or two manufacturers of materials of which the Commission could have had no cognizance. These cases, however, would doubtless receive due consideration from the Authorities as they arose. Not the least important recommendations made in the Report are those dealing with the existing Sale of Food and Drugs Acts, and all who are concerned in the administration of these Acts can only hope that before long full effect will be given to those recommendations.

Mr. G. F. **English** wrote: "In his remarks to the meeting, Mr. Gordon Salamon said 'he could have wished, with regard to the sulphuric acid, that the Royal Commission had seen its way to insist that all sulphuric acid manufactured from pyrites should be de-arsenicated.' This is a very serious suggestion to come from such an authority as Mr. Salamon.

"The amount of sulphuric acid used in the manufacture of foodstuffs is only a very small percentage of that produced for other important industries. Large quantities of acid made from well-known ores such as the Rio Tinto, Tharsis and others, containing about 0·1 per cent. of arsenic are used in the soda, &c., cotton-bleaching and dyeing, manure, explosive, celluloid and other industries without detriment. As to the cost of de-arsenication, which Mr. Salamon considers so small as to be almost negligeable, I may say, from practical experience, that it adds materially to the cost of producing sulphuric acid.

"To insist that all sulphuric acid made from pyrites should be subjected to the process of de-arsenication to ensure that the manufacture of foodstuffs should be guarded against the introduction of arsenic into their products would indeed be a serious, and at the same time, an unnecessary piece of legislation.

"It would add considerably to the cost of production of many articles manufactured in the industries cited and add further restrictions to many trades which are now struggling in the face of severe competition from abroad.

"Mr. Salamon's suggestion is no doubt made with the best intention, namely, that the public be safeguarded against any recurrence of the arsenical poisoning which has been traced to the use of highly arsenical sulphuric acid in the manufacture of glucose, &c., but I do not think that he has taken into consideration how unfair it would be to other manufacturers, to insist upon such measures, which he evidently deplores have not been taken, for the benefit of one class of manufacturers.

"The public can be ensured against arsenical poisoning, without resorting to such extreme measures, by compelling the manufacturer of foodstuffs to examine carefully every article which he uses in the manufacture of his products, and to insist upon the examination of such products before leaving his works."

The **Chairman** said they had had a most interesting discussion. No doubt a great number of articles of food were liable to contamination from arsenic, and it was fortunate that the death rate kept falling, instead of rising under these conditions. He was glad to find that articles of food were so carefully watched, but there was one question he should like to ask, and that was with regard to the very large quantities of glucose which came into this country for the manufacture of beer and other articles of food. He was in the law courts some time ago and heard two witnesses, large confectioners, swear that they did not test the glucose as they used it in the manufacture of the articles they made. It that was the general state of affairs, and they got materials like that from abroad, there seemed to be a great opening for analytical chemists.

Mr. A. G. **Salamon** said he had made many tests of this foreign glucose, and though he would rather see it made in England, he was bound to say that, as a rule, it was extremely free from arsenic.

The **Chairman** said he did not mean to say that imported articles were impure, but he did not think Mr. Salamon had quite given the information he wished for, which perhaps, someone else could supply, namely, whether there was any control of such materials that came to this country. They knew English manufacturers were conscientious, they believed the Germans were also, and they thought the American manufacturers were highly conscientious, but at the same time he should like to have some little analytical control over the large quantities of glucose that came to this country.

An important point had been raised as to the fuel; it seemed they were in rather a bad way with regard to that. It was naturally a disadvantage if they could not use coke, and if anthracite were unreliable, where was pure British beer to come from. He believed there were methods of purifying fuel, and possibly some fuels, such as peat, might be utilised, but clearly some kind of fuel by which they could cure or dry malt without the danger of contamination was evidently a great want. They were importing such large numbers of cheap articles that it would be almost worth while importing fuel if they could find one free from arsenic.

Mr. **Baker**, in reply, said there was one point which he should like to refer to, as it was probably the most important raised during the discussion and that was the statement of Dr. Thorpe about malt containing 1/100th gr. of arsenic per lb. The wording of the report was, "We think that no substances should be used as an ingredient of food that contains a larger proportion of arsenic than 1/100th gr. per lb." And then later on it said, "in many cases, particularly glucose and malt, more stringent limits are now attainable commercially, and should be insisted on."

Then turning to the question of malt, the Commissioners reported: "All our evidence goes to show that it is now commercially practicable to produce malt which either may be considered free from arsenic or in which the amount is certainly less than 1/250th of a gr., most malts prepared during the past two years being of this nature." He thought it was clearly in the minds of the Commissioners that malt should not be allowed to contain

1/100th gr. of arsenic per lb., but from what Dr. Thorpe had just now said he gathered that 1/100th was his limit, and if a malt contained 1/100th the Inland Revenue would presumably allow it to be used. Now, if malt were allowed to contain that quantity, which was really much larger than was necessary nowadays, he thought that in the course of a short time it would contaminate the beer to an extent exceeding 1/100th grain of arsenic per gallon. Assuming the grist, as it passed the mill, contained 1/100th gr. of arsenic per lb., presumably in the first batch of beer prepared it would not contain 1/100th gr. per gallon, because the yeast would absorb a large quantity of it. But in the succeeding gyle, where a similar malt was used containing 1/100th gr., if it were pitched with the arsenical yeast, then the beer would contain 1/100th gr. or more, for the reason that the pitching yeast was already saturated. That was rather the point he thought the Commissioners had in view when they put in that paragraph in the case of malt and glucose more stringent limits should be insisted upon."

Dr. Thorpe said he might add another word or two in order to remove any misconception. In the first place with regard to imported glucose. He did not pretend that imported glucose had the same stringent surveillance that the home made article had, but nevertheless all imports were sampled, and they came either directly or indirectly under the purview of the Government Laboratory either at the Customs or eventually at the Excise branch of the Revenue Laboratories, and so a very considerable amount of surveillance was exercised even on imported glucose.

With respect to the other point to which Mr. Baker had referred, it was their practice in the laboratory whenever they got malt trespassing closely on the limit to require the officers to send samples of the wort produced from such malt. They had pointed out what was the limit suggested; they had no legal power in these matters, but they pointed out to brewers that the malt was perilously near the limit suggested. But as they had no knowledge of the real proportion which would go in practice into solution by continuous use they required their officers to take samples of the wort produced from any sample of malt on the confines of insecurity as defined by the Royal Commission.

THE POSSIBILITY OF MALT BECOMING CONTAMINATED WITH ARSENIC WHEN SULPHUR IS EMPLOYED DURING KILNING.

BY JULIAN L. BAKER AND W. D. DICK.

For some years past many brewers have demanded that the malts used in the preparation of certain beers, such as pale ales, should be very bright and light in colour.

By throwing sulphur into the kiln fire at certain stages of curing, the maltsters have obtained this effect, and the practice is more or less common in this country. Apart from giving the malt an appearance not commensurate with its value, sulphuring is apt to be dangerous to the maltster, for, if improperly carried out, the malt instead of being bleached is darkened, owing to the production of small quantities of sulphuric acid which caramelise portions of the corns.

Since the epidemic of arsenical poisoning chemists have warned maltsters that by using the cheaper kind of sulphur the malts might become contaminated with arsenic. Since 1901 maltsters have been careful to use Sicilian sulphur, which is practically free of arsenic.

For some time past we have noticed that sulphured malts contain relatively large traces of arsenic, whereas previous and subsequent curings in the same kiln of the same type of malt, and with the same fuel, but unsulphured, contained no arsenic.

The possibility occurred to us that the sulphur when thrown on the fire would exert a temporary reducing action whereby the arsenates in the burning anthracite might become reduced to arsenites and so rendered volatile.

To determine this point a number of experiments were carried out in which arsenical anthracites and cokes were burnt alone and in presence of sulphur. The method of experiment was as follows: 5 grms. of the arsenical fuel was burnt in a porcelain capsule, and when the combustion was complete the ash was treated with dilute arsenic-free hydrochloric acid made up to a given volume, and an aliquot portion submitted to the Marsh-Berzelius test. An equal weight of the same fuel was burnt under similar conditions with this difference, that 0·5 grm. of sulphur free from arsenic was added in small portions before the fuel was completely burnt. The arsenic was then determined in the ash. The following results were obtained:—

——	Without Sulphur.	With Sulphur.	Arsenic volatilised by addition of Sulphur.
	Parts per Million.	Parts per Million.	Parts per Million.
1. Coke	47·6	28·5	19·1
2. Anthracite	35·7	10·3	25·4
3. Anthracite	71·4	35·7	35·7

Other experiments were carried out with malting anthracites to which known quantities of sodium arsenate had been added. The difference in the amounts of arsenic remaining in the ash of the fuel when burnt alone and in presence of sulphur was very marked, and confirms the results obtained by burning naturally contaminated fuels in presence of sulphur.

The experimental results clearly indicate that sulphur effects the partial volatilisation of fixed arsenic in anthracite and cokes, and the assumption that the sulphur acts as a reducing agent when thrown on to the fire appears to us to be reasonable. If maltsters desire to sulphur malt great care should be exercised in selecting an anthracite which contains a minimum amount of arsenic.

An ordinary malting anthracite containing an amount of fixed arsenic which would be unnoticeable in the malt cured by it may show an appreciable quantity of arsenic, if, during some stage of the combustion, sulphur is added.

The practice of bleaching hops in the oast houses by burning sulphur before and during the drying may possibly account for the heavy traces of arsenic (frequently 1/5th to 1/100th grn. of arsenious acid per lb.) which are sometimes found in hops. Probably hop growers are not so alive to the importance of the proper selection of fuel as are maltsters.

Meeting held at Chemists' Club, on Jan. 22nd, 1904.

DR. VIRGIL COBLENTZ IN THE CHAIR.

THE MAKING AND SETTLING OF BLEACHING POWDER SOLUTIONS.

BY MARTIN L. GRIFFIN.

Messrs. Carey and Muspratt have treated this subject in the June 15 number of this Journal (1903, 674—676). I desire here to make some additional observations and to supplement their work from the consumer's point of view.

The Duncan Company, manufacturers of pulp and paper, with which I have been connected for nearly 20 years, has been using from 100 to 250 tons of bleaching powder per month during this time, and we have at intervals modified our plant and process of making up solutions until we feel satisfied that we are getting out of it all there is in it. During this time the makers of bleaching powder have greatly improved the quality of their product, and I think they should continue to do so. The sludge resulting from solutions of bleaching powder is a very objectionable waste, and will have to be dealt with very differently in the future from what has been done in the past. The manufacturers of bleach can contribute very much to the solution of this problem if they will give us a powder containing 38 to 39 per cent. of chlorine, which is a very easy thing to do. When we receive bleach of this strength, our sludge will be of very little consequence, and there will be much less difficulty in settling out what there is.

There is frequently a difference in the deportment of bleaching powder made in different countries as regards settling, but at the present time there is little variation in the product of the same manufacturer of high grade goods.

Without doubt the quality of the water supply has an important influence, but the problem is simply one of relative specific gravity of the insoluble matter and the solution. I have observed that natural waters containing even a small amount of available carbon dioxide will settle much more readily than those without. The reason for this is apparent.

The temperature of the water does exert a decided influence on the rate of settling, because the warmer the water is the less dense, and consequently the less buoyant it is. While heating may be employed to hasten the settling I do not think it advisable to resort to it largely, and in large works the cost for steam would amount to a considerable item in cold weather. The only steam we use is that to work a siphon moving the final washings of the sludge, to be described later. We have no trouble if we keep our water up to a temperature of 55° to 60° F.

With regard to the effects of prolonged agitation on the rate of settling, I agree with Carey and Muspratt that simple wetting out and mixing, which may be accomplished in ten to fifteen minutes with a good apparatus, is all that is necessary, and further agitation would be objectionable.

One of the most important problems to decide in making bleaching solutions and not definitely discussed by Carey and Muspratt, is what the strength should be. I have found after many trials that a solution between 4·5° and 5° B. (about 6° to 7° Tw.) is by far the most convenient to make up, and from this, together with the liquor from the first washing of the sludge, a finished solution of 3° (4·2° Tw.) gives the best results in practice. It is a good strength for all kinds of work, and much greater uniformity and accuracy can be had by it than by employing stronger solutions. Whether the amount of bleach consumed be large or small I would recommend this strength. This would require a capacity in making of about 1 cb. ft. for each 3·75 lb. of high test powder.

Let me now describe a plant for small requirements, then for larger. Two round or square concrete tanks of the same size, somewhat deeper than their width, are each provided with agitators and adjustable siphons for drawing off the clear liquor into one common pipe leading to a storage tank at least equal in capacity to the two mixers, larger would be preferable. These mixers should be set level with the floor for convenience in furnishing the powder, and dumping it at once into the mixer without screening, which is good but not practicable. The storage tank should be situated on a lower level so that the liquor would flow into it by gravity. Square mixers are preferable because much better agitation can be had in them than in round tanks. The operation of this system is as follows: One mixer of freshly-made solution of about 4·5° B. is made up to settle, the other we will say has the sludge from a former make of same strength; this is filled up with fresh water only, or a weak liquor as will be described later, and agitated just enough to stir it up uniformally. The strength of this will be about 1½°, depending, of course, much on the volume of the strong sludge. The two mixers when settled sufficiently are drawn off in about equal volumes in equal times, giving a finished liquor of 3° B. With proper care in drawing down, regulating the flow of second liquor, an exact and uniform strength may be had for work at all times. This is very desirable for good work. The sludge from the second liquor is again covered with fresh water, filling the mixer, and stirred up as before, making what we may call a third liquor. This is settled and drawn off by a small pump and discharged into the other mixer containing strong sludge in order to wash it. It is then agitated just enough to mix for the second liquor. The sludge from the third liquor is now washed out, and is practically free from bleach. This mixer is then ready for a fresh charge of powder, and when settled is to be drawn down with the second liquor in the manner described; this is the best practice possible with two-mixer tanks. It will be seen that much time is lost in making up the third liquor, and that this is used in washing up the strong sludge, for which it would be better to use fresh water, and the third liquor for making up the next strong liquor. In order to do this conveniently four mixers would be required.

At one time we used three mixers, making our strong solution test 6° B. or a little more, the second 2°, and the third 1° or less. These three were drawn down together in about equal volumes making the finished liquor 3° B. They were operated in cyclic order, using fresh water for each making. With water uniformly 70° to 75° F. this is a very satisfactory way, and there is no loss of time and no pumping of liquors necessary.

We are now using about 10 tons of bleaching powder daily, and our plant consists of four large concrete settling tanks of a capacity of about 1,100 cubic feet each, provided with adjustable syphons leading into a common conduit. These siphons have their outlet point very near the bottom of the tank, and consist of pieces of three-inch cast-iron pipe fixed in a movable joint or elbow at the outlet from the tank and reaching to the top. These are let down into the liquor and held in place by a chain. By this arrangement, the fixing of any particular point for the "run off" and sludge is of little consequence, only to have it low enough to get off all the clear liquor. Another advantage is that clear liquor can be drawn off as fast as it settles, if desired.

The balance of the plant includes a mixer of about a quarter of the capacity of a settler, without any agitator, but provided with a 4-in. centrifugal pump and suitable piping for circulating the contents from bottom to top, discharging in such a way as to give the mass a rotary motion in the mixer. The pump is also so piped that the contents of any settler may be moved into any other, receiving it into the mixer or not. There are also two large settling tanks for the final washings, and the storage system for finished liquor. The pump mentioned is the only power used.

The plant is worked on the two-liquor plan above described. A full settling tank of strong solution is made by the discharge of the prepared contents of three or four mixers of same strength, requiring about one hour. The tank is then ready to settle, and with water as cold as 55° F. will settle in five to six hours, leaving about 3 cubic feet of sludge for each 100 lb. of powder. It must be borne in mind that at the end of this settling period all the solution may have been siphoned off.

It is customary to draw off all that can be drawn in the time available. The strong sludge is washed successively with two waters, making what is called second and third liquors. The second liquor is made by running off the settled strong sludge into the mixer by gravity, and it is to remain there without agitation until the tank has been about three quarters filled with third liquor, when the valve on the mixer is opened and the pump throws it on top of the settler containing the weak liquor. In this way the strength of the sludge becomes diffused through the water and washed, being denser and heavier. The result is a weak liquor of uniform strength with no agitation except what it gets in passing through the pump and connecting piping.

The third liquor is made by repeating the above operation on the sludge of the second liquor, using water only. When this has settled and the liquor has been pumped off for the making of a second liquor, the sludge is washed out into one of the two final settling basins or tanks. These tanks will hold the sludge from several settlers and ample time is given for a thorough settling. This very weak liquor is thrown up into the mixer by a bronze steam siphon or injector and used for the making, in part, of the strong bleach, and is a very satisfactory arrangement. The sludge is then finally discharged. By the above practice almost nothing is lost, and we could not afford to lose even as much as 2 per cent. of the powder, as this loss would amount to some 1,500 dols. yearly.

With the exception of the second liquor, which is a little handicapped for time in settling, the sludge in each settling tank will usually be less than 3 cb. ft. for each 100 lb. of powder of a strength of 35 to 36 per cent. chlorine, and, as noted above, with 38 to 39 per cent. chlorine it would be inconsiderable with high-grade lime, which abounds in many parts of this country. We would be glad to pay the relatively higher price for such high test goods.

From this review, the important points to note are, care in determining the most available making strength and with this a fixed temperature.

If the temperature varies, the equivalent strength must be determined. Of course it is understood that the hydrometer test is not an accurate guide as to the amount of available chlorine, but simply indicates the gravity of the liquid, but it is usually a safe guide for mill practice when the supply of bleaching powder is uniformly regular. If, however, a mill were in the habit of receiving fresh shipments and then for some reason a shipment which had been lying in store or out of doors for some weeks or even months, the hydrometer test ought to be supplemented by a determination of the actual chlorine in solution, and the strength or rate of consumption gauged accordingly. I have found that a difference of 5° F. will make a difference of about 0·1° B. in a 3° solution between 60° and 100°. So that the temperature plays a very important part during the changing seasons of the year when the temperature of the water varies. Uniformity in strength is very desirable in doing uniformly good work whether the bleaching operations are carried on by successively charging kiers or engines in a continuous process, as is now commonly done in bleaching chemical wood pulp. By this latter process the strength and rate of flow have to be very carefully gauged. Lastly, the plant should be of ample capacity for easy work, in which the powder can be properly treated, and the sludge well washed.

ARTIFICIAL SILK.

BY J. MERRITT MATTHEWS.

In this age of industrial and chemical syntheses, it would be natural to expect that such a valuable and useful substance as the fibre spun by the silk worm would be subject to many attempts of artificial imitation, if not of actual synthetic preparation. In fact, the entomologist Reaumur, as early as the year 1734, in a memoir on the history of insects, seemed to look forward to the possible preparation of silk by artificial means. It was not until 1885, however, that the first commercial process for the preparation of artificial silk was taken out in patent form by the Count Hilaire de Chardonnet.

At this point I wish to define clearly the substance which is commonly understood by the general name of artificial silk. We have grown so accustomed at the present time to the preparation of naturally occurring substances by means of purely chemical methods, that when we use the term artificial silk, many may reasonably suppose that the substance so designated is the same in composition and nature as the fibre derived from the silk worm, but made by chemical or other artificial means. Unfortunately this is not the case, however, and the term "artificial silk" proves to be a rather misleading one in this sense. What the name really does stand for is a fibre, resembling in its lustre and general appearance the true silk of nature; but the identity goes no further than this, for, in its chemical composition and other properties, the artificial silk of trade is entirely distinct from that produced by the silk worm. It would be better to call the artificial product "imitation silk," or give it some other name more distinctive of its origin and true nature, such as the term "lustra-cellulose," proposed by Cross and Bevan. This latter term is especially adapted to the product in question, for the different varieties of artificial silk which have acquired any degree of technical importance are all made from cellulose derivatives, and their chief quality is their high degree of lustre.

The idea of preparing lustrous filaments of cellulose to be used as substitutes for silk seems to have grown out of the manufacture of carbon filaments for use in incandescent electric lamps. Chardonnet discovered that a solution of pyroxylin (known as collodion) could be drawn out very satisfactorily into delicate threads, and then coagulated or hardened to a comparatively strong and coherent fibre possessed of a very high lustre. The original patent of Chardonnet was taken out in 1885, but some years elapsed before this new material could be prepared in a manner sufficiently successful to allow of it appearing in commerce. Although in its conception, the idea of preparing these lustrous threads of pyroxylin appears to be of a simple character, yet the conditions of the treatment and preparation are in reality quite complex and difficult.

The pyroxylin employed for the production of Chardonnet's silk may be prepared for either wood-pulp, cotton, ramie, or other source of purified cellulose. As there are several nitrated compounds of cellulose soluble in the alcohol-ether mixture (which is employed as the pyroxylin solvent), and as it is difficult to obtain satisfactory separations of the individual compounds, it is probable that the pyroxylin contains penta-, tetra-, tri-, and di-nitro-cellulose, the tetra- and tri-nitro-compounds probably occurring in larger amounts. The preparation of a pyroxylin suitable for use in the making of Chardonnet silk, as prescribed by Wyss-Naef, calls for a nitrating mixture of 15 parts of fuming nitric acid (of 1·52 sp. gr.), with 85 parts of sulphuric acid. For 4 kilos. of cellulose, about 35 litres of this acid mixture are required, and the time of action is from four to six hours. Samples are examined from time to time with the micro-polariscope in order to ascertain the degree of nitration, and when all the fibres appear of a uniform bright blue under the polariscope the action of the acid mixture is discontinued. The excess of acid is removed from the fibre by means of a hydraulic press, after which the nitro-cellulose is washed for several hours with water, and then pressed again, until the mass contains only about 30 per cent. of water. At first, the pyroxylin so prepared was dried before being dissolved in the alcohol-ether solvent, but it was subsequently discovered that a better solution could be obtained by using the pyroxylin containing the amount of water above noted. This form of pyroxylin has been called by Chardonnet "pyroxylin hydrate," but it is doubtful if the substance is a true hydrate. However, it appears to be about 25 per cent. more soluble than the dry pyroxylin. The solvent employed for the pyroxylin consists of a mixture of 40 parts of 95 per cent. alcohol with 60 parts of ether, and 100 parts of this liquid will dissolve about 28 to 30 parts of pyroxylin. The collodion so produced is filtered several times under pressure, in order to free it from all non-nitrated and undissolved fibres, and to obtain a perfectly clear and homogeneous solution. This condition is a very essential one for the successful production of the silk, as any irregularity in the solution would cause a break in the continuity of the spun filament, or a stoppage of the machine. The pyroxylin requires from 15 to 20 hours for complete solution, and that prepared from cotton requires a longer time to dissolve than that from wood-pulp. In order to properly filter the solution a pressure of 30 to 60 atmospheres is necessary.

The next operation in the manufacture of the silk is purely a mechanical one, and yet one which has required the use of considerable ingenuity and skill. The object is to force the collodion solution through very fine capillary glass tubes, so that it may be drawn thence as a fine continuous filament. The collodion solution is quite viscous, and requires a pressure of from 40 to 50 atmospheres to force it through capillaries of 0·08 mm. in diameter. The flow of solution and pressure must be so adjusted and capable of regulation as to provide a uniform filament, and this involved many mechanical difficulties, which were only overcome after long experimenting and numerous failures. I will not, however, enter into a consideration of the various mechanical devices, ingenious though they are, which have been perfected for the proper spinning and handling of this artificial fibre.

The thread as it emerges from the capillary tube is rapidly coagulated in the air by the evaporation of the solvent. By suitable arrangement of a hood over the machine and condensing chambers in connection therewith, a large portion of the mixed volatile vapours of the alcohol and ether employed as the solvent are condensed and collected, thus effecting a considerable saving in the amount of solvent required, and also minimising the danger of explosions occurring. Several of the individual filaments are brought together into a single thread and wound on to spools in the manner of ordinary silk. In this operation a certain amount of adhesion takes place between the separate filaments, which considerably enhances the ultimate strength of the finished thread. The thread in this form now consists of pyroxylin or nitrated cellulose, and is highly inflamable and otherwise unsuitable for use in textile fibres. The next operation through which it passes is one for the purpose of denitrating the cellulose, in order that the fibre may ultimately consist of what might be termed "regenerated" cellulose, the exact chemical nature of which it is not possible to definitely state, though it is evidently some form of cellulose. The denitration is accomplished by passing the pyroxylin threads through a bath of ammonium sulphide, though other alkali sulphides, and some other compounds also, will effect the result. The silk in this condition has a rather yellow colour, which, however, may be bleached out in the usual manner with a solution of chloride of lime. The fibre, as finally obtained, possesses a very high lustre, though it is somewhat metallic in appearance; it has considerable tensile strength, though in this respect, as also in elasticity, it is considerably below true silk. The fibre is also rather harsh and brittle, and does not possess the softness and resiliency of natural silk.

The Chardonnet process that I have outlined is the principal commercial method for the production of artificial silk at the present time, and very considerable quantities are being manufactured, principally at the town of Besançon, in France. There are other methods, however, for the production of this fibre, or at least of analogous fibres, which I will briefly review.

Vivier's silk was also produced from pyroxylin, the product used being said to consist of trinitro-cellulose; this was dissolved in glacial acetic acid, and mixed with solutions of guttapercha and fish-glue. This mass was forced through capillary tubes in the usual manner, and then coagulated by a passage through a variety of solutions such as caustic soda, sodium bisulphite, albumen, mercuric chloride, and aluminium sulphate. The process proved to be complicated and costly, and, though some of the silk so prepared appeared in the market under the name of "soie de France," I believe that the process has now been abandoned.

Lehner's silk is produced by much the same means as that of Chardonnet, and the fibre is very similar to that of the latter. Lehner at first attempted to obtain a fibre from a mixture of pyroxylin solution with various vegetable gums and oils, with solutions of cotton in copper-ammonium sulphate, and even with solutions of waste silk itself. None of these, however, proved a success, and he reverted to the more simple solution of pyroxylin in combination with a drying oil. He also discovered that the fluidity of the collodion could be materially enhanced by the addition of sulphuric acid, and consequently he was able to work his solution under much less pressure than Chardonnet.

Other processes have been suggested for the manufacture of artificial silk which do not employ solutions of pyroxylin. Pauly has suggested the use of a solution of cellulose (wood-pulp or cotton) in copper-ammonium sulphate, while others have considered the solutions of cellulose in concentrated solutions of zinc chloride. None of these methods have attained to any commercial importance. We next come to the use of "viscose" solutions for the spinning of artificial silk. The nature of viscose is probably well known to most chemists at the present time; it is obtained by dissolving wood-pulp (or other form of cellulose) in caustic soda and carbon disulphide, whereby a very viscous solution of presumably cellulose thiocarbonate is obtained. This is forced through capillary tubes, and coagulated in a bath of ammonium chloride or other suitable salt, which causes the precipitation or regeneration of the cellulose. This process, originating with Stearn of England, has received considerable development, and the fibre has been manufactured to some extent in England and the continent, and its manufacture has even received some encouragement in this country by the establishment of a small factory at Lansdown, near Philadelphia. Its commercial development, however, may be said to be still in the experimental stage. This factory is now turning out about 300 pounds of artificial silk per day.

During the year ending 30th June 1902, there was imported into the United States about 170,000 dols. worth of artificial silk fibre. This does not include the large amount of manufactured articles composed either partially or totally of this fibre. The uses to which artificial silk may be put in the textile industry are varied. It is being used extensively for the manufacture of fancy braids and trimmings, and a wide variety of miscellaneous and small articles which come under the general name of "passementerie." It is also used with true silk or cotton in the weaving of material for cravats, scarves, and for various effects in ladies' dress silks. It cannot be used as warp threads on account of its lack of strength and elasticity, but for filling threads it may be used without special precaution. Owing to its high lustre, which is rather metallic in appearance, it is especially suitable for certain effects in ornamental upholstery material, for hangings and draperies. It has not adapted itself, however, to the manufacture of pile fabrics, as it is too brittle and harsh. Artificial silk readily lends itself to dyeing, and no difficulty is encountered in dyeing it in all manner of colours. The chief drawback to artificial silk is the fact that it weakens to a considerable extent on becoming wet with water.

MR. J. T. WOOD IN THE CHAIR.

THE ELECTROLYTIC ESTIMATION OF ARSENIC.

BY S. R. TROTMAN.

The publication of the report of the Commission on Arsenic in Brewing Materials has attracted considerable attention partly because certain methods of testing are recommended by the specially appointed Excise Departmental Committee. The most important of these is that known as the electrolytic method of testing, which has also been described by Prof. Thorpe in considerable detail before the Chemical Society. The method is an adaption of the use of a double cell which appears to have been originally suggested by Bloxam, though, as Prof. Thorpe says, the method "had several disadvantages which prevented it from being generally adopted by chemists."

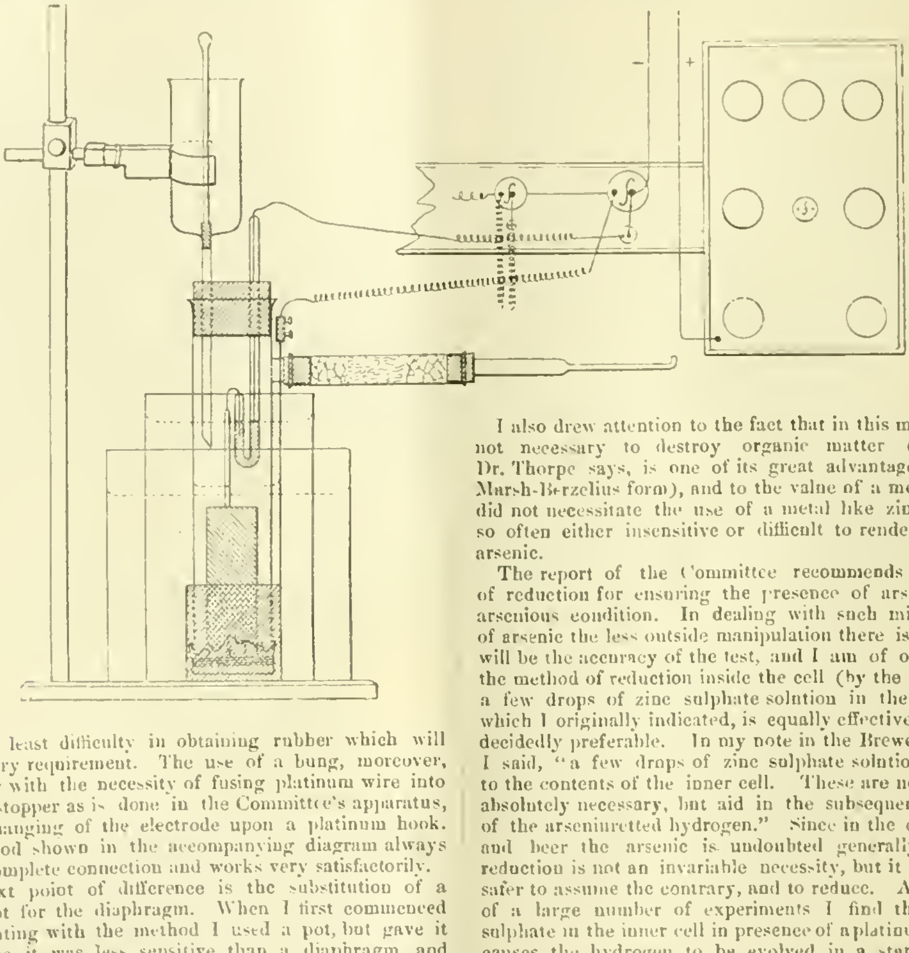
The description of a method by which the principle could be employed in a satisfactory manner for the detection of minute quantities of arsenic was originally published by me in the Brewers' Journal in July 1902, and the main features of the test communicated to the Commission some three months earlier. In a slightly modified form the apparatus has been constantly used in my laboratory ever since. The apparatus recommended by the Excise Committee is similar in principal with that previously described by me, and differs only in certain details, namely, the substitution of glass for rubber joints and a porous pot for a parchment-paper diaphragm. After a very careful trial of this apparatus I am convinced that it has no advantages over mine, and that, on the other hand, it is more difficult to manipulate, more costly, and distinctly less sensitive.

The accompanying diagram shows the form of apparatus I use. The double cell is made of glass with a parchment-paper diaphragm, the upper end of the cell being fitted with a rubber bung, through which pass the tap, funnel, and electrode. The substitution of glass for this rubber bung is no advantage, and makes the apparatus more costly and difficult to replace if broken. If care be taken in the selection of the rubber there is not the least danger of introducing arsenic. This point was apparently recognised by the Joint Committee of this Society and the Society of Public Analysts in their report of Jan. 1902. I have never found the least difficulty in obtaining rubber which will satisfy every requirement. The use of a bung, moreover, does away with the necessity of fusing platinum wire into the glass stopper as is done in the Committee's apparatus, and the hanging of the electrode upon a platinum hook. The method shown in the accompanying diagram always ensures complete connection and works very satisfactorily.

The next point of difference is the substitution of a porous pot for the diaphragm. When I first commenced experimenting with the method I used a pot, but gave it up because it was less sensitive than a diaphragm, and more difficult to clean. It is much easier to clean a glass apparatus and renew a paper diaphragm than a porous cell.

With a perfectly clean pot I have repeatedly found it impossible to detect 0·000001 grm. of arsenious oxide. It appears that the pot has a certain coefficient of absorption, and it is not until this absorptive capacity is satisfied that it becomes sensitive. As the result of a large number of experiments I find that the smallest quantity of arsenious oxide that I can detect with certainty by the apparatus of the Committee is 0·000002 grm., and that, further, with a freshly mufiled pot even this quantity does not give its full mirror.

With my apparatus I can always detect 0·0000002 grm. of arsenious oxide with certainty, so that, apparently, the substitution of the pot causes a great diminution in the delicacy of the test. This power of absorption which the pot possesses also shows itself in another way. When a large quantity of arsenic has been introduced into the inner cell, it is extremely difficult to get it all out, and unless the pot be ignited in the muffle, subsequent tests are inaccurate. This difficulty never arises in my apparatus. I note that other chemists have drawn attention to these points, and that the absorptive power of the pot has been specially noticed by Mr. A. C. Chapman in a recent paper. If the cell be placed in an outer vessel of water, as shown in the diagram, there is not the slightest risk by rupture of the diaphragm. The parchment paper is cut into suitable squares, which are kept soaking in water till required. They are thus rendered quite pliable. I have made several thousand tests with perfectly satisfactory results. The arrangement for utilising the main current by means of lamp resistances was described by me in the paper mentioned, and I have carried out several tests side by side.



I also drew attention to the fact that in this method it is not necessary to destroy organic matter (which, as Dr. Thorpe says, is one of its great advantages over the Marsh-Berzelius form), and to the value of a method which did not necessitate the use of a metal like zinc, which is so often either insensitive or difficult to render free from arsenic.

The report of the Committee recommends a method of reduction for ensuring the presence of arsenic in the arsenious condition. In dealing with such minute traces of arsenic the less outside manipulation there is the greater will be the accuracy of the test, and I am of opinion that the method of reduction inside the cell (by the presence of a few drops of zinc sulphate solution in the inner cell), which I originally indicated, is equally effective, and hence decidedly preferable. In my note in the Brewer's Journal, I said, "a few drops of zinc sulphate solution are added to the contents of the inner cell. These are not, however, absolutely necessary, but aid in the subsequent evolution of the arseniuretted hydrogen." Since in the case of malt and beer the arsenic is undoubted generally arsenious, reduction is not an invariable necessity, but it is of course safer to assume the contrary, and to reduce. As the result of a large number of experiments I find that the zinc sulphate in the inner cell in presence of a platinum electrode causes the hydrogen to be evolved in a state of supertension possessed of increased chemical activity. I have proved that a solution containing only arsenate will, when treated in this way, give mirrors of exactly equal intensity to those obtained from an equivalent quantity of arsenious oxide. I find that, even if the metabisulphite be used for the reduction, the production of the mirror is much assisted by the use of zinc sulphate.

A further point in favour of my form of apparatus is its cheapness and the ease with which the parts may be replaced. The Committee's apparatus is costly, and once broken is useless. The chief criticisms that have been passed on the electrolytic apparatus, described by the Excise Committee, have been directed to its alleged insensitiveness, but they certainly do not apply to the apparatus here described. A method that will detect 0·0000002 grm. of arsenious oxide with certainty satisfies, I think, the most stringent requirements.

A copy of this paper was sent by the author to Prof. Thorpe, who in his reply says:—

"You say, and rightly so, that the method described by me is a modification of the Bloxam method. Would it not be desirable to say in explicit terms that yours, too, is a modification of that method, and that it bears even a closer resemblance to it in its details than mine does? In your paper in the Brewer's Journal you omitted all reference to Bloxam's prior method.

"As I have already informed you, I am not in a position to say anything about your modification of Bloxam's process, as I have not put your apparatus together. It has certain features in its construction which would make it open to attack in judicial proceedings, and I should deprecate its adoption, therefore, in connection with any work which may be the subject of guarantees or warranties.

"Your statement that the use of the Pukal cell interferes with the sensitiveness of the electrolytic test is entirely groundless, as I am in a position to demonstrate. I am not able to perceive any difference as regards the apparent amount of arsenic deposited by the ordinary Marsh-Berzelius method and the electrolytic method, as we practise it here; the main difference appears to be that the electrolytic mirrors tend to be more uniform in character and more evenly deposited than the zinc and acid mirrors.

"As regards the rheostat, this is a common article of electrical furniture, and has long been employed here as in other laboratories, where a main current has to be reduced for electrolytic operations.

"You say, 'that there is no doubt that the presence of zinc in the inner cell causes the hydrogen to be evolved in a condition of increased chemical activity.' I, in common with others, would be glad to be furnished with the evidence upon which this hypothesis of a peculiarly active hydrogen is based."

In reply, Mr. Trotman remarked that the reason why no reference was made to Bloxam in his original paper was that at the time he was not aware of the latter's publication in 1861. The paper was published many years before he was born and, as Prof. Thorpe himself said, the method was never generally used, and hence it was not surprising that he should not have known of the paper. In the present paper he thought it was sufficiently clearly indicated that his method was a modification of that proposed by Bloxam. In any case, however, the point at issue was not which apparatus was more like Bloxam's, but which was the more sensitive. All he claimed was, firstly, priority of publication of a workable modification of Bloxam's idea; and, secondly, that his apparatus was simpler and more delicate than the other. The only objection to the apparatus that could be urged in cases connected with guarantees or judicial proceedings was its excessive delicacy. Dr. Thorpe did not state the nature of the objection which he would raise, but one might assume that he referred to the use of a rubber bung; but carefully selected bungs were no more likely to contain arsenic than glass. Even glass sometimes contained very distinct traces of arsenic and vitiated tests.

Dr. Thorpe stated that his apparatus gave results comparable with the ordinary Marsh-Berzelius method. He had never denied this, but that was an additional proof that his apparatus was even more delicate, for one could never detect with any certainty so small a quantity as 0·0000002 grm. of arsenious oxide by the Marsh-Berzelius method.

In reply to Prof. Thorpe's question about the facts upon which the hypothesis of the action of zinc in the inner cell was founded it appeared to the writer that the facts were fairly plain. In the first place Prof. Thorpe had stated that the electrolytic method would not detect arsenates, with which statement the speaker agreed; but if arsenates were reduced to arsenites before introduction to the inner cell they were readily detected. When the author introduced an arsenate into his apparatus in the absence of zinc sulphate no mirror was obtained, but in the presence of the zinc sulphate the correct mirror was always produced. Therefore the arsenate must have been reduced inside the cell. The facts appeared to him capable of only one explanation. He might state, however, that experiments had been for a long time in progress, by one of his assistants and Dr. Sand, who first suggested the use of zinc sulphate, which would probably throw more light upon the question. Lastly, with reference to the rheostat, he had not claimed to have invented tapping the main current, but he claimed to be the first to realise its possibilities in the production of arseniuretted hydrogen and therefore fully described his method of using it by means of a lamp rheostat.

Patent Specifications may be obtained by post by remitting as follows:—

English.—8*d.* each, to the Comptroller of the Patent Office, C. N. Dalton, Esq., Southampton Buildings, Chancery Lane, London, W.C.

United States.—1*s.* each, to the Secretary of the Society.

French.—1 fr. 25 c. each, to Belin et Cie., 56, Rue des Francs-Bourgeois, Paris (3^e).

I.—PLANT, APPARATUS, AND MACHINERY.

Steam Boilers; Internal Rusting of ——. J. Reischle. Zeits. Bayer Revisionsver f. Kraft, Heiz- u. Licht-Anlagen, 1903. [23]; through Woch. f. Brau., 1904, 21, 82—83.

The author believes that the internal corrosion of steam boilers by rusting, generally attributed to the action of purely chemical agents, is more often due to feeble electric currents set up by the differences in potential between the iron and any other more negative metals which may be present (*e.g.* copper). Even if no metal other than iron be present, there are distinct differences of potential between the various forms of iron used in the construction of the boilers, and even between different portions of the same plate, in virtue of the different proportions of carbon contained in the metal. As an instance of this, it is remarked that wrought-iron rivets in cast-iron plates are frequently corroded. The strains produced in iron by drawing or pressure, also cause differences in chemical activity, and for this reason plates with punched rivet holes are less permanent at those spots, than plates with drilled holes. Further, electrical currents may be set up by thermo-electric phenomena caused by differences in temperature in various parts of the boiler. Once corrosion has been started it will be continued owing to the difference of potential between the iron and its oxide. Plates of zinc suspended in the boiler will themselves become rapidly corroded, thus saving the iron because of their more positive nature.—J. F. B.

English Patents.

Covers or Stoppers of Vessels in which it is desired to Maintain a Vacuum; Impts. in ——. J. Maiden, Manchester. Eng. Pat. 3287, Feb. 11, 1903.

The combination is claimed of an outer edge of a cover or stopper making an airtight joint with a suitable bearing surface formed on or in the neck or mouth of the vessel thus covered or stoppered. The cover or stopper of a vessel having a flared or conical mouth, may have an exhausting aperture adapted to be closed tightly by a wooden or other peg, after the vessel has been exhausted. Or, the cover or stopper may be formed with a recess having at the bottom an exhausting aperture covered by a valve, the recess being filled with melted wax, paraffin, fat, &c., after the vessel has been exhausted.
—R. A.

Drying, Grinding, and Screening; Apparatus for ——. L. Rissmuller, Brooklyn, N.Y. Eng. Pat. 22,164, Oct. 14, 1903. Under Internat. Conv., Jan. 31, 1903.

The apparatus is especially applicable for treating materials of a fibrous nature, such as meat, and consists of a rotary drum provided internally with a crushing roller and a screening device operated by the rotation of the drum. The crushing roller is journalled in a U-shaped support mounted to rotate independently on the axis of the drum, the roller being capable of sliding towards and away from the axis of the drum, and tending to return by gravity to a position below the axis. The screening device, with a screen adjacent, is located at the discharge end of the drum, the screen co-operating with a roughened face on the crushing roller. Means are also provided for passing a heating medium through the drum.—R. A.

Filters; Impts. in ——. O. Loffler and W. Weidle, Vienna. Eng. Pat. 21,149, Nov. 6, 1903.

The filtering chamber is formed by two plates of filtering material and a washer, against which the plates are pressed by suitable means, between them, a suction pipe being connected to a tube passing through the washer. The walls of the casing are perforated opposite the filtering plates, to admit the liquid, and are shaped so that spaces are formed between them and the plates. A modified form, for pocket use, is provided with a screw-threaded cover.—R. A.

United States Patents.

Distilling Apparatus. J. M. Moore, Wena, Ala. U.S. Pat. 749,316, Jan. 12, 1904.

This apparatus comprises a horizontal cylindrical receiver, having within it a single central flue stretching beyond it, and so of relatively longer diameter; a detachable dome mounted on top of the receiver, near one end, and communicating with the interior of the receiver; and a condenser, provided with inlet and outlet valves, mounted near the other end of the receiver. A condensing-pipe leads from the top of the dome to the bottom of the condenser, and a conducting-pipe leads from the top of the condenser to a worm. A discharge-valve is provided in the bottom of the receiver.—R. A.

Distilling Apparatus. A. C. G. Dupuis, New Orleans, and W. S. Fell, Waveland, Miss., Assignors to F. P. Morrill, and G. E. Pitcher, New Orleans, La. U.S. Pat. 749,368, Jan. 12, 1904.

The liquid-containing receptacle is formed with walls corrugated internally, and is surmounted by a conical vapour chamber, having an outlet at its apex for the lighter vapours. A foraminous chemical-containing plate is mounted between the receptacle and the chamber, and converging plates extending upwards are arranged in the chamber above the partition, outlet conduits for the heavier vapours being formed between these plates and the walls of the chamber.—R. A.

Centrifugal Machine. J. J. Berrigan, Orange, N.J., Assignor to F. J. Arend, New York, and J. Bernstrom, Stockholm, Sweden. U.S. Pat. 750,079, Jan. 19, 1904.

This machine is adapted for separating combined liquid and solid materials, and consists of a rotary receptacle having within it two eccentrically-disposed separating vessels, which are arranged concentrically one within the other, whereby the combined materials are subjected to two successive separations in the vessels. A conduit for the separated solid material and an outlet are provided. (See also Eng. Pat. 12,181 of 1901, and U.S. Pats. 689,570–2 and 696,130; this J., 1901, 1095, and 1902, 244 and 597.)
—R. A.

Centrifugal Machine. J. J. Berrigan, East Orange, N.J. U.S. Pat. 750,080, Jan. 19, 1904.

This machine is adapted for the separation of solids and liquids, and consists of a rotary receptacle provided internally with a cylindrical chamber, having a perforated wall. The inner surface of this wall is provided with bars arranged parallel to the axis of rotation, to prevent the circulation of the liquid around its inner periphery. The solid material is deposited in the sections of the inner periphery of the perforated chamber, surplus solid material being conveyed away through a conduit. The rotary receptacle is provided with a liquid-outlet outside of the perforated chamber. (See also preceding abstract.)
—R. A.

French Patent.

Centrifugal Purifier-Separator. C. E. Lossignol. Fr. Pat. 335,268, Aug. 22, 1903.

The patent relates to a machine for separating solid materials from gases or liquids which contain them, by centrifugal force. It consists of a turbine formed of three truncated conical parts, one within another, the lengths of which are in certain ratios, mounted on a vertical or horizontal axis, and rotating in a vat containing water, which, by the motion of rotation, is formed into a parabolic wave, which forms the bottom of two compartments in the turbine, one of ingress, and the other of egress. In these two communicating vessels, the separation is effected by centrifugal force, the solid particles being thrown to the outer edge of the turbine into the water, from which they can be collected, and the fluids flowing away, under the equilibrium of the pressures existing in the communicating vessels, from the openings of ingress and egress of the turbine.—W. C. H.

II.—FUEL, GAS, AND LIGHT.

Unburnt Products in Chimney Gases; Determination of ——, *by a Modified Orsat Apparatus.* W. H. Sodeau. XXIII., page 206.

English Patents.

Coke; Manufacture of——. A. Custodis, Düsseldorf. Eng. Pat. 501, Jan. 8, 1903.

ee Addition, of Jan. 7, 1903, to Fr. Pat. 305,879 of 1900; his J., 1903, 944.—T. F. B.

Turf [*Peat*] *Bricks; Manufacture of*——. G. Peters, Langenberg, Germany. Eng. Pat. 4978, March 3, 1903.

The turf is reduced to fibres or small pieces and piled up n heaps about 30 feet high. The heaps become heated, robably in consequence of oxidation, and the proportion f water is reduced sufficiently to allow the turf to be ompressed into bricks.—H. B.

Smokeless Fuel; Manufacture of ——. A. Hage. Eng. Pat. 27,355, Dec. 14, 1903.

 smokeless fuel is prepared by suitably mixing a ground mokeless coal, such as long flame coal or coke, with a round smoky coal, such as non-flaming coal or brown coal, nd forming the mixture into briquettes, with or without the ddition of tar as a binding material.—L. F. G.

roducer Gas; Process and Apparatus for Generating ——. F. Jahns, Saarbrücken, Germany. Eng. Pat. 1994, Jan. 27, 1903.

n order to obtain, from bituminous coal, producer gases ontaining no tar, or very little, a number of producers are rouped together. Each producer is charged and allowed burn out without recharging; then it is cleaned out, gain charged, and again connected into the series. The roducers are kindled in succession, with due intervals etween, so that there is always one in which tarry gases re no longer being produced; and the gases from all the ther producers are finally led through the latter, in order hat any tarry matters they contain may be fixed. When e fuel in this producer is exhausted, it is cut out to be eaned and recharged, the next in succession becoming the xing producer, and so on continuously in rotation. The ases may be drawn through all the producers, arranged in eries, or may be drawn from each producer directly rough the fixing producer.—H. B.

oal Gas or other Gas; Apparatus for the [*Benzol*] *Enrichment of* ——. H. Pooley and A. Poulson, Stafford. Eng. Pat. 20,330, Sept. 22, 1903.

 vertical steam chest, provided externally with projecting rizontal ribs, is enclosed in an outer casing having ternal ribs which interlace with those on the steam chest. benzol supply-pipe passes vertically up through the eam chest and discharges any unvolatilised benzol, which ay escape from it, into a tray on the top of the steam-est, whence it trickles down over the baffling ribs. A pe supplying the gas to be carburetted likewise passes up rough the steam-chest and opens above the tray; the s thus receives a preliminary heating and then passes wn the space between the interlacing ribs, mingling with e benzol vapours and passing out by a pipe at the base the apparatus. The enriched gas is subsequently mixed th uncarburetted gas.—H. B.

as; Process and Apparatus for Producing Combustible ——. L. Herzog, Arbon, Switzerland. Eng. Pat. 22,547, Oct. 19, 1903.

he apparatus, which is adapted for use with a suction-tor or exhauster, comprises a central generator-furnace, rmounted by a tubular evaporator which surrounds the eding hopper; a water supply-pipe opening into the aporator; a thermostatic device placed in the path of the ses which heat the evaporator, this device regulating the pply of water according to the temperature; three con-ntric cylinders surrounding the generator, forming two nular spaces, the inner one serving to lead off the nerator gases, and the outer one for giving a preliminary heating to the air supply which is drawn up through it; an air fan for use in kindling the fire when the generator is first started; a closed ash-pit, suitable valves, &c. When the plant is operating, air is drawn in at each suction, through openings in the outer cylinder; the heated air is led through the evaporator and passes down, mixed with steam, to enter at the grate of the furnace; and the gases generated are led off through the annular space surrounding the furnace. The heat of the latter is thus conserved, permitting a large proportion of steam, to be used.—H. B.

Gas; Generator for a Simultaneous Production of Heating and Lighting ——. E. Meininghaus, Barmen, Germany. Eng. Pat. 10,597, Nov. 23, 1903.

A vertical retort, having an inclined discharge end, is arranged inside a vertical generator furnace. The retort is fed intermittently with coal, the coal gas being led off at the top, and the coke withdrawn at the lower end; while the generator is fed with coke, and the generator gas is led off at the top. Charging, discharging, and gas-purifying devices are provided.—H. B.

Gas; Improved System of Purifying and Distributing ——. E. Meininghaus, Barmen, Germany. Eng. Pat. 10,770, Nov. 23, 1903.

Coal gas and the like, instead of being distributed by pipes in the usual way, are to be compressed and distributed in the liquid state in cylinders. Before compression, carbon dioxide is removed from the gas by means of caustic potash or other suitable material.—H. B.

Burners for Testing Gas. W. T. Sugg. Eng. Pat. 4052, Feb. 20, 1903. XXIII., page 205.

United States Patent.

Gas; Process of Manufacturing ——. P. Naef, New York. U.S. Pat. 749,945, Jan. 19, 1904.

See Eng. Pats. 20,658 and 20,659 of 1899; this J., 1900, 10,904 and 10,905.—H. B.

Furnace [*Carbide*]; *Electric* ——. Stevens and Timmerman. U.S. Pat. 749,461, 1904; also *ibid.* U.S. Pat. 749,462. XI. A., *page* 192.

Furnace [*Carbide*]; *Electric Resistance* ——. A. H. Cowles. U.S. Pat. 750,093; also *ibid.* 750,094; 750,095; 750,096: 750,170; and 750,171. XI. A., *page* 192—193.

French Patent.

Gas-Generator for the use of Small Coal or Coal-Dust. Vereinigte Anthracit Werke, G. m. b. H. Fr. Pat. 335,291, Sept. 11, 1903.

In order to diminish the pressure of the fuel on the grate, a horizontal supporting surface is arranged in the upper part of the generator immediately above the grate; the latter consists of a number of rings arranged one above another, of decreasing diameters, thus forming an inverted cone. The fuel falls from the supporting surface into the conical grate, and the gas produced is led away through a central vertical pipe, which is surrounded by a similar pipe of larger diameter, and in the hollow space between these the steam necessary for the generation of the gas is produced and led from the upper part of the hollow space by a pipe and introduced beneath the grate. In another form of the apparatus the fuel is supplied to a funnel-shaped vessel, with its narrow end pointing downwards, arranged inside the generator, the inclined side of which vessel acts as a supporting surface; the fuel falls from this on to an erect conical grate. In another form the lower portion of the generator is narrowed below the fuel-supply chamber—the distance between the bottom of which and the narrow portion of the generator can be regulated according to the size of the fuel. The fuel, as it falls from the supply chamber, forms a conical mass from the free surface of which—between the bottom of the supply chamber and the wall of the generator—a regular supply of gas is produced. The lower part of the generator is used chiefly as a steam chamber and acts as an ash-pan after the insertion of a grate into the narrowed portion of the generator chamber. —W. C. H.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM AND MINERAL WAXES.

English Patents.

Pitch ; Process for the Manufacture of ——. C. G. von Wirkner, Schalke, Westphalia. Eng. Pat. 13,185, June 12, 1903.

See Fr. Pat. 333,011 of 1903 ; this J., 1903, 1259.—T. F. B.

Naphthalene ; Method for Purifying ——. H. J. Haddan, London. From I. Paradell-Mateu, Barcelona. Eng. Pat. 25,989, Nov. 27, 1903.

Naphthalene vapour is subjected to a process of fractional condensation by driving it along a chamber or tube by means of a current of air or other inert gas.—T. F. B.

Yeast ; Manufacture of Certain Products from Waste Brewery or Distillery ——. P. Schidrowitz and F. F. Kaye. Eng. Pat. 6601, March 21, 1903. XVII., page 200.

IV.—COLOURING MATTERS AND DYESTUFFS.

Indigo ; Manufacture of —— [*from Indigo Plant*]. C. Rawson. J. Soc. Dyers and Colourists, 1904, **20**, 35.

Contrary to Bréaudat's experience (this J., 1904, 15), the author has never found any loss of indigotin, real or apparent, to take place during the drying of natural indigo. On the contrary, it is stated that indigo slowly dried in the usual way invariably contains a slightly higher percentage of indigotin than indigo dried rapidly. This is explained by the fact that some of the impurities present are decomposed into ammonia, carbon dioxide, &c., by the fungus always present. The following example is given. Two cakes of indigo were taken from the centre of a press ; one, dried in an air oven, gave 39·5 per cent. of dry substance, containing 58·8 per cent. of indigotin, corresponding to 23·22 per cent. on the moist cake. The second sample was dried in the drying-house in the usual way for nearly two months, and, after a final drying in the air-oven, yielded 38·3 per cent. of dry matter, containing 60·4 per cent. of indigotin, or 23·13 per cent. on the moist cake.—T. F. B.

Anthraquinone ; β-Substitution Products of ——. P. Kaufler. Ber., 1904, **37**, 59—66.

The author diazotised β-aminoanthraquinone by means of amyl nitrite, and obtained β-iodo-, β-chloro-, and β-nitro-anthraquinone from the diazonium salts by elimination of nitrogen, and β-bromo-anthraquinone by decomposition of the diazonium perbromide. The products are fairly stable, yellow, crystalline compounds. β-Iodoanthraquinone forms no addition-product with chlorine. β-Anthraquinonediazonium salts are not explosive. Even the nitrate is not affected by percussion, and only decomposes locally on contact with a hot glass rod.—E. F.

Anthraquinone-α-sulphonic Acids. R. E. Schmidt. Ber., 1904, **37**, 66—72.

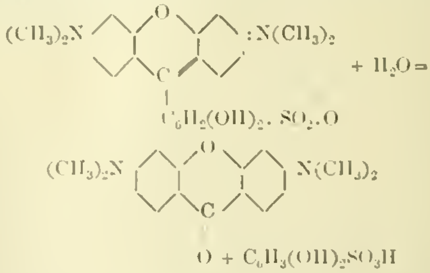
The author claims priority with regard to the formation of anthraquinone-α-sulphonic acids in presence of mercury or its salts. The mercury, or mercury salt, must be very finely divided, but only very small amounts are necessary. Exact recipes for the preparation and isolation of anthraquinone-α-sulphonic acids and of the 1.5- and 1.8-disulphonic acids are given. They all form rather insoluble and characteristic potassium salts. Instead of obtaining them by sulphonating anthraquinone in presence of mercury, these acids may also be obtained from the corresponding α-nitro-anthraquinones by boiling with 10 per cent. sodium sulphite solution. They are readily converted into the corresponding hydroxy-compounds by heating under pressure with milk of lime. With ammonia or alkylamines in aqueous solution, they form amino- or alkylamino-anthraquinones. With methyl alcoholic potassium hydroxide solution they yield methoxy-anthraquinones, and with phenolic potassium phenolate solutions they yield phenyl ethers of hydroxyanthraquinones. Anthraquinone-α-sulphonic acid is reduced by zinc dust and ammonia to anthracene-α-sulphonic acid, which yields α-anthrol on fusion with caustic alkalis. With 80 per cent. fuming sulphuric acid, anthraquinone-α-sulphonic acid may be oxidised to 1.2.4-trihydroxyanthraquinone-5 (or 8) sulphonic acid. On nitration it yields 1.5- and 1.8-nitro-anthraquinone sulphonic acids, which are reduced by sodium sulphide solution to the corresponding aminosulphonic acids. These latter can be diazotised and coupled with phenols or amines, and form aminohydroxyanthraquinones with milk of lime and 1.5- and 1.8-monomethyldiamino-anthraquinones with methylamine. Various other derivatives of anthraquinone-α-sulphonic acids are also described. They are all characterised by exceptional tendency to crystallisation.—E. F.

Dimethylaniline ; Addition Products of ——. C. L. Jackson and L. Clarke. Ber., 1904, **37**, 176—180.

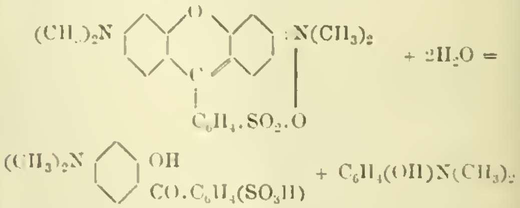
Substituted quinones combine with one molecule of dimethylaniline to form dark-blue unstable compounds, crystallising in prisms, of definite melting-point. They gradually decompose at the ordinary temperature into their constituents. The compounds with chloranil and with trichloroquinone are described. Substituted nitrobenzenes form similar compounds with dimethylaniline, which differ, however, by being brown, yellow, or red. Some of these have already been described by Hepp. The authors describe compounds with 1.3.5-trichlorotrinitrobenzene, 1.3.5-tribromotrinitrobenzene and with several highly substituted dinitrobenzenes.—E. F.

Dihydroxytetramethylrosaminesulphonic Acid ; Decomposition of ——. C. Liebermann and A. Glawe. Ber., 1904, **37**, [1], 203—210.

When dihydroxytetramethylrosaminesulphonic acid is boiled with dilute caustic alkali, it is decomposed, forming tetramethyldiaminoxanthone and catecholsulphonic acid, according to the equation—



When tetramethylrosaminesulphonic acid is treated in a similar manner, the molecule is broken up with greater difficulty and then separates in quite a different direction, according to the equation—



forming dimethylaminohydroxybenzophenonemonosulphonic acid. The authors remark that triphenylmethane dyestuffs in general are capable of decomposition with formation of benzophenone derivatives, but that the line of cleavage of the molecule varies with the nature of the dyestuff, as indicated by the above-mentioned cases. The corresponding leuco-compounds decompose in this manner either with very great difficulty or not at all.—E. F.

Colour-Acids; Action of ——, on Cellulose, Alcohol, and Acetone; and Nile Blue Base as a Reagent for Carbon Dioxide in Air. M. Heidenhain. Pflüger's Arch., **100**, 217—241. Chem. Centr., 1904, **1**, 116.

Michaelis (compare this J., 1903, 1083) has brought forward instances of histological colorations which he considers support Witt's solid solution theory of dyeing. The author, however, maintains his view that the property of albuminoids of taking up and fixing dyestuffs is of a chemical nature. The fact that whilst basic aniline dyestuffs are more readily soluble in alcohol than in water, yet dyeing with such dyestuffs is effected more easily in alcoholic than in aqueous solution, is incompatible with Witt's theory. White insoluble powders, *e.g.*, antimony oxide, zinc oxide, aluminium hydroxide, &c., when treated with dye liquors, condense the dyestuffs on their surface, and acquire various colours depending upon the nature of the dyestuff; for example, antimony oxide when shaken with the yellowish solution of *Hæmatoxylinum puriss* is coloured blue. In these cases, and also in the cases of histological colorations, absorption processes first come into play, but only as a preliminary to chemical action. According to Michaelis the fact that indifferent bodies, as cellulose, alcohol, and acetone, give the same colour reactions with colour-acids and bases as albuminoids, negatives the idea of salt formation, and confirms the view that the alteration of colour is due to the substitution of one solvent for another. The author, however, maintains that in all these cases salt formation takes place. He states that the blue coloration produced by spotting filter paper with the yellowish red solution of Nile Blue base is caused by the carbon dioxide present in the air, as is shown by the fact that the solution of the base when allowed to stand in a test-tube becomes coloured blue on the surface. The blue coloration produced when Nile Blue base is dissolved in alcohol is caused by an acid which is present in small quantity in alcohol. If the alcohol be first treated with calcium hydroxide, it dissolves the colour base to a yellowish-red solution. Like Eosin acid, the colour-acids Benzopurpurin 6B and Congo acid stain cellulose the colour of the colour salts. Here, also, however, chemical combination takes place between the colour-acid and the cellulose, for whilst the alkali salts of the colour-acids are turned blue by both hydrochloric and glacial acetic acids, the red stain produced on cellulose is turned blue by hydrochloric, but not by glacial acetic acid. The solutions of the colour acids named in glycerol, phenol, and cresol, as in methyl and ethyl alcohols, have the colour of the colour salts. The author points out that all these solvents contain hydroxyl groups, and in support of his view that the change of colour is due to chemical action, he cites the facts that Benzopurpurin acid and Congo acid dissolve in pure water with a blue colour; are insoluble in absolute alcohol; and dissolve in aqueous alcohol with the red colour of the colour salts. This change of colour in aqueous alcohol is explained as being due to the dyestuff undergoing electrolytic dissociation when dissolved by the water, and thus being rendered susceptible to chemical reaction. (See also this J., 1902, 966, 1072.)—A. S.

English Patents.

Azo Dyestuff; Manufacture and Production of a New ——. H. E. Newton, London. From the Farbenfabr. vorm. F. Bayer and Co., Elberfeld. Eng. Pat. 5269, March 6, 1903.

See Fr. Pat. 329,866 of 1903; this J., 1903, 1042.—T. F. B.

Azo Colouring Matter; Manufacture of ——. J. Y. Johnson, London. From The Badische Anilin und Soda Fabrik, Ludwigshafen-on-the-Rhine, Germany. Eng. Pat. 5689, March 11, 1903.

A monoalkyl-*p*-phenylenediamine or homologue thereof is treated with two molecular proportions of nitrous acid. The *p*-diazomonoalkyl-alphylnitrosamines so formed combine readily with 1.8-dihydroxy-3.6-disulphonic acid to form dyestuffs containing a nitroso group, which dye in violet red shades from a bath containing acetic acid. In presence of a mineral acid they dye in blue shades, the nitroso group being split off. By heating aqueous solutions of these new dyestuffs with saponifying agents, such as dilute hydrochloric acid or caustic alkali, the nitroso group is split off, and dyestuffs result which dye wool in blue shades.—E. F.

Indoxyl and Indoxylic Acid; Manufacture of ——. J. Y. Johnson, London. From Badische Anilin und Soda Fabr., Ludwigshafen-on-Rhine. Eng. Pat. 6119, March 19, 1903.

See U.S. Pat. 731,385 of 1903; this J., 1903, 861.—T. F. B.

Sulphurised Colouring Matters [Sulphide Dyestuffs]; Manufacture of ——. G. B. Ellis from Soc. Chim. des Usines du Rhone, Lyons, France. Eng. Pat. 6078, March 16, 1903.

Azo compounds of *p*-phenylenediamine and phenols or naphthols or their substitution products are heated with alkali polysulphides or with sulphur and alkali sulphides at a low temperature, so that the azo group apparently remains intact. From *p*-aminophenyleneazonaphthol there is obtained in this way a green dyestuff, the melt being heated to 120°—130° C. In a similar manner a greenish-black dyestuff is obtained from *p*-aminophenyleneazophenol at 140°—160° C. Under similar conditions β-naphtholazophenyleneazo-β-naphthol yields a yellow, β-naphtholazophenyleneazophenol an olive green, and phenolazophenyleneazophenol a bluish black dyestuff. The products dye cotton directly in presence of an alkali hydroxide or carbonate without the addition of an alkali sulphide and can be used for printing from ordinary copper rollers.—E. F.

United States Patents.

Purpurin α-Sulphonic Acid. K. Thun, Elberfeld, Assignor to Farbenfabr. of Elberfeld Co., New York. U.S. Pat. 746,405, Dec. 8, 1903.

See Fr. Pat. 334,658 of 1903; this J., 1904, 113.—T. F. B.

[Sulphide] Dyestuff; Green ——. A. Lüttringhaus, Assignor to Badische Anilin und Soda Fabrik, Ludwigshafen-on-Rhine. U.S. Pat. 750,113, Jan. 19, 1904.

Methylene violet is "treated with sodium tetrasulphide, carbon bisulphide, and alcohol." The dyestuff produced is soluble in sodium sulphide solution, the solution obtained dyeing unmordanted cotton green, which changes to blue on treatment with potassium bichromate and sulphuric acid. Compare Fr. Pat. 322,784 of 1902; this J., 1903, 360.
—T. F. B.

French Patents.

Sulphurised Dyestuffs [Sulphide Dyestuffs]; Preparation of Violet-Red ——. Raison Commerciale Kalle et Cie. Fr. Pat. 335,383, Sept. 16, 1903.

A polyhydroxylated rosinduline is obtained by melting substances capable of forming 1.4-naphthylenediamine, such as the azo-dyestuffs formed from α-naphthylamine, with *p*-aminophenol and hydrochloric acid. Or naphthylenediamine may itself be melted with aminophenol and hydrochloric acid in presence of a suitable oxidising agent, preferably in the form of an aromatic nitro-compound. Or α-nitronaphthylamine may be melted with *p*-aminophenol in presence of hydrochloric acid. The hydroxylated indulines obtained by any of these methods are melted with sulphur and sodium sulphide. The products dye unmordanted cotton in reddish-violet shades fast to washing and to light.—E. F.

Red Dyestuff [Azo Dyestuff]; Manufacture of New Compounds of the Benzene Series, and their Transformation into a ——. Cie. Paris. Coul. d'Aniline. Fr. Pat. 328,130, Nov. 3, 1902.

o-Chlorobenzylsulphonic acid is nitrated, forming *p*-nitrochloro-o-benzylsulphonic acid. This is converted into "*p*-nitranilinehomosulphonic" acid by heating with ammonia. This latter body yields a red dyestuff, very suitable for the manufacture of lakes, on diazotisation and combination with β-naphthol.—E. F.

Rhodamines [*Pyrone Dyestuffs*] *of a Yellow Shade derived from Tetra-Alkylated Rhodamines; Preparation of* ——. Cie. Paris. Coul. d'Aniline. Fr. Pat. 328,139, Nov. 12, 1902.

The tetra-ethyl rhodamine derived from phthalic acid is treated with caustic alkali in dilute aqueous alcoholic solution. The product dyes in more yellow shades than the original dyestuff and its tinctorial power is greater. —E. F.

Sulphide Dyestuff; Preparation of a Bluish-Black ——. Cie. Paris. Coul. d'Aniline. Fr. Pat. 328,158, Nov. 28, 1902.

See Eng. Pat. 25,851 of 1902; this J., 1903, 1191.—T. F. B.

Indoxyl and its Derivatives; Production of ——. Badische Anilin und Soda Fabrik. First and Second Additions, each dated Dec. 8, 1902, to Fr. Pat. 328,148, Nov. 21, 1902.

See Eng. Pat. 26,372 of 1902; this J., 1903, 1289.—T. F. B.

V.—PREPARING, BLEACHING, DYEING, PRINTING, AND FINISHING TEXTILES, YARNS, AND FIBRES.

Printing of Cotton, by the Discharge or Reserve Methods, with Blue Sulphide Dyestuffs. A. Sansone. Rev. Gén. des Mat. Col., 1904, **8**, 37—39.

It is probable that in the printing of cotton, indigo will be partly replaced by the blue sulphide dyestuffs. The latter can be applied in discharge or reserve printing by the same methods as those employed for indigo, except that the chromic acid discharge is not suitable to them. For reserve printing, the material is printed, either with sulphate of lead or with a mixture of zinc white and zinc sulphate, thickened with gum. The following is a typical white reserve:—250 grms. of zinc white paste 1 : 1, or the same quantity of kaolin paste; 300 grms. of sulphate of zinc; the whole thickened with 450 grms. of gum water, 1 : 1. After printing, dry at a moderate heat and dye as rapidly as possible so as to avoid the penetration of the reserve by the dye solution. It is best to dye in a padding machine, which must have no copper used in its construction. The padding should take from one to two minutes and be done cold for light shades and not above 80° C. for full colours. The padding solution is made up of the sulphide dyestuff dissolved with the necessary amounts of sodium sulphide and soda ash, and thickened with a suitable thickening such as gum tragacanth. After padding, the cloth is exposed to the air in order to develop the colour: it is then washed, passed through a weak acid bath, again washed and finally soaped and dried. The chlorate discharge gives the best results with sulphide colours. The cotton is dyed in the usual manner and then printed with a discharge such as the following:—70 grms. of kaolin made into a paste with 70 grms. of water; a solution of 175 grms. of chlorate of soda in 240 grms. of British gum thickening added; the mixture warmed to 60° C.; 125 grms. of tartaric acid, finely powdered, added; and, after cooling, 70 grms. of solution of ammonium ferrocyanide 25° B. Print dry at a moderate temperature and steam one to three minutes in a Mather-Platt at 98°—100° C., using dry steam. The discharge method gives a better white than the reserve method, but the latter is good enough for most purposes. —A. B. S.

English Patents.

Bleaching Flax, Hemp, Cotton, Jute, Ramie, Straw, and the like; Process of ——. L. C. P. Jardin, Cambrai, France. Eng. Pat. 9724, April 29, 1903.

Bleaching Apparatus; Continuous ——. M. Muntadasy, Rovira, Barcelona. Eng. Pat. 11,200, June 25, 1903. Under Internat. Conv., Nov. 10, 1902.

See Fr. Pat. 327,931 of 1902; this J., 1903, 948.—T. F. B.

Polychrome Printing on Calico and other Materials. E. Rolffs, Siegfeld, Germany. Eng. Pat. 1583, Jan. 22, 1903.

The patterns to be printed are transferred by photographic means to the surface of the printing cylinders, and there etched in. To produce a coloured print, the object to be printed is photographed through light filters of various colours, and the resulting negatives are transferred to different rollers, and the material is printed by each of these rollers with the colour corresponding to the light filter used in its preparation. Soluble colours are employed. For the preparation of rollers, see Eng. Pat. 16,944, 1899. —A. B. S.

Printing Vegetable Fabrics. H. Schmid, Mülhausen, Germany. Eng. Pat. 3778, Feb. 17, 1903.

See Fr. Pat. 329,747 of 1903; this J., 1903, 1044.—T. F. B.

Steaming Cloth and other Fabrics; Apparatus for ——. F. I. Burgher, Stapleton, U.S.A. Eng. Pat. 25,369, Nov. 20, 1903.

The peripheral face of the steaming cylinder has a longitudinal shoulder or offset, so that the covering, of suitable fabric material, forms a similar offset, which leaves room for one edge of the cloth to be treated to abut against, thus preventing the formation of a crease in the cloth. The steaming cylinder contains inside a longitudinally corrugated tubular stiffener, one end of which is non-corrugated to form an annular water draining chamber. The cylinder and stiffener have registering perforations for the passage of steam which comes from a perforated chamber within the cylinder and passes out, finally, through the material to be treated.—E. F.

Metallisation of Textile Fibres and Products therefrom, and also of Leather, Paper, and the like. A. Forster, Plauen i. V., Germany. Eng. Pat. 24,289, Nov. 9, 1903.

Solutions of nitrocellulose are thickened by the addition of water. The fibre or fabric is saturated with the thick liquid so obtained, and the metallic powder is either held in suspension in this solution, or is afterwards strewn over or applied to the materials. The metallised material may then receive an external coating by the application of a thinly-liquid solution of nitrocellulose to which water has not been added. It is then preferably passed through "satining" machines ["Satinirmaschinen"] whilst being warmed. —E. F.

Waterproof Cloths and Fabrics; Manufacture of certain kinds of ——, *and Machinery for use therein.* W. M. Mackintosh, Liverpool, and A. Smith, Manchester. Eng. Pat. 218, Jan. 5, 1903.

The composition used is made from a vegetable oil, an alkali or metallic carbonate or oxide, and resin or other analogous substance or starch or starch preparation. The fabric is first passed through heated drying rollers, and then through a vat containing the fluid composition, passing over rollers which are immersed in the same. It is then passed over scraping knives, which remove the excess of composition from both surfaces, and finally is pressed between heated nipping rollers which thoroughly force the composition into the fabric.—E. F.

French Patents.

Mordanting of Cotton; Process for ——. F. L. Grenot. Fr. Pat. 334,945, Aug. 31, 1903.

The cotton is padded in a solution of barium aluminate, then dried slowly in the air, the carbon dioxide of which converts the barium into carbonate and the aluminium into its hydrate. The cotton is then washed either in water or in a chalk bath, which, in the latter case, fixes lime on the fibre. It is then dyed as usual. The mordant can also be applied by alternate paddings in Turkey red oil and barium aluminate. The alumina can also be fixed by steaming at low pressure in presence of carbon dioxide or ammonium carbonate.—A. B. S.

[Dyeing, Bleaching, Mercerising, &c.] Treatment of Textiles; Apparatus for ——. T. de Naeyer. Fr. Pat. 334,828, Aug. 25, 1903.

The material to be treated is placed in a vertical vessel between perforated plates. This vessel is preferably larger at the top than at the bottom, in order that the liquid which has been weakened in strength by passing through the upper layers of material, should have a smaller amount of material to act on. The liquid is showered over the top in the usual way by means of a circulating pump; it passes out of an opening at the bottom of the apparatus into a jacketed heating vessel, where it is heated to the desired temperature, and then circulated by the pump. This avoids dilution of the liquid employed, by condensed steam.
—A. B. S.

Printing or Decoration of Fabrics, Paper, &c.; Process for ——. C. L. Burdick and H. Pervilhac. Fr. Pat. 334,667, Aug. 17, 1903.

In printing designs such as annular rings by means of stencil plates, use has to be made of wires, &c., to support the central portion of the stencil. To avoid this the material is first printed with a resist so as to cover the central parts which it is not desired to print; after this the colour paste is printed through a larger stencil so as to cover the resist and also form the required pattern around it. The colour is fixed as required and then the resist is removed, and leaves the centres uncoloured. A good resist consists of a mixture of resin, paraffin, beeswax, and turpentine. It can be removed by means of benzene.—A. B. S.

Multicolour Effects on Silk or Mixtures of Silk and Cotton; Process for Obtaining ——, by Printing a Single Mixture of Colours. J. Mennweg and D. Mennweg. Fr. Pat. 334,874, Aug. 27, 1903.

The mixed fabric is treated with tannic acid in the usual way, and then printed with a mixture of mordant, and basic and substantive dyestuffs, to which is added chromium acetate or a salt of similar properties. After printing, the fabric is steamed and washed. The chrome compound prevents the substantive dyestuff from dyeing the tanned silk, whilst the cotton takes all the dyestuffs and so gives a mixed effect. To obtain two-colour effects on silk alone, the warp or the weft is mordanted with tannin before weaving. A mixture of acid and basic dyestuffs can be then printed on, in which case the mordanted silk is only dyed by the basic dyestuff, whilst the unmordanted is dyed by both. Three-colour effects on cotton and silk mixtures can be obtained by mordanting part of the materials before weaving.—A. B. S.

Painting on Tissues; Process for ——. A. Boyeux and F. Prud'hon. Fr. Pat. 334,886, Aug. 27, 1903.

The colour is made into a paste and supplied to a printing roller by a metallic furnisher. The printing roller is in contact with another roller, and the fabric to be printed passes between them. The printing roller can either be simply engraved in fine lines for printing a plain colour, or it can be engraved in any desired pattern. The fabric can be printed on both sides if desired.—A. B. S.

Finishing of Textiles; Continuous Process for ——, with Intermediate Drying. Soc. F. Bertrand and Co. Fr. Pat. 334,890, Aug. 14, 1903.

The machine for treating the cloth with the finishing material consists of three or more rollers placed one above another; the lower one dips into the finishing liquid, and pressure can be applied as usual. The cloth passes first between the two upper rollers, and is thus impregnated with the liquid; it is then passed over a drying arrangement. If the treatment with the finishing liquid has to be repeated, the cloth is passed back between one of the lower pairs of rollers and again dried. This process is repeated as often as necessary.—A. B. S.

VI.—COLOURING WOOD, PAPER, LEATHER, Etc.

English Patent.

Colouring and Hardening Natural Stone; Process for ——, also applicable to Organic Materials such as Ivory. H. H. Lake. From Chem.-Tech. Fabr. Dr. A. R. W. Brand and Co. Eng. Pat. 5594, March 10, 1903. IX., page 188.

VII.—ACIDS, ALKALIS, AND SALTS.

Peroxylaminesulphonic Acid. E. Divers. J. Chem. Soc. (Trans.), 1904, 108—110. (See also this J., 1904, 60.)

The formation of peroxylaminesulphonic acid, with evolution of nitric oxide, when sulphur dioxide is passed into the Gay-Lussac tower, *i.e.*, into sulphuric acid containing nitroso-sulphuric acid, is explained by the fact that nitroso-sulphuric acid consists of the mixed anhydrides of sulphuric and nitrous acids ($N_2O_3 + 2SO_3$), and is decomposed in accordance with the equation $2N_2O_3 + 4SO_2 + 2H_2O = 2NO + [ON(SO_3H)_2]_2$, just as nitrous anhydride is decomposed into nitric oxide and peroxide, the latter, in the case under notice, being sulphonated. The purple peroxylaminesulphonic acid is also formed, along with nitroso-sulphuric acid, from nitric oxide and sulphuric acid in presence of cupric or ferric sulphate as catalytic agent; the sulphuric acid acts in its "pyro" form in presence of the nitric oxide, and the reaction is as follows: $6NO + 4O(SO_3H)_2 = 4NO.O.SO_3H + [ON(SO_3H)_2]_2$.—T. F. B.

Salts; Preparation of ——, by Double Decomposition. W. Meyerhoffer. Ber., 1904, **37**, 261—263.

The explanation given by Witt and Ludwig (this J., 1904, 61) of the separation of barium nitrite, in their method of preparation, is hardly justified, the author thinks. The following principles, due partly to van't Hoff and partly to the author, afford a truer explanation:—1. Of two reciprocal salt-pairs, as $KCl + NaNO_3$ and $KNO_3 + NaCl$, one is always (in the solid state) stable at a given temperature; in this case, at the ordinary temperature, $KNO_3 + NaCl$. Hence the other pair will slowly change into the stable pair, and the change will be greatly accelerated by addition of a little water. 2. Under certain circumstances a "labile" pair may dissolve, and only one salt deposit; *e.g.*, $NaNO_3 + NH_4Cl$, from which NaCl will deposit, within a certain range of temperature only, "the exchange interval." 3. In the case in question, $Ba(NO_2)_2 + 2NaCl$ is the stable pair. When the pair $2NaNO_2 + BaCl_2$ begins to dissolve and to form the stable pair $Ba(NO_2)_2 + 2NaCl$, $BaCl_2$ also separates out. This involves $NaNO_2$ remaining in solution. By doubling the quantity of sodium nitrite the separation of $BaCl_2$ is prevented, and $Ba(NO_2)_2 + 2NaCl + 2NaNO_2$ remain in solution. This is at 100° C.—J. T. D.

Sodium Ferric Sulphates; Preparation of Two ——. A. Skrabal. Zeits. anorg. Chem., 1903, **38**, 319—321.

If a solution of 50 grms. of ferric sulphate, to which 10 c.c. of dilute sulphuric acid (1:6) have been added, is warmed with 300 grms. of Glauber's salt on the water-bath, the solution becomes lighter in colour, and a yellowish-white salt is precipitated. After cooling, a large quantity of water is added to dissolve the separated Glauber's salt, the mother-liquor filtered off, and the salt washed with a little cold water, alcohol, and ether, and dried between filter-paper. Analysis shows its composition to be—

$$2Na_2O.Fe_2O_3.4SO_3.7H_2O.$$

Another double salt is obtained by melting 100 grms. of Glauber's salt, adding 10 grms. of ferric sulphate and 15 c.c. of concentrated sulphuric acid, and continuing the heating till the solution becomes nearly colourless, when a white salt is precipitated. After cooling, the precipitate is filtered off, washed with alcohol acidified with sulphuric acid, alcohol, and ether, and dried between filter-paper. Its composition is $3Na_2O.Fe_2O_3.6SO_3.6H_2O$. Both salts are white, and decomposed by water.—L. F. G.

Carbon; Action of —— on Lime at the Melting-Point of Platinum. H. Moissan. Comptes rend., 1904, **138**, 243—245.

Carbon and lime, in the proportions for CaC_2, were heated in a graphite boat in a tube of quartz by means of a small oxy-coal-gas furnace. At a temperature at which platinum was melted, and at which the quartz tube softened but did not run down or rupture, there was not the slightest reaction. Neither lime itself, nor calcium carbide, shows signs of even incipient melting at the melting-point of platinum, and apparently lime and carbon only react above the melting-point of the lime. At the temperature of these experiments, silica was found to have a sensible vapour-pressure, for needles of a calcium silicate were seen to form slowly on the surface of the lime.—J. T. D.

Ozone; Action of —— on Hydrogen. G. Pickel. Zeits. anorg. Chem., 1903, **38**, 307—310.

Sulphuric acid of sp. gr. 1·18 was electrolysed in a cell, 20 cm. high and 7 cm. in diameter, using lead electrodes, the current strength being about 0·9 ampère and the potential difference 3—7 volts. The anodes were small, and made of lead wire, 1 mm. in diameter and 3 mm. in length. They soon become covered with lead peroxide, and ozonised about 3 per cent. of the oxygen. The ozonised electrolytic gas thus produced, was dried by sulphuric acid and passed through a glass spiral heated in a paraffin or air bath, and the water formed absorbed in a weighed tube containing sulphuric acid. The experiments lasted several hours, and when the spiral was heated to 174° C. 4·45 mgrms. of water were found to be formed per hour, at 128° C. 3·8 mgrms., at 100° C. 3·7 mgrms., at 75°—90° C. 2·6 mgrms., and at 20° C. 0·4 mgrms. This is about two-thirds of the amount that would be produced if all the ozone present combined with hydrogen to form water.—L. F. G.

Yeast; Manufacture of Certain Products from Waste Brewery or Distillery ——. P. Schwidrowitz and F. Kaye. Eng. Pat. 6604, March 21, 1903. XVII., page 200

United States Patent.

Sulphur; Apparatus for Burning ——. J. A. Marsden. Assignor to A. R. Paul, both of Lyon Falls, N.Y., and A. Tromblee, Carthage, N.Y. U.S. Pat. 749,311, Jan. 12, 1904.

A vertical rotary cylindrical retort, having reduced axial openings at the top and bottom, is divided as to a portion of its interior by longitudinal and transverse partitions, forming a chamber adapted to hold a molten or fluid mass. The lower, discharge end of the retort opens into an oxidising chamber, within which is arranged a melting tank, utilising the heat of the former; this tank is connected by a pipe to the retort, into which it discharges. Means for producing combustion and circulation of gases, within and through the retort, are provided.—E. S.

French Patents.

Cuprammonium; Manufacture of ——, in Closed Vessels and with "Hyperhermetic" Conditions. A. H. Bellot Des Minières. Fr. Pat. 335,207, Aug. 17, 1903.

A series of jars, each having a charge of copper fragments within a perforated cylinder resting on the bottom, and closed air-tight by a removable cover, is supplied with compressed air and with ammonia in a stated order, the transfer of liquid, when required from jar to jar, or to or from the feeding carboys, being effected by using the compressed air, suitably arranged tubes for charging and discharging being provided. The end jar of the series discharges any small portion of ammonia that may remain unabsorbed, into a vessel containing water.—E. S.

Sulphur; Retort for Continuous Work in the Sublimation and Refining of ——. A. A. Consoli, Italy. First Addition, dated Aug. 21, 1903, to Fr. Pat. 316,226 of Nov. 25, 1901. See Eng. Pat. 8757, 1902; this J., 1902, 970.

A battery of several retorts is arranged in a furnace, each of which communicates with a condenser for the sulphur vapour produced, and with a trough on the same level from which it receives a continuous or regulated supply of melted sulphur, through a tube curved downwards in the trough, so as to be always covered by liquid, access of air to the retorts being thus prevented. The trough is fed from a higher trough, which is itself charged by a horizontal pipe from a reservoir in which the raw sulphur is melted, the flow taking place from above the bottom, so that the impurities deposited by gravity are not disturbed. Special regulating valves are shown.—E. S.

Nitrous Anhydride and Salts of Nitrous Acid; Production of ——. Soc. Anon. des Prod., F. Bayer and Co. Fr. Pat. 335,229, Aug. 27, 1903.

A mixture of ammonia with air or oxygen is passed over ferric oxide (or other oxide of a heavy metal, such as copper oxide) heated to about 700° C. The nitrogen trioxide produced is caused to react upon a caustic alkali, or metallic oxide, hydroxide or carbonate, and water, to form the corresponding nitrite.—E. S.

Gaseous Reactions; Process for Facilitating Electrochemical ——. W. Ostwald. Fr. Pat. 328,157, Nov. 27, 1902. XI. A., page 193.

Oxides of Nitrogen; Electric Production of ——. Siemens and Halske. Fr. Pat. 335,453, Sept. 21, 1903. XI. A., page 193.

VIII.—GLASS, POTTERY, ENAMELS.

French Patent.

Ceramic Articles; Manufacture of Enamelled and Glazed ——. A. Bigot. First Addition, of Sept. 7, 1903, to Fr. Pat. 323,657 of Aug. 11, 1902. See this J., 1903, 496.

The enamel or vitrifiable colouring matter is applied to the article during the moulding in the form of thin plates or leaves formed by mixing the ground colour with a binding agent such as collodion, gelatin, casein, or flour, with which a fibrous material such as paper-pulp has been incorporated, these leaves being placed inside the mould during pressing. —A. G. L.

IX.—BUILDING MATERIALS, CLAYS, MORTARS AND CEMENTS.

Lime-Sand Bricks; Influence of Pressure in the Manufacture of ——. S. V. Peppel. Thonind.-Zeit., 1904, **28**, 3—4.

The test blocks were made of 60 parts of coarse sand, 30 parts of fine sand, and 5 per cent. of white lime or dolomitic lime, the whole being subjected in the moulds to pressures ranging from 350 to 1,400 kilos. per sq. cm., and hardened under high pressure steam for 10 hours. The maximum crushing-strength (about 210 kilos. per sq. cm.) in the white lime series was shown by the blocks formed under 1,150 kilos. pressure, the curve receding beyond this point. In the dolomite lime series, the maximum (about 315 kilos. per sq. cm.) was attained under the same conditions, but here the strength was greater throughout. To ascertain whether this pressure is the optimum for bricks of other proportional composition, the tests were repeated with blocks made from 66 parts of coarse sand, 33 parts of fine sand, and 10 per cent. of white or dolomitic lime respectively. Broadly speaking, the results were parallel, the maxima being furnished by the blocks pressed to 1,150 kilos., though the curves proved irregular, the white lime series showing the same strength at 700 kilos. pressure as at 1,150 kilos., with a sharp decline in the case of the blocks pressed at 875 kilos. The author also found that the use of hardened steel mould plates facilitated the ejection of the finished blocks.—C. S.

Lime-Sand Brick; Influence of Steam Hardening on the Strength of ——. S. V. Peppel. Thonind.-Zeit., 1904, **28**, 23—25.

The tests performed by the author were made on blocks composed of 66 parts of coarse sand and 33 parts of fine sand, *plus* 10 per cent. of white lime or dolomitic lime, with or without 10 per cent. of kaolin, the whole moulded under a pressure of 1,050 kilos. per sq. cm. In the white lime series, without kaolin, the maximum crushing-strength —398 kilos. per sq. cm.—was attained by hardening under a steam-pressure of 8 atmos. for 8 hours, and the same applied to the dolomite series, with (410 kilos.) and without (422 kilos.) kaolin; but in the case of the lime-kaolin series, hardening for 10 hours at the above pressure gave the highest results (431 kilos.).

The hypothesis that equality in the factor of atmosphere-hours gives equality of crushing-strength was also investigated, but is considered not to hold good, except in the case of the white lime mixture.

When felspar is employed as an ingredient, the crushing-strength suffers considerably by prolonging the exposure to high pressure steam, the assumption being that potash and soda are thereby liberated and cause efflorescent incrustations.—C. S.

Cement; Composition of Roman ——. — Gresly. La Céramique, 1904, **6**, 114—115.

The analysis of a number of the best Roman cements of French origin gave the following mean proportions of essential constituents:—Silica, 23 per cent.; alumina and ferric oxide, 13 per cent.; lime and magnesia, 59 per cent.; sulphur trioxide, 3 per cent.; or a ratio of acids to lime and magnesia, 39 : 59. A corresponding synthetical cement may be prepared from 259 parts (30·2 per cent.) of kaolin and 600 parts (69·8 per cent.) of calcium carbonate, made up into briquettes, and burned at 1190°—1250° C. If materials free from iron be used, a perfectly white product will be obtained, and this, when ground to powder, exhibits excellent hydraulic properties, though in the state of lumps it seems to react but very slightly with water. The technical difficulties in the way of firing mixtures rich in lime are overcome by adding a small quantity ($\frac{1}{5}$—$\frac{1}{4}$ mol.) of calcium sulphate to the ingredients. This method furnishes highly energetic cements, and allows of greater variation in compounding the mixture.—C. S.

Blast-Furnace Slag and Portland Cement. M. Gary. Mitt. königl. techn. Versuchsanst., 1903, **21**, 159—169.

The strength of mixtures of blast-furnace slag with a binding agent decreases rapidly if the mixture is preserved for some time. This effect of keeping is more noticeable with regard to the crushing-strength than to the tensile strength. During the first week of storing, the tensile strength increases, but the crushing-strength begins to diminish immediately after preparation of the mixture. The effect is greater in the case of mixtures containing Portland cement than in those containing lime. The volume-weight of test-pieces prepared with mixtures containing blast-furnace slag also decreases considerably when the mixture has been kept for some time.—A. S.

Portland Cement in Concrete. C. Pars. Centralbl. d. Bauverw., 1903, 608; Thonind.-Zeit., 1904, **28**, 25.

It is claimed that the results of the Vicat test cannot be correlated directly to practical conditions. For instance, a Portland cement which, under this test, commenced to set in 32 minutes and 25 seconds, gave a concrete with the tensile strength of 21·4 kilos. (per sq. cm.) after 28 days, when the block was made immediately after mixing, but when the cement mortar was kept 10 minutes before making the block, the strength fell to 20·1 kilos., and when the delay was increased to 20 minutes, it was found impossible to prepare the block at all, the mortar having become unusable. Concrete that is to be deposited direct under water should be dumped in large masses with as little fall as possible, in order to give the core of the mass a good opportunity of setting, and prevent separation of the mixture, but no attempt should be made to use coarsely ground cement as a remedy for this latter evil. The loss on calcination test is recommended as affording an indication of proper burning, and the lime content should also be determined when the tensile strength is high, since an excess of this constituent causes gradual diminution of the cohesive power.—C. S.

Concrete; Crushing-Strength of ——, *and Influence of the Size of the Blocks (Cubes) upon the Setting and Strength of Cement-Mortar and Concrete.* H. Burchartz. Mitt. königl. techn. Versuchsanst., 1903, **21**, 111—159.

The author gives, in a long paper accompanied by numerous tables and curve-diagrams, an account of a series of experiments on the crushing-strength of mortar and concrete mixtures. The results show that the prevailing view that concrete mixtures attain a greater strength than the mortar used in their preparation is not always correct; on the contrary, concrete mixtures, especially when formed into cubes, may, under certain conditions, be considerably inferior in strength to the mortar present in the mixtures. In general it may be stated that within the time usually allowed in the examination of mortar and concrete mixtures, the strength decreases with increase of the size of the cubes formed of the mixtures, and this variation in strength persists, at all events, up to a period of 180 days. In view of these results, it is pointed out that the size of cubes prepared for strength tests, should as far as possible approximate to that of the concrete blocks used in practice. —A. S.

Cement Kiln: Thermal Efficiency of a Rotary ——. J. W. Richards. J. Amer. Chem. Soc., 1904, **26**, 80—88.

Experiments made on a rotary cement kiln 60 ft. long and 6 ft. external diameter, fired by pulverulent bituminous slack coal, gave the following results :—

Theoretical heating power of fuel	790,000 cal.
Heat of formation of cement	142,819 „
Total.............	932,819 „

	Calories.	Per Cent. of Total.
Heat in hot clinker	100,050	10·7
Heat in chimney gases	676,000	72·1
Heat in flue dust	2,112	0·2
Loss by imperfect combustion*...............	12,248	1·3
Evaporation of moisture in charge...........	1,446	0·2
Expulsion of carbon dioxide from carbonates	21,628	2·3
Loss by radiation and conduction (by difference)................................	119,335	12·8

* Estimated from the amount of carbon monoxide escaping.

The temperature at the lower end of the kiln was 1,200° C., and in the waste gases in the chimney 820° C. This latter represents the greatest heat loss, and could be remedied by using a longer kiln and also by admitting less air. The temperature of the gases in the kiln, calculated from their composition, is 1,000° C., that of the clinker being 1,200° C., the excess in the clinker being accounted for by the heat of combination of the ingredients. The temperature of the kiln gases is found thus : The available heat of combustion of the fuel is 790,000 cals., and this is taken up by the products of combustion and the excess of air, *viz.* :—

	Cb. m.	
Nitrogen............................	1,737	2,004
Oxygen	263	
Carbon monoxide	4	
Carbon dioxide......................	136	
Water vapour........................	128	

The maximum temperature of the gases in the kiln is the temperature to which 790,000 cals. will heat these volumes of gas. Using the specific heats of these gases as elsewhere in the paper, this temperature is calculated as 1,000° C. The kiln under notice turned out, on an average, 3,635 lb. of clinkered cement per hour from 5,980 lb. of mixture introduced, 200 lb. of fine dust being also produced. 110 lb. of coal were used to produce one barrel (380 lb.) of cement.—T. F. B.

English Patents.

Non-Conducting Coverings, Blocks, and Slabs suitable for Covering Steam Pipes, Boilers, and the like, and for other Purposes. H. C. Mitchell, London. Eng. Pats. 21,386 and 21,387, Oct. 1, 1902.

A solution of sodium silicate, or other silicious binding agent, is mixed with mica or asbestos, or with both, the mixture being then moulded, dried, and burnt at a temperature of about 1,000° C., so as to cause the asbestos and sodium silicate to fuse and unite. The slabs or blocks may be made hollow and filled with mica or with organic substances, which last become charred during the subsequent heating.—A. G. L.

Artificial Stone. C. Reinke, Bredelar, Germany. Eng. Pat, 26,478, Dec. 3, 1903.

Four parts of Permian limestone are mixed with 1 part of cement and a small quantity of magnesium oxide; the whole is moistened with water and moulded as usual.
—A. G. L.

Waterproofing Bricks, Stone, and like Porous Materials. N. Farnham, New York. Eng. Pat. 27,928, Dec. 19, 1903.

See U.S. Pat. 748,595 of 1904; this J., 1904, 116.—T. F. B.

Colouring and Hardening Natural Stone; Process for ——, also applicable to Organic Materials, such as Ivory. H. H. Lake, London. From Chem. Techn. Fabr., Dr. A. R. W. Braud and Co., Charlottenburg, Germany. Eng. Pat. 5594, March 10, 1903.

The stone or other article to be coloured is freed from hygroscopic moisture at a gentle heat *in vacuo*; it is then placed in a vacuum chamber filled with the colouring liquid, and the vacuum is applied until the enclosed air is removed as much as possible from the stone or other material. After this, the liquid is allowed to act either under atmospheric or increased pressure. When completely impregnated, the material is suitably dried. For colouring purposes, coal-tar dyestuffs may be employed, dissolved in water or alcohol. Liquids, such as ammoniacal oxide of copper, which give a precipitate on heating, may also be used, or two liquids which react to form a coloured precipitate may be used successively; for example, lead acetate and potassium chromate. In the latter case, in order to avoid the immediate combination of the two interacting substances on contact, which would block up the pores of the substance and so retard penetration, solvents are chosen which dissolve only one of the ingredients. In the case given, the stone can be impregnated with potassium chromate dissolved in water, and then the water removed by means of the vacuum. The stone is then impregnated with an alcoholic solution of lead acetate and the alcohol removed. At this point there is no combination between the two bodies, but if water is forced in, it dissolves both of them, and they immediately interact to form chrome yellow throughout the whole mass of the stone. For hardening purposes a solution of soluble glass, potassium borate, or some similar body is employed.—A. B. S.

French Patents.

Wood Uninflammable; Process for Rendering ——. J. Wetter. Fr. Pat. 335,427, Sept. 21, 1903. Under Internat. Conv., Sept. 22, 1902.

See Eng. Pat. 20,592 of 1902; this J., 1903, 998.—T. F. B.

Kiln for Burning Cement, Lime, &c. N. Perpignani and E. Candlot. Fr. Pat. 335,377, Sept. 18, 1903.

The kiln is characterised by a chimney, the bottom of which is placed in the material to be burnt to a depth determining the zone of combustion. In the lower part of the kiln is placed a circular grating of vertical bars, through which air enters and becomes heated in its passage upwards through the burnt material. This grating is surrounded by masonry in which openings are made to allow the material to be raked.—A. G. L.

X.—METALLURGY.

Steel-Production; Continuous ——, in Fixed Siemens-Martin Furnaces. S. Surzycki. Stahl u. Eisen, 1904. **24**, 163—164.

Since September 1902, the author has worked a continuous process in fixed open-hearth furnaces at the works at Czenstochau, in Russian Poland, by the device of a double tap-hole, one of the twin holes being at a higher level than the other. The arrangement is sufficiently explained by the figures, of which the first represents a front elevation, the second a vertical section, and the third a plan. In a furnace holding in all, with a sufficiently deep hearth, 45—50 tons of melted metal, the higher tap-hole is so adjusted as to allow of tapping 25—30 tons, and the lower so as to empty the charge. In starting, cold scrap is put in, and when this is melted, the molten iron is poured in either direct from the blast-furnace or from a ladle. When agitation has ceased in the bath, the latter also remaining quite fluid, the necessary quantity of ore is added, and then more iron, till the capacity of the furnace is reached. The charge is dephosphorised by lime, and then tapped through the higher hole; during the flow, the requisite amounts of charcoal and of finely-divided ferromanganese are thrown into the ladle, and cause a violent reaction.

which, however, rapidly subsides, and the contents of the ladle are soon ready to be poured. It is stated that the blocks roll well, and give a steel of excellent quality in every respect. The tap-hole is plugged with well-burnt dolomite, the lining repaired where necessary, ore is added to the bath, and the charge of fluid iron added, during which a reaction evolving considerable heat raises the temperature of the furnace though the gas is shut off, and the process is correspondingly accelerated. In this manner the furnace works continuously for a week or two at a stretch; when the process must be interrupted, the furnace can be emptied through the lower tap-hole. The results, during a year, have been very satisfactory. A furnace which in the ordinary way gave per 24 hours, using 80 per cent. of pig, and 20 per cent. of scrap, 65—70 tons of steel, yielded during this continuous working, using 20—25 per cent. of ore and rolling-mill scale, 75—90 tons of steel. It is advantageous, in this continuous process, to have a capacious furnace, so that the quantity remaining continuously in the furnace is considerable in comparison to the amount discharged at each tapping. The process is based on the Talbot process; but an ordinary furnace can be adapted for it at a fraction of the cost of erecting a tilting furnace of the Talbot type.—J. T. D.

Fig. 2.

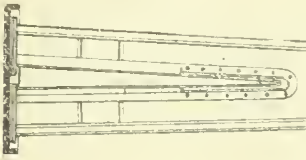

Fig. 3.

Iron and Steel Alloys. R. A. Hadfield. Iron and Steel Metall., 1904, 7, 3—21.

The author describes the properties of alloys of iron with manganese (this J., 1888, 211—212; 1895, 641), silicon (this J., 1889, 788—797), aluminium (this J., 1890, 1131—1133), chromium (this J., 1892, 910), nickel (this J., 1900, 150), tungsten (this J., 1903, 1050), cobalt, copper, titanium, molybdenum, and vanadium.

Alloys of Iron and Cobalt.—The effect of cobalt as an addition to iron is very similar to that of nickel.

Alloys of Iron and Copper.—The elastic limit of iron is raised considerably by the addition of a certain amount of copper, but considerable "red-shortness" is also caused.

Alloys of Iron and Titanium.—Titanium appears to act somewhat like aluminium in absorbing gases; small quantities cause an increase in the elastic limit, but amounts exceeding 0·3 per cent. have an injurious effect on the physical properties of the metal.

Alloys of Iron and Molybdenum.—Molybdenum acts in a somewhat similar manner to tungsten, "though a much lower percentage than of tungsten is necessary to produce the same effect."

Alloys of Iron and Vanadium.—The action of vanadium appears to be somewhat similar to that of chromium, though a smaller amount is required to produce a given effect. It has been claimed that vanadium greatly increases the elastic limit, but the author points out that a steel containing nickel and chromium can be produced having a higher elastic limit and tenacity and also comparatively higher elongation than iron-vanadium alloys have. (See also this J., 1900, 911; 1902, 411.)—A. S.

[*Coke-*] *Oven Gas and Tar as Fuels for the Open-Hearth Furnace.* D. Baker. Iron and Steel Metall., 1904, 7, 21—26.

An attempt to use coke-oven gas (from Otto-Hoffmann retort ovens) as sole fuel for open-hearth furnaces resulted in failure, but by using, in addition, a certain amount of coke-oven tar, delivered to the burner in the furnace through a steam-heated main, there was no difficulty in maintaining the desired temperature in the furnace. The tar also gave satisfactory results when used alone as fuel. For the production of 1 ton of steel, 17,127 cb. ft. of coke-oven gas (550 B.T.U. per cb. ft.) and 584·2 lb. of tar (15,781 B.T.U. per lb., "solid") were required, whilst, when producer-gas was employed, 1,076 lb. of coal (12,500 B.T.U. per lb.) were needed. In the furnace, 1 lb. of tar is equal to 12·52 cb. ft. of coke-oven gas, and 1,952 lb. are equal to 1,076 lb. of coal. The sulphur introduced into the process by the fuel (1,076 lb. of coal) amounted to "22·596 lb." when producer-gas was used, and 13·693 lb. when the fuel consisted of coke-oven gas and tar (17,127 cb. ft. gas and 584 lb. tar). If tar alone had been used, only 4·88 lb. of sulphur would have been introduced.—A. S.

Cyanide Process; Notes on the Limitations of the ——. H. T. Durant. J. Chem. and Min. Soc. of S. Africa, 1903, 4, 233—235.

Ores amenable to cyanide treatment are classed as: (1) those in which the gold is carried mainly in the mineralised portion of the ore, as in iron-, copper-, and arsenical pyrites, &c., and (2) those in which the gold is carried free in quartz or other gangue. In the case of the second class of ores, the value of gold extracted depends on the fineness of the crushing, whether the amalgamation or the cyaniding process is used; but ores vary in respect of the coarseness or otherwise of the gold in them, and the procedure needs to be adjusted to each case. An instance is given in which fine crushing of the whole ore followed by amalgamation yielded exactly the same results, as regards recovery of gold, as coarser crushing with amalgamation followed by cyanide treatment for the sands.—E. S.

Smelting and Cupellation; Notes on ——. F. L. Piddington. J. Chem. and Min. Soc. of S. Africa, 1903, 4, 232—233.

The notes relate to the methods generally used in treating small parcels of rich material, such as cyanide precipitates, sweepings, and drosses. A simple smelting is effected with litharge and a reducing agent in a reverberatory furnace. If a removable hearth is used, it may be in the form of a large cupel. When the smelting is finished, the slag is skimmed, the blast turned on, and the bullion concentrated up to about 50 per cent. of precious metals, when it is transferred to a smaller refining cupel. For the avoidance of absorption, it is recommended to enclose the bottom and sides of the hearth in a water-jacketed pan. A cupel may be cooled by an embedded water pipe or by an enclosing jacket. The test frame is mounted on jack-screws, and a water-cooled breast of a casting of iron, gunmetal, or preferably of copper, is used. For the test filling, any one of the four following mixtures may be used:—

	Parts by Volume.			
Limestone	7	4	8	4
Cement	2	1	1	1
Fireclay	1	1	1	1
Magnesite	..	4	..	2

When much zinc is present in the ore, roasted pyrites concentrates are stated to be a good flux, any valuable metals present in them being thus recovered. In the cupellation of zincy bullion, a purple fume, containing both gold and silver, condenses on the outside of the cupel, particularly on the door. "The amount lost in this way depends very largely on the care taken to keep the bath well covered with litharge."—E. S.

Metals; Decay of ——. J. T. Milton and W. J. Larke. Proc. Inst. Civil Eng., 1903, **154**.

THE examples of deterioration considered were (1) the pitting of tubes of marine surface-condensors; (2) the decay of brass or yellow metal bolts in composite vessels; (3) the decay of brazing metal in copper steam pipes; (4) the deterioration (other than oxidation) of cast-iron parts in frequent or constant contact with sea-water; (5) the decay of propellers made of certain bronzes when fitted to copper-bottomed vessels. The action seems to be erratic and often extensive before ordinary examination will reveal it. Chemical analysis shows that a change of composition has taken place, but does not explain why, but microscopic examination shows that the chemical constituents have been unequally affected, owing in many cases to the setting up of local galvanic currents. Certain illustrative experiments and observations, and particulars of methods employed, are detailed in two appendices. The authors summarise their conclusions as follows:—(1) "Decay" is more frequent in the metals which have the more complex structure; (2) is due to a slower or less energetic action than "corrosion," and, moreover, requires an action which removes part only of the constituents; (3) both "decay" and "corrosion" may result from chemical action alone, or from chemical and electrolytic action combined; (4) "pitting," or intense local corrosion, is probably often due to local segregation of impurities in the metal; but it may also in some places be due to favourable conditions furnished by local irregularities of surface or structure producing local irregularities in the distribution of galvanic currents; (5) in brass exposed to sea-water, the presence of tin is distinctly preservative, while lead and iron are both injurious, rendering the alloy more readily corrodible; (6) the internal surfaces of condenser tubes should be as smooth and uniform as possible; (7) the experiments with an applied electric current show that electrolytic action alone, even where exceedingly minute currents are employed, may result in severe corrosion or decay.—J. H. C.

Gold in Cyanide Solution; Colorimetric Method for the Determination of ——. A. Prister. XXIII., page 207.

Nickel Carbonyl; Chemical Reactions of ——. *Part I. Reactions with the Halogens and other Inorganic Substances.* J. Dewar and H. O. Jones. Proc. Chem. Soc., 1904, **19**, 5.

THE previous study of the physical properties of nickel carbonyl (this J., 1903, 626) showed that it was a comparatively stable substance when heated under pressure. Nickel carbonyl is completely decomposed by solutions of chlorine, bromine, iodine, cyanogen, and sulphur in organic solvents, carbon monoxide and a nickel compound being produced; in no case was any combination of the carbon monoxide with the halogen or other reagent observed, even when a considerable excess of the latter was present. Liquid chlorine and bromine decompose solid nickel carbonyl, but solid iodine appears to have no action on liquid nickel carbonyl. Iodine mono- and trichlorides and cyanogen iodide in carbon tetrachloride solution react with nickel carbonyl in two distinct stages, the free iodine liberated at first subsequently decomposing a further quantity of nickel carbonyl. Hydrogen iodide readily interacts with nickel carbonyl, whereas the corresponding bromide and chloride do not affect it. Hydrogen sulphide reacts very slowly with nickel carbonyl, producing nickel monosulphide, hydrogen, and carbon monoxide. Sulphuric acid also decomposes the compound slowly, giving rise to nickel sulphate, hydrogen, and carbon monoxide.

ENGLISH PATENTS.

Manganese Steel; Toughening ——. R. A. Hadfield, Sheffield. Eng. Pat. 4981, March 3, 1903.

THE manganese steel, after being heated to from 940° to 1125° C., is allowed to cool down to about 800° C., and is then again heated to the proper toughening point, after which it is quenched in cold water. The supplementary cooling and reheating operations may in some cases be repeated before the final quenching. Reference is made to Eng. Pats. 11,833 of 1896 and 5604 of 1902; this J., 1897, 544, and 1903, 870, respectively.—E. S.

Gold from Sea Water; Process and Apparatus for the Extraction of ——. W. L. Peet, Portsmouth. Eng. Pat. 3470, Feb. 13, 1903.

SEA water is raised to an elevated tank, whence it passes by gravity through a pipe reaching to the bottom of a vertical vessel, wider at the top than at the bottom, containing mercury. A series of such mercury-charged tanks is used, and in each there are "one or more perforated plates for the purpose of dividing the bulk of the sea water into a number of small divisions or currents." A chamois leather or other strainer may be placed at the top of each tank to prevent loss of mercury during the process.—E. S.

Copper; Process for the Extraction of ——, *from its Sulphuretted Ores.* G. Gin, Paris. Eng. Pat. 2036, Jan. 28, 1903.

SEE Fr. Pat. 328,801 of 1903; this J., 1903, 1002.—T. F. B.

UNITED STATES PATENTS.

Ores; Process of Lixiviating ——. P. Naef, New York, N.Y. U.S. Pat. 749,700, Jan. 12, 1904.

THE powdered ore is passed in thinly-divided layers downwards in a zigzag path through an ascending stream of leaching solution, whilst a current of air or gas is passed repeatedly through the ore layers in "numerously divided" jets, the ore particles being thus agitated in the solution, and the same volume of gas acting successively as an agitating medium. Compare U.S. Pat. 700,972 of 1902; this J., 1902, 916.—E. S.

Metallurgical Furnace. W. S. Dempsey, New York, N.Y. U.S. Pat. 750,022, Jan. 19, 1904.

IN a horizontal furnace, the combustion chamber opens into the working chamber, and in the former, blasts are arranged above the grate to drive the gases generated towards the working chamber, whilst other blasts below the grate are directed angularly in an opposite direction. Within the working chamber cross blasts are directed from opposite sides, and backward from near the end towards the combustion chamber. Air-supply heating coils are interposed between the sources of supply and the various blast pipes, &c.—E. S.

Zinc Blende; Process of Separating —— *from Ores.* W. Jamieson and F. J. Odling, Melbourne, Australia. U.S. Pat. 750,034, Jan. 19, 1904.

ORES containing zinc blende are powdered, moistened with water, and treated with chlorine so as to act superficially on the particles of blende. The ore is then vanned with the aid of appropriate apparatus, until the attacked blende particles adhere together in groups, and admit of separation from the rest of the ore and gangue by suitable mechanical means.—E. S.

Steel for Springs of all Kinds. Soc. Anon. Fried. Krupp, Akt.-Ges. Fr. Pat. 335,405, Sept. 17, 1903.

See Eng. Pat. 3822 of 1903; this J., 1903, 1246.—T. F. B.

Steel or Iron; Manufacture of ——. B. Talbot. Fr. Pat. 335,698, Sept. 29, 1903. Under Internat. Conv., Nov. 5, 1902.

See U.S. Pat. 747,662 of 1903; this J., 1904, 66.—T. F. B.

Zinc [Soft]; Manufacture of ——. L. Gührs, Veuve. Second Addition, dated Aug. 31, 1903, to Fr. Pat. 332,657, of May 30, 1903. (See this J., 1903, 1247.)

The alloy intended to be added to zinc for the improvement of the latter, is obtained by melting together zinc with aluminium; or the zinc is added to the melted aluminium, and (in either case) the viscosity of the molten mass is destroyed by the addition of tin. The zinc melted with this alloy is stated to give better adherence in coating iron plates with zinc, besides possessing other advantages. —E. S.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

(A.)—ELECTRO-CHEMISTRY.

Ozone; Production of ——, by the Silent Electric Discharge in the Siemens Ozoniser. A. W. Gray. Sitzungsber. Kgl. pr. Akad. Wiss., Berlin, 1903, 1016—1020. Chem. Centr., 1904, **1**, 9.

In the Siemens apparatus the yield of ozone per coulomb appears to attain an almost constant value, which is independent of the difference of potential between the electrodes of the generator, and probably also of the quantity of electricity passed; in the apparatus used by the author, this constant value was 0·27 grm. Apparently, therefore, for a given consumption of energy the best yield of ozone will be obtained when the difference of potential between the electrodes is only just sufficient to cause the luminous discharge in the gas passed through the apparatus.—A. S.

Ozonising of Oxygen by the Silent Electric Discharge. E. Warburg. Sitzungsber. Kgl. pr. Akad. Wiss., Berlin, 1903, 1011—1015. Chem. Centr., 1904, **1**, 9.

The author's experiments were made with a view to determine the physical conditions which influence the amount of ozone produced by the electric discharge from a point electrode. Commercial 93 per cent. oxygen was led by an electrode maintained at a constant potential, which varied in different experiments from 4,000 to 12,000 volts. When the potential of the electrode was negative, the amount of ozone produced per coulomb was influenced only by the strength of the current, in that with increase of the latter the yield of ozone per coulomb slowly decreased. The actual figures were 0·0431 grm. at 29×10^{-6} ampère and 0·0370 grm. at 94×10^{-6} ampère. When the potential of the electrode was positive, the yield of ozone per coulomb increased rapidly with the strength of the current, and was smaller with weak currents, but greater with strong currents, than when the potential was negative (at 29×10^{-6} ampère, 0·02 grm., and at 94×10^{-6} ampère, 0·06 grm.). By the discharge between dielectric surfaces the yield of ozone per coulomb was from four to five and a half times greater than by the discharge from point electrodes.—A. S.

Chloric Acid and Chlorates; Electrolysis of ——. A. Brochet. Comptes rend., 1904, **138**, 200—203.

The author confirms the conclusions of Bancroft and of Burrows, that when barium, sodium, or cupric chlorate is electrolysed with a copper anode, more copper is dissolved than corresponds with the current which passes. This is because the copper dissolves partly in the cuprous condition. No cuprous compounds are found in solution, because they are converted into cupric compounds by the chlorate, which is partly reduced to chloride. The quantity of cuprous ions dissolved, depends on the physical conditions and on the nature of the electrolyte, so that the amount of copper dissolved from the anode may be anything from one to two times that deposited in a voltameter in the circuit. The conversion of the cuprous compounds involves the formation of cupric chloride and hydroxide. The latter is dissolved in an acid solution; but in a solution of cupric chlorate it forms basic salts. With sodium or barium chlorate, these basic salts are decomposed by the hydroxide formed at the cathode, and the precipitate contains cupric chloride and chlorate, which consume some of the cathodic hydrogen; there is consequently but little copper in the cathodic deposit, while, when the electrolyte, sodium sulphate, for example, gives no reducible compounds, the cathode deposit consists almost entirely of copper.—J. T. D.

Potassium Chlorate; Electrolytic Reduction of ——. G. H. Burrows. J. of Phys. Chem., **7**, 537—538. Chem. Centr., 1904, **1**, 74.

In a previous communication (this J., 1903, 33) the author overlooked the fact that the oxides of nitrogen present in nitric acid reduce potassium chlorate to chloride. By taking this fact into account the maximum apparent current-yield falls from 200 to 160 per cent. Brochet (this J., 1903, 215) has stated that no true electrolytic reduction of potassium chlorate occurs, and that the high yield is due to a purely chemical reaction between potassium chlorate and metallic copper. This reaction could cause an apparent yield of 600 per cent., but is balanced to a certain extent by a re-formation of potassium chlorate by the action of caustic potash, formed at the cathode, on copper chlorate. If Brochet's view were correct, an apparent yield of 600 per cent. should result if the caustic potash formed at the cathode were separated from the anode products; this, however, is not the case. Experiments with platinum anodes showed that a direct electrolytic reduction of potassium chlorate can be effected, and the probable explanation of the high yield lies in the fact, proved by Gladstone and Tribe, that the potassium chlorate is reduced by hydrogen occluded by the copper.—A. S.

Periodic Acid and Periodates; Electrolytic Production of ——. E. Müller. Zeits. f. Elektrochem., 1904, **10**, 49—68.

Iodates can be almost quantitatively oxidised to periodates by the following method:—Normal caustic potash solution, to which a little potassium chromate has been added, is saturated with potassium iodate and electrolysed with smooth platinum electrodes at an anodic current-density of 0·05 ampère per sq. cm. The current-efficiency increases in the course of electrolysis, the more so the higher the density; high temperatures depress it somewhat. In neutral or acid solutions hardly any periodic acid is formed, but it is remarkable that an addition of sulphate enables the oxidation to take place in neutral solutions. In acid solutions the use of lead peroxide anodes brings the current-efficiency to near 100 per cent.; this appears to be due to the fact that lead peroxide has the purely chemical property of oxidising iodic to periodic acid.—W. A. C.

Lead Dioxide; Electro-deposition of ——, in Quantitative Analysis. A. Hollard. XXIII., page 207.

English Patents.

Batteries; Storage ——. W. Fennell and W. P. Perry, both of Leytonstone. Eng. Pat. 6145, March 17, 1903.

The active material, in the form of a paste, is mixed with a hard, rough, porous substance, such as powdered or granulated pumice, earthenware, porcelain, or the like, or the latter substances may be used in the form of tubes, spheres, rods, honeycomb, or network. The plates may thus be packed closely together, and in block-like form, and holes or passages are made in the blocks in the direction of the path of the current, so as to reduce the internal resistance, the holes being lined with porous or perforated material so as to hold a surplus of electrolyte. A second form is described in which a network honeycombed support is used, on which is spread a film of active material. Granules of conducting substance, such as metallic balls or the like, are rolled in active material, and then filled into the containing vessel, grid, or support, while the layer of active material is still soft, thus ensuring good contact. The honeycomb support may be made in one piece by mixing the clay with pellets or rods of wax, charcoal, and the like, and then burning away these substances so as to leave interstices, into which, after damping, active material may be blown so as to form a layer. The thickness of the latter may be increased by plating with metal, or by depositing litharge from a warm alkaline solution. In both forms a conductor is embedded in the mass, and coated with a dense layer of active material, which serves to protect the conductor and also to make good contact with the bulk of active material.—B. N.

Batteries; Secondary ——. G. Rosset, Paris. Eng. Pat. 23,482, Oct. 29, 1903. Under Internat. Conv., Nov. 24, 1902.

The active material consists of a paste made from oxide of lead and dilute sulphuric acid, the latter containing acetic acid, or an acetate, or compounds capable of producing acetic acid, such as ordinary alcohol. Finely-divided lead, obtained by the electrolysis of lead acetate, using lead electrodes, may be employed instead of lead oxide. The precipitated lead is scraped off the electrodes, and washed with water in such a manner as to leave a little acetate in the pores of the metal. After drying, the metal is oxidised, pulverised, sifted, mixed with dilute sulphuric acid, and filled into grids or supports made from a lead-antimony alloy, the support being coated electrically with metallic antimony. The plates may be formed in a 2 to 3 per cent. solution of an alkali sulphate, bisulphate, persulphate, or pyrosulphate, rendered ammoniacal, and with 1 to 2 per cent. of acetic acid or of an alkali acetate added.—B. N.

Reducing Elements which are Reduced and Volatilised at nearly the same Temperature; Method of ——. F. J. Tone, Niagara Falls. Eng. Pat. 23,964, Nov. 4, 1903.

See U.S. Pat. 745,122 of 1903; this J., 1903, 1356.—T. F. B.

United States Patents.

Carbon Articles; Method of Making ——. E. G. Acheson, Niagara Falls. U.S. Pat. 749,118, Jan. 12, 1904.

The carbon articles are embedded in material, the specific resistance of the entire volume of which is greater than that of an equal volume of the completed carbon articles, the latter being arranged in separate piles with their longest dimensions in the same general direction, and so that the current of electricity traverses the mass in a direction approximately at right angles to the longest dimensions of the articles. The heat, produced within the mass of the resistance material, "polymerises the carbon articles without graphitising them." The piles may be separated by a mass of granular coke, the latter being thus purified.—B. N.

Furnace; Electric ——. Le Roy W. Stevens and B. Timmerman, Chicago, Assignors to Advance Furnace Co., New York. U.S. Pat. 749,460, Jan. 12, 1904.

The material for making carbide or like substances was fed from a hopper into a vertical main flue, in which was maintained a flame zone, so that the falling material received a preliminary heating. Near the bottom of the main flue was fixed a baffle plate, which directed the falling material to one side of the flue, and immediately under the plate was a side flue for withdrawing the resulting gases, and for maintaining a down-draught in the main flue. The heated material was fed into an electric furnace provided with one vertical and one horizontal electrode, the latter forming the floor of the chamber, a suitable arrangement being provided for withdrawing the carbide; the furnace may be removable, and may be made with an open top provided with a cover carrying the vertical electrode. The upper portion of the furnace is connected by a gas flue to the upper part of the main flue, the down-draught in the latter drawing off the gases formed in the furnace, and these gases are ignited by suitable means, one or more burners being provided for directing the flame into the main flue.—B. N.

Furnace [*Carbide, &c.*]; *Electric* ——. Le Roy W. Stevens and B. Timmerman, Chicago, Assignors to Advance Furnace Co., New York. U.S. Pat. 749,461, Jan. 12, 1904.

The apparatus is the same as that described in the preceding patent. The material is first fed into the main flue, so as to form by its accumulation, a baffle in the lower portion, and is afterwards supplied in a relatively small stream. From the lower portion of the main flue it is fed into the furnace by means of a pusher, at a speed and in quantities equal to the discharge of carbide, the pusher being arranged so as to form a valve in the main flue. —B. N.

Furnace: Electric ——. Le Roy W. Stevens and B. Timmerman, Chicago, Assignors to Advance Furnace Co., New York. U.S. Pat. 749,462, Jan. 12, 1904.

The apparatus is similar to the one described in the two preceding patents. The main flue is provided with a safety-valve, and is made to discharge into one or more electric furnaces, the rate of supply of the material to the main flue being equal to the combined discharges into the furnaces. The gases produced in the formation of carbide are conducted from one or all of the furnaces to the main flue. The material is stored at the bottom of the main flue in an enlarged portion, surrounded by a casing through which the gases are exhausted, so as to maintain the material in its heated condition preliminary to its discharge into one or other of the furnaces, the exhaust flue being fixed above the casing surrounding the heated material.—B. N.

Furnace [*Carbide*]; *Electric-Resistance* ——. A. H. Cowles, Cleveland, Ohio. U.S. Pat. 750,093, Jan. 19, 1904.

A resistance-conductor, of varying cross-section and made of loose, broken, or granular material, is in proximity to the charge of carbide-forming materials, so as to heat the charge, and means are provided for passing through the conductor an electric current, the density of which increases, inversely as the cross-section of the conductor. The heat generated by the resistance of the conductor gradually increases to a point at which the materials react to form and melt the carbide, and the latter is withdrawn by gravity in a molten condition at a point adjacent to the region of maximum current density.—B. N.

Smelting Materials [*Carbide Production, &c.*] *and Producing Carbide: Process of* ——. A. H. Cowles, Cleveland, Ohio. U.S. Pat. 750,094, Jan. 19, 1904.

The charge of lime and carbon is heated, preliminary to the formation of carbide, by passing hot gases through it, whereby its electrical conductivity is increased, the gases formed in the production of the carbide (see previous abstract, U.S. Pat. 750,093) being burnt for the purpose of preheating the charge.—B. N.

Heating Materials; Process of Electrically ——. A. H. Cowles, Cleveland, Ohio. U.S. Pat. 750,095, Jan. 19, 1904.

The process of heating materials as described in U.S. Pats. 750,093 and 750,094 (see preceding abstracts) is claimed, and, in addition, the process of reducing a compound by placing a mixture of a compound and a reducing agent in proximity to a resistance-conductor, which is heated in a non-uniform manner, an electric current of sufficient volume being passed to effect reduction. Fresh materials are supplied as required.—B. N.

Chemical Changes [*Carbide Production*]; *Process of Effecting* ——. A. H. Cowles, Cleveland, Ohio. U.S. Pat. 750,096, Jan. 19, 1904.

This invention consists of a process for producing carbide, the terminals of a source of electric current being placed in contact with different parts of a body of carbide-forming materials, such as a calcium compound and carbon. An electric current is passed between the terminals, so as to cause the lines of current-flow to converge from one terminal or set of terminals to the other, and thereby increase the energy and current density along the path of the current (see preceding abstracts, U.S. Pats. 750,093–5). The body of carbide-forming materials may be used as the resistance-conductor in the electric circuit, and the charge is moved along the path of current-flow.—B. N.

Heating [Calcium Carbide]; Method of Electric ——. A. H. Cowles, Cleveland, Ohio. U.S. Pat. 750,170, Jan. 19, 1904.

This invention consists of a process for making calcium carbide, the method being similar in principle to those described in preceding abstracts (U.S. Pats. 750,093–6). The electric current is passed through a pool of conductive material, such as calcium carbide, in which is maintained a region of maximum energy and current density. A suitable charge, as, for instance, a calcium compound mixed with carbon, is fed into contact with the pool, and the product, calcium carbide, is withdrawn from the region of maximum energy and current density.—B. N.

Furnace [Carbide, &c.]; Electric ——. A. H. Cowles, Cleveland, Ohio. U.S. Pat. 750,171, Jan. 19, 1904.

This invention consists of a modification of the furnace described in U.S Pat. 750,093 (see above). The furnace is provided with a hearth, which may be an inclined one, an annular one, an annular one with converging sides, or with downwardly-converging sides, and the hearth is arranged to support a body of conductive material, such as carbide or carbide-forming materials, an electric current being passed through the latter by means of a number of electrodes. A tap-hole extends through the hearth at or near the lower end of the furnace, and adjacent to the region of maximum current density, for withdrawing the product by gravity.—B. N.

Furnace; Electric ——. R. C. Contardo, Sèvres, France. U.S. Pat. 750,753, Jan. 26, 1904.

The hearth of the furnace is depressed on all sides towards the centre, above which are arranged the electrodes. Above the hearth is an arch, formed of two inclined plates placed in a symmetrical manner, and sloping downwards from the point of junction above the centre to the outer edges of the inclined hearth. The side walls are parallel to these plates, and thus form, with the latter, two inclined feed flues, which unite above to form a vertical charging shaft. The latter has a suitable arrangement for opening and closing, and is also provided with an outlet near to the top, through which the escaping gas may be aspirated.—B. N.

French Patents.

Insulated Electric Conductors; Impts. in ——, and in their Mode of Manufacture. J. A. Heany, United States. Fr. Pat. 335,612, Sept. 29, 1903.

The metallic wire passes through a bath of adhesive material, such as glue, and, whilst turning on its axis, it then passes over a belt carrying asbestos, and is thus covered with a layer of that substance. The covered wire passes through compression rollers, and finally through a mixture of 4 parts of glue and 1 part of the following :—6 parts of clay, such as kaolin, 4 parts of calcium sulphate, 2 parts of alumina, $1\frac{1}{2}$ parts of aluminium sulphate, and $\frac{1}{16}$ part of boric acid. The excess of this material is removed by compression rollers. It is claimed that the covering, when dry, resists fire, and is impermeable to water.—B. N.

Gaseous Reactions; Process for Facilitating Electro-Chemical ——. W. Ostwald. Fr. Pat. 328,157, Nov. 27, 1902.

Better yields are obtained when mixtures of nitrogen and hydrogen, or nitrogen and oxygen, are sparked for the production of ammonia or nitrogen peroxide, or when the electric discharge is passed through oxygen for the production of ozone, if more than 1·5 per cent., preferably 10 per cent.. of argon, or one of the gases of the argon type (argon, helium, neon, metargon, krypton, and xenon), is previously mixed with the gases.—B. N.

Gaseous Mixtures; Process for the Production of Intense Chemical Reactions in ——. S. Eyde and K. Birkeland. Fr. Pat. 335,692, Sept. 18, 1903.

The gases are subjected to the action of a luminous arc, extended in the form of a disc. The latter is obtained by producing the arc between electrodes in a powerful magnetic field, the disc being perpendicular to the lines of force. A vibratory movement is given to the electrodes, so as to produce a rapid series of pulsations of current; and, with a current of high tension, the electrodes are so fixed that a slight longitudinal and slow movement is imparted to them. A number of such luminous discs are produced between the poles of a powerful electro-magnet, and the air or gas to be treated is passed upwards and downwards alternately over the discs. The process is carried out in a furnace consisting of a narrow chamber formed of two walls of insulating and refractory material, the electrodes penetrating to the centre of the chamber and parallel to the two walls. The poles of a U-shaped electro-magnet are disposed one on each side of the furnace. The electrodes are made hollow for passing the air or gas to be treated, or for the circulation of water or oil for cooling. In the middle of the furnace, where the heat is most intense, there is fitted into each wall a safety plate, formed as a grill with bars of iron separated by sheets of mica, the edges of the latter projecting from the furnace. The interior walls are made of iron or other metal, with an internal lining of mica. With a current of high tension, several similar furnaces are disposed in series, each furnace being connected, in parallel, with a condenser; or the series of furnaces may be preceded by a single condenser of very high capacity.—B. N.

Oxides of Nitrogen; Electric Production of ——. Siemens and Halske Actien-Ges. Fr. Pat. 335,153, Sept. 21, 1903.

A mixture of nitrogen and oxygen in the proper proportions is circulated, under a pressure of 5 to 10 atmospheres, first through an apparatus containing an electric arc and then through a cooling or absorption apparatus. The residual gas is repeatedly circulated through the arc and cooling apparatus instead of allowing it to escape into the outer air. The circulation may be established automatically by the heating effect of the arc and the cooling effect of the refrigerator, or by means of a fan. Oxygen and nitrogen are introduced, under convenient pressure, by means of a junction pipe connected to a vessel containing these gases in the correct proportions, according to the consumption of nitrogen and oxygen within the apparatus.—B. N.

Air or Oxygen strongly Ozonised; Apparatus for the Production of ——. A. Déchaux. Fr. Pat. 335,092, Sept. 8, 1903.

The ozonising tubes consist each of a pair of metallic tubes, hexagonal in cross section, separated from one another by a cylindrical glass or porcelain tube, forming between the inner and outer tube a series of alternately angular and segmental spaces. The metal tubes are connected, through certain intermediate apparatus, one to each pole of a source of electricity. These ozonisers are packed within a rectangular box, having a space on one side for admission of air, and on the other side a chamber for reception of the ozonised air. Below the box is a bath containing a liquid at low temperature, and above it is a reservoir, perforated in certain parts, into which the liquid is pumped. The air to be ozonised is passed successively through sulphuric acid and caustic alkali, and then through a great number of very small tubes immersed in the cold liquid contained in the elevated reservoir. The cooled air is then conducted to the entrance chamber to the battery of ozonisers, themselves suitably cooled by a circulation of cold liquid. At suitable intervals, the battery of ozonisers and certain other parts of the apparatus are cooled externally.
—E. S.

Alkali Chlorides; Process and Apparatus for the Electrolysis of the ——. C. Kellner. Fr. Pat. 335,633, Sept. 29, 1903.

See Eng. Pat. 20,889 of 1903; this J., 1904, 24.—T. F. B.

Water; Apparatus for Purifying —— by Electrolysis. W. B. Hardy. Fr. Pat. 328,155, Nov. 26, 1902.

See Eng. Pat. 25,041 of 1902; this J., 1904, 67.—T. F. B.

(*B.*)—ELECTRO-METALLURGY.

Silver-Plating; Current Efficiency in ——. W. Pfanhauser. Zeits. f. Elektrochem., 1904, **10**, 68—70.

In examination of the results of Langbein (this J., 1904, 25), the author made, by the aid of a copper voltameter, measurements with the cyanide bath used commercially for heavy deposits. At a density of 0·3 ampère per sq. dcm. the values 99·99 and 99·96 per cent. were found, at 0·2 ampère per sq. dcm., 99·72 per cent. With a cathode kept moving up and down, efficiencies of 99·3—98·4 were obtained. The author shows by experiment that this is due to the re-solution of exposed parts of the cathode through oxidation, and that when this is quantitatively allowed for, the corrected current efficiencies are not less than 99·56 per cent.—W. A. C.

English Patent.

Metals from Ores and the like; Electrolytic Process for the Direct Extraction of ——, and for the Precipitation of the Metals from the Solutions, and Apparatus therefor. Meckwart, Coltri, et Cie., Milan. Eng. Pat. 2574, Feb. 3, 1903. Under Internat. Conv., Aug. 1, 1902.

See Fr. Pat. 328,850 of 1903; this J., 1903, 1004.—T. F. B.

United States Patents.

Metals, Precious; Extracting ——, by Electrolysis. H. R. Cassel, New York. U.S. Pat. 749,843, Jan. 19, 1904.

This invention constitutes a step in the process, and consists in simultaneously lifting the pulp and mercury by an air jet, distributing and circulating the pulp between vertical electrodes, and at the same time amalgamating the cathodes. This is accomplished by successively deflecting the rebounding mercury back upon or towards the cathode, and diverting the pulp towards the anode. The coarse amalgam is collected, purified, and neutralised by treatment with acid, and the mercury returned to the cathode.—B. N.

Metals, Precious; Apparatus for Extracting ——, by Electrolysis. H. R. Cassel, New York. U.S. Pat. 749,844, Jan. 19, 1904.

This invention refers to the apparatus for carrying out the process described in the previous abstract (U.S. Pat. 749,843). A tank, with an inclined bottom, is provided with enclosed vertical electrodes, with surrounding guards, the cathodes being flanked with a series of mercury deflectors, the latter being inclined towards the cathodes from top to bottom, and approaching the same at their lower ends. Pulp-guards project from the deflectors, and serve to divert the pulp towards the anodes, an elevated pulp box communicating with distributing launders above each anode. An elevated mercury pot communicates with a perforated movable mercury trough extending over the cathodes, and a reciprocating movement is imparted to the trough. The latter communicates with an enclosed filter and an acid box provided with transverse open partitions, the mercury being admitted at one end and discharged by suitable means at the other end. A jet of air returns the pulp and mercury from the inclined bottom of the tank to the pulp box and mercury pot, and means are provided for circulating the mercury and for separating it from the cathode.—B. N.

Iron or Steel; Electro-metallurgy of ——. H. Harmet, St. Etienne, France. U.S. Pat. 750,361, Jan. 26, 1904.

The ore, mixed with an excess of reducing carbon, is charged into the upper portion of an electric blast-furnace, the base of the latter being heated by means of electrodes, so as to form a fusion zone or crucible. The gas, escaping near the top of the furnace, is conveyed to and forced through the fusion zone adjacent to the electrodes, and the heat is thereby diffused, the zone extended, and the gas converted into carbon monoxide. The latter is forced by pressure through the charge, and thus forms a reducing zone above the fusion zone.—B. N.

French Patent.

Alkaline Earth Metals, especially Calcium; Electrolytic Process for Obtaining ——. Elektro-Chem. Werke, G. m. b. H. Fr. Pat. 335,568, Sept. 26, 1903.

See Eng. Pat. 20,655 of 1903; this J., 1903, 1299.—T. F. B.

XII.—FATTY OILS, FATS, WAXES, AND SOAP.

Sesamé Seed; Substances which Accompany the Oil in ——. F. Canzoneri and F. Perciabosco. Gaz. chim. ital., 1903, **33**, [2], 253—260. Chem. Centr., 1904, **1**, 45. (See this J., 1897, 1045.)

Sesamé seeds were extracted for 7—8 days with boiling 93 per cent. alcohol, the greater part of the alcohol was evaporated from the solution, and the residue repeatedly extracted with ether and light petroleum spirit. The greater portion of the sesamin remains in the alcoholic residue, whilst the light petroleum extract contains the higher alcohol discovered by Villavecchia and Fabris (*loc. cit.*), and a new substance, X. This latter substance, which readily changes to a rubber-like mass, is accompanied by a small quantity of a yellow oil of strong aromatic odour, which is volatile with steam, and is probably a decomposition product of X. The compound X forms broad tablets; it contains 66·62 per cent. of carbon, and 5·89 per cent. of hydrogen; it melts at 91°—92° C., and is soluble in alcohol, ether, and chloroform. When X is treated with hydrochloric acid, two new compounds are obtained: (*a*) a red oil which is readily soluble in alcohol and ether, insoluble in light petroleum spirit, gives a strong reaction with furfural, and immediately reduces ammoniacal silver nitrate solution; and (*b*) a resinous mass which does not give the furfural reaction. On exposure to the air, the red oil is converted into a product which crystallises from alcohol in leaflets, melts at 185°—186° C., and does not give the furfural reaction. The authors state that the higher alcohol discovered by Villavecchia and Fabris has the composition $C_{26}H_{44}O + \frac{1}{2}H_2O$. If the red solution obtained by treating a mixture of sesamé oil and hydrochloric acid of sp. gr. 1·18 with furfural, be shaken for 2—3 minutes with 3 vols. of ether, the red colour disappears. The abnormal behaviour of old sesamé oils when tested by means of Baudouin's reaction is due to the fact that the compound X, which is probably the cause of the red coloration, when heated with hydrochloric acid, imparts a green coloration to the latter; this green coloration is also produced when alcoholic solutions of the red oil or of the other oxidation products of X are treated with hydrochloric acid.—A. S.

Butter Fat; Interdependence of the Physical and Chemical Criteria in the Analysis of ——. T. E. Thorpe. Proc. Chem. Soc., 1904, **19**, 12.

In the course of an investigation of the chemical nature of butter produced within the British Isles, which was instituted by the Board of Agriculture for the information of a Departmental Committee, observation has shown that the chemical nature of butter fat is dependent, to a certain extent, on the climatic influences to which the cows are exposed, on the nature and amount of the food supplied, and on the breed, period of lactation, and idiosyncrasy of the individual cow.

Linseed Oil; Determination of Unsaponifiable Matter in ——. C. Niegemann. XXIII., page 207.

English Patents.

Fatty Acids of the Oleic Series and Derivatives thereof; Process for Converting ——, into Lactones. A. A. Shukoff, St. Petersburg. Eng. Pat. 1570, Jan. 22, 1903.

See Fr. Pat. 328,604 of 1903; this J., 1903, 1006.—T. F. B.

Soaps, Medicated, or Ointments; Production of Readily Resorbent ——. R. Reiss, Charlottenburg, Germany. Eng. Pat. 24,240, Nov. 9, 1903.

A melted mixture of fatty acids and hydrocarbons is treated with a ley of fixed alkali in insufficient quantity for saturation, and the resulting soap base heated to expel water, and incorporated with the required medicated substance. The removal of the water is stated to prevent the gradual decomposition that occurs in ordinary medicated soaps.—C. A. M.

United States Patents.

Fatty Substance; Process of Making ——. O. Liebreich. Berlin. U.S. Pat. 746,638, Dec. 8, 1903.

See Ger. Pat. 136.917 of 1900; this J., 1903, 149.—C. A. M.

Oils; Process of Treating ——. F. B. Pope, Augusta, Ga., U.S.A. Assignor to M. Swenson, Chicago, and L. L. Fleming, New York, U.S.A. U.S. Pat. 749,322, Jan. 12, 1904.

The oil is heated to a high temperature as it leaves the press, and passed, whilst hot, through a filter bed and refining apparatus, where the free acid is neutralised and separated. The process is carried out continuously.

—C. A. M.

Oil; Process of Refining ——. J. C. Fleming, New York. U.S. Pat. 749,925, Jan. 19, 1904.

"Oil" is agitated with a solution of borax, and carbon dioxide is blown through the mixture, which is then "subjected to a sucking and forcing action, whereby it is atomised." The mixture is allowed to stand and the oil is separated.—T. F. B.

French Patents.

Hydraulic Press for Oils. B. Santisteban, Lopez. Fr. Pat. 335,139, Sept. 10, 1903.

The material is placed in alternate layers with perforated plates in the cylinder of the press, in which is a central guiding rod. The wall of this cylinder is constructed in three parts, so arranged that the conduit holes for the oil can be opened or closed by rotatory motion from outside. The head of the press is screwed to a movable support fixed to the platform, and can be removed at the end of the expression to allow the piston to expel the pressed cake from the top of the cylinder. The apparatus is specially intended for the expression of olive oil.—C. A. M.

Soap containing Alcohol. Lebreton-Deshayes. Fr. Pat. 335,126, Aug. 10, 1903.

Fats or oils are saponified with a mixture of pure alcohol and caustic soda ley at a temperature of 40° to 50° C.

—C. A. M.

Zinc-White Paints; Substitution of* ——, *for White Lead Paints. J. L. Breton. Ann. Chim. Phys., **30**, 554—574. Chem. Centr., 1904, **1**, 201.

As an additional reason, from the hygienic standpoint, for the use of zinc-white paints in place of white-lead paints (see this J., 1903, 807), it is stated that freshly-applied white-lead paint yields an exhalation containing lead, the presence of the lead being detected by means of tetramethyldiaminodiphenylmethane, $CH_2[C_6H_4.N(CH_3)_2]_2$, with which the smallest trace of lead peroxide gives a blue coloration.

—A. S.

United States Patent.

White Lead; Manufacture of ——. J. W. H. James, Philadelphia, Pa., U.S.A. U.S. Pat. 750,541, Jan. 26, 1904.

As an improvement in the process of making white lead which consists in submitting lead oxide to the action of acetic acid and carbon dioxide, the lead oxide is first heated to about 200° F. The oxide is then treated with acetic acid to convert into a salt any metallic lead which may be present, the mixture is heated, then subjected to the action of acetic acid and carbon dioxide, and the resulting lead carbonate is exposed to the action of oxygen gas.—M. J. S.

French Patent.

Bronze Colours and Tinsel; Manufacture of ——. Soc. G. Benda. Fr. Pat. 335,112, Sept. 10, 1903.

To obtain bronze powders, tinsel, and the like, the suitable metal or alloy is melted and run upon the cylinders by which it is to be laminated, dispensing with the customary intermediate process of first casting the metal or alloy in rods. The thinly-rolled metal is subjected to usual processes to form it into powder, &c.—E. S.

(*B.*)—RESINS, VARNISHES.

United States Patent.

Varnish Substitutes; Process of Manufacturing ——. R. Blume, Magdeburg. U.S. Pat. 750,575, Jan. 26, 1904.

See Fr. Pat. 333,602 of 1903; this J., 1903, 1358.—T. F. B.

(*C.*)—INDIA-RUBBER.

French Patent.

Caoutchouc Substitute; Process of Manufacturing a ——. E. H. Fayolle. Fr. Pat. 335,584, Sept. 26, 1903.

Two kilos. of sulphuric acid (66° B.) are added to 1 kilo. of glycerin, the mixture is allowed to cool, and from 1 to 1½ kilo. of formalin (40 per cent.) is then added. The mixture is again cooled, and, after adding ½ kilo. of water, 1—1·4 kilo. of commercially pure phenol are slowly poured into it, with constant stirring and external cooling. The mixture is then left at rest for 20 hours, when the new product will be found as a layer on the surface of the liquid. The substance gradually hardens on exposure to the air, and before it has become too hard it must be subjected to prolonged kneading. The formaldehyde may be replaced by methylal and the phenol by cresol. The new substance may be used for rendering fabrics waterproof or as an electric insulator.

—M. J. S.

XIV.—TANNING; LEATHER, GLUE, SIZE.

Infusions of Tanning Materials; Notes on the Changes which take place in ——. E. Nihoul and L. van de Putte. Bull. de l'Assoc. Belge des Chim., 1903, **17**, 390—398.

Extractions of oak-bark (27 grms.), pine bark (17·8 grms.) and sumac (17·5 grms.), were made in Koch's apparatus, adjusted to 1 litre with the usual precautions, and entirely filtered, the first 100 c.c. being rejected and the rest thoroughly mixed in each case. From these filtered liquors (about 900 c.c. each) four lots each of 150 c.c., were drawn off, and the remainder at once analysed by the official method. The 150 c.c. lots were treated as follows:—

Process (*a*).—Diluted with 150 c.c. of water and analysed at once.

Process (*b*).—Diluted with 150 c.c. of water and analysed after standing for three days.

Process (*c*).—Diluted with 150 c.c. of water, preserved with a trace of thymol, and analysed after three days.

Process (*d*).—Diluted with 100 c.c. of water in a 300 c.c. flask, which was plugged with wool, boiled on three successive days for a few minutes, and on the third filled up to the mark, cooled, and filtered.

None of these liquors became turbid within three days, apparently because of the increased dilution. The general conclusions from these parallel experiments on the three different liquors are as follows:—(1) Dilution of the liquors before analysis appreciably lowers the amount of total soluble matter and organic soluble matter. Procter's opinion, that liquors must be sensibly of the same strength to secure concordant results, is fully supported. In two of the three cases (pine bark and sumac) the loss in tannin (1·19 and 0·96 per cent.) is greater than the loss of total soluble matter (0·98 and 0·68 per cent.); so that a direct action of the water on the tannin, promoting its volatility (*cf.* sugar and glycerin evaporations) appears to be indicated. This conclusion is arrived at after giving full weight to the loss caused by precipitation of less soluble tannins during the long filtration of the original liquor, which has not been proved to exceed 0·3 per cent., and in some cases does not take place (mangrove). In all cases the difference between loss in tannin found in processes (*b*) and (*c*) on the one hand and (*a*) on the other, shows that precipitation is responsible for only a small part of the loss. (2) Substances which in the official method are soluble in the warm infusions and slowly separate on cooling may remain dissolved when the proportion of solvent is increased, *i.e.*, when the concentration is diminished. (3) To obtain concordant analytical results, extractions must be at once analysed (*cf.* also Paessler, this J., 1904, 71 and 123).—R. L. J.

Tanning Analysis; Notes on ——. G. Schweitzer. XXIII., page 207.

Hide Powder; Determination of Acidity in ——. J. Paessler. XXIII., page 207.

English Patent.

Adhesives; Manufacture of ——. H. Arledter, Garston, Lancs. Eng. Pat. 1049, Jan. 15, 1903.

Resin (up to 80 per cent. of the final mass) is dissolved in soap, oils, fats, hydrocarbons, or other organic solvents at 180° F., and mixed with glue or other adhesive, with or without the addition of a phenol.—R. L. J.

French Patents.

Deliming and Degreasing Agent for Skins, and Mode of Employment. C. Paton and C. Pujol. Fr. Pat. 335,178, Sept. 12, 1903.

Chromic acid solution, the effect of which is moderated, if desirable, by the addition of sodium bisulphite, metabisulphite, or similar substance, is used for removing lime and grease from skins, (1) as a weak solution, the skins being soaked in it for 2—4 hours with milling, or about 12 hours without milling, and then washed freely; or (2) as a strong bath, in which case 3—4 minutes' immersion, followed by lengthy washing, is sufficient.—R. L. J.

Coriaceous Substance [Leather Substitute]; Manufacture of a New ——. A. Menesdorffer. Fr. Pat. 335,543, Sept. 24, 1903.

See Eng. Pat. 20,488 of 1903; this J., 1903, 1300.—T. F. B.

XV.—MANURES, Etc.

Potash in Soil; Distribution of ——. J. Dumont. Comptes rend., 1904, **138**, 215—217.

The author has investigated the distribution of potash among the different elements of two soils—one from Grignon, containing 8·53 of total potash per 1,000, and the other from La Creuse, with 8·94 of potash per 1,000—varying widely in their physical composition. In the Grignon soil, more than 5/6 of the total potash occurs in the finer portions, and the clay only contains the fifth part of it. In the La Creuse soil, however, the coarse sand includes 7/10 of the potash present, and the fine sand nearly the whole of the remainder, since the clay only contains 2·7 per cent. of the total. Admitting that the chemical activity of the soil is exercised most effectively by means of the very fine particles, it will be understood why potash manures are generally found to be inefficacious with the Grignon soil, whilst they act favourably on granitic soils, which are rich in passive potash but too poor in fine elements. The quantity of potash rendered active, under natural conditions and in the same time, being very different for the two soils, it follows that the needs of the vegetation are not equally well satisfied, so that the use of potash manures is rendered necessary whenever the fine sand and clay occur in the soil in less proportion than 25 per cent. —T. H. P.

Phosphorite; Increased Solubility of ——, in presence of "Physiologically Acid Salts." J. W. Schulow. Biel. Centr., 1904, **33**, 79—80; from Jour. exper. Landw., **3**, 711—719.

The term "physiologically acid salts" is applied to salts which (as ammonium salts, for example) are decomposed in the soil, the base being taken up by the plant and the acid left behind. The results of pot experiments with barley showed that much larger yields are obtained when a mixture of phosphorite and ammonium salt is used as a manure, than when the two substances are separated. This is attributed to the action of the acid of the ammonium salt on the phosphorite.—N. H. J. M.

Yeast; Manufacture of certain Products from Waste Brewery or Distillery ——. P. Schidrowitz and F. Kaye. Eng. Pat. 6604, March 21, 1903. XVII., page 200.

XVI.—SUGAR, STARCH, GUM, Etc.

Sugars; Synthesis of —— from Trioxymethylene. Seyewetz and Gibello. XXIV., page 209.

Molasses; Barbados and Porto Rico ——. Imp. Dept. of Agriculture for the West Indies. Pamphlet No. 28, 1903.

As the result of enquiries made in the United States markets as to the relative values of Barbados and Porto Rico molasses, the Commissioner states that Barbados molasses is equivalent to the second quality of Porto Rico molasses, termed "choice." The best quality of "fancy" Porto Rico molasses is worth 7 cents per gallon more, and there is a market for larger quantities. At the present average prices of muscovado sugar and Barbados molasses, the planter obtains 1·45 cents per lb. for the saccharose in his sugar, and 2·09 cents per lb. for the saccharose in his molasses. It would therefore pay to convert the whole of the cane crop into a golden-coloured table syrup equal to the Porto Rico "fancy" molasses, until the limits of demand were reached. On estates provided with vacuum pans, the Commissioner recommends bleaching the cane-juice with sulphur dioxide, "tempering" with lime almost to neutrality, evaporating the juice in the "taybes" (teaches) to a thin syrup, with the addition, if necessary, of a little citric acid, clarifying the syrup by settling, and concentrating to a table syrup in the vacuum pan. The presence of a little free acid in the syrup is advantageous, for the following reasons: it preserves the pale colour during boiling; it inverts some of the saccharose, thus preventing crystallisation; and it imparts "baking" properties, *i.e.*, reacts with the sodium carbonate in the flour when the syrup is used for making cakes, &c. The syrup should be packed in casks which have been sterilised, first by steaming, and then by burning lumps of sulphur inside them until the oxygen in the cask is exhausted.—J. F. B.

French Patents.

Saccharine Juices or other Matters from Plants, Roots, &c.; Extraction and Utilisation of ——. A. Montupet. Second Addition, dated Aug. 18, 1903, to Fr. Pat. 329,947, March 1, 1903 (this J., 1903, 1058).

The juices prepared by this process, being very concentrated, may be sterilised by boiling at temperatures of 100° C. and over, in order to destroy all ferments, and to preserve them in a suitable condition for subsequent fermentation, with or without the addition of marcs of a similar origin. In the case of beet juices defecation may also be performed. A form of apparatus with a heating jacket and means for the circulation of the heating medium through the centre of the bulk is also described.—J. F. B.

Sweetening Agent; A New ——. A. H. Tissot. Fr. Pat. 335,379, Sept. 14, 1903.

The "edulcorant Porchère" is a liquid with a great sweetening power in relation to its weight and volume. This substance, previously perfumed if desired, is converted into a plastic body by incorporation with powdered gum arabic. Tablets and pastilles are then prepared from the mixture, suitable for making sweetened drinks.

—J. F. B.

Carbohydrates in General; Process of Dissolving ——. A. Boidin. Fr. Pat. 335,366, Sept. 18, 1903.

The dialkali phosphates and phosphates of magnesium in grains have the effect of retarding the solution of the carbohydrates on boiling in the open air or under pressure with water; some of the alkali phosphates also promote caramelisation. These phosphates are converted into primary phosphates or into inert calcium phosphate by steeping the meal in cold or warm water to which an acid or a metallic salt, such as calcium chloride, has been added in such proportions that, after one or two hours, no free acid can be detected by a suitable indicator.—J. F. B.

Organic Acids contained in the "Vinasse" of Molasses; Process for the Extraction and Utilisation [*as Mordants*] *of the* ——. H. Schrader. Fr. Pat. 328,160, Dec. 1, 1902.

See Eng. Pat. 20,851 of 1902 and U.S. Pat. 735,599 of 1903; this J., 1903, 920 and 993 respectively.—T. F. B.

XVII.—BREWING, WINES, SPIRITS, Etc.

Malting; Carbon Dioxide in ——. C. Bleisch. Zeits. ges. Brauw., 1904, **27**, 45—50.

The Pneumatic Drum (*Galland's System*).—In the large pneumatic malting drums a distinct proportion of carbon dioxide can always be detected. If the ventilation be stopped, the proportion of carbon dioxide in the air inside the drum rises rapidly, and the rapidity and extent of this rise afford a measure of the intensity of the respiration. This is at a maximum on the fourth day, when a proportion of carbon dioxide of about 0·5 per cent. before the ventilation is stopped, may increase to 4·5 per cent. after 30 minutes without aeration. During malting with continuous ventilation the proportion of carbon dioxide in the air of the drum amounts to an average of about 0.5 per cent., rising towards the fourth day to 0·7 per cent. The recent improvements in the drums, by increasing the number of ventilating pipes from eight to nine, have had the effect of ensuring a remarkable uniformity in the composition of the air in different parts of the drum, so long as the latter is kept in motion. During the periods of rest an accumulation of carbon dioxide does take place, to a slight extent, in the places behind the air-channels.

Kilning.—In the Bavarian system of malting, the green malt is withered on the upper floor of the kiln at a temperature of 25°—28° C., during which process growth continues for a few hours. A sample of air taken from the mass of malt after four hours on the upper floor of the kiln contained from 0·7 to 1·1 per cent. of carbon dioxide resulting from this continued respiration; the loss of malt substance at this stage is not, however, very considerable. The present series of investigations has led the author to the conclusion that the presence of even comparatively high proportions of carbon dioxide in the growing mass is quite unimportant; the malt always manages to get as much air as it requires. The proportion of carbon dioxide in the air taken from the couches of malt on the floor is about 1·5 per cent. higher than that contained in the air from the pneumatic drum. But in the chest system of pneumatic malting, the carbon dioxide in the air in the mass of grain sometimes amounts to five or six times that found in the floor system of malting, and yet the growth of the malt does not appear to suffer. An accumulation of carbon dioxide in pneumatic drums or chests can be removed by full ventilation in a few minutes. The main object of ventilation in the pneumatic systems is, therefore, to cool the grain. This method of cooling possesses the drawback of removing large quantities of moisture from the grain, and it would be distinctly advantageous if it were possible to perform the necessary cooling by some other means, since the means for replacing the moisture so lost are somewhat imperfect in their action.—J. F. B.

Malt; The Polishing of ——. J. Fries. Zeits. ges. Brauw., 1904, **27**, 61—63.

If the work of a malt-polishing machine be examined it will be found that the waste consists of two kinds of products. On the one hand is the coarse waste, consisting of husks, coombes, and dust, and on the other hand there is a greyish-brown, very fine, flour-like dust, which collects chiefly in the pipes leading to the exhauster. This latter consists of very minute splinters of husks, together with a considerable proportion of malt starch, which is also found to some extent in the coarse waste. It therefore follows that some of the good malt is destroyed and wasted by the polishing operation. But at the same time, malt, even if properly cleaned, still contains a certain amount of impurities, which, if not separated, may have a bad effect on the flavour and quality of the beer. This is shown by mashing the two kinds of waste from the polishing machine; the mash from the coarse waste has an odour of brewed malt-germs, whilst that from the fine dust is distinctly disagreeable. The polished malt is heavier by about 0·4 kilo. per hectolitre than the unpolished malt, and it requires about 71 brews of unpolished malt to make the same quantity of beer at the same strength as is obtained from 70 brewings of polished malt. This is an important factor in countries like Bavaria, where the excise is levied on the malt. The proportion of waste removed during the polishing operation is about 1·4 per cent. of the malt by volume, and the extract value of this waste is about 40 per cent. of that of the malt. The value of the waste by polishing is estimated at 4·8 pfennige, and the cost of running the machine is 2 pfennige per hectolitre of malt. The superiority of the quality of the beer from polished malt, however, cannot be denied. If the polishing machine be kept in perfect working order, the destruction of good malt can be kept down to a minimum, but without care more harm than good may be done.

—J. F. B.

Potatoes; Method of Improving the Fermentation of Difficultly Fermentable ——. P. Jensch. Zeits. Spiritusind., 1904, **27**, 38.

The experiments here described were made with "Fürst Bismarck" potatoes containing 20·7 per cent. of starch. Mashes of 26°—27° Balling were readily obtainable, but could not be fermented, while those having the gravity 22°—24° Balling never fermented lower than 1·5°. The effect of aëration was tried, air being passed into the sweet wort for an hour after the addition of the yeast. When cooled to 19° C. the mash was introduced into the fermenting vat, the yeast beginning to act after about an hour, and the temperature rising to 29·5° C. in 15 hours' time. There was a vigorous formation of foam and a brisk after-fermentation, but the increase in acidity only amounted to 0·3 in spite of the infection to which the wort was subjected by the aëration. The attenuation reached was 1·0° Balling, the yeast employed being Race XII.—T. H. P.

Reverted Starch; Formation and Saccharification of ——. L. Maquenne. Comptes rend., 1904, **138**, 213—214.

Solutions containing increasing amounts of starch, gelatinised in a boiling water bath, and afterwards heated at 120° C. for 15 minutes, were allowed to undergo reversion for four days at 9° C., and were then saccharified at the same temperature by the addition of equal amounts of malt extract. The relative amounts of amylo-cellulose obtained were estimated by comparison with similar solutions saccharified immediately after removal from the autoclave

In these check solutions the weight of soluble matter formed is proportional to that of the starch taken, but with the reverted solutions the concentration of the filtered liquid increases less rapidly than the amount of starch employed. It is clear from this why a weak starch solution becomes turbid less readily than a stronger one, and why amylo-coagulase acts more especially on concentrated starch solutions. On allowing malt extract to act at temperatures of from 22°—70° C. on starch solutions after reversion, it is found that the effect of rise of temperature is to facilitate the solution of the reverted starch, but that this solution never becomes complete, as is the case at all temperatures with fresh starch paste.

It is concluded that amylo-cellulose is not a single principle, but a mixture of several different condensation products, which have the common property of giving no coloration with iodine, but which offer varying resistances to the dissolving action of amylase.—T. H. P.

"Spring" Mashing Process; Regulation of the Final Attenuation of the Beer by the ——. W. Windisch. Woch. f. Brau., 1904, **21**, 65—68.

The underlying principle of the "spring" mashing process is the avoidance of those intermediate mashing temperatures at which saccharification takes place so rapidly that it is almost impossible to restrict the formation of highly fermentable products by the selection of a high temperature for the saccharification proper. These intermediate temperatures are entirely avoided by establishing the desired high saccharification temperature by a process of cooling down instead of heating up as heretofore. The grist is mixed with water at so low a temperature that no saccharification can take place; the thick, cool mash is then "sprung," *i.e.*, dropped rapidly, into a sufficient quantity of water near the boiling point, until the temperature of the mixture is that at which the restricted saccharification is desired to take place. Subsequent operations then depend on the general policy of mashing, whether by infusion or decoction, adopted. This power of restricting saccharification to a definite extent enables the brewer to obtain a wort of any fermentability he may desire, and the attenuation of the beer may, if desirable, be kept down to a degree hitherto unattainable. Such a restriction is, however, only advantageous if the type of malt is such that it will yield good, full-bodied beers of small attenuation. The "spring" mashing process is only to be used as one of the factors in producing such beers; the mere fact of small attenuations will not impart "body" to beer made from malt unsuitable for that kind of beer, since the "body"-forming carbohydrates are only produced on the malting floor. The "spring" mashing process is the means by which the qualities of a suitable malt may be developed to a fuller extent than by other processes. The preparation of such a malt is perhaps a matter of some difficulty; the author, without laying down any exact specification, describes it as one having an average length of acrospire of two-thirds the length of the corn, *i.e.*, a short-grown malt; it must nevertheless be perfectly modified, and must be kilned at a high temperature. Perhaps the Bohemian type of malt most nearly approaches the type desired. Above all, the restriction of the fermentability of the wort must not be pushed too far, otherwise difficulties will occur in the secondary fermentation and clarification of the beer. For German lager beers it is not advisable to curtail the final attenuation below 65 per cent.; and a "standard" beer may be defined as one brewed from an 11 per cent. wort with a final attenuation of 65 per cent., and racked off at a gravity corresponding to 3·85 per cent. of apparent solids.
—J. F. B.

"Spring" Mashing Process; Regulation of the Attenuation by the ——. O. Kleinke. Woch. f. Brau. 1904, **21**, 68—73.

The author, having practised the "spring" mashing process from its inception, concludes that the fermentability of the wort can easily be restricted thereby to any desired limit; very low attenuations are obtained by "springing" the mash at temperatures above 75° C. The grist should be mixed with water at a temperature insufficient to permit of the saccharification of the still ungelatinised starch, but sufficient, if desirable, to permit of the activity of the proteolytic enzyme. For the preparation of beer with an abnormally low proportion of alcohol, wort having a final degree of attenuation of only 28—30 per cent. is mashed as follows:—The grist is mixed with water at about 52° C., and digested for 15—30 minutes; it is then "sprung" into water at 88° C., the clear mash being "sprung" first, until the temperature falls to 77·5° C. Heat is then applied so as to keep the temperature constant until the whole of the cool mash has been "sprung," saccharification being then allowed to proceed at a temperature of 80° C. Such worts are, however, only intended for special purposes; for ordinary beers they should be combined with worts mashed carefully in the ordinary way, so as to have more fermentable sugar. Worts from "spring" mashes made exclusively at very high temperatures (77·5°—80° C.) are liable to give abnormal iodine reactions, and the beers never clarify of their own accord. Such difficulties do not occur if the restriction of the fermentability be not pushed below 40—45 per cent. Worts with very restricted fermentability require very high fermentation temperatures, *viz.*, about 25° C.; if the temperature be 15° C. or lower, the fermentation is liable to proceed with a series of somewhat lengthy and dangerous pauses. It is therefore better, except for extraordinary purposes, to keep the fermentability of the wort above 40 per cent., and to ferment at lower temperatures; in fact, for ordinary beers from original worts of medium strength, the attenuation should not be restricted below 55 per cent. The unfermentable extract obtained by restricted saccharification is composed almost entirely of dextrins, which do not have any perceptible influence on the flavour of the beer, and cannot in any sense replace the nitrogenous constituents, which are so important for full-flavoured beers.—J. F. B.

Fermentation Energy in Highly Concentrated Salt Solutions. A. J. J. Vandervelde. Bull. de l'Assoc. Belge des Chim., 1903, **17**, 398—411.

The author has already shown that fermentation energy, as gauged by the time taken by yeast to decompose a known weight of sugar, is not impaired by neutral salts (*i.e.*, non antiseptic), even when rather highly concentrated. He has now determined the rate of decomposition of 5 grms. of sugar by 5 grms. of yeast in solutions of 18 different single salts, the strengths being 2, 4, 6, 8, and 10 grms. of salt per 100 c.c. The loss of carbon dioxide was determined at set intervals of 5, 16, 40, 64, and 96 hours; the molecular concentration and osmotic pressure were calculated in the usual manner, and the fermentation energy found by interpolation. As the rate of decomposition is much less in the final stages than the mean rate, the energy is defined as the number of hours required to decompose only a portion of the sugar, *viz.*, three-fourths of the whole, or the hours required to evolve 2·56 × 0·75 = 1·92 grms. of carbon dioxide, instead of the 2·56 grms. possible. The salts employed were chlorides and nitrates of potassium, sodium, ammonium, calcium, strontium, and magnesium; the sulphates of ammonium, magnesium, and zinc; phosphates of potassium and ammonium; and barium chloride. The general conclusions arrived at are that the fermentation energy is independent of the concentration and of the osmotic pressure of the salts present, and, consequently, of the life of the cell (which must be influenced by these factors), and is the result of enzymatic processes in accordance with Buchner's theory.—R. L. J.

Fermentation Tuns; Treatment of ——. W. Windisch. Woch. f. Brau., 1904, **21**, 49—53. (See also this J., 1903, 1302.)

When wild yeast turbidities occur in beer, the source of infection is almost invariably traced to badly lacquered fermenting tuns. Infection of the fermenting tuns is far more general than is supposed, but this infection does not always succeed in establishing a "sickness" sufficient to spoil the beer. It may safely be assumed that a very large proportion of all the beer made suffers infection by wild yeasts in a potentially virulent condition. Whether turbidity follows such infection, depends on the nature and the power of resistance of the beer. Strong beers, fully fermented, rich in alcohol and carbon dioxide, well matured under pressure, and properly treated, may be fairly expected to resist the infection to which they are exposed in the fermentation tuns. The tun question concerns those breweries which produce thin beers far more closely. With lacquered tuns it is not, as a rule, a question of avoiding infection, but rather of maintaining conditions favourable to resistance, which, however, is constantly liable to be broken down.

Pitch.—The efficacy of pitch depends on the maintenance of a perfect coating. This coating must be as thin as possible, and can only be applied satisfactorily by a suitable form of spraying apparatus. The great advantage of pitch lies in the fact that, when defects are detected, a fresh coat can be applied in a minimum of time without disturbing the tun, whereas a lacquered tun which has become defective has to wait until the annual re-lacquering. The application of a perfect coat of pitch requires some skill; the coating is more easily damaged than lacquer, but can often be repaired by the hand-lamp. Above all, great care is requisite in cleaning out the tuns; the men must wear rubber shoes. An addition of paraffin to the pitch is sometimes advantageous.

Solid Paraffin.—This appears to be the most favourable material, in the author's opinion. The wax must be made to penetrate deeply by heating the tun, but not to such an extent as to crack the wood. Only the very best quality of paraffin is admissible; the melting point should be fairly high.

Lacquer.—Alkaline reagents for removing the old lacquer are objectionable; if they be used, the wood should be planed down every two years. Scratching or sand-papering is preferable to alkaline treatment, but very laborious. The tun must be dry before applying the fresh coat, but on no account should either the wood or the lacquer be hot. Heat causes a too rapid evaporation of the alcohol, leaving the shellac in the form of films across the pores and cracks. For the same reason, the concentration of the lacquer solution should not be too great; dilution assists the penetration of the lacquer into the smaller pores. It cannot be denied that a perfect coating of lacquer is as good as any other; the whole question turns on the resistance to wear and tear and to the ease of renewal. In the last respect lacquer leaves much to be desired, and paraffin would appear to be the most promising material for general satisfaction. Brand strongly recommends paraffin for preserving the exteriors of the tuns. The new tuns, perfectly dry, should be painted with a coat of paraffin, applied at a temperature of 150° C. with a large brush; the coat of wax should then be melted with the hand-lamp until strong frothing occurs; such a coating is said to last for years.—J. F. B.

Fermentation Tuns; Internal Coating of ——. A. Vogel. Zeits. ges. Brauw., 1904, 27, 78—81.

The operation of coating is very much easier in the case of new tuns than in the case of tuns which have been in use without a coating or which have been coated with a different material.

Lacquer.—The tuns must be thoroughly dried before treatment, and this drying should on no account be hurried by the use of steam or the heat of a fire. The tuns should be placed in a draughty position, sheltered from the sun, and allowed to dry naturally. The old wood should then be planed off, or preferably scraped with a special tool. The lacquer should be diluted with alcohol, spirit of the purest and strongest quality being used for this purpose. For the first coating, the lacquer as purchased should be diluted with an equal quantity of spirit, in order that it may penetrate deeply into the pores of the wood. The second coat must be applied only when the first is perfectly dry, and this also should be diluted. The final coat is applied in the undiluted condition. The tuns must be re-lacquered every year, and the old lacquer should be removed, not by heat or chemicals, but by the scraper. The burning-in of the coating of lacquer is not desirable. Above all, the lacquer used must be a solution of genuine shellac in pure alcohol; no rosin or turpentine should be present.

Paraffin.—This has the advantage of very deep penetration, provided the wood be dry. The paraffin should be heated to 180°—190° C: the tun must be well heated and supported in a slanting position, the paraffin is then run down the sides by means of a ladle; the spraying apparatus is also advantageous. Re-paraffining can be done in the fermentation cellar, the tuns being first cleaned, scraped slightly, and heated by steam.

Pitch.—This has many advantages in presenting an absolutely impervious surface to the beer, so long as the coating is undamaged. The spraying apparatus is absolutely necessary, the wood must be perfectly dry, and a certain amount of penetration is essential in order to hold on the external surface-coating, which should be no thicker than a sheet of paper. Re-pitching is very easily performed, but it is desirable that the tuns should be removed from the cellar for the purpose. They should be returned whilst still warm, since the pitch is then in a condition sufficiently elastic to resist the shocks caused by moving them.—J. F. B.

Filtering Material [*for Beer*]; *Purification of* ——. E. V. Zeits. ges. Brauw., 1904, 27, 65—66.

Whether the filter be used constantly or only occasionally it is absolutely necessary, for the preservation of the beer, that the filtering-pulp should be sterile. A large number of machines are available for cleansing the pulp by beating it up with water and washing off the greater part of the albuminoid deposit and yeast cells by a stream of water. But no amount of mechanical washing can ensure sterility, and it is therefore necessary to boil the mass. Direct steam is used for this purpose, but the steam should be clean and should not be raised in boilers containing disincrustants with a penetrating odour. The steaming produces a thorough agitation of the mass, and 10 minutes' boiling is sufficient for sterilisation. Steaming is necessary every time the pulp comes out of use to be washed, otherwise it may be found that the unfiltered beer remains clear in bottle longer than the filtered beer. Chemical disinfectants are to be avoided on account of the difficulty of removing their odour from the pulp. When the mass has been purified it should be pressed into thin cakes and dried in the air, or if a press be not available, the water should be squeezed out by hand, and the lumps should be broken into small flakes before drying.—J. F. B.

Barley and Malt; Relations between the Percentage of Extract and Protein in ——. Merz. Zeits. ges. Brauw., 27, 63—65.

In the collection of analytical statistics with the endeavour to trace some relationship between the percentage of protein in barley and malt, and that of the extract obtainable, the conclusions may be entirely vitiated by the fact that the samples of malt received, frequently do not represent averages of the bulk. This may be due to inequalities in the working of the kilos. The author has frequently found differences of temperature taken in different places in the same kiln, of 17°—25° C., and the malt varies in composition correspondingly. In recording the curing temperature, it is generally considered sufficient to take the readings in four or five different places; the author considers, however, that readings should be taken in at least 17 places, and the thermometers should remain in the malt for 20

	Maximum and Minimum Temperatures registered out of 17 simultaneous Readings.			
	Kiln E. 116°—94° C.		Kiln R. 104°—84° C.	
Sample taken at	94° C.	116° C.	84° C.	104° C.
Moisture	3·75 %	2·1 %	3·1 %	2·9 %
Extract on dry substance	75·3 %	71·7 %	77·6 %	76·4 %
Maltose : non-maltose	1:0·50	1:0·84	1:0·51	1:0·60
Colour on 10 per cent. wort.	4·5 c.c.	14 c.c.	5·2 c.c.	11·7 c.c.
Yellow-coloured corns	6 %	43 %	11 %	29 %
Scorched corns	..	3	..	..
Aroma	Very faint	Scorched	Very moderate	Aromatic

minutes before reading, the bulbs being about 1 cm. from the floor. The foregoing table shows the differences in composition and character of the malt caused by the irregular distribution of heat in the kiln.—J. F. B.

"Poussé" Wines; Ferment of ——. J. Laborde.
Comptes rend., 1904, **138**, 228—231.

In April 1901, two young wines, one white and the other red, containing a small quantity of reducing sugar, were each inoculated with the three following organisms:—(1) Gayon and Dubourg's mannitic ferment. (2) The ferment from a wine previously become "poussé" or "tourné." (3) The ferment isolated from an 1890 "poussé" bottled wine. These samples and also non-inoculated samples of the wines were kept at the ordinary laboratory temperature until October 1903, when estimations of the volatile acidity (calculated as sulphuric acid) and of the residual reducing sugar gave the following results.—

	Volatile Acids.		Reducing Sugars.	
	White Wine.	Red Wine.	White Wine.	Red Wine.
Non-inoculated	0·75	0·83	2·90	2·00
Inoculated with (1)....	0·94	1·08	1·60	0·90
" " (2)....	1·02	1·27	1·40	Traces
" " (3)....	1·08	3·38	Traces	"

Microscopic examination showed that the three organisms had developed the usual appearance of the "poussé" ferment, both in the white and red wine, the activity being greater in the latter case. As the activity is seen to vary for the three organisms, these must be regarded as distinct. Of the six inoculated samples, only number (3) could be considered as "poussé": not only had its reducing sugar completely disappeared, but the cream of tartar (not attacked in the other wines) had diminished by 1 grm. per litre, and its volatile acids consisted of a mixture of 4·53 grms. of acetic with 0·47 grm. of propionic acid. Ferment (2) was less active than in the 1899 wine, from which it was isolated, for in that wine it had given 3·01 grms. of acetic and 0·30 grm. of propionic acid, while the cream of tartar was reduced in quantity by 0·86 grm. per litre. All three organisms were living in the inoculated wines, and were introduced into yeast water containing 20 grms. per litre of (1) dextrose and (2) levulose, and allowed to develop until all the sugar had disappeared, after which the three dextrose solutions were found to have the same composition, as also were the three levulose solutions. That the three organisms are really different, however, was shown by further analysis of the levulose solutions two months later, the following being the results:—

	(1)	(2)	(3)
	Grms.	Grms.	Grms.
Mannitol	9·86	9·15	Traces
Fixed acid	2·22	1·47	2·80
Volatile acid	2·88	3·76	5·44

As shown under (3), after the levulose has disappeared, it is possible for the mannitol to be attacked and completely destroyed.—T. H. P.

Wine; Production of Mannitol by the Disease Organisms of ——. P. Mazé and A. Perrier. Ann. de l'Inst. Pasteur, 1903, **17**, 586; through Woch. f. Brau., 1904, **21**, 85.

The authors have studied the micro-organisms present in "turned" bitter and viscous wines, especially the bacterium which produces mannitol in the course of its activity. This organism possesses the same physiological properties as the mannite ferment of Gayon. It secretes zymase, a lactic acid enzyme, and apparently a third enzyme, which splits up sugar into three molecules of acetic acid. In the presence of fructose the bacterium produces mannitol, apparently by the decomposition of water, the oxygen of which converts the alcohol into acetic acid, whilst the hydrogen reduces the fructose to mannitol. The authors therefore place this organism in a special group, which apparently contains other representatives. Many bacteria, notably the butyric acid bacteria, produce hydrogen, but the gas, when evolved in presence of fructose, does not reduce the latter to mannitol. It is true that these latter bacteria also decompose mannitol, but the excess of hydrogen developed ought, if a direct reduction were possible, to reproduce mannitol in presence of fructose, so that it would be detected in the liquid. The reduction of the fructose by the special bacterium is therefore independent of the direct action of the hydrogen.—J. F. B.

Methyl Alcohol; Determination of ——, *in Presence of Ethyl Alcohol.* T. E. Thorpe and J. Holmes. XXIII., page 208.

Corks; Impt. in ——. H. Helbing. XIX., page 202.

English Patents.

Beer; Brewing ——, *and Apparatus therefor.* A. G. Southby, Forest Gate, Essex. Eng. Pat. 4872, March 3, 1903.

The process and apparatus described in Eng. Pat. 2669 of 1902 (this J., 1903, 156) are applied to the mashing of raw grain. The ground grain is heated with water until the starch is gelatinised. The goods are cooled down to the mashing temperature and treated with a suitable proportion of ground malt or malt wort. The heating and cooling, with the addition of malt or malt wort, may be repeated until the whole of the starch is converted. The wort is then heated in a closed vessel above the boiling point of water, so as to impart to it the flavour of wort from kiln-dried malt.—J. F. B.

Yeast; Manufacture of Certain Products from Waste Brewery or Distillery ——. P. Schidrowitz and F. Kaye, London. Eng. Pat. 6604, March 21, 1903.

Waste yeast is pressed and then partially or wholly dried by heat, with or without an admixture of unslaked lime. The product is transferred to retorts, preferably of a type similar to those used for distilling bones, and subjected to dry distillation with or without the addition of a small quantity of unslaked lime. There are then obtained an aqueous ammoniacal yeast liquor, a yeast tar somewhat similar to bone tar, and a yeast coke rich in potash and phosphates.—J. F. B.

Beer and other Casks, and Beer and other Bottles; Purifying and Drying ——. J. D. Noble, Bristol, and H. J. Hamblin, Ashwick, Bath. Eng. Pat. 6758, March 24, 1903.

The casks or bottles, after being washed or rinsed, are cleansed, purified, and dried, by subjecting them to the suction action of a vacuum.—R. A.

French Patents.

Absolute Alcohol; Industrial Production of ——.
R. Sunyé. Fr. Pat. 328,143, Nov. 15, 1902.

Hydrated manganese protoxide is mixed with calcium hydroxide and the mixture is oxidised by air. The mixture of "calcium manganites" obtained, is then triturated with a suitable proportion of coke. By the fusion of this mass, a polycarbide of manganese and calcium is said to be obtained. This carbide is treated with steam and the original mixture of hydrated oxides is thereby regenerated for future use, and acetylene, methane, hydrogen, and steam are evolved, and are said to be suitable for the synthetical production of alcohol. (See also this J., 1903, 1361.)—J. F. B.

Vinegar; Apparatus for Making ——. R. Douglas. Addition, dated July 17, 1903, to Fr. Pat. 332,816, May 19, 1903.

See Eng. Pat. 11,526 of 1903; this J., 1903, 1144.—T. F. B.

XVIII.—FOODS; SANITATION; WATER PURIFICATION, & DISINFECTANTS.

(*A*.)—FOODS.

English Patent.

Milk and other Liquids; Process and Apparatus for Sterilising ——. C. de Jong, Nieuwer Amstel, and J. K. van der Heide, Amsterdam. Eng. Pat. 5446, March 9, 1903.

The milk or other liquid is forced at a high speed through a suitably heated pipe, where its temperature is raised to 130° C. or higher. It then passes into another coil or pipe surrounded by a cooling liquid. A stopper for a storing vessel, permitting sterilised liquid to be introduced into the vessel without liability of infection from the air, is also claimed. It consists of two perforated discs or plates capable of being rotated over each other on a pin, one of which is provided with an india-rubber washer in combination with an india-rubber ring placed between the plates. A cam-lever mounted on the pin serves to close the stopper.—W. P. S.

United States Patents.

Butter; Process of Testing ——. M. Vogtherr. U.S. Pat. 749,343, Jan. 12, 1904. XXIII., page 208.

Butter; Process of Making ——. J. Estep, Tacoma, Wash., Assignor to R. L. Bloom, Lakeview, Wash. U.S. Pat. 749,853, Jan. 19, 1904.

Fresh cream is treated with alum, pepsin, lactose, and potassium nitrate, and then churned. After removing the butter-milk, the butter is washed to free it from these added substances, salted, and worked.—W. P. S.

Casein Compound, and Process of Producing same. H. K. Brooks, Bellows Falls, Vt., Assignor to Casein Company of America, New Jersey. U.S. Pat. 750,048, Jan. 19, 1904.

The compound claimed consists of dry casein containing about 5 per cent. of ammonium persulphate. The latter s dissolved in its own weight of water and thoroughly ncorporated with the casein.—W. P. S.

French Patent.

[*Casein Substitutes*] *Decolorised Albuminous Substances; Manufacture of* ——. Aktien-Gesellschaft für Chemische Industrie. Fr. Pat. 335,359, Sept. 11, 1903.

Casein-like proteids are prepared from blood-clot, pulverised bone, &c., by treating the same with chlorine, hydrochloric acid, or hypochlorites, and compressing the resulting mass, with the previous addition, if necessary, of milk of lime or other alkalis. Alternatively, potassium permanganate is used as a bleaching agent, the precipitated manganese oxide being dissolved out with sulphuric acid before alkalis are added. Sulphurous acid is further employed when a specially light colour is desired.

—R. L. J.

(*B*.)—SANITATION; WATER PURIFICATION.

English Patent.

Sedimentation Tanks or the like, especially for Sewage Treatment. W. J. Dibdin, London. Eng. Pat. 16,851, July 31, 1903.

The sedimentation tank is packed with ribbed plates, of glazed earthenware, arranged horizontally or inclined, laid upon each other so as to break joint irregularly. When the liquid is run off, it flows off the plates without the formation of any specific currents, the sediment being undisturbed and subject to aëration as the liquid drains away. It is preferred that each plate should be very slightly arched, so as to entrap a little air when the tank is full. The packing may be effected with slate refuse, the plates being kept apart by suitable slate fragments, and prevented from shifting by means of thick slate slabs or the like.

—E. S.

(*C*.)—DISINFECTANTS.

French Patent.

Disinfectants; Process of Making Solutions of ——, *hitherto considered Insoluble or Slightly Soluble.* Chem. Werke Hansa G. m. b. H. Fr. Pat. 335,306, Sept. 15, 1903.

Solutions containing free thymol, salol, menthol, &c., suitable for disinfecting purposes, are obtained by dissolving the disinfectant in, or mixing it with, a neutral solution of soap, and adding formaldehyde to the mixture; such solutions can be diluted without precipitation taking place. For example, 325 grms. of thymol are dissolved in "860 grms. of a neutral soap solution," and formaldehyde is added until a specific gravity of 1·025 is reached; the solution will then contain about 25 per cent. of thymol and 10 per cent. of formaldehyde.—T. F. B.

XIX.—PAPER, PASTEBOARD, Etc.

Cotton-Rag Papers; Knots in ——. M. Papier-Zeit., 1904, **29**, 371. (See also this J., 1904, 127.)

The specific tendency of the cotton fibre, especially in the unsized state, to roll and curl up so as to form clots is well known. These clots are not, however, "knots" in the true sense of the word, and they are easily disintegrated by gentle agitation, such as pouring the pulp from one vessel to another. The rolling up of the fibres is caused on the one hand by the friction of the arms of the stirrer on the pulp, but, on the other hand, in a far greater degree, by the friction of the pulp against the sides and bottom of the stuff-chest. The trouble will be greater the rougher the internal surface of the chest, and it can be obviated to a large extent by lining the stuff-chest with glazed tiles. The fibres will then tend to slide over the glazed surface instead of rolling. Reducing the speed of the stirrer and discharging the pulp into the chest simultaneously with a large volume of water will reduce the evil, but will not prevent it entirely. The ease with which the clots are disintegrated in presence of water enables them to be disposed of in the knotter. If the knotter be adjusted so as to give it the greatest possible vertical motion, *i.e.*, to work with a heavy "jog," the beating action of the knotter plates on the pulp will completely unroll the clotted bundles of fibres. It is true that a violent action of the knotter permits a few of the true knots, *i.e.*, unreduced particles of rag and thread, in the pulp to pass through into the paper, but a pulp which has been carefully and thoroughly prepared in the beater ought not to contain a serious proportion of such knots.—J. F. B.

China Clay [*for Paper Manufacture*]; *Moisture Content and Fineness of* ——. Winkler. Papier-Zeit., 1904, **29**, 259.

In England, china clay is purchased with 5 or 6 per cent. of moisture, but in Germany there appears to be no agreed limit to the proportion of moisture sold with the clay. After long exposure to the air various samples of china clay were found to retain from 0·5 to 3 per cent. of moisture, and variations according to the hygrometric state of the atmosphere were scarcely perceptible. A certain degree of moisture in the clay is desirable, since it facilitates its admixture with water when required for use; a proportion of 6 per cent. is therefore quite reasonable. Certain German traders have supplied china clay containing as much as 17 per cent. of water, and have contended that in the determination of the moisture, the sample should not be dried at temperatures above 40° C. This contention is quite erroneous, since the chemically combined water of crystallisation in kaolin, which does not exceed 5 per cent., is not expelled below a red heat. As regards fineness, a normal, well-levigated china clay, when passed through the finest sieve procurable, containing 3,600 meshes to the sq. cm., should not leave a residue exceeding 0·33 per cent. of its weight.—J. F. B.

Corks; Impt. in Quality of ——. H. Helbing. Chem. and Druggist, 1904, **64**, 189.

The cork is impregnated with a solution of casein, and then the latter is fixed and rendered insoluble by treatment with formaldehyde.—A. S.

Cellulose and its Nitrated Derivatives; Optical Activity of ——. L. Vignon. Bull. Soc. Chim., 1904, **31**, 105—108.

Nitro Derivatives.—Cotton, dried at 110° C., was nitrated by immersion for 24 hours at 16° C. in a mixture of the following composition:—Sulphuric acid (H_2SO_4) 38·95, nitric acid (HNO_3) 42·15, water 18·90 per cent. The purified product, in the dry state, contained 10·5 per cent. of nitrogen and had a composition approximating to the formula $C_{24}H_{32}(NO_2)_8O_{24}$. It may therefore be regarded as practically consisting of a dinitro-oxycellulose [C_6 basis]. Its solutions in ether-alcohol mixture and in acetone were turbid. The nitrated product was therefore boiled with a 1 per cent. solution of ammonium persulphate, slightly acidulated, for five minutes. The resultant product contained 10·68 per cent. of nitrogen, and its solubility in the above solvents was slightly increased; the solutions were then transparent. Examined in the polariscope, a solution in ether-alcohol, at a concentration of 1·4943 grms. per 100 c.c., showed a specific rotatory power of $[\alpha]_j = +19\cdot3$; a solution in acetone (at a concentration of 3·848 grms. per 100 c.c.) showed $[\alpha]_j = +21\cdot1^{\circ}$.

Cellulose Thiocarbonate.—A filtered solution of "viscose" containing nearly 2 per cent. of cellulose was precipitated by sodium chloride, and the precipitate was washed, first with brine, and then with diluted alcohol, until it was no longer alkaline. The product was dissolved in water, treated with animal charcoal, and filtered perfectly clear. A solution containing 0·998 per cent. of cellulose thiocarbonate appeared to have a very feeble dextro-rotatory power, which however, could not be ascertained with certainty.—J. F. B.

English Patents.

Paper-making Machines; Impts. in ——. O. M. Farwell, Kaukauna, Wis., U.S.A. Eng. Pat. 18,030, Aug. 20, 1903. Under Internat. Conv., Aug. 20, 1902.

The ordinary method of water-marking paper by a dandy roll situated between the suction boxes does not give satisfactory results with long-fibred thin papers and tissues. According to this invention, with a single drying cylinder machine, a type-bearing roll is caused to press upon the paper against the drying cylinder shortly after the paper has first come into contact with the hot cylinder. The water-mark impressions are obtained by the interposition of a fabric, such as the top felt of the paper machine, between the type roll and the paper; the marked paper does not leave the drying cylinder until the impressions have been fixed by drying.—J. F. B.

Compounds having a Nitrocellulose and Casein Base; Manufacture of ——. H. Ensminger, Talmontier, France. Eng. Pat. 3045, Feb. 6, 1903.

See Fr. Pat. 326,576 of 1902; this J., 1903, 817.—T. F. B.

United States Patent.

Paper, and Method of Making Same, for Obtaining Fast Copies from Writings of Aniline Inks. M. H. Chapin, Bridgeport, Assignor to Wyckoff, Seamans, and Benedict, Ilion, N.Y. U.S. Pat. 749,681, Jan. 12, 1904.

In order to render copies taken from "aniline inks" fast, the copying paper is impregnated with a suitable mordant, thus causing a lake to be formed on the paper with the ink in the presence of moisture.—T. F. B.

French Patent.

Rosin Size; Manufacture of ——. M. Erfurt. First Addition, dated Aug. 29, 1903, to Fr. Pat. 325,901, Oct. 24, 1902. (See this J., 1903, 757.)

The hot rosin emulsion, prepared according to the original specification, shows a tendency to coagulate when it is cooled. This tendency it not manifested when the emulsion is cooled rapidly. The emulsion prepared with hot water by means of a steam "atomiser" is therefore injected directly into a tank containing cold water; the size then shows no tendency to deposit.—J. F. B.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

Sulphates of Tetravalent Cerium. R. J. Meyer and A. Aufrecht. Ber., 1904, **37**, 140—153.

When cerium dioxide is treated with excess of sulphuric acid, the anhydrous ceric sulphate $Ce(SO_4)_2$ is formed exclusively. In presence of water, however—as when the acid reacts on moist cerium dioxide or on ceric hydroxide—a product is obtained the solution of which yields, first, an acid cero-ceric sulphate, which probably has the composition $2Ce(SO_4)_2.Ce_2(SO_4)_3.H_2SO_4.26H_2O$, and which is to be regarded as the cerous salt of a ceric-sulphuric acid, $H_4Ce(SO_4)_4$. A better yield of this salt is obtainable by partial reduction of an acid solution of ceric sulphate by the calculated amount of sulphur dioxide. It can be crystallised unchanged from 1:5 sulphuric acid; but from diluted, feebly acid solutions, on slow crystallisation, there separates the ordinary dark orange-red salt, which contains rather less sulphuric acid. On recrystallising several times from very weakly acid solutions, the proportion of sulphuric acid falls further, and the proportion of trivalent cerium increases. The authors have not obtained a neutral cero-ceric sulphate, which Rammelsberg and others supposed to exist: these experimenters explained the acidity of their preparations as being due to the tenacity with which the supposed neutral salt retained free acid from the mother-liquors, whereas the authors regard it as due to the fact that the salt—really an acid salt—is stable only in solutions of a certain acidity.—H. B.

Aldehydes; New General Method of Preparation of ——. A. E. Tschitschibabin. Ber., 1904, **37**, 186—183.

Aldehydes may be readily and conveniently prepared by the action of organo-magnesium compounds on the esters of orthoformic acid. The first step in the reaction is the formation of an acetal—

$$HC(OR)_3 + R_1MgI = ROMgI + R_1.HC(OR)_2,$$

which is converted into the corresponding aldehyde by saponification with a dilute acid. The *modus operandi* of the method is as follows:—Ethereal solutions of the formic ester and the organo-magnesium compound are mixed together, and the ether then distilled off, the solid or thick oily product obtained being decomposed by faintly acidified water, by which means the acetal separates out as an oil; the latter may be purified by fractionation, after which hydrolysis with dilute acid yields the aldehyde. The acetals and aldehydes already prepared in this way are the following, the figures representing the percentage yields obtained in each case:—Acetal, 25; butyraldehyde, 22; acetal of isopropylacetaldehyde, 80; acetal of benzaldehyde, 45; acetal of phenylacetaldehyde, 62; *p*-bromobenzaldehyde, 40; anisaldehyde, 15.—T. H. P.

Cotarnine and Hydrastine; Condensations of —— with Ketones. C. Liebermann and F. Kropf. Ber., 1904, **37**, 211—216.

Cotarnine and hydrastine readily combine with acetone with the elimination of water, the acetone residue joining up with the –CHO (or the tautomeric form –CH.OH) group of the alkaloid. Ten grms. of powdered cotarnine are suspended in 30 c.c. of acetone, and a few c.c. of a saturated solution of sodium carbonate are added. In a short time, with vigorous agitation, the whole of the cotarnine enters into solution, and crystals begin to separate out. After 6—8 hours' repeated agitation, the excess of acetone is driven off and the product is separated. This product is *anhydro-cotarnine-acetone*, which forms large crystals, m. pt. 83°C., from dilute acetone; it differs from cotarnine in being insoluble in presence of excess of sodium carbonate. The hydrochloride melts at 171° C. and the methiodide at 144° C.

Cotarnine and hydrastine unite in exactly the same way with other ketones; compounds have been prepared with methylpropyl ketone and with acetophenone. The reaction is probably general with all methyl ketones, and apparently also with compounds containing a methylene group, since an analogous product has been obtained by the condensation of cotarnine with ethyl malonate.—J. F. B.

Santal-*Wood Oil.* E. J. Parry and C. T. Bennett. Chem. and Drug., 1904, **64**, 292.

The authors have examined authentic specimens of pure English, Dutch, and German santal-wood oil. The acetylated oil which must be prepared in order to determine the content of santalol, has the following characters:—Sp. gr. at 15° C., 0·9860 to 0·9885; optical rotation (in a 100 mm. tube), from −13° 50′ to −14° 30′; and refractive index at 20° C., 1·4894 to 1·4916. Four of the samples of oil were distilled under reduced pressure, and 10 per cent. fractions collected. The individual fractions gave the following results:—Sp. gr., 0·954—0·988; optical rotation, −14° to −22°; refractive index, 1·5038—1·5123. The conclusions drawn are that no fraction should be obtained with a refractive index below 1·5000, and that the optical rotations of the individual fractions should only vary within narrow limits. The refractive index of pure santal-wood oil is about 1·5060, and should never fall below 1·5030; in eight samples examined, it varied between 1·5040 and 1·5075.—A. S.

Boldo (Boldoa fragrans, Pneumus boldus, of the order Monimiaceæ), Essential Oil from ——. E. Tardy. J. Pharm. Chim., 1904, **19**, 132—136.

The essential oil distilled from the leaves contains a dextro-rotary terebenthene-like hydrocarbon; a terpene which is lævo-rotary and present in large amount; somewhat smaller proportions of cuminic aldehyde and inactive terpineol and possibly a little eugenol. Acetic acid and a lævo-sesquiterpene were also found.—F. S.

Papaw and Papaïn. F. Watts. Agricultural News; through Chem. and Drug., 1904, **64**, 185.

Papaïn is obtained from the fruit of the papaw-tree (*Carica Papaya*). An incision is made in the rind of the fruit with a bone or wooden instrument, and the juice or milk which flows out is collected in earthenware or glass vessels. The fruit is not removed from the tree, and may be tapped several times at intervals of two or three days. The juice soon coagulates, and the coagulum is spread on sheets of brown linen stretched on light wooden frames and dried in a drying-stove. The drying must be effected as soon as possible after the coagulum is obtained, as the latter rapidly undergoes decomposition. The coagulum is dried at as low a temperature—if possible, not above 100° F.—as is consistent with the obtainment of a dry product, before decomposition sets in. The papaïn shrinks considerably during drying. When it is quite dry, it is finely ground whilst still slightly warm; it should yield a white or cream-coloured powder with a characteristic but not putrid smell. It is packed in tins or bottles and carefully preserved from contact with the air.—A. S.

Iboga. Landrin and Dybowsky. Schweiz. Woch., **42**, 819. Pharm. J., 1904, **72**, 117.

Iboga, a woody plant of low growth, with a large root, is found in the Congo, and is stated to possess properties similar to those of coca and kola. All parts of the plant, but especially the root, are used by the natives. The active principle of the plant is an alkaloid named *ibogaïne*, $C_{26}H_{33}N_3O$, which is obtained from the powdered root (yield, 6—10 grms. from 1 kilo) by treating with milk of lime, extracting with ether, and taking up the alkaloid from the ethereal solution by means of sulphuric acid. Ibogaine is insoluble in water, but soluble in alcohol, ether, chloroform, and benzene. It is readily oxidised when exposed to the air, acquiring a yellowish-brown colour and becoming uncrystallisable. The hydrochloride crystallises well, especially from an acid solution.—A. S.

Epinephrine; Constitution of ——. H. A. D. Jowett. Proc. Chem. Soc., 1904, **20**, 18.

"Epinephrin" is the name given by Abel and Crawford to the active principle of the suprarenal glands, and the substance is identical, when pure, with the "adrenalin" of Takamine and the "suprarenin" of von Fürth. As Abel and Crawford were the first to isolate the active principle, although in an impure condition, the author has adopted the name proposed by them. On oxidation with potassium permanganate, methylamine and oxalic and formic acids are formed. By fusion with potassium hydroxide, a small amount of a crystalline substance is obtained which gives the protocatechuic acid reaction with ferric chloride. On methylation with methyl iodide and sodium in methyl alcohol, and subsequent oxidation with potassium permanganate, trimethylamine and veratric acid are obtained. The most probable formula is considered to be the following:—$C_6H_3(OH)_2(CH.OH.CH_2.NH.CH_3)(1:2:4)$.

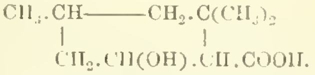
English Patents.

Odoriferous Substance ["*Farnesol*"] *suitable for Perfumery; Manufacture of an* ——. A. G. Bloxam, London. From Fab. Prod. de Chimie Organique de Laire, Paris. Eng. Pat. 540, Jan. 8, 1903.

See Fr. Pat. 328,146 of 1903 among Fr. Pats. hereinafter following.—T. F. B.

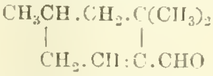
Perfume; Manufacture of Artificial ——, *and of Intermediate Products therefor.* O. Imray, London. From Farbwerke vorm. Meister, Lucius und Brüning, Hoechst a/Main. Eng. Pat. 3173, Feb. 10, 1903.

Cyclogeraniolidene-acetone, which, when concentrated, has an odour of cedar, and, when dilute, smells of violets, is prepared as follows:—Trimethylcyclohexanone is treated in ethereal solution with sodium and carbon dioxide, trimethylcyclohexanone carboxylic acid being formed; on reduction with sodium amalgam, this latter gives trimethylhydroxycyclohexane carboxylic acid, of the probable constitution—



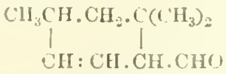
$$\begin{array}{l}\mathrm{CH_3.CH{-}{-}{-}{-}CH_2.C(CH_3)_2}\\ \qquad\quad |\qquad\qquad\qquad |\\ \qquad\mathrm{CH_2.CH(OH).CH.COOH.}\end{array}$$

On distilling the calcium salt of this acid *in vacuo* with calcium formate, cyclogeraniolene aldehyde is produced in two isomeric modifications, probably—



$$\begin{array}{l}\mathrm{CH_3CH.CH_2.C(CH_3)_2}\\ \quad |\qquad\qquad |\\ \quad\mathrm{CH_2.CH:C.CHO}\end{array}$$

α modification.



$$\begin{array}{l}\mathrm{CH_3CH.CH_2.C(CH_3)_2}\\ \quad |\qquad\qquad |\\ \mathrm{CH:CH.CH.CHO}\end{array}$$

β modification.

These modifications have not been separated. By condensing cyclogeraniolene aldehyde with acetone, cyclogeraniolidene acetone, $C_9H_{15}.CH:CH.CO.CH_3$, is obtained as a colourless oil, b. pt. 132°—134° C. (10 mm.). —T. F. B.

Pharmaceutical Compounds [*Alkyloxyalkylidene Esters of Salicylic Acid*]; *Production of* ——. H. E. Newton, London. From Farbenfabr. vorm. F. Bayer and Co., Elberfeld. Eng. Pat. 5772, March 12, 1903.

Aromatic Esters [Bornyl Esters]; Manufacture of New ——, and of Useful Products therefrom. G. B Ellis, London. From Chem. Fabr. von Heyden, Akt.-Ges., Radebeul. Eng. Pat. 26,785, Dec. 7, 1903.

Esters of borneol, of the general formula—

$$C_{10}H_{17}O.CO.R.OH.$$

R being an aromatic radical, are prepared by heating aromatic monohydroxycarboxylic acids with terpenes, particularly pinene or camphene, or substances containing these. For instance, bornyl salicylate is obtained by heating equal weights of turpentine oil and salicylic acid to about 120° C. for about 50 hours. The esters thus produced possess anti-rheumatic properties, particularly bornyl salicylate and *p*-cresotinate; they are decomposed by alkalis to borneol and alkali salt of the acid used, thus being suitable as intermediate products in the preparation of camphor from turpentine oil, since borneol on oxidation is converted into camphor.—T. F. B.

Soaps, Medicated, and Ointments; Production of ——, readily Resorbent. R. Reiss. Eng. Pat. 24,240, Nov. 9, 1903. XII., page 195.

United States Patents.

Geraniol Derivative. F. Hofmann, Elberfeld, Assignor to Farbenfabr. of Elberfeld Co., New York. U.S. Pat. 746,703, Dec. 15, 1903.

Alpha-substituted geraniol derivatives of the general constitution—

$$(CH_3)_2C : CH.CH_2.CH_2.C(CH_3) : CH.CH(R).OH$$

are prepared by treating with water the product formed by the interaction of citral and the addition products of alkyl- or alphyl-magnesium halogen compounds and ethers. Thus α-methylgeraniol is prepared by adding an ethereal solution of citral (1,400 parts) to the product of the reaction of magnesium (240 parts), methyl iodide (1,420 parts), and anhydrous ether (1,500 parts). The iodo-magnesium compound of geraniol is decomposed by adding ice water and the ethereal solution is dried and distilled off, when α-methylgeraniol is obtained, b. pt. 112°–113° C. (12 mm.), having an odour similar to that of rose oil, and suitable for use in perfumery. When heated with acids these compounds split off water, forming unsaturated hydrocarbons, that from α-methylgeraniol being 2.6-dimethyl-2.6.8-nonatriene—

$$(CH_3)_2C : CH.CH_2.CH_2.C(CH_3) : CH.CH:CH_2.$$

French Patents.

Odoriferous Substance ["Farnesol"]; Process of Obtaining a New ——. Fabr. Prod. de Chimie Organique de Laire. Fr. Pat. 328,146, Nov. 19, 1902.

A sesquiterpene alcohol, "Farnesol," $C_{15}H_{26}O$, is a constituent of certain essential oils, either in a free or combined state, notably in cassia oil and in ambrette oil. If it be present in combination, the oil is saponified, and then fractionated; if, on the other hand, it be present uncombined, the saponification is dispensed with; the fraction containing it comes over between 150° and 200° C., and is treated with an acid anhydride (*e.g.*, phthalic anhydride); the "Farnesol phthalate" thus obtained is saponified and the product distilled with steam and fractionated. "Farnesol" is a colourless oil: b. pt. about 160° C. (10 mm.), sp. gr. (18° C.) 0·885: it has an agreeable floral odour, and can be used for the preparation of perfumes.

—T. F. B.

Perfume from Citrylidene Aceto-acetic Ether; Process for Making a ——. E. Knoevenagel. Fr. Pat. 335,380, Sept. 15, 1903.

Citrylidene aceto-acetic ether, obtained by condensing aceto-acetic ester with citral, may be heated for 5 or 6 hours at 160° C., with or without water. If the ether obtained, and thus "isomerised," be gradually run into 5 to 6 times its weight of 80 per cent. sulphuric acid, the temperature being kept at or below 0° C., and the whole allowed to stand for some hours and then poured on to ice, the product, on distillation with steam, gives an oil of which the fraction distilling between 150° and 190° C. (12 mm.) is applicable to perfumery, having an odour resembling that of the lupin, but at the same time recalling that of ionone. Acids other than sulphuric acid may be used for this reaction.—T. F. B.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Silver Chloride Sensitive to Colour. E. Baur. Zeits. physik. Chem., **45**, 613—626. Chem. Centr., 1904, **1**, 13.

Emulsions were prepared by treating 1 per cent. solutions of Carey Lea's golden brown modification of silver with varying amounts of chlorine water, and then adding 5 per cent. gelatin to the mixtures of silver chloride (AgCl) and sub-chloride (Ag_2Cl) produced. Plates coated with these emulsions reproduce, after one hour's exposure, the solar spectrum in its natural colours. The last traces of sub-chloride can only be dissolved out from the "photo-chloride" of silver with difficulty by nitric acid, corresponding to the last traces of silver in a gold-silver alloy. The melting points of the photo-chlorides rich in sub-chloride appear to be higher than that of pure silver chloride; the melts are always clear and of uniform colour. In the author's opinion, the "photo-chlorides" represent an uninterrupted series of homogeneous mixtures of silver chloride and sub-chloride.—A. S.

English Patents.

Multicoloured Photographs; Process for the Production of ——. A. Lemberger and G. L. Böhm, Munich. Eng. Pat. 372, Jan. 6, 1903.

The relief positive formed by exposing under a negative, paper coated with gum arabic and sensitised with bichromate, and subsequently developed in water, is coloured by hand in suitable colours, the portions which are not to be coloured being covered with a layer of gum arabic.

XXII.—EXPLOSIVES, MATCHES, Etc.

Explosives in Coal Mines Order, Dec. 10, 1903. A. Akers-Douglas, one of H.M. Principal Secretaries of State.

The following have been added to the list of "permitted explosives" under above date:—

Ammonal.—Ammonium nitrate (93—97 parts), aluminium (4—6 parts), moisture (0—1 part). The explosive to be contained in a case of paper and tinfoil thoroughly waterproofed.

Bobbinite (1st Definition).—Potassium nitrate (62—65 parts), charcoal (17—19½ parts), sulphur (1½—2½ parts), ammonium sulphate and copper sulphate (15—17 parts), moisture (0—2½ parts).

Bobbinite (2nd Definition).—Potassium nitrate (63—66 parts), charcoal (18½—20½ parts), sulphur (1½—2½ parts), rice or maize starch (7—9 parts), paraffin wax (2½—3½ parts), moisture (0—3 parts).

Each pellet to be thoroughly coated with paraffin wax, and contained in a wrapper of brown paper.

Faversham Powder (1st Definition).—Ammonium nitrate (84—86 parts), trinitrotoluene (10—12 parts) ammonium chloride (1—2 parts), sodium chloride (2—3 parts), moisture (0—½ part).

Faversham Powder (2nd Definition).—Ammonium nitrate (87—93 parts), trinitrotoluene (9—11 parts), moisture (0—1 part). The explosive to be enclosed in a case of an alloy of lead, tin, zinc, and antimony thoroughly waterproofed.

Geloxite.—Nitroglycerin (54—64 parts), nitrocotton (4—5 parts), potassium nitrate (13—22 parts), wood meal (4—7 parts), ammonium oxalate (12—15 parts), red ochre (0—1 part). The explosive to be contained in a non-waterproofed wrapper of parchment paper.—G. W. McD.

United States Patent.

Explosive. H. Dreany. Sudbury, Canada. U.S. Pat. 750,175, Jan. 19, 1904.

See Eng. Pat. 26,802 of 1902; this J., 1903, 1208.—T. F. B.

XXIII.—ANALYTICAL CHEMISTRY.

APPARATUS, ETC.

Vacuum Distillations; Attainment of High Vacua without Mercury Pumps or Liquid Air. P. Krafft. Ber., 1904, **37**, 95-100.

The following procedure, though not likely to supersede the use of mercury pumps and liquid air where these are obtainable and in skilled hands, yet allows of exhaustion sufficient for the production of cathode rays, and requires but little supervision. The successful working of the apparatus depends entirely on the perfect tightness of the stopcocks and stoppers, which the author lubricates with a mixture of 2 parts of white wax and 1 of wool grease. The distillation-flask is stoppered, and has also a side-tube close to the stopper, provided with a stopcock. The receiver communicates, on the side away from the distillation-flask, by means of a tube carrying as appendages a mercury manometer and a Hittorf's tube, with an apparatus for evolving carbon dioxide. A branch from this connecting-tube divides in its turn into two branches, one communicating with a small reservoir for caustic potash solution, the other leading, through a mercury-valve to prevent air-return, to the water-aspirator. This latter branch carries a connection to a mercury manometer, and also a by-pass communicating with a large vacuum-reservoir, which can be shut off at will. Stopcocks are provided so that there can be separately shut off—the distilling flask, the receiver, the carbon dioxide apparatus, the caustic potash apparatus, and the aspirator. The apparatus is put together, and the vacuum-reservoir is exhausted. When ready, the rest of the apparatus is opened to this and the pump; soon the vacuum-reservoir is shut off, and the exhaustion is continued to 15—20 mm. Carbon dioxide is admitted, and the residual air expelled as completely as possible by opening the outer stopcocks and allowing the carbon dioxide to stream through for a while. The apparatus is again exhausted, refilled with carbon dioxide, and this cycle repeated three or four times. After the last exhaustion, strong caustic potash solution is admitted to the reservoir by the tall tap-funnel connected with it. When absorption is complete at the ordinary temperature, the potash-reservoir is cooled by ice and salt, or carbon dioxide and ether; with the latter mixture, exhaustion to cathode-rays in the Hittorf-tube is attained. With good stopcocks, the apparatus will retain its vacuum for days.

—J. T. D.

English Patent.

Burners for Testing Gas. W. T. Sugg. Eng. Pat. 4052, Feb. 20, 1903.

To avoid the inconvenience of changing the burner when a different quality of gas has to be tested, a number of burners are fixed by means of branches to a hollow barrel rotating on a hollow plug fixed to the gas-supply pipe. The hollow plug is provided with a lateral opening, and by rotating the barrel, any desired burner may be connected with the gas supply.—L. F. G.

INORGANIC—QUALITATIVE.

Cobalt and Nickel Salts, Distinctive Reaction for ——. G. Guérin. J. Pharm. Chim., 1904, **19**, 139.

If a solution of a cobalt salt is precipitated by excess of caustic potash and then treated with an excess of iodine in potassium iodide, after a few moments, the whole of the cobalt is precipitated as a black hydrated sesquioxide. Nickel gives a light green hydroxide. The same behaviour is shown by cobalt and nickel when already precipitated by other radicles, except when precipitated as ferricyanides. In this case the potash alone produces a black precipitate of cobalt hydrated sesquioxide.—F. S.

Molybdenum; A New Reaction of ——. E. Lecocq. Bull. de l'Assoc. Belge des Chim., 1903, **17**, 412—414.

Diphenylcarbazide in alcoholic solution produces a characteristic coloration when added to ammonium, potassium, or sodium molybdate in the presence of a trace of acid. (See Cazeneuve, this J., 1900, 1007 and 1040). A single drop of the reagent, when not too freshly prepared, causes a magnificent indigo-violet colour, which increases as more is added, and finally a violet precipitate is formed. The test is sensitive to 0·007 part of ammonium molybdate per litre, but strong acids in excess and alkalis destroy the colour. Tungsten, titanium, and vanadium do not respond to the test, copper gives a violet-brown colour, and mercury a strong blue. Mercury, however, also reacts with a benzene solution of diphenylcarbazide which molybdenum fails to do. This last fact and the distinct influence of age in the sensitiveness of the reagent suggests that the reaction is due to an interaction of the alcohol with the carbazide. A small quantity of carbazide was dissolved in methyl, ethyl, propyl, butyl, isobutyl and amyl alcohols, and each in turn added to ammonium molybdate solutions (0·5 grm. in 10 c.c. of water and 2 drops of hydrochloric acid. A regular scale of colours, from indigo-blue to rose, was obtained, but not sufficiently defined to afford a means of identifying any one alcohol, except amylic alcohol, which gave two layers of liquid, the upper rose-coloured, and the lower colourless.—R. L. J.

Carbon Dioxide in Air; Nile Blue Base as a Reagent for; and Action of Colour-Acids on Cellulose, Alcohol, and Acetone. M. Heidenhain IV., page 183.

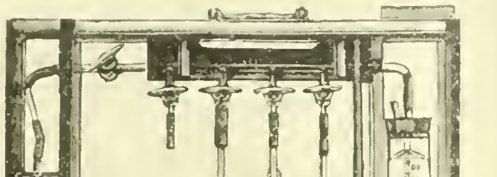
INORGANIC—QUANTITATIVE.

Titanium; Sensitive Reaction of ——. A. Jorissen. Bull. Acad. Roy. Belg., 1903, 902–907. Chem. Centr. 1904, **1**, 55.

A small quantity of the solid substance is mixed with six times its weight of potassium bisulphate, and the mixture fused in a platinum loop till the fused bead becomes clear and does not effervesce. The bead is then broken up and treated with 0·01—0·02 grm. of salicylic acid dissolved in 20—30 drops of concentrated sulphuric acid. If titanium be present, the pieces of the bead are coloured red, and the liquid also gradually acquires a red colour. The reaction is applicable in presence of cerium, iron, aluminium, beryllium, lanthanum, didymium, thorium, zirconium, chromium, and silicon compounds, but not in presence of vanadium, molybdenum, or tungsten compounds.—A. S.

Unburnt Products in Chimney Gases; Determination of ——, *by a Modified Orsat Apparatus.* W. H. Sodeau. Chem. News., 1904, **89**, 61–62.

For the determination of the hydrogen, carbon monoxide and carbon dioxide, the author uses a modified Orsat apparatus, provided with a Winkler combustion pipette, O, by means of which the use of cuprous chloride can be dispensed with. The sample of gas is measured in L in the ordinary way except that instead of pinching the tube it is convenient to use the stopcock S (connected at one side with the measuring tube L, at the other, with the reservoir M R), when adjusting the pressure of the gas in L before reading the volume. The carbon dioxide is absorbed by potash solution in K, and the residual gas after measurement is then passed into O (the current having previously been switched on) and back to K for absorption of the carbon dioxide formed by the explosion, and thence to L for measurement of the contraction due to combustion of hydrogen and carbon monoxide. In cases where it is desirable to know the percentage of oxygen originally present, this may be done by finally absorbing with phosphorus or pyrogallol solution in the pipette P, and adding to the result the amount of oxygen required to burn the combustible gas.—D. H. J.



Chlorates, Bromates, and Iodates, Volumetric Determination of ——. L. Débourdeaux. Comptes rend., 1904, **130**, 147.

A solution of oxalic acid containing 5 grms. of manganese sulphate and 12 c.c. of concentrated sulphuric acid per 100 c.c. of solution (see this J., 1903, 883) reacts quantitatively with chlorates and bromates thus—

$$HClO_3 + 3H_2C_2O_4 = HCl + 6CO_2 + 3H_2O,$$

and with iodates thus—

$$2HIO_3 + 5H_2C_2O_4 = I_2 + 10CO_2 + 6H_2O.$$

Hence chlorates, bromates, and iodates can be determined by heating with an excess of the oxalic acid mixture, and titrating the undestroyed oxalic acid with permanganate. Silver iodate, however, is an exception, since silver iodide is partially formed. The reacting liquid must be slowly heated to about 94° C., and the concentrations given above rigidly adhered to. In titrating back with permanganate the evil influence of halides is guarded against by previously adding excess of silver nitrate.—W. A. C.

Uranyl Compounds; Iodometric Method of Determining Uranium in ——. B. Glasmann. Ber., 1904, **37**, 189—191.

The method depends on the reaction of neutral solutions of uranyl salts on a mixture of potassium iodide and iodate:—

$$3UO_2(NO_3)_2 + 5KI + KIO_3 + 3H_2O =$$
$$3UO_2(OH)_2 + 6KNO_3 + 3I_2.$$

Any excess of acid in the solution must be neutralised with sodium carbonate, which is added till a precipitate begins to be permanent; this precipitate is then just redissolved in dilute acid. Place the solution in a 300 c.c. distillation flask provided with a ground stopper carrying a funnel with stopcock, the tube of which reaches to the bottom of the flask. Insert the exit-tube of the flask into the receiver containing potassium iodide solution, add to the uranyl solution the requisite amount of iodide and iodate mixture, dilute to 120 c.c., close with the stoppered funnel, and slowly heat on gauze to boiling. When boiling, cool the receiver with water, and lead a stream of hydrogen through the boiling liquid. When the liquid is reduced to 50 c.c. withdraw the flask from the receiver, remove the burner, wash the delivery tube into a beaker, rinse the contents of the receiver into the same beaker, and titrate with thiosulphate. With 0·2—0·3 grm. of uranyl compound the whole operation requires 20 minutes. The results are accurate, and are not affected by the presence of alkaline-earth chlorides.—J. T. D.

Aluminium from Iron, Separation of ——. A. Leclère. Comptes rend., 1904, **138**, 146.

In the somewhat dilute solution of mixed iron and aluminium salts, slightly acidified with sulphuric acid, the iron is first reduced to the ferrous state by ammonium thiosulphate. A large excess of ammonium formate is then added, together with more ammonium thiosulphate, and the whole boiled. The aluminium is thrown down as basic formate, mixed with a little sulphur; in drying the precipitate nitric acid is added to prevent carbonisation. The iron in the filtrate is precipitated by a soluble sulphide and weighed as iron sulphide.—W. A. C.

Rubidium and Cæsium [*and Potassium*]; *Determination of* ——. C. Montemartini and G. Mattucci. Gaz. chim. ital., **33**, 189—201. Chem. Centr., 1904, **1**, 119.

For the determination of rubidium and cæsium, the authors use the following method, described by K. Gilbert (Inaug. Diss., Tübingen, 1898), for the determination of potassium. Two solutions are prepared:—(*a*) 10 grms. of cobalt carbonate are dissolved in the smallest possible amount of acetic acid, the solution is boiled to expel carbon dioxide, and after cooling, is made up to 1 litre; (*b*) a solution containing 150 grms. of sodium nitrite, free from potassium, per litre. For the precipitation of the potassium, a mixture of equal volumes of these two solutions are used (60 c.c. for each 0·1 grm. of potassium). A solution of potassium chloride (0·4 grm. in 25 c.c.) was treated with 140 c.c. of the sodium-cobalt reagent, the mixture heated for 6—7 hours at 40° C., allowed to stand overnight, filtered, and the precipitate washed first with the sodium-cobalt reagent and then with 80 per cent. alcohol, and dried at 110° C. It was then decomposed by heating to 300° C., the residue treated repeatedly with hydrochloric acid, a few c.c. of 30 per cent. perchloric acid added, the excess of free acid expelled by heating, the residue treated with absolute alcohol, the insoluble portion washed with alcohol till neutral, then dried at 110° C. and weighed. Rubidium and cæsium are determined in a similar manner. The authors point out that not only sodium as stated by Gilbert, but also small amounts of other metals are precipitated with the potassium, rubidium, and cæsium, and the efficacy of Gilbert's method depends not only upon the quantitative precipitation of potassium, rubidium, and cæsium by the sodium-cobalt reagent, but also upon the fact that whilst perchlorates in general are soluble in absolute alcohol, the perchlorates of the metals named are insoluble in that medium.—A. S.

Gold in Cyanide Solutions; Colorimetric Method for the Determination of the ——. A. Prister. J. Chem., Met. and Min. Soc. of S. Africa, 1903, **4**, 235—237.

The cyanide solution to be assayed is first heated with hydrochloric acid to destroy the free potassium cyanide, ferrocyanides of zinc and copper and thiocyanates (sulphocyanides) being precipitated. To decompose the double cyanide of gold and potassium, a few drops of a solution obtained by boiling cupric sulphate solution with sodium chloride and copper shavings, and after cooling adding acetic acid, are introduced, with boiling, followed by addition of a little sodium sulphide. The first reaction is—

$$2KAuCy_2 + 2CuCl = 2AuCuCy_2 + 2KCl,$$

followed by a secondary reaction in which copper sulphide is formed. The double cyanide of copper and gold ($AuCuCy_2$), as well as the copper sulphide, are insoluble, and mix with the other precipitated salts. These are collected, redissolved in potassium cyanide solution, and the gold is precipitated by digestion with zinc powder. Silver, some copper, and the excess of zinc, accompany the gold. The precipitate, after separation, is treated with hydrochloric acid, and after filtering off the zinc chloride solution, with *aqua regia.* The solution is then treated with stannous chloride solution, the shade of the Cassius purple produced being compared against a standard. The process is stated to be capable of giving higher results than the fire assay.—E. S.

Lead Dioxide, Electro-deposition of ——, in Quantitative Analysis. A. Hollard. Comptes rend., 1904, **138**, 142.

When lead dioxide is deposited from solutions of lead salts on an anode of blackened (platinised) platinum, it contains more oxygen than corresponds to the formula PbO_2, so that the analytical factor is less than 0·866. The factor varies regularly with the concentration of the electrolyte, from 0·740 for a bath containing 0·01 grm. of lead in 300 c.c. to 0·861 in one containing 10 grms. If the platinum anode be merely sand-blasted, the composition of the deposit is practically independent of the concentration, the mean factor being 0·853, with limits of 0·857 to 0·848. This holds good both for baths of lead nitrate and of lead sulphate dissolved in ammonium nitrate, with excess of nitric acid in either case.—W. A. C.

ORGANIC—QUALITATIVE.

Antipyrine and Salophene; New Reactions for ——. G. M. Bérenger. Amer. J. Pharm., **75**, 435. Pharm. J., 1904, **72**, 117.

If antipyrine be treated with sodium hypochlorite solution, the odour of chlorine disappears and is replaced in a few minutes by that of bitter almonds. If chlorine water be substituted for the sodium hypochlorite solution, the odour of chlorine disappears in a similar manner, whilst an abundant white precipitate is formed. If 1 grm. of salophene (acet-*p*-aminophenyl salicylate) be boiled with a dilute solution of caustic soda, and, after cooling, 5 c.c. of sodium hypochlorite solution added, a green coloration is immediately produced, which changes finally to a mahogany brown, the change of colour taking place slowly in the cold, but rapidly if the liquid be boiled. On adding excess of acid to the green or brown solution, a scarlet colour, changing to orange red, is produced.—A. S.

Alkaloids; Analysis [Identification] of ——. P. Kley. Rec. trav. chim. Pays-Bas, **22**, 367—384. Chem. Centr., 1904, **1**, 123.

The author has devised a rapid and reliable method, by means of which, with the aid of the polarising microscope, the different alkaloids can be identified by their refractive indices. A very small crystal, which acts to some extent as a convex lens, is placed on the object-glass of the microscope, together with a liquid of known refracting power. In making the examination, parallel light is used; on adjusting the microscope, one can recognise by certain phenomena whether the liquid is more or less refracting than the crystals. The liquid is then replaced by another and so on, until, when the refractive indices of the crystals and of the liquid are identical, the contour of the crystal can no longer be perceived, but only coloured rings. In this manner definite values can be obtained for the various alkaloids, without determining the crystalline form, angles of the two optical axes, &c. The author examined in the above manner the alkaloids of strychnos, of opium and of cinchona bark; cocaine, atropine, hyoscyamine, hydrastine, berberine, cytisine, physostigmine, sparteine sulphate, aconitine, delphinine, veratrine, cantharadine, piperine, caffeine, and theobromine. By setting out the results graphically, a right-angled field is obtained, in which the different alkaloids are represented by points; the diagonal separates the positive and negative crystals; and the distance from it indicates the intensity of the double refraction. The points representing different alkaloids coincide only in a few cases, and then only when the alkaloids in question can be easily distinguished by other means. On the other hand, alkaloids which can only be distinguished with difficulty by other means (*e.g.*, strychnine and brucine) are represented by points widely removed one from the other.—A. S.

ORGANIC—QUANTITATIVE.

Linseed Oil; Determination of Unsaponifiable Matter in ——. C. Niegemann. Chem.-Zeit., 1904, **28**, 97.

The author has found in 18 determinations on pure linseed oil that the maximum amount of unsaponifiable matter was 2·15, the minimum 0·74, and the average 1·35 per cent., this average being exceeded in seven of the samples. The author therefore concludes that it is not justifiable to condemn a linseed oil solely because the amount of unsaponifiable matter exceeds the highest limit (1·3 per cent.). —C. A. M.

Tanning Analysis; Notes on ——. G. Schweitzer. Collegium, 1904, 21—23.

The author proposes to attach close fitting covers, like those on platinum crucibles, to the flat-bottomed nickel basins employed for evaporations in tanning analysis so as to avoid increase of weight during weighing. He uses flat-bottomed glass dishes with a rim 5—7 mm. wide and covered with a glass plate.—R. L. J.

Hide-Powder; Determination of Acidity in ——. J. Paessler. Collegium, 1904, 23—24.

The acidity of hide-powder is tested at the Research Station at Freiberg in the following manner:—2 grms. of air-dried powder are left to soak in 50 c.c. of water for about two hours. Azolithmin solution is added to colour the whole distinctly red, and the contents of the beaker are titrated with decinormal sodium hydroxide solution till a permanent blue colour is obtained, the result being calculated as acetic acid. It is usually about 0·15 per cent.—R. L. J.

Organic Matter [Determination of ——] in Soils and Subsoils. F. K. Cameron and J. F. Breazeale. J. Amer. Chem. Soc., 1904, **26**, 29—45.

A comparative examination of the various methods in use for determining organic matter in soils indicated that oxidation by means of chromic acid gave the most reliable results. The method used was as follows:—About 10 grms. of the soil were mixed with 5—10 grms. of potassium bichromate, and concentrated sulphuric acid added gradually. The volatile oxidation products were passed first through a slightly acidified solution of silver sulphate (to arrest hydrochloric acid, sulphur dioxide and trioxide) and the carbon dioxide absorbed by potassium hydroxide. A stream of air, freed from carbon dioxide, was aspirated through the apparatus during the operation. The amount of organic matter is taken as being the weight of carbon dioxide obtained × 0·471, this factor appearing to be the most suitable. The method is slightly modified when chlorides are present in the soil, the bichromate being dissolved in the acid and added to the soil; it was found that, in this way, no hydrochloric acid, chlorine, or chromyl chloride was evolved. When carbonates are present, they may be determined separately by treatment with dilute acids. This method was found to give, in all cases, results lower than those obtained by dry combustion in a current of oxygen.—T. F. B.

Methyl Alcohol; Determination of ——, in Presence of Ethyl Alcohol. T. E. Thorpe and J. Holmes. J. Chem. Soc. (Trans.), 1904, **85**, 1—6.

The process is based upon the fact that on treating methyl alcohol with a mixture of potassium bichromate and sulphuric acid under certain conditions, it is wholly decomposed into carbon dioxide and water: with ethyl alcohol under the same conditions, 0·5 per cent. is converted into carbon dioxide and the remainder into acetic acid. On making the determination, the sample is diluted with water till 50 c.c. do not contain more than 1 grm. of methyl alcohol, or if ethyl alcohol be also present, not more than 4 grms. of the mixed alcohols. 50 c.c. of the diluted sample are then treated with 20 grms. of potassium bichromate and 80 c.c. of dilute (1 : 4) sulphuric acid in a stoppered flask fitted with a funnel and side tube, and the mixture allowed to stand for 18 hours. A farther quantity of 10 grms. of potassium bichromate and 50 c.c. of sulphuric acid mixed with an equal volume of water are then added, and the mixture boiled for about 10 minutes, the carbon dioxide evolved being carried over by a current of air and collected in weighed soda-lime tubes. From the total weight of carbon dioxide, 0·01 grm. must be subtracted for each grm. of ethyl alcohol present. The total amount of the two alcohols can be determined in the usual way by the aid of the same table of densities, the relative densities of the two alcohols being almost identical. The method may be used to determine whether tinctures or other medicinal preparations contain methylated spirits, and to what extent. The spirit from 25 c.c. of the sample, or from 50 c.c. if it contains less than 50 per cent. of alcohol, is freed from essential oils, &c., in the manner previously described by the authors (this J., 1903, 232); it is then distilled, diluted with water to 250 c.c., and 50 c.c. treated in the manner described above. If the weight of carbon dioxide does not exceed 0·01 grm. for each grm. of alcohol present, it may be concluded that the sample contains only spirits of wine. If the weight of carbon dioxide exceeds this amount, its equivalent in methyl alcohol by volume, must be corrected by subtracting 0·7—1 per cent. (depending on the amount of methylated spirit present), the percentage of methylated spirit being calculated on the assumption that the percentage of methyl alcohol in dehydrated methylated spirit does not exceed 8·8 per cent.—A. S.

Hydrazine and its Derivatives: Determination of —— [and of Mercury]. E. Rimini. Atti R. Accad. dei Lincei Roma, **12**, 376—381. Chem. Centr., 1904, **1**, 213.

If a known quantity of hydrazine sulphate be boiled in a Schulze-Tiemann's apparatus with a solution of mercuric chloride, and, after the air is completely expelled, a concentrated solution of alkali be introduced, an amount of nitrogen equivalent to the hydrazine present is evolved, the reaction proceeding according to the equation—

$$N_2H_4.H_2SO_4 + 6KOH + 2HgCl_2 =$$
$$K_2SO_4 + 4KCl + 2Hg + N_2 + 6H_2O.$$

In using this method for hydrazine derivatives the sample is boiled with a solution of mercuric chloride, acidified with hydrochloric acid. Semicarbazides are first hydrolysed by the acid, according to the equation—

$$NH_2.CO.NH.NH_2HCl + H_2O + 2HCl =$$
$$N_2H_4(HCl)_2 + NH_4Cl + CO_2.$$

Semicarbazones are split up into the corresponding ketone or aldehyde and the semicarbazide salt, the latter being then further decomposed in the manner shown above. The author has determined by this method the amount of hydrazine-nitrogen in the semicarbazones of menthone, fenchone, and tanacetone. By using an excess of hydrazine or semicarbazide, mercury may be determined by this method, even when considerable amounts of alkali salts are present. With solutions containing less than 1 per cent. of mercuric chloride, the determination is carried out in the Schulze-Tiemann apparatus, but with concentrated solutions or with the powdered salt, it is better to work in the cold, with a Lunge or Knop-Wagner nitrometer and measure the air displaced by the nitrogen evolved.—A. S.

United States Patent.

Butter: Process of Testing ——. M. Vogtherr, Berlin. U.S. Pat. 749,343, Jan. 12, 1904.

A known quantity of the melted butter is agitated with a definite quantity of "sulphuric acid containing 4 per cent. of amyl alcohol," and the amount of fat rising to the surface and the increase in the volume of the acid layer due to the water in the butter are measured.—C. A. M.

XXIV.—SCIENTIFIC & TECHNICAL NOTES.

Radium Bromide; Gases Occluded or Emitted by ——. J. Dewar and P. Curie. Comptes rend., 1904, **138**, 190—192.

Radium bromide (0·1 grm.) left in a vacuous space for three months, gave off about 3 c.c. of gas showing the spectrum of hydrogen. This was transferred to a quartz flask, exhausted, the flask heated to redness so as to fuse the radium bromide, and the evolved gases collected after passage through tubes cooled by liquid air. These gases (2·6 c.c.) still contained some radium emanation, were radio-active and luminous. The light emitted showed in the spectroscope three lines belonging to nitrogen. The gas, transferred to a Geissler tube, gave with the induction coil the spectrum of nitrogen. The quartz flask was sealed while the salt was melted. Twenty days afterwards the gas within showed the complete spectrum of helium.—J. T. D.

Radium; Contribution to the Knowledge of ——. W. Marckwald. Ber., 1904, **37**, 88—91.

Separation of Radium from Barium.—By treating a concentrated aqueous solution of radium-barium chloride with a 1 per cent. sodium amalgam, a radium-barium amalgam is formed, in which the proportion of radium to barium is much greater than in the original solution.

Phosphorescence of Anhydrous Radium-Barium Chloride.—The different behaviour of anhydrous radium-barium chloride, which exhibits strong phosphorescence, and of the crystallised salt, which is practically non-phosphorescent, is due to the fact that anhydrous barium chloride is caused to phosphoresce by Becquerel, α-, and β-rays, whilst crystallised barium chloride is not affected in a similar manner.

Induced Radio-activity.—If strips of metal be immersed in a freshly-prepared solution of a radium-barium chloride as obtained direct from Joachimsthal pitchblende, the metal becomes radio-active, the maximum effect being attained in 15—30 minutes. The metals are not all affected to the same degree.—A. S.

Colloidal Metals of the Platinum Group. I. C. Paal and C. Amberger. Ber., 1904, **37**, 124—139. (See this J., 1902, 916, 994, 995, 996.)

By the aid of sodium protalbinate and lysalbinate, the authors have now succeeded in preparing colloidal solutions of platinum, palladium, and iridium.—A. S.

Radium Bromide; Influence of ——, on the Electrical Resistance of Bismuth. R. Paillot. Comptes rend., 1904, **138**, 139.

A SPIRAL of bismuth wire enclosed between thin mica plates was exposed to the emanation of 0·03 grm. of radium bromide of high activity, contained in a thin glass tube. At a distance of ½ mm. the resistance of the spiral was diminished by about 0·034 per cent. The effect is instantaneous and does not change with time; it rapidly falls off on increasing the distance, and at 1 cm. ceases altogether. When the radium bromide is removed, the spiral almost immediately returns to its original resistance.
—W. A. C.

Active Oxygen. IX. Autoxidation of Cerous Salts. C. Engler. Ber., 1904, **37**, 49—59. (See also this J., 1903, 969 and 1121.)

A REPLY to Baur. The author and others have made a large number of experiments, of which the details are given, on the lines indicated by Baur, and the results all confirm the view that one atom of cerium in the form of an alkaline cerous salt takes up only one atom of oxygen. The active oxygen present as peroxide in the autoxidised cerium solution was also determined by titration, the cherry-red solution being added to a known volume of arsenite solution until it was no longer reduced to the yellowish colour characteristic of ceric solutions. The results showed that one half of the oxygen taken up had been rendered active which is in agreement with the author's contention, and opposed to that of Baur.—H. B.

Colloidal Solutions. J. Duclaux. Comptes rend., 1904, **138**, 144.

THE author has studied the conditions under which colloids are produced by double decomposition. When dilute solutions of potassium ferrocyanide and of a copper salt are mixed, a copper ferrocyanide is formed which contains potassium and has a definite composition varying with the proportion of the reagents, which proportion also determines whether it will remain in solution or be coagulated; addition of one or other of the reagents displaces the equilibrium. The composition of this product may be represented by $K_nCu_mFeCy_6$, where $m + \frac{n}{2} = 2$; for cupric chloride n decreases from 1·3 to 0 as the copper increases from 0 to near infinity. If the proportion of ferrocyanide to copper is exactly molecular, n has a mean value of 0·4, though it varies with the dilution; at this "critical point" a minute excess of reagent, or an addition of foreign salt, causes a considerable change in the composition of the colloid; with excess of copper it remains in solution, whilst excess of ferrocyanide coagulates it. The composition of the dissolved colloid differs definitely from that of the precipitated body, and it may be concluded that the coagulation is not exclusively a physical phenomenon. In the case of "double colloids," such as copper and cadmium sulphides, all the four radicals of the two reagents are found in the precipitate
—W. A. C.

Indium; Studies on ——. A. Thiel. Ber., 1904, **37**, 175—176.

THE author has obtained metallic indium electrolytically, in regular crystals, of sp. gr. 7·12 (13°/4° C.) and m. pt. 155° C. The atomic weight, determined from the sublimed trichloride, was obtained as 115·08 ± 0·03, which figure was confirmed by researches on the tribromide and the oxide. The oxide is not absolutely fixed, and is hence not very trustworthy as a basis for such determinations. The following compounds have been prepared: *Oxide*, in chlorine-green shining crystals, apparently rhombohedra. *Sulphide*, In_2S_3, scarlet powder with metallic lustre, or cinnabar-red columnar crystals. *Sulphide*, In_2S, volatile; black-brown powder, or yellow-brown transparent microscopic crystals. *Fluoride*, $InF_3.3H_2O$, shining, strongly double-refracting crystals, moderately soluble, easily decomposed. *Oxychloride*, white, slightly soluble powder. *Mono- and di-bromides*, like the corresponding chlorides. Also compounds which are perhaps a higher bromide and iodide. The electrolytically deposited metal is between silver and platinum in colour; it is extremely soft, and can be squeezed into wire in a sodium press.—J. T. D.

Formaldehyde; Presence of ——, in Atmospheric Air. H. Henriet. Comptes rend., 1904, **138**, 203—205.

RAIN-WATERS, especially those from fogs, were concentrated from 30—40 litres to 200 c.c., and the concentrates distilled. The distillates contained formic acid and formaldehyde. The presence of the latter was confirmed by tests with resorcinol, with peptone and ferric chloride, with hydroxylamine (formation of oxime and thence of hydrocyanic acid), and with dimethyaniline and sulphuric acid. Attempts to determine the amount of formaldehyde gave from 0·00001 to 0·00005 parts of the weight of the air. The antiseptic properties of this atmospheric formaldehyde are no doubt of great importance.—J. T. D.

Sugars: Synthesis of ——, from Trioxymethylene. Seyewetz and Gibello. Comptes rend., 1904, **138**, 150.

TRIOXYMETHYLENE (paraformaldehyde) is easily soluble in aqueous solutions of sodium sulphite. On boiling it with 20 parts of anhydrous sulphite in 10 per cent. solution, the aldehyde is completely decomposed after 10 minutes, with formation of sugars. The mixed osazones obtained from the resulting liquid yield a small quantity of *formosazone*, m. pt. 148° C., on extraction with boiling 80 per cent. alcohol. The residue is washed, dried on tiles, and boiled with benzene, On cooling the benzene solution, the osazone, m. pt. 131°, of *glycerose* separates. The residue, insoluble in benzene, after repeated crystallisations from 50 per cent. alcohol, yields shining yellowish laminary crystals, of which the composition has not yet been determined.—W. A. C.

Fermentative Action of Manganous Salts in presence of Colloids. A. Trillat. Comptes rend., 1904, **138**, 274—277.

MANGANOUS salts in presence of colloids and a trace of alkali (this J., 1904, 138), show among others the following reactions, noteworthy for their similarity to the actions of oxydases:—1. Exposed to air, the solution oxidises and turns brown, though without precipitation. 2. With tincture of guaiacum, out of contact with air, no reaction, or a very faint one is shown; while when air has access, an intense blue colour is formed. 3. Quinol (hydroquinone) is converted into quinone. 4. Added to solution of pyrogallol, and air passed through, these solutions yield purpurogallic acid, in quantity six times as great as is yielded in the same time by pyrogallol and alkali alone. 5. The successive formation and reduction of manganese dioxide in these experiments can be seen and followed by the reaction with the tetramethyl derivative of diphenylmethane (this J., 1903, 761). 6. The oxidation of phenols is accompanied by evolution of carbon dioxide. 7. In certain cases, the active portion of the colloidal solution can be isolated by precipitation, and can be then redissolved to form an active solution. 8. The properties of the solution are destroyed by heating for 20 minutes to 105° C., though it slowly regains them after cooling. 9. The action on gallic acid shows that heat destroys the activity due to the manganese compound, but does not affect that due to the alkali.—J. T. D.

Soluble Ferments; Emission of Blondlot Rays during Action of ——. Lambert. Comptes rend., 1904, **138**, 196—197.

FIBRIN, acted on in a test-tube by pancreatic juice rendered active by kinase, showed on a calcium sulphide screen an emission of N-rays, which ceased after the fibrin was dissolved. A similar result was given when an artificial gastric juice was substituted for the pancreatic juice. Photographic as well as visual evidence of this was obtained. These results are possibly analogous to those obtained by M. Blondlot from tissues under constraint.
—J. T. D.

Camphor; Formation of ——. H. Shirasawa. Bull. Coll. Agric., Tokio. Pharm. J., 1904, **72**, 77.

ACCORDING to the author, oil cells appear very early under the vegetative point of the camphor plant. In the young organs, the oil cells contain an essential oil, formed in the layer called by Tschirch, the "resinogenous" layer. In tropical countries the oil and the "resinogenous" mass in that layer are of a thicker consistence than in the temperate climate of Southern Europe. Old leaves contain more oil than young ones. The transformation of the oil into camphor does not take place until some time after the formation of the oil. In the old wood the oil is more frequently colourless and crystals of camphor are more abundant than in the young wood, in which the oil is often yellow. The oil cells do not exist in the woody parts, fibro-vascular bundles, or in the epidermis; there are more oil cells in the secondary than in the primary bark, but they are more abundant in the wood parenchyma than in any other tissue. The parenchyma also yields more colourless oil and crystals than other tissues. In the young pith, the oil cells are numerous, but diminish in number with age. The autumn wood contains more oil than spring wood.—A. S.

Living Cells; Functions of Peroxides in the Chemistry of ——. VII. The Chemical Nature of the Oxydases. R. Chodat and A. Bach. Ber., 1904, **37**, 36—43.

Aso (this J., 1903, 1097) has suggested that the principles in the plant organs which yield the blue reaction with guaiacum tincture on the one hand and liberate iodine from potassium iodide on the other, are not identical, but that the latter reaction is due to nitrous acid, which he has detected in the buds of *Sagittaria sagittifolia*. The authors point out that if it were a matter of oxidation by nitrous acid, all the usual reactions of the oxydases (such as the bluing of guaiacum resin, the oxidation of pyrogallol, &c.) would also be attributable to that acid. As a matter of fact, a series of quantitative experiments shows that the oxidation of pyrogallol by nitrous acid follows exactly the same mechanism, as regards the influence of time and proportions of oxidising agent, as the oxidation by oxydases. It may fairly be assumed, therefore, that oxidations by nitrous acid are effected by means of an intermediate hypothetical peroxide of the type ON.O.O.NO. [Compare this J., 1904, 60, col. 1, four lines from bottom.] In view of the great similarity between the oxidising properties of nitrous acid and those of the oxydases, the authors have applied a number of tests to a very active, purified, preparation of *Lactarius* oxydase. The solution of this oxydase reacted very powerfully with guaiacum tincture and with potassium iodide and starch. It gave, however, no coloration with diphenylamine and concentrated sulphuric acid nor with *m*-phenylenediamine in presence of sulphuric acid [Griess' test]. There can, therefore, be no possibility of the active principle being identical with nitrous acid. With *m*-phenylenediamine in presence of very dilute acetic acid, a coloration, violet at first, and subsequently an intense blue, was formed. This coloration is characteristic of oxydases, as also of peroxydases in presence of hydrogen peroxide. A dark violet-blue coloration was developed with *a*-naphthylamine and sulphanilic acid in presence of dilute acetic acid. The oxydases prepared from fungi yielded the reactions of the albuminoids only to the slightest extent, and their albuminoid nature is very questionable. In investigating the nature of all preparations of this sort, it must be borne in mind that the composition of the active products always partakes of the nature of the substrata from which they have been isolated.—J. F. B.

Aromatic Haloid Derivatives; Direct Reduction of ——, by finely divided Nickel and Hydrogen. P. Sabatier and A. Mailhe. Comptes rend., 1904, **138**, 245—248.

Monochlorobenzene vapour and hydrogen, passed over finely-divided nickel at 160° C., give cyclohexane and nickel chloride, and the action ceases when the whole of the nickel has been converted into chloride. At 270° C., however, the products are benzene and a little diphenyl, and the action is continuous, for the nickel chloride is reduced by the excess of hydrogen. The more highly chlorinated benzenes give mixtures of benzene and lower chlorinated derivates and no doubt could be completely reduced by longer exposure or by a repetition of the process. Haloid derivatives of alkylated or hydroxy-benzenes are more readily reduced than the corresponding derivatives of benzene; haloid-amino-derivatives are still more easily reduced, while haloid-nitro-derivatives have the nitro-group reduced and the halogen removed simultaneously. Bromo-derivatives are reduced less easily than chloro derivatives, and iodo-derivatives only by passing their vapour alternately with hydrogen over the metal, as the vapour of the iodo-derivative prevents or hinders the reducing action of the hydrogen on the nickel iodide.—J. T. D.

Specific Rotation of strongly Optically Active Compounds; Influence of Temperature on the ——. H. Grossmann and H. Pötter. Ber., 1904, **37**, 84—88.

As the temperature rises, the specific rotation of ammonium molybdenylbimalate, $MoO_2(C_4H_5O_5NH_4)_2$, increases to a maximum at about 35° C., and then continuously falls with the further rise. Thus, for a solution containing 19·313 per cent. of the complex salt, the values of the specific rotation at 10°, 35°, and 95° C. are −57·0°, −60·5°, and −55·5° respectively. As the dilution of the solution increases, the difference between the initial and maximum values of the specific rotation becomes less, but the diminution at higher temperatures becomes more and more marked. A similar behaviour is met with in the case of the corresponding sodium salt, the specific rotation of which reaches its maximum at about 50° C. This phenomenon is perhaps analogous with that exhibited by nicotine, which shows a minimum rotation at a certain concentration. With potassium molybdenyltartrate, no such maximum is observed, the specific rotation diminishing continuously as the temperature rises.—T. H. P.

Nickel Carbonyl; Chemical Reactions of ——. Part II. Reaction with Aromatic Hydrocarbons in presence of Aluminium Chloride. Synthesis of Aldehydes and Anthracene Derivatives. J. Dewar and H. O. Jones. Proc. Chem. Soc., 1904, **19**, 6.

Nickel carbonyl does not react with either aluminium chloride or benzene separately, but with a mixture of the two substances, a violent reaction begins immediately, hydrochloric acid being evolved.

From benzene at the ordinary temperature, benzaldehyde is produced together with traces of oils having high boiling points. At 100° C., the quantity of benzaldehyde is much smaller, and anthracene, which is now the chief product, is produced in considerable quantities. The reduction is probably due to the action of the nickel produced by the decomposition of the nickel carbonyl.

Toluene gives *p*-tolualdehyde and 2 : 6 dimethylanthracene (m. pt. 215—216°). *m*-Xylene similarly yields 2:4-dimethylbenzaldehyde and a tetramethylanthracene melting at 280° C., which is in all probability 1 : 3 : 5 : 7-tetramethylanthracene. Mesitylene yields an aldehyde only, condensation to an anthracene derivative being in this case impossible.

Naphthalene behaves in an entirely different way; no aldehyde is formed either in the cold or at 100° C., and a hydrocarbon, $C_{10}H_{12}$, is produced together with oily or resinous substances having very high boiling points.

New Books.

Karl Heumann's Anleitung zum Experimentiren bei Vorlesungen über Anorganische Chemie, zum Gebrauch an Universitäten, Technischen Hochschulen und höheren Lehranstalten. Von Prof. Dr. O. Kühling. Dritte Auflage. Friedrich Vieweg und Sohn, Braunschweig. 1904. M. 19 (paper); M. 20 (cloth).

8vo volume containing preface, table of contents, 808 pages of subject-matter, illustrated with 104 engravings. At the end is an alphabetical index of subjects. The great feature of this work consists in the illustrated descriptions of methods of preparation and apparatus used therein. I. Introduction. The Auditorium for Experimental Chemistry. General Remarks on the Preparing of Experiments, &c. Mechanical Operations. II. Metalloids.

II. METALS. The author is specially indebted to the folowing for communications of value and other assistance :—Buchner, Bunte, Erdmann, E. Fischer, Giesel, Harries, . Knorre, Lange, Landolt, Marckwald, Miethe, and Peters.

THE PHASE RULE AND ITS APPLICATIONS. By ALEX. FINDLAY, M.A., Ph.D., &c. Together with an introduction to the Study of Physical Chemistry by Sir WILLIAM RAMSAY, K.C.B., F.R.S. Longmans, Green, and Co., 39, Paternoster Row, London; New York and Bombay. 1904. Price 5*s.*

SMALL 8vo volume containing preface, table of contents, ntroduction by Sir William Ramsay (17—64), and 302 ages of subject-matter on the main question, subdivided as ollows :—I. The Phase Rule. II. Typical Systems of One Component. III. General Summary. IV. Systems of Two Components. Phenomena of Dissociation. V. Soluions. VI. Solutions of Solids in Liquids, only One of he Components being Volatile. VII. Solutions of Solids n Liquids, only One of the Components being Volatile. VIII. Equilibria between Two Volatile Components. X. Solid Solutions; Mixed Crystals. X. Equilibrium etween Dynamic Isomerides. XI. Summary; Applicaons of the Phase Rule to the Study of Systems of Two Components. XII. Systems of Three Components. XIII. Solutions of Liquids in Liquids. XIV. Presence of olid Phases. XV. Isothermal Curves and the Space Model. XVII. Systems of Four Components. APPENDIX. Experimental Determination of the Transition Point. There s finally an index of names and one of subjects. The book s one of a series of text-books of physical chemistry, dited by Sir William Ramsay. The introduction above eferred to may be had separately bound, as a small 8vo olume of 48 pages, at a price of 1*s.*

LEMENTS OF INORGANIC CHEMISTRY. By HARRY C. JONES, Assoc. Professor of Physical Chemistry in the Johns Hopkins University. The Macmillan Co., New York and London. 1903. Price 6*s.* 6*d.*

MALL 8vo volume containing preface, table of contents, 26 pages of subject-matter, and the alphabetical index. here are 59 illustrations, and the subject is treated of nder the following heads :—I. The Science of Chemistry. I. Oxygen. III. Hydrogen. IV. Water. V. Chlorine. I. Laws of Chemical Action. VII. Ozone and Hydrogen ioxide. VIII. Compounds of Chlorine with Hydrogen nd Oxygen. IX. Nitrogen and Compounds. X. Neutralision of Acids and Bases. XI. Atmospheric Air also ertain Rare Elements in it. XII. Determination of elative Atomic Weights. XIII. The Periodic System. IV. Bromine, Iodine, Fluorine. XV. Sulphur, Selenium, ellurium. XVI. Phosphorus, Arsenic, Antimony, also ismuth, and Compounds. XVII. Carbon, Silicon, and oron. Rôle of Carbon in Producing Light. XVIII. Trade Report.

I.—GENERAL.

MONTHLY TRADE ACCOUNTS FOR 1904; CHANGES IN THE ——.

Bd. of Trade J., Feb. 11, 1904.

The Board of Trade desire to direct attention to the fact at several important changes have been introduced into e statements relating to imports and exports to be conined in the *Monthly Accounts of Trade and Navigation*, r 1904. A comparison of the accounts for January with ose issued during each month of 1903 will show that the incipal of these changes, so far as they relate to the specification of new headings or to changes in previously existing ones, are as follow:—

I. *Import Section of the Accounts.*—In Group II., relating to imports of "Raw Materials," the imports of "Linseed Oil," "Cotton Oil," "Rape Oil," and "Other Sorts" of seed oils are to be separately distinguished instead o being included under the general head of "Seed Oil," a formerly.

Several alterations have also been made in Group III. ("Articles wholly or mainly manufactured"). New headings are introduced under "Chemicals" for "Coal Tar Products, not Dyes," "Cream of Tartar," "Muriate of Ammonia," "Sulphuric Acid," and "Tartaric Acid"; and the sub-division of the former heading for "Chinaware or Porcelain and Earthenware," so as to show separately particulars of the imports of "Porcelain, Chinaware, and Parian," "Earthenware (including Semi-Porcelain, Majolica, and Glazed Hearth or Wall Tiles)," "Jet, Rockingham, and Glazed Terra Cotta Ware," "Red Pottery, Stoneware, Brown, and Yellow Ware," and "Other Sorts (including Electrical Ware and Door Fittings, and Chemical Ware)." "Oil Seed Cake" is also sub-divided so as to show "Linseed Cake," "Cotton Seed Cake," "Rape Seed Cake," and "Oil Seed Cake of Other Sorts" separately.

Additional information is also given under various headings in this section of the accounts in respect of the countries from which goods are imported.

II. *Section relating to Exports of British and Irish Produce.*—In this section of the accounts, in addition to various alterations as regards the statement of countries to which goods are exported, the following changes are noticeable:—

Under the head of "Seed Oils" the exports of "Linseed Oil," "Cotton Oil," "Rape Oil," and "Other Seed Oil" are now separately distinguished. Considerable changes have also been made in the classification of "Chemicals, Drugs, Dyes, and Colours," particulars now being shown separately for "Cream of Tartar," "Muriate of Ammonia," "Sulphuric Acid" and Tartaric Acid," while the heading for "Coal Tar Products, not Dyes," has been sub-divided into "Aniline and Coal Tar Oils," "Carbolic Acid," "Naphthalene and Anthracene," and "Other Sorts." Under "Chinaware or Porcelain and Earthenware," separate particulars are given for the different heads enumerated above as among the changes introduced into the Import Section of the Accounts, and similar alterations to those specified in that Section are also made in respect of exports of "Oil-Seed Cake."

It is further intended to publish each quarter an account of the value of the re-exports (*i.e.*, the exports of goods previously imported (to each Foreign Country and British Possession, as is already done in the case of imports and of exports of British and Irish Produce.

SWITZERLAND; TRADE OF ——, IN 1902.

Foreign Office Annual Series, No. 3111.

The total imports of druggists' sundries and chemicals in 1902 amounted to 1,538,000*l.* (55,000*l.* from the United Kingdom). The principal imports from the United Kingdom consisted of :—varnishes, 6,600*l.*; stearin, 6,000*l.*; arsenical acid, sugar of lead, borax, and salts of soda, 5,000*l.*; and pharmaceutical preparations packed for wholesale and for retail, 4,000*l.*

Out of a total import of 53,000*l.* for porcelain and china, the United Kingdom only supplied to the value of 1,200*l.*, and of the imports of superior pottery (total 57,000*l.*), only 2,000*l.* The total importation of lavatory fittings of porcelain was 13,000*l.*, of which 8,000*l.* came from the United Kingdom, an increase of 3,000*l.* on the previous year's figures.

The total imports of paper, &c., amounted in 1902 to 365,000*l.*, an increase of 18,000*l.* on the imports of 1901. The imports from the United Kingdom amounted only to 12,500*l.*, a decrease of 1,300*l.* More packing-paper and common cardboard were imported than hitherto.

The import of brandies, rums, &c., from the United Kingdom was 3,000*l.*, out of a total import of 34,000*l.*

The total imports of oils, soap, and fats amounted to 568,500*l.*, of which the United Kingdom supplied 22,500*l.*, or 8,000*l.* more than in 1901. The imports of oils for various trade purposes amounted to 18,000*l.*, an increase of 8,000*l.*, while the value of the imports of cod liver oil and soaps decreased. The importation of the latter article is greatly decreasing as the factories established in Switzerland are now fully able to supply home requirements.

The following articles were imported into Switzerland from India :—Chemical products, 64,700*l.* ; tin in bars, 52,500*l.* ; oil seeds and oil fruits, 4,700*l.*

Switzerland's exports to India included chemicals, 41,500*l.*

SARDINIA ; BRITISH TRADE WITH ——, IN 1902.

Foreign Office Annual Series, No. 3110. *Dec.* 1903.

Imports at the Various Ports of Sardinia during the year 1902.

Articles.	Africa.	America.	Austria Hungary.	Belgium.	France.	United Kingdom.
	£	£	£	£	£	£
Spirits, beverages, and oils	758	5,756	1,278	21	278	45
Colonials, drugs, and tobacco	2	18,323	176	10	72	67
Chemicals, medicines, resins, and perfumery	1,129	..	..	1,245	201	655
Colours, paints, and dyes	..	..	..	..	152	594
Metals, manufactures of, and minerals	215	2	525	1,983	1,899	3,223
Stones, earthenware, and glass	247	..	24	382	239	10,526

Though in 1902 the United Kingdom has been foremost in the imports into the province of Cagliari, that is due to the amount of coal entered, as there still is but a trifling trade in British industrial products, which once was of great importance.

The principal causes of the fall are :—the heavy duties imposed on British industrial imports ; the successful competition of other countries, especially of Germany and France ; the refusal of British manufacturers, traders and merchants to use the decimal system for weights and measures for the sales here.

MEXICAN TRADE IN 1902.

Foreign Office Annual Series, No. 3112, *Jan.* 1904.

Imports.

The value of all kinds of chemicals and drugs imported into Mexico in the year 1902 was 552,594*l.*, as against 508,181*l.* in the preceding year.

The principal articles imported under the heading *Chemicals* in 1902 were colours of all kinds, prepared, and in powder or crystals, valued at 92,926*l.* ; drugs of all kinds, including patent medicines and pills, valued at 92,345*l.* ; caustic soda and potash, valued at 52,720*l.* All kinds of perfumery and soaps are included under this heading, as well as a number of smaller and less important articles.

Stones and Earths, including Lime, Hydraulic Lime, and Cement.—The total quantity was 44,332 tons, valued at 90,722*l.*, as against 30,034 tons, with a value of 59,677*l.*, in 1901. This increase is accounted for by a greater demand for cement, not only for street paving but also for buildings.

China and Earthenware were imported into Mexico during the year 1902 to the value of 66,198*l.*, compared with 66,006*l.* in the year preceding. Most of the china and earthenware comes from France and Germany, and though it is not, perhaps, of such good quality as that of British manufacture, it is more suited to the wants of the market, as on account of its being lighter it pays less duty, and is consequently in greater demand, as it is so much cheaper.

Glassware.—The importation of glassware may be divided into several headings, the principal of which are common glass bottles for wines, beers, and vinegar, &c., representing a value of 87,628*l.*, the greater part of which is supplied by Germany. Fine glass for table and other purposes was imported to the value of 70,872*l.*, mostly from France and Germany, but this amount includes a fine quality of moulded glass from the United States in imitation of the best kind of cut glass. The value of the imports of plate glass was 25,615*l.* The new glass factories recently erected in the city of Puebla are turning out all kinds of glassware, which is not only superior to any that has been made in the country before, but is copied from the best styles, and the prices are very much lower than foreign glass.

Fire-arms, &c.—The value of all kinds of fire-arms and ammunition imported in the year 1902 was 315,996*l.*, as against 292,739*l.* in the preceding year. Of the former amount, 168,163*l.* represents the value of dynamite and other explosives, the remainder being the value of fire-arms, mining fuse and mining powder.

Leather Goods.—Prepared hides and skins represent a large portion of the value of the imports of leather goods, the value in 1902 being 46,863*l.* Most of these come from Germany, and are in all probability those exported from Mexico in a dry or salted condition, and which are nearly all sent to that country for preparation.

Petroleum.—Although several petroleum springs are said to have been found in many parts of the country, the importation of both crude and refined petroleum in 1902 amounted to 120,493*l.*, as compared with 102,716*l.* in 1901.

Paper.—The importation of paper, and the manufacture thereof, including cardboard, in 1902 show a decrease on the previous year, the value in 1902 being 388,355*l.*, as compared with 401,152*l.* in 1901.

Exports.

The exports of gold amounted, in 1902, to 1,926,241*l.*, as against 1,817,960*l.* in 1901. Of this, the greater quantity was in bullion, and amounted to 1,839,665*l.*, as compared with 1,666,675*l.* in the previous year. The gold ore represented a value of 60,796*l.*, the gold coin 25,780*l.*, of which 21,123*l.* was Mexican, and the remainder foreign gold coin re-exported.

The export of silver in the year 1902, as compared with the previous years, is as follows :—

——	1900.	1901.	1902.
	Dols.	Dols.	Dols.
Silver ore and dust	12,495,524	9,668,042	4,108,089
" bullion	43,517,899	38,860,104	47,975,236
" coin—			
Mexican	22,239,953	11,769,213	17,621,700
Foreign	430,704	267,948	131,825
Total	78,693,080	60,565,607	69,836,850

The increase in the exports of copper is proof of the increased development of the mining industry of Mexico. The quantity exported in 1902 amounted to 62,087 tons, as compared with an export of 42,017 tons in 1901 ; of this quantity only 5,000 tons were exported in the shape of ore. The value reported in the official returns for the exports in 1902 was 18,230,268 dols., which, converted into sterling at the rate of 1*s.* 8⅜*d.* to the dollar, gives a sterling value of 1,566,713*l.*, as compared with 1,295,434*l.* in 1901, when the price of silver was at 1*s.* 11⅝*d.* to the dollar.

The greater part of the copper exported, either as ore or matte, finds its way to the United States, which acts as the principal distributing centre of the world. The only other country which supplies that market with copper in any quantity is British Columbia ; but it is now said that the production of Mexico exceeds that from the latter country.

A further increase in the quantity and value of the lead exported in 1902 is also visible. The amount exported in 1902 was 105,783 tons (of which only 116 tons were in the shape of lead ores), and was valued at 527,697*l.*, as compared with 78,241 tons, valued at 447,931*l.*, in 1901. The lead is nearly all sent to the United States.

Many other metals are also found throughout the country, including antimony, iron, tin, mercury, and zinc, and it is quite probable that others also exist, as also sulphur deposits and coal and salt beds.

There was a decrease in the value of the exports of dyewoods in 1902, but this is in all probability due to the lower rate of exchange at which the silver values have been converted into sterling. The only two woods of any importance which are covered by this heading are logwood and fustic; 34,718 tons of the former and 5,504 tons of the latter having been the total amount exported in 1902.

Indigo, cochineal, and orchil were at one time exported in sufficient quantities from Mexico, but since the introduction of the aniline dyestuffs the cultivation of the indigo plant, the moss for the extraction of orchil, and the cactus on which the cochineal was propagated, have almost entirely died out; it is to be expected, however, that if any impulse is given to agriculture in general, these particular industries will also come in for a share. the more so as it appears that none of them require very expensive or arduous labour for their cultivation.

The cultivation of vanilla is now being more extended, and as it grows luxuriantly in the warm lands along the coast there seems no reason why the exports should not show a greater increase. The amount exported in 1902 was 113,576 lb., as compared with 43,991 lb. in 1901, and the values of these exports were respectively 98,550*l*. in 1902 and 57,426*l*. in 1901.

III.—TAR PRODUCTS, PETROLEUM, Etc.

Petroleum; Russian ——.

Chem. and Druggist, Jan. 30, 1904.

The production of petroleum in the Baku district during 1903 shows a considerable falling-off as compared with the years immediately preceding it. It is calculated that the output amounted to 595 million poods, as against 637 millions in 1902, 672 millions in 1901, and 600 millions in 1900. During the first eight months of 1903 the prices of naphtha remained low, but in the later months a perceptible improvement took place.

VII.—ACIDS, ALKALIS, Etc.

Arsenic; Production of ——, in 1903.

Eng. and Mining J., Jan. 14, 1904.

The production of arsenious oxide in the United States during 1903 was 590 short tons, as compared with 1,353 short tons in 1902 and 300 short tons in 1901. The sole producer of white arsenic is the Puget Sound Reduction Company, at Everett, Washington, which has recently passed into the control of the American Smelting and Refining Company. Prior to 1899 the world's supply of arsenic and its compounds was derived mainly from the mines in Cornwall and Devon, and near Freiberg, Germany. The closing down of the Devon Great Consols mine in 1901 led to the exploitation of deposits in other countries, Canada becoming a new producer in 1900 and the United States in 1901.

Although arsenical pyrite occurs in many places in Ontario, Canada, the total output of arsenic has been derived from the mines of the Canadian Gold Fields, Ltd., at Deloro, Hastings county, the production of which continued to increase until April, 1903, when the mines were closed down pending negotiations, with the view of consolidating the arsenic properties at and near Deloro into a single company in order to produce a largely increased annual output at a smaller cost per ton.

The United States Arsenic Mines Company has been developing an arsenic deposit at Pilot Mountain, 17 miles from Christiansburg, Va. An adit 215 ft. has been driven into the hillside, and from it a drift of 55 ft. extends to an 8-ft. vein of arsenic ore reported to average 25 per cent. of arsenic, which can be mined at a cost of 70c. per ton. A building 300 ft. by 70 ft. has been erected for the mills and furnaces, and a colony of dwelling-houses for the labourers, a store, blacksmith's shop, saw-mill, office, laboratory, &c., have been put up. The plant is equipped with a 125-h.p. Westinghouse engine, two 75-h.p. return tubular boilers, four dynamos (one of 75-h.p., one of 15-h.p., and two of 2-h.p.), a 10 by 20-in. Blake crusher, a 27-ft. Howell-White calcining furnace, a set of rolls for pulverising the product, pumps, &c. The capacity of the plant, when finished, will be 70 tons of refined arsenic per day. The region is wild and mountainous, and a traction engine was used to transport the machinery from Christiansburg. The company expects to begin producing white arsenic early in 1904.

The Mineral Creek Mining Company, owning an arsenic property at Mineral Creek, Washington, reports a large body of regular ore which can be mined and converted into white arsenic very cheaply. About 1,000 tons of ore have been mined and are held in stock awaiting the completion of the smelter, which is nearly ready for operation. Mineral Creek is situated not far from Elba, which is on the line surveyed for the Tacoma Eastern Railroad.

A recent discovery of metallic arsenic has been made at Washington Camp, Santa Cruz county, Arizona. The metal occurs in masses attached to the walls of small pockets in a dolomitic limestone, and in some instances the pieces of arsenic weighed several pounds each. From one pocket more than 50 lb. of metallic arsenic was obtained.

VIII.—GLASS, POTTERY, AND ENAMELS.

Glass Making in Germany and Austria.

Bd. of Trade J., Feb. 11, 1904.

The Technical Instruction Committee of the Staffordshire County Council has issued a pamphlet containing extracts from a report by Mr. Frederick Carder (of the Wordsley School of Art), on a visit to the glass-making districts of Germany and Austria.

At works near Koepenick the furnaces are worked on the Siemens' regenerator system, the gas being produced from anthracite; they are oblong in shape, with five pots on each side. The men work on a stage or platform of wood, about 2 ft. 6 in. in height and 7 ft wide, erected round the furnace.

At Tschernitz there are six Siemens' regenerative furnaces, some with 12 pots and others with 10 pots in each furnace, all the pots being open.

In the cutting and grinding shop, with one or two exceptions, all the mills run horizontally and not vertically as in England, and vary in diameter from 2 feet up to 5 feet.

X.—METALLURGY.

Platinum Production of Russia.

Eng. and Mining J., Jan. 21, 1904.

The production of platinum in 1903 is reported by the Russian Department of Mines to have been 389 poods 3 funts, which is equivalent to 204,892 troy oz., as compared with 446 poods, or 234,878 troy oz., in 1902.

Mining in Spain.

U.S. Cons. Reps., No. 1868, *Feb.* 4, 1904.

The *Finanz Chronik* states that the revival of Spanish industries, which is usually not sufficiently appreciated, is especially noticeable in the mining and metallurgical branches. The production of silver ores, manganese, lead, and sulphur is constantly increasing; that of copper has increased but little during the past few years; that of silver-bearing lead ore has decreased. The Somorrostro Mine deserves special mention as a big producer, with about 350,000 tons per year. The copper mines of Cordoba, Huelva, and Seville, as well as those of Tharsis, and Rio Tinto, have a world-wide reputation. The latter has a production valued at about 550,000*l*. per annum. The lead mines of Jaen, Murcia, Almeria, and Linares yield an annual output of nearly 100,000 tons. Santander and Murcia produce 86,000 tons of zinc per year; Oviedo, Huelva, and Seville, 30,000 tons of manganese; and Caceres, 10,000 tons of phosphorite. Of the mercury mines in the province of Ciudad Real, the most important one, operated by the Government, is the Almaden. During the year 1901, 443 new borings were made in this mine, and the total production of pure mercury amounted to 630,689 lb.

Gold; Occurrence of ——, in Great Britain and Ireland.

J. M. Maclaren. Trans. North England Inst. Mining and Mech. Eng., 1903, **52**, 437—510.

The author gives a description of the conditions under which gold occurs in Great Britain and Ireland. A bibliography is appended to the paper. The yield of gold in

Great Britain and Ireland is estimated as follows:—England: North Molton, 581*l.*; Wales, since 1844, 280,547*l.*; Scotland: Leadhills, 100,000*l.*; Sutherland (1868—1869), 3,000*l.*; Ireland, 28,855*l.*; total, 412,983*l.* Of the total production, almost all, except that from the Leadhills, has been obtained during the nineteenth century, and nearly half of it during the last 14 years. For the present century the outlook is by no means promising, except in North Wales, where, in the author's opinion, there is no reason why the veins should not be worked with commercial success, provided that when a "bonzaoa" is encountered, a large reserve fund be set aside in order that the vigorous prospecting which should be the distinctive feature of "patchy" mines, can be carried on.—A .

XII.—FATS, FATTY OILS, Etc.

Soap and Perfumery; Hints to Exporters of ——.

Ch. of Comm. J., Feb. 1904.

The following particulars as to the trade in perfumery and soap in various countries have been collated by *Handels Museum*:—

Roumania.—The import duties are so high that only the best and second best descriptions can be imported. Native-made soaps are dear, and there is an important demand for foreign goods, particularly the French article. Perfumery and cosmetics have to pay a duty of 100 lei (4*l.*) and toilet soap 180 lei (7*l.* 4*s.*) per 100 kilos.

Russia.—In Russia also the high tariff allows of the import of the finer perfumes only. The native soap industry, however, only produces the cheaper qualities.

Finland.—Finland imports cheap as well as the better qualities of perfumery. The demand is to a great extent limited to the former, but at the same time fancy goods suitable for presents are saleable if not too dear. As a rule, however, the Finns use fewer perfumes than the Russians. In their articles of toilet they prefer antiseptic preparations rather than scents. The home manufacture of soap is cheap. Importers in Helsingfors buy chiefly from commission agents in Berlin, Lubeck, and Hamburg. Toilet soaps have to pay 105·90 Finnish marks (about 85*s.*) per 100 kilos.

Sweden and Norway.—In Sweden, owing to large home manufactures of perfumery, the import trade is confined to small quantities of superior makes. Cheap perfumes, as well as finer scents, have to pay 2 kroner (2*s.* 2*d.*) per kilo. duty. The duty on toilet soap amounts to 0·50 kroner, (6½*d.*) per kilo. French, German, English, and United States manufactures are chiefly in request, and latterly German in particular. Norway, in spite of a considerable home production, imports a fair quantity of toilet articles, the cheaper kinds from Germany and better qualities from England and France. Toilet soaps are subject to a duty of 0·50 kroner per kilo. (minimum tariff).

Zanzibar.—The Austro-Hungarian Consul reports that in Zanzibar, owing to the stringent regulations in respect of the sale of spirits to the natives, the introduction of alcoholic perfumes and essences is difficult.

China and Korea.—In China, European perfumery and soap is mostly too dear and insufficiently known. The European population at Foochow obtain their supplies chiefly from England and America. Into Hankow imports consist chiefly of very cheap lines, principally rouge and scent. Korea, in respect of its capital, Seoul, obtains its supplies of perfumery and soap (chiefly fine and medium goods) *viâ* Shanghai or Japanese ports. In 1900, Custom statistics showed an import of perfumery value 6,750 frs. (270*l.*) and of toilet soap value 11,025 fr. (440*l.*).

Switzerland.—Switzerland imports all kinds of fancy soaps and perfumes, but rarely cheap or medium articles. France is the chief supplier of perfumery, and Germany of soap.

Turkey.—Turkey imports all the superior descriptions of toilet articles from France, England, and Germany. In the country itself only a small quantity of the cheaper kinds of scents is produced. Traders in Adrianople make their purchases—mostly cheap goods—principally from Constantinople. Inquiry for such goods at Monastir is limited, and chiefly in the direction of inferior goods; but, at the same time, the trade might be increased if a low-priced good article were introduced. In Salonika, a local manufactory competes keenly with foreign goods.

Aden and Beirut.—In Aden, the annual import, mostly of French origin, of toilet soaps, extracts, washes, and cosmetics amounts in value to 20,000 fr. (800*l.*). Cheap goods with a basis of musk, civet, rosewater, jasmin, or geranium are in good request.

XIII. C.—INDIA-RUBBER, Etc.

Rubber Production; The World's ——.

Ch. of Comm. J., Feb. 1904.

Figures published by *Handels Museum* show that the world's production of caoutchouc fell from 57,500 tons in the year 1900 to 54,000 tons in 1902. The largest diminution was shown in the case of East and West Africa, including the Congo—namely, from 24,000 tons to 20,000 tons. On the other hand, Brazil, Peru, and Bolivia show an advance from 25,000 tons in 1900 to 30,000 tons in 1902; and the Straits Settlements, whose production was unimportant in 1900, appear with 1,000 tons in 1902. The output of the Netherlands East Indies (1,000 tons in 1900), Madagascar and Mauritius (1,000 tons in 1900), India, Burma, and Ceylon (500 tons in 1900), was not, however, considered large enough to be recorded. The share of the South American States not specifically mentioned fell from 3,500 tons to 1,000 tons, and that of Central America and Mexico from 2,500 tons to 2,000 tons.

Patent List.

N.B.—In these lists, [A.] means "Application for Patent," and [C.S.], "Complete Specification Accepted."

Where a Complete Specification accompanies an Application, an asterisk is affixed. The dates given are (i) in the case of Applications for Patents, the dates of application, and (ii) in the case of Complete Specifications Accepted, those of the Official Journals in which acceptances of the Complete Specifications are advertised.

Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

Notices.

ANNUAL GENERAL MEETING, NEW YORK, 1904.

The Annual General Meeting will be held in New York City on Thursday, Sept. 8th, and following days. Members who contemplate attending are requested to communicate with the General Secretary as soon as possible, in order that suitable travelling arrangements may be made. A programme appears in the Jan. 30 issue of the Journal.

ST. LOUIS EXHIBITION, 1904.

The St. Louis Chemical Society has established a Bureau of Information for the benefit of members of foreign chemical societies who may visit the World's Fair. Any members of such societies who desire information in regard to the Exhibition are invited to write to the Secretary, Prof. E. H. Keiser, Washington University, St. Louis, Mo.

COMMUNICATIONS.

Authors of communications read before the Society, or any of its Local Sections, are requested to take notice that under Rule 43 of the Bye-laws the Society has the right of priority of publication for three months of all such papers. Infringement of this Bye-law renders papers liable to be rejected by the Publication Committee, or ordered to be abstracted for the Journal, in which case no reprints can be furnished to the author.

Changes of Address.

When notifying new addresses, members are requested to write them distinctly, and state whether they are temporary or permanent. Multiplication of addresses is also to be avoided as tending to create confusion. When sending subscriptions, the use of the form attached to the application helps in the verification of addresses, on which the safe delivery of the Journal depends.

Meeting held at the University, on Wednesday, February 24th, 1904.

MR. FRANK TATE IN THE CHAIR.

THE MANUFACTURE OF SULPHURIC ACID FROM ARSENICAL PYRITES.

BY W. ROSCOE HARDWICK, B.SC., F.I.C.

Some years ago I was asked to go to a sulphuric aci works that were in difficulty. The "difficulty" tha presented itself was far beyond anything that I ha expected to encounter, for in every part of the plant I sa arsenious acid, or rather oxide, As_4O_6. Crystals of arseniou oxide were on the doors and drum plates of the burne that were not working hot. Quantities of pasty mass were raked from a horizontal pipe connecting the pottin oven with the Glover tower. From the Glover tower itse came a dirty rather milky liquid, which deposited arseniou oxide in the cooler shoots as it gradually became colder a colder. Many connecting pipes, especially those carryi cold strong liquor to the strong egg cistern were stopped up, and on being cut, the filling, so hard did it appear, seemed like a piece of flint.

On examination, the eggs themselves were found to be encrusted with arsenious oxide, especially the strong acid egg, which was so much so that its capacity was thereby halved. Many inches of a white deposit of the oxide were in the cisterns on the Gay-Lussac tower, and the distributing shoots and lutes on the tower top were so filled with the deposit that the liquor found its way into the tower by one or two channels only. But by far the worst effect of arsenious oxide, in fact the fatal effect, to the possible working of the ore under normal conditions was seen in the Gay-Lussac tower itself. The coke had acted as a filter for the oxide which eventually and effectually choked up the tower. A strong pressure on the last chamber resulted, and this soon told upon the whole plant's working, even to the burners themselves—in short the works had stopped. Such was the state of things that I was invited to remedy.

The working of liquors saturated with arsenious oxide is possible (though by no means easy or agreeable) in all parts of the plant except the Gay-Lussac tower, for as soon as the oxide gets on to the coke, the draught is impeded, and the working of the whole plant is thus upset. It was therefore to the prevention or cure of the ill effects due to the arsenious oxide in the Gay-Lussac tower that my attention was primarily directed. By what means does the arsenious oxide get into the Gay-Lussac tower? Let us trace its course from the burners. When the ore is burned the sulphur comes off as sulphur dioxide, and the arsenic as arsenious oxide. It is stated in treatises on the subject that, of the total arsenic present in the ore when the ore is burned, 20 per cent. is left in the cinders, 20 per cent. is absorbed by the chamber acid, 30 per cent. is trapped in the Glover tower, and 30 per cent. passes through the plant and is caught in the Gay-Lussac tower. With these figures my experience has made me entirely disagree. Considering that arsenious oxide is volatile at something above 300° F., it cannot in any great quantity escape solution in the Glover tower, much less escape condensation in the large cool chamber space through which it must needs pass to the Gay-Lussac tower. Of the 20 per cent. left in the cinders I may say that I have frequently, in properly working burners, burned the ore down to one quarter of that amount.

From observations and tests of the Glover liquor I am of opinion that from 70 to 75 per cent. of the total arsenic present is volatilised and caught in the Glover liquor. I have therefore come to the conclusion that practically the whole of the deposited oxide in the Gay-Lussac tower had been precipitated there by the filtering action of the coke on the strong liquor from the Glover tower, which was being run down for the ordinary absorption purposes.

The first idea that occurred to me was that the ore could have been burned under normal conditions of working, had care been taken to keep the plant generally as clean as possible, *e.g.*, by flushing the Glover tower at regular intervals, and rejecting the muddy washings for Gay-Lussac purposes and like precautions, of which I shall speak later.

To put this system of working to the test it was necessary to make a clean sweep of all obstructions and to start afresh. To make a clean sweep of arsenious oxide is more easily suggested than effected, an arrangement having been made by the management of the works to have this cleaning operation carried out by contract. You will realise the difficulties met with when I tell you that I found the workmen at some fused deposits in the burner pipe, with sharpened bars and sledge hammers vainly endeavouring to remove the deposits, or, as I found them, endeavouring to remove the incrustation on the eggs by making a fire inside. But the most obstinate of all obstructions was the Gay-Lussac tower itself. The coke having become locked by the cementing action of the arsenious oxide, and all attempts to tickle the coke out proving futile, the use of blasting powder was resorted to.

Hot liquor will dissolve arsenious oxide, and can in many instances be resorted to as a solvent to remove the oxide in parts of the plant. When, however, there is a complete block, and there is no channel, however small, for the liquor to follow, it is useless as a cleaner. The best and in every way most effectual method of loosening if not removing deposits of arsenious oxide I found to be by the use of steam.

In the case of deposits in the burner pipes, *e.g.*, a small hole was made by a sharpened bar and sledge, and steam applied through an iron nozzle, and in a short time the whole mass was softened and readily split up. In the case of the Gay-Lussac tower the inlet and outlet were dampered off (this to avoid draughts, whereby the steam would be condensed) and steam introduced at the bottom. In a few hours the whole tower was perceptibly warm to the touch, and an examination showed the coke to be in a perfectly loose state.

Having at length cleaned the plant to my satisfaction I repacked the Gay-Lussac and started working on the lines above indicated—that is to say, by using every precaution to ensure the freedom of the strong liquors from arsenious oxide. My great hope lay in the utilisation of two large tanks holding about 20 tons each, as settlers for the strong liquors. But after fixing cans over the plug holes of the vats; after avoiding all undue disturbance of the liquors (for example, by taking the precaution of allowing the strong liquors entering the vats to break their fall by running on to a baffle plate); in short, after taking all precautions to ensure a precipitation and separation of the oxide, two facts militated against the success of the operation. First, the exposure of strong liquor seriously affects the specific gravity, and secondly, the rapid precipitation of arsenious oxide depends not only upon the cooling of the liquor, but upon its agitation, and cold liquor such as that lying in the settling tanks only threw down its arsenious oxide, when it became churned in the egg and in the cisterns on top of the Gay-Lussac. But even with the above precautions, and all care being taken with the flushing of the Glover tower, it soon became evident that some radically different *modus operandi* had to be instituted. I might here mention the trouble caused by the arsenious oxide in the antimony jag valve used on the eggs. The valve consists of an antimony plug and seating; the latter being bolted on to the flange of the egg, the plug is driven into the seating by a screw lever, by means of which great force can be applied. These valves I have found generally satisfactory. Now one would have understood that any gritty matter being entrapped between the plug and the seating when the valve is screwed down would cause it to leak, but one would have thought that a light flocculent precipitate would be harmless in its effect; but this was not so, for so coagulated and flint-like did the oxide become that the valves became leaky by undue pressure brought to bear in an attempt to stop the blowing back into the strong liquor cistern.

Character of the Ore.—The ore, to all outward appearance, seemed a clean sound ore containing about 10 per cent. of smalls. In colour it was of a decidedly pale appearance. I have learned to look upon what I might call "silvery" ores with suspicion. When riddled and freed from the smalls, and thrown on the burners in lumps not larger than a man's fist, it burned with a slight explosion that was merely sufficient to split and not shatter the lumps. There resulted at the end of 12 hours, the time for recharging, a bright red bed of well-burned ore; so that as regards the actual burning of the ore no great difficulty was encountered.

Analysis of the Ore.—It contained arsenic, 1·7; sulphur, 45; copper, 3·5; silica, 2·5 per cent. Suppose, then, that 42 of the 45 per cent. of sulphur was burned off and formed 156 parts by weight of sulphuric acid of 150° Tw. Again, of the 1·7 per cent. of arsenic let us assume that 1·5 per cent. is burned off, and of that 1·5 per cent. 1·1 per cent. is entrapped in the Glover tower, the remaining 0·4 per cent. going over into No. 1 chamber. We have then 1·1 parts by weight of arsenic, or 1·45 parts by weight of arsenious oxide, to be dissolved by twice the make of sulphuric acid, *i.e.*, the sulphuric acid coming down the Glover tower. The sulphuric acid made equals 156 parts by weight of 150° Tw.; therefore 1·45 parts by weight of arsenious oxide has to meet 2 × 156 or 312 parts by weight of 150° Tw. liquor in the Glover tower; so that, in order that the arsenious oxide may be dissolved and retained in solution, sulphuric acid of 150° Tw. ought to absorb 0·46 per cent. of As_4O_6.

Laboratory experiments were then made to ascertain the solubility of arsenious oxide in sulphuric acid at different strengths and different temperatures. I might here just indicate the method employed. As I have already stated, agitation, as might be expected, has much to do with the precipitation of arsenious oxide. It therefore became necessary, in making laboratory experiments, to imitate as closely as possible the condition of things actually occurring in the plant. An indefinite quantity of acid of known strength was taken, and arsenious oxide added in quantity well over that required to saturate it at the highest temperature to be dealt with. The acid was then heated to such an extent that when cool it formed a supersaturated solution. The solution of oxide was then cooled in a water-bath kept for some hours at a definite temperature with repeated agitation. The liquor was then filtered through glass wool, and the clean filtrate tested for arsenious oxide. The operation was repeated afresh for the determination of the solubility at other temperatures and other strengths. The results are as follows: Generally, the hotter the acid the more soluble the oxide, and the stronger the acid the more soluble the oxide, particularly in the case of liquor of 150° Tw.; 0·36 per cent. is dissolved at 60° F., 0·50 per cent. at 80° F., 1·00 per cent. at 110° F. From these figures it is shown that an ore of the burning quality above indicated cannot retain in solution all the arsenious oxide that must necessarily be caught in the Glover tower.

As Dr. Harger, who was working in my laboratory at the time that I was engaged upon this work, pointed out to me, arsenic oxide, As_2O_5, is soluble in strong sulphuric acid, and arsenious oxide in solution can be converted into arsenic oxide by heating the liquor with the theoretical quantity of strong nitric acid at 190° F., the reaction taking place according to the equation $As_2O_3 + 2HNO_3 = As_2O_5 + H_2O + N_2O_3$. Theoretically, therefore, where strong sulphuric acid containing arsenious oxide is treated with nitric acid, the nitrogen trioxide evolved is absorbed by the sulphuric acid, and no loss of nitre ensues. The fact that the sulphuric acid must necessarily be at a high temperature for the reaction to take place does not mean an expulsion of oxide of nitrogen, because the sulphuric acid is present in so large an excess.

My first idea was to treat the liquor immediately issuing from the Glover tower, which it does at a temperature of 300° F., with sufficient nitric acid to convert the insoluble excess of arsenious oxide into arsenic oxide. This had to be done by dropping nitric acid at a definite rate into the basin at the bottom of the tower.

The uncertainty of the amount of arsenious oxide present in the acid, which was always found to increase before the time of flushing, which operation had to be still carried out, together with the difficulty of making a serviceable apparatus for delivering regular drops—both these things necessitated the constant attention of a chemist or skilled workman, or the application of some automatic action for the successful carrying out of the process, which were not found feasible.

The method eventually worked consisted of heating up the liquor in tanks, treating with nitric acid and cooling down again. For this purpose two tanks were erected side by side just above the strong acid egg, so that any liquor that they contained would gravitate naturally to the egg. The tanks were each 4 ft. deep and 5 ft. square, and lined with 10 lb. lead. The bottom was covered with bricks laid a few inches apart to allow of the circulation of the liquor. On these a lead pipe of about 1 inch internal diameter was coiled, and the inlet, strapped to the side of the tank, was provided with a Y-piece and two valves, by means of which either steam or cold water could be admitted to the coil. The outlet was carried from the centre of the coil out at the side to waste.

A staging was erected alongside, and rather higher than the tanks, whereon were placed carboys containing strong nitric acid. The strong liquor from the Glover tower was cooled in the ordinary way in the shoots and then run into the big settlers of which I have spoken above. By running in at the far end, much of the precipitate was enabled to settle out. When a big deposit had accumulated, the mud was blown up into the last chamber, thus saving a loss of liquor, and at the same time draining the liquor from the other parts of the vat.

The mud, then very largely free from liquor, was run below by lifting a plug in the bottom of the tank.

One of the tanks supplied with a coil was then about three-quarters filled with strong liquor, a sample taken, and the amount of arsenious oxide ascertained. The arsenious compound only being required, the test is quickly carried out by neutralising partly with sodium carbonate, and finally with sodium bicarbonate, and titrating the arsenious compound with standard iodine with starch as indicator.

To oxidise the arsenious acid that was present in excess of that which the sulphuric acid was capable of dissolving, the requisite amount of nitric acid was added. This addition had to be carefully carried out; a glass syphon was employed to introduce the nitric acid, the long limb dipping some two or three inches below the surface of the liquid. The temperature of the acid should be raised to about 180° F., and then the required amount of nitric acid run in with stirring and the temperature raised to 200° F. If the liquor in the tank was not kept stirred, or if the delivery limb was not below the surface of the liquid, it fumed, and there naturally resulted a loss of nitric acid.

The steam valve was then closed and the water valve opened, and the liquor allowed to cool with occasional agitation. The water for this purpose was taken from the cistern that supplied the cooler shoots. Whilst the one tank was cooling the other was being filled and treated, so that the Gay-Lussac tower never wanted clear liquor.

The amount of oxides of nitrogen in the strong liquor consequent on this action of nitric acid was never so great as to seriously affect the absorbing power; for, suppose we had 0·25 per cent. of As_4O_6 over and above that capable of solution by the sulphuric acid, we had in the tank 3 tons of liquor = 0·15 cwt. of arsenious oxide, and this required for oxidation 0·235 cwt. of nitric acid evolving 20 lb. of nitrous oxide. So that by such action the strong liquor contained only 0·3 per cent. of nitrous oxide, which is so far from saturation that the acid may be safely used in the Gay-Lussac.

The process thus worked did not do all that I, at first, was sanguine enough to hope for it, but it did make the burning of a highly arsenical ore possible in the ordinary way, and with a considerable reduction in the consumption of nitre.

The cost of the process over and above that of the ordinary working of the plant consists in the cost of steam, which, I believe, works out to a shade over one penny per ton in raising 150° Tw. liquor 150° F., together with the difference in cost of sodium nitrate and nitric acid for the equivalent of oxides of nitrogen obtainable.

DISCUSSION.

Mr. MANNINGTON said that he thought the method adopted by Mr. Hardwick a very ingenious one. The ordinary Spanish pyrites contained, he thought, about $\frac{3}{4}$ per cent. of arsenic, and it seemed that double that amount produced an extremely unpleasant effect in the work of the chambers. He asked whether all the mass of precipitate occurring in the tower was almost exclusively arsenious oxide; it seemed so extraordinary that such an amount of arsenious oxide travelled through the Glover, and a series of chambers, and was landed in the Gay-Lussac to such an extent as to choke it up in the thorough manner mentioned. He thought that arsenious oxide in the presence of nitric acid would go into solution almost at normal temperature to some extent. If sulphuric acid which contained any nitrogen compounds, and also sulphide of arsenic, were allowed to stand, one would very often find included in the precipitate a sulphide which would apparently oxidise the arsenious sulphide, and the arsenic would go into solutio again. It vitriol, which might be apparently freed b sulphuretted hydrogen from arsenic, were allowed to stan one would generally find that some arsenic had gone int solution again. That was the point which had to b attended to in the removal of arsenic by sulphurette hydrogen, and that he had known to take place at normal temperatures.

Mr. **Eustace Carey** suggested that if the vitriol were to be used for making sulphate of soda, it might be advantageous to add nitrate of soda, instead of nitric acid, to the vitriol.

Prof. **Campbell Brown** said that as a consumer of sulphuric acid to some considerable extent, the securing of sulphuric acid absolutely free from arsenic was of the greatest importance to him, and it was exceedingly difficult to get it. Sulphuric acid dissolved arsenic out of the bottles in which it was stored. The matter was of very great importance also to manufacturers and the public. In the course of investigation of the Arsenic Commission a good many occurrences of arsenic in the most unlooked-for places had appeared, and lately he had traced it in other most unexpected places, and he believed that it had all gone back originally to pyrites acid, but if it could be produced practically free—less than 0·001 per cent.—it would relieve their minds from all fear. In the last few months he had been very much impressed with the necessity of getting pure sulphuric acid. Sulphuric acid and things made from it were used for so many different purposes, that if arsenic were allowed to get into circulation at all one never knew where it might or might not crop up, so that all the methods that could be employed in improving sulphuric acid were well worthy of most serious consideration, and he had no doubt that manufacturers would find that the increased price would be exceedingly well-spent money.

Mr. **Towers** said that, in connection with the storing of the acid, he had experienced a good deal of trouble. When absolutely pure acid was put into a Winchester, and stored for a short time, traces of arsenic were found in it. In order to overcome this difficulty he had had bottles made from special glass in a clean pot, from special materials, and no arsenic put into it, so that if he did happen to produce any good acid it remained good.

Dr. **Colman** said Mr. Hardwick had told them that he dissolved up the arsenious oxide in his acid in the form of arsenic oxide, but he did not tell them how he got rid of the arsenic oxide eventually. Did it stay in the acid, or was there a further process of getting rid of it?

Mr. **Leighton Edwards** said it seemed to him, in view of the remarks passed, that Mr. Hardwick had been experimenting in the direction of putting more arsenic into the acid than it would have had in it if he had not treated it.

Dr. J. T. **Conroy** said that from certain figures which had come before his notice he felt that certainly between 50 and 60 per cent., at least, of the arsenic was taken out in the Glover tower. From other figures he could also state that somewhere about 98 per cent. of the remaining arsenic was retained in the first three chambers out of a system of seven chambers. The towers were certainly a very effective means of getting the arsenic out of acids, and this method of removal, which he believed had been brought to a very great degree of perfection by some German firms, was, he understood, simply by a very careful washing with water and vitriol. He had read an article by a French scientist, who had been examining living organisms, both plant and animal, and he stated that he had not yet examined a living substance in which arsenic was not present, and he believed that it was an essential constituent of all living matter.

Mr. W. R. **Hardwick**, in reply, said that Mr. Mannington had remarked on the fact that, whereas Spanish pyrites containing 0·75 per cent. of arsenic worked very well, it was an extraordinary thing that so small a difference as 1·00 per cent. should give such results. It was this extra 1·00 per cent. that made the insoluble excess of As_4O_6. The strong sulphuric acid would dissolve a certain amount and no more. With regard to the As_4O_6 in the Gay-Lussac tower, in his opinion the As_4O_6 did not travel through the chambers, but was precipitated there by the cooling of the Glover liquors. The white deposit contained only traces of lead. In answer to Dr. Colman and Mr. Edwards, his object had not been the elimination of arsenic, but the conversion of insoluble arsenic into soluble, and thereby rendering an otherwise unburnable ore burnable. Mr. Carey's remarks as to nitrate of soda being used instead of nitric acid were well worth consideration, for in all probability the nascent nitric acid would be very active.

London Section.

Meeting held at Burlington House, on Monday, February 22nd, 1904.

MR. WALTER F. REID IN THE CHAIR.

THE NEED OF DUTY-FREE ALCOHOL FOR INDUSTRIAL PURPOSES.—PART II.

BY THOMAS TYRER, F.I.C., F.C.S.,
Past President.

For the paper on this subject read last year no originality was claimed. So now, obligations are due to the same gentlemen, and especially to officials and experts of the Excise branch of Inland Revenue. It will be conceded that the present time is appropriate for further consideration of a subject so important to chemical industry, partly because of the effect of recent modifications of the patent law—still however, ineffective for the promotion of industries in Great Britain—and partly on account of considerations involved in changes in the fiscal system of this country. Without being tempted into controversy, one may safely and fairly assume that, whether change in fiscal principle results or not, attention is directed as never before to the relation of the State to industry, means of transit, charges, freight, classification, taxation, merchandise marks, patent laws, and technical education. Owing to the labours of the joint committee of Chambers of Commerce and our Society, the question we have under consideration has become not the least pressing. It may broadly be stated that no progress can be made in the production of a large class of bodies employed freely in medicine and the arts in this country, and for exportation to our colonies and dependencies, unless large facilities are given by the State. The drawback or rebate on exporting medicinal spirituous preparations and perfumery was referred to in a former paper. Little remains to be granted, except as regards some simple mixtures of plain spirit with medicaments, such as chloroform and ether, solid and liquid extracts, and some concessions as to samples. These facilities, let it be emphasised, are accompanied by the very smallest possible inconvenience or interference, whether exported from manufacturers' warehouses under drawback, having been first made from duty-paid spirit or from manufactories of perfumery in bond (with unpaid duty spirit). It may be noted that this concession by the Excise has materially increased British trade abroad by causing accompanying orders for products other than spirituous. The total rebate over the period from 1889 to March 31, 1902, was given as 489,076 proof gallons, or 261,375*l.* 1*s.* 6*d.* value. For the year ended March 31, 1903, the quantity exported was 118,357 proof gallons and the rebate 65,137*l.* It should always be remembered that the principle underlying the concessions just referred to existed long ago, when specified preparations were permitted by the Customs for exportation under drawback in 9-gallon casks. The principle was there, but the extension of it was an act of official confidence and generosity which will ever stand to the credit of the Revenue. In this connection it may be stated, as a check on large expectation, that duty-free spirit is not likely to be conceded for the manufacture of medicinal preparations for internal use in which any portion of potable spirit remains in the finished product, or in a form in which it can be extracted by distillation or liberated by any cheap chemical process. This can hardly be expected, and to ask for it is to jeopardise the whole question. It is but fair to be reminded that quite recently in Germany, where so much is conceded, prohibition as regards medicinal preparations has taken the place of freedom in pharmacies.

With regard to the last expression of opinion the question may arise, "What is a manufacturing pharmacist?" As a medicinal spirituous preparation maker he has to-day all he can desire for exportation. Does he want internal excise control and supervision in bond, and duty payable on exit from bond? Then he will, as regards the class of preparations referred to, be worse off, particularly when he remembers that an agreed and acceptable allowance for waste of spirit in the liquid class of spirituous preparations is now made. Logically, the same benefit should be extended to the manufacturers of medicinal and other chemical products if made in bond or under supervision, namely, that whatever the concession as to duty it must extend to the inevitable waste in process of production. In Germany and Switzerland the form of spirit accounts in factories is simple but clear; recovered spirit is entered as such and accounted for as new or freshly supplied spirit, showing on balance of account the true ultimate waste. This is obviously fair—as would be the necessary visit of competent superior and properly paid officials to the factory itself—for the purpose of verifying processes and usage. This is no more nor less than is already done in our own country by the chemical staff of Inland Revenue. If manufacturers desire facilities of the kind we are discussing, it will be the height of folly to interpose any objection on the ground of secresy or fear of communication. Many of us are officially visited already by other State departments, notably the Home Office, under the Alkali and Factory Acts, and one ventures to assert that no evil has resulted from such visits, and consequently it is germane to refer to the conditions laid down in the Finance Act, 1902, and embodied in the 46th Report of the Commissioners of His Majesty's Inland Revenue tor the year ended 31st March, 1903. In the former paper on this subject, of 1903, the author briefly discussed these conditions, and has but little additional comment to make. Yet one must reiterate the difficulty of proving absolutely that the use of methylated spirits is "unsuitable or detrimental." It has been done in a few cases, and one can but believe that the ventilation of this subject coupled with a sincere desire to promote British interests as far as the existing law allows, and recognition of a latitude given by the Act of 1880 (43 & 44 Vict. c. 24. s. 123. ss. 3) as to denaturing by "some other substance approved for the purpose" has contributed to such result. It is clear that the onus of proof as to "slight or immaterial advantage" is with the authorities. A case in point is that of an important manufacture which last year replied to the questions issued by the Joint Committee that in a period "5,000 galls. of methylated spirit were employed. Of that 5,000, 500 were unnecessary, being crude, unpotable wood-spirit, which was positively harmful, giving a tint to the British product which prevented its extended sale, and throwing some proportion of business into the hands of foreign competitors." Upon representations under the concessions of the Excise under the Finance Act, 1902, the manufacture in question is now conducted with a spirit suitably denatured. A considerable increase of business, involving a very considerable increase in the use of that spirit, has resulted. In this case supervision exists, for three excise officers are employed at a total cost of about 400*l.* a year. Convenient and suitable lodging has been provided. No interference with processes or limitation of hours takes place, and the Finance Act of 1902 is acclaimed a benefit. This case is a practical comment on the reply of the Chief Inspector and Dr. Thorpe to the deputation of the Joint Committee some time ago and on the official Memorandum specially quoted last year as to denaturing. The industry is large and special. The denaturing agent is not prejudicial in any way to the manufacture. The supervision is complete, and can be borne. In this connection a trade journal stated that the manufacture of a now dutiable article—saccharin—is now carried on here, under supervision, and with no inconvenience whatever. The results increase trade. Another case exists, in which fulminate of mercury is now made with a suitably denatured spirit. Concessions for using methyl alcohol were made to more than one British manufacturer, which differed but little from the freedom of their foreign competitors, but considerations altogether dissociated from the duty or supervision prevented them being utilised. In this connection one is informed that enquiry was, and is, being pursued as to the use of *absolute* alcohol, duty-free. It is known that enquiries are at this time being made under the Act for suitably denatured spirit by an artificial silk company and by a great industrial corporation. A case of refusal is known, where the conditions of magnitude, of wealth and necessity exist, namely, in the application of perfumes to soap. We regret the official refusal, but we hope for the best. One is—with Sir Wm. Ramsay last year—not delighted to learn that alcohol in quantity, if at all, is not made in this country. It cannot be made except under the licence of a compounder and rectifier, and under the working conditions of such licence as laid down in the Act of Parliament of 1880. Now, why cannot one of the British licensed rectifiers make alcohol? Surely the operation is not beyond his skill, certainly not his means (for the distiller's riches are popularly supposed to be beyond the dreams of avarice). Squibb at least has taught some of us a good deal about absolute alcohol, and scientific fractionation is not a lost art, as Dr. Sydney Young has indicated in valuable papers to the Chemical and other societies. It must be the small quantity—trivial when compared with the millions of gallons at proof; but after all it is about 25 tons, surely not too small a quantity for one distiller, by arrangement with his fellows, to produce, and when spirit is to-day cheaper in England than in Germany. We may quote an official reply to an enquiry on the subject.

"It will be observed that these provisions of the law do not in any way prevent the production of absolute alcohol in the United Kingdom, but that they merely confine such production to certain specified classes of persons. The Board are not given any discretionary power in the matter, and they feel, therefore, that they would not be justified in allowing any departure from the Act.

"If the persons who are authorised to produce pure alcohol in the United Kingdom do not find it worth their while to do so, the reason must, in the opinion of the Board, be sought, not in any restrictions imposed for the security of the Revenue, but in the insignificance of the demand for the article in this country."

The Spirits Act, 1880, Part I., section 5, clause 7, says:—

No person may, without being licensed to do so, or on any premises to which his licence does not extend,—

(*a*) have or use a still for distilling, rectifying, or compounding spirits; or

(*b*) brew or make wort or wash, or distil low wines, feints, or spirits; or

(*c*) rectify or compound spirits.

Clause 2.—If any person contravenes this section he shall for such offence incur a fine of 500*l.*, and all spirits, and vessels, utensils, and materials for distilling or preparing spirits in his possession shall be forfeited.

By section 8 (1) "A person shall not have a licence to keep a still of less capacity than 400 gallons unless he has in use a still of that capacity or produces to the Commissioners a certificate, signed by three justices for the county or place, that he is a person of good character and fit and proper to be licensed to keep such a still, and that the premises in which he proposes to erect the still and of which he is in actual possession are of the yearly value of 10*l.* at least." Under licence surely there can be no reason why a chemical manufacturer should not make absolute alcohol from duty-paid spirit; but according to this Act he may not.

It is said that the over-production of spirit from grain for whisky resulted in the shutting down of some Scotch distilleries whose supply would have drenched the London markets to ruination point—hence cheap spirit. Over-production always effects something of the kind, and it would be well if this capacity for over-production was considered by both the distiller and the Excise—and the Board of Agriculture of Great Britain and Ireland too—from the industrial point of view. Encouragement of British manufactures will go a long way to make supply and demand equal, and, if the facts are as stated and commonly believed, there is in them a convincing case for the exemption of the *British* surplus from the differential duty on spirit for selected manufacturing purposes. It was said by Mr. John C. Umney last year, in reference to the differential duty, "that it is a form of compensation." Undoubtedly it is, and of the nature of a bargain for hindrances to free working imposed by law. Mr. Umney intimated that we had better do away with the distiller, who wanted compensation, so that we get duty-free alcohol for industries. He probably said more than he meant, for he, as an industrial, would be no party to killing a cognate industry. But the conditions may without difficulty be altered, and, while retaining that protection as against the usually cheaper conditions of foreign production, free our distilling industry from hampering restrictions as to production. There is no question of the growing importance of the use of alcohol for motors. Suitable petroleum is said to be a diminishing quantity, and the use of alcohol on the Continent lends force to the opinion that the distiller may look favourably in this direction for an outlet. This may well form the subject of a useful paper; in fact it will.

One intended to describe and discuss the conditions of Continental distillation, material, plant, and supervision. These were indicated sufficiently in the former paper, to show that they were not beyond the possibility of imitation in Great Britain and Ireland; but Dr. Squire has expressed his intention to deal with "Distillery Systems"; and at an early date we may expect, from his expert knowledge and skill, much information as to—

(*a*) A change in the mode; processes of fermentation and distillation, with perfect freedom as regards "residuals."

(*b*) An extension of materials in the direction of both cheapness and nature.

Suffice it here to state that the production of spirit from materials such as potatoes, &c., cannot be effected by rectifying apparatus of the Coffey still type; hence a difficulty as to a form of plant which is an exceedingly expensive apparatus to scrap without adequate cause. Perhaps there is no need now to further pursue the arguments, but it is clear that the reply to the Somerset House deputation quoted last year anticipated the Finance Act of 1902, and undoubtedly definite action has resulted; methylation has received wider application, and more widely still may it be with the illustrations then given of denaturing agents. Consideration has been given to the possibility of manufacturing, not any or one special substance, such as those instanced, but the large class of medicinal, pharmaceutical, and photographic products now chiefly made abroad. Syndicated or combined manufacture, under reasonable supervision, was referred to because of the definite terms of the official memorandum. We were seeking to add to the uses for spirit; we admitted that the probable dimensions of these industries could not be stated, but the known extent of increasing applications and of imports provides a sufficient argument against their "trivial importance" or "as in the purely personal interest of individuals" (we quote from the Official Memorandum). Now collectively the value and quantity is considerable. Some values are now less, owing to lapsing of patents and competition between Continental rivals, chiefly in this country, which from its internal consumption, but more because of its free position as an exporting centre. New products are week by week being patented (and protected from being made, under our illogical laws) and registered, in the production of very many of which alcohol in some form has been used, either chemically or physically. If "magnitude" is a factor, here is that element in force, and we may boldly claim that "the magnitude and importance" of industrial enterprise in colouring matters and artificial dyestuffs on the one hand, and fine chemicals and therapeutic agents on the other, is such as to give the consideration of their economic production, public interest for national trade. Conditions of unpotability, supervision, and guarantee of good faith, will be readily acquiesced in by individual capitalists where the industry is large enough, or by syndicates or companies where co-operation is desirable. The authorities need have no fears on these points.

Now, by implication, "no recovery of spirits or redistillation can be allowed." This is an impossible condition —for two reasons: first, it is economically unsound; second, waste must be allowed for, as in the drawback on manufactured spirituous preparations, where the allowances are: (*a*) The duty on alcohol per proof gallon. (*b*) The differential duty of 5*d.* per proof gallon. (*c*) An allowance for waste in production, which has been ascertained by actual working by excise examination at the works of producers. (*d*) A margin for error in estimation or assay. Here we have precedents on all points. On the Continent, we repeat, the supervision and control is effective, and we submit that, given guarantees by respectable people and necessary oversight, for which a large single industry or a composite one can probably afford to pay, the question of difference in values in spirit on the Continent should not be raised as almost the one and only answer. We referred in our first paper to the position of the distiller, and we submit that it is not at this moment a question of over-production, but of absorbing the surplus for industries—not for drinking; and we urge that the quantities required for *bona fide* manufacturing should be free from two loads—one the duty itself. Second, as regards the quantity employed, in industries, of the differential duty. It may be admitted that there is no pressing need for anything cheaper than the existing methylated spirit for many purposes, such as polish, &c.

This great economic question presses as severely in our New York Section, which is at present co-extensive with the United States of America. The movement in America for duty-free alcohol has gained in force; but one does not claim freedom here for such a range of products as our friends desire, many of which would be classed as polish, lacquer, varnish, &c.

> In support of the Bill these manufacturers claim that the use of alcohol in the industrial arts is only limited by its cost. The number of articles of which it is an important element in their manufacture are too numerous to be given in detail.
>
> Alcohol is also used in automobiles, yachts, launches, and for small power plants: in rural and farm engines and motors for all purposes: for heating and lighting; for preserving and a large number of domestic uses; for massage, medicinal, and many other purposes
>
> Alcohol, if free from tax, could be used with advantage as a preservative of food products in their fresh state, such as fruits, nuts, meat, &c., in a manner similar to the effect of cold storage.
>
> Further, this agent could be made use of with great economy for the purpose of evaporating moisture in general industrial pursuits where the vacuum pan is used, such as in the manufacture and refining of sugar, the condensing of milk and other similar liquids, and in the manufacture of chemical salts and many other substances in the heavy chemical lines.

They ask for a drawback on exportation, so that they may have an outlet for their ever expanding production, and as an offset against their comparatively high internal duty. Is it improbable that for some of these purposes no relief will be granted? Yet it is quite odd to read how our friends assume that Great Britain has manufacturing facilities in common with Germany, France, and Russia: they credit this country with the advantage of methylated spirit, which they have not. In fine and pharmaceutical chemicals their troubles are similar to ours. They cry out for opportunities for export trade and a bigger share in the world's commerce, and the chances are they will get facilities in cheap spirit and drawback on products exported sooner than we shall.

A United States trade organ says:—

> "The failure of the Ways and Means Committee to make a favourable report upon the Joy Bill reducing the tax on alcohol to 70 cents per gallon was not a surprise to those who were familiar with the situation. The committee was practically pledged at the beginning of the last session not to report any revenue legislation, the intention being to carry the whole question over until the Fifty-eighth Congress. The demand for cheaper alcohol, however, has been general, and the work done in its behalf so effective that it is safe to say that four-fifths of the members of the next House of Representatives now stand committed in writing to a reduced tax, a majority favouring the 70-cent rate. Hand in hand with the effort to secure a lower tax on distilled spirits will go a movement for free alcohol in the arts, and it can be stated positively that the outlook for success is better than at any time since these important questions were first broached in Congress. As heretofore stated, the Ways and Means Committee to-day stands ready to permit the use of domestic alcohol free of internal revenue tax for the export trade as an independent measure, and it is believed that this concession will be much broadened in scope during the coming Congress."

So late as January of this year a report appeared in a United States trade organ of the text of the Bill to provide untaxed denatured alcohol. We quote it:—

> Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled. That distilled spirits of an alcoholic strength of not less than one hundred and

sixty per centum proof, as defined by sections thirty-two and forty-nine of the Revised Statutes of the United States, may, when rendered unfit for drinking purposes, or for use as a beverage, be removed from distillery warehouses free of tax under such regulations as the Commissioner of Internal Revenue, with the approval of the Secretary of the Treasury, shall prescribe: Provided, That sulphuric ether, wood alcohol, methylic alcohol, wood naphtha, or other substances approved by the Commissioner of Internal Revenue and the Secretary of the Treasury, shall be mixed with such distilled spirits so as to render the same unfit for drinking purposes, or for use as a beverage.

Sec. 2. That distilled spirits, before being removed from distillery warehouses free of tax under the provisions of this Act shall be marked or branded as the Commissioner of Internal Revenue, with the approval of the Secretary of the Treasury, shall prescribe, and shall have affixed to each cask or package an engraved stamp indicating that such distilled spirits have been rendered unfit for drinking purposes, or for use as a beverage, said stamps to be provided and furnished by the several collectors as in the case of other stamps, and to be charged to them and accounted for in the same manner; and for the expense attending the providing and affixing of such stamps, ten cents for each stamp shall be paid to the collector of the district on making the entry for such removal.

Sec. 3.—That any person who shall rectify or purify distilled spirits which have been removed from distillery warehouses free of tax under the provisions of this Act, by removing or separating the sulphuric ether, wood alcohol, methylic alcohol, wood naphtha, or other substances from such distilled spirits, by any process whatever, shall, on conviction, be subject to a fine of not less than five hundred dollars nor more than five thousand dollars, and be imprisoned not less than six months nor more than three years.

Sec. 4.—That distilled spirits, removed free of tax from distillery warehouses under the provisions of this Act, shall not be stored or deposited on any premises in which the business of a distiller, rectifier, wholesale liquor dealer, or retail liquor dealer is carried on, or on any premises connected therewith by any private or internal communication. And every distiller, rectifier, wholesale liquor dealer, and retail liquor dealer who shall store or deposit, or cause to be stored or deposited, such distilled spirits on the premises in which such business is carried on, after such distilled spirits have been removed from distillery warehouses, shall, on conviction, be fined not less than two hundred dollars nor more than one thousand dollars, and imprisoned for not less than six months nor more than two years.

The organisations of farmers throughout the country, and especially the big Granges of the middle and far West, have been prompt to see the importance to them of the adoption by the Government of a liberal alcohol policy, and are already petitioning Congress in behalf of the Boutell bills, which reduce the tax on pure spirits from 1·10 dols. to 70 cents per gallon and grant free denaturised alcohol for use in the industrial arts.

The important interest which the farmer has in this question, and which will make him the strong ally of the manufacturer in this campaign, is succinctly set forth in a memorial just received by the Ways and Means Committee, which is in part as follows:—

> "The lack of any provision in our revenue laws for the use, free of tax, of alcohol which has been rendered unfit for drinking purposes is an injury to the American farmer, restricting his markets, lessening the selling price of the largest crop, increasing the cost of living, and preventing him from enjoying the benefits to be derived from the general use of alcohol in the domestic and industrial work of the farm.
>
> "We would ask your especial attention to the highly successful operations during a period of nearly 20 years of the liberal legislation relating to the alcohol now in force in Germany. In that country, under laws providing for untaxed denaturised alcohol, that is, alcohol mixed with some noxious substance so as to render it unfit for use as a beverage, about 60,000,000 proof gallons of tax-free alcohol are annually used for industrial purposes. All the materials from which this great quantity of alcohol is produced are grown by German farmers, who also benefit by the opportunity to secure cheap fuel, light, and power for farm machinery, &c.
>
> "We are confident that the proposed system would work equally well in this country, and that the consumption of alcohol for manufacturing purposes and as a motive power would be so greatly increased as to create a new market for many millions of bushels of corn annually. The low price at which untaxed denaturised alcohol, suitable for use in lighting, heating, and as a motive power, would be furnished would greatly benefit the farmers of the whole country, apart from their special interest as the producers of the material from which alcohol is distilled.
>
> "We would also submit that the farmers are directly injured by our antiquated laws relating to alcohol through their effect in checking our export trade in many articles in the manufacture of which alcohol is an important material. Germany practically controls the export trade to neutral markets in all articles of this kind, our manufacturers being unable to compete successfully, owing to the prohibitive cost of their alcohol as compared with that of their German rivals. The result is that millions of dollars' worth of goods that should be made in this country are now made in Germany, the German workers who make these goods buying the products of German farmers. Under the proposed changes in our laws, American workmen would make these goods, and would buy the products of American farmers.
>
> "Believing that this is a matter of far-reaching importance to the farming interests of the country, and that the enactment of the proposed legislation would be of very great benefit to them, we would ask that you favourably report House Bill 9302, so that it can become law at the present Session.
>
> "The German farmer not only has this market for his produce, but, in addition, untaxed alcohol gives him cheap light, heat, and power. The German farmer lights and heats his house and buildings, cooks his food, threshes his grain, runs his creamery and machinery for other purposes, and markets his products in a motor waggon, all with alcohol.
>
> "If the German farmer, why not the American farmer? The only obstacle is the United States internal revenue tax, which makes alcohol artificially dear to both the American farmer and manufacturer, thereby prohibiting its use."

The oddest thing about the matter as affecting the States is that the opposition is a "women's temperance" affair, and probably the influence of this body of "enthusiasts" has been very great. This on the authority of the esteemed chairman of our New York Section, Prof. Coblentz, whose paper in this month's Journal on "Newer Remedies" is timely for our contention.

A consideration of profound importance arises. If now Germany competes under conditions such as we ask for, and America obtains them in the near future—and both are protected countries, with facilities for drawback on exportation—where does Great Britain come in? This is not a "fiscalitis" meeting, but it is obvious and logical, whatever becomes of home supplies, that existing Acts, notably the Customs Consolidation Act of 1876, involving duties, must have consideration as regards the scope of their operation. We quote the clauses of the Acts again:—

Customs Consolidation Act, 1876 (*not repealed*).

Appendix 39th and 40th Victoria, Chap. 35.

"Goods not prohibited to be imported into or used in Great Britain and Ireland, composed of any article liable to duty as a part or ingredient thereof, shall be chargeable with the full duty payable on such article, or if composed of more than one article liable to duty, then with the full duty payable on the article charged with the highest rate of duty."

"Upon the importation into Great Britain and Ireland of any articles in the manufacture of which spirit has been used, there shall be charged in respect of such quantity of spirit as shall appear to the satisfaction of the Treasury to be used in the manufacture of such articles, a duty equivalent to that which would be chargeable on the like quantity of spirit on its importation into the United Kingdom."

Note also—Finance Act, 1902, *Chap.* 7, *Part I.*, *Sec.* 7.

"Where any manufactured or prepared goods contain, as a part or ingredient thereof, any article liable to any duty, customs duty shall be charged in respect of such quantity of the article as shall appear to the satisfaction of the Treasury to be used in the manufacture or preparation of the goods, and in the case of goods so containing more than one such article, shall be charged in a similar manner on each article liable to duty at the rates of duty respectively applicable thereto, unless the Treasury shall be of opinion that it is necessary for the protection of the revenue that duty should be charged in accordance with the Customs Tariff Act, 1876."

"Any rebate which can be allowed by law on any article when separately charged shall be allowed in charging goods under this section in respect of the quantity of that article used in the manufacture or preparation of the goods."

The principle of duty *pro rota* is no new one. As regards obvious spirituous preparations there can be no doubt. Examination is not a novelty. In 1902 156,987 samples of wines, spirits, and compounded spirits were examined, besides innumerable other things—tea, chicory, sugar, tobacco, &c. Parenthetically it may be stated that 972 samples of wood naphtha, for methylating, representing 381,509 galls., were examined at the Government laboratory. Of these 36 samples, representing 14,231, were rejected as unsuitable. So also for the benefit of traders and others the methods employed for determining the amount of alcohol in medicinal preparations, essences, and perfumes has been published in the Journal of the Chemical Society, 1903, p. . So again, and notably, 26 samples of special "petroleum ether" for use in certain manufacturing operations in conjunctio with methylated spirit were also examined. 25 samples representing 1,032 galls., were approved.

The quantity in proof gallons of foreign plain spirit (or "unenumerated, not sweetened," as it is classed) cleared for home consumption in 1902—1903 was 1,629,924, duty 888,729*l*. Of this quantity 1,196,711 were for methylating, under a duty of 23,661*l*.

It should be remembered that in consequence of the imposition of the corn duties the Finance Act of 1902 placed an additional duty of 1*d*. per gallon upon foreign spirits other than rum and brandy, as from the 17th June 1902. The spirit duties are based upon a rate of 10*s*. per proof gallon on home-made spirits, to which there had been added a surtax of 4*d*. per proof gallon on imported spirits. In 1890 6*d*. per gallon was added for certain purposes connected with local taxation, and in 1900 a further 6*d*. was added for the expenses of the South African war. Spirits imported in bottle, other than unenumerated unsweetened spirits, were subjected to an additional duty of 1*s*. per proof gallon in 1899.

One may remark that for spirit which would here be classed as methylated, in Germany and Switzerland the price is at least 40 per cent cheaper; therefore, on the quantity indicated they pay 14,197*l*., as against our 23,661*l*. Molasses figure in the returns as freed from duty in accordance with the provisions of the Finance Act, 1902, to the extent of 445,283 cwts. (see 47th Report of Customs), surely a concession to an industry protected somewhat already. It is stated that there is available a very large quantity of molasses—practically for the getting. Thus drawback is familiar to the revenue departments, on substances for internal consumption in a degree, but vastly more so on exportation. Beginning with cocoa, chicory, and ending with wine, the returns naïvely put the "total amount of duty that would have accrued thereon" as 5,724,764*l*.—so that for reasons, presumably for excellent reasons, this concession is made, and among the substances are manufactured goods; of course the majority are for re-exportation. Drawback repayments, &c., are nothing new, and they amount to 1,337,225*l*. for 1903 (47th Customs Report), and this out of a gross aggregate of total receipts, 35,798,095*l*. Including the amounts collected on behalf of the Inland Revenue Department, the Customs collected 39,785,212*l*., and the net produce, after deducting drawbacks, &c., was 38,746,339*l*., at a cost of 954,608*l*., equal to 2*l*. 8*s*. 0*d*. per cent. on gross, or 2*l*. 9*s* 3*d*. per cent. on the net. In 1894 the gross was 23,168,696*l*. net, after drawbacks 22,979,183*l*.; at a cost of 3*l*. 17*s*. 3*d*. and 3*l*. 17*s*: 9*d*. respectively. These figures are quoted to show that the cost of doing work by this able department has not increased with the increase, and stress is laid upon the fact in case the Customs Consolidation Act, 1876, should be put in force upon importing a further selection of articles alcoholic in themselves, or containing ethyl or methyl radicles, or in which these alcohols have been employed in their production. The list now is not extensive, and is quoted here, but it is clear that, in view of existing and increasing and possible competition from other quarters, action may have to be taken. No departure from principles already acted on is involved, only their extension—internally on the one hand and externally on the other. If by adequate concessions internally we can compete fairly; if not by these, then externally, to the extent of refund or drawback. In either case, neither manufacturers nor officials will, we feel sure, flinch from the labour imposed. But it surely is the patriotic way to promote internal industry.

Confessedly the task of the Government Chemical Departments, now united in one staff and head, will not be light or easy, but it may rely upon the honest and intelligent, if interested, assistance of the manufacturers of the country. The distilling industry, somewhat nurtured in the atmosphere of restrained privilege, will, we are sure, not be less patriotic than its fellow countrymen. The Excise can, if it will, indicate what restrictions—admittedly necessary in 1880—can now be dispensed with.

A quotation from Scarisbrick's "Spirit Manual" may be useful at this point:—

"The distiller was required to produce 1 per cent. at proof for each 5° attenuated in the case of wash from grain or potatoes, and for each 4 in the case of sugar wash.

"The use of mangold wurtzel in preparing wort was sanctioned in 1833,[*] the old regulation still being continued that no two kinds of material (except malt and unmalted corn) were to be used in combination. This restriction was justified by the fact that worm-ends and spirit store were open and under the distiller's absolute control. The subject was pressed on the attention of the country in 1846. It was found that the restriction to use only one class of material at one time, together with the exaction of a Customs duty on sugar, virtually prohibited distillation from any material except grain. This attracted attention, owing to the complaints of West Indian planters, who happened to be the largest sugar producers. They strongly urged the impolicy and injustice of excluding their produce from the breweries and distilleries of this country, and it became a question of moment to determine whether the use of sugar and molasses, mixed or unmixed with other materials, could be allowed without impairing the security of the revenue. Experiments for this purpose were commenced by Messrs. Dobson and Phillips, in the Excise laboratory, where the comparative values of barley, malt, sugar, and molasses to the distiller and brewer were accurately ascertained. An Act[†] was therefore passed in 1847 authorising the use of sugar in distilleries, with drawback of the Customs duty, excepting so much as would be sufficient to countervail the duty on the small quantity of malt necessarily used by distillers. In the following year molasses and treacle were allowed.

"As the trade wished an allowance for deficiencies in spirit store, it was found necessary, in 1853, to insist upon the worm-end being enclosed, and the stock placed under the officer's control.[‡] Decreases from natural waste, filling, &c., not exceeding 1 per cent., were then exempt from duty. The contents of casks were to be determined by gauge or weight, and the distillation process of determining original gravity of beer was extended to distillers' wash. In 1855 all materials were allowed to be used duty free, thus ending the frauds in connection with the drawback on materials. The duties in England and Scotland were equalised in 1856, and in the United Kingdom in 1858, the rate being 8*s*. per proof gallon.

"Owing to the higher character of the trade, and the revenue safeguards furnished by closing the worm-end, and the system of determining original gravities, the time had come for concessions. It was considered safe to abolish the following prohibitions: (*a*) against grinding malt with stones; (*b*) use and sale of yeast; (*c*) continuous running of common stills. It was also found that the following could be granted without impairing revenue security: (*a*) giving up the annual balance account; (*b*) larger allowance for waste in warehouse; (*c*) greater facilities for obtaining remission of duty on spirits lost by accident; (*d*) dispensing with certain regulations which increased the expense of making malt for distilling purposes; (*e*) allowing the use of any materials in making wort, provided gravity of extract could be obtained by saccharometer; (*f*) 2½ per cent. yeast to be removed from wash; (*g*) beginning of brewing period as soon as last back of preceding period removed to wash-charger; (*h*) removal of spirits from receiver when depth amounted to 15 ins.; (*i*) limit of decrease in store raised to 1½ per cent.

[†] 10 Victoria, c. 6.

[‡] 16 and 17 Victoria, c. 37.

"These were embodied in an Act of 1860,* which consolidated the spirit laws of the United Kingdom and removed any restriction not absolutely necessary to secure the revenue. Their being granted enabled the distillers to compete with foreigners on terms of greater equality, and thus merely carried out Free Trade principles to their logical conclusion.

"Besides settling the question of restrictions, the Act also dealt with another important matter. It became known in February 1860, from the Chancellor's financial statement, that, owing to the commercial treaty with France, foreign spirits would be admitted for consumption into the United Kingdom at the same rate of duty as British spirits *plus* a small surtax of 2*d.* per gallon—same as that charged on Colonial spirits imported from 1848. The distillers became alarmed, as 2*d.* per gallon was considered an insufficient compensation for the disabilities under which they laboured. Deputations represented trade views to the Government, and put forward certain claims. It was admitted by the Board of Inland Revenue that Excise restrictions increased the cost of manufacture by 5½*d.* per gallon. There was also a claim made on account of the difference in the mode of charging duty on foreign spirits, which obtained in the Customs, said to favour importers to the extent of 4*d.* per gallon. The full claim would not, therefore, have been met by a lower differential rate than 9½*d.* per gallon.

"The restrictive operation of Excise regulations was modified by abolishing the prohibitions already detailed and granting the concessions enumerated, with the net result that 5*d.* per gallon was considered sufficient to meet trade claims.

"Distillers and rectifiers had established the fact that restrictions caused a loss of 2*d.* or 3*d.* per gallon, and naturally considered that they had a claim to allowance on exporting, so that they might compete with foreign distillers in Colonial and other markets. By resolution of the House of Commons, on 5th March, export allowances of 2*d.* per gallon on plain spirits and 3*d.* on compounds were granted, the duty on British spirits being raised 1*d.* per gallon, to make up for the decrease thus caused in the revenue. The surtax on foreign spirits was imposed at 5*d.* per gallon, and that on Colonial spirit continued at 2*d.*

"The claims advanced and allowed are shown in the following schedule :— *

	1860. Amount claimed by		Amount allowed in 1860.	1860. Considered by the Inland Revenue Board to be admissible.	
	Scotch Distillers.	English Distillers.		For Uncoloured Spirits.	For Coloured Spirits.
	d.	*d.*	*d.*	*d.*	*d.*
1. Compensation for duty on foreign grain	0¾	0¾	0¾	0¾	0¾
2. Prohibition against brewing and distilling at same time	1½	1½	1	1	1
3. Against distillers mixing worts in several vessels while in process of fermentation	0¼	0¼	0¼	0¼	0¼
4. Loss of duty on rectification and flavouring spirits in separate premises	3	3	1	2¼	2¼
5. Colouring matter in foreign spirits	2	2	2	Nil	2½
6. Increased expense in making malt consequent on Excise restrictions	0¾	0¾	Nil	Nil	Nil
7. Difference in mode of charging duty in favour of foreign spirits	1	1¼	Nil	Nil	Nil
8. Duty evaded upon foreign spirits, and by samples drawn in bond	0¼		Nil	Nil	Nil
	9	9½	5	4¼	6¾

"The estimate of 1*d.* per gallon in the second item of the schedule was in respect of extra cost, owing to plant lying idle, repairs, lighting, coal, wages, &c. In the fourth item 1¼*d.* was considered an equivalent for the waste which occurs in rectifiers' stocks from the time of delivering spirits from the distillery until they reach the consumer. The loss is supposed to be 1 per cent.; the other 1*d.* is on account of being bound to use separate premises for rectifying, thus incurring expenses of rent, plant, cartage, wages, &c. The seventh item was found to be groundless. Experiments were made with a large number of consignments of foreign spirits, and it appeared that the Customs charge was rather above than below that of the Excise.

"Since 1860, the changes have been few and unimportant. They include (*a*) increased percentage of yeast allowed to be taken from wash; (*b*) shortening of interval between brewing and distilling periods; (*c*) extended range of warehousing strengths; (*d*) repeal of limitation as to smallest still being 40 gallons; (*e*) concessions in respect of bub, use of spent wash, yeast pressings, &c. The spirit laws were again consolidated in 1880 (43 and 44 Victoria, c. 24)."

We think we have made out a case, stated thus in our former paper:—(*c*) A rebate of surtax to distillers for spirit destined and *certified for certain uses in a "licensed" and approved factory, and consideration for inevitable loss in manufacture.* (Remembering always that the *present* output will not be affected.)

It may be desirable to state what has been done to expedite this matter since the passing of the Finance Act, 1902. The Associated Chambers of Commerce passed a resolution (this Journal, 1903, 286). The Manchester Chamber, acquiring precedence, drafted a memorial to the late Chancellor of the Exchequer, in accordance with practice of the Chambers. In this memorial, reading as follows :—

Manchester Chamber of Commerce.
1903.

SIR,

I AM instructed on behalf of the Association of Chambers of Commerce of the United Kingdom to invite your attention to the serious disability imposed upon chemical and other manufacturers who use imported pure spirit as a raw material of their industry by Section 8 of the Finance Act, 1902.

The section provides that such spirit "may not be received or used until the difference between the duty of Customs chargeable thereon and the duty of Excise chargeable on British spirits has been paid."

The "difference thus prescribed to be paid, though apparently small, is in reality a differential duty which constitutes a special and repressive charge on certain British industries from which their foreign competitors are entirely free." The consequence is that the production of perfumes and of some pharmaceutical requisites, which has attained important dimensions on the European continent, is effectually kept in check by this duty in the United Kingdom. The manufacture of perfumes by chemical process is rapidly superseding the extraction of them from flowers, and this new and profitable industry cannot become an important one in this country so long as the disability remains.

So urgent has the question of its removal become, that at the annual meeting of the Association of Chambers of Commerce, held in London in March last, the following resolution was unanimously adopted :—

"That the provision of Section 8 of the Finance Act, 1902, requiring the payment of duty on imported pure spirit for manufacturing purposes at a rate equivalent to the difference between the Customs and the Excise duty on spirit, adds about 50 per cent. to the original value of such spirit, and that this addition places British manufacturers who use it in a position of serious disadvantage in relation to their continental competitors, who are able to purchase it entirely duty-free; and that representations be made to the

---

* 23 and 24 Victoria, c. 114.

* Twenty-eighth Report of Commissioners of Inland Revenue.

proper Governmental Department with a view to the removal of this disadvantage."

In pursuance of this resolution, I am respectfully to urge that you will, at the earliest possible opportunity, take such steps as may be necessary for relieving the industries in question of this respective burden.

I have the honour to be,
Sir,
Your most obedient Servant,
EDMUND W. FITHIAN.
Secretary.

Rt. Hon. C. T. Ritchie, M.P.,
Chancellor of the Exchequer.
The Treasury, London.

Reference to "perfumes" is made. A correction suggested at the time appears to have escaped attention, for the word "synthetic" was inserted before "perfumes" in the third paragraph. Mr. Ritchie's reply, through the secretary, was as follows:—

Treasury Chambers.
Whitehall, S.W.,
25th August 1903.

SIR.

THE Chancellor of the Exchequer has under consideration your letter of the 4th instant and the resolution contained therein, which was passed by the Association of Chambers of Commerce last March, on the subject of the duty on spirits used in manufactures, and especially in the preparation of perfumes, &c.

He does not altogether understand the reference in your letter to Section 8 of the Finance Act, 1902, inasmuch as the provisions of that section have not as yet been applied to the manufacture of perfumes: nor does he understand how the manufacturers of perfumes in this country are subject to any disability either in the home or in the foreign market, as competing perfumes from abroad are liable to Customs duty on importation here, and when perfumes made at home are exported a full equivalent of duty paid is given in the shape of drawback or allowance.

Mr. Ritchie does not think that it will be practicable to abolish the differential duty on spirits used in manufactures, nor would it be equitable to the home producers of spirits. He proposed to remedy certain anomalies in this connection in the Revenue Bill which has just become law: but the clause on this subject unfortunately met with opposition, and it proved impossible to carry it through Parliament.

I am, Sir,
&c., &c.

Now it is quite clear that the Chancellor's reply as regards perfumes is right, and fulfils all the conditions we desire. "Compounded perfumes" ready for sale were not meant, but "synthetic" perfumes, such as we saw under Mr. Gordon Salamon's guidance at Courbevoie on our visit to Paris in 1900. As regards the "differential duty," we agree that as then advised the Chancellor had little choice. Things have changed, and we think a powerful case is made out for consideration, but we should like to know about the opposition to the correction of "anomalies"—what the anomalies were, and who opposed. We have unsuccessfully tried to discover; we shall yet know. Pursuing our enquiry as to what has been done, the committees have conferred jointly and separately. It was suggested by Mr. Umney to ask members to set out the actual amount of ethyl and methyl entering into the composition of certain typical bodies much in demand, upon which, under the Customs Consolidation Act of 1876, duty would have been imposed on entry into this country, but which the present general conditions of trade have made it necessary should not be imposed, but rather, preferably, in order to protect the trade of the country, should be made capable of being produced from duty-free alcohol. Also, to set out the amount of alcohol wasted.

The queries were set out as upon a 100*l*. value—some replies have been received, not all upon values, and are tabulated:—

TABLE I.

Contributed at the request of the Joint Committee by A. G. Green, Professor of Tinctorial Chemistry, Yorshire College, Leeds.

Name of Dyestuff.	Percentage of Methyl Alcohol.	Percentage of Ethyl Alcohol.	Price per Lb. (Wholesale for Pure Product.)	Unpaid Duty per £100 Value.	Estimated Annual Imports.
			s. *d.*	£	
Malachito Green	27	..	2 3	34	10 tons

With regard to Table I. Prof. Green observes that the calculations are for the *pure* dyestuffs and that some brands of the commercial dyestuffs are more or less diluted with dextrin, salt, &c. Also that there would in addition be a considerable loss of alcohol in the process of manufacture. Prof. Green reminds us that while the calculations are for the most important brands—and these brands vary—hence the alcohol requirement will vary. Further, one alcohol may be substituted for another. For example Auramine O contains methyl groups, Auramine G ethyl groups. Roughly speaking the alcohol tax would vary from one-fourth to one-half of the dyestuff. Methyl alcohol is more important than ethyl alcohol in colour making. It must be remembered that methyl alcohol is dutiable to the same extent as ethyl alcohol, and is intrinsically dearer.

A case is given by a member of gingerine, which may be extracted with methylated spirit; but, assuming duty paid spirit to be employed, 48*l.* per 100*l.* value would go in duty, as against probably only 4*l.* in Germany or Switzerland.

Take the case of rebate on methylated spirit on exportation—3*d.* per proof gallon. Why cannot the exporter of home-made ether or chloroform get a rebate of 3*d.* per proof gallon on the quantities of methylated spirit used?

The comparison between production with duty-free spirit and taxed spirit is convincingly shown by Table II., and examples, most kindly placed at disposal by Mr. P. Leuthardt-Thornton, and who alone is responsible for them.

The spirit value of Table II. is based on 2*d.* per lb. of German or Swiss spirit, 95 per cent. by weight, in 1900. British spirit of same strength and date at 2*s.* 0½*d.* per lb. The writer may point out that to-day, 1904, 95 per cent. by weight alcohol is about 2*s.* 7*d.* per lb., so that the values of British spirit, duty-paid, required would be considerably enhanced.

For a rough calculation of the resultant at 2*d.* per pound of 95 per cent. spirit abroad in 1900 is multiplied by 12·50, an approximation to the British spirit equivalent will be arrived at.

Excepting Rhodamine B, G and 6 G (Table III.), all the other products of this group are sold as "Rhodine."

TABLE III.

Bulk of spirit used in manufacture, without deductions. Read figures as so many pounds.

ALCOHOL, 1900.

The quantities here given have been actually employed in manufacture, the prices being those ruling in 1900:—

Alcohol 95 per cent. at 2*d.* per lb.
Alcohol 100 per cent. at 2·2¼*d.* per lb.
Methyl alcohol at 6·5 per lb.
Alcohol 95 per cent. is generally used, also in some cases alcohol 100 per cent.

1,345 lb. alcohol 100 per cent. require—

	1,762 lb. alcohol 95 per cent.,
of which are returned...	323 lb.
or nett	1,439 lb. at 2*d.* = 11*l.* 19*s.* 10*d.*

1 lb. alcohol 100 per cent. therefore costs 2·14*d.*

Antipyrine.

(*a*) 4,0[illegible]8 lb. acet. acetic ester require—

12,540 lb. acetic ester.
2,200 lb. being returned.

nett 10,340 lb. at 55 per cent. alcohol 95 per cent –	5,687 lb.
less returned	3,300 lb.
alcohol 95 per cent. used nett....	2,387 lb.

or for 1 lb. acet. acetic ester, 0·595 lb. alcohol 95 per cent.

(*b*) 1,044 lb. bromester require 522 lb. ethyl alcohol, or for 1 lb. bromester, 0·5 lb. ethyl alcohol.

(*c*) 4302 lb. quinizine base require—

3,740 lb. acet. acetic ester, at 0·595 lb.	2,225 lb.	alcohol	95 per cent.
add further	2,002 lb.	,,	,,
	4,227 lb.	,,	,,
less returned.....	1,848 lb.	,,	,,
nett used.........	2,379 lb.	,,	,,

or for 1 lb. quinizine base, 0·553 lb. alcohol 95 per cent.

(*d*) 3,630 lb. antipyrine require—

4,125 lb. quinizine base, at 0·553 lb.	2,281 lb.	alcohol	95 per cent.
2,010 lb. acetic ester, at 55 per cent	1,105 lb.	,,	,,
	3,386 lb.	,,	,,

or for 1 lb. antipyrine, 0·933 lb. alcohol 95 per cent. Further—

2,310 lb. bromester, at 0·5 lb...........	1,155 lb.	methyl	alcohol.
in addition.........	528 lb.	,,	,,
	1,683 lb.	,,	,,
less—bromester returned— 112 lb. at 0·5 lb.	56 lb.	methyl	alcohol
nett used..............	1,627 lb.	,,	,,

or for 1 lb. antipyrine, 0·448 lb. ethyl alcohol.

100*l.* import value at 5*s.* 6*d.* per lb. = 364 lb., for which were employed: 339 lb. alcohol 95 per cent. at 2*d.* = 2*l.* 16*s.* 6*d.*; 163 lb. methyl alcohol at 6·5*d.* = 4*l.* 8*s.* 3*d.*

Ethyl Chloride.

3,344 lb. require 3,344 lb. alcohol 95 per cent.; 1 lb. ethyl chloride = 1 lb. alcohol 95 per cent.

100*l.* import value at 11*d.* per lb. = 2,182 lb., for which were used 2,182 lb. alcohol 95 per cent. at 2*d.* = 18*l.* 3*s.* 6*d.*

Phenacctine.

(*a*) 5,765 lb. nitrophenetol require—

2,745 lb. ethyl chloride.............	2,745 lb.	alcohol	95 per cent.
in addition.................	4,576	,,	,,
	7,321	,,	,,
less returned..............	3,850	,,	,,
nett used	3,471	,,	,,
for 1 lb. nitrophenetol	0·602	,,	,,

(*b*) 4,048 lb. phenetidine require—

5,808 lb. nitrophenetol at 0·602 lb. .	3,496 lb.	alcohol	95 per cent.
in addition................	6,098	,,	,,
	9,594	,,	,,
less returned..............	4,510	,,	,,
nett used	5,084	,,	,,
for 1 lb. phenetidine	1,255	,,	,,

(*c*) 5,214 lb. phenacetine require—

4,158 lb. phenetidine at 1·255 lb....		5,218 lb.	alcohol	95 per cent.
in addition................		10,340	,,	,,
		15,558	,,	,,
less returned:				
66 lb. phenetidine at 1·255 lb.	83			
further.................	4,620			
		4,703	,,	,,
nett used		10,855	,,	,,
1 lb. phenacetine		2,082	,,	,,

100*l.* import value at 3*s.* per lb. = 667 lb., for which were used 1,389 lb. alcohol 95 per cent. at 2*d.* = 11*l.* 11*s.* 6*d.*

Salipyrine.

330 lb. require—

211 lb. antipyrine at 0·448 lb.	95 lb.	methyl	alcohol.
1 lb. salipyrine	0·288	,,	
further, at 0·933 lb.......	197 lb.	alcohol	95 per cent.
in addition	416	,,	,,

P. Leuthardt-Thornton.

In Tables IV. and V. ordinary trade and chemically descriptive names are given—with the formula. The percentages of the equivalents of alcohol and methyl are given—by easy calculation by the factors previously given the comparative alcohol (95 per cent.) values can be approximately found. If Prof. Green's reminder and the Thornton illustrations as to returns and waste, a fair idea of our disadvantages may be gained.

TABLE IV.

Some Substances which have Ethyl or Methyl as a necessary Component.

			Percentage of Combined Ethyl as Alcohol.	Percentage of Combined Methyl as Methyl Alcohol.

Table VI. illustrates the real need for alcohol in manufacture for solution—purification and crystallisation—

TABLE VI.

A few Substances the Manufacture of which could be greatly extended by Means of Alcohol Undenatured; or, if inevitable, Suitably Denatured.

Atropine.
Aconitine.
Aloin.
Agaracine.
Berberine.
Cantharidine.
Conine.
Cannabin.
Cimicifugin.
Cocaine.
Emetine.
Ergotine.
Eucaine.
Gelsemine.
Glycerophosphates.
Hydrastine.
Hyoscyamine.
Hydroquinone.
Iridine.
Jalapine.
Santonine.

Pancreatine.
Pilocarpine.
Tannic.
Thymol.
Salicylates.
Aldehyde.
Paraldehyde.
Bromoform.
Iodoform.
Ethyl bromide.
Ethyl chloride.
Ethyl iodide.
Pure caustic.
Oleo resins.
Ethyl acetate.
Ethyl butyrate.
Ethyl formate.
Ethyl benzoate.
Chloral hydrate, &c.
Many alkaloids and fine chemicals.

Now with these illustrations, what more convincing case can we build up for official information. Our last paper grew, so to say, as the case developed, and one is glad to believe it has been of service, for many enquiries and requests for copies of the paper have been made to the writer, indicating that the question of duty-free alcohol occupied the minds and was the subject of study with the energetic and aspiring officials who looked forward to promotion, and who probably may be numbered among the technical advisers of the Board of Inland Revenue, in, we hope, the not-distant future.

You are aware that special concessions were made under the Finance Act, 1902, and at the instance of a British Association Committee, headed by our first President, Sir Henry E. Roscoe, for the use of duty-free alcohol (the differential duty excepted) in approved laboratories, universities, or colleges. A letter was sent by the author to the collegiate authorities, thus:

> "*Re* Alcohol duty-free.—In view of the further action being taken in the matter of duty-free spirit for industrial use by the joint committee of the London Chamber of Commerce and the Society of Chemical Industry, it would be of service to know—
>
> "(*a*) How the regulations work?
>
> "(*b*) Whether the facilities afforded by the use of duty-free alcohol has answered your expectation?
>
> "(*c*) Whether the researches for which it was mainly intended have been of an industrial character or tendency as is stated to be chiefly the case in Germany?
>
> "(*d*) Any opinion or suggestion for duty-free spirit for industrial use."

The replies are interesting:—

Our President, Sir William Ramsay, writing from University College says—the regulations work well. It has proved a great convenience and enables work to be done, which was formerly shirked on account of expense. The researches have not been of an industrial character, though no doubt some of them may have an industrial bearing in future. The President affirms his conviction that chemical industry would reap great gain by having duty-free spirit—and ultimately the revenue—be in no way affected, but the reverse.

Prof. Armstrong goes so far as to say that all research ultimately leads to industrial application—hence the necessity for freedom.

The Secretary, at the Examination Hall, Victoria Embankment, replies approvingly, but says that the researches there are entirely of a scientific character in regard to bacteriology and pathology

Prof. M. M. Pattison Muir writes appreciatively and says that the alcohol has been used entirely for organic research. He says it would be an advantage if chemists could work with pure ether and ethereal salts.

Prof. Dixon, of the Owens College, Manchester, agrees in every point with others, and observes that "we have not consciously aimed at any industrial application of such researches. No doubt such applications will be made." Prof. Dixon then makes a criticism of profound interest. "We are somewhat astonished at the fact that so far we have not been able to obtain pure alcohol, except from German firms. When we have bought from an English dealer, it has come from Germany."

From Balliol College Laboratory, Oxford, confirmatory approval comes, with the remark "that the experience of industrial chemistry which would make an opinion (as to question II.) of any value."

Mr. Edmund White, late head of the Pharmaceutical Department of St. Thomas's Hospital, now of Messrs. Hopkin and Williams, writes similarly to the Secretary of the Examination Hall.

Prof. Henderson, of the Glasgow and West of Scotland Technical College, writes that the regulations have given no trouble whatever, that the permission has much facilitated our work, whilst a considerable saving has been effected. As regards (*c*) he writes: "The researches we have made with the aid of duty-free alcohol have not had any direct bearing on chemical industry." Now, observe the remark, which we all shall endorse: "The manufacturers in this country, as a general rule, do not communicate any problems they meet with to those who have time and opportunity for investigation, and therefore, while manufacturers themselves often cannot tackle the subjects on which they would like research work to be done, chemists are able and willing to do such work, do not know what manufacturers want. You know," he writes, "that manufacturers in Germany make much more use of the facilities for research afforded by the University Colleges there." Prof. Henderson also cannot see why the permission to use duty-free spirit should not be extended to all manufacturers where the use of pure alcohol is essential." No, he cannot, because he scarcely apprehends the intricate condition of the case. Yet once again we urge an attitude of a bold and brave attempt by the authorities to place us speedily in a position of equality with our at once energetic, able, and scientific rivals.

Dr. T. E. Thorpe writes—

> "The subject is one in which I am greatly interested. It is, as you know, surrounded with departmental difficulties, but these difficulties ought to be made subservient to the general convenience. Public departments, after all, exist for the benefit of the public. The difficulty is that, as regards alcohol, the revenue authorities are too apt to regard it solely as potential whiskey, and not as a chemical capable of being turned to account for the manufacture of innumerable articles which have no necessary relation to potable spirits. I am quite sure the revenue authorities are not unsympathetic. I am sure some modus vivendi can be found."

One cannot help referring to a very recent and not unimportant occasion, namely, a discussion under the auspices of the London Chamber of Commerce on "British Industrial Neglect of Applied Science." At our suggestion the metropolitan professors were invited, and interesting comments were made by them. One thing was clear, we were quite as learned and well equipped as our rivals. Our educational system and raw material for educating was all wrong. Our vice was "self-reliance," hitherto regarded as a virtue. We blundered on, never asking advice, nor taking it when given. Industrialists came last and late, and your Chairman, the writer, contributed some observations of a practical character, which are recorded elsewhere. We both agreed that manufacturers might well consult the "doctors" for their ailments, and frequently, but before all, the conditions must be equal for equal advance, and the opportunity was not neglected by us to urge the removal of obvious disabilities, notably that of the want of duty-free spirit suitably denatured for industries. What is wanted, is not so much technical schools for workmen—as, after all, a workshop is the best school of apprenticeship—as polytechnics for employers, foremen, managers, and superintendents. "They too often cling to old methods and are not so assimilative and adaptable as they ought to be." As several members of Parliament were present, one hopes recruits to our cause may have been gained. Last year Mr. Howard and Mr. Umney spoke to the positive danger, as well as the absurdity, of giving to research, facilities which were not given under proper conditions to industry. Here are unimpeachable testimonies to the value of free alcohol for scientific research, the direction of which is not industrial, because there is no demand. Give the facilities for utilising scientific industrial research and we shall be ashamed if the "self-reliance" of the British manufacturer does not take an active form. One must repeat the deep conviction that the pecuniary results to the Exchequer in other ways, will far outweigh any loss of revenue by concessions in the direction of new or seriously hampered existing but struggling industries. This, the time of the nation's industrial stocktaking, is scarcely that at which our able public servants, with sons of their own and inheritors of the nation's glories, shall hesitate to meet imperative and vital industrial conditions and to assist in restoring some which had birth in our land, and developing and maturing those whose inception is but now a matter of circumstance and opportunity. Let all put a hand to the wheel of industrial progress, the professor and his students, the business man, the manufacturer, the chemist, and last, but not least, our STATE. Again grateful acknowledgements are made to many contributors, and among them, greatly to my successor at the Chamber of Commerce, Mr. John C. Umney, the Joint Committee, my assistant Mr. Gosling, in the matter of diagrams, and, most appositely, to Mr. P. Leuthard-Thornton for his very useful technical matter.

Supplementary Material considered of Value.

In continuation of Table II. of last year's paper, the following figures may well be given :—

YEARS 1902–3.

Potato Crop Average 43,462 *millions of tons of* 1,000 *kilos. each.*

Whole spirit production from all materials	74·129
Potable spirits consumed	51·35
Free spirits consumed	28·36
Free spirits denatured	19·899
Free spirits for vinegar, and free spirits for other purposes by deduction	8·46
Export	8·28

of which 2·621 to Great Britain, British W.A., and British India.

All these are million gallons liquid 100 per cent. The stock at the end of 1903 was 6·6 million gallons liquid 100 per cent., as against 22·198 million gallons liquid 100 per cent. at the end of 1902.

To Table I. add :—

Raw Material used in German Distilleries.

Year.	Potatoes.	Molasses.
	Tons.	Tons.
1900–1	2,790,000	29,843
1901–2	3,088,000	32,303

The sale of motor spirit, which was in 1901–2 286,000 gallons liquid 100 per cent., has gone up to 528,000 gallons liquid 100 per cent. in 1902–3.

GERMANY'S TRADE IN DYES AND CHEMICALS.

Oil, Paint, and Drug Reporter, Sept. 16, 1903.

In recent years Germany has rapidly advanced to first place among the countries producing dyes and chemicals. Her success in the manipulation of coal tar reads like romance. Perkin, the English chemist, might discover that Germany alone has learned the art of exploiting. In 1892 the Empire exported 21,879,204 lb. of coal-tar dyes, of which England took 4,146,872 lb. and the United States 5,153,448 lb. In 1901, 51,060,7[illegible] lb. were exported—11,830,776 lb. to Great Britain, and 10,461,324 lb. to the United States. German price lists put the price of these coal-tar products at 57 cents per lb. in 1892 and 37 cents in 1901.

One hundred and twenty companies, working under the limited liability laws, with a paid-up capital of 83,931,914 dols., paid out 10,323,520 dols. as interest to the stockholders in 1901—at 12·3 per cent. dividend. This is a trifle less than the one paid in 1900, and a little more than 1 per cent. less than in 1899, when the dividend was 13·52 per cent.

Nothing in the long list of modern discoveries is more wonderful than Germany's investigations and success in the production of indigo. For a long time it had been the dream of dyers and chemists to find a substitute for India's natural product. They had driven French farmers to desperation when they destroyed the value of madder by substituting an artificial red won from coal tar. They expected to do nearly as much with a substitute for natural indigo. In 1892 the Empire had to import 3,556,740 lb. of natural indigo, valued at 4,450,600 dols.; in 1896, 4,026,756 lb., worth 4,926,000 dols.; in 1902, only 1,074,468 lb., valued at 833,000*l*. India, the Dutch East Indies, and parts of Central America were the great producers. They, too, were watching the work going on in the Empire's laboratories, for they were very much interested. At last, in May 1897, Baeyer, a great chemist at Munich, made the long-looked-for and longed-for discovery. Since then the exports of the German Empire have gone on increasing, while the exports of natural indigo from other countries have been diminishing. In 1897 the exports were 1,036,116 lb.; in 1902, 10,779,972 lb.; expressed in values, 1,142,400 dols. and 5,950,000 dols.; or nearly 500 per cent:—and this notwithstanding the fact that the effect of the discovery of artificial indigo was to reduce the prices of this dye. Germany paid for natural indigo an average of 2,737,000 dols. in the years previous to 1896; since that time, less than 238,000 dols.: last year, only 166,600 dols.; while it exports millions of dollars' worth of the artificial, Great Britain taking 710,124 lb. last year, and the United States 1,449,012 lb. Even the East Indies are down for quite a large quantity in 1902—85,476 lb. One company, the Aniline Factory at Ludwigshafen on the Rhine, is reported to be producing more than 1,000,000 marks' worth of artificial indigo every 12 months. Once familiar with the Empire's methods of investigation and experimentation, all wonder at results vanishes.—Textile Mercury.

ALCOHOL; CONGRESS ON ——, AT THE GENERAL MEETING OF THE ASSOCIATION DES CHIMISTES DE SUCRERIE ET DE DISTILLERIE DE FRANCE ET DES COLONIES.

Bull. de l'Assoc. des Chim. de Suer. et de Dist., 1903, **20**, [9], 943—944.

Germany produces four million hectolitres of alcohol and devotes 1,161,000 to industrial purposes; France produces 2,656,000 hectolitres, of which only 221,000 are used industrially, so that to reach the same proportion as in Germany (where the consumption of alcohol in beverages is stationary) 521,000 hectolitres more than at present would have to be denatured.

The principal object of the Congress was to indicate the means to be adopted and the reforms necessary to attain this result. The following are the chief recommendations to be submitted to the Agricultural Commission of the Chamber of Deputies :—

1. Abolition of the large dose of wood spirit now used as a denaturing agent and the adoption of a mixture of 2 litres of wood spirit bases, 1 litre of excise wood spirit, and $\frac{1}{2}$ litre of benzene per hectolitre of alcohol. This improvement would effect a saving of 6·45 frs. per hectolitre over the present method of denaturing.

2. Unification of the tariffs for the whole of the companies, and the return, free of charge, of packages used for the carriage of denatured alcohols.

3. That all alcohols considered as raw material of the various industries be exempt from duty; that the denaturing be suited to the use for which it is intended, and that for alcohols which are to undergo no denaturing there be established supervised factories.

4. That a special study be made of the various pharmaceutical and perfumery preparations with an alcoholic basis, in order to find out the possibility of adapting denatured alcohol to the whole or a part of these preparations.

5. That French manufacturers using denatured alcohol as a raw product in their manufacture have the right to establish works placed under the supervision of the excise, in which this alcohol can enter free of all inland duty.

Denaturising Alcohol in Argentina; Formula to be Used.

Bd. of Trade J., April 23, 1903.

In the *Boletin Oficial* of Argentina of March 11, a decree is published, to come into force three months from 5th idem, requiring all alcohol intended for illuminating, heating, and preparation of varnish to be denatured by the use of the following formula, *viz*:—

Pyridine, 45 per cent.
Acetone (commercial), 45 per cent.
Eucalyptus essence (commercial), 10 per cent.

The alcohol is then denatured by an addition of 1 part of the mixture so obtained to 50 parts of alcohol.

When, however, special systems of illuminating require for the best results of their plans the use of certain formulæ, the National Chemical Office will examine experimentally the necessity for the modification of the general formula just expressed and will report to the "Ministerio de Hacienda," who will decide.

From the *Civilian*.

There has been of late a decrease in the quantity of German cheap spirit imported into this country. Up to last week there had been a falling off, compared with the corresponding 11 months of 1902, to the extent of 70 per cent. Fifteen months ago this market was almost flooded with Continental neutral spirit. The Berlin Clerical organ, *Germania*, a few days ago called attention to the extent to which the revenue, which is not in a very healthy condition in the Fatherland, suffers by reason of studied laxity on the part of officials. The manufacturing tax on alcohol is 7*d.* per gallon, but by improved mechanical means makers produce so much more than the Government standard that the tax they pay amounts to less than 5*d.* In the old days when our own spirit duty was levied upon the capacity of the still, and on the assumption that it would be used from four to six times weekly, Scotch and Irish distillers, by altering the shape of the still, but without interfering with its capacity, were able to use it half-a-dozen times in the day, much to their profit. Although their German competitor has quite a number of taxes on his spirit—a maker's tax, an ingredients tax, and a distilling tax—he appears to manage very well, for while the three imposts cost him 5*d.* he receives from a paternal Government a "drawback" of 7*d.* on every gallon of spirit he exports or methylates, and in the former case he also receives a number of bounties, which, for a distiller who makes at least 100,000 gallons a year, amount to not less than 3*d.* per gallon, and probably much more. The working of a law passed eight years ago, by which the receipts from a new tax placed upon spirit were devoted in great part to encouraging the export of that article, is rather obscure, but it appears to be equivalent to a bounty of $\frac{3}{4}$*d.* per gallon. It would seem, then, that the exporter in Germany receives by way of gift from his Government between 5*d.* and 6*d.* on each gallon of spirit he sends here or elsewhere. As our differential duty is but 5*d.*, the German Government pay it and a little more for their exporters. It is not surprising therefore, to find that in their estimates for 1904, provision is made for a decreased receipt from spirit duty of 289,200*l.* The beer duty, too, is worked on somewhat similar lines. To exporters the Government give a drawback of the nominal duty, which is one-third greater than the actual duty. Under this head of receipt too, it is contemplated that there will be a decrease of 64,800*l.* next year.

Duty on Celluloid Articles: U.S. Customs Decision.

Dec. 2, 1903.

The Board of General Appraisers held that in assessing duty on articles composed in part and in chief value of celluloid, the whole weight of the articles, and not that of the celluloid alone, should be taken.

Salol and Phenacetin: U.S. Customs Decision.

Dec. 1903.

Salol, phenacetin and other medicinal preparations were assessed for duty at 55 cents per pound, under paragraph 67 of the Tariff Act, as "medicinal preparations in the preparation of which alcohol had been used." The importers endeavoured to show that alcohol was not necessary for their manufacture. The Board held this evidence to be insufficient and affirmed the assessment of duty. (See preceding decision.)

Chloral Hydrate and Salol: U.S. Customs Decision.

The United States Circuit Court of Appeals has rendered a decision regarding the dutiable character of salol and chloral hydrate which has an important bearing on the imports into the United States in the manufacture of which alcohol is used. The Court of medicinal preparations held that if alcohol is used in any way, and even if it is broken up or removed, the finished product is subject to a duty of 55 cents per pound under paragraph 67. In order to be dutiable at 25 per cent. *ad valorem* under paragraph 68, evidence must be submitted showing that alcohol was used at no stage of the process. This decision reverses numerous decisions of lower courts.

Potatoes: Ireland and Chemical Manufacturers.

It is hard for the average man to discover from amidst the volume of material which is being daily poured forth by the Press, whether we are in full career of decadence, or may still hold the old point of view of the pre-eminence of Great Britain. Is the man in the street to think that our career is one of headlong descent when he reads of industries killed by stupidities of legislature, or may he comfort himself with the thought that some decay of the sort is natural, and will by-and-by be filled up with new outlets to trade? The nation would be careless, indeed, were it to accept the optimistic view. The industries that are manifestly being lost and already lost to us, if to be regained by any sort of effort, are worthy a fight. Of all the industries in which German competition has almost completely ousted the British manufacturer, the trade in dyestuffs is a most conspicuous example. It is a favourite cry with many self-constituted authorities that the English have lost place in such trades through want of technical and scientific training. However much truth there may be in this statement—and there is doubtless a great deal—still it is not absolutely the sole cause of our retrogression. In this particular trade much has been done for the foreigner and against the British manufacturer by the English legislature itself. In the manufacture of aniline dyes and many chemical products, spirit is an essential adjunct. The German manufacturer can buy alcohol at 10*d.* a gallon for industrial purposes, the British manufacturer pays for his 21*s.* a gallon, for all spirit in this country, irrespective of the use to which it is to be put, has to pay excise duty. Is it surprising that Germany has appropriated the aniline dye trade? How can the British trader put any on the market in the face of such opposition? The political cry of the moment is free trade, but she hardly realises that she has long been playing the protective rôle, but in the wrong direction, towards the foreign trader. If free trade is such a boon, let us have it, but let us abolish protection of the foreigner. This intrusion of the synthetic substitutes for aniline has had a far-reaching effect. But a decade ago, the total output of natural indigo in the whole world was some 5,000,000 per annum. Of this, India contributed no less than three-quarters. That important source of Indian revenue of some millions sterling per annum no longer exists. The German artificial dyes have ousted natural indigo from India in the industrial market.

In this field, again, the Germans are the masters, nor can we hope to wrest it from them until the Chancellor of the Exchequer shall screw his courage to the sticking point, and make alcohol for industrial purposes duty-free. Our law makers at Westminster have been dealing tenderly with Ireland of late. Were they but to grasp the full significance of such an exemption from excise duty, they would add to their gift to Erin yet another infinitely great benefit. The demand for cheap alcohol for manufacturing purposes could well be supplied by a greater output of the potato. The House may consider the question of duty-free alcohol at an early date. Any continuance by Government of the present system of excise duty on all kinds of alcohol render irretrievable to a most important British trade a loss which has already assumed regrettable dimensions.

NEW IRISH INDUSTRY: ALCOHOL DRIVEN MOTOR-CARS.

Mr. R. J. Mecredy, the Irish motorist, whose scheme for the manufacture of alcohol in Ireland is now under the consideration of the Department of Agriculture, is very hopeful of a great success in regard to its use for motor-driving purposes.

The international race which he proposes should take place in Ireland next year should induce some wealthy supporter of motoring to offer a cup for the best alcohol-driven motor-car over the Gordon-Bennett course. Mr. Mecredy issued a circular setting forth the conditions a few days ago.

In the course of conversation with a correspondent in Dublin, he seemed full of enthusiasm. The idea occurred to him about a month ago, and he placed himself in communication with Sir Horace Plunkett, who told him that he thought the idea a splendid one, and that it would have his most careful attention.

"You see," said Mr. Mecredy, "it is a case of alcohol versus petrol, and at recent trials in France, the result demonstrated that there is no practical difference between the efficiency of alcohol-driven and petrol-driven motor-cars where the carburettors were specially designed to suit the occasion. To be sure, the consumption was greater, but once the duty is removed, the spirit would be so cheap that this difficulty would disappear."

"How do you propose to meet this difficulty of removing the duty?" he was asked.

That point, I understand, is having the consideration of Sir Horace Plunkett, and it could not be in abler hands.

"As regards the manufacture of alcohol from an industrial point of view, there are enormous possibilities for Ireland in it. A great impetus will be given to the growing of potatoes and beetroot, from which the alcohol could be extracted, and the Irish farmers will not be slow to see the advantage of taking it up. This in turn will make a vast field of work for factory hands and operatives. Light railways are also certain to come into line for propulsion by alcohol, so you see the possibilities for Ireland of the new industry are almost without limit."

FERTILISERS AND THE PREPARATION OF POTATO LAND IN GERMANY.

U.S. Cons. Rep., Oct. 17, 1903.

This, from the standpoint of German agriculture, is by far the most complicated and important portion of the subject. The three essential elements to be provided by artificial fertilisation are phosphoric acic, potash, and nitrogen. The first is obtained through the application of mineral phosphate, Thomas slag phosphate meal, or bone dust. Thomas meal is applied in the proportion from 1,000 to 1,200 lb. per acre, but being sparingly soluble, it acts very slowly on the growing crop, and in dry seasons hardly at all. It is most effective in moist soils and in seasons of abundant rainfall. Steamed bone-dust is used—300 to 400 lb. per acre—by being strewn over the land in late autumn, and ploughed in. Superphosphate fertilisers are used in the spring, and are deposited and covered with the seed at planting time. Far more important, however, for potato culture are the potash-bearing fertilisers, such as kainite and carnallite. The enormous development of potato production in this country during the past 30 years has been due to the exclusive possession of an unlimited supply of potash minerals. Many of what are now the best potato lands were, 20 years ago, deficient in potash, for the reason that the potato consumes that element in large proportion, so that the original natural supply had long been exhausted by ignorant, unskilful cultivation. What was needed was to restore the exhausted potash. But it was found that neither kainite nor carnallite—both of which contain traces of chlorine—could be used raw and directly as a manure for the growing crop without impairing the flavour and quality of the potato. To produce the best effect, these mineral fertilisers have to be digested and assimilated with other elements in the soil. To secure this result, they are applied during the preparatory process, one or two years before the land is planted to potatoes, and serve to nourish the clover, the lupine, or other fallow crops that are grown and ploughed under as manure. By this method the potash salts are not only digested, purified from chlorine, and mingled thoroughly with the soil, but it is enriched by the nitrogen of the buried vegetation, and prepared for the abandant growth of potatoes of the highest quality, rich in starch, and of standard flavour.

Nitrogen is applied in the form of stable manure worked into the soil during the one or two years previous to potato planting, and of nitrate of soda, which is used as a top-dressing, applied directly while the plants are growing. Nitrate of soda covered in the earth leaches away into the subsoil, and is thereby lost to the farmer. Used as a top-dressing, it has an immediate, and often important, effect, in reviving and stimulating a crop, but it should never be applied to the soil in autumn, nor in the spring before the potato sprouts have appeared above ground.

Reduced to its simplest terms, the secret of German pre-eminence in potato cultivation consists in the careful, patient scientific preparation of the soil, not only by the restoration of its exhausted elements, but by mellowing, enriching, and revivifying it by deep cultivation and the ploughing in of green manure crops, which have taken up and digested the crude mineral fertilisers. Land thus prepared will yield three, or even four, crops of potatoes before their quantity or quality will begin to deteriorate.

Potatoes.

It will astonish most people to hear that 28,856,637 acres are annually under potato-culture in Europe, and that the total yield therefrom is estimated at 2,329,211,560 cwt. The *Gardeners' Magazine* states that in the matter of area Russia occupies the highest position with 9,645,869 acres, Germany ranks next with 8,004.225 acres, and France occupies the third place with 3,818,378 acres. The potato areas in the other countries of Europe are as follows:—Austria, 2,802,677 acres; Hungary, 1,477,161 acres; United Kingdom, 1,203,184 acres; Italy, 516,000 acres; Holland, 386,049 acres; Sweden, 381,973 acres; Belgium, 348,398 acres; Denmark, 133,387 acres; Norway, 90,661 acres; Roumania, 28,642 acres; Servia, 15,549 acres; and Bulgaria, 1,481 acres.

Yield.

In the matter of yield, Germany is first with 855,277,805 cwt., Russia second with 519,045,932 cwt., and France third with 236,469,441 cwt. The yields of other countries are: Austria, 234,100,082 cwt.; United Kingdom, 118,398,380 cwt.; Hungary, 95,442,205 cwt.; Holland, 77,929,500 cwt.; Sweden, 54,821,800 cwt.; Belgium, 47,083,147 cwt.; Norway, 21,906,142 cwt.; Denmark, 21,177,681 cwt.; Italy, 13,818,293 cwt.; Roumania, 2,495,314 cwt.; Servia, 835,083 cwt.; and Bulgaria, 410,755 cwt. These figures illustrate the great difference in the yield per acre in the different countries. The United Kingdom, which is sixth in area, is fifth in yield, heading Hungary by nearly 23,000,000 cwt., although having an area of about 273,000 acres less.

DISCUSSION.

Mr. CHARLES UMNEY said he took some considerable part in obtaining the concession which had been alluded to, which was made to wholesale druggists some years ago, of a drawback upon exportation of medicinal tinctures. Experiments were then conducted in his Company's laboratory, because Dr. Bell, the then Head of the Somerset House Laboratory Department, said that if the drug trade could only convince the Inland Revenue what amount of alcohol on manufacture was lost on a large scale, the Department would take the matter into consideration. He immediately replied "come and see." Dr. Bell sent his officers, and they worked for two or three weeks, and at the end of that time the Department gave the trade more than they asked for, and the arrangements had worked without any friction whatever, to the great advantage of the exporting wholesale chemists and druggists. With this particular matter of free alcohol for manufacturing now referred to, he had had very little to do, but he failed to see why, the perfumery trade having had the concession of free alcohol, similar concessions should not be extended to other manufacturers. The perfumery trade now worked with duty-free alcohol, though there was no permission to recover from their residues the alcohol left therein. The perfumers did work, however, under Excise supervision in bond, and, as he had learned from manufacturing perfumers, without any undue friction. These, however, were very small matters compared with the large industry which Mr. Tyrer had alluded to, viz., the colour trade. The Customs seemed to have shirked their responsibility given in the Act of Parliament in not charging duty on many materials entering our ports. If the Customs were to put a duty on now, it would simply ruin the dyeing industry of the country when in keen competition with their continental opponents. So far as substances such as antipyrin, sulphonal, phenacetin, &c. were concerned, no doubt a duty could be imposed, but it never had been. Almost the whole of this class of chemical which the wholesale druggists distributed in England and abroad was made in Germany. He had been deeply depressed within the last few months at seeing some of the colossal works where these and other medicaments were made, when he knew that we had no facilities in England to enable us to compete. He thought Dr. Thorpe's letter which had just been read augured well for the future; his predecessor, Dr. Bell, and also the former Chief of the Revenue Department at Somerset House, had made in the past valuable concessions, and he still hoped there was a prospect of getting, at no distant date, free alcohol for manufacturing purposes.

Mr. David Howard said he was afraid that it was no use preaching to the House of Commons because they would not listen. The late Chancellor of the Exchequer did not even know that perfumes could be made synthetically, and yet he was a man who governed us. We were ruled by politicians who cared not one rap for the prosperity of the manufacturers and to whom it was much less trouble to tax manufacturers than to give them a chance. So the manufacturers were taxed, as only the Revenue Acts could tax them, rated as only mysterious decisions of judges could rate them, hampered with a Patent Law, made solely in the interest of the foreigner, and were deprived of alcohol except at a fabulous price. Let them have something like a fair chance. Too much self-reliance might be a mistake, but if they relied on the justice of their rulers, it would be a greater one. They must keep on putting these tremendous figures before their rulers and ask them, were they in the name of common honesty going to ruin English manufacturers by this monstrous system of protection of the foreigner at every turn. They had the power of taxing all these things, and why did they not do it?—because they dare not, that was the plain truth.

Dr. Squire said that, so far as he knew, the distillers were quite unaware of this agitation which was being engineered by Mr. Tyrer, and he did not think any opposition need be expected from them. There was no doubt, however, that the subject was attended with all kinds of difficulties—difficulties which had been created by mistaken regulations, starting almost from grey antiquity, and which were extremely difficult to alter. There was a parallel case in the matter of railways. Mr. Muspratt had taken up the question of carriage, and said the railways must lower their rates; the reply was that such enormous prices had been paid for land, at a time when land was worth a great deal more than at present, and in consequence of heavy capital accounts, that they could not see their way to lower the rates. In the matter of spirit, the difficulties arose mainly from an attempt made by the Government to check the actions and working of the distillers. The accurate working of the still, which was accurate, must be checked by something which was not accurate. The attenuation charge fixed by the authorities, *viz.*, that five degrees of gravity on 100 galls. of wort should produce 1 gall. proof of spirit, was not accurate. Usually about 8 per cent. more spirit was produced in practice. As many of them knew, the splitting up of sugar into alcohol and carbon dioxide could be expressed by a simple formula, but in practical working several other bodies were produced; glycerin, instead of attenuating the liquor, made it stronger, and lactic acid had a similar effect. Then there was a considerable increase of yeast in the manufacture of spirit. This was largely derived from the carbohydrates, in fact there were so many complications from disturbing causes that the attenuation charge was worth very little as an accurate check. If it were otherwise possible, he believed he could take 2,000 galls. of spirit every week out of a large distillery and the attenuation charge would not indicate it. This charge was the point around which the Spirit Act turned; all the regulations and restrictions were based upon it. He had no opinion of it, and many others, whose opinions ought to carry some weight, had no opinion of it either. But the unfortunate position was this: in order to work the attenuation charge the Government insisted on distillers making certain arrangements which were thought to be necessary. For example, to avoid fraud, before distilling could commence, everything connected with the wort must be locked up, and under the charge of the Excise officers. The same thing with the still; before mashing, the still must be locked up; in the case of pot stills the fire doors were locked up; in fact, nobody who had not worked in a large distillery had any idea of the number of excise locks. This was all for the purpose of the attenuation charge. The effect of these regulations was that, in as much as brewing and distilling, or mashing and distilling would not be done at the same time, the still was twice as big as it need be, and the mashing part of the plant was five times as big as it need be. In order to work the attenuation charge it was necessary to make use of more or less clear worts of which the gravity could be ascertained by the prescribed saccharometer. Whereas, in Germany, they mashed in a grain distillery 10 times in 24 hours, they could not do so more than six times in England to produce the same result. If that $2\frac{1}{2}$ was multiplied by 2, which represented the way in which the distilling operations were limited, that means that the mashing plant was five times as big as it need be. In consideration of all these restrictions there was a differential duty put on of 5*d*. In 1880 it went down to 4*d*. but it was 5*d*. again now. He was not prepared to say that that was the exact measure of the loss put upon the distiller; it might be a little more or a little less, but what was perfectly clear was that the distillers had been forced into an immense expenditure which would be entirely thrown away if these restrictions were removed. The capital account was three times what it need be, and therefore the distillers would say, no doubt—is it fair to take off these restrictions and allow us to double our already existing over-production, whilst other men are starting with about one-third of the capital, and doing as much work as we can do? Another question was the enormous stock of spirit, millions and millions of gallons, for it should be remembered distillers had been making two gallons where one was consumed. There must be an end to that some day, but if these restrictions were taken off and the general cost of spirit came down to 6*d*. or 7*d*., there would be a tremendous stock to be dealt with, which had cost very much more, and the distillers would require, and would insist upon, compensation for it. The capital employed in the spirit industry was about 30,000,000*l*., so that if they were to compensate distillers in anything like the degree they would be entitled to, it would cost 15,000,000*l*. or 20,000,000*l*. This coming on the top of the South African War and the Irish Land Purchase would be another considerable load on the Exchequer. He had been much impressed by the zeal and ability with which Mr. Tyrer had worked this problem out. He had shown that the free use of spirit was of the greatest possible importance in this country for chemical manufactures, but he had not attempted to deal with the enormous difficulties which had grown up in the last 100 years, which would have to be faced if spirit was to be made as cheap here as it was in Germany. The only way in which he thought it could possibly be done would be as follows:—In certain industries where it could be shown to be advisable and justifiable, there might be a drawback allowed on the spirit used; but to attempt to do away with the present regulations and to upset the whole system of excise would cause such complication and expense that no Government would face it. If Mr. Tyrer could persuade the Chancellor of the Exchequer to allow a drawback on every gallon used for certain purposes it would be a solution of the problem. Whether this would be granted was another question. He might allude incidentally to a statement he had heard made several times, and it occurred at the end of this paper, but he did not know where it came from. It was to the effect that there was a new field for Ireland, to come to the rescue of chemical manufacturers by distilling alcohol from potatoes. Supposing Ireland were allowed to make potato spirit free from all regulations, and Irishmen could make spirit for 8*d.* a gallon or less, what would they do? He thought if the Scotch distillers were getting about 1*s.* 2*d.* per gallon the Irishman would not sell it for 7*d.* or 8*d.* He felt perfectly certain that whatever regulations or allowances the Excise might think it right to recommend, they would never allow the use of pure alcohol. It must be denatured because of the heavy duty in England. 1*s.* 6*d.* duty in Germany was one thing, but 11*s.* per gallon was quite another. There were extremely honourable people, and the reverse. Honourable people would take care that no spirit was made use of in a fraudulent way, but others would not act in this manner. Many persons would remember the tricks that were played with methylated spirit. The incentives to fraud would be much greater if the spirit were pure and potable. The Excise, whose duty it was to protect the Revenue, would never see their way to recommend the free use of potato spirit. To meet the requirements of certain purposes the Excise had agreed to use any substance for denaturing provided it was efficient. Further than that they should not be asked to go. Indeed they could not.

Mr. **Helm** said there was one observation made by Mr. Umney which might lead to misapprehension. He said that duty-free alcohol was used for making perfumes, but that only applied to perfumes made for exportation; those made for sale in this country paid the ordinary duty. He had listened with great pleasure to this paper, and also read with great interest and profit the former one by the same author. This was about as complete a paper on the subject as could well be written, and he would venture to suggest that it should be printed separately as a pamphlet and circulated amongst the members of the House of Commons. The House of Commons was their master; they were not law makers, either at Somerset House or at the Government Laboratory; they had simply to carry out the laws which were laid down for them, and he might claim for the Government Laboratory that whenever they had to advise the Government, it would be found, as Mr. Tyrer had borne testimony, that the users of industrial alcohol had always met with the greatest sympathy and support from the heads of those branches. Mr. Tyrer alluded to the tinctures regulations in which Dr. Bell was engaged. He had had to do with the administration of those regulations since they were issued, and he was glad to say that they had worked very successfully and profitably to the home trade. The drawback had risen gradually, and was now 65,000*l.* per annum, and that represented a very great benefit to home manufacturers, who formerly had to send tinctures intended for the Colonies viâ Hamburg. In the drawing up of those regulations, Mr. Umney was assisted and advised by the then principal of the Department, Dr. James Bell, and no one who knew him would ever accuse him of being anything but broad-minded and liberal in anything he had to do with. The same might be said of their present chief, Dr. T. E. Thorpe. But, as Dr. Squire had pointed out, there were very many difficulties, and it was a rough and thorny question. In the first place 20 millions of revenue depended on it; in the second place much had been said about good faith, common honesty, and so forth, but there were in this country, people, who, as soon as an Act of Parliament was passed, attempted to drive a carriage and pair through it. If it were not so, their difficulties would be comparatively slight, and the road to duty-free alcohol would be much smoother. He had had a considerable amount of experience in these things—having been over 40 years in that branch. Taking that very beneficent Act, the Methylated Spirit Act of 1855, it was a grand advance in the way of alcohol for use duty-free; prior to that it was all duty-paid. The first Act simply allowed alcohol, on being denatured with one-ninth of its bulk of wood naphtha, to be used for certain purposes duty-free. But in six years they had to pass an amending Act. It was found that it was being purified, and being made fit for use as a beverage, and in 1861, they had to pass an Act forbidding under severe penalties methylated spirit to be coloured, flavoured, purified, or in any way made fit for use as a beverage. That was a grave abuse of the privilege Parliament intended to confer on the industrial community. But that was not all; after a little time it was found that alcohol was being purified for use as a medicine. In the ordinary course of things, perhaps this might not have been interfered with if the medicines had been ordinary ones, but they came upon medicines which were sold and extensively used in the North of England under the name of Indian brandee, Indian gindee, and Indian whiskee, preparations which were supposed to be medicines, but which were in reality sold and used as stimulants. The result was they had to have another Act passed forbidding methylated spirit to be coloured, flavoured, or prepared for use in medicine. This showed that the privileges which the Revenue tried to confer on industries had been stopped by these unscrupulous persons because the Revenue authorities had not the power to discriminate, for they could not examine into the moral character of a man who wanted to do what somebody else had the privilege of doing. They allowed methylated spirit to be sold without a licence when mixed with 3 oz. of gum resin per gallon; that went on some time, and then they found a large manufacturing chemist distilling finish, and getting methylated spirit in an irregular way and using it for manufacturing purposes. Whatever restrictions there were on the use of methylated spirit, or on any privileges that might be conferred, they were tied hand and foot, partly by law and partly by the abuses which crept in. He was quite sure that everyone connected with the Revenue sympathised in theory with the object Mr. Tyrer aimed at; but in the first place there was the very great revenue dependent on it, and the next difficulty was the great danger there would be of workpeople and others using it improperly, even with the best intentions on the part of the manufacturer. They had had a great deal to do with various denaturing agents. The Act allowed either wood spirit or any other approved denaturing agent, but they had never been able to come on any denaturing agent quite so effective as wood spirit. Many others at one stage or another, either by acidification or making it alkaline, could be distilled and got rid of, but with wood spirit there was always some of the methyl alcohol remaining in the recovered alcohol. He should advise that any measures that might be taken for getting duty-free alcohol might be combined very well with measures for cheapening methylated spirit. With regard to the use of duty-free alcohol, it had to be proved that methylated spirit was detrimental or unsuitable, and there was no doubt that as between the two, methylated spirit would always be considered detrimental and unsuitable. He did not know any case where it would be more effective than alcohol itself, irrespective of the fact that it is double the price. But he did not see why measures should not be taken to cheapen methylated spirit. He should much like to see methylated spirit as cheap here as alcohol was abroad, for that would be a very great benefit. He thought they might fairly go to the Chancellor of the Exchequer and propose that he should pay the cost of denaturing alcohol; it was denatured for Revenue protection, and why should not the Revenue bear the charge? If he could give the differential duty back on the alcohol in methylated spirit as well as on alcohol itself when exported, why should he not allow the differential duty on alcohol used for manufactures in this country, whether as ordinary alcohol or as methylated spirit. It was no secret that in 1860 the exporters of alcohol wanted an allowance of 2*d.* or 3*d.* a gallon from Mr. Gladstone. He said, "No, the Revenue cannot afford it"; but he said, "I will give it if you will assent to an extra duty of 1*d.* per gallon on alcohol," and he did so. This differential duty was allowed and the Revenue lost nothing, but the consumers of alcohol had to pay an extra 1*d.* per gallon. He did not see any injustice in that to the spirit trade, because anything that improved the general trade of this country was sure to increase the consumption of potable spirit. They saw that every day: if trade went down, down went the revenue from beer and spirits; when trade went up, up went the revenue. Therefore anything that would increase the trade of this country and give the working classes better wages, was sure to redound to the profits of the distiller, the spirit merchant, and the publican. Many times they had knocked at the door of Inland Revenue and at the door of the Government Laboratory, but they had always been knocking at the wrong door. In 1902 they found out that the right door to knock at was the door of the Treasury and the Chancellor of the Exchequer. If the Chancellor of the Exchequer wanted advice, he could assure them that he would get advice sympathetic from their point of view. Mr. Howard had spoken about knocking at the door and getting tired of knocking, but he could give them an illustration of where knocking was at least likely to come to something. The cigar manufacturers asserted that they had a very inadequate drawback granted them in 1863 by Mr. Gladstone: simply 1*d.* per lb. more than the duty, when by his own showing the differential duty should have been from 3½*d.* up to about 1*s.*, but he would only allow 1*d.* For the last 40 years the cigar manufacturers had been knocking at one door and another to try to get an increased drawback, until last year they went to the Government, and convinced Mr. Ritchie that they had a case for enquiry. It was referred to an inter-departmental committee of which he was a member. The committee had not yet reported, and of course he could not disclose any official secrets. It was better in this matter not to go as single manufacturers, but to go through their Chambers of Commerce. So far as he was concerned he wished them all success, but he could see there were very narrow limits within which it would be safe for the Revenue to allow the use of duty-free alcohol, and should advise them to combine with it a claim for a reduction in the cost of methylated spirit.

Dr. Ormandy read as follows from a letter from Dr. Markel, of Messrs. Crosfield and Sons, Ltd. "If you get an opportunity to take part in the discussion of Mr. Tyrer's paper, I should be glad if you would mention that you and Mr. Allan represent Messrs. Crosfield and Sons, Ltd., and that you were specially sent to this meeting in order to express the importance which we attach to this subject, and to welcome Mr. Tyrer's efforts to bring the matter before that class, which is the one that could grasp the national importance of the subject most rapidly, namely, the class of chemical manufacturers. So much are we impressed with the importance of the matter that we are determined to second Mr. Tyrer's efforts by bringing the matter before that part of the public which Mr. Tyrer does not address." The speaker then pointed out that the greater part of Mr. Tyrer's remarks were addressed more particularly to the interests of manufacturing and pharmaceutical chemists, but the great future in the utilisation of alcohol, at least in the eyes of the continental governments, seemed to lie more in the direction of its utilisation for lighting and heating purposes, and as a source of power. He might say that he had that day called upon Dr. Boverton Redwood, who, in answer to an enquiry, stated that, if our automobile industry advanced at the rate it was doing, unless fresh sources of petrol were discovered, the price was bound to advance, and that rapidly. In that case the English people would be very badly situated. It was not likely the Americans would send their petrol over here, as their own consumption was growing, and at present they were practically the only manufacturers, since practically no petrol was obtainable from Russian petroleum. The Continent would be able to utilise cheap alcohol, but we should be left far in the background, with no other course than to use such expensive petroleum as we could get, or we should be amateur manufacturers of alcohol, starting at the points which Germany and France had left behind years ago. The remark made by Mr. Helm was very pertinent. He thought it would be easier to get reductions in the cost of methylated spirit, and the method suggested of appealing to the Chancellor of the Exchequer to remit this additional tax of 5*d.* on that portion of the alcohol which was used for industrial purposes, was a very good one. It was on these lines that the German Government tackled the problem. They put a special additional tax on the manufacture of alcohol, and the money accruing from that special tax was applied solely in diminishing the cost of alcohol used, when denatured, for industrial purposes. He had recently paid a visit to Germany to specially enquire into this subject, and he found that the amount of money spent in that way, in reducing the cost of alcohol for industrial purposes, was approximately 1,000,000*l.* This seemed a large sum, but a large portion of it was raised by increasing the tax on alcohol used for potable purposes. If the statement which had been made, that as trade increased the amount of potable alcohol consumed increased, were correct, they might hope that the duty arising from that increased use of alcohol might be expended in diminishing the cost to manufacturers and those who wished to use it for motive purposes.

Dr. Silberrad said that there seemed to be two principal difficulties in the way of duty-free alcohol. The first was referred to by Dr. Squire, and was based on the fact that the removal of duty and consequent excise control would double the output from the distilleries and so flood the market. It seemed to him that if the duty were once removed chemical industry would grow to such an extent that the quantity of spirit required would rapidly become far more than double that used at present. The second difficulty was that bogey, the 18 millions revenue, which was so forcibly brought up by Mr. Grant Hooper in discussing the paper read by him (Dr. Silberrad) rather more than a year ago. With regard to this it was self-evident that the money was paid by the British Public. This in itself, seemed, at first sight anyhow, a good deal worse than making foreigners pay it by the introduction of a preferential tariff, but surely some better means of raising it could be found than this which so completely crippled so large and important an industry. Were the duty removed, doubtless drunkenness would be more prevalent at first, but soon it would probably lead to the elimination of inveterate inebriates and so exercise a purging effect on society. Statistics showed that drunkenness varied with the duty on alcohol, and in Switzerland, where the duty is negligible, drunkenness was very seldom met with.

The Chairman said they were much indebted to Mr. Tyrer for the great amount of trouble he had taken in connection with this matter, and in preparing this paper, which was upon thoroughly broad lines. Since the question had been raised by this Society, they had gained very material advantages and considerable concessions, especially in regard to tinctures, in connection with which an enormous amount of money had been saved to British manufacturers. Then there were the more modern cases of fulminate of mercury and nitro-cellulose manufactures, in which they had been very much behind because they could not compete with foreign manufacturers, who were placed by their Governments in a more favourable position. In England they rather objected to State assistance or State help of any kind, but that view arose when the State was outside and beyond the people. The State was the people in this country at the present time, and its action was simply the co-operation of the whole body of the community, or it ought to be. By using that pressure which Mr. Howard indicated, they ought to be able to persuade those officials at the head of affairs to do what the nation required. From that point of view he did not think at all that State assistance should be rejected by any trade; it did not in any way eliminate self-help. Abroad, especially in Germany, people interested in various industries united and formed guilds. Their action was felt here commercially, but in their own country they were powerful politically, and unless we combined in some similar way we should have great difficulty in putting the requisite pressure on those at the head of affairs. Mr. Tyrer had foreshadowed one point which perhaps might weigh with them in the future, and that was the action of their colleagues and fellow members in the United States. If they should come in first, and obtain privileges from their Excise that we did not have, it would be good-bye to our industries in which alcohol was used, because they had manufacturing facilities which we could not dream of. In the first place they had cheap land, and that meant cheap alcohol if it were not taxed too highly. With regard to the taxes which were imposed on some of these chemicals, it was a most difficult subject, because many of the materials mentioned in the tables were the raw materials of other industries. If they taxed acetic ether they made it impossible to use it in connection with the celluloid industry, and there was a great celluloid industry which could not be carried out in this country because acetic ether and similar solvents used for it were heavily taxed. The dyes in which either ethyl or methyl alcohol were used as constituents were very largely employed by dyers, and to put a tax on them, as Mr. Tyrer had pointed out in his previous paper, would render it impossible for many of our producers of cotton fabrics to sell their goods in competition with foreigners. They must, therefore, not move rashly in the matter; but if they all put their heads together, and especially if they formed joint committees of those concerned, as had already been done, with the London Chamber of Commerce and other Chambers, he thought they might easily find a *modus vivendi* and strike an average which would be reasonably satisfactory to all parties. He was glad to hear that the distillers were, to a very great extent, with them in this matter. He believed, at the commencement of Mr. Tyrer's work, there was some antagonism shown by some gentlemen connected with the distilling industry, but as they had gone into it they saw that the production of alcohol was bound to grow enormously if people were allowed to obtain it at a price bearing some reasonable relation to the cost of production for certain purposes which would not affect the Revenue. As Dr. Squire had pointed out, there was quite enough spirit produced for potable purposes—more than could be drunk under existing conditions. He said that two gallons were made where one would suffice, and he was afraid there was at present no way of getting rid of the surplus. They would always produce more than could be drunk—at least he hoped so—and the only way would be to have a free year every now and then. He was not quite sure whether, on the principle of the survival of the fittest, it would not be ultimately better. At any rate he had noticed that where alcohol was perfectly free, and one could have it for the making, there was no drunkenness. He knew that of his own experience, for he had seen it in more than one country. He thought a good deal of the excess in drinking which took place in this country was because drink was a thing that cost a good deal of money, and people looked upon it as a kind of luxury to be proud of.

Mr. R. F. **Nicholson** said his was one of the four distilleries now at work in the London district, which showed that the trade could not be in a very prosperous state, and anything which would produce a larger consumption would receive the greatest approbation from those connected with the manufacture, and he was quite sure they would render assistance in trying to bring about a better state of affairs. In the first place the spirit law as at present existing was rather an anomaly. The law itself was made in 1821, and for the last 80 years had been almost exactly the same. It was cleverly worked out at the time, no doubt, but the conditions had altered, and there was now room for an immense amount of improvement. First of all, the spirit duty was probably imposed on moral grounds; it was not merely a question of an ordinary tax, and the House of Commons could not be expected to view with approval any proposal for diminishing that duty. The Excise, who had to collect it, had very great difficulties in carrying out the law, and preventing smuggling, of which a certain amount still went on. People got sugar and water, and fermented it with yeast, and distilled it off in a small still, and made a rough spirit. The duty was so high that there was a great temptation for a certain class of people to smuggle if they could. He quite agreed that it would be possible for manufacturing chemists to work in bond, as perfumers did for export; but, as one who had had a certain amount of experience, he could warn them of the difficulties in working under a Government body like the Excise. He wished to speak well of the Excise in every way, for they were most considerate in listening to anyone's complaint; still it was not their business to learn your trade; if you wanted to make any improvement, you had to teach them, and if you made an improvement in the distillery the officers were moved on from one place to another, and there was always a chance that your invention would be at the disposal of your competitors. It was not possible to work a secret or private process. He was quite sure that chemists would not find it at all acceptable to be obliged to disclose their quantities and processes to the world at large, because it was not merely to the chemists of this country, but for chemists all over the world. If they could manage to attain the object of getting cheaper alcohol without working in bond, he thought they would be wise. Mr. Howard had spoken strongly about pushing the matter forward on all occasions, in season and out of season, but if they would take a word of advice from him it would be not to make themselves a sort of Irish party, or they would not be listened to at all. First of all, if they could thoroughly master the whole situation as it was at present, and state how many gallons of alcohol were used by manufacturing chemists in the United Kingdom at the present time, it would be of great assistance in showing the magnitude of the trade, and they would have then more chance of being listened to. Then he thought if they could get a remission of some of the differential duty on methylated spirit it would be a great advantage, but they would not get the 5*d.*; that was absolutely certain, because the 5*d.* was made up of various small items, 2*d.* of which stood for rectification in the rectifier's premises under duty-paid conditions; so that the actual drawback that they would be able to obtain would only be 3*d.*; that would be equivalent to the duty refunded to the distiller if he exported the same amount of alcohol, and he thought they might ask to be put in the same position as if they were working in a duty-free country such as the Channel Islands. Then they would get the 3*d.* This was a very important question, and he thought he could speak for the London distillers in saying that they would be happy to co-operate in any way whatever. They had always been successful in any application to the Excise, for many years past, they had interviewed every Chancellor of the Exchequer at some time or another, and he thought if they could only come to some arrangement a good deal might be done. He cordially agreed with the gentleman from Somerset House who put forward the suggestion of applying for some repayment of the differential duty on methylated spirit.

Mr. **Tyrer** said the discussion had exceeded his anticipations, and ventured to think that if it had taken place on the reading of the last paper it would not have been so practical or so useful for the object in view. A good deal had happened in 12 months: the Society, the Chambers of Commerce, and the trade papers had been educated. Although the distillers were stated to have been out of touch with them it had only been apparent, for it was clear that Mr. Nicholson apprehended the position and saw where the surplus spirit could go. It was a welcome sign of that co-operation which received so signal an illustration from Mr. Helm, and he hoped the same spirit would continue. He was quite sure that if there were a board of green cloth round which all the interests concerned could meet, something could be done, and they should not be sent away empty from the Chancellor of the Exchequer's door. The cost of spirit in Germany was 2*d.* per lb. according to the figures which Mr. Leuthardt-Thornton gave for 1900. Spirit here cost to-day 2*s.* 7*d.* per lb. for 95 per cent. alcohol by weight, or 15½ times as much. The figures as to the dye trade were taken from the American statistics, furnished by American Consuls; they showed the trade that might have been done by England. The figures showed the amount of the German production and exportation in 1901 to Great Britain and America, each taking about an equal quantity—11,000,000*l.* to Great Britain, and America 10,000,000*l.* This business was done chiefly because of the cheapness of raw material. So far as the products were concerned, they had been turned out, not only by the aid of cheap labour and science, but they had been made in Germany under conditions which our laws did not allow. That was an argument which no Chancellor of the Exchequer could afford to ignore. Mr. Helm's contribution to the discussion was of the highest importance, and it showed the spirit in which these matters were viewed officially. The suggestion to reduce the differential duty allocation on methylated spirit for industrial use was one originally made by Mr. Alfred White, a well-known manufacturer. With regard to Dr. Ormandy's remarks he was much interested the other day to see a paper which referred to this very matter from someone largely interested in the question of alcohol for motors, where there was a reference to a mixture of certain proportions of alcohol and petrol which was found to be extremely useful. He hoped that, when this paper was printed, particular attention would be paid to the tables to which he referred, which showed the broad principle that in the production of a great many articles a certain percentage of alcohol had to be used which cost only 2*d.* in Germany. In conclusion, he disagreed with Dr. Squire as to the loss of so great a capital by distillers in certain eventualities. Had the common practice of depreciation been neglected in distilleries? He should think otherwise, and understood that much of the plant was of an unusually stable character, possibly least affected by wear and tear of any chemical plant. In a word, most distilleries had written off very considerably by this time. If so, the capitalisation argument failed. Dr. Squire would no doubt be equal to the occasion when cheap spirit was granted. It must be granted if the common sense exhibited by the distillers represented by Mr. Nicholson prevailed. An important advance was made when they or he was willing to meet matters by relinquishing 3*d.* of the surtax. He thanked all who had so generously helped in this matter.

DR. J. T. DUNN IN THE CHAIR.

NOTES ON THE PRODUCTION AND USE OF LIQUEFIED CARBON DIOXIDE.

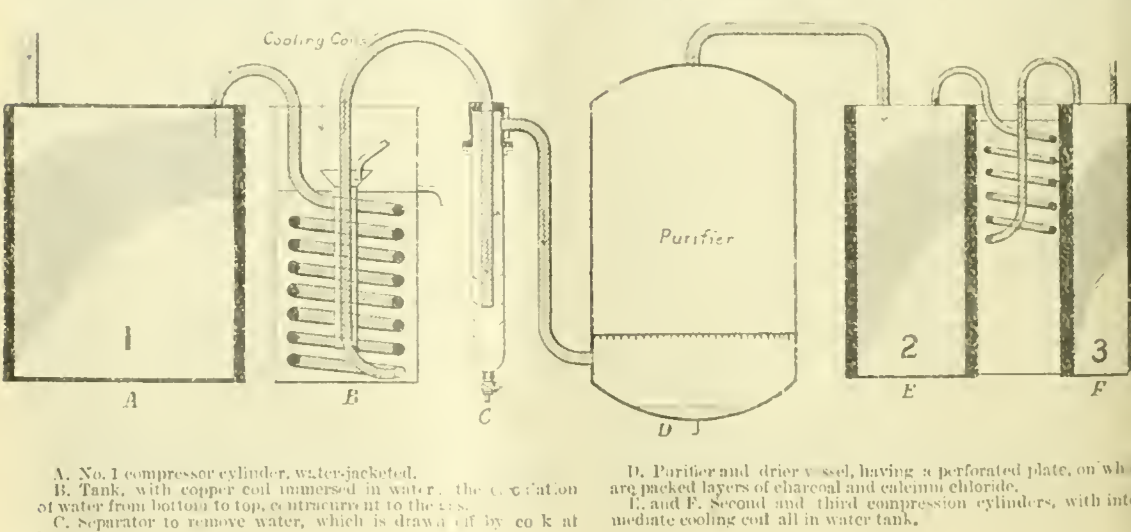
BY GEORGE SISSON.

Before describing the use of liquid carbon dioxide, it may be interesting to give a short account of the nature of the machinery used to liquefy and store the gas in such a condition that it may be easily and safely transported and handled. The gas, after being produced, is best stored in a holder built in an exactly similar manner to an ordinary gas-holder, the tank being filled with water on which is a layer of about $\frac{1}{4}$ in. or $\frac{1}{2}$ in. of mineral oil free from smell or action on the plates of the holder. The object of the mineral oil is to prevent absorption of the carbonic acid, which would cause the water to have a strong action on the plates of the holder: it also has the further advantage of protecting the outside of the holder from rusting, as every time it moves up and down the metal comes into fresh contact with the layer of oil, which obviates the necessity of painting the holder, with the exception, of course, of the top. The compression itself is best done in three stages—the first stage up to about 5 atmospheres, the second to about 15 atmospheres, and the third up to whatever pressure is required to liquefy the gas at the temperature at which the machinery is working. Between each two stages, the gas passes through a cooling coil surrounded by water, or other apparatus by which the heat of each compression is abstracted before the gas passes on to the next cylinder. The first cylinder receives a small injection of water along with the gas, the water acting partly as a lubricant and partly to reduce the temperature of the first compression: this water is separated by means of a receiver before the gas passes on to No. 2 cylinder. Cylinders Nos. 2 and 3 work in leather rings similar to a hydraulic packing, and are lubricated by means of an injection of glycerin, the glycerin being separated by a special receiver before the liquefied gas is passed through cooling coils into the tubes in which it is stored. With reference to the working of such a compressor, it is well known that if the final temperature be above 31° C. (which is the critical temperature for carbon dioxide), no liquid will be formed; consequently, it is necessary, especially in warm weather, to have a large final cooling surface, which is most conveniently made in the form of a copper coil in a tank of cold water. From this the gas is led into a long copper tube having several attachments so that several bottles can be filled at the same time. The course of the gas through the apparatus is shown in the diagram.

As these bottles have to stand a very considerable pressure (varying from about 800 to 1,200 lb. per square inch according to the temperature of the air) and are also sometimes subjected to a large amount of rough usage, it is necessary that there should be a large factor of safety and that they should be made in a special manner. The modern practice in this country is to make them of solid-drawn, soft steel, either from a plate or a bloom, the average composition of the steel being:—

	Per Cent.
Iron	99·2
Manganese	0·5
Phosphorus	0·04
Sulphur	0·04
Carbon	0·2 to 0·25

The neck of the tube is welded up, and screwed to receive the valve. Prof. Ferrier, of the Durham College of Science, made several tests of strips cut from one of the bottles so manufactured, and found the metal to have a breaking strain of 35 tons per square inch. After manufacture, the tubes are carefully annealed by heating to a dull red heat and allowing to cool gradually, after which they are subjected to a hydraulic test of 3,360 lb. ($1\frac{1}{2}$ tons) per square inch. The weight of a tube to contain 28 lb. of the liquid is



A. No. 1 compressor cylinder, water-jacketed.

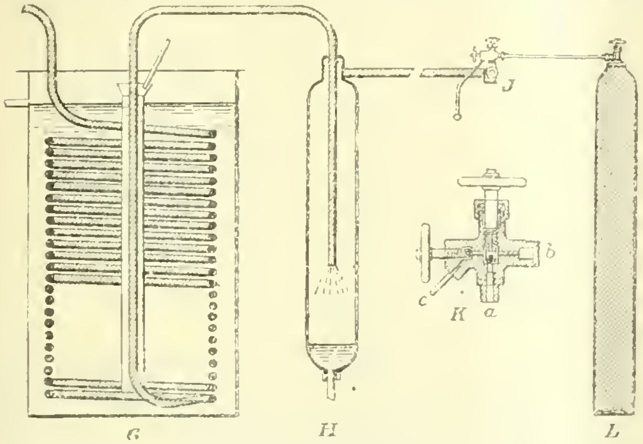
B. Tank, with copper coil immersed in water, the circulation of water from bottom to top, contracurrent to the gas.

C. Separator to remove water, which is drawn off by cock at bottom.

D. Purifier and drier vessel, having a perforated plate, on which are packed layers of charcoal and calcium chloride.

E. and F. Second and third compression cylinders, with intermediate cooling coil all in water tank.

from 70 to 80 lb. and the capacity of such a tube is about 38 lb. of water, that is to say that for ordinary use three-quarters of the weight of water which the tube will contain is the amount of gas which ought to be filled into the tube, while for tropical climates or stokeholds of vessels, the weight of gas ought to be two-thirds of the water capacity, allowing a larger margin for expansion. The process of annealing and hydraulic testing is repeated about every three years, and any tubes which show an appreciable amount of permanent expansion are rejected. For example, the usual amount of stretch of such a tube when under 3,360 lb. pressure is about 10 cb. ins., or 1 per cent. of total volume. When the pressure is relieved, the amount of permanent expansion must not exceed 1 cb. in. With fair treatment, the loss of weight by corrosion in such cylinders is extremely small, the principal damage being from outside rusting through exposure to weather or salt water. Some of the tubes used by the Washington Chemical Co., Ltd., were protected on the outside by the Cowper-Coles cold galvanising process, in which process the iron is cleaned without the use of sulphuric acid by means of a sand-blast and the zinc deposited electrolytically. The valves are made from dense brass or gun-metal. Fig. 1 shows a section, *a* being screwed into the neck of the steel tube, *b* screwed outlet. A vulcanite inserted plug, actuated by a wheel on spindle, opens or closes the communication between *a* and *b*. Fig. 2 shows a form of valve fitted with Carty's safety disc, which, on excessive pressure, bursts and allows escape of gas through hollow spindle. Fig. 3 shows a section of Hall's safety disc valve, *a* being the steel tube communication, *b* the outlet, and *c* having a closing disc of copper, adjusted to burst at excessive pressure. These two latter forms of valve are particularly suitable for the tropics and for use on board ship. It is one of the regulations of the railway companies that a woven mat protection be used when full carbonic acid tubes are sent by rail.



G. Final cooler, where the liquefying takes place.

H. Separator, to remove any glycerin which passes over from the cylinders.

J. A long copper tube fitted with several valves, similar to K, by which several store bottles may be filled simultaneously.

K. Filling valve :—*a*. Liquid gas inlet from compressors. *b*. Outlet to store tube. *c*. Communicates with gas-holder and serves to discharge residual gas from filling-tube, before detaching tubes.

Unlike liquid air, it is not possible to have liquid carbon dioxide at atmospheric pressure, as the liquid, when released from pressure, become partly gasified and partly solid. This is shown by allowing an escape from one of the tubes, the valve of which has a pipe dipping down inside to the bottom of the bottle.

The commercial uses of the liquid are: first, in the manufacture of various aërated drinks, the apparatus for which is no doubt familiar. Another use of the tube gas, which is almost universal in Germany, is for forcing beer from the casks to the taps. The advantage of this over pumping is that the beer is constantly kept aërated, or rather carbonated, and that no foul air from the cellar is drawn into the cask as in the ordinary method of pumping; on this account, I understand, such a method is compulsory in Germany.

The next great use is for refrigeration; this use depends, of course, upon the fact that the whole of the heat given out in compressing and liquefying the gas is abstracted on the evaporation of the liquid, also that the work done in the expansion of the gas absorbs heat, as is shown by the small engine which can be worked by the carbonic acid stored in the tube. The two substances principally used in refrigerating machinery are ammonia and carbonic acid gas; each material has its advantages and disadvantages, the advantage in the case of ammonia being low liquefying pressure (under ordinary circumstances about six atmospheres, while carbonic acid requires about 40 or 50), but the poisonous nature of any escape from an ammonia machine in a confined space (as, for example, on board ship) may lead to serious accident, while the same amount of escape of carbon dioxide is quite harmless, especially as the escape being at high pressure, the gas mixes to a considerable extent with the air. The principle of the carbonic acid refrigerating machine is entirely based upon the evaporation of the liquid.

Some experiments have recently been made by the London Fire Brigade with a jet of water propelled by means of high-pressure carbonic acid, as a means of extinguishing fires. With such an injector it would be possible to force water up to a great height without any mechanical pumping, or to supplement the deficiency of pressure in the hydrants, and, of course, the carbonic acid would tend to extinguish the fire, apart from the water.

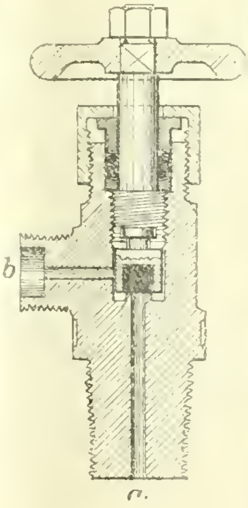


Fig. 1.

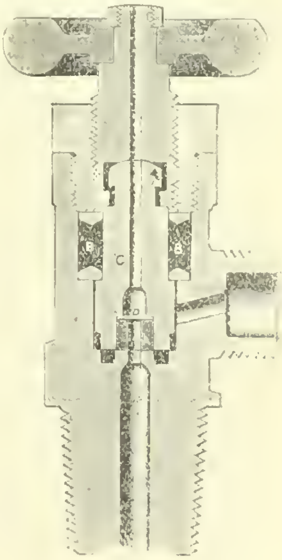

Fig. 2.

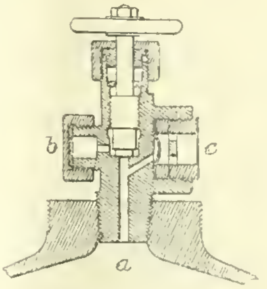

Fig. 3.

Finally, I might draw attention to the Westinghouse electro-gas method of railway signalling, described in "Engineering" of Dec. 4 last. Here a tube of gas is used at outlying stations to supply motive power for working the signals in order to avoid the expense of having compressing machinery or long lengths of connecting pipes. The carbonic acid tube is connected to the piston working the signal, and the valve admitting the gas is controlled by an electric current which is transmitted by wire to any distance. The details given in the above named paper show that with a working pressure of 25 lb. per square inch in the expansion chamber (which pressure can, of course, easily be obtained by the use of a regulator), an average of 215 signal movements to each pound of liquid gas was obtained, so that one tube, containing 28 lb. of gas, will suffice for about 6,860 movements.

MR. T. L. PATTERSON IN THE CHAIR.

THE ESTIMATION OF CYANATES.

BY THOMAS EWAN, PH.D.

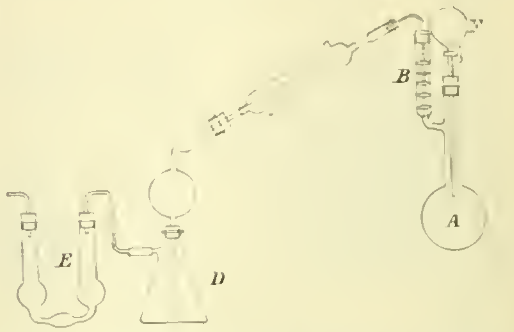
When potassium or sodium cyanide is heated in presence of air, oxidation takes place and a cyanate is formed. For this reason commercial cyanides frequently contain small quantities of cyanate. Owing to the difficulty which I experienced in determining the quantity of this substance in samples of cyanide I was led to investigate the sources of error in the known methods and to try to eliminate them. The quantitative determination of a cyanate may be based on (1) the insolubility of the silver salt, (2) the decomposition of an aqueous solution of cyanic acid into carbon dioxide and ammonia.

1. Silver cyanate is somewhat soluble in water. I found that 100 c.c. of water at 12° C. dissolve 0·006 grm. of it; the precipitation of small quantities of cyanate is, therefore, by no means complete. The separation of silver cyanate and cyanide by means of dilute nitric acid is also unsatisfactory: silver cyanate dissolves somewhat slowly in cold 5 per cent. nitric acid, whilst the hot acid dissolves silver cyanide. It is therefore difficult to make sure of dissolving all the cyanate without dissolving some of the cyanide. The following analysis of a sample of sodium cyanate will serve as an example. The only impurities present were sodium cyanide and a little water. The cyanate and cyanide were precipitated together by an excess of N/20 silver nitrate solution and the excess of silver determined in the filtrate by titration with ammonium thiocyanate. The silver cyanate was then dissolved by digestion with cold 7 per cent. nitric acid, and the dissolved silver titrated with ammonium thiocyanate. This gave NaCNO = 90·10 per cent.; NaCN = 5·15 per cent. Direct titration of the cyanide by Liebig's method gave 4·53 per cent. NaCN, hence the silver cyanate would appear to have been incompletely dissolved by the nitric acid. The excess of silver nitrate used in precipitating the silver cyanate diminishes its solubility to some extent; an approximate calculation showed that the filtrate and washings contained silver cyanate equivalent to 2·75 per cent. of the substance used. These two errors therefore make the determination of the cyanate about 3·5 per cent. too low, or the real content would be 93·65 per cent. The average of several determinations made by the method described below was 93·7 per cent.

The sources of error mentioned become of greater importance when the quantity of cyanate is small compared with that of cyanide, and in presence of hydroxides and some other substances giving silver salts soluble in nitric acid the method was found to be incapable of giving even approximately accurate results.

2. The method based on the decomposition of cyanic acid, $HCNO + H_2O = NH_3 + CO_2$, was found to possess the advantage of being applicable in presence of any of the substances which usually occur along with cyanides. The accuracy is not very great, but it is sufficient for most purposes.

The apparatus used, which has proved very serviceable in several other cases in which a quantitative distillation has to be made, is shown in Fig. 1. About 1 grm. of the sample, dissolved in 50 c.c. of water, is brought into the 100 c.c. distilling flask A, the side tube of which is bent upwards and sealed to a "rod and disc" fractionating column B about 4 inches long. This is very effective in preventing splashes or spray from the distilling flask being carried over into the condenser. The flask D and the U-tube E contain a dilute solution of caustic soda and baryta free from carbonate. A quantity of alkali equivalent to 40—50 c.c. of normal caustic soda is sufficient; a large excess makes it difficult to wash the precipitate of barium carbonate completely. The pressure within the apparatus is kept slightly below that of the atmosphere during the distillation. The determination is made by adding (by means of the funnel F) hydrochloric or sulphuric acid to the liquid in the distilling flask until it is acid to methyl orange, avoiding a large excess of acid, and then distilling off 30—40 c.c. of liquid, finally sweeping out the apparatus with a slow current of air free from carbon dioxide. The $BaCO_3$ formed in D and E is filtered off, washed, and titrated with N/10 HCl. The amount of carbonate present is determined in another portion of the sample by precipitating with barium chloride in the cold (since barium cyanate decomposes when boiled). It is of course equally possible to remove the carbonate from the cyanate solution before distillation.



The hydrocyanic acid passes over quantitatively along with the carbon dioxide, and may be determined by titrating the filtrate from the precipitate of barium carbonate in the usual way. The following estimations were made in this way:—

Real Percentage of NaCN.	NaCN found by Distillation.
47·02	46·86
32·94	33·14
16·49	16·87

The solution remaining in the distilling flask contains the whole of the ammonia, formed by the decomposition of the cyanate, in the form of chloride or sulphate. After addition of caustic soda it is distilled off and collected in N/10 hydrochloric acid, when, as is usually the case, there is no other substance present which can form ammonia by boiling with caustic soda. This is a very useful check on the figure obtained from the carbon dioxide. If more ammonia is found than corresponds with the carbon dioxide the presence of some nitrogenous substance other than cyanide or cyanate may be inferred.

The following analyses will serve to indicate the degree of accuracy which may be obtained with the method described:—

Percentage of NaCNO present.	Percentage of NaCNO found.	
	From CO_2.	From NH_3.
28·87	..	26·29
20·19	..	19·12
42·54	43·67	..
42·54	41·41	..
..	92·60	94·25
..	93·17	94·25
3·86	3·47	3·57
3·66	..	3·62
3·06	2·84	3·72
3·06	3·09	3·72
..	3·10	3·57

The samples analysed contained most of the impurities which are usually to be found in commercial cyanides. It may be pointed out that if sodium or potassium carbamate were present it would behave in the same way as cyanate.

I am indebted to the Directors of the Cassel Gold Extracting Company for permission to publish these results.

Yorkshire Section.

Meeting held on Monday, January 25th, 1904.

MR. JAS. E. BEDFORD IN THE CHAIR.

NOTE ON "SOME RECENT METHODS OF TECHNICAL WATER ANALYSIS," BY PROF. H. R. PROCTER.

(This J., 1904, 8—11.)

BY L. ARCHBUTT.

The method of determining free carbon dioxide in water by titrating with a standard solution of sodium carbonate,* attributed to me by Prof. Procter, I first heard of by reading a paper by Leeds (J. Amer. Chem. Soc. 1831, page 98), abstracted in this Journal, 1891, page 726. Having been in want of a good simple method, and finding this answered my purpose, I adopted it, and mentioned it in a discussion which took place at a meeting of the Yorkshire Section in April 1892, which I happened to attend, in answer to a question put to me. The process has since been thoroughly investigated by Seyler (Chem. News, Vol. 70, 1894, pp. 104, &c.), and again in the Analyst (Vol. 22, 1897, p. 312), and by Ellms and Beneker (Chem. News, Vol. 84, 1901, p. 145, from the J. Amer. Chem. Soc., Vol. XVIII., No. 6.).

The method was also described by Trillich, of Munich, in 1890, and is sometimes referred to as the Lunge-Trillich method; but Leeds, working independently, was the first to make it known in this country.

---

* H. Bretel (J. Pharm., 23, 339—341), abstracted in Chem. Soc. 1891, 862, recommended standard K_2CO_3 solution for the above purpose. This is practically the same method.

PATENT SPECIFICATIONS may be obtained by post by remitting as follows:—

English.—8*d.* each, to the Comptroller of the Patent Office, C. N. Dalton, Esq., Southampton Buildings, Chancery Lane, London, W.C.

United States.—1*s.* each, to the Secretary of the Society.

French.—1 fr. 25 c. each, to Belin et Cie., 56, Rue des Francs-Bourgeois, Paris (3e).

I.—PLANT, APPARATUS AND MACHINERY.

Factory Chimneys; Wind Pressure on ——. A. Ostenfeld. Ingeniøren, 1903, 199; Proc. Inst. Civil Eng., 1903, **154**, 61—62.

THE following conclusions are drawn, as the result of an examination of the dimensions and details of several factory chimneys damaged by a gale in Denmark on Dec. 25—26, 1902:—(*a*) The empirical rules for calculating the stability of chimneys from their dimensions are unreliable; (*b*) the wind pressure should be taken as 150 kilos. per sq. m. (31 lb. per sq. ft.) acting, for round chimneys, on two-thirds of their external diameter; (*c*) for hard-burnt brick laid in cement mortar, the greatest crushing strain, when free from wind pressure, should not be allowed to exceed 15 kilos. per sq. cm. (220 lb. per sq. in.), unless the crushing strength has been directly proved to be not less than 250 kilos. per sq. cm., in which case a crushing strain of not more than 25 kilos. per sq. cm. is permissible.—T. F. B.

ENGLISH PATENT.

Drying Apparatus; Impts. in ——. H. J. Haddan, London. From The Edson Reduction Machinery Co., Ohio, U.S. America. Eng. Pat. 25,059, Nov. 17, 1903.

THE dryer is composed of a number of renewable and interchangeable annular cylindrical chambers, surrounded by a steam heating jacket, and provided with suitable flanges, so as to be bolted together and threaded on to a central horizontal shaft passing through their midst, to which are attached stirring arms, radially arranged. Openings are provided for the admission of the substance to be dried, for drainage, and for the escape of the hot vapours.—L. F. G.

UNITED-STATES PATENTS.

Motive Power; Process of Generating ——. A. Schütt, Charlottenburg, Germany. U.S. Pat. 750,493, Jan. 26, 1904.

METHYL chloride is mixed with water and heated, the methyl chloride vapours being used to drive a motor. —L. F. G.

Motive Power; Generation of ——. A. Schütt, Charlottenburg, Germany. U.S. Pat. 750,194, Jan. 26, 1904.

SULPHUROUS acid is mixed with a mineral oil and the mixture heated, the sulphurous acid vapour being used as a driving medium.—L. F. G.

Furnace. G. Garrett, Coatbridge, Scotland. U.S. Pat. 750,635, Jan. 26, 1903.

A HOLLOW annular casing, with its inner side perforated, is placed beneath the furnace and supporting its side walls. The casing is connected with an air-blower and water-boxes placed in the side walls of the furnace.—L. F. G.

Flask for Volatile or other Liquids. H. Goetz, Frankfort-on-Maine, Germany. U.S. Pat. 750,637, Jan. 26, 1904.

A COLLAR is cemented to the neck of a flask, and a sleeve, divided into two parts by a perforated partition, screwed on to it. A washer is placed between the partition and the neck, and a flanged capillary tube passed through the partition into the flask, the flange resting upon the partition in the sleeve. Above this is placed another capillary discharge tube containing a plug of absorbent material, and the whole closed air-tight by a cap screwed on to the sleeve. —L. F. G.

Centrifugal Apparatus. A. Liedbeck, Stockholm. U.S. Pat. 750,668, Jan. 26, 1904.

THE apparatus contains an outer drum, tapering upwards, and a similar inner drum, provided on its outer surface with screw threads, these fitting closely to the inner surface of the outer drum. Outlets are arranged near the bottom of the inner drum between the threads, and discharge apertures at the bottom of the outer drum, the liquid being thus subjected to the action of the centrifugal force for a long period.—L. F. G.

Suspended Matter; Apparatus for Removing —— from Liquids by Continuous Decantation. T. R. Wollaston, Manchester. U.S. Pat. 751,038, Feb. 2, 1904.

INSIDE a precipitating vessel are arranged a series of pivoted parallel depositing shelves, with corrugations running transversely to the path of the liquid, and to the pivots, and provided alternately with openings at the ends, so that the liquid circulates over them in zigzag fashion. —L. F. G.

Filtering Machine. J. W. Osborne, Winchester, Ill., U.S.A., Assignor to C. Smithson and S. Hainsfurther. U.S. Pat. 751,805, Feb. 9, 1904.

THE apparatus consists of a cylinder with a filtering diaphragm at one end, a piston and a piston rod; this latter extends through the other end, and is connected by a rack and pinion to a handle, by means of which it can always be returned to its initial position. Steam, admitted through a pipe, forces the piston towards the diaphragm, and a liquid, which is admitted through suitable supply pipes, is thus filtered through under pressure.—L. F. G.

FRENCH PATENTS.

[illegible] Copper (Heat-retaining) Vessel. I. Rosberg and Co. Fr. Pat. 335,178, Sept. 21, 1903.

THE apparatus consists of an inner and an outer cylindrical vessel, the intermediate space being filled with some non-conducting material, such as wood shavings or paper clippings. An insulating cover, with a grooved rim, fits hermetically on the outer vessel.—L. F. G.

Incrustation of Boilers; Means for Preventing the ——. W. Gawlikowski. Fr. Pat. 335,597, Sept. 28, 1903.

To remove, and prevent scale forming in boilers, coal or charcoal dust is mixed with the feed-water. Before using a boiler, after an interval of rest, $1\frac{1}{2}$ litres of coal-dust are put into it.—L. F. G.

II.—FUEL, GAS, AND LIGHT.

Incandescent Gas Mantle; Unbreakable ——. Sysoyeff. J. Usines à Gaz, 1903, 178. Proc. Inst. Civil Eng., 1903, **154**, 45.

IT is stated that, by adding fragments of old mantles to the thorium-cerium impregnating bath, mantles of great strength are obtained, whilst the luminous efficiency is in no way diminished.—T. F. B.

Osmium [Electric] Lamps; Efficiency and Colour of ——. F. G. Baily. Electrician, 1904, 646.

THE average results obtained by the author with a number of 32 candle-power 55-volt osmium lamps (see Eng. Pats. 13,116 and 17,580 of 1898, 7210 and 7211 of 1900; this J., 1899, 571, 746; 1901, 32, 236) were as follows:—

E.M.F.	Current.	Candle Power.	Watts per Candle.	Candles per Watt.	Resistance.
Volts.	Amperes.				Ohms.
30·3	0·744	2·30	9·80	0·102	40·7
35·4	0·812	4·81	6·00	0·167	43·7
40·4	0·900	8·76	4·26	0·235	45·0
45·5	0·970	14·50	3·04	0·330	46·8
50·5	1·032	22·00	2·37	0·422	48·8
55·6	1·106	32·60	1·89	0·529	50·2
60·6	1·178	45·40	1·57	0·637	51·4

With regard to the life of the osmium lamps, Wedding found that of 18 lamps, the average life was over 1,900 hours, whilst some of them lasted for upwards of 4,000 hours. The average candle-power at the end of the life was about 80 per cent. of the initial value. The author considers that though the low resistance of the osmium lamps renders them inconvenient for use as single lights, yet their high efficiency (1·9 watts per candle at the normal E.M.F. of 55 volts) may allow of their being used advantageously in place of carbon filament lamps, when groups of lights are required. Taking into consideration the life and maintenance of efficiency of the osmium lamp, it may be considered to have at least double the efficiency of the carbon lamp under equivalent conditions. The colour of osmium lamps appears to be similar to that of carbon lamps having an efficiency of 2·1 watts per candle. Osmium lamps are suitable for use as secondary standards of light, owing (1) to the whiteness of the light; (2) to the small deterioration of the candle-power; and (3) to the smaller variation of candle-power with change of E.M.F., rendering error of adjustment of E.M.F. less serious than in the case of the carbon lamp. When used as standards, the lamps should be adjusted to a definite E.M.F., not to a definite current.—A. S.

Mercury Arc-Lamp of Quartz Glass [Mercury Vapour Lamp]. M. Bodenstein. Zeits. für Elektrochem., 1904, **10**, 123.

THE author describes an H-shaped mercury vapour lamp of fused quartz, with iridium electrodes fused into the quartz. The capillary passages around the iridium are protected by external mercury cups, which prevent ingress of air. The arc—2 amperes at 100 volts—plays between the two mercury surfaces, along an almost horizontal tube, 1 cm. diameter and 17 cm. long. The striking of the arc is effected by electrically heating one of the side tubes, the pressure of mercury vapour causing the mercury to flow along the tube and make contact with the metal contained in the other limb, after which the heating current is automatically cut out.—R. S. H.

Gas-Analysis by Combustion ; Calculation of ——. A. Wohl. XXIII., page 269.

UNITED STATES PATENTS.

Fuel Blocks [Briquettes] ; Artificial ——. M. W. Cottle, St. Louis, Mo., U.S.A., Assignor to Coaleo Fuel Manufacturing Co. U.S. Pat. 751,468, Feb. 9, 1904.

EIGHTY-FIVE parts of powdered coal, 8 parts of sawdust. parts of rosin, and 2 parts of glue are intimately mixed ogether, heated by steam, and moulded while hot into riquettes.—L. F. G.

Gas ; Manufacture of ——. W. A. Könemann, Chicago, Ill. U.S. Pat. 749,302, Jan. 12, 1904.

STEAM is introduced into a producer containing a bed of arbonaceous material, briquetted carbonaceous fuel, or fuel briquettes composed of an agglutinated mixture of anthracite and bituminous coals, whilst surplus heat, practically free rom nitrogen, from an operating electric furnace is conducted into the producer ; the arc generates gas and upplies more heat to the producer than is abstracted by dissociation of the water-vapour ; alternatively the materials are fed into the producer, air being excluded.—J. K. B.

Carbonic Acid in Gases ; [Electrical] Method of Determining the Quantity of ——. G. Bodländer. U.S. Pat. 751,897, Feb. 9, 1904. XXIII., page 273.

FRENCH PATENTS.

Gas Retorts ; Manufacture of ——. R. J. P. Cottancin. Fr. Pat. 335,625, Sept. 14, 1903.

To prevent the iron or steel framework of furnaces from being carbonised by the action of the oxides of carbon diffusing through the refractory lining, the steel or iron columns are surrounded by a protective casing of copper, or some other metal which does not get carbonised, and the space between filled in with some oxidising material, either in the form of powder or mixed with clay. The furnace is built up of square hollow iron boxes, filled with a refractory material, and clamped or hinged together, and to the framework by suitable means. Or, the iron boxes may be dispensed with, and the bricks embedded in some refractory clay. The bricks may be perforated or hollow, so as to allow any desired oxidising, reducing, or carbonising material to be filled in.—L. F. G.

Gas Scrubber. L. Valette. Fr. Pat. 335,803, Sept. 19, 1903.

THE scrubber comprises three concentric vertical casings, the middle and outer casings being closed by means of dome-shaped tops ; the inner casing is filled with coke or the like, and water is distributed over both the coke and the exterior of the middle casing. The gas to be purified is led up through the coke, whereby most of the impurities are eliminated ; it then passes down the annular space between the inner and middle casings, and finally passes up the outer annular space, where it is further purified by the descending water. A readily accessible water-seal device is provided at the base of the apparatus for removing the collected dirt and letting the wash-water pass off.—H. B.

Gas-purifying Materials ; [Automatic] Revivification of ——, *used in Gas Works.* E. E. Delcourt. Fr. Pat. 335,647, Sept. 30, 1903.

THE main gas-meter of the works is connected by means of a chain and cog-wheels to a smaller meter, the rate of transmission being such, that the latter admits 14 litres of air into the purifiers for every cubic metre of gas that passes. This amount of air is sufficient to continuously revivify the spent materials. To compensate for the loss in illuminating power caused by dilution with this amount of air, the gas may be bubbled through a mixture of water and benzol ; thereby the naphthalene is retained, and choking of the pipes prevented.—L. F. G.

Mantles ; Incandescence ——. L. Faucillon. Fr. Pat. 335,811, Oct. 5, 1903.

MANTLES are strengthened by interweaving into the impregnated fabrics strong longitudinal threads, of ramie or the like, which have been impregnated with a solution of nitrates of thorium, cerium, and didymium.—H. B.

Shale Oil and Similar Substances ; Method of Treating [Desulphurising] ——. A. Adiassewich, London. Eng. Pat. 4431, Feb. 25, 1903.

SHALE oil and other mineral oils are desulphurised by heating under pressure successively with dilute sulphuric acid, caustic soda, and aluminium chloride. For example, the burning oil obtained by the distillation of shale oil is heated with about 0·75 per cent. of its weight of 60 per

cent. sulphuric acid, to 40°—50° C., under a pressure of 15 to 20 lb. per sq. in., for about half an hour, the whole being agitated during the process. The oil is separated, washed, and treated with about 0·3 per cent. of its weight of caustic soda liquor (sp. gr. about 1·32) at a temperature near the boiling point of the oil, the pressure being maintained at 25 to 30 lb. per sq. in. This treatment is continued until the mixture is completely emulsified. The oil is then washed, dried, and heated with about 2 per cent. of aluminium chloride to about 150° C., under reflux condenser. The pressure is then raised to 10—12 lb. per sq. in., and maintained for about three hours, when the oil is separated, washed with water containing a little lime, and finally distilled. The temperatures and pressures used, vary, in general, with the boiling point of the oil to be treated.
—T. F. B.

United States Patent.

Wood Distillation; Apparatus for——. J. W. Spurlock, Tyty, Ga. U.S. Pat. 751,698, Feb. 9, 1904.

A vertical retort is provided at its bottom with a tar-discharge pipe, and at the top with a vapour-outlet pipe; the condensed creosote is drawn off through a pipe leading from the vapour-outlet pipe, and the more volatile portion of the distillate passes to a separator, where a further portion of the vapour is condensed and removed; the vapours pass thence through a series of condenser pipes "forming a circuitous passage," and discharging into a tank. Just below the upper end of the condenser pipes there is fitted a valve-controlled water-discharge pipe.—T. F. B.

IV.—COLOURING MATTERS AND DYESTUFFS.

Symmetrical γ-dihydroxy-γ-diphenyl Anthracene Dihydride from Anthraquinone. A. Haller and A. Guyot. Comptes rend., 1904, **138**, 327—329.

The authors have, with the aid of magnesium phenyl, prepared this substance, which bears the same relation to phthalic green and kindred derivatives (this J., 1903, 1240) that triphenylcarbinol does to the triphenylmethane derivatives. To magnesium powder suspended in ether are added a fragment of iodine and the calculated amount of monobromobenzene. When reaction is complete, anthraquinone suspended in ether, is very gradually added. Ultimately a pasty mass is formed, which is treated with water acidulated with hydrochloric acid, and purified by a long series of treatments with boiling methyl alcohol. Colourless brilliant needles are formed, which quickly lose alcohol of crystallisation, and effloresce to a white powder, m.pt. 242° C. The substance dissolves in strong sulphuric acid with a fine indigo colour, which becomes orange-yellow on heating on the water-bath.—J. T. D.

Anthraquinone-α-monosulphonic Acid. M. Dünschmann. Ber., 1904, **37**, 331—333.

It is usually supposed that in sulphonating anthraquinone for "blue shade," β-sulphonic acid is formed with varying quantities of α- and β-disulphonic acid, depending on the strength of sulphuric anhydride employed and the temperature used. The author, however, shows that α-monosulphonic acid is simultaneously produced, though only in small quantity, whilst, owing to oxidation, hydroxysulphonic acids are formed, especially hydroxyanthraquinone disulphonic acid. The isolation of the α-acid was effected by removing the main portion of "silver salt" (sodium anthraquinone-β-monosulphonate) and concentrating the filtrate by evaporation to separate a further batch of crystals, so that the final solution contained chiefly the 2:7-disulphonic acid. The middle fraction is a mixture of the sodium salts of the following acids:—2:6-anthraquinone disulphonic acid, α- and β-anthraquinone monosulphonic acids, and hydroxy anthraquinone-sulphonic acids. On treating a hot saturated solution with 10 per cent. of a 45 per cent. solution of caustic soda and cooling to 50°—55° C., the greater part of the 2:6-disulphonate salt crystallises out with the "silver salt," whilst the mother liquor on further cooling deposits the sodium salt of α-monosulphonic acid, which, when purified by repeated recrystallisation from dilute caustic soda solution, forms golden-yellow, lustrous laminæ. On treating the alpha salt with ammonia and zinc dust, a deep reddish-yellow coloration is obtained, whilst the beta salt gives, under similar conditions, a brownish-yellow colour reaction. The α-position was further confirmed by the formation of erythrohydroxyanthraquinone according to a method recently patented, and consisting in heating the salt with lime under pressure. The conversion takes place at 130°—140° C., at which temperature the "silver salt" fails to react with lime.—D. B.

Bisulphites; Action of —— on Aromatic Amino and Hydroxy Compounds. H. T. Bucherer. J. für Prakt. Chem., 1904, **69**, 49—91.

If aromatic amino compounds be heated with aqueous sodium bisulphite to a moderate temperature, ammonia is evolved, and products are formed which appear to be sulphurous acid esters, *e.g.*, *m*-phenylenediamine gives aminophenol sulphurous acid ester, and also dihydroxybenzene esters; the equation in the first case being $H_2N.C_6H_4.NH_2 + 2NaHSO_3 = H_2N.C_6H_4.O.SO_2H + Na_2SO_3 + NH_3$. These esters are easily saponified by alkalis, and thus it is possible to convert amino groups into hydroxyl groups. Similar esters are produced by the action of sodium bisulphite on aromatic hydroxy compounds, as shown by the following example:—$C_{10}H_6(OH)(SO_3H) + 2NaHSO_3 = Na_2SO_3 + H_2O + C_{10}H_6(O.SO_2H)(SO_3H)$. If aromatic hydroxy compounds are heated with ammonium sulphite and ammonia, the hydroxyl groups are replaced by amino ones, sulphurous esters being formed as intermediate products, *e.g.*, β-naphthol gives β-naphthylamine. The ammonium sulphite appears to act as a carrier, thus—

$$\begin{aligned}C_{10}H_7OH + (NH_4)_2SO_3 + NH_3 &= C_{10}H_7.O.SO_2.NH_4 + 2NH_3 + H_2O\\ &= C_{10}H_7.NH_2 + (NH_4)_2SO_3 + H_2O.\end{aligned}$$

—A. B. S.

Betaïnes; Some Aromatic ——. R. Willstätter and W. Kahn. Ber., 1904, **37**, 401—417.

The behaviour on warming of the trimethyl-betaïnes of *o*-, *m*- and *p*-aminobenzoic acids, and of the betaïne from phenylglycocoll, was investigated, and it was found that they all behaved in a similar manner, being converted by intramolecular transformation into the corresponding dimethylaminobenzoic acid methyl ethers, whilst the betaïne from phenylglycocoll formed the methyl ether of phenylmethylglycocoll. In the case of the betaïne from anthranilic acid, the transformation was accompanied by a bye-reaction, a certain amount of dimethylaniline being formed. Whereas *m*- and *p*-aminobenzoic acids are readily methylated by means of methyl iodide to the corresponding betaïnes, the preparation of the betaïne of anthranilic acid requires much more energetic alkylation.—E. F.

Nitro Compounds of the Naphthalene, Anthracene, and Phenanthrene Series; Electrochemical Reduction of——. J. Möller. XI. A., page 257.

English Patents.

Indigo [Indigo Dyestuffs], Soluble; Manufacture of——. B. Bury, Church, and B. W. Gerland, Accrington. Eng. Pat. 5328, March 7, 1903.

Refined natural or artificial indigo is heated with one to three times its weight of concentrated sulphuric acid. The temperature may be finally raised to 120°—140° C. The resulting product sets to a dry or stiff pasty mass on cooling, containing 50—70 per cent. of indigo disulphonic acid, or a mixture of mono- and disulphonic acids, which dyes in brighter shades than the soluble indigo ordinarily used, and is more completely absorbed by the fibre.—E. F.

Indigo; Purification of ——. J. Y. Johnson. From The Badische Anilin und Soda Fabrik, Ludwigshafen a. Rh., Germany. Eng. Pat. 7395, March 30, 1903.

Indigo is purified by dissolving out the impurities with phenol or a phenolic ether, such as α-naphtholethyl ether.

It may also be purified by heating it to temperatures below its sublimation or decomposition point, for instance to 270° C. By this means the red admixtures are destroyed and partially escape as gas.—E. F.

[Azo] Dyes ; Manufacture of ——. H. H. Lake, London. From K. Oehler, Offenbach-on-Main. Eng. Pat. 8575, April 15, 1993.

See U.S. Pats. 740,767 and 740,768 of 1903 ; this J., 1903, 1191.—T. F. B.

Tetrazo- [Azo-] Dyestuffs ; Manufacture of New Substantive ——. O. Imray, London. From Society of Chemical Industry in Basle, Basle, Switzerland. Eng. Pat. 27,630, Dec. 16, 1903.

One molecule of the tetrazo-derivative of an azoxyamine of the type $NH_2.R.N_2O.R.NH_2$, or of the tetrazo-derivative of an azoamine of the type $NH_2.R.N_2.R.NH_2$ is combined with 2 mols. of 2.5.7-aminonaphtholsulphonic acid or 2.5.1.7-aminonaphtholdisulphonic acid, or with 1 mol. of either of these sulphonic acids, and 1 mol. of a sulphonic or carboxylic derivative of a phenol or naphthol or of an aminoalphylacidyl-derivative of 2.5.7-aminonaphtholsulphonic acid, or 2.5.1.7-aminonaphtholdisulphonic acid. The products dye cotton directly in reddish-orange shades, which, on diazotisation on the fibre and development with β-naphthol, produce Bordeaux tints, fast to washing.—E. F.

French Patents.

Benzyl Compounds ; Preparation of New ——. Cie. Parisienne de Couleurs d'Aniline. Fr. Pat. 328,170, Dec. 9, 1902.

Mono- and dichlorobenzylsulphonic acids are obtained by treating benzylsulphonic acids in aqueous solution with chlorine or chlorinating agents. Dichlorobenzylsulphonic acids are also obtained by treating monochlorobenzylsulphonic acids in the same manner. The products are intended for use in the preparation of dyestuffs after being nitrated and reduced or treated with ammonia, amines, or caustic soda.—E. F.

Indigo Dyestuffs derived from Benzene and from Naphthalene, and Intermediate Products ; Preparation of ——. C. and H. Dreyfus. Second Addition, dated Aug. 25, 1903, to Fr. Pat. 326,168, Nov. 8, 1902 (this Journal, 1903, 792 and 903).

Hydrocyanocarbodialphylamides, prepared by the methods described in the main patent and its first addition, are converted into their thioamides by treating them with a mixture of sulphur and an aqueous solution of a sulphide (such as sodium or potassium sulphide). α-Derivatives of naphthisatins are prepared by heating the corresponding hydrocyanocarbodialphylamides or their thioamides with concentrated sulphuric acid, cooling, and pouring into ice and water. Sulphonated α-derivatives of naphthisatins are obtained from the corresponding hydrocyanocarbodialphylamides or their thioamides by a more vigorous treatment with concentrated sulphuric acid and subsequent pouring into ice and water. By suitable reducing agents they are converted into sulphonated indigos. α-Derivatives of isatins or their salts are converted into indigos, derived from benzene or from naphthalene, by the action of hydrogen sulphide in presence of alkali carbonates or other alkaline substances.—E. F.

Sulphide Dyestuff, Blue, derived from p-Hydroxy-p′-amino-m′-methyldiphenylamine ; Production of ——. Fabr. de Prods. Chim. ci-devant Sandoz. First Addition, dated Sept. 26, 1903, to Fr. Pat. 332,560 of May 28, 1903 (this J., 1903, 1241).

Alphyl-*p*-amino-*p′*-hydroxydiphenylamines and their homologues are heated to 160°—200° C. with sulphur, with or without addition of hydrated chromium oxide. Indigo-blue to greenish-blue dyestuffs are so obtained, fast to washing and to light.—E. F.

V.—PREPARING, BLEACHING, DYEING, PRINTING, AND FINISHING TEXTILES, YARNS, AND FIBRES.

Flax Retting ; The Bacteria which are concerned in ——. M. W. Beijerinck and van Delden. Mitt. Konigl. Akad. Wissensch. Amsterdam, 1903, 673 ; through Woch. f. Brau., 1904, **21**, 85—86.

The retting of flax involves essentially a fermentation of the pectose in the layers of cells above and below the system of bast fibres, whereby the latter are loosened. The specific bacterium of the process of "water-retting" is *Granulobacter pectinovorum,* which is accompanied by a less powerful species, *G. urocephalum.* According to Behrends the active agents in the "dew-retting" process are, mould fungi. Certain aerobic bacteria, notably species of the group of hay bacilli, also known as potato bacilli, are likewise capable of effecting the retting of flax with full exposure to the air. The acetic and lactic acid bacteria and certain species of yeast-like organisms, which are also found in the retting waters, have no retting action. The retting depends on the secretion by the bacteria of the enzyme pectosinase, which acts on the pectose after the manner of a hydrolysing acid, converting it first into pectin and the latter into sugars. These are fermented, in the case of *G. pectinovorum,* with the production of hydrogen, carbon dioxide, and a little butyric acid, but in the case of the hay bacilli they are assimilated and respired. The sugars produced, are most probably galactose and xylose, perhaps in some cases also glucose and arabinose. Pectosinase can be extracted by water and precipitated by alcohol, but the isolated enzyme is feeble in its action as compared with the living bacteria. The authors have found that the active retting bacteria are best favoured by removing the soluble matters of the flax stems by changes of water in the early stages of retting. In this way the butyric and lactic acid bacteria are suppressed by the removal of their nutrients. The species of *Granulobacter* then gain the ascendancy, since, owing to their great proteolytic power, they are able to utilise the sparingly soluble protoplasmic albumin of the flax. The best practical process for the retting of flax is that of water-retting in vats. The flax is packed tightly in deep wooden vats provided with false bottoms. The quantity and temperature of the water can thus be controlled, and the water can be discharged from time to time for the purpose of aerating the goods and removing the lactic and other bacteria. The first steep water containing the soluble matters should be discharged after 24 hours ; the second steep should consist of a mixture of fresh water and good retting liquor from a previous fermentation. This may be replaced on the third day with fresh water, since the true retting bacteria will then have become established. Pure cultures of the pectose bacteria are made by pasteurising a portion of well-retted flax stems at 90° C. for a short time and developing the surviving spores anaerobically on wort-agar at 35° C. Besides the two active species of *Granulobacter,* two other species, *G. saccharobutyricum* and *G. butylicum* are thus isolated, which have no retting properties. The cells of *G. pectinovorum* have a shape resembling tadpoles; only the swollen ends, which contain the spores, are sharply defined. In malt extract, in absence of air, a powerful evolution of gas is produced without the formation of butyric acid. In other saccharine liquids containing peptone or meat extract, a little butyric acid is produced during fermentation. Only in presence of pectin can ammonium salts be utilised as nitrogenous nutrients. The cells of *G. urocephalum* are more sharply defined and shaped like drum-sticks. This species can utilise ammonium salts as the source of nitrogen for the fermentation of all kinds of carbohydrates.—J. F. B.

Textile Fibres and Dyestuffs ; Relations between ——. H. Behrens. Chem.-Zeit., 1903, **27**, 1252—1254.

Certain Physical and Chemical Properties of Textile Fibres.—Textile fibres are doubly refractive and optically positive, the colours which they exhibit in polarised light extending, in the case of hemp and ramie, to green of the second order, and, in that of wool and silk, to orange of the first order, the least doubly refractive being cotton and wood cellulose. In proportion to the degree in which they possess, in the undyed state, the property of double refraction, vegetable fibres may be rendered dichroic by dyeing: slightly so, for example, with basic dyestuffs, such as Bismarck brown, safranine, and methylene blue, when these are absorbed from neutral solutions; much more so with the benzidine dyestuffs—Congo red, benzoazurin, &c.—applied from baths containing sodium carbonate, and with iodine dissolved in zinc chloride solution or in sulphuric acid. Crystalline dichroism is not the cause of the phenomenon. Wool and silk are not rendered dichroic by dyeing. The distribution of dyestuffs probably takes place regularly throughout the fibre substances in the case of the vegetable fibres, irregularly in that of the animal fibres, the dyeing of the latter being doubtless ascribable to the formation of solid solutions or to chemical combination. Cellulose hexanitrate is not dyed by benzoazurin. The penta- and tetranitrates (collodion cotton) are slightly dyed by the same dyestuff, but without being rendered dichroic. Cellulose dibenzoate (from linen) is also slightly dyed by the same colouring matter, but it is strongly dyed by safranine and malachite green, the dyed fibres not displaying dichroism. By the action of benzene sulphonic chloride on cellulose, esters may be produced which are not dyed in the least degree by benzoazurin, but which, on the other hand, are very strongly dyed by safranine and methylene blue, without becoming, however, dichroic. From these results it would appear that, in the dyeing of cellulose fibres with substantive cotton dyestuffs, the hydroxyl groups of the former, and particularly those two which are most readily attacked in the esterification of the fibre molecule, are acted upon, with the probable formation of sodium salts of cellulose colour-esters.

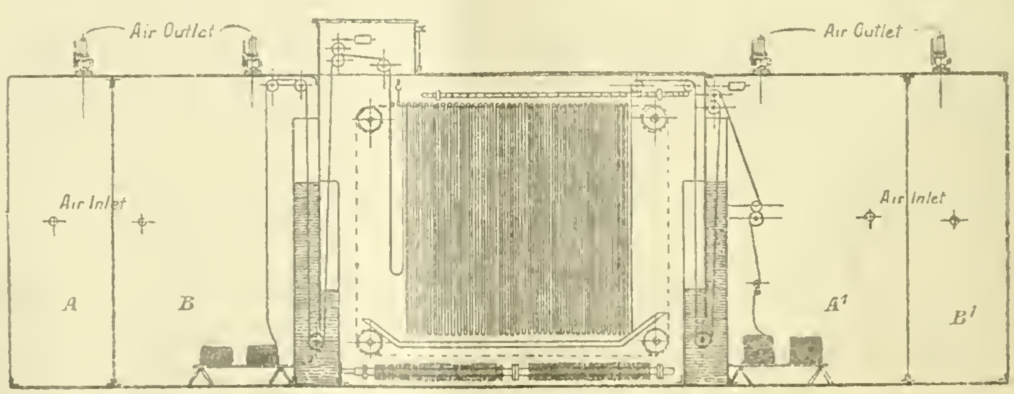
Functions of Alkalis and Alkali Salts in Dyeing.—When linen fibres which have been dyed with benzoazurin are mercerised with caustic soda, their colour changes from blue to red, the soda-lye becoming also coloured red. The combination of the dyestuff and fibre is resolved, the solubility of the dyestuff being increased, and the dyestuff being driven into the walls of the fibre as these thicken. On adding an alkali bicarbonate or a large volume of water to the solution, the red colour of the latter is changed to blue, whilst the dissolved dyestuff is again to some extent absorbed by the fibre. The more thorough penetration of the fibre by the dyestuff, induced by the action of the alkali, is easily perceptible under the microscope in cross sections of the fibre. It is due to the increased osmotic pressure of the solution of the dyestuff in the caustic soda-lye. It is not produced by the addition of common salt or sodium sulphate to the bath when dyeing with Benzoazurin, the deeper shades resulting from such additions corresponding merely with the further deposition of dyestuff on the surface of the fibres. The action of the alkali is, further, seen with linen fibres which have been dyed with indigo in strongly alkaline vats, as compared with fibres which are dyed in nearly neutral vats, the former, under the microscope appearing dyed more deeply and uniformly throughout than the latter.

Behaviour of Wool and Silk in Dyeing.—Silk is dyed by malachite green, methylene blue, and safranine in neutral baths, and by croceine scarlet and eosine in acid baths at the ordinary temperature. To obtain equally intense dyeings on wool, the temperature of the baths must be raised to at least 70° C. In cross sections of dyed wool fibres, the central, medullary part of the fibre cylinders appears less coloured than the surrounding, fibrillary mass, but much more deeply coloured than the external, cuticular scales. Wool fibres which have been strongly pressed in places are dyed by malachite green at the ordinary temperature in the places to which the pressure has been applied. The author thinks that useful application might be made of this observation.—E. B.

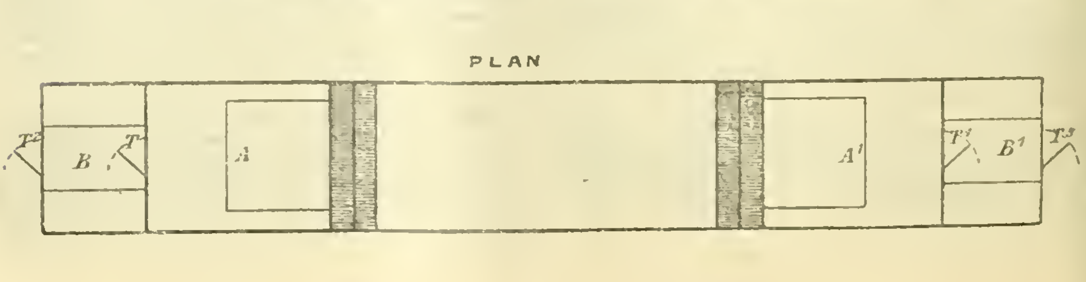
Bleaching Apparatus; The Endler-Welter Continuous ——. W. Elhers. Zeits. f. Farben- u. Textil-Chem., 1904, **3**, 39—41.

Tissues are sewn together end to end, and passed at full width and in a continuous manner through an apparatus consisting of (i) a central steaming chamber (see figures) to which steam is admitted and heated by means of a superheater until it attains a pressure of 2—2½ atmospheres; (ii) two liquor seals, in the first, or both, of which a solution of the scouring agent, *e.g.*, caustic soda, is contained, and through which the tissues successively pass; and (iii) a number of chambers, A, A_1, B, B_1, containing air under a pressure of 1½—2 atmospheres, which serve the purpose of maintaining the height of the liquor in the seals at a convenient level. Access is had to the air chambers through the doors T, T_1, T_2, T_3, which are kept tightly closed when

SECTIONAL ELEVATION



PLAN



the apparatus is in use. The apparatus, it is considered, is likely to be especially serviceable in the bleaching of flannelettes, moleskins, and similar tissues. It is stated that the men in charge can work in the compressed air chambers, provided the pressure in these does not exceed 2 atmospheres, without detriment to their health.—E. B.

Turkey-Red Oil, and the Action of Concentrated Sulphuric Acid on Olive Oil. W. Herbig. Färber-Zeit., 1904, **15**, 38—46.

An examination of the washings of the product resulting from the action of concentrated sulphuric acid on olive oil shows that a portion of the triglyceride has been saponified, the amount of sulphuric acid entering into the reaction being, in general, equivalent to the amount of oleic acid required for the formation of stearosulphonic acid; under certain conditions a larger amount of free oleic acid can result than corresponds to the sulphuric acid used for the sulphonation. The glycerin is found in the washings in the free state, and occasionally as glycerosulphonic acid. In drying the sulphonated oil, and also, under certain conditions, during the treatment with sulphuric acid, decomposition of the sulphonic acid into hydroxystearic acid takes place. This change also occurs during treatment of the fabrics with the oil, since stearinsulphonic acid is converted, by prolonged heating with water, into hydroxystearic acid. An examination of the lake-forming properties of oils sulphonated under various conditions showed that the presence of hydroxystearic acid was necessary, whilst stearosulphonic acid appeared not to assist in the lake formation at all. It also appeared a necessary condition that only a certain percentage of stearosulphonic acid should be present, and also that some unsaponified triglyceride should still exist. The best dyeing results were obtained by using an oil of which 20—25 per cent. was saponified; further saponification (by using more acid, higher temperatures, &c.) gave an oil yielding inferior results.—T. F. B.

English Patents.

Dyeing, Mordanting, or Washing Fibrous Materials; Apparatus for ——. W. Dargue, F. L. Dargue, Halifax, and H. Barker, Bradford. Eng. Pat. 14,125, June 25, 1903.

The machine is used for dyeing, mordanting, or washing fibrous material in hanks. The hanks are passed through the liquor on endless carriers slung from rollers supported above the dye-vessel. Mechanism is provided for rotating the rollers carrying the hanks and for lowering, raising, or traversing the hank roller-lifting frame and also for interlocking the levers controlling these two operations, and for preventing the actuation of the raising or lowering gear except when the sockets, in which the ends of the hank rollers engage, are in the proper position for the rollers to register or to be withdrawn. Mechanism is also provided for automatically throwing out of action the raising and lowering gear and the traversing gear. A new form of hank carrier is also claimed which automatically stretches the hanks of material carried and so prevents "lapping" of the fibres.—E. F.

Glue or Size especially adapted for the Warp Threads of Fabrics; Process for the Manufacture of ——. H. J. Haddan, London. From P. F. Oliva, Barcelona. Eng. Pat. 22,697, Oct. 20, 1903.

See Fr. Pat. 335,506 of 1903; following these.—T. F. B.

United States Patent.

Yarn; Apparatus for Colouring ——. A. Fornander, New York, Assignor to the Carpet Yarn Printing Co., N.Y. U.S. Pat. 750,758, Jan. 26, 1904.

In an apparatus for printing yarns by means of a disc revolving in a trough of colour on a travelling carriage, scrapers are provided for scraping the colour after printing on the yarn, and mechanism is added to automatically remove the scrapers from contact with the yarn drum when the printing of each stripe of colour is completed.
—A. B. S.

French Patents.

Sizing or Dressing suitable for the Warp Threads of Textiles; Process of obtaining ——. P. F. Oliva. Fr. Pat. 335,506, Sept. 14, 1903.

Gluten is subjected to fermentation by suitable substances (*e.g.*, 3 per cent. of carrot juice), and is then treated with substances which prevent any further fermentation (*e.g.*, 1 per cent. of oak-bark). The dressing obtained by this process is applied in the usual manner.—T. F. B.

Dressing [for Textiles] consisting of a Coating of Viscose. Soc. Franc. de la Viscose. Fr. Pat. 335,598, Sept. 28, 1903.

The fabric is passed over rollers successively through water, a solution of cellulose (Fr. Pat. 334,636 of 1903; this J., 1904, 75), a "precipitating" bath (preferably an ammonium chloride solution), a solution of sea-salt (20 per cent.) to remove impurities from the cellulose, and an acid bath, preferably 3 per cent. hydrochloric acid, and is finally washed with water. In this way the fabric is coated with cellulose, and is said to be easily bleached or dyed by any process.—T. F. B.

Bleaching Apparatus; Continuous ——. M. Muntadas y Rovira. Addition, dated Sept. 29, 1903, to Fr. Pat. 327,931, Nov. 10, 1902.

As an improvement on the main patent (see this J., 1903, 948), an arrangement is added to circulate the liquid in the opposite direction to the movement of the cloth.

By a special arrangement the cloth is made to alternately roll and unroll on a series of rollers, whilst all the time moving in the same direction.—A. B. S.

Cotton Dyeing; Apparatus for ——. Wegmann and Co. Fr. Pat. 335,596, Sept. 28, 1903.

In a dye vat are placed a series of connected horizontal pipes, one above the other. These have a number of lateral openings into which are screwed perforated bobbins, which are closed at the other end. The cotton as it comes from the carding machine, is wound around these bobbins, and tightly compressed between two end plates. The dye-liquor is forced by means of a pump through the main pipes, and passes through the cotton by means of the perforations in the bobbins. The liquid is continuously circulated by means of a pump, and by suitable valves water can be circulated for washing, &c. The bobbins bearing the dyed cotton can be easily removed and replaced by fresh ones.—A. B. S.

Finishing Process for Textiles; Continuous ——, *with Arrangement for Drying between each Bath.* F. Bertrand and Co. Addition, dated Sept. 14, 1903, to Fr. Pat. 334,890, Aug. 14, 1903. See this J., 1904, 185.

The cloth passes between two rollers which impregnate it with the finishing material; it then passes over a drying arrangement and is carried round by a series of rollers so as to pass between the same finishing rollers a second time. The same process of alternate impregnation and drying can be repeated as often as required.—A. B. S.

VII.—ACIDS, ALKALIS, AND SALTS.

Nitric Acid; Hydrates of ——. F. W. Küster. Chem.-Zeit., 1904, **28**, 132—135.

The nitric acid of constant boiling-point has long been considered to result from physical causes, and not to be a chemical compound; but Erdmann considers it as a true compound, and that others exist, *e.g.*, an "ortho-" and a "pyro-" nitric acid, H_3NO_4 and $H_4N_2O_7$, corresponding to the two phosphoric acids. Kremann undertook a re-investigation of Erdmann's work. A complete examination of the freezing-points of nitric acids of gradually increasing strengths shows that two maxima exist, corresponding to the hydrates $HNO_3.3H_2O$ and $HNO_3.H_2O$, and three minima indicating cryohydrates. None of the compounds mentioned by Erdmann exist. The two hydrates exist not only in the solid form, but also as liquids, after fusion; the trihydrate is somewhat more stable than the monohydrate. (See also this J., 1903, 1227.)—J. T. D.

Sodium Nitrite; Action of Carbon Dioxide on Solutions of ——. C. Marie and R. Marquis. Comptes rend., 1904, **138**, 367. (See also Moody, this J., 1903, 1352.)

From the following experiments the authors conclude definitely that nitrous acid is liberated from solutions of sodium nitrite by the action of carbon dioxide. (1) If a stream of purified carbon dioxide be passed through a solution of sodium nitrite containing potassium iodide and starch paste, iodine is liberated after a short time. (2) A solution of sodium nitrite mixed with potassium iodide, when shaken with chloroform, imparts no coloration to the latter, but when saturated with carbon dioxide, the chloroform layer becomes coloured owing to the liberation of iodine on shaking. (3) When the purified gas is passed through a solution of sodium nitrite, and then into a solution of potassium iodide and starch paste, the latter becomes slightly but distinctly blue.—J. F. B.

Lead Salts; Basic ——. D. Strombolm. Zeits. anorg. Chem., 1904, **38**, 429—455.

The methods of preparation (only practicable where the substances to be produced are insoluble) were two. (1) Lead hydroxide was prepared by precipitating lead acetate by a very slight excess of sodium hydroxide, thoroughly washing, and draining off the surplus water as far as possible (in all the operations avoiding the introduction of carbon dioxide as far as possible). To the moist hydroxide was added, gradually, N/20 solution of the desired alkali-salt (usually potassium or sodium, but, where these proved inactive, ammonium salt). The completion of the reaction is recognised (*a*) by the alkalinity of the solution, which remains practically constant as long as sodium hydroxide is still being formed in amount proportional to the volume of liquid added, and then begins to diminish; (*b*) by the presence of the acid radicle in solution; or (*c*) by the disappearance from the solution of lead, dissolved as hydroxide in the alkali formed. The salt thus formed is well washed, drained, and dried over soda-lime and sulphuric acid. This method yields the most basic salt of the possible series. (2) To the normal lead salt is gradually added dilute alkali hydroxide till the alkalinity of the solution begins to increase. This method yields the basic salt of the series containing least base (or most acid radicle). The salts prepared by either method are nearly all microcrystalline and very voluminous. The following are the chief results:—

Formula.	Prepared from	Characteristics.
$6PbO.PbCl_2.2H_2O$	$Pb(OH)_2 + KCl$ ..	White crystals, yellow on heating.
$3PbO.PbCl_2.\frac{1}{2}H_2O$	$PbCl_2 + NH_4OH$ ..	Light yellow needles.
$6PbO.PbBr_2.2H_2O$	$Pb(OH)_2 + KBr$ ..	White crystals, bright yellow on heating.
$3PbO.PbBr_2.\frac{1}{2}H_2O$	Next salt + NaOH	Bright yellow needles.
$PbO.PbBr_2.H_2O$.	$PbBr_2 + NH_4OH$.	White, red-yellow while hot.
$6PbO.PbI_2.2H_2O$.	$Pb(OH)_2$ KI....	Light yellow, loses iodine on heating.
$9PbO.2PbI_2.2H_2O$	Last salt + KI....	Bright yellow.
$3PbO.PbI_2.H_2O$ ..	Next salt NaOH	Faint yellow; strong yellow after heating.
$PbO.PbI_2.H_2O$ ..	$PbI_2 + NH_4OH$ ...	Light yellow; golden yellow after heating.

Similar methods yielded one thiocyanate, one bromate, one iodate, two sulphates, one selenate, two chromates, several nitrates, no phosphate, one arsenate, one carbonate ($3PbO.4PbCO_3.2H_2O$), one oxalate, and one picrate. The methods failed with several other salts, often because of the solubility of the basic salt (chlorate, fluoride). The types illustrated by the three bromides, especially the middle one, are the most frequent; 2, 4, 5PbO with PbR_2 are much less common.—J. T. D.

Boric Acid; Determination of ——, *as Phosphate.* F. Mylius and A. Meusser. XXIII., page 269.

Zinc Blende; Roasting of ——, *with Recovery of the Evolved Sulphur Dioxide for the Manufacture of Sulphuric Acid.* F. Kellermann. X., page 255.

English Patents.

Sulphuric Anhydride; Manufacture of ——. W. Garroway, Glasgow. Eng. Pat. 1755, Jan. 24, 1903.

Cooled air under pressure is passed through an ozonising cylinder in which numerous platinum points are oppositely arranged, so adjusted that intermittent electric discharges from a transformer up to 8,000 volts can be maintained. The air thus charged with ozone and nitrogen oxides is conducted to towers to come into contact with gases from a sulphur burner, and form sulphuric anhydride, which is collected by known means. The sulphur fumes, before coming into contact with the ozonised air, are passed through channels containing "brick made of oxide of iron and oxide of manganese."—E. S.

Hydrochloric or Nitric Acid, Regenerated; Treatment of ——, *to Remove Calcium Sulphate.* P. De Wilde, Brussels. Eng. Pat. 25,388, Nov. 20, 1903. Under Internat. Conv., Aug. 3, 1903.

See First Addition to Fr. Pat. 333,344 of 1903; this J., 1904, 116.—E. S.

Glauber Salts, Ferrous Carbonate, Ferrous Hydrate, and Ammonia; Production of —— *from Nitre Cake.* Eng. Pat. 24,639, Nov. 12, 1903.

Solution of nitre cake of sp. gr. 1·250 to 1·275 is brought into contact with a large excess of iron. The ferric sulphate at first formed is reduced to the ferrous state by the nascent hydrogen, and any nitric acid or nitrogen oxides present yield ammonia as ammonium sulphate. To the solution, run off from the iron scrap, a small proportion of acetic acid is added, and then sodium carbonate or hydroxide to precipitate ferrous carbonate or hydroxide; and, after heating, more of the alkali is added to decompose the ammonium sulphate. The ammonia evolved is collected, the ferrous salt is separated, and the sodium sulphate is crystallised out of the solution. Zinc or the like may replace iron in the process.—E. S.

United States Patents.

Phosphoric Acid; Method of Making ——. N. B. Powter, Brooklyn, N.Y.; E. H. Fallows, executor of said Powter, deceased. U.S. Pat. 751,753, Feb. 9, 1904.

"Phosphate rock," aluminic and similar phosphates, are heated in a suitable retort, and the fumes evolved are drawn off by suction, cooled, and passed into water for absorption therein.—E. S.

Sulphuric Anhydride; Process of Making ——. E. Raynaud, Spy, and L. Pierron, Jette St. Pierre, Belgium. U.S. Pat. 751,941, Feb. 9, 1904.

See Eng. Pat. 16,254 of 1900; this J., 1901, 42.—T. F. B.

Hydrated Sulphide of Zinc; Process of Producing ——. V. Bermont, Paris. U.S. Pat. 751,712, Feb. 9, 1904.

See Eng. Pat. 6752 of 1902; this J., 1903, 214.—T. F. B.

French Patents.

Hydrochloric Acid and Sulphuric Acid; Process for the Production and Simultaneous Separation of ——. Consortium für Elektrochem. Ind. Fr. Pat. 335,496, Aug. 21, 1903.

Chlorine, sulphur dioxide, and water are brought into contact in regulated proportions and in a continuous manner, the final products of the reactions being nearly pure hydrochloric acid gas and liquid sulphuric acid. In order to control the proportions of the gases admitted to the reacting chamber, a portion of the mixture is passed continuously into water constantly being renewed, the excess of one gas over the other being measured by the potential which the solution gives to a neutral electrode, in respect to another electrode at a constant potential. The potentials of the oxidation and of the reduction of the two gases are sufficiently wide apart to give precise indications for regulating the process, which regulation may be rendered automatic. An excess of chlorine is used when it is desired to produce hydrochloric acid as free as possible from sulphuric acid.—E. S.

Hydrocyanic Acid; Process of Preparing ——, by Aid of a Mixture of Nitrogen with Hydrocarbons. Deutsche Gold und Silber-Scheide-Anstalt v. Roessler. Fr. Pat. 335,562, Sept. 25, 1903.

A MIXTURE of nitrogen with a hydrocarbon gas, such as lighting gas, is passed into contact with an electric arc of high tension, to produce hydrocyanic acid gas. Compounds of nitrogen, such as ammonia gas, may be substituted for nitrogen. If nitrogen, saturated with benzene vapour, be used, a current of hydrogen may advantageously be passed with the mixture to avert liability to deposition of carbon. —E. S.

Sodium Hydroxide; Manufacture of ——. G. Latham and G. Kinsbourg. Fr. Pat. 335,623, Sept. 10, 1903.

LEAD, or lead monoxide (litharge) is added to fused sodium chloride, and the fluid mass is well agitated until the reaction is complete. If metallic lead be used, it is first rapidly oxidised under the conditions. The product consists of sodium monoxide and lead chloride, from which, by lixiviation, sodium hydroxide solution is obtained. The residue of lead chloride may be utilised to recover lead or litharge. Instead of sodium chloride, sodium sulphate or carbonate may be used in the process.—E. S.

Barium Oxide, Porous; Manufacture of ——. H. Schulze. Fr. Pat. 335,677, Oct. 1, 1903.

A MIXTURE of barium carbonate or sulphate with carbon some combination of alkaline earths, and barium nitrate, or a modification of such a mixture, is formed into a mass about the sides of an electric furnace, heated by radiation from an arc, or from a resistance rod connecting the poles, air being excluded. Barium oxide that has been melted in the process of obtaining it in an electric furnace, may also be rendered porous by mixing it with barium hydroxide and carbide, and heating the mixture as described.—E. S.

Dicalcium Orthophosphate; Manufacture of ——. E. Bergmann. Fr. Pat. 335,790, Sept. 7, 1903.

To a solution of tricalcium phosphate in cold aqueous sulphurous acid; or to the precipitate obtained on heating the same, monocalcium orthophosphate is added, and sulphurous acid is expelled by heat. Instead of adding monocalcium phosphate in the process, this may be produced in the sulphurous solution of the tricalcium salt itself, by addition of an acid, such as hydrochloric, sulphuric, or phosphoric acid, in order to obtain the dicalcium salt, sulphurous acid being expelled as before.—E. S.

Metallic Salts; [Electrolytic] Process of Manufacture of ——, and of Regeneration of Electrolytic Baths. E. A. Campagne. Fr. Pat. 335,972, Oct. 15, 1903. XI. A., page 258.

Oxygen; Extraction of —— [from the Atmosphere, by Magnetism]. L. Benier. Fr. Pat. 335,473, Sept. 22, 1903. XI. A., page 257.

VIII.—GLASS, POTTERY, ENAMELS.

Quartz Glass; Mercury Arc Lamp of ——. M. Bodenstein. II., page 246.

Syrian Asphalt for Printing Plates and Window Transparencies. C. Fleck. XXI., page 268.

English Patent.

Silica Glass; Furnaces for Use in the Manufacture of ——. W. A. Shenstone, Bristol. Eng. Pat. 4031, Feb. 20, 1903.

THE furnace itself is made of silica, preferably in the form of bricks. The silica to be fused is introduced through a number of openings and falls on to a sloping channel, where it is melted by means of electric arcs passing between suitably placed carbon electrodes, the heat from which is supplemented by a number of oxy-hydrogen blow-pipes, introduced through other openings. These blowpipes are made either of iridium or silica, and serve to burn any carbon falling from the electrodes, thus preventing contamination of the silica with silicon or carborundum The melted silica runs down into a central well, from which it may be removed by means of an iridium blow-pipe or by tilting the furnace, or by simply letting it overflow through a suitable opening.—A. G. L.

French Patents.

[Glass] Synthetic Granite; Garchey ——, and Method of Manufacturing the same. L. A. Garchey First Addition of Sept. 18, 1903, to Fr. Pat. 325,475, Sept. 27 1902 (see this J., 1903, 697).

THE melted glass is first run into a cold metallic mould of suitable shape; when sufficiently hardened it is then removed to a heated mould of refractory material and allowed to cool very slowly. The inside of this second mould is sprinkled with hot sand, powdered mica, &c., to make a tight joint between it and the object, which is also covered with a layer of hot powdered refractory material. In certain cases the article may also be compressed in a hydraulic press in which it is allowed to remain until devitrified, after which it may be re-heated and annealed. —A. G. L.

Arsenious Oxide [for Glass Manufacture]; Preparation of Briquettes of Solidified ——. L. Souheur. Fr. Pat. 335,753, Oct. 6, 1903.

ARSENIOUS oxide, whether in powder or in fragments, coloured or otherwise, is subjected to high pressure with or without preliminary or simultaneous heating in suitable apparatus, to form it into briquettes suitable for use in the manufacture of glass.—E. S.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

Road Materials; Testing of ——. L. W. Page and A. S. Cushman. XXIII., page 269.

Lime, Free, [in Portland Cement]; New Method for the Determination of ——; and on so-called "Dead Burnt" Lime. E. H. Keiser and S. W. Forder XXIII., page 272.

English Patents.

Ovens and Kilns [for Pottery and Bricks]. W. H. Owen, Wolstanton. Eng. Pat. 5145, Mar. 5, 1903.

THE air necessary for supporting combustion in the kiln receives a preliminary heating by passing through a heater, consisting of a number of tubes connecting a receiving and distributing head; this heater is placed in the path of the escaping products of combustion. In cases where gaseous fuel is used, a second heater is provided for heating the gas, the waste gases from the kiln being caused to surround the two heaters alternately, so as to heat both the gas and the air.—A. G. L.

[Bricks, &c.] "Gas Lime" and other Spent Lime; Method of and Apparatus for Converting —— into a more Marketable Commodity or Product. J. Lowden, Leeds. Eng. Pat. 7622, April 2, 1903.

THE spent lime is exposed, either alone or mixed with clinker, to the action of hot air from a furnace, which expels a large proportion of the sulphur compounds from the lime and oxidises the remainder to calcium sulphate. The treatment is carried out by allowing the lime to fall down a shaft, at the bottom of which a suitable furnace is placed. In the walls of the shaft there are a number of projections opposite each other, dividing the shaft into a number of chambers, within each of which a horizontal drum revolves; these drums are provided with longitudinal openings, and contain vertical perforated partitions. The material in its passage downwards has to pass through these drums, and is fully exposed to the action of the hot gases. The resulting material is mixed with clinker and coke breeze, or other suitable fuel, and burnt, a current of steam being preferably passed through the kiln during the burning. The mass obtained, consisting of calcium oxide, carbonate, and silicate, and aluminium silicate, is ground and moulded into bricks or slabs, the further hardening of which may be effected by exposure to hot waste gases containing carbon dioxide.—A. G. L.

Tiles or Bricks for use in Regenerative Furnaces. J. C. Moon, Ilford, and F. C. Moon, Scarborough. Eng. Pat. 14,420, June 29, 1903.

In order to afford increased support to the vertical tiles forming the walls of the air- and gas-passages, they are made of rectangular or square shape and may also have a reduced central portion; at the ends of each of the baffle tiles, or at one end when a fire-brick lining is applied to the waste- gas- and air-passages, a reduced portion of rectangular form and of the same width as one of the vertical tiles is provided. The remaining portion of the baffle tiles is made of increasing cross-section, so that this portion constitutes a shoulder running around the whole of the reduced portion. The vertical tiles are made to break joint both vertically and horizontally in the case of the tiles forming the division walls.—A. G. L.

Stone, Artificial; Manufacturing —— suitable for Pavements, Buildings above and below Ground, and for Hydraulic Purposes. J. J. Niessen, Cologne, Germany. Eng. Pat. 25,393, Nov. 21, 1903.

Bauxite, preferably containing a large quantity of ferric oxide, is heated at a high temperature, alone or with fluxes, until "perfectly sintered." The resulting mass is reduced to small pieces, mixed with a binding medium, such as clay, cement, or asphalt, and burned.—A. G. L.

Water-proofing [Building Materials]; Process of Treating Surfaces for —— and Preservative Purposes. E. M. Caffall, Sparkhill, N.Y. Eng. Pat. 27,126, Dec. 15, 1903.

The surface to be treated is heated with hot compressed air. The hot material, *e.g.*, asphalt or paraffin, is then sprayed upon it, after which the surface is again treated with hot compressed air, which forces the material into the pores of the surface. The air may be heated out of contact with the fuel, if desired, by passing it through a pipe placed in a stove.—A. G. L.

Bricks or Blocks; Manufacture of Porous ——. H. Herschbach, Neuwied, Germany. Eng. Pat. 27,626, Dec. 16, 1903.

Three parts by volume of volcanic sand are mixed with 1 of blast-furnace slag; the whole is then moistened with 1 part of water and again mixed, after which it is moulded in iron moulds. The moulded bricks are allowed to dry for two or three weeks, after which they are stacked for several months, a space of about 2 cm. being left around each brick to allow free access of air; in hot, dry weather they should be kept moist by occasionally spraying with water. The resulting brick is claimed to be strong and light.
—A. G. L.

Wood and other Materials; Compositions for the Preservation of —— from the Attacks of, and Destroying, White Ants and other Insects or Growths, and for Preserving such Materials generally. P. Zimmer, Bremen, Germany. Eng. Pat. 28,218, Dec. 23, 1903.

The wood to be preserved is coated once or twice with a composition obtained by adding 1 oz. of "arsenic (powder)," 1 oz. of camphor, 3 oz. of dried chillies (powder) to 400 grms. of wood oil and 700 grms. of "Rangoon oil," boiling for a quarter of an hour, stirring till cold, adding 360 grms. of common kerosene oil and [illegible] oz. of camphor, stirring the whole and filtering.—A. G. L.

Mortar or Cement; Combination of Ingredients for Manufacturing a Water-Resisting ——. W. Staab, Ehrenfeld, Cologne. Eng. Pat. 11,802, May 23, 1903.

See Fr. Pat. 321,171 of 1902; this J., 1903, 556.—T. F. B.

United States Patents.

Bricks or Material; Manufacture of Fireproof ——. F. Krüger, Berlin. U.S. Pat. 751,080, Feb. 2, 1904.

See Eng. Pat. 3483 of 1903; this J., 1903, 867.—T. F. B.

Wood; Process of Preserving ——. G. W. Gordon, Assignor to H. Arzt and J. Sostman, all of Philadelphia, Pa. U.S. Pat. 751,981, Feb. 9, 1904.

The wood to be preserved is soaked in a solution of calcium hydroxide and glycerin, to which sugar may also be added.
—A. G. L.

French Patents.

Wood; Process for Preserving and Fireproofing ——. G. Beaulieu-Marconnay. Fr. Pat. 335,112, Sept. 19, 1903.

The wood is soaked in a solution of polybasic salts, such as ammonium borate or sulphate, dissolved in an excess of ammonia, which renders the impregnation more thorough by saponifying the resins and fatty matter of the wood.
—A. G. L.

Wood; Process for Preserving ——. C. F. Reichel. Fr. Pat. 335,781, Oct. 7, 1903.

The wood to be preserved is painted with a mixture of chalk or slaked lime and tannin.—A. G. L.

Masonry; Composition for Protecting ——, against Weathering, leaving it Permeable to Gases. H. Gärtner and F. Kremen. Fr. Pat. 335,862, Oct. 10, 1903.

The composition consists of a mixture of 200 parts of sodium silicate dissolved in a convenient quantity of boiling water, with 45 to 50 parts of carnauba wax and 15 to 20 parts of olive oil soap. Colouring matter may also be added.—A. G. L.

Paving; Material for ——, and similar Purposes. H. Morin. Fr. Pat. 335,909, Oct. 14, 1903.

Sifted river sand is mixed with raw or boiled linseed oil, to which litharge or other driers may be added. The mixture is then moulded under pressure, and dried at a gentle heat. Part or the whole of the oil may be replaced by caoutchouc, glue, celluloid, rubber surrogates, &c. Sulphur may also be added to the oil, and part of the sand may be replaced by sawdust or other vegetable matter.
—A. G. L.

Cement Mortar; Process for Preserving the Binding Properties of Prepared ——. J. H. Magens. First Addition, of Sept. 12, 1903, to Fr. Pat. 330,393, March 18, 1903 (see this J., 1903, 1089).

Instead of keeping the prepared mortar at 0° C., as described in the original patent, it suffices to bring it to this temperature immediately after mixing, and then keep it cold during storing by simply sprinkling it with cold water, the evaporation of the water lowering the temperature sufficiently to arrest the binding action of the mortar.
—A. G. L.

X.—METALLURGY.

Nickel Steels; Allotropic Transformation of the ——. O. Boudouard. Comptes rend., 1904, **138**, 370—371.

Bars of two series of nickel steels were heated at one end, and curves were plotted showing the temperatures of the bars as abscissæ and the differences of potential between the two extremities of the bars as ordinates. Observations were taken both in heating up and cooling down, and the points at which irregularities in the curves were observed were noted as corresponding to phenomena which tend to modify the thermal state of the bar, *i.e.*, to the molecular transformation of the particular alloy under observation. The following table shows the effect of increasing proportions of nickel on the properties of steels of approximately the same composition otherwise :—

Series I. (*Carbon about* 0·120 *per cent.*)

Composition of Steel.		Critical Points.	
Carbon.	Nickel.	Heating up.	Cooling down.
Per Cent.	Per Cent.	° C.	° C.
0·07	2·23	830. 775. 725	830, 710
0·125	5·23	770, 695	710
0·125	7·13	690, 660	650
0·132	10·10	675, 650	575
0·125	12·07	640, 640	420

—J. F. B.

Vanadium Steels; Constitution and Properties of ——. L. Guillet. Comptes rend., 1904, 138, 367—369.

The author has studied two series of vanadium steels, one containing 0·2 per cent. of carbon and the other 0·8 per cent. In each series the percentage of vanadium was increased from 0 to 10 per cent.

Micrography.—Those steels containing 0·2 per cent. of carbon and less than 0·7 per cent. of vanadium, and those containing 0·8 per cent. of carbon and less than 0·5 per cent. of vanadium, when etched with picric acid, showed a "perlite" structure similar to that of carbon steels, but the "ferrite" structure was rapidly coloured a deep brown by the reagent. Above 0·7 per cent. of vanadium for the one series, and 0·5 per cent. for the other, the "perlite" became interspersed with a number of white grains, which increased with increase in the proportion of vanadium, until, in the steels containing more than 3 per cent. of vanadium, the "perlite" was entirely replaced by these white grains. These grains are a special form of the carbon, consisting of a carbide of vanadium or a double carbide of vanadium and iron. Thus there are three classes of vanadium steels:—(1) Those having the same structure as carbon steel, and containing less than 0·7 per cent. of vanadium. (2) Those having a mixed structure of "perlite" and the special form of carbon. (3) Those containing carbon solely in the form of the special constituent above referred to. The last class is of no industrial importance.

Mechanical Properties.—The steels of the two first groups had breaking strains and elastic limits higher than those of ordinary steels, with the same percentage of carbon. The elongations and mean contractions were normal. These steels are far harder and more brittle than the carbon steels. The steels of the third group had extremely low breaking strains and elastic limits, the elongations and contractions were high, but the steels were very brittle and deficient in hardness. A short annealing at 900° C. softened all the steels slightly. When annealing was sufficiently prolonged at a sufficiently high temperature, carbon was precipitated in the form of graphite. Tempering hardened the steels of the first two groups to a remarkable extent, and softened those of the third group slightly, but it did not affect the structure of the special carbon constituent. In view of the brittleness of the vanadium steels, only those of the first group are capable of industrial application, and these apparently offer little interest except as tool steels.—J. F. B.

Zinc Blende; Roasting of ——, with Recovery of the Evolved Sulphur Dioxide for the Manufacture of Sulphuric Acid. F. Kellermann. Zeits. Berg. u. Huttenw., 51, 606—608. Zeits. angew. Chem., 1904, 17, 179.

The difficulties met with in the roasting of zinc blende are due to the strong tendency of the zinc to form basic zinc sulphate, which on reduction is decomposed into zinc, zinc oxide, and zinc sulphide. The causes of the formation of the basic zinc sulphate in Hungarian reverberatory furnaces are as follows:—(1) High charges of ore on the roasting hearth. (2) Overheating of the ore, especially near the fire-bridge. (3) Direct contact of the fire-gases with the charge. The large amounts of smoke and fire-gases which mix with the evolved sulphur dioxide also hinder the recovery of the latter. In the author's opinion the roasting should be carried on under the following conditions:—(1) An oven with several hearths, one above the other, should be used. (2) The smoke and fire-gases should not be allowed to come into contact with the charge. (3) Each hearth should be furnished with an air-supply to effect the combustion of the sulphur and the oxidation of the blende. (4) The sulphur dioxide should be removed, with the excess of air, through separate outlets. (5) Steam should be supplied to the lowest hearth towards the end of the roasting.—A. S.

Lead-Tin Alloys. I. Chemical Equilibrium between Lead and Tin in Presence of Solutions of their Salts. O. Sackur. Arb. a. d. Kaiserl. Gesundheitsamte, 1903, 20, 512. Chem.-Zeit., 1904, 28, Rep. 33.

As lead and tin stand close together in Volta's contact series, it would be expected that one metal would not completely precipitate the other from its solution. It was found that in acetic acid solution lead is almost completely precipitated by tin, the deposition of lead being more rapid the greater the acidity of the solution. On the other hand, in nitric acid solution, tin is precipitated by lead. In hydrochloric acid solution a state of equilibrium is attained when the salts of the two metals are present in certain concentrations. These concentrations were determined at 18° C. and 25° C. with solutions containing varying amounts of free hydrochloric acid, and it was found that the amount of stannous chloride in solution is a linear function of the amount of lead chloride; this fact is in agreement with Nernst's theory and the law of mass action. The author concludes that the apparently contradictory phenomena observed in the precipitation of lead and tin from different solutions are due to the facts that lead has a greater electrolytic solution pressure than tin, and that stannous chloride and tin acetate are only dissociated to a very small extent, with production of free tin ions.—A. S.

Metals of the Cerium Group. W. Muthmann and L. Weiss. Annalen, 1904, 331, 1—46.

In continuation of their previous work (this J., 1902, 412), the authors have now improved the electrolytic process, and have been able to prepare all five metals of the cerium group in sufficiently large quantities to allow of an investigation of the physical properties of the metals. All the metals are harder than lead and tin; cerium is rather softer than lanthanum, and both are softer than zinc; neodymium and praseodymium are somewhat harder than zinc; samarium is the hardest of the five metals. The metals have the following specific gravities:—Cerium, 7·0424; lanthanum, 6·1545; neodymium, 6·9563; praseodymium, 6·4754; samarium, 7·7—7·8. Melting points:—Cerium, 623° C.; lanthanum, 810° C.; neodymium, 840° C.; praseodymium 940° C. On burning, cerium forms cerium dioxide, with evolution of 1603·2 cals. per grm.; lanthanum gives the sesquioxide and 1602·1 cals.; neodymium, the sesquioxide, and 1506 cals.; and praseodymium, the sesquioxide, and 1466·8 cals. The high heats of combustion indicated that the metals might be used as reducing agents in a manner similar to that wherein aluminium is used in Goldschmidt's thermite process. The alloy of metals of the cerium and yttrium groups obtained directly from the very cheap residue obtained as by-product in the manufacture of thorium nitrate, was found to have a heat of combustion of 1655·5 cals. per grm., and in preliminary experiments with it as a reducing agent, small amounts of pure chromium, tungsten, molybdenum, niobium, vanadium, and tantalum, were prepared.—A. S.

Cerium and Lanthanum ; Some Alloys of ——. W. Muthmann and H. Beck. Annalen, 1904, **331**, 16—57.

The authors describe the preparation and properties of alloys of cerium and lanthanum with aluminium ($CeAl_4$ and $LaAl_4$) and of cerium with magnesium, zinc, and mercury. —A. S.

Zinc Dust ; Gasometric Assay of ——. A. Wohl. XXIII., page 273.

Tin Ores ; Losses in Vanning ——. R. Pierce. XXIII., page 273.

English Patents.

Iron and Steel Manufacture ; Furnaces for Use in ——. G. Quambusch, Dortmund, Germany. Eng. Pat. 3475, Feb. 13, 1903.

The furnace may have one or more hearths, mounted on wheels, and enclosed in a casing having running channels serving as guides for the hearth trucks, provided with projections packed with sand so that the heated gases have no access to the supporting iron mechanism. The truck ends are also so formed as to close the passage for the gases. Air is admitted through suitable openings to cool the iron work, and the air thus heated is directed into the region of combustion through lateral passages in the longitudinal walls. The heating gases may be directed from either side, or from both sides, or alternately from one or the other, as desired.—E. S.

Steel ; Manufacture of ——. T. J. Tresidder, Sheffield. Eng. Pat. 8298, April 9, 1903.

See Fr. Pat. 333,582 of 1903 ; this J., 1903, 1353.—T. F. B.

Ores ; Smelting of ——. F. H. Schwartz, Chicago. Eng. Pat. 3194, Feb. 10, 1903. Under Internat. Conv., April 9, 1902.

See U.S. Pats. 708,782 and 708,783 of 1902 ; this J., 1902, 1235.—T. F. B.

Ores ; Separation of the Metallic Constituents of —— from Gangue. A. E. Cattermole, London. Eng. Pat. 18,589, Aug. 28, 1903.

The pulped ore is mechanically agitated in a connected series of vessels, with oil and water, and a suitable proportion of an emulsifying agent, which may be either an acid or an alkali, or a soap. The granules of oiled mineral thus formed, which are specifically heavier than the particles of gangue, are classified by methodical treatment with an upward-current of water in separators. When but little mineral is present in the ore, powdered mineral matter from a previous operation, or other matter having an affinity for oil, may be introduced to assist in the formation of granules of metalliferous matter. Compare Eng. Pats. 26,295 and 26,296 of 1902 ; this J., 1904, 118.—E. S.

Tin and Terne Plates ; Means for Reducing the Thickness of the Coating on ——. A. J. Maskrey, Martins Ferry, Ohio. Eng. Pat. 27,425, Dec. 15, 1903.

In a tinning pot, a longitudinal wiper inclined inwards is mounted parallel to the discharge rolls, the tips of the wipers meeting at a point directly below the point of contact of such rolls, whereby the faces of a sheet of metal rising to the rolls are wiped. There is also a longitudinal strip or brush of non-carburising material, mounted parallel to and in contact with each of the rolls, whereby the latter are wiped and cleared of scruff and superfluous molten metal. The brush may be of asbestos strengthened with wire netting, of fine wire or metal strips, or it may be a scraper made of solid graphite.—E. S.

United States Patents.

Ores [Lead-Zinc] ; Method of Treating Refractory ——. E. H. Miller, London. U.S. Pat. 751,401, Feb. 2, 1904.

See Eng. Pat. 20,465 of 1902 ; this J., 1904, 118.—T. F. B

Copper Ores ; Process of Treating ——. N. V. Hybinette, Plainfield, N.J. U.S. Pat. 751,648, Feb. 9, 1904.

The coarsely-divided copper ore is mixed with a salt of an alkali metal, such as sodium sulphate, and is roasted to convert the copper compound, at least in part, into a soluble condition, as into a double salt of copper and an alkali metal. The mass is then heated with a reducing agent, to render the newly-formed copper compound insoluble. Finally, the product is treated with water, and the valuable finely divided material is mechanically separated from the coarse gangue.—E. S.

Uniting Two Metals ; Process of ——. W. H. Wherry, Cleveland, Ohio. U.S. Pat. 750,511, Jan. 26, 1904.

A flux is applied to one of the two metals to be united, that will combine chemically with both metals, and will lower their fusing point and increase their fluidity ; to the other metal, in a molten state, is applied approximately "one-fifth per cent. of phosphorus," and the compound of molten "metal and phosphorus is then poured upon the other treated metal."—E. S.

Flux [for Uniting Metals]. W. H. Wherry, Cleveland, Ohio. U.S. Pat. 750,512, Jan. 26, 1904.

The flux for uniting metals contains phosphorus, or red phosphorus, with an acid, hydrochloric acid being specified as one that may be used.—E. S.

French Patents.*

Aluminium ; Soldering ——. E. H. Moreau. Fr. Pat. 335,413, Sept. 19, 1903.

The solder consists of equal parts, by weight, of pure tin and of pure zinc, melted together.—E. S.

Aluminium ; Process for Tempering ——. C. Sorensen. Fr. Pat. 335,857, Oct. 10, 1903.

See Eng. Pat. 20,758 of 1903 ; this J., 1903, 1353.—T. F. B.

Air for Blast Furnaces ; Extraction of Moisture from the ——. J. Gayley. Fr. Pat. 335,957, Sept. 28, 1903.

See Eng. Pat. 19,933 of 1903 ; this J., 1904, 22.—T.F.B.

Furnace for Roasting Finely Powdered Minerals, Calcining Dolomite, &c. G. O. Petersson. Fr. Pat. 335,977, Oct. 15, 1903. Under Internat. Conv., Jan. 27, 1903.

See Eng. Pat. 22,162 of 1903 ; this J., 1904, 22.—T. F.B.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

(A.)—ELECTRO-CHEMISTRY.

Electrolysis ; Alternating Currents in ——. A. Brochet and J. Petit. Comptes rend., 1904, **138**, 359—361.

The authors have used the public supply of the left bank of the Seine, having a frequency of 42, and transformed down to an E.M.F. of 7 volts. They have assumed that the mean current is 0·9 of the effective current, as measured by a thermal ammeter, and have examined the solution of copper electrodes in a solution of potassium cyanide. The reaction $Cu_2 + 8KCN + 2H_2O = Cu_2(CN)_2 . 6KCN + 2KOH + H_2$ occurs, and proceeds steadily till the solution is saturated with copper, when the rate of yield falls off abruptly. The process is a practicable method of preparing cuprous potassium cyanide. The authors do not agree with Le Blanc and Schick's assumption that the solution of the copper depends on the formation of a complex ion which prevents re-deposition ; for copper can be deposited electrolytically from solution in potassium cyanide, whilst potassium cyanide solution dissolves copper slowly in the cold without the intervention of the electric current. Zinc and nickel behave like copper with the alternating current, yielding $M(CN)_2.2KCN$. Lead, silver, mercury, cadmium, are practically unaffected.—J. T. D.

Alternating Currents: Phenomena of Reduction produced by ——. F. Pearce and C. Couchet. Comptes rend., 1904, **138**, 361—362.

Reducing effects are exhibited, under certain circumstances by alternating currents in electrolytic cells. The effects are, as a rule, produced only with oxidisable electrodes, and depend on the nature of these electrodes, the current density, and the frequency. With feeble current density, solution of the electrodes is all that occurs. Iron alum, for example, is hardly perceptibly reduced when the electrodes are of platinum, much more considerably with aluminium, lead, or cadmium electrodes, and almost quantitatively with iron electrodes. The metal from the attacked electrode usually deposits as oxide in the bath. Alkali nitrates are reduced to nitrites—quantitatively with elec rodes of cadmium or zinc, very slightly with electrodes of ron, copper, or carbon. Cupric and mercuric salts are similarly reduced to the cuprous and mercurous condition; chromates to chromic salts, nitrobenzene to aniline.

—J. T. D.

Nitro-Compounds of the Naphthalene, Anthracene, and Phenanthrene Series; Electro-chemical Reduction of ——. J. Möller. Electrochem. Zeits., **10**, 199—202, 222—226; Chem. Centr., 1904, **1**, 461.

Reduction of 1.5- *and* 1.8-*Dinitronaphthalene.*—The cathode liquid consisted of 2 grms. of the nitro compound dissolved in 270 c.c. of glacial acetic acid and 10 c.c. of concentrated sulphuric acid. the anode liquid consisted of 170 c.c. of water and 6 c.c. of concentrated sulphuric acid; he cathode was a lead cylinder; and the anode was a piece of sheet platinum in a porous cell. Temperature, 80°—90° C.; E.M.F., 4 volts; current, 2 ampères; time, 30 minutes. The products were 1.5- and 1.8-naphthylenediamine melt ng at 189°—190° C. and 66°—67° C. respectively.

Reduction of 2-*Nitrophenanthraquinone.*—E.M.F., 3·8 volts; current 1·6 ampères; time, 20 minutes; other conditions the same as above. The cathode liquid was coloured dark brown. Reduction product, 2-aminophenanthraquinone melting at above 320° C.

Reduction of 2.7-*Dinitrophenanthraquinone.*—Tempera ure. 90°—95° C.: current and time, 65·4 ampère-minutes, Reduction product, 2.7-diaminophenanthraquinone melting at above 315° C.

The experiments show that in general the nitro compounds are reduced directly to amino compounds; in no case could intermediate compounds be isolated. (See also this J., 1901, 1001.)—A. S.

Organic Salts, Fused; Electrolysis of ——. E. Berl. Ber., 1904, **37**, 325.

Lassar-Cohn (Ann. 251, 357) found that fused potassium acetate on electrolysis yields hydrogen and methane at the cathode and carbon dioxide at the anode. The author confirms this, and shows the production of methane to be secondary, since metallic potassium reacts on fused potassium acetate with evolution of methane. The fused potassium salts of nitrobenzoic acids and of benzoic acid (dissolved in excess of free acid) behave analogously.

—W. A. C.

Mercury Arc Lamp of Quartz Glass. M. Bodenstein. II., page 246.

English Patents.

Cell; An Improved Galvanic Dry ——. G. Schauli and D. Löwenstein, London. Eng. Pat. 23,389, Oct. 27, 1902.

The negative pole consists of a zinc vessel coated internally with mercury, and this is surrounded by a sheet-iron containing vessel, an insulating medium being placed between the two vessels so as to leave a circular aperture between the bases. When the inner zinc cylinder is corroded through, the exciting liquid will come into contact with the zinc lining of the outer cylinder and thus prolong the life of the cell. The positive pole consists of a rod of retort carbon of low resistance, surrounded by the following depolarising mixture:—Antimony sulphate, 4 parts; powdered Siberian graphite, 5 parts; granular gas carbon, 20 parts; manganese dioxide, 41 parts, half powdered and half granular; solid zinc chloride, 10 parts; solid ferric chloride, 20 parts. This mixture, slightly moistened with water, is contained in a fabric bag tied round the positive electrode. The exciting electrolyte is prepared by dissolving 1 oz. each of ammonium chloride, ammonium alum, and ammonium sulphate in 400 c.c. of water, cooling slightly in a closed vessel, and then adding 1 oz. of mercury bisulphate, the solution being cooled and allowed to stand for two or three days in a sealed vessel. One part by weight of this solution is mixed with one part by weight of hot rice, previously soaked and cooked to a syrupy consistency, and the paste, when cold, is placed between the inner zinc cylinder and the bag containing the depolariser. The cell is closed with layers of powdered sulphur and pitch.—B. N.

Drying by Hot Air or by the Use of Electric Currents; Methods for —— *Materials which Clog or Matt under Compression, and other Substances.* J. Doall, London. Eng. Pat. 1717, Jan. 23, 1903.

A horizontal cylindrical chamber made of steel or iron, and mounted on hollow trunnions, is fixed inside, but electrically insulated from, another cylinder made of perforated metal or wire netting. To the outer cylinder is secured a copper strip for making electrical contact. The outer cylinder is fitted with beaters or brushes, and radial ribs, to prevent the material from running. The whole is enclosed in an airtight case. The material to be dried is placed in the outer cylinder, both cylinders are rotated, and hot air is forced through the hollow trunnions into the inner one, the material being dried by radiant heat. To accelerate the drying, electric heating may be applied by means of the copper strip and a contact brush. Openings are provided for the collection of the vapours given off.

Purifying Liquids; [Electrical] Apparatus for ——. O. Kartzmark, Brooklyn, N.Y., Assignor to W. Davis, Jersey City. U.S. Pat. 751,986, Feb. 9, 1904.

The liquid is passed upwards in a continuous stream between a series of detachable electrodes, the latter being supported upon stops located above the bottom of the containing vessel; the liquid flows over the edges of the vessel, which is open to the air, into an overflow tank.

—B. N.

Carbonic Acid in Gases; [Electrical] Method of Determining the Quantity of ——. G. Bodländer. U.S. Pat. 761,897, Feb. 9, 1904. XXIII., page 273.

Oxygen; Extraction of ——, *[by Magnetism, from the Atmosphere].* L. Benier. Fr. Pat. 335,473, Sept. 22, 1903.

Advantage is taken of the magnetic property of oxygen to effect its separation from the non-magnetic nitrogen of the atmosphere. A drum of iron or of soft steel, rotating between two electro-magnets in such manner that its peripheral surface is magnetised, is stated to accumulate upon it a thin layer of oxygen from the atmosphere, which oxygen may be continuously detached by a fixed rubbing appliance within a box, applied to any convenient portion of the rim of the drum.—E. S.

Hydrocyanic Acid; [Electrical] Process of Preparing ——, by Aid of a Mixture of Nitrogen with Hydrocarbons. Deutsche Gold und Silber-Scheide-Anstalt. vorm. Roessler. Fr. Pat. 335,562, Sept. 25, 1903. VII., page 253.

Barium Oxide, Porous; [Electrical] Manufacture of ——. H. Schulze. Fr. Pat, 335,677. Oct. 1, 1903. VII., page 253.

Metallic Salts; [Electrolytic] Process of Manufacture of ——, and of Regeneration of Electrolytic Baths. E. A. Campagne. Fr. Pat. 335,972. Oct. 15, 1903.

The metal or alloy to be treated is used as the anode, and sheet iron as the cathode in a half-saturated solution of sodium sulphate. Metallic sulphates and caustic soda are formed, and reacting together, precipitate hydroxides of the metals and regenerate sodium sulphate. Carbon dioxide may be afterwards used to convert the hydroxides into basic carbonates, and, by solution of the latter in suitable acids, salts are formed which may be separated by fractional crystallisation. When an impure metal or alloy is used as the anode for depositing a pure metal on the cathode, the bath becomes impoverished in the salt of the metal, and the salts obtained as above may be added to the bath instead of crystallising fractionally; or if a bath become acid in character, as in the cases where antimony and bismuth alloys are used as the anode, the precipitated hydroxides or basic carbonates may be added to neutralise the acid and thus regenerate the bath.—B. N.

(*B.*)—ELECTRO-METALLURGY.

Iron and Steel; Manufacture of ——, by Electrical Process. A. Neuburger, Zeits. angew. Chem., 1904, **17**, 104—112; 129—140.

For the manufacture of iron and steel by the aid of electricity, the author describes the following processes, which are now being worked on the large scale:—Stassano (Eng. Pats. 11,604 of 1898 and 8288 of 1902; this J., 1898, 1155; 1902, 1284), Héroult and the "Soc. Electrometall. Française" (Eng. Pats. 11,643, 14,486, and 14,576 of 1901, U.S. Pat. 707,776 of 1902, Fr. Pat. 318,638 of 1902, Eng. Pat. 3912 of 1902, U.S. Pat. 721,703 of 1903, and Fr. Pat. 328,350 of 1903; this J., 1902, 915, 917, 1029, 1237, 1459; 1903, 217, 426, 955), Harmet and "Fonderies, Forges et Acières, St. Etienne" (Fr. Pat. 318,283 of 1902 and Additions to same; this J., 1902, 1459; 1903, 501, 658), Keller and "Cie. Electrotherm. Keller, Leleux and Co." (Eng. Pats. 24,234 and 24,235 of 1901, and 15,271 of 1902, Fr. Pat. 329,013 of 1903; this J., 1902, 354, 410; 1903, 371, 1004), Kjellin (see Benedick's Eng. Pat. 18,921 of 1900; this J., 1901, 370), Girod (Fr. Pat. 329,822 of 1903; this J., 1903, 1054), Conley (U.S. Pat. 697,810 of 1902; this J., 1902, 623), Ruthenburg (Eng. Pat. 13,867 of 1901, U.S. Pats. 722,253 and 722,254 of 1903; this J., 1901, 1218; 1903, 127), and Neuburger-Minet. The Neuburger-Minet apparatus is suitable for countries poor in water-power. It is so designed that three sources of heat can be made use of:—(1) Combustible or non-combustible furnace gases; (2) gases from gasworks or gas-producers; (3) electricity, either as a current flowing through the material to be treated, or in the form of an arc. The furnace is shown in vertical section in Fig. 1 and in horizontal section in Fig. 2. The reaction chamber W is separated by the walls D from the combustion chambers S, into which, through the openings O, flow either blast-furnace gas from the passage C, or gas from gasworks or gas-producers from the passage C^{1}. The blast furnace gas is led into the heating chambers R; a portion passes into the passage C through the flap-valve X, and is burnt in the chamber S, air entering from the passage V through openings U. Part of the blast-furnace gas passes through R unaltered and can be used for feeding gas-engines, &c. The position and arrangement of the electrodes, E, E^{1} are varied according to the nature of the material under treatment. It is stated that steel and various kinds of iron and alloys of iron can be produced in this furnace.

Fig. 1.

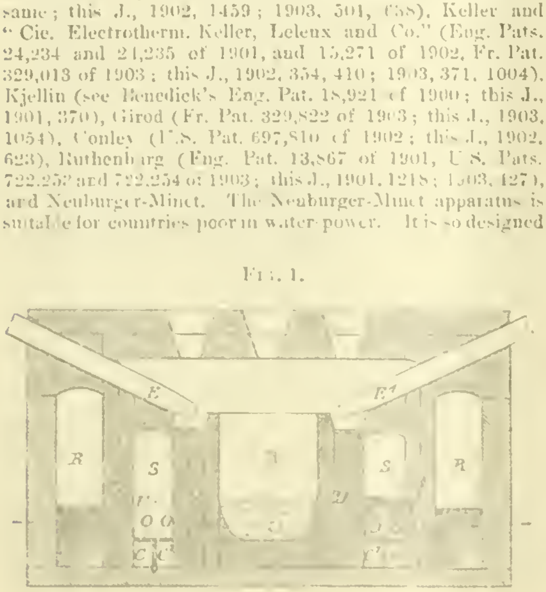

Fig. 2.

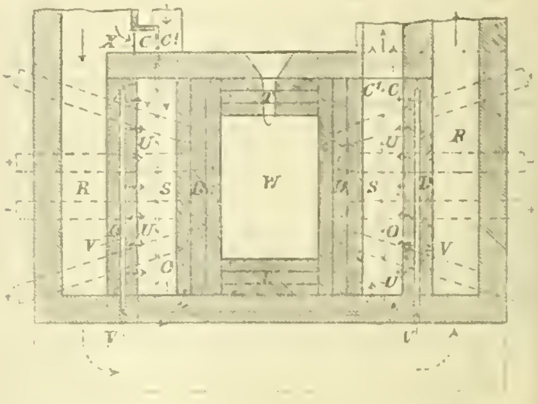

L. Simpson has recently described the advantages possessed by the electrical method for the manufacture of steel over the usual processes as follows:—(1) The steel obtained is more compact and more uniform in quality; (2) in the same works different qualities of steel and steel alloys can be manufactured at a minimum cost; (3) the capacity of the works can be easily increased, whilst on the other hand the works can be closed at wish and started again without the furnaces suffering injury; (4) the cost of the electric power is more than balanced by the lesser cost of the furnaces; (5) the work is less liable to interruptions. Repairs can be effected without stopping the work, as the low cost of erection of electric furnaces allows of the building of reserve furnaces, which can readily and rapidly be brought into operation. It seems to be the general opinion that even where the direct electro-metallurgical treatment of iron ores cannot be carried on economically, the production of steel from pig-iron in the electric furnace could be effected with advantage. An ideal works of this kind would be one in which blast-furnaces were used for smelting, the Bessemer plant for the production of the lower qualities of steel, and plant for the production of electric power from the blast-furnace gases, this electric power being used in suitable apparatus for the production of the finer qualities of steel. (See also this J., 1901, 816; 1902, 621, 622, 1048, 1402; 1903, 305, 749, 1198.)—A. S.

Tin Scrap; Electrolytic Treatment of ——. H. Paweck. Oesterr. Zeits. Berg- u. Huttenw., 1903, 341. Proc. Inst. Civil Eng., 1903, **154**, 36.

The tin scrap is held in iron baskets, which form the anode of the apparatus, the cathodes being of sheet iron and the electrolyte a 10 or 12 per cent. solution of caustic soda, heated to 60°—70° C. The material treated contains 7 per cent. of tin, the tension used varying from 1 to 2 volts.

with current density of 100 ampères per square metre of cathode surface. The metal obtained is preferably melted in a reducing furnace, giving a product which contains about 1·5 per cent. of lead. The electrolyte is found to contain 0·9 to 1·2 per cent. of tin in solution as sodium stannate. It is stated that a dynamo giving 6·4 kilowatts will treat from 10—12·5 tons of tin-plate cuttings per week. —T. F. B.

Cyanide Silver Baths; Yield, with Moving Cathodes in ——. W. Pfanhauser. Zeits. f. Elektrochem., 1904, **10**, 101.

The author has experimented with a platinum foil cathode of 100 sq. cm. area, supported between two parallel platinum wires of 0·5 mm. diameter, to which it was welded. Two experiments, of 45 minutes and 2½ hours duration respectively, with a current density of 0·3 ampère per 100 sq. cm., gave, after making allowances for the very small area of electrode (short lengths of the two wires) exposed to the air, 99·721 and 99·879 per cent. respectively of the quantitative yield of silver. The author's contention, therefore, that the yield with a moving cathode is less than that with a fixed cathode only when the former is partially exposed, during its motion, to the air, is upheld.—J. T. D.

English Patent.

Magnetic Ore Separator. F. T. Snyder, Oak Park, Ill., U.S.A. Eng. Pat. 28,399, Dec. 24, 1903.

A magnet pole piece has a flat vertical face applied to one side of a rotating iron cylinder, there being means for directing ore between the pole face and the cylinder. A magnetic pole-piece of opposite polarity is diametrically opposite the first-named pole piece, and has a curved face to embrace a large area of a cylindrical armature, which armature comprises a shaft and toothed circular discs of sheet iron side by side upon the shaft, the teeth forming points of magnetic concentration, rotating between the pole pieces. The more permeable particles of ore are attracted towards the armature, in which a neutral point is established between the two pole pieces, at which point the attracted ore is released. The frame is in horizontal box form, with an opening from top to bottom, the armature being mounted to rotate horizontally between the pole pieces which project inwardly from the sides of the frame, the journals being at substantially neutral points in the sides of the frame, which is made separable for convenience in removing the armature. —E. S.

French Patents.

Metals of the Alkali Group; Process and Apparatus for Producing the ——, *by Electrolysis.* E. A. Ashcroft. Fr. Pat. 335,829, Oct. 8, 1903.

See Eng. Pat. 12,377 of 1903: this J., 1904, 25.—T. F. B.

XII.—FATTY OILS, FATS, WAXES, AND SOAP.

Oil of Rice. Schweiz. Wochenschr. **42**, 66. Pharm. J., 1904, **72**, 216.

The high percentage (from 31·6 to 77·2) of free fatty acids in the oil from Rangoon rice is due to the presence in the bran of a lipase which effects the decomposition of the glycerides, with the formation of free fatty acids.—A. S.

Aspidium spinulosum; Fatty Oil of ——. P. Farup. Archiv der. Pharm., 1904, **242**, 17—24.

The powdered rhizomes of *Aspidium spinulosum* yielded, on extraction with ether, a viscous brownish-green oil, which was decolorised with animal charcoal, and examined by the usual methods. It was found to consist, in the main, of olein, together with glycerides of linolic acid (about 4 per cent. of the total liquid acids), solid fatty acids (not further examined), and probably isolinolenic acid. Phytosterol (m. pt., 126°—129·5° C.) was also isolated, although it was not found by Katz in the fatty oil of *Aspidium filix*. —C. A. M.

Fats; Enzymic Decomposition of ——, *by Vegetable Seeds.* S. Fokin. Chem. Rev. Fett- u. Harz-Ind., 1904, **11**, 30—32.

The author has made experiments to determine the hydrolysing action on fats of oleaginous seeds of different orders and families of Russian plants, and especially of those growing in the central districts. Of the seeds of the various plants tried (of which a list is given) the following were found to effect the decomposition of fats:—(1) *Euphorbia cyparissias*, which liberated 16 per cent. of fatty acids, with 30 per cent. of the seed employed (*i.e.*, 30 grms. of crushed seeds to 100 grms. of oil). (2) *Brunella vulgaris*, liberating 30 per cent. of acids when used in the proportion of 40 per cent. (3) *Cynoglossum*, yielding 30 per cent. of fatty acids (proportion 24 per cent.). (4) *Aquilegia vulgaris*, 11 per cent. of fatty acids (proportion 20 per cent.); and (5) *Aconitum Lycoctonum*, liberating 11 per cent. of fatty acids when used in the proportion of 15 per cent. More active than any of these were the seeds of *Chelidonium majus*, yielding about 95 per cent. of fatty acids from sunflower oil under experimental conditions, of which the following are typical:—Crushed seed, 4 grms. = 27 per cent.; sunflower oil, 15 grms.; sulphuric acid (N/20), 4 c.c.; water, 6 c.c. The reaction was complete in three days. In another experiment in which the proportion of seeds to oil was 5 per cent. 84·93 per cent. of fatty acids were liberated in 3½ days. Since the husks of the seeds were present in each case, and should be taken into account, the author considers that *Chelidonium* seeds have as great (or greater) enzymic activity as castor seeds, though apparently yielding lower results than the latter. (See also this J., 1902, 1541; 1903, 639, 873, 1031, 1137.)—C. A. M.

Stearine from Fatty Acids; Preparation of ——, *by Means of Alcohol.* P. Pastrovitch. Chem. Rev. Fett- u. Harz-Ind., 1904, **11**, 1—3.

Preliminary experiments on a small scale showed that alcohol of sp. gr. 0·872—0·885 at 15° C. was the most suitable for keeping an equal volume of oleic acid in solution whilst dissolving but little stearine. In the experiments on a larger scale, 100 kilos. of the fatty acids were melted and poured into two or three times their volume of alcohol of this strength and allowed to stand for 12 hours. The crystalline magma was then pressed in a filter-press and washed with alcohol of the same strength, the final (colourless) washings being separately collected and used for the treatment of fresh portions of fatty acids. Finally, the

alcohol was evaporated from the stearine and the distillate condensed, and either rectified or used for the dilution of stronger alcohol. In this way the typical results shown on the previous page were obtained.

Acceleration of the crystallisation effected a slight increase in the yield of stearine. Thus, in two parallel experiments the amounts obtained by stirring the solution during crystallisation and by leaving it alone were 57·25 per cent. ("titre," 51·6° C.) and 45·0 per cent ("titre," 52·75° C.) respectively. In the ordinary methods of preparing stearin by hot expression, the first yield under the most favourable conditions is only about 27 to 30 per cent. ("titre," 44° C.) from tallow fatty acids, or 40 to 45 per cent. ("titre," 54·0° to 57·0° C.) from the fatty acids of pressed tallow, the remainder being in the returns which must be further worked up, thus increasing the cost. In the alcohol method, however, the first yield of stearine amounts to 80 to 95 per cent. of the total amount obtainable. All the stearine had a more or less pronounced reddish tinge, but could be rendered permanently white, it was stated, by being stirred with 2 to 10 per cent. of China clay. The loss of alcohol was 5·35 to 8·59 per cent.

Oil-Cakes; Process and Apparatus for Obtaining ——. E. C. Bisbee and C. F. Elmes, U.S.A. Fr. Pat. 335,444, Sept. 22, 1903.

In the ordinary methods the press-cake is not obtained in a perfect form owing to some of the oil exuding and adhering to the plates of the press, whilst this necessitates frequent cleaning. In the apparatus claimed these drawbacks are obviated. The material coming from the kettles is moulded by slight pressure so as to form cakes, which are afterwards pressed between the plates of the press, the cloths being automatically stretched over them.—C. A. M.

Fats and Fatty Acids; Treatment of —— [*for Candle Material*]. O. Hausamann. Fr. Pat. 335,768, Oct. 6, 1903.

The fats or fatty acids are treated with sulphuric acid in the cold, the products distilled in the usual manner, and the cold solidified distillate again treated with sulphuric acid to re-convert into solid products iso-oleic acid, &c., formed during the distillation. In the apparatus claimed for this process, a cylinder, through the interior of which passes a current of water, is made to revolve in the hot distillate. The adherent flakes are removed from the surface of the cylinder by means of a scraper, and fall into a tank below, where they are mechanically mixed with the sulphuric acid.
—C. A. M.

XIII.—PIGMENTS, PAINTS; RESINS, VARNISHES; INDIA-RUBBER, Etc.

(*A.*)—PIGMENTS, PAINTS.

English Patent.

Lithopone; Manufacture of ——. X. Fischer, Goslar-am-Harz, Germany. Eng. Pat. 17,956, Aug. 19, 1903.

It is found that the slight darkening in colour to which lithopone is subject is due to the presence of traces of chlorine. The compounds used in the manufacture should, therefore, be free from chlorine, and the following process is recommended:—The crude zinc sulphate solution is heated with some oxidising agent (*e.g.*, a manganate or permanganate) and "soda, potash," lime, &c., and filtered; it is then treated with zinc dust, filtered, and precipitated with barium sulphide or a mixture of barium and sodium sulphides in the usual manner.—T. F. B.

United States Patent.

Pigments; Process of Making ——. W. J. Armbroster, St. Louis. U.S. Pat. 751,444, Feb. 9, 1904.

Zinc ores or compounds are dissolved in a suitable acid, and the iron precipitated from the solution by addition of "suitable quantities of a zinc salt." The zinc is then precipitated by means of barium hydroxide, and the filtrate is precipitated by sulphuric acid; the precipitated zinc hydroxide and barium sulphate are washed and mixed together, forming a pigment, whilst the acid solution may be used again for dissolving further quantities of the zinc compound.
—T. F. B.

French Patent.

Arc-Lamp Carbons; Utilisation [*as Pigments*] *of Waste* ——. R. Peters. Fr. Pat. 335,795, Sept. 16, 1903.

The carbon fragments are heated in crucibles to about 2,000°—2,500° C., and plunged whilst still hot, into an oil-bath, where they are left for 12 to 36 hours. By this treatment they are rendered very friable, and can be pulverised and mixed with adhesive material, &c., to form pigments, like Chinese ink, &c.—C. A. M.

(*B.*)—RESINS, VARNISHES.

Turpentine; Examination of ——. H. Herzfeld. XXIII., page 274.

(*C.*)—INDIA-RUBBER.

United States Patent.

India-Rubber; Method of Manufacturing a Substance Resembling ——. D. H. Dupont-Franklin, New York. U.S. Pats. 746,688 and 746,689, Dec. 15, 1903.

A hydrocarbon such as coal-tar or tar of petroleum is mixed with boric, phosphoric, hydriodic, or other acid, dissolved in alcohol; oxygen is passed in, and the mixture is boiled until a green flame appears on igniting the vapours. A product resembling india-rubber is stated to be obtained.
—J. K. B.

XIV.—TANNING; LEATHER, GLUE, SIZE.

Bating and Drenching Light Skins. Leather Trades Rev., 1904, **37**, 98—99.

Goat and calf skins, to be tanned with palmetto and gambier, should be bated with pigeon manure, whilst for combination chrome-tannage, bran-drenching is recommended. For ordinary chrome tanning, goat skins should be puered with dog-dung; sheep, lamb, kangaroo, and calf skins answer well with bran drench and lactic acid, and for the one-bath chrome process with salt and alum, the bran drench gives excellent results.—R. L. J.

French Patent.

Leather or Waste; Process of Detanning ——, *for the Preparation of Gelatin and Glue.* A. R. Weiss. Fr. Pat. 335,996, Oct. 2, 1903.

See U.S. Pat. 738,709 of 1903; this J., 1903, 1096.—T. F. B.

XV.—MANURES, Etc.

French Patent.

Phosphoric and Silicic Acids; Preparation of a very Soluble Compound of ——. Dr. Wolters. Phosphat. Gesellschaft. Fr. Pat. 335,509, Sept. 16, 1903.

Compounds of silicic acid, fused with neutral or basic compounds of phosphoric acid, and suddenly cooled, are stated to yield a product in which the phosphates are soluble n citric acid, &c. Natural phosphates may be mixed with silicates previously prepared, as by the fusion of sand with alkalis, for the described treatment. The best results are obtained by such treatment of a mixture containing 0 to 12 per cent. of alkalis; 25 to 30 per cent. of silica; and 18 to 20 per cent. of phosphorus, the non-alkaline bases being chiefly such as are alkaline-earthy. The phosphates in such a mixture, fused and suddenly cooled, re stated to be wholly soluble in weak solvents; whereas with ordinary cooling only from 25 to 40 per cent. of the phosphates are so soluble. Reference is made to Ger. Pat. 114,482 of 1898. Compare U.S. Pat. 721,489 of 1903; his J., 1903, 429.—E. S.

XVI.—SUGAR, STARCH, GUM, Etc.

Raw Sugar in Store. A. Herzfeld. Zeits. Vereins Deutsch. Zucker-Ind., 1903, **53**, 1201—1277.

The phenolphthaleïn alkalinity of sugars decreases during torage and the diminution proceeds more quickly in propor-on as the alkalinity to litmus is smaller. The cupric reducing ower gradually increases with the decrease of alkalinity, lthough not always quite regularly, acid sugars showing the reatest variations. The cause of loss of alkalinity is to be ttributed to the influence of micro-organisms. The chemical composition—amount of lime or sulphurous acid—does not stand in any exact relation to the reducing power or to he colour. The amount of water appears to be also of no ssential importance in causing fall in alkalinity, but no xceptionally moist sugars were met with. These would aturally not keep well during storage. The fact, already ell known in practice, that sugar keeps better in bags han when accumulated in heaps, is confirmed. Although ost of the sugars alkaline to phenolphthaleïn keep better han acid sugars, there are exceptions. Zettnow found, owever, that moulds were the cause of an alkaline sugar ndergoing alteration. Alkalinity is thus not a direct easure of the keeping quality of a sugar, but is a practical dication which answers generally, but occasionally fails. a convenient method could be found of determining verting moulds, it would be preferable to the determination f alkalinity. It should be clearly noted that it is infection th fungi which alone causes the deterioration in quality uring storage, but only when the fungi are active and creasing in numbers. For under conditions unfavourable development they do the sugar but little harm. Sufficient tention is apparently not given to the keeping of the ores (at least in raw sugar works) in an antiseptic state. Hamburg sugar is found to keep best in corrugated iron eds; wooden sheds come next, and then stone. This pears to be connected with the sensibility of the moulds change of temperature, uniformly heated rooms favouring owth. Care should be taken to cool the sugar as quickly possible, to ventilate the store thoroughly, and to have it parated from the factory.—L. J. de W.

XVII.—BREWING, WINES, SPIRITS, Etc.

Raw Starch; Nature of ——. L. Maquenne. Comptes rend., 1904, **138**, 375—377.

Freshly prepared starch paste is completely saccharified by diastase as well as by hydrolysing acids, but paste which has been kept for some time contains insoluble reversion products which are saccharified only with difficulty. Treatment of ungelatinised starch and of starch-paste with malt extract at 55° C. showed the following percentage of soluble matter, calculated on the original starch: Raw starch granules, 2·8; raw starch ruptured by trituration, 94·8; starch paste, 102·2. Thus, mechanical rupture of the granules acts almost as efficiently as gelatinisation, the residue consisting of amylo-cellulose to the extent of 3—4 per cent. of the original starch. From a chemical point of view, the raw starch possesses the same composition as reverted starch paste, and both may be regarded as containing amylo-celluloses in varying stages of condensation. These amylo-celluloses are produced from the soluble granulose in the cold, and are therefore found both in stale starch paste and in the raw starch granule. They are dissolved at high temperatures, and are therefore not apparent in fresh starch paste. In the plant the soluble granulose is probably reverted under the influence of electrolytes or of coagulating enzymes. This coating of reverted starch would modify the osmotic properties of the starch granule and attenuate to a large extent the solvent action of the diastase. Lastly, it is probable that the more or less advanced stage of reversion is one of the factors which differentiate the natural starches and change the composition of their iodides.—J. F. B.

Barley. Guinness Research Lab. Trans., 1903, **1**, 96—141.

The subject is dealt with under the following headings:—(1) Correlation of "mealiness" and density of barley. (2) Microscopical differences between "mealy" and "steely" grains. (3) Artificial production of "mealiness" in "steely" or partly "steely" grains. (4) The air-content of "mealy" grain. (5) Experiments on the density of starch containing varying amounts of moisture. (6) Density of air-free substance of barley containing varying amounts of moisture. (7) Application of the foregoing considerations to a determination of the interspaces of barley by indirect means. (8) A cytological test of physiological maturation. (9) "Coarseness" of barley and its correlation with other qualities.—A. S.

Malt; The Specifications of Contracts for the Purchase of ——. W. Windisch. Woch. f. Brau., 1904, **21**, 91—93.

In "Der Bierbrauer," 1903, 487, Ebrich contends that for contracts for the purchase of malt it is sufficient to specify that the malt shall contain a guaranteed minimum percentage of extract in the air-dry state as delivered, providing for rebates on any deficiency by simple proportion. The author points out that this view is quite erroneous; quantitatively, it does not matter in what state a definite amount of extract is delivered, but qualitatively it is a very serious fault if the malt be delivered in too moist a condition. An excessive proportion of moisture involves great deterioration of the malt during storage This deterioration may have taken place before delivery, or it may occur during storage in the brewery. A guaranteed maximum limit of moisture is, if the malt be well modified, to a certain extent, a guarantee of quality, and if the excess of water be very considerable, the consignment should be rejected. In less serious cases, slight excess of moisture may reasonably be accepted on payment of a fine. The Berlin Research Brewery purchases its malt on the following conditions:—(*a*) and (*b*) For each 1 per cent. of moisture in excess of 0·1 per cent. a deduction of 2 cwt. and a fine of 10s. is made per truck load of 10 tons; (*c*) if a deficiency of extract be due solely to the presence of an excess of moisture, *i.e.*, if the deficiency of extract do not exceed 0·7 per cent. per 1 per cent. excess of moisture, no deduction is made, but any deficiency of extract beyond this amount is to be allowed for by simple proportion. (This clause is equivalent to a guarantee of a certain percentage of extract calculated on the dry malt.) Alternatively, in the case of an objectionable excess of water, the consignment may be refused on that ground.—J. F. B.

"Spring" Mashing Process and its Effect on Top-Fermentation Yeast. R. Lehmann. Woch. f. Brau., 1904, 21, 103—104.

The author has successfully applied the "Spring" mashing process (this J., 1904, 198) to the brewing of top-fermentation dark sweet beers of high palate fulness. The malt used for the production of these beers is not of the first quality; it contains a large proportion of ungerminated and abnormally grown corns; it is kilned for four hours at a temperature of 100° C. The yields from this malt by the old method of mashing were very good, but the worts always ran turbid for the greater part of the time, and in spite of the use of a low attenuating yeast, the beers were always too highly attenuated, and consequently harsh and poor in flavour. The author therefore tried the "spring" mashing process for preparing the mashes of this kind of beer; the grist was mixed with water at a temperature of 45° C., digested for half an hour, then "sprung" into water at 87·5° C., and saccharified at a temperature of 74° C. for 40 minutes. One-half of the mash was pumped back to the tun, and the other half was boiled for 30 minutes, and the whole was struck at a temperature of 75° C. By this treatment the worts ran perfectly clear, and were in every respect normal; the yield was 0·2 per cent. lower. The worts were pitched with plenty of yeast at 15° C., and fermented rapidly and well. The beers showed apparent attenuations 12 per cent. lower than those brewed in the old way, and occasioned general satisfaction owing to their fuller and thicker flavour. But the yield of surface yeast was very small, whilst the bottom yeast had increased to three or four times the amount usually collected. This fact was repeatedly observed when the "spring" mashing process was applied, and it was found impossible to skim off sufficient top-yeast to serve for pitching the next brew. The "spring" mashes contain so little fermentable sugar that the nutrition is not sufficient to enable the yeast to work its way to the surface. In ordinary worts the sedimentary yeast behaved perfectly normally as a top-yeast. The difficulty has been surmounted by a compromise, by "springing" the cool mash into hot mash instead of into hot water, and conducting subsequent saccharification at 75° C.—J. F. B.

Alcoholic Fermentation; Chemical Mechanism of ——. E. Buchner and J. Meissenheimer. Ber., 1904, 37, 417—428.

In cell-free fermentations it is never possible to recover, in the form of alcohol and carbon dioxide, the whole of the sugar consumed; lactic acid and acetic acid are also produced. The formation of these acids takes place under conditions which preclude the activity of bacteria or the presence of air. The authors have determined the quantities of these acids in the cell juice before and after fermentation. When the cell juice was kept without the addition of sugar for four days, the results of the lactic acid determinations were different in different series of experiments. In some cases the whole of the lactic acid originally present disappeared, and when small quantities of lactic acid were added to the juice these also disappeared on standing. On the other hand, in other experiments, especially in the case of very active extracts, there was a production of lactic acid under the same conditions, but the amount of acid freshly produced, decreased in proportion as that originally added to the juice was increased. The production of lactic acid in the experiments in which no sugar was added may be assumed to be at the expense of the glycogen. When cane sugar was added to the juice, the quantity of lactic acid already present either remained the same or increased considerably. The varying results recorded in the above experiments are to be attributed to differences in the physiological condition of the yeast from which the extracts were prepared. From these results the authors are led to conclude that lactic acid (which may be regarded as the carboxylic acid of ethyl alcohol) is an intermediate product in alcoholic fermentation. Glucose may be regarded as breaking up into 2 mols. of lactic acid through a hypothetical α-δ-dihydroxy-γ-ketonic acid as an intermediate stage. The lactic acid is then hydrolysed into carbonic acid (H_2CO_3) and ethyl alcohol. This view is supported by the action of different alkalis upon glucose; under some conditions lactic acid is produced, whilst under other conditions (sunlight) alcohol is formed. Zymase, therefore, may be assumed to consist of two enzymes, one converting the sugar into lactic acid, and the other converting the lactic acid into alcohol and carbon dioxide. The lactic acid bacteria probably secrete only the first of these enzymes, whilst both are present in yeast. In the case of fermentations with yeast cells, both enzymes would be present in excess, owing to continuous secretion, and the final products of fermentation only would be found. In cell juice, where no further secretion of enzymes can take place, one or other might be in excess, according to the condition of the yeast at the time of extraction, hence the variable results recorded above.

Acetic Acid.—In all the experiments a production of acetic acid was observed in the juice on standing for four days; the amount of this acid produced was much greater when sugar was added to the juice than when no sugar was added.—J. F. B.

Attenuation [Beer]; Effect of Different Temperatures and Processes of Mashing upon the Final Degree of ——. C. Bleisch and P. Regensburger. Zeits. ges. Brauw., 1904, 27, 109—114.

The authors have investigated the effect of different temperatures of mashing upon the final degree of attenuation, *i.e.*, the maximum fermentability of the wort, when fermented on the one hand by the feebly attenuating Saaz yeast and on the other with the highly attenuating Frohberg yeast. The mashes were made in the laboratory with both dark and pale malts, the grist being mixed with water, so that the desired temperature of saccharification was established as soon as the mixture was made, and maintained constant until saccharification was complete. In certain cases, where saccharification was unsatisfactory, the mash was boiled up subsequently and again saccharified. Mashes, which were made at 60° C. and at 75° C. respectively, saccharified with extreme slowness, and saccharification was not complete in three hours. Between these limits the mashes saccharified rapidly and well. The fermentations showed that the temperature at which the mashes were made had a very great influence on the final attenuation with both types of yeast, the attenuations being restricted as the mashing temperatures were increased. To those worts which had been fermented with Saaz yeast a similar quantity of Frohberg yeast was subsequently added, with the result that the attenuations were raised to the same points as were attained with Frohberg yeast alone. Worts prepared in the above way, by mashing at definite high temperatures from the first, were compared with worts mashed on the principle of Windisch's "Spring" mashing process (this J., 1904, 198), by pouring cold mash into very hot water in such proportions that the same mashing temperatures were ultimately obtained in both

Dark Malt.

70 *b*	2 hours 30 mins.	55·94	65·67

a denotes mash mixed at that temperature from beginning.
b denotes mash according to the "Spring" process, temperature reached from above.

cases. In the latter case, however, the diastase would be partially crippled, owing to the principle of reaching the mashing temperature from above instead of establishing it at once. The above table shows the result of fermentation of both types of mash.

The crippling of the diastase by the "Spring" mash process is very clearly shown by the reduced attenuations of the wort prepared in that manner. The principle of mashing at high initial temperatures, comparable with those produced in the laboratory, can be applied in practice by suitable mash tuns and coppers. The principle underlying the "Spring" mashing process has been used in Bavaria for a long time by boiling a large portion of the total mash at once and letting down the residual cool mash into the hot decoction. The main difficulty in applying this principle to the dark Bavarian malts lies in the excessive crippling of the diastase and the consequent danger of imperfect saccharification.

—J. F. B.

Attenuation; Determination of the Maximum Degree of ——. W. Windisch. Woch. f. Brau., 1904, 21, 101.

With the introduction of processes for reducing the fermentability of the wort, the methods for determining this factor become of greater importance. The general procedure for the determination of the maximum degree of attenuation, which a particular yeast is capable of producing n any given wort, consists in fermenting a sample of the wort with a large proportion of yeast under the most favourable conditions. In order to obtain a result in the shortest possible time, the test wort is generally fermented at a temperature as high as 25°—28° C., and fermentation s assisted by frequent agitation to remove the carbon dioxide. But the author points out that under such conditions, with a very rapid and vigorous fermentation at a high temperature, a notable loss of alcohol may occur by volatilisation, especially if the surface of the fermenting wort be relatively large. This loss of alcohol involves an rror in the gravity determination, with the result that the beer on racking may show an apparent attenuation greater han the possible maximum as determined by the test. For his reason it is better to ensure greater accuracy at the xpense of a longer time, and to conduct the test fermentaion more slowly at a temperature of 20° C. only. With a arge proportion of seed yeast and frequent shaking, a result is generally obtainable in three or four days.

—J. F. B.

Beer Filtration and Albuminoid Turbidity ——. W. Windisch. Woch. f. Brau., 1904, 21, 93—95.

The most insidious and puzzling of the turbidities occurring n beer, apart from microbic infection, is the so-called gluten" turbidity. It is caused by the separation of lbuminoid compounds in a state of infinitesimal fineness. A "gluten" turbidity is often present in the beer in the ager cask, but in most cases this is removed by filtration. Unfortunately, however, the beer, which has left the filter bsolutely bright, may again become turbid after a few ays' storage, especially if exposed to low temperatures. Hence it is often said that a beer is sensitive to chill. In esting for this liability to become turbid when chilled, it is ot sufficient in the laboratory merely to cool the sample by means of an ice-bath; the turbidity will frequently fail to ppear by the mere application of cold, but will be found o develop if the samples be placed all night in the open ir exposed to a cold wind. In a series of investigations n the appearance of "chill turbidities" in filtered and nfiltered beer, the author found that only a very few of the amples were inherently—*i.e.*, without filtration—liable to "gluten" turbidities by chilling. Those samples which had been passed through a filter which had not been cleaned for some time were not very liable to this turbidity, but were not so free from it as the unfiltered samples. On the other hand those samples which had been filtered in a filter which had recently been thoroughly cleaned with chemical agents showed a most remarkable tendency to turbidity. This series of experiments shows conclusively that the liability to turbidity is imparted to the beer by the filter, and that it is worst in the case of new or recently cleaned filters. Moreover, the experiments showed, and experience on the large scale has confirmed the fact, that exposure to cold is not an absolutely necessary factor in the production of turbidity after filtration, since these turbidities, although hastened by cold, will develop when the filtered beer is stored at the ordinary temperature. It is now established that the turbidities, often wrongly attributed to chill, are due to the separation of metallic compounds of the albuminoids. The metal which is the chief cause of the trouble is undoubtedly tin, which, either in the pure form or in the form of alloys, is used as a coating on certain of the brewery plant, and especially in the beer-filter. The metal may be present in the beer in such minute traces as to evade detection by chemical tests. In fact, Bergsten has shown that the addition of 0·00025 grm. of tin to a hectolitre of beer is sufficient to bring about a characteristic turbidity after 24 hours. This explains the trouble on the practical scale when a beer, which has been filtered perfectly clear through a new or recently cleaned filter, becomes turbid after standing for a couple of days. The bright, tinned surface of the beer filter must be allowed to become insulated by a thin coating of beer scale. This can be effected at once by allowing beer to remain in the filter all night. When once a deposit has formed, care should be taken to allow it to remain on, consequently all cleansing agents which remove beer scale should be avoided, and the filter should only be cleansed by steeping it in hot water, and brushing the interior gently. The use of filters enamelled internally with glazed enamel, and provided with horse-hair sieves instead of wire gauze, is to be recommended.—J. F. B.

Beer Turbidity caused by Metallic Surfaces. C. F. Woch. f. Brau., 1904, 21, 108.

Referring to the article by Windisch (see preceding abstract) on the production of turbidities in beer through contact with bright metallic surfaces, the writer remarks that a large proportion of the beer, returned by the retailers as turbid and unfit for sale, has been spoilt by contact with the metal pipes leading from the cellar to the bar. The writer has observed that complaints of turbid beer have generally occurred immediately after the innkeeper has given his pipes a thorough cleansing. He therefore concluded that objectionable chemical agents were used for cleaning the pipes, and gave orders that only a weak solution of sodium carbonate in conjunction with lime, or even merely hot water, should be employed for that purpose. This practice proved an almost perfect cure for the trouble.—J. F. B.

Distillery Washes of the Present Season; Analyses of ——. H. Hanow. Zeits. Spiritusind., 1904, 27, 58.

The author has analysed 11 samples of fermented wash from potato mashes in order to check the yield of alcohol and the efficiency of the fermentation. The quantity of fermentable extract still unfermented was determined by evaporation of the alcohol on the water-bath, neutralisation of the acidity down to about 3°, and fermentation of the extract with pure yeast, if necessary, after saccharification with malt extract. The results are shown in the table on page 264. The attenuation and percentage of alcohol in samples 1 and 2 were satisfactory, and the fermentation was pure. Nos. 3 to 5 were also fairly satisfactory. No. 6 is very badly attenuated, and the fermentation had been impure, as is shown by the high acidity, and that the quantity of diastase was insufficient. In Nos. 7 to 11, the attenuation is more or less deficient in spite of the presence of sufficient diastase, but the acidity is not excessive. In such cases it may be assumed that the yeast has ceased to work too early. This

No.	Original Concentration of the Mash. Bg.	Attenuated Wash. Bg.	Alcohol per cent. by Vol.	Degree of Acidity.	Diastase.	Alcohol obtainable from Residual Extract. Vol. per cent.

may be due to the faulty preparation of the pitching yeast, or to the temperature in the primary fermentation having risen too high, or to that in the secondary fermentation having fallen too low.—J. F. B.

Citric Acid in Wine; Simple Method for the Detection of ——. A. Devarda. XXIII., page 273.

Turpentine in Denatured Spirit; Determination of ——. U. Chierego. XXIII., page 274.

English Patents.

Wort contained in the Malt of Breweries, Distilleries, and Similar Industries; Rapid Extraction of ——. E. de Meulemeester, Brussels. Eng. Pat. 25,582, Nov. 23, 1903. Under Internat. Conv., Dec. 1, 1902.

The apparatus employed consists of a vertical cylinder containing two sets of concentric perforated walls, and into the space between these latter is introduced the "sacrated malt." The wort drains away through the perforations, and the grains are washed by introducing hot liquor into the annular space between the outer perforated partition and the casing, this liquor then traversing the grains and draining away through the inner perforated partition.
—C. S.

Brewing; Impts. in ——. J. St. P. Macardle, Dundalk. Eng. Pat. 23,456, Oct. 27, 1902.

To supply pure air, in order to prevent wild yeast infection in the brewery, the air is drawn in through a fan and forced through a succession of filters, of large superficial area, whence it is delivered to the various parts of the brewery through pipes. The intrusion of unfiltered air is prevented by providing air-locks at the entrances to the building.
—C. S.

Wines and the like; Apparatus for Use in the Manufacture of ——. G. Driancourt, St. Quentin, France. Eng. Pat. 2986, Feb. 7, 1903. Under Internat. Conv., Feb. 8, 1902.

See Fr. Pat. 318,506 of 1902; this J., 1903, 224. T. F. B.

Filtering Apparatus [Distillers' Slops, &c]; Impts in ——. A. E. Cummer, Cleveland, Ohio. Eng. Pat. 23,230, Oct. 27, 1903.

The apparatus is designed for the filtration of distillers' slops, waste from glucose works, and similar liquids containing starch and the like, which are to be recovered. It consists of an outer casing or cylinder having a series of lengthwise slots, so as to afford free outlet for the filtered liquid. Suitable supports are provided, bearings for a central shaft, and supply tubes. The inside of the casing is lined with a perforated sheet metal plate, which overlies the slots and acts as a filtering material, although a mesh of wire gauze may be added as well. A continuous flow of liquid is sent through the apparatus under pressure, and the separation of the solid particles effected by stirring blades fixed to a central shaft. Over the back end of the shaft is fitted a spiral conveyor, the spirals getting closer together near the exit; this serves to force out the separated solid matter through a terminal opening closed by a cover controlled by a spring. To keep the inside of the filtering plate clean, a cleanser travelling backwards and forwards, is provided, having a scraper edge, and fitted with pipes through which steam or hot water may be admitted.—L. F. G.

Yeast; Preparation of ——, *capable of Fermenting at High and Low Degrees of Density, Acidity, and Attenuation.* G. Jacquemin. Second Addition, dated Sept. 14, 1903, to Fr. Pat. 307,950, Feb. 7, 1901.

In the original specification a means was described for the production of seed yeast for the distillery, possessing any desired special characters, by acclimatising it by aseptic fermentations through a number of vessels to the conditions desired. It is now found that the number of vessels may be reduced, by omitting some of them and replacing those omitted by ordinary fermentation tuns in which the bacteriological purity of the unsterilised worts is ensured by the presence of copper salts or of a mixture of hydrofluosilicic and formic acids. The yeast grown in the laboratory should be taken from a vessel containing a larger proportion of antiseptic than the wort to be fermented by it on the large scale. These antiseptics are also claimed for general use in distillery worts and in the saccharification of grain by the mucedine.—J. F. B.

XVIII.—FOODS; SANITATION; WATER PURIFICATION, & DISINFECTANTS.

(A.)—FOODS.

Margarine; Micro-Organisms in ——. A. Zoffmann. Chem. Rev. Fett-u. Harz-Ind., 1904, **11**, 7.

The chief micro-organisms that attack margarine are mould fungi (*penicillium*) and different species of saccharomycetes. In order to protect margarine from mould fungi it should be covered with sound parchment paper taken directly from concentrated brine, and should be packed so that there is no air space between the packages and the interior of the case. The main predisposing cause is the presence of a large amount of casein in the margarine. A product which has been mixed and kneaded with over-soured milk will contain flecks of casein on which the mould fungi will develop on standing. Yeasts develop in margarine chiefly in the autumn, and when present in large quantity may produce so much carbon dioxide as to burst the packages. Hence it is dangerous to add either cane sugar or glucose to margarine. The temperature to which the fats are heated during the manufacture is quite insufficient to sterilise infected materials.
—C. A. M.

Caffeine in Coffee Infusions; Amount of ——. J. Katz. Archiv der Pharm., 1904, **242**, 42—48.

Experiments were made to determine the proportion of caffeine extracted by treating 15 grms. of powdered roasted coffee with 300 c.c. of boiling water in (1) Arndt's percolator; (2) for five minutes in a covered vessel in a boiling water bath; and (3) in an ordinary percolator. In each case the amount of caffeine and total extract was determined, the caffeine by the author's method (this J., 1903, 1300) with the following average results: Proportion of caffeine extracted in (1), 96·5; (2), 85·2; and (3), 60·3 per cent. The amount of total extract in the infusions showed parallel variations. The addition of sodium bicarbonate to the water in the proportion of 1 grm. per litre only increased the amount of caffeine extracted to an insignificant extent.

Emulsifying Apparatus; Impts. in ——. F. W. Howorth, London. From E. Bazzi and Co., Milan. Eng. Pat. 28,022, Dec. 21, 1903.

The apparatus is specially adapted for emulsifying fats in separated milk. It consists of a hollow disc or drum, with a central aperture, through which the two liquids to be emulsified are fed from a hopper or feeding funnel The disc contains one or more radial vanes, and is rapidly rotated, the liquids being forced out centrifugally in an emulsified condition, through circumferential openings.

—L. F. G.

Flavouring Preparations. E. J. Boake, Stratford. Eng. Pat. 28,226, Dec. 23, 1903.

"Natural copra as imported," is pressed and the oil extracted and refined; the harder portion of the oil is then separated by crystallisation, and, on account of its high melting point and lack of odour, is used as a solvent for flavouring or essential principles. For instance, esters or essential oils may be dissolved in it, or it may be added to the warm (undistilled) product of the esterification of alcohols, whereby the ester is dissolved in the fatty substance and can be removed when cold, and washed.

—T. F. B.

Cocoa Paste; Manufacture of ——. F. E. F. Neumann, Wandsbek, Germany. Eng. Pat. 7595, April 1, 1903.

See Fr. Pat. 330,616 of 1903; this J., 1903, 1099.—T. F. B.

United States Patents.

Casein for Food; Preparation of ——. A. A. Dunham, New York. Assignor to the Casein Co. of America. U.S. Pat. 750,832, Feb. 2, 1904.

Casein is dissolved and partly digested by a suitable digestive agent, the peptonising process being interrupted by desiccating the solution, applied as a thin film, on cylinders heated to not less than 212° F. The proteid matter is removed and powdered.—R. L. J.

Albuminous Compounds; Process of Making Water-Soluble ——. A. Busch, Brunswick, Assignor to Bauer and Co., Berlin. U.S. Pats. 750,945 and 751,428, Feb. 2, 1904.

See Fr. Pat. 333,334 of 1903; this J., 1903, 1362.—T. F. B.

Centrifugal Separator [Milk]. P. L. Kimball, Bellows Falls., Vt., Assignor to Vermont Farm Machine Company. U.S. Pat. 751,178, Feb. 2, 1904.

The separator consists of a cylindrical drum, with a conical upper part and a short cylindrical piece attached, through which passes a milk admittance tube reaching nearly to the bottom of the drum. Above the bottom is placed a horizontal perforated plate, and the drum also contains a liner with vertical slots in its walls, for the purpose of directing the milk radially. Outlets are provided for the cream and for the separated milk.—L. F. G.

French Patent.

Casein; Clear Solutions of ——. P. Horn. Fr. Pat. 335,799, Sept. 18, 1903.

A 10—20 per cent. solution of commercial casein is made by using 7—8 per cent. (on the dry proteid) of caustic alkali. Ether (20—40 per cent.) is added, and the mixture is shaken, allowed to stand, and the clear casein solution drawn off.—R. L. J.

(*B.*)—SANITATION; WATER PURIFICATION.

Chloroform as an Antidote to the Injurious Effects of the Inhalation of Nitrous Fumes. Seyfferth. Concordia, Zeits. f. Arbeiter-Wohlfahrtseinrichtungen, **10**, 319. Chem. Centr., 1904, **1**, 472.

The author recommends the proposal of E. Weiskopf to use chloroform in cases of inhalation of nitrous fumes. The chloroform should be administered in doses of 3—5 drops (0·045—0·078 grm.) at intervals of 10 minutes till ·5 grms. have been used.—A. S.

French Patent.

High-Pressure Filters [Water]. W. S. Rawson. Fr. Pat. 335,676, Oct. 1, 1903.

A metal cylinder, fixed to the water-tap by means of the usual caoutchouc cone connection, which is pressed tightly against the tap by the water pressure, contains a block of filtering material, preferably made of calcined magnesia, and this is retained in its place by another caoutchouc cone. Or, the second caoutchouc cone may be attached to another pipe delivering the filtered water, and thus several filters may be mounted in parallel between the supply and delivery pipes. The upper portion of the filtering block may be made star-shaped, to increase the filtering area.—L. F. G.

(*C.*)—DISINFECTANTS.

Ammonium Fluoride for the Disinfection of Rubber Hose. J. Brand. Zeits. ges. Brauw., 1904, **27**, 115—117.

Commercial acid ammonium fluoride, $NH_4F.HF$, is one of the most valuable disinfectants in the brewery, both on account of its power and absence of odour. The chief use to which the salt is put, in solutions containing 0·5— per cent., is for the disinfection of rubber hose pipes. It has recently been suggested, however, that the rubber hose is attacked by the acid and caused to crack and perish. The author has examined specimens of hose which were supposed to have become corroded, and from his experiments it may be concluded that dilute fluoride solutions may safely be used for disinfecting rubber hose pipes, although it is conceivable that badly mixed rubber containing basic mineral loading matter would show a corrosion due to the action of the acid on the loading material. The disinfecting power of the fluoride is doubtless mainly due to the loosely combined hydrofluoric acid. The commercial preparations never correspond exactly to the formula $NH_4F.HF$ and the active hydrofluoric acid varies largely in different samples. The loosely combined acid is best determined by titration in a platinum or silver dish with N/5 baryta solution; using litmus as an indicator, the end point is not very sharp. Most of the commercial samples contain considerable proportions of hydrofluosilicic acid, which, however, is also a valuable disinfectant.

—J. F. B.

XIX.—PAPER, PASTEBOARD, Etc.

Bamboo Pulp. C. D. Ekman. Wochenbl. f. Papierfab., 1904, **35**, 461—462.

The author calls attention to the extreme fitness of the bamboo fibre for mixing with sulphite wood pulp to improve the quality of the paper and to take away its "woody" appearance. In length of fibre, softness, and whiteness, bamboo pulp is equal to the best cotton pulp. The bamboo is obtainable in unlimited quantities in tropical climates, but the cane itself will not bear the cost of transportation to Europe. The pulp would have to be manufactured in the district in which the bamboo is grown. Every species of bamboo is not equally suitable for pulp-making; the pulp is generally difficult to bleach and requires a large proportion of bleaching powder. Some species can be bleached to a good white with 15 per cent. of bleach, whilst others, treated in the same way, give a poor colour with even 25 per cent. of bleach. Only the fully grown canes can be treated economically. There should be a good sale in Europe for the best quality of bamboo pulp for the purpose indicated above.—J. F. B.

Hydrocellulose; So-called ——. A. L. Stern. Proc. Chem. Soc., 1904, **20**, 43.

When cellulose is exposed to the action of dilute acids under certain conditions, the tenacity of the fibre is destroyed, and it falls to a powder which has been called hydrocellulose, and stated to have the empirical formula $C_{12}H_{22}O_{11}$. It is now shown that when the above reaction takes place, instead of a gain in weight, as theory indicates, there is invariably a loss, and that a small amount of soluble matter is formed, a portion of which, in all probability, is *d*-glucose. The elementary composition of the powder is also shown to be identical with that of cellulose, the previous statements bearing on this point being founded on faulty experimental methods. A hydrated cellulose is not formed under these conditions, but a hydrolysis takes place similar to that undergone by other carbohydrates under comparable conditions.

English Patents.

Paper Pulp; Manufacture of —— [from Furze]. G. P. Horteloup, Paris. Eng. Pat. 26,149, Nov. 30, 1903. Under Internat. Conv., Dec. 9, 1902.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

Bismuth; Some Combinations of ——, with Hydroxybenzoic Acids. P. Thibault. Bull. Soc. Chim., 1904, **31**, 36—38.

Bismuth p-hydroxybenzoate, $Bi(C_7H_5O_3)_3$.—This salt is obtained by heating on the water-bath pure anhydrous bismuth oxide, prepared according to the author's method, with an excess of *p*-hydroxybenzoic acid in the presence of water, so that reaction takes place with a saturated aqueous solution of the acid. When microscopical examination shows that the yellow needles of the anhydrous oxide have disappeared, the mixture is evaporated to dryness, and the cold residue washed with absolutely anhydrous ether. The salt consists of minute acicular transparent crystals, which are decomposed by the least trace of moisture. It cannot be obtained by double decomposition, nor by treating hydrated bismuth oxide with the acid.

Bismuth m-hydroxybenzoate is formed in a similar manner, but has not been isolated in a state of purity, since it is decomposed by all solvents, even by anhydrous ether.

Bismuth β-resorcylate, $C_6H_3(OH)_2(CO.O.BiO)[1.3.4]$.—This salt is a white powder comprised of minute transparent needles, insoluble in water and ordinary solvents. It is obtained by heating anhydrous bismuth oxide for several hours with excess of β-resorcylic acid. The insoluble matter is then washed with alcohol or with boiling water, and dried.

Bismuth hydroxysalicylate, $C_6H_3(OH)_2(CO.O.BiO)$ $[1.4.6]$, is obtained in a similar manner by the action of hydroxysalicylic acid on anhydrous bismuth oxide. It occurs in small yellowish-white transparent needles, stable in presence of water.—J. O. B.

Camphor; Synthetic ——. M. O. Forster. Chem. and Druggist, 1904, **64**, 289.

The author points out that the compounds, called "pinyl oxalate" and "pinyl formate," obtained as intermediate products in the manufacture of synthetic camphor (see this J., 1904, 75) are bornyl hydrogen oxalate ($C_{10}H_{17}O.CO.CO_2H$) and bornyl formate ($C_{10}H_{17}O.CH:O$) respectively. The reactions which occur in the conversion of bornyl hydrogen oxalate into camphor and of bornyl formate into borneol, when the mixture of the two compounds is heated with alkalis, are represented by the following equations:—

$$(1)\quad C_{10}H_{17}O.CO.CO_2H = C_{10}H_{16}O + H_2O + 2CO.$$

$$(2)\quad C_{10}H_{17}O\cdot CH:O = C_{10}H_{18}O + CO.$$

—A. S.

Nicotine; Reciprocal Solubility of —— in Water. C. S. Hudson. Zeits. physik. Chem. 1904, **47**, 113—115.

The behaviour of nicotine with water is peculiar, and affords evidence of the existence of combination of the base with water. When equal volumes of nicotine and water are mixed at ordinary temperatures, a marked evolution of heat, and a considerable contraction in volume occur, the resulting mixture having a viscous consistence resembling that of glycerin. On warming, separation occurs, and two layers of liquid are formed, the upper stratum consisting of a saturated solution of nicotine in water, the lower of a saturated solution of water in nicotine. When nicotine is frozen in a mixture of solid carbon dioxide and ether, it solidifies to an amorphous mass which does not crystallise when slowly warmed. Nicotine mixes with water in all proportions at temperatures under 60° F., and above 210° F. Between these temperatures the reciprocal solubilities vary. This was determined by the method of Alexejew, by noting the temperature at which turbidity occurs in mixtures of known weights of the two bodies. The temperatures of separation and re-solution of known quantities of nicotine in water were found to be as follows:—

—	Separates at	Redissolves at
	° F.	° F.
6·8 per cent. of nicotine........	94	95
7·8 " "	89	155
10·0 " "	75	..
14·8 " "	65	200
32·2 " "	61	210
49·0 " "	64	205
66·8 " "	72	190
80·2 " "	87	170
82·0 " "	129	130

The physical properties of the two layers of liquid containing nicotine and water, are of interest. "At about 90° F. a saturated solution of water in nicotine has the same density as a saturated solution of nicotine in water." Above this temperature the density of the nicotine layer is less than that of the water layer; below it, the nicotine layer is the denser. Consequently when a mixture of equal weights of nicotine and water are heated above 210° F. and cooled; at 205° F. it becomes turbid and a layer of nicotine saturated with water separates and floats on the top. When the mixture cools to 90° F. the layers change places, the nicotine layer sinks and the aqueous stratum rises. At 64 the layers mix and the solution becomes homogeneous. The development of heat on mixing nicotine with water is probably due to the formation of a hydrate; the same is borne out by the effect of dilution on the optical rotation and refraction equivalent of nicotine. The formation of this hydrate is the probable cause of the apparent reciprocal solubility of the two substances really insoluble in each other.—J. O. B.

Alkaloids in Conium maculatum; Distribution of the ——. E. H. Farr and R. Wright. Pharm. J., 1904, **72**, 185.

The plant was dried in warm air, extracted with cold 70 per cent. alcohol, and the extract added to water containing a few drops of sulphuric acid; the liquid was then evaporated till free from alcohol. The solution was made alkaline with potassium hydroxide, extracted with chloroform, and the chloroform solution extracted with dilute acid, again made alkaline, extracted with choroform, and the alkaloids taken up in dilute acid, liberated by means of alkali, extracted with chloroform, and converted, by means of fuming hydrochloric acid, into the hydrochlorides, vhich were weighed. The results showed the very apid production of alkaloids as growth proceeds, espeially during the flowering and fruiting stages; in the atter, the increase goes on until the fruit is about three arts grown, after which the percentage of alkaloid liminishes. The table shows the amount of alkaloid hydrochloride found in the various parts of hemlock taken from the same source.

Stage of Development.	Root.	Stems and Stalks.	Leaves.	Flowers.	Green Fruit.
Young plants, 4—6 ins. high	0·047	0·017	0·039	..	..
ft.—3 ft. 6 ins. high, showing incipient inflorescence	0·035 0·052	0·037	0·030	..	..
ft. high, in full flower	0·050	0.064	0·187	0·236	0·905

The amount of alkaloids calculated as hydrochlorides found in the dried hemlock fruit of commerce averaged 0·674 per cent., whilst that found in English fruit gathered by the author averaged 2·13 per cent. (limits, 1·05 and 3·57 per cent.).—T. F. B.

Orange Oil; South American ——. J. C. Umney and C. T. Bennett. Pharm. J., 1904, **72**, 217.

The authors have examined a sample of South American orange oil, which resembled in appearance Paraguay petit grain oil, but had a more delicate odour. The characters of the oil more closely resembled those of orange-leaf oil than of orange-flower oil. A comparison of the oil with some other oils is given in the following table :—

—	South American Orange Oil.	Paraguay Petitgrain Oil.	French Petitgrain Oil.	French Neroli Oil.	Chinese Neroli Oil.
pecific gravity.......................	0·887	0·891	0·885—0·900	0·870—0·880	0·850
ptical rotation	+ 2	+ 0 30	About 2	+ 1 to + 5	+ 35
sters, as linalyl acetate	36·5 per cent.	52·4 per cent.	50—75 per cent.	10—20 per cent.	4·79 per cent.
ree alcohols as geraniol	38·4 ,,	18·9	25—35 ,,	20—35 ,,	21·4 ,,
otal alcohols.	67·1 ,,	60·0 ,,	..	..	25·17 ,,

Owing to its low content of terpenes, the oil is readily oluble in alcohol (*e.g.*, in 2 vols. of 70 per cent. alcohol) Vhen the oil is fractionally distilled under reduced pressure, he optical rotation of the fractions gradually increases and he refractive index decreases with increase of specific gravity and boiling point. In the various fractions the uthors have detected *l*-pinene, dipentene, furfural, geranyl cetate, linalol, and geraniol. The oil also probably ontains terpineol, but, at the most, only traces of methyl nthranilate. For soap-scenting and perfumery purposes he oil appears to compare very favourably, with regard to odour value, with French petitgrain oil.—A. S.

Salicylic Acid [Free] in Bismuth Salicylate; Suggested Test for [Detection of] ——. W. Lyon. XXIII., page 273.

Chloral and Butylchloral; Reaction for Distinguishing between ——. E. Gabutti. XXIII., page 273.

See Fr. Pat. 329,529 of 1903; this J., 1903, 1063.—T. F. B.

Citrylidene-Acetic Acid, its Nitrile or its Ethers; Manufacture of New Compounds derived from ——. A. Verley, Paris. Eng. Pat. 25,695, Nov. 24, 1903. Under Internat. Conv., Nov. 27, 1902.

See Fr. Pat. 326,771 of 1902; this J., 1903, 819.—T. F. B.

United States Patents.

Rufigallic Acid Ethers; Acidyl Derivatives of ——, *and Process of Making same.* K. Stephan and F. Kaiser, Assignors to Chem. Fabr. auf Actien, vorm. E. Schering, Berlin. U.S. Pat. 751,216, Feb. 2, 1904.

By reacting on the alkyl ethers of rufigallic acid with acidylating agents, acidyl derivatives are obtained, which are nsoluble in water, and sparingly soluble in alcohol and ether; they have a yellow or brownish colour, are tasteless, and have a purgative action.—T. F. B.

Dialkyl-Barbituric Acid; Process of Making ——. M. Engelmann, Elberfeld, Assignor to Farbenfabr. vorm. F. Bayer and Co., New York. U.S. Pat. 751,724, Feb. 9, 1904.

See Eng. Pat. 22,967 of 1903; this J., 1904, 76.—T. F. B.

French Patent.

Dihydroxybenzenes, Formaldehyde, and Ammonia; Preparation of Compounds Soluble in Water from ——. Soc. Möller and Linsert. Fr. Pat. 335,725, Oct. 3, 1903.

See Eng. Pat. 20,223 of 1903; this J., 1903, 1306.—T. F. B.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Matt Gelatin [Photographic] Paper; Preparation of —— P. Hanneke. Phot. Mitt., 1904, **41**, 49—51.

A suitable unsized paper is provided, on the side to be coated, with a layer of chrome-gelatin (7·5 grms of gelatin, 200 c.c. of distilled water, and 15 c.c. of 2 per cent. chrome-alum solution), which prevents the emulsion from sinking into the paper. This preliminary treatment can be dispensed with by using the matt baryta paper now obtainable commercially. The preparation of the following solutions, which may be effected in ordinary daylight, is next carried out :—I. Emulsion gelatin, 25 grms.; distilled water, 400 c.c.; ammonium chloride, 2 grms. II. Silver nitrate, 14 grms.; water, 100 c.c. III. Citric acid, 3 grms.; water, 50 c.c. These are then brought to 50 C. and mixed by lamplight in the following way: solution II. is run into I., which is kept well stirred, solution III. being then added. The emulsion obtained is filtered through flannel and applied to the paper (by lamplight) as follows :—A portion of the emulsion, heated to 40°—50° C., is poured into a clean flat basin, in which it should have a depth of about 1 cm. A sheet of paper, with the prepared surface downwards, is laid carefully on the emulsion, the corners being raised to see if any air bubbles are present on the paper; these must be removed by means of a glass rod. The paper is left on the emulsion for a minute, after which it is carefully raised by two corners, so that the excess of emulsion may drain off without running on to the back of the paper. The sheets are then hung by wooden clamps in a dark, moderately warm room (near the stove). After two or three hours they become dry, and are then smoothly rolled on to a pasteboard roller. The paper can then be exposed, toned, and fixed as usual. A suitable combined toning and fixing bath is the following :—Water, 1,000 c.c.; sodium thiosulphate, 200 grms.; crystallised sodium acetate 12 grms.; lead acetate, 12 grms.; ammonium thiocyanate (sulphocyanide), 10 grms.; citric acid, 4 grms.; and 1 per cent. gold chloride solution, 60 c.c. The prints must be strongly overprinted and placed direct in the above bath, which gives good purple and violet tones.—T. H. P.

Platinotype Process. L. Ebert. Phot. Corr.; through Phot. Mitt., 1904, 41, 33.

The following sensitising solution is recommended for platinotype papers:—Potassium platinochloride solution (1:6), 12 c.c.; "normal iron solution" (commercial), 7 c.c.; "iron chlorate solution" (commercial), 4 c.c. For cold tones gelatin is used for the film, and arrowroot for warm tones. For use with thin negatives, the "normal iron solution" is omitted, and the chlorate solution is increased to 11 c.c., whilst for hard negatives the chlorate solution is dispensed with, the sensitising bath consisting of platinochloride solution, 12 c.c.; "normal iron solution," 11 c.c. Development is carried out at about 50° R. (62·5° C.) with a solution containing potassium oxalate solution (1:3), 100 c.c.; oxalic acid solution (1:10), 20 c.c.; water, 100 c.c. For sepia tones it is preferable to add 20 c.c. of saturated mercuric chloride solution to the developer. It is stated that a sepia print prepared in this manner has been exposed to the light for 12 years without deteriorating sensibly.

—T. F. B.

Syrian Asphaltum for Printing Plates and Window Transparencies. C. Fleck. Sprechsaal, 37, 111—112.

The asphaltum is purified by mixing the powdered mass to a thick pulp with chloroform or oil of turpentine, and then shaking up several times with fresh ether. Finally, the ethereal mixture is filtered, and 5 parts of the residue are dissolved with 50 of pure chloroform, 75 of 85 per cent. benzol, and 1 part each of chemically pure lavender oil and Soudan brown, this last-named increasing the sensitiveness to light, whilst the lavender oil increases the tenacity of the film and facilitates development. The filtered and clarified solution is used for coating metal plates, and these, when dry, are copied under a negative or transparency, with an exposure of 30—45 minutes in strong daylight. After cooling down, the plates are developed with oil of turpentine, or a negative print can be obtained by developing with alcohol, this solvent taking up the parts of the asphaltum acted on by light and leaving the shaded parts. If the asphaltum solution be mixed with solutions of caoutchouc and sulphur in chloroform and benzene, the resulting film (without gelatin or collodion), will give delicate line prints on glass, suitable for fine etching with hydrofluoric acid. Very delicate screens can be produced on glass or stone with a film composed of Syrian asphaltum, 1 part; virgin wax, 1·2; stearic acid, 1·2; and "gas black," 0·2 part, dissolved in oil of turpentine on the water-bath. An open grain on granulated litho stone can be prepared by traversing the surface with a printing roller charged with a nitrobenzene solution of asphaltum. The gradation of half tones can be increased, and the use of a reversed negative dispensed with, by coating metachromotype paper with asphaltum preparation, transferring the exposed print to the stone, and developing after removing the paper or celluloid film. For coloured prints on marble, the unpolished surface is coated with a mixture of Syrian asphaltum, 5 parts; virgin wax, 1; oil of turpentine, 100; petroleum spirit, 100 parts. After development, all the parts to be left uncoloured are protected by a coating of rubber solution, and the dye is poured on to the stone, into the pores of which it penetrates, and reproduces the design with softened outlines. For window transparencies, the preparation first mentioned is applied to glass plates, previously coated with a 10 per cent. solution of gelatin or 4 per cent. crude collodion.

—C. S.

Photo-Retrogression, or the Disappearance of the Latent Photographic Image. L. Baekeland. Brit. J. Phot., 1904, 51, 146—148.

When exposed photographic plates, films, bromide papers, and, in some cases, chloride papers (of the "velox" class) are not developed for a considerable time after exposure, the latent image will gradually diminish and at length nearly, if not totally, disappear. Dry plates are least subject to this change, while bromide papers and films show rapid "retrogression" under certain conditions. The nature of the developer used has no influence on the extent of this change; that it is a chemical change is shown by the following facts:—Plates kept at a temperature of 0°—4° C. showed no sensible retrogression after two weeks, while those which had been kept at 40°—48° C. showed marked change after three days; plates stored over sulphuric acid showed much less deterioration of the latent image than when kept in a moist atmosphere; if the emulsion has a slight acid reaction, or contains any considerable amount of chromium salts, the retrogression is much more marked than in a neutral or chromium-free emulsion, while if the emulsion be slightly alkaline, the retrogression is reduced to a minimum, even in the presence of chrome alum. An over exposed plate has practically no tendency to this change, under-exposure affording the most favourable circumstances. It thus appears that photo-retrogression will vary with different brands of plate, film, or paper, and with certain kinds of film and paper will be very apparent, even 48 hours after exposure.—T. F. B.

Developers; Constitution of ——, which Develop in Absence of Alkali. A. Lumière and A. Seyewetz. Phot. Mitth., 1904, 41, 51—54.

Substances which have the property of developing the latent image of a photographic plate contain in their molecule an aromatic nucleus possessing either two hydroxyl residues, or two amino groups, or one hydroxyl and one amino group standing in the ortho- or para-position one to the other. It was formerly thought that the only compounds capable of developing without the addition of alkali were such as contain in their molecules two of the above arrangements, but certain developers, such as *o*- and *p*-amino-phenol, *o*- or *p*-phenylenediamine, and *o*-toluylenediamine, which contain only one of these groupings, have the power to develop in the presence only of sodium sulphite: these all contain at least one amino group. This power of developing in absence of alkali is not affected by the introduction of alkyl groups into one or both of the amino groups, but an acid residue diminishes the reducing power considerably. Compounds (like, *e.g.*, hydroquinone) having a double developing function due to hydroxyl groups develop too slowly in absence of alkali to be of practical use; but if amino groups occur simultaneously with the hydroxyl in such a compound, the developing property is considerably enhanced, and this more so as the number of amino groups is multiplied. Certain other substances are able to develop without the addition of alkali. These are formed either: (1) by the combination of an amino developer with a non-developing phenolic compound; all these act too slowly to be of practical use; or (2) by the combination of a phenolic developer with an amino developer; when these are sufficiently soluble in alkali sulphite solutions, they may be practically employed.—T. H. P.

English Patents.

Photographic Films. E. F. Beckwith and T. A. Carten, Ionia, Mich. Eng. Pat. 27,059, Dec. 10, 1903.

Photographic plates, films, papers, &c. are placed vertically in a receptacle into the bottom of which a sensitising liquid is slowly introduced; the plates, &c. are thus more highly sensitised at the bottom than at the top, this being to "compensate for variations in the actinic intensity of light due to differences in altitude."—T. F. B.

Photographic Developer ["Metoquinone"]; Preparation and Employment of a New Substance as a ——. B. J. B. Mills, London. From Soc. Anon. Plaques et Papiers Photographiques. A. Lumière et ses Fils, Lyon-Monplaisir. Eng. Pat. 7163, March 27, 1903.

See Fr. Pat. 325,385 of 1902; this J., 1903, 709.—T. F. B.

French Patent.

Photographic "Developing" Paper with Covering, soluble in Water, to Protect it from "Fog" [Stains]. Chem. Fabr. auf Actien vorm. E. Schering. Fr. Pat. 335,807, Sept. 21, 1903.

The film of gelatino-bromide or similar "developing" papers is protected from mechanical damage, or from contact with foreign substances, by a coating of dextrin or similar soluble inert substance. A 5 per cent. solution of dextrin is suitable for ordinary gelatino-bromide papers. —T. F. B.

XXII.—EXPLOSIVES, MATCHES, Etc.

Explosives; Progress in the Manufacture of ——, since the Development of Organic Chemistry. W. Will. Ber., 1904, **37**, 268—298.

The author describes the developments in the manufacture of explosives from the discovery of gunpowder in the fourteenth century up to the present time.—A. S.

Explosion of Nitroglycerin; Circumstances attending an ——, which occurred in the Final Washing House of the Factory of the Cotton Powder Co., Ltd., at Upleas Marshes, Faversham, on Nov. 9, 1903. By Captain J. H. Thomson, H.M. Chief Inspector of Explosives.

This explosion resulted in the death of one man. There were at the time of the explosion 1,000 lb. of nitroglycerin in the building, the whole being contained in the washing tank. The crater formed was about 30 ft. in diameter and 4 to 5 ft. deep. The possibility of the vibration of an air-pipe or the friction of a rubber shoe as the originating cause of the explosion is dismissed as improbable, and Captain Thomson arrives at the conclusion that it was due to the dropping of a small lead filter on to a tray containing some 3 lb. of nitroglycerin. It is suggested that it would be better "to carry out all such operations as filtering samples in the laboratory on a much smaller scale; but if it is required to do this in the final washing house, the filter should be made of some lighter material, such as ebonite, and should be mounted on a fixed stand."

In connection with the report, Dr. Dupré carried out some experiments as to whether it was possible to produce an explosion of nitroglycerin with a rubber shoe on a lead surface. Drops of nitroglycerin were placed on the lead and were submitted to violent glancing blows from a rubber-shod foot, but without effect. The experiment was repeated with some fine sand sprinkled on the explosive, with the nitroglycerin frozen, and finally with a little powdered sulphur added, the last experiment being to ascertain whether free sulphur in the india-rubber could have produced the effect. In all cases the result was nil. (See also this J., 1903, 650 and 1366.)—G. W. McD.

Explosion of Fulminate-Composition; Circumstances attending an ——, at the Factory of the Blenheim Engineering Co., Ltd., at Tunnel Lane, Greenwich Marshes, on Dec. 18, 1903. By Major A. Cooper-Key, H.M. Inspector of Explosives.

The explosion, which seriously injured a workwoman, took place during the filling of tubes with a composition of potassium chlorate, antimony sulphide, and amorphous phosphorus, and was undoubtedly due to the friction caused by the withdrawal of the wooden rammer which fitted too tightly. The explosion was communicated to some 3 to 4 oz. of composition lying on the table, and this caused the chief damage.—G. W. McD.

United States Patents.

Explosive, and Process of making same. B. D. Pike, San Francisco, Cal. U.S. Pat. 751,751, Feb. 9, 1904.

Metallic salts containing oxygen are reduced to powder which is mixed with "china-nut" oil so as to cover the particles of powder with the oil. Carbon and sulphur are then added and the whole mixed.—A. G. L.

Explosive. H. Poetter, Dortmund. U.S. Pat. 751,807, Feb. 9, 1904.

See Eng. Pat. 21,189 of 1902; this J., 1902, 1471.—T. F. B.

Priming Composition [for Detonators, &c.] M. Bielefeldt, Berlin. U.S. Pat. 751,605, Feb. 9, 1904.

See Fr. Pat. 326,055 of 1902; this J., 1903, 760.—T. F. B.

French Patent.

Explosives; Manufacture of ——. M. Bielefeldt. Fr. Pat., 335,801, Sept. 19, 1903.

An addition of potassium perchlorate to the other ingredients is claimed to increase the safety of the explosive in presence of fire-damp, without decreasing its explosive power.—C. A. M.

XXIII.—ANALYTICAL CHEMISTRY.

INORGANIC—QUANTITATIVE.

Nitrogen; Determination of ——, by Kjeldahl's Method. Guinness Research Lab. Trans. 1903, **1**, 13—16.

The various modifications of the Kjeldahl method are discussed and the results of a number of test analyses by Gunning's modification are given. In an addendum it is pointed out that when testing natural products like barley, a larger amount of sulphuric acid must be used than when working with pure nitrogenous compounds. The amount of acid should be sufficient to completely oxidise all carbonaceous matter, and to leave an excess in which the potassium sulphate forms a tolerably liquid solution on cooling.—A. S.

Gas Analyses by Combustion; Calculation of ——. A. Wohl. Ber. 1904, **37**, 429—432.

The errors introduced into the calculation of gas-analyses by combustion, through the assumption that the molecular volumes of all gases are alike, are very considerable, compared with the accuracy of modern gasometric methods. The molecular volumes of some common gases according to the latest determinations of density and molecular weight, are as follows, that of oxygen being taken as unit:—Hydrogen, 1·0017; oxygen, 1·0000; carbon monoxide, 1·0000; methane, 1·0020; and carbon dioxide, 0·99393. Hence 100 volumes of carbon monoxide exploded with 50 volumes of oxygen yield 99·4 volumes of carbon dioxide, a contraction of 50·6; and if the carbon monoxide be calculated, as usual, from the contraction, we get for its volume 2 × 50·6 = 101·2, an error of 1·2 per cent. The true molecular volumes should therefore always be used, and the calculations in the commonest cases will take the following forms, where the symbols or formulæ indicate the volumes of the respective gases, and K stands for the contraction:—Hydrogen: $H = 0{\cdot}6670\ K$; $H = 2{\cdot}0034\ O$. Carbon monoxide: $CO = 1{\cdot}9760\ K$; $CO = 1{\cdot}0061\ CO_2$; $CO = 2\ O$. Methane: $CH_4 = 0{\cdot}4990\ K$; $CH_4 = 1{\cdot}0082\ CO_2$; $CH_4 = 0{\cdot}5010\ O$. Other cases can of course be easily worked out.—J. T. D.

Boric Acid; Determination of ——, as Phosphate. F. Mylius and A. Meusser. Ber., 1904, **37**, 397—401.

Boric acid is separated from other substances by forming with methyl alcohol the volatile methyl borate (b. pt., 65° C.) and distilling this off. The authors then recommend the use of phosphoric acid, the aqueous distillate of methyl borate being mixed with phosphoric acid and excess of ammonia, and evaporated till evolution of vapours ceases, and finally heated at 400° C. in a current of steam till the excess of phosphoric acid is completely driven off. Boryl phosphate, BPO_4, is thus left behind, and is then weighed. The method is said to be sufficiently accurate to be useful in technical work.—J. T. D.

Road Materials; Testing of ——. L. W. Page and A. S. Cushman. U.S. Dep. of Agr., Bureau of Chem., Bull., No. 79, 1—46.

The most important physical and mechanical properties of road materials are hardness, defined as the resistance which a material offers to the displacement of its particles by friction; toughness, or the power to resist fracture under impact; and cementing or binding power, or the power possessed by rock-dust to act as a cement on the coarser fragments composing crushed stone or gravel roads. The tests in use at the School of Bridges and Roads in France are as follows:—

The *Deval* test is used for determining the resistance to abrasion, and has been found exceedingly useful. It is carried out by breaking the rock into uniform pieces capable of passing in all positions through a 6-cm. ring; 5 kilos. of these pieces are washed and dried, and then placed in an iron cylinder on which a cover is bolted. These cylinders are 20 cm. in diameter and 34 cm. in depth and are mounted in pairs on a shaft so that the axis of each cylinder is at an angle of 30° with the axis of rotation. The shaft is revolved at the rate of 2,000 revolutions per hour. At the end of 5 hours the machine is stopped, the contents are emptied into a basin, using water to wash out the cylinder, and the washed broken material is separated into three sizes: above 1 cm., between 1 cm. and 0·16 cm., and below 0·16 cm. diameter. The weight of this last portion is ascertained. As it has been found that only the best varieties of rock give less than 100 grms. (2 per cent.) of powder under 0·16 cm., the number 20 was adopted as a standard of excellence, and the "co-efficient of wear" of any rock is calculated from the formula—

$$\text{Co-efficient of wear} = 20 \times \frac{20}{W} = \frac{400}{W},$$

in which W is the weight in grms. of detritus under 0·16 cm. obtained per kilo. of rock used.

The *compression* test is made on at least three 25 mm. cubes of rock with a hydraulic compression machine. The cubes are tested either after desiccation in the open air, or at a temperature of 40° C., or after being saturated with water. The number 20 is again taken as the coefficient of the hardest rocks, the coefficient of any rock being calculated from the formula—

$$\text{Coefficient} = \frac{3000}{20} \times E = 150\ E,$$

where E represents the breaking load in kilos. per sq. cm. To determine the *density* of the rock, the cubes used for this test are measured and weighed.

The test for *hardness* is made with the Dorry machine. At least three specimens of each sample are prepared, 8 cm. high, and 4 cm. by 6 cm. in cross-section. These specimens are placed, two at a time, so that they rest on the upper surface of a circular grinding disc of cast-iron, rotated at the rate of 2,000 revolutions per hour, in a horizontal plane, by a crank. The specimens are held by clamps 26 cm. from the centre of the disc, and weighted so as to press against it with a pressure of 250 grms. per sq. cm. Standard sand, obtained by crushing quartzite rock and screening it, is fed on to the disc from a funnel, four litres of sand being used for each test. The diminution of height and loss in weight of the specimen is ascertained after every 1,000 revolutions; after 2,000 revolutions the specimen is reversed, so as to expose both ends to the grinding action. The loss in height after 4,000 revolutions is taken as the result of the test.

The *impact* test consists in letting two hammers, one weighing 12 kilos., the other 20 kilos., fall from heights of 100 cm. and 80 cm., respectively, on 4 cm. cubes of the materials, at least three cubes of each material being used with each hammer. The number of blows necessary to crack the specimen, as well as that needed for its complete destruction, is noted. The determination of the porosity, of the effect of frost, and of transverse breaking are also occasionally carried out.

For *wood paving blocks*, the resistance to wear when saturated with water is measured by the Dorry machine as above, except that emery is substituted for quartz sand. The *compression* test is made with a hydraulic press upon prismatic specimens with a base 8 cm. square, and a height equal to that of a paving block, the grain of the wood being parallel to the direction of the load. The test specimens are either dried at 30° to 40° C., or saturated with an amount of water, equal to that absorbed in service. The resistance to impact is determined on three dried and three wet specimens, using the 20 kilo. hammer, and a fall of 200 cm. The test piece has a base 6 cm. square, and a height equal to that of the paving block, and is placed in a cast-iron case 7 cm. square, open at top and bottom, the prism being held in place by a resinous cement, and projecting 1 cm. above the case. The number of blows which cause an appreciable breakage, indicated by a smaller rebound of the hammer and a diminution in height of the specimen, is noted. For determining the *thrust* caused by absorption when expansion is partially prevented, whole paving blocks are used. The thoroughly dried block is placed in a watertight receptacle and held between two plates at top and bottom, so that the top face rests against a stationary block of cast-iron, the lower plate being supported on the small lever arm of a cement-testing machine. Water at 30° C. is poured around the paving block; as soon as the lever arm of the machine tends to rise through the expansion of the block a valve is opened through which mercury pours into a vessel supported at the end of the arm till the arm comes back to mid-position, when the valve is closed. The weight of mercury in the vessel is consequently a measure of the force exerted by the test piece, and, as the vessel is supported on a spring balance, can be read at any time.

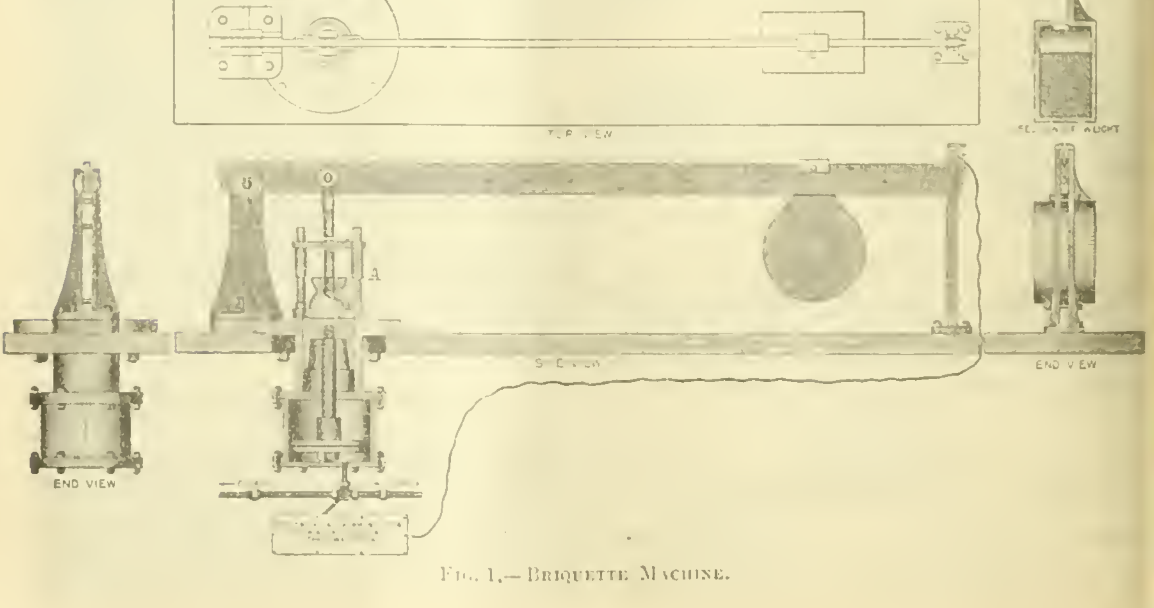

Fig. 1.—Briquette Machine.

bservations are made at first every three hours, then ery 12 hours, and finally every 24 hours until all increase ases.

For asphalts only chemical analyses are made.

In Portugal the Deval test is used, as well as a comession test, carried out on dry and wet 10, 7, and 5 cm. bes, the number of kilos per sq. cm. required to destroy test piece being used for comparison.

The following are the tests used in the road material laboratory in the United States. The *Deval* test is carried out practically as in France, the pieces used being of such a size as to pass through a 6 cm., but not through a 8 cm., ring. They are dried at 100° C. before being put into the machine. Besides the French coefficient, a "Department coefficient" is calculated by subtracting 4,000 grms. from the weight of the remaining fragments over 3 cm. in size, and dividing the difference by 10. If the result be 0, the material is considered unfit for road-making.

For the *cementation* test, 1 kilo. of rock fragments passing through a 6 mm., but not through a 1 mm., screen are ground in a ball-mill for $2\frac{1}{2}$ hours. The mill contains two iron balls weighing 25 lb. each, and makes 2,000 revolutions per hour. The powder obtained, which should pass through a 0·25 mm. mesh, is mixed with water to a stiff dough, and kept in a closed jar for 24 hours. About 25 grms. of this dough are then placed in a cylindrical metal disc, 25 mm. in diameter (A., Fig. 1), and subjected, by means of a closely fitting plug, to a pressure of 100 kilos. per sq. cm. For this purpose the die is placed on a platform supported by a hydraulic piston, below which water is admitted, the whole being so arranged that as soon as the platform is raised $\frac{1}{8}$ in., which requires one minute, an electric circuit is completed which shuts off the water-supply and opens an exhaust, the maximum pressure being only exerted for an instant. If the height of the resulting briquette is not exactly 25 mm., more or less material is taken so as to obtain a briquette of this height. Five such briquettes are then made, dried 12 hours in air, 12 hours in a steam bath, and tested in the machine shown in Fig. 2. It consists of a 1 kilo. hammer (H), guided by two rods (D) and ending in a small cone (L) at the top, which is caught on its lower side by two spring bolts, and lifted by a cross-head (I) joined to a crank shaft above. A vertical rod (P) directly over the cone can be adjusted so as to give a drop to the hammer varying from less than 1 mm. to 10 cm., the standard drop being 1 cm. When the cone of the hammer is brought into a hollow cone at the lower end of (P), the hammer is exactly centred, and is free of the rods (D). As the cross-head (I) rises, the cross-bolts are thrust open by the rod, releasing the hammer, which falls on a flat-end plunger (B) of 1 kilo.

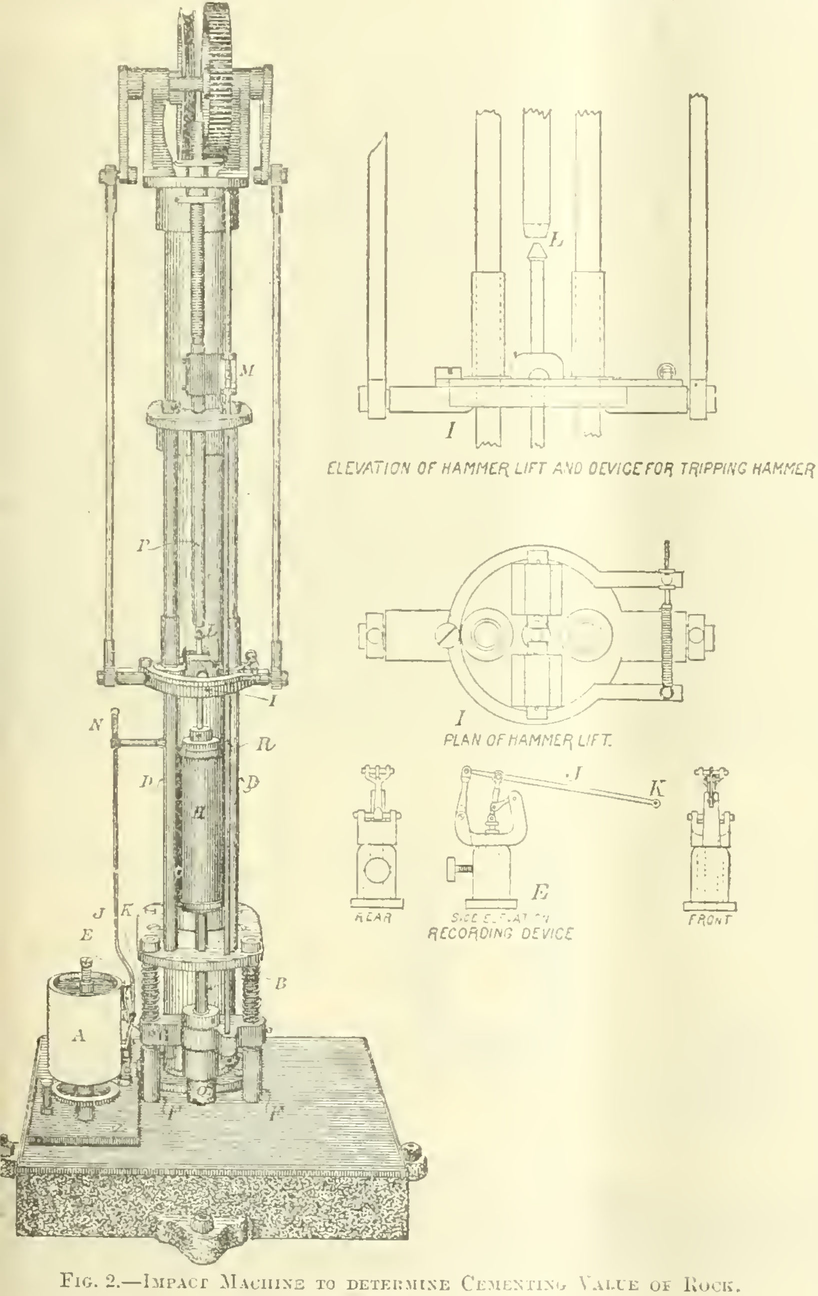

Fig. 2.—Impact Machine to determine Cementing Value of Rock.

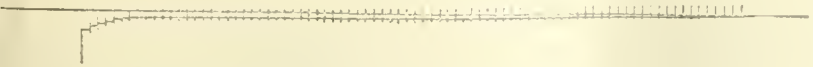

Fig. 3.—Showing Point of Failure in Cementation Test.

weight, pressed on the briquette (O), by two springs surrounding the guide rods (F). This plunger (B) is bolted to a cross-head (G) with which a small lever (J), holding a brass pencil (K), is connected by a link motion, giving the pencil a vertical movement five times as great as the movement of the cross-head. The movement of the pencil is recorded on a slip of silicated paper fastened on a drum (A) which moves through a small angle at each stroke of the hammer. A steel rod (R), passing up through (I), and through a piece of metal attached to the cone rod (P) is fastened to the cross-head (G). By means of this and a vernier scale (M) the fall of the hammer can be regulated, and by lowering the cone rod until it rests on the hammer cone, the height of the briquette can also be measured. The number of blows needed to destroy the bond of cementation of the material is noted, a diagram similar to that in Fig. 3 being obtained. At the last point the material does not recover from the blow, and the plunger stops at the point to which it is driven. The briquette itself is fastened to the bed-plate of the machine by means of a drop of thick shellac. The test is stated to give very useful comparative results.

The test for *toughness* is made on 25 × 25 mm. cylinders cut by means of a spherical core saw. The impact machine used is similar to that employed for the cementation test, except that a plunger with a hemispherical end, 2 cm. in diameter, is used, the idea being to imitate the blows caused by traffic. The hammer used weighs 2 kilos.; it is allowed to fall 1 cm. for the first blow and an additional 1 cm. for every successive blow until the test piece fails.

For the *absorption* test, a smoothly worn stone from the abrasion test, weighing 20 to 60 grms., is used. It is weighed in air (A), immersed in water, immediately reweighed in water (B), and again weighed in water after 96 hours' immersion (C). The number of lb. of water absorbed by 1 cb. ft. of rock will equal $\frac{C-B}{A-B} \times 62 \cdot 5$. The specific gravity and weight per cb. ft. are also determined. The Dorry machine is used for determining hardness. Compression and tensile tests are also carried out occasionally.

For paving bricks the most important is the *rattler test*. The drum is 28 in. in diameter, and 20 in. long, and has 14 cast-steel slats. It is run at a rate of 30 rotations per minute for 1,800 revolutions. A sheet-iron cover prevents the escape of dust, which falls into a pan. The charge consists of 9 paving blocks or 12 dry bricks; 75 lb. of cast-iron shot with slightly rounded ends, $2\frac{1}{2}$ by $4\frac{1}{2}$ in., and weighing $7\frac{1}{2}$ lb. each; and 225 lb. of smaller shot, $1\frac{1}{4}$ in. cubes, weighing about $\frac{1}{2}$ lb. each. The shot are replaced when they have lost about 0·1 of their weight. Since the loss in weight of the bricks in the first 400 or 600 revolutions is due mainly to chipping action, and the loss in the last 600 mainly to abrasive action, both are reported. The total loss in weight after 1,800 revolutions should not exceed 18 per cent. for the best class of paving bricks.

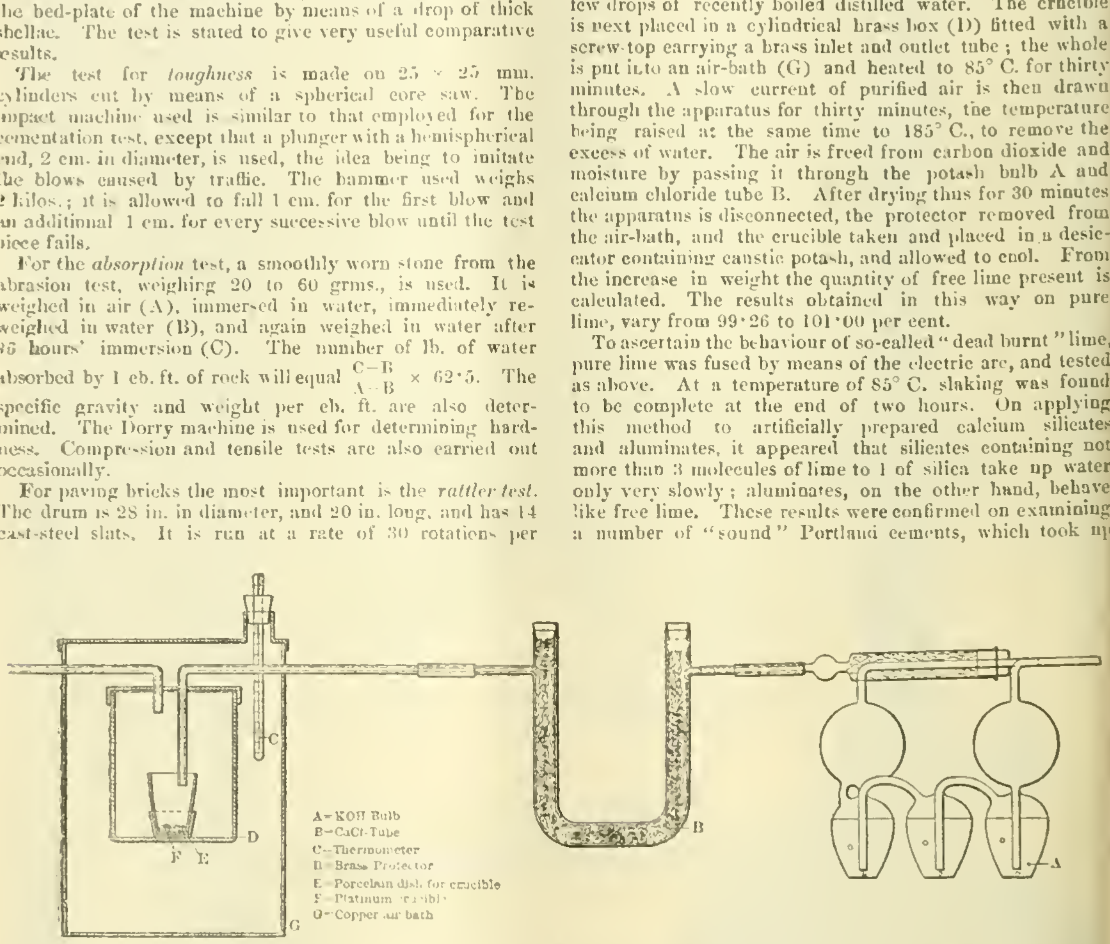
For the *absorption* test, the gain in weight after 96 hours' immersion in water is noted on a brick which has been through the rattler test, and has then been dried. *Cross-breaking* and *compression* tests are also made on cylinders 1 or 2 in. in diameter, but are of less value than the rattler and absorption tests.

For testing cement, the methods of the American Society of Civil Engineers are followed. All rocks are also analysed petrographically and chemically, the methods of analysis used being given.—A. G. L.

Lime, Free [in Portland Cement]; New Method for the Determination of ——, and on so-called "Dead Burnt" Lime. E. H. Keiser and S. W. Forder. Amer. Chem. J., 1904, **31**, 153.

This method for the determination of free lime in Portland cement depends on the fact that free lime combines almost instantly with water, whereas basic calcium silicates are acted upon much more slowly. It is carried out by first heating 0·2 to 0·5 grm. of the substance over the blast lamp for a few minutes in a platinum crucible to expel moisture and carbon dioxide, weighing, and then adding a few drops of recently boiled distilled water. The crucible is next placed in a cylindrical brass box (D) fitted with a screw-top carrying a brass inlet and outlet tube; the whole is put into an air-bath (G) and heated to 85° C. for thirty minutes. A slow current of purified air is then drawn through the apparatus for thirty minutes, the temperature being raised at the same time to 185° C., to remove the excess of water. The air is freed from carbon dioxide and moisture by passing it through the potash bulb A and calcium chloride tube B. After drying thus for 30 minutes the apparatus is disconnected, the protector removed from the air-bath, and the crucible taken and placed in a desiccator containing caustic potash, and allowed to cool. From the increase in weight the quantity of free lime present is calculated. The results obtained in this way on pure lime, vary from 99·26 to 101·00 per cent.

To ascertain the behaviour of so-called "dead burnt" lime, pure lime was fused by means of the electric arc, and tested as above. At a temperature of 85° C. slaking was found to be complete at the end of two hours. On applying this method to artificially prepared calcium silicates and aluminates, it appeared that silicates containing not more than 3 molecules of lime to 1 of silica take up water only very slowly; aluminates, on the other hand, behave like free lime. These results were confirmed on examining a number of "sound" Portland cements, which took up from 1·81 to 3·04 per cent. of water, due to decomposition of the aluminates. All these cements contained less than 10 per cent. of alumina. A sample of cement containing 15 per cent. of alumina, 15 of silica, and 70 of lime took up 4·65 per cent. of water. The authors conclude that if the quantity of water taken up by a Portland cement containing not more than 10 per cent. of alumina, exceeds 3 per cent., the excess is due to the presence of free lime.—A. G. L.



Gold in the Residues from the Zinc Boxes [Cyanide Gold Extraction]; Determination of ——. R. W. Lodge. Amer. Inst. Mining Eng., New York, 1903.

The author has examined the methods which have been proposed for the determination of gold in the residues from the zinc boxes. He found that the cupellation method gives much better results than any of the other methods, but to obtain uniform results, the material must be very finely divided (to pass a 200 mesh sieve), and a large proportion of borax must be used, viz., 3—10 grms. for each 0·1 assay-ton of the sample. Spurting can be prevented by using the muffle at a sufficiently high temperature, and, at the beginning, keeping the door of the muffle closed.—A. S.

Zinc-Dust; Gasometric Assay of ——. A. Wohl. Ber., 1904, **37**, 451.

For accurate analysis, a flask of about 100 c.c. capacity is used, to the neck of which is fused a stopcock. A weighed quantity of zinc-dust having been introduced, the flask is brought to the temperature of the air or of a water-jacket, and evacuated to an accurately measured pressure of about 700 mm. below barometric pressure. The tubulure of the stopcock is now filled with water, and 5 c.c. of hydrochloric acid, sp. gr. 1·1, to which a drop of platinum chloride solution has been added, are sucked into the flask. After reaction, the temperature is re-adjusted, and the pressure measured. Assuming that the flask contains exactly 100 c.c., the temperature is 20° C., and 0·1788 grm. of substance was weighed out, the percentage of metallic zinc is expressed by twice the difference of pressures in mm. of mercury.

—W. A. C.

Tin Ores; Losses in Vanning ——. R. Pearce. Eng. and Mining J., 1904, **77**, 116.

In Cornwall the vanning process is in general use for the determination of the tin oxide in crude tin ores. In order to test the efficacy of this method, the author prepared an artificial mixture from 150 parts of a gangue consisting mainly of quartz, chlorite, and small amounts of pyrite and arsenopyrite, and 5 parts of Bolivian cassiterite, containing 70·38 per cent. of tin. The mixture was pounded in a small mortar until the whole passed through a 30-mesh screen; it was then ground to a pulp, and subjected to the vanning process. The actual percentage of tin oxide in the mixture was 3·225; the percentages found by the vanning process by three independent assayers were 2·970, 2·530, 2·360; mean 2·620. The percentage of tin in the concentrated product was determined in each case, and it was found that the mean percentage of the total tin recovered was 78·447, or a loss of 21·553 per cent. In an ore containing less than 3·225 per cent. of tin oxide, such as is produced in Cornwall at the present time, the loss of tin in vanning would, of course, be proportionately greater. Further, the artificial mixture would give more favourable results on vanning than a natural ore, as the tin oxide would not be contaminated by attached particles of gangue.

United States Patent.

Carbonic Acid in Gases; Method of Determining [Electrically] the Quantity of ——. G. Bodländer, Brunswick, Germany. U.S. Pat. 751,897, Feb. 9, 1904.

The gas is passed through a primary and secondary battery connected together in opposition, the latter battery being adapted to neutralise that part of the electromotive force of the primary battery which owes its existence to the hydrogen or oxygen contained in the gas. This results in an electromotive force, the measure of which may be used for determining the amount of carbonic dioxide in the gas. The primary and secondary batteries each contain an electrode which is not attacked, and a second one of a suitable metal, the electrolytes of the primary consisting of a carbonate and a compound of the last-named metal, while the electrolytes of the secondary consist of a substance acting like an acid, and a salt of the last-named metal.

—B. N.

ORGANIC—QUALITATIVE.

Liebermann's Thiophene Reaction. C. Schwalbe. Ber., 1904, **37**, 324—325.

The author finds that "Pure Benzene" as now supplied to the large colour-factories does not show Liebermann's reaction for thiophene (blue coloration with concentrated sulphuric acid containing nitrous acid), although thiophene is undoubtedly present and can be detected and estimated in other ways. He concludes, therefore, that some other impurity, which prevents Liebermann's reaction, must be present.—E. F.

Citric Acid in Wine; Simple Method for the Detection of ——. A. Devarda. Zeits. landw. Versuchsw. in Oesterr., 1904, **7**, 1; Chem.-Zeit., 1904, **28**, Rep., 38.

Fifty c.c. of the wine are freed from alcohol by boiling, made up to the original volume, shaken for 1 minute with 2 c.c. (4 c.c. in the case of adulterated red wines rich in extract and tannin) of a 10 per cent. solution of malic acid and about 1 grm. (or 1½—2 grms. in the case of adulterated wines) of yellow mercuric oxide, and immediately filtered through a small folded filter. 40 c.c. of the filtrate are treated with 6 c.c. of 95 per cent. (by vol.) alcohol, shaken with 2 c.c. of mercuric nitrate solution (16 grms. of mercuric nitrate and 2 c.c. of glacial acetic acid dissolved in water and made up to 100 c.c.), cooled to 10°—12° C., and the precipitate collected on a washed filter. When the solution has completely drained from the precipitate, the latter is treated on the filter with 15 c.c. of dilute acetic acid (20 c.c. of the glacial acid diluted with water to 300 c.c.), and the acid solution allowed to drain through the filter. 10 c.c. of this solution are treated with 1·5 c.c. of an acetic acid solution of lead acetate (1 vols. of cold saturated solution of lead acetate with 1 vol. of glacial acetic acid), the mixture is heated to boiling, and then rapidly filtered through a small washed filter. The filtrate is slowly cooled, finally to 10°—12° C. In the case of wine free from citric acid, the solution remains clear, or at the most a slight crystalline precipitate of lead tartrate is formed, which soon settles to the bottom; but, in presence of citric acid, a milky turbidity is produced in the solution, and the latter does not become clear unless allowed to stand for a long time.—A. S.

Salicylic Acid [Free] in Bismuth Salicylate; A Suggested Test for [Detection of] ——. W. Lyon. Pharm. J., 1904, **72**, 219.

As a solvent for use in the detection of free salicylic acid in bismuth salicylate, alcohol is unsatisfactory, as it causes decomposition of the salicylate. A better solvent is 90 per cent. benzol, the test being carried out in the following manner:—A small quantity of the bismuth salicylate is placed on a thick filter-paper in a funnel and 90 per cent. benzol poured on. The filtrate is received in a test-tube containing a solution of ferric chloride (1 in 3,000), when, if free salicylic acid be present, a violent ring is produced where the two liquids come in contact.—A. S.

Chloral and Butylchloral; Reaction for Distinguishing between ——. E. Gabutti. Boll. Chim. Farm, **42** 777—778; Chem. Centr., 1904, **1**, 480.

The so-called butylchloral $CCl_3.CH_2.CH_2.CHO$, is frequently adulterated with the cheaper chloral. The latter may be identified by means of its melting point, by the formation of chloroform on treatment with alkalis, and by the following reaction:—A solution of pyrogallol in pure 66 per cent. sulphuric acid gives when gently and carefully warmed, a blue colour with chloral, a ruby colour with butylchloral, and a more or less violet to blue colour with mixtures of the two compounds. On addition of a large quantity of water, the blue colour obtained with the chloral changes to yellowish brown, and the ruby colour obtained with the butylchloral to a more or less deep violet colour, according to the amount of water added.—A. S.

ORGANIC—QUANTITATIVE.

Fats and Fatty Oils; Relative Inner Friction of Edible ——. M. Pleissner. Archiv der Pharm., 1904, 242, 24—31.

The apparatus used by the author was the simple viscosimeter described by Ostwald. The efflux velocity at the given temperature between marks above and below the bulb is measured in seconds, and the relative inner friction calculated by means of the formula $\rho = \frac{s.t}{1}$, where *s* represents the sp. gr. of the oil, t, the time of efflux, and T the efflux velocity of water at 20° C. As the temperature rises, the relative inner friction of an oil decreases, so that at 100° C. the value is only about a tenth of that found at 20° C. Oils differ considerably in their behaviour in this respect, and this is notably the case with castor oil, as is seen in the following table, which gives the co-efficients $\frac{\rho 20}{\rho 100}$

Oil.	20° C.			100° C.			$\frac{\rho 20}{\rho 100}$
	s.	t.	ρ.	s.	t.	ρ.	
Olive	0·915	348	57·9	0·864	34	5·30	10·9
"	0·912	339	56·2	0·868	30	4·73	11·9
Arachis	0·914	310	56·5	0·864	31	5·30	10·7
Linseed	0·927	219	35·9	0·886	29	4·67	7·8
Rape	0·911	421	76·2	0·859	42	6·63	10·6
Cotton-seed	0·922	410	68·7	0·874	33·5	5·32	12·9
Sesamé	0·924	292	49·0	0·866	35·5	5·27	9·2
Castor	0·957	4,273	743·5	0·911	82	13·58	54·7
Bone	0·910	350	57·9	0·863	33	5·19	11·1
Paraffin	0·877	686	101·4	0·805	27·3	3·99	25·4
Vaseline (lubricating).	0·868	178	28·7	0·847	15·5	2·38	12·0

The liberated mixed fatty acids of oils have a much smaller relative inner friction than the original glycerides. Thus the following values for ρ at 100° C. were obtained with the fatty acids of the following oils:—Olive oils, 2·3 and 1·8; arachis oil, 2·75; cotton-seed oil, 1·69; sesamé oil, 2·45; and castor oil, 7·09. The relative inner friction of fatty acids of the type $C_nH_{2n}O_2$ increases with the molecular weight. The method does not give sufficiently distinctive differences to afford a means of detecting arachis oil in olive oil, but may be found of service for the detection of margarine in butter and for the identification of castor oil.—C. A. M.

Turpentine in Denatured Spirit; Determination of ——. U. Chierego. Oesterr. Chem.-Zeit., **6**, 562; Chem. Centr., 1904, **1**, 321.

The method depends upon the determination of the bromine-absorption value. 50 c.c. of the denatured spirit are treated with 25 c.c. of water, 10 c.c. of dilute (1 : 3) sulphuric acid and 10 c.c. of an aqueous solution of dimethyl orange (0·02 grm. per litre). The bromine solution (50 grms of hydrobromic acid and 15 grms. of potassium bromate per litre) is then run in, drop by drop, from a burette, with continuous agitation till the rose coloration disappears. The conditions described must be followed; if the degree of dilution be altered or the bromine solution be allowed to run in too quickly, less reliable results are obtained. For the determination of the bromine-absorption value of turpentine, the latter is titrated in 0·5 per cent. alcoholic solution. A number of samples of turpentine were examined by this method, and it was found that 50 c.c. of the 0·5 per cent. alcoholic solution required 11·7—12·4 c.c. of the bromine solution, corresponding to 1·87—1·98 grms. of bromine for 1 c.c. of turpentine.
—A. S.

Turpentine; Examination of ——. H. Herzfeld. Zeits. öffentl. Chem., 1903, **9**, 454—457; Chem. Centr., 1904, **1**, 548.

In the Zeiss butyro-refractometer, turpentine shows usually a refraction of 68°—72°, rarely as much as 75°. By fractional distillation even small quantities of admixtures can be detected, as, with pure turpentine, the refraction of the different fractions and of the original sample varies only to a small extent.

For the separation of mineral oil from turpentine, the author recommends treatment with sulphuric acid. 10 c.c. of the sample are slowly run, with cooling, into 40 c.c. of concentrated sulphuric acid. After 10—12 hours, 8—9 per cent. by volume of the turpentine separates. The lower dark-brown layer is run off, and the remainder shaken with 3—4 c.c. of fuming sulphuric acid. After standing for several hours 0·1—0·2 c.c. of the turpentine again separates. Mineral oil is scarcely attacked by the acid and is recognised by the increase in the volume of the separated upper layer. If the fuming sulphuric acid dissolve more than 0·9 c.c. of the layer which separates after treatment with concentrated sulphuric acid, this soluble portion in excess of the 0·9 c.c. will correspond to the quantity of benzene present in the turpentine.—A. S.

Mono-amino-acids and their Amides; Determination of ——. Guinness Research Lab. Trans., 1903, **1**, 17—56.

The subject is dealt with under the following headings:—(1) Sketch of the known methods of estimation. (2) Determination of ammonia by Knop's (hypobromite) method. (3) The Sachsse-Knop method applied to the determination of asparagine. (4) Determination of ammonia and asparagine by the Sachsse-Schloesing-Longi method, using oxalic acid and hydrochloric acid as the hydrolysing agents (see this J., 1904, 135). (5) The Sachsse-Kormann (nitrous acid) method for determining amides and amino acids. (6) New apparatus for the Sachsse-Kormann process. (7) The improved Sachsse-Kormann process applied to pure substances (amides and amino-acids). (8) New method for the direct estimation of tyrosine in mixtures of amides and amino-acids. (9) Application of a combination of the foregoing methods to the analysis of mixtures of amides, amino-acids, and ammonium salts. (10) Attempts to estimate asparagine and certain amino-acids by precipitation with mercuric nitrate and subsequent formation of their copper salts.
—A. S.

XXIV.—SCIENTIFIC & TECHNICAL NOTES.

Phosphorus Sulphides; Preparation of ——, in the Cold. R. Boulouch. Comptes rend., 1904, **138**, 363—365.

Dervin (see following abstract), by reacting on the sulphide P_4S_3 with sulphur in solution in carbon bisulphide, obtained after some months' exposure to sunlight the sulphide P_3S_6 and another substance possibly of formula P_8S_{11}. The author finds that the reaction is enormously accelerated by the addition to the mixture of a small amount of iodine. After one or two days only, good crystals are obtained, having the composition P_4S_5; a substance of quite constant composition, but probably, like P_8S_{11}, a solid solution, rather than a definite compound. Phosphorus and sulphur, dissolved in carbon bisulphide, will not react, even in sunlight; but on adding a little iodine, reaction occurs and abundant crystals of P_3S_6 are obtained.—J. T. D.

Phosphorus Sesquisulphide and Sulphur in Carbon Bisulphide; Action of Heat and Light on Mixed Solutions of ——. E. Dervin. Comptes rend., 1904, **138**, 365—366.

When a mixture of 110 grms. of phosphorus sesquisulphide P_4S_3 and 16—32 grms. of sulphur, dissolved in 400 c.c. of carbon bisulphide, is subjected to the action of light or of heat, two products are obtained, namely, pale yellow transparent needles of the sulphide P_2S_4 and spherical masses of crystals corresponding to the formula P_8S_{11}, or rather $P_4S_3.2P_2S_4$. The action of light alone requires a period of 1 or 2 months to complete the reaction, whereas at a temperature of 210° C. the same result is produced in 2 hours. The sulphide P_8S_{11} is not identical with the sulphide P_4S_5 obtained by Boulouch from the same materials by the action of light in the presence of traces of iodine (see preceding abstract). When heated at 210° C. with carbon bisulphide, the compound P_8S_{11} is split up into $2P_2S_4$, which crystallises out, and P_4S_3, which remains in solution. The sulphide P_2S_4 when heated at 210° C. with a solution of P_4S_3 in carbon bisulphide reproduces the compound P_8O_{11}.—J. F. B.

Hydrides and Nitrides of Neodymium and Praseodymium. W. Muthmann and H. Beck. Annalen, 1904, **331**, 58—59.

The preparation and properties of neodymium hydride (NdH_2?) and nitride (NdN) and of praseodymium hydride (PrH_3) and nitride (PrN) are described.—A. S.

Intramolecular and Originally Reversible Changes Extending over Prolonged Periods of Time; Observations on Some ——. R. J. Friswell. Proc. Chem. Soc., 1904, **20**, 36.

After long periods of time, changes occurred involving the slow appropriation by aminoazobenzene base from a solution of aniline hydrochloride of sufficient hydrochloric acid to saturate itself; this reaction was shown to occur even in the presence of much free aniline, and the variations due to changes of temperature were described.

Lead Salts; Solutions of ——. *Sensitive to Light.* K. A. Hofmann and V. Wölfl. Ber., 1904, **37**, 249—252.

Mixed and left in the dark or in diffused light, solutions of lead chloride and sodium thiosulphate yield lead sulphide. But when kept ice-cold and in sunlight they form a red crystalline crust on the walls of the vessel, which, to avoid its decomposition, must be washed, in bright light, first with ice-cold water and then with alcohol and with ether. A similar but more stable and much more beautiful scarlet-red iodine compound, looking under the microscope like metallic copper leaflets dendritically arranged, is obtained by adding to the lead chloride and thiosulphate mixture some iodine dissolved in potassium iodide. Since this compound can also be prepared from yellow ammonium sulphide and lead iodide, its constitution will be that of a halo polysulphide. The composition of the chlorine and iodine compounds is expressed by $Pb_4S_6Cl_2$ and $Pb_3S_4I_2$ respectively. —T. H. P.

Cupric Metaborate; Evolution of Oxygen from ——. W. Guertler. Zeits. anorg. Chem., 1904, **38**, 456—460.

Cupric metaborate, CuB_2O_4, is prepared by (1) evaporating to dryness a solution of 1 molecule of copper nitrate and 2 molecules of boric acid, and melting the product. If the temperature has not reached 950° C., fine blue doubly-refracting needles are obtained, of sp. gr. 3·86, unattacked by cold dilute acids, even hydrofluoric, or by sodium hydroxide or sulphide solution, but slowly dissolved by hot concentrated hydrochloric acid. When carefully melted and cooled, the product yields a deep green, almost black, glass of sp. gr. 3·61, extremely hard, but much more readily attacked by reagents than the blue crystals. (2) By fusing copper nitrate with excess of boric anhydride; the fusion separates into two layers, the upper containing practically nothing but boric anhydride, the lower cupric metaborate. When heated, cupric metaborate begins to give off oxygen at a temperature below its melting-point (about 970° C.), and at 1,000° C. the evolution is rapid and even violent. Determination of the amount of oxygen evolved and analysis of the residue show that the reaction is $6CuB_2O_4 = 3Cu_2O.2B_2O_3 + 3O + 4B_2O_3$. The cuprous borate so obtained cannot be prepared directly from cuprous oxide and boric anhydride.—J. T. D.

Iso-rhodeose, the second Methylpentose from Convolvulin. E. Votoček. Zeits. f. Zuckerind. Bohmen, 1904, **28**, 209—212. See this J., 1902, 1353.

The author obtains confirmation of his assumption that *iso*-rhodeose is a methylpentose by converting it into methylfurfural and estimating as phloroglucide, by direct determination of the rotation in a 1·44 per cent. solution, from which $[a]_D = + 20·3$, and by the analysis of the phenylosazone. Convolvulin is thus found to give a syrup consisting of one molecule of glucose ($[a]_D = + 52·5$), one of rhodeose, + 75·2, and two molecules of *iso*-rhodeose + 20·3.—L. J. de W.

Seaweed (Fucus), Laminaria and Carragheen Moss; Products of the Hydrolysis of ——. A. Müther and B. Tollens. Ber., 1904, **37**, 298—305.

Seaweed (Fucus species) from Heligoland was extracted with cold 2 per cent. sulphuric acid for 24 hours. From the extract, in addition to inorganic salts, crystals of mannitol were obtained. The residue was hydrolysed by heating with 5 per cent. sulphuric acid at the temperature of the boiling water-bath for eight hours. The hydrolysed extract yielded fucose, galactose, and small quantities of arabinose. *Laminaria digitata* from Heligoland also yielded mannitol. The products of hydrolysis included fucose and a sugar yielding a glucosazone m.pt. 204° C. Carragheen moss probably contains fructose groups in the form of a lævulan. Besides the decomposition products of fructose, galactose was isolated from the hydrolysed solution, and the presence of glucose groups was indicated by the production of saccharic acid on oxidation.—J. F. B.

Leucine and Tyrosine; Note on the Purification of ——, *by E. Fischer's Method of Esterisation.* H. T. Brown. Trans. of the Guinness Research Lab., 1903, **1**, 57—60.

The article is subdivided as follows:—(1) Esterification of leucine. (2) Saponification of the ester with production of pure leucine. (3) Properties of the pure leucine. (4) Esterification of tyrosine. (5) Properties of the pure tyrosine. (6) Examination of a tyrosine from another source.—A. S.

Oxido-reducing Enzyme in Plants; Existence of an ——. J. E. Abelous and J. Aloy. Comptes rend., 1904, **138**, 382—384.

The authors have shown that the animal organism contains an enzyme capable of oxidising certain substances (*e.g.*, salicylic aldehyde), not like oxydases of the laccase type by utilising free or dissolved oxygen, but at the expense of certain highly oxidised constituents of the organism which are thereby reduced. The enzyme is therefore simultaneously an oxidising enzyme towards one substance and a reducing enzyme towards others. A similar enzyme has now been observed in the expressed juice of potato pulp. Potato juice alone, whether in presence or absence of oxygen, has no sensible oxidising action upon salicylic aldehyde; but if a small quantity of a highly oxidised compound like potassium chlorate be added, considerable oxidation of the aldehyde takes place. If, instead of the chlorate, potassium nitrate be added, oxidation takes place, but to a much smaller extent than in the case of the chlorate. Potato juice alone does not oxidise salicylic aldehyde at the expense of the more highly oxidised constituents of the juice, probably because the dissociated oxygenated constituents have already been rendered stable by the action, in presence of air, of the oxydases of the laccase type also contained in the juice.—J. F. B.

New Books.

Traité d'Analyse des Substances Minérales. Par Adolphe Carnot, Directeur de l'École Supérieure des Mines, &c. Tome Second. Métalloïdes. Vve. Ch. Dunod, éditeur, 49, Quai des Grands Augustins, Paris. 1904. Price 25 francs.

The first volume of this work was devoted to the subject of "General Methods of Analysis, Qualitative and Quantitative." The present volume (on the Metalloïds) is an 8vo volume, containing 808 pages of subject-matter, with 81 illustrations, a table of contents, and the alphabetical index. The text is subdivided as follows:—I. Hydrogen II. Oxygen. III. Nitrogen. IV. Argon. V. Neon, Krypton, and Xenon. VI. Helium. VII. Carbon. Combustible Minerals. VIII. Cyanogen. IX. Chlorine. X. Bromine. XI. Iodine. XII. Fluorine. XIII. Sulphur. XV. Selenium. XVI. Tellurium. XVII. Germanium. XVIII. Phosphorus. XIX. Arsenic. XX. Boron. XXI Silicon. XXII. Titanium. XXIII. Tantalum. XXIV Niobium. XXV. Tungsten. XXVI. Molybdenum. XXVII Vanadium. The method of dealing with each of the elements above classified is fairly uniform, and may be illustrated by the example of one of them:—(i) Natural state. (ii) Analytical methods of determination. (iii) Volumetric methods. (iv) Minerals and mineral products. (v) Analysis of the latter.

THE ELECTROLYSIS OF WATER: PROCESSES AND APPLICATIONS. By VICTOR ENGELHARDT, Chief Engineer and Chemist of the Siemens and Halske Co., Ltd., Vienna. Translated by J. W. RICHARDS, M.A., Ph.D. Chemical Publishing Co., Easton, Pa. 1904. Price: Paper, 1 dol.; cloth, 1 dol. 25 cents.

8vo volume containing 131 pages of subject-matter with 90 illustrations, and followed by 15 tables. The work closes with an alphabetical index of authors. The table of contents at the beginning serves as index. The subject is treated under the following heads:—I. Historical Review. II. Constants of the Electrolytic Decomposition of Water. III. Review of the Processes. A. Processes and Apparatus for the Separate Production of Oxygen and Hydrogen. (*a*) With Porous Diaphragms of Non-conducting Material. (*b*) With Complete Non-conducting Partitions. (*c*) With Complete or Perforated Conducting Partitions. B. Processes and Apparatus for the Electrolysis of Water without Separation of the Gas (Production of Detonating Gas). (*a*) For Purposes of Instruction and Laboratory Work (Voltameter). (*b*) For Technical Purposes. C. Processes for the Simple Evolution of Oxygen. (*a*) Through Depolarisation at the Cathode. (*b*) By the Precipitation of Metal at the Cathode. Chronological Review. IV. Applications. (1) Electro-chemical Processes. (2) Physical Processes. (3) Chemical. Compression. Special Applications. (1) Detonating Gas. (*a*) High Temperature. (*b*) Lighting. (*c*) Blasting. (2) Hydrogen. (*a*) Ballooning. (*b*) Soldering. (*c*) Lighting. (*d*) Motoring. (3) Oxygen.

DIE ELEKTROMETALLURGIE DER ALKALIMETALLE. Von H. BECKER. Wilhelm Knapp's Verlag, Halle a/S. 1903. Price M. 6.

8vo volume, containing 133 pages of subject-matter with 83 illustrations and 3 tables. There is an index of names at the end, and a table of contents at the beginning. The method of treatment of the subject is as follows:—I. Chemical Methods for preparing the Alkali Metals. II. The Electro-chemical Methods for preparing the Alkali Metals. A. Processes and Apparatus for the Electrolytic preparation of Sodium and Sodium Chloride. B. Process and Apparatus for the Electrolytic preparation of Sodium from Caustic Soda. C. For the Electrolytic preparation of Sodium from Sodium Carbonate or from a Mixture of Carbonate and Caustic. D. For that of Sodium from Sodium Nitrate. E. For that of Sodium Alloys. Potassium. Lithium. III. The Electrothermic Process. IV. Experiments and Apparatus for Laboratories.

DIE TROCKENPLATTE: Ihre Eigenschaften und ihre Behandlung in der photographischen Praxis. Von Dr. LÜPPO-CRAMER. Gustav Schmidt's Verlag, Berlin. 1903. Price M. 2.50.

SMALL 8vo volume containing 99 pages of subject-matter, with 7 illustrations. The subjects treated of under the chief title are as follows:—I. Properties of the Dry Plate, generally. Composition of the film, &c. II. Measuring the Rapidity of the Dry Plate. III. The Latent Image. IV. Gradation. V. Solarisation. VI. Dark Room Illumination. VII. Development. VIII. Fixing. IX. Washing. X. Drying. XI. Intensification and Reduction. XII. Plates sensitive to Colours, &c. Diapositive Plates.

LEHRBUCH DER MIKROPHOTOGRAPHIE; nebst Bemerkungen über Vergrosserung und Projektion. Von Dr. CARL KAISERLING. Gustav Schmidt's Verlag, Berlin. 1903. Price M. 4.

SMALL 8vo volume containing 171 pages of subject-matter, with 54 illustrations. There is an alphabetical index of subjects and names at the end, and a table of contents at the beginning of the treatise, which is divided into three sections:—I. The Subject Treated Generally. II. The Special Section; and III. The Photographic-Technical Section.

AN ATTEMPT TOWARDS A CHEMICAL CONCEPTION OF THE ETHER. By Prof. D. MENDELÉEFF. Translated from the Russian by GEORGE KAMENSKY. Longmans, Green, and Co., 39, Paternoster Row, London; New York and Bombay. 1904. Price 2*s*. nett.

8vo volume containing 51 pages of subject-matter. The author shows that if the ether be conceived as a peculiar all-permeating gas, the lightest, most mobile, and chemically inactive, certain difficulties in the explanation of phenomena of recent observation, are greatly reduced if not fully removed.

Trade Report.

I.—GENERAL.

BRITISH INDIA; VALUATION TARIFF OF ——.

Bd. of Trade J., Feb. 1904.

A Customs Circular (No. 1 of 1904) issued by the Finance and Commerce Department of the Government of India, on the 23rd of December, 1903, revises from 1st January, 1904, the "Tariff Valuations" fixed for various classes of goods imported into British India.

Schedule IV.—Import Tariff: General Duties.

No.	Names of Articles.		Tariff Valuation.	Duty.
			R. a.	
5	Mineral and aerated waters, and all unfermented and non-alcoholic beverages	..	*ad val.*	5 %
8	Sugar—			
	China, candy	Cwt.	15 0	„ *
	Loaf	„	14 0	„ *
	Crystallised, beet	„	9 12	„ *
	„ and soft (other than beet) refined in the United Kingdom	„	9 12	„ *
	„ and soft from China	„	10 0	„ *
	„ and soft from Egypt	„	9 12	„ *
	„ and soft white from Java	„	9 8	„ *
	„ and soft from Mauritius	„	9 4	„ *
	All other sorts, including saccharine produce of all kinds and confectionery	..	*ad val.*	„ *
	CHEMICALS, DRUGS, MEDICINES, AND NARCOTICS, AND DYEING AND TANNING MATERIALS.			
10	Chemical products and preparations—			
	Acid, sulphuric	Lb.	0 1½	5 %
	Alkali, Indian (sajji-khar)	Cwt.	2 4	„
	Alum	„	4 10	„
	Arsenic	„	23 0	„
	„ (China mansil)	„	19 0	„
	Bicarbonate of soda	„	6 4	„
	Copperas, green	..	*ad val.*	2½ %
	Explosives, namely, blasting gelatin, dynamite, roburite, tonite, and all other descriptions, including detonators and blasting fuse	..	„	%
	Sal ammoniac	Cwt.	30 0	„
	Sulphate of copper	„	16 8	„
	Sulphur (brimstone), flour	„	7 0	„
	„ („), roll	„	5 8	„

	Orchilla weed	„	5 4	„
	Sappan wood and root	..	*ad val.*	„
	Turmeric	..	„	„
	All other sorts of dyeing and tanning materials	..	„	„
	OILS.			
16	Petroleum, including also naphtha and the liquids commonly known by the names of rock-oil, Rangoon oil, burma oil, kerosene, paraffin oil, mineral oil, petroline, gasoline, benzol, benzoline, benzine, and any inflammable liquid which is made from petroleum, coal, schist, shale, peat, or any other bituminous substance, or from any product of petroleum	Imp. gall.	..	1 anna.
	Petroleum, which has its flash point at or above 200° F., and is proved to the satisfaction of the Customs collector to be intended for use exclusively for the batching of jute or other fibre or for lubricating purposes	..	*ad val.*	5
	Petroleum which has its flash point at or above 150° F., and is proved to the satisfaction of the Customs collector to be intended for use exclusively as fuel	..	„	„
	All other sorts of oil, animal or vegetable (including otto of all kinds) and mineral (including paraffin wax)	..	„	„
31	Earth, common clay, and sand	..	..	Free
32	Earthenware (except earthenware piping, china, china clay, porcelain, and imitation or false coral	..	*ad val.*	5 %
34	Fireworks, all sorts, including fulminating powder	..	„	„
37	Gums, gum-resins, and articles made of gum or gum resin—			
	Copal	Cwt.	70 0	„
	Cutch and gambier	„	23 0	„
	Gamboge	Lb.	1 12	„
	Gum ammoniac	Cwt.	10 0	„
	„ Arabic	„	14 0	„
	„ bdellium	..	*ad val.*	„
	„ Benjamin, ras	Cwt.	25 0	„
	„ „ cowrie	„	70 0	„

---

* The duty on opium, under Schedule III., is fixed at Rs. 24 per ser of 80 tolas.

Schedule IV.—Import Tariff: General Duties.—cont.

No.	Names of Articles.		Tariff Valuation.	Duty.
			R. a.	
46	Manures of all kinds, including animal bones	..	..	Free
47	Oilcake, also bran, fodder, and cattle food of all kinds	..	..	„
48	Oil-cloth and floor-cloth, including lincrusta, linoleum, and tarpaulins	..	*ad val.*	5 %
49	Paints, colours, painters' materials, and compositions for application to leather, wood, and metals—			
	Lead, red, dry	Cwt.	13 0	„
	„ white, dry	„	17 0	„
	Ochre, other than European, all colours	„	1 8	„
	Paints, composition	..	*ad val.*	„
	„ patent driers	..	„	„
	Turpentine	Imp. gall.	3 0	„
	Verdigris	..	*ad val.*	„
	Vermilion, Canton	Box of 90 bundles.	115 0	„
	Zinc white, dry	..	*ad val.*	„
	All other sorts, including glue and putty	..	„	„
50	Paper, pasteboard, millboard, and cardboard of all kinds	..	*ad val.*	5 %
	Paper, articles made of paper, and papier-maché	..	„	„
51	Perfumery—			
	Gowla, husked and unhusked	Cwt.	40 0	„
	Kapurkachri (zedoary)	„	12 8	„
	Patch leaves (patchouli)	„	28 0	„
	Rose-flowers, dried	„	13 0	„
	Rose-water	Imp. gall.	2 0	„
	All other sorts, except perfumed spirit (for which see Schedule III.)*	..	*ad val.*	5 %
52	Pitch, tar and dammar—			
	Bitumen	..	..	
	Dammar	Cwt.	5 0	„
	Pitch, American and European	..	*ad val.*	„
	„ coal	Cwt.	4 0	„
	Tar, American and European	„	6 8	„
	„ coal	„	4 0	„
	„ mineral	..	*ad val.*	„
55	Pulp of wood, straw, rags, paper, and other materials	..	..	Free
60	Seeds—			
	Castor	Cwt.	4 0	5 %
	Cummin	„	13 0	„
	„ black	..	*ad val.*	„
	Linseed	Cwt.	5 8	„
	Methi	„	4 8	„
	Mustard, rape or sarson	„	6 8	„
	Poppy	„	6 0	„
	Quince bihidána	„	60 0	„
	Til or jinjili	„	6 0	„
	All other sorts	..	*ad val.*	„
64	Soap	..	„	„
66	Tallow and grease, including stearin	..	„	„

---

* The duty on perfumed spirits, under Schedule III., is fixed at Rs. 8 per imp. gall. or 6 quart bottles.

NATAL; TRADE OF ——, IN 1903.

Bd. of Trade J., Feb. 25, 1904.

The following information relating to the value of the trade of Natal for the year ended 31st December, 1903, as compared with 1902, is based on statistics published in a supplement to the *Natal Government Gazette* for 26th January last:—

The following table shows the value of some imports into Natal (by sea) in 1902 and 1903:—

Articles.	1902.	1903.
	£	£
Metals and manufactures of (includes agricultural implements, bicycles, hardware, ironmongery, machinery, sewing machines, &c.)	[illegible]	[illegible]
Leather and manufactures (includes saddlery)	533,000	[illegible]
Beverages (includes ale, spirits, wine, and aerated waters)	[illegible]	[illegible]
Oilman's stores (includes oils and paints)	[illegible]	[illegible]
Drugs and chemicals	169,000	[illegible]
Soap and candles	145,000	[illegible]
Earthen, china, and stone ware, &c.	52,000	[illegible]
Cement	49,000	[illegible]
Cocoa, chocolate, and confectionery	107,000	[illegible]

Included in the exports from Natal are the following :—

Articles.	1902.	1903.
	£	£
Sugar	163,000	162,000
Bark	75,000	71,000
Hides and skins	36,000	23,000
Beer	9,000	2,000

II.—FUEL, GAS, AND LIGHT.

COAL TAR ; PROPOSED REDUCTION OF DUTY ON ——, IN RUSSIA.

Foreign Office Annual Series, No. 3115.

The British Vice-Consul at Marinpol reports that, with the view of developing the manufacture of briquettes from the large amount of small coal to be found at all the mines in the Donetz basin, the existing high Customs duty (2*l.* per ton) on coal tar will be greatly reduced, if not altogether abolished.

III.—TAR PRODUCTS, PETROLEUM, Etc.

ASPHALT MINES IN COLOMBIA (S. AMERICA).

Foreign Office Annual Series, No. 3114, *Jan.* 1904.

Asphalt mines have been recently discovered, and are now being worked under the direction of the Home Land and Mining Company of New York.

At the present time the Company has one mine or deposit working near Chaparral, Tolima, from which about 2,000 tons are shipped per year ; of this a little more than one-half goes to the United States, the balance to Germany. The asphalt is of the hard variety, and it is almost impossible to tell the difference between it and Egyptian, which contains 99·75 per cent. of bitumen, compared with 99·65 (Crane) and 99·45 (Guzman) in that mined by the Home Land and Mining Company.

This asphalt is used entirely for the body of paints and the making of fine varnish. It is shipped from the mines in sacks, and sells f.o.b. New York for 65 dols. (13*l.*) the short ton. The Chaparral mines are some 1,000 yds. from the Saldaña river, which empties into the Magdalena a few miles above Girardot. The asphalt is sent down to Honda in rafts, where it is embarked in steamers for the coast. The markets for this grade of asphalt are the United States, the United Kingdom, Germany, France, and Austria-Hungary. This Company owns all the asphalt deposits of this grade known in Colombia. The ocean freights on this kind of asphaltare about 5 dols. 50 cent. (1*l.* 2*s.*) per ton.

NAPHTHA NEAR THE BAGDAD RAILWAY (ASIA MINOR).

Dr. P. Rohrbach. Bd. of Trade J., Feb. 25, 1904.

A broad zone, lying between the Persian frontier mountains in the region of the Lower Sab, and stretching in a south-westerly direction over the Tigris and Euphrates into the Arabian Desert, including Kerkuk, Tekrit (on the Tigris) and Hit (on the Euphrates), appears to be full of bitumen, naphtha, and carburetted hydrogen gases. The inflammable exuding gases near Baba Gurgur, and the naphtha springs at Kerkuk are more abundant than those in Russian Transcaucasia, on the Apsheron Peninsula, before borings were commenced. The importance of this fact is evident when the Bagdad railway passes through this district close to rich petroleum wells.

This naphtha supply will be all the more important for the Bagdad railway, seeing that the supply of coal along the line, as far as yet explored, appears to be inconsiderable. The largest coal supply is in the neighbourhood of Eregeli, north-west of the Alican Taurus on the River Chabur, which joins the Tigris above Mosul.

VII.—ACIDS, ALKALIS, Etc.

TARTAR MATERIALS ; EXPORT OF ——, FROM ITALY.

Foreign Office Annual Series, No. 3118.

The appended table shows the exports of various tartaric materials from Italy during the 12 months ended Sept. 30, 1903, the figures for the previous 12 months being added for comparison :—

Article.	1901 2.		1902 3.	
	Tons.	£	Tons.	£
Half-refined tartar	960·5	50,500	632	38,500
Vinaccia argols	2,180	103,500	2,801	153,500
Crude argols	2,918·5	122,500	3,826	192,900
Wine lees	2,433	34,000	3,386	84,300
Totals	8,492	310,500	10,645	469,200

—T. F. B.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

BUILDING MATERIALS ; TRANSVAAL PRODUCTION OF ——.

Bd. of Trade J., Feb. 18, 1904.

The following figures show the value of the output of the various industrial concerns in the Transvaal during the year ended June last, with comparisons for the preceding year :—

——	1901-2.	1902 3.
	£	£
Machine-made bricks (building)	7,113	59,741
" " " (fire)	5,126	7,961
Cement	17,639	9,880
Lime (blue)	9,606	41,129
" (white)	2,923	12,727

CEMENT IMPORTS OF U.S.A.

Eng. and Mining J., Feb. 4, 1904.

Imports of cement into the United States in 1903 were 463,590 short tons, against 399,098 tons in 1902, an increase of 64,492 tons. Of the imports last year 275,483 tons were from Germany, 147,515 tons from Belgium, 29,399 tons from Great Britain, and 8,456 tons from other European countries.

X.—METALLURGY.

TIN PRODUCTION OF BOLIVIA IN 1903.

J. B. Minchin. Eng. and Mining J., Feb. 11, 1904.

The production of metallic tin from the mines in the neighbourhood of Oruro in 1903 was 3,838,520 lb., from 2,855 short tons of concentrates, or an average of 67·2 per cent The Avicaya mine showed the largest output, *viz.*, 1,001 tons of concentrates, and also the highest yield of tin, 71 per cent. ; the other important mines are at Huanuni, Chuncho, and Uncia, all producing over 500 tons of concentrates, with a yield of not less than 60 per cent. Other important deposits of tin appear also to exist, but they have not yet been worked.—T. F. B.

PIG-IRON ; U.S. PRODUCTION OF ——, IN 1903.

Bd. of Trade J., Feb. 25, 1904.

The American Iron and Steel Association has received from the manufacturers statistics of the production of all kinds of pig-iron in the United States in 1903.

According to the *Bulletin* of the Association for the 25th January, the total production was 18,009,252 tons against 17,821,307 tons in 1902, 15,878,354 tons in 1901, and 13,789,242 tons in 1900. The following table gives in half yearly periods the production of pig-iron in the last four years :—

Periods.	1900.	1901.	1902.	1903.
	Tons.	Tons.	Tons.	Tons.
First half	7,642,569	7,674,613	8,808,574	9,707,367
Second half	6,146,673	8,203,741	9,012,733	8,301,885
Total	13,789,242	15,878,354	17,821,307	18,009,252

The chief pig-iron producing States in 1902 were Pennsylvania, 8,211,500 tons; Ohio, 3,287,434; Illinois, 1,692,375; and Alabama, 1,561,398 tons.

Of the total iron produced last year 504,757 tons only were made with charcoal as fuel; 927 tons with mixed charcoal and coke; 1,911,347 with coke and anthracite coal, and 15,592,221 tons with bituminous coal.

The division according to classes of iron made in 1902 and 1903 was as follows.—

—	1902.	1903.
	Tons.	Tons.
Foundry and forge iron	5,176,568	5,785,257
Bessemer pig	10,393,168	9,989,908
Basic pig	2,038,590	2,040,726
Spiegeleisen and ferromanganese	212,981	192,661
Total	17,821,307	18,009,252

The stocks of pig-iron which were unsold in the hands of manufacturers or which were under their control at the close of 1903, and were not intended for their own consumption, amounted to 591,438 tons, against 49,951 tons at the close of 1902, and 70,647 tons at the close of 1901.

The whole number of furnaces in blast on 31st December, 1903, was 182 against 307 on 31st December, 1902, and 266 on 31st December, 1901.

Pig-Iron Production of Germany in 1903.

Bd. of Trade J., Feb. 25, 1904.

The output of pig-iron in Germany during each of the last five years was as follows, in metric tons:—1899, 8,143,132; 1900, 8,520,540; 1901, 7,880,081; 1902, 8,442,660; 1903, 10,085,634.

Mercury Production in Europe.

Eng. and Mining J., Feb. 11, 1904.

A recent communication from Vincent Spirek, of Santa Fiora, Italy, gives the production of mercury in 1903 as follows, in metric tons:—Spain, 930; Austria, 520; Italy, 270; total, 1,720 tons. The output of the Spanish mines shows a marked falling off from the production in 1902, while the output of Austria and Italy increased slightly.

Mercury in Russia.

Eng. and Mining J., Feb. 25, 1904.

According to a special report furnished by Mr. W. A. Abegg, of Warsaw, the production of mercury by Russian mines in 1903 was 22,110 poods, equivalent to 362 metric tons. The output in 1902 was 416 tons.

XII.—FATS, FATTY OILS, Etc.

Cotton Seed Oil Industry, and the Establishment of Cotton-Seed Mills in India.

J. Mollison. Agric. Ledger, 1903, 215—232.

The average percentages of oil and of crude fibre in 64 samples of Indian cotton-seed were as follows:—

Seed from	Oil.	Crude Fibre.
	Per Cent.	Per Cent.
Madras (26 samples)	17·41	17·41
Bombay (18 samples)	17·66	17·04
Central Provinces (15 samples)	19·65	16·90
United Provinces (5 samples)	19·89	16·89

The present export of Indian cotton-seed consists mainly of the Jari variety from the Central Provinces and the Varadi variety from Bombay; these seeds contain, on the average, about 20 per cent. of oil and 17 per cent. of crude fibre. The seeds of exotic varieties of cotton acclimatised in India diminish in size, and contain, on the average, less oil and more crude fibre than indigenous varieties. F. G. Sly considers that Indian cotton-seed would give a yield of 13 per cent. of oil under treatment by proper machinery, and it is proposed to test this conclusion by having specimens of Indian cotton-seed treated in American and English machines.

In the following table is shown the result of a comparison of Egyptian and Bombay cotton-seed cakes, and an analysis of Indian cotton-seed, by S. H. Collins, together with analyses of English-made samples of undecorticated Indian cotton-seed cakes, by J. W. Leather.

—	Egyptian Cotton-Seed Cake.	Bombay Cotton-Seed Cake.	Indian Cotton-Seed.	Undecorticated Indian Cotton-Seed Cakes.		
				1.	2.	3.
Moisture	14·13	12·41	10·5	10·41	10·90	10·75
Oil	5·17	5·35	14·7	4·77	4·76	4·94
Albuminoids	24·19	21·19	16·6	17·87	17·50	17·44
Carbohydrates	32·10	35·19	29·7	39·41	43·35	42·60
Woody fibre	19·31	18·65	23·3	20·55	17·27	18·75
Mineral matter	5·10	5·91	5·2	6·99	6·22	5·54
Nitrogen	3·87	3·39	2·66	3·07	3·06	3·05
Sand	0·05	1·24	1·10	1·98	1·29	0·95

With regard to chemical composition, the difference between Egyptian and Bombay cotton-seed cakes is not important, but the fibre of the latter is of an objectionable woolly character, and having regard also to the rather large amount of sand in the Bombay cake, this must be regarded as slightly, but certainly, inferior to the Egyptian cake as a cattle-food.—A. S.

XVII.—BREWING, WINES, SPIRITS, Etc.

Alcohol Trade of Italy.

Foreign Office Annual Series, No. 3118, *Feb.* 1904.

The export of alcohol from Italy in 1902 was 1,506,166 galls., as compared with 310,407 galls. in 1901, and in fact the figures for the last 10 years show a steady increase. This industry is largely beneficial to agriculture, and therefore highly important to this district. The distilleries are divided into three categories, of which the first is concerned with the distillation of saccharine residuum—beetroot and cane. In this are 17 establishments, which used up 37,237 tons of material, and produced 2,771,323 galls. of spirit. The second deals with wine refuse, stalks, skins, &c., and with wine itself. This is divided into three classes, all using the same materials. The first class consumed 157,147 tons of material and produced 1,236,543 galls. of spirit. The second class is of small stills, which work under special conditions, and produced 124,950 galls. The production by agricultural co-operative societies is also encouraged by special enactments, and amounted to 28,590 galls.

No reason has been assigned for the extraordinary boom in the trade in 1902.

The spirit is largely utilised in the country for making essences, preserving fruit and kindred purposes, as well as for fortifying wine for export, as is shown by the following table:—

Articles.	Quantity Exported.	Added Spirit.
	Hectolitres.	Hectolitres.
Marsala	25,462	1,6[illegible]
„ (red)	36	1·2
Vermouth	39,488	2,0[illegible]
Liqueurs	11,699	5,5[illegible]
Pure spirit	1,455	81[illegible]
Cognac	129	69
Common wines	180,521	4,02[illegible]
	Tons.	Tons.
Fruit	135	41[illegible]

The net taxation on the above reached 86,900*l*. From this table it appears that exported wine is fortified to the extent of 2·16 per cent. From the port of Naples alone 14,420 hectolitres were exported, to which 64,894 litres of spirit were added, which is equal to 4·5 per cent. The increase in the export of Italian Cognac has not realised the expectations of manufacturers.

Vinegar makers consumed 4,500 hectolitres of spirit to produce 46.226 hectolitres of their wares, but there is no increase on preceding years.

The importation of spirit in 1902 amounted to 68,431 hectolitres. This comes almost entirely from Austria-Hungary and Germany, and shows a very large increase over the preceding quadrennial average. The duty on foreign alcohol being 30 lire per hectolitre, besides the octroi dues of the various towns where it is used, the sum realised by the State by this sudden increase of importation has been remarkable.

SPIRIT; EXPORT OF ——, FROM THE GERMAN CUSTOMS UNION IN 1903.

M. Student. Zeits. Spiritusind., 1904, **27**, 48.

The exports of spirit in casks amounted to 232,797 German centners in 1903, as against 313.502 centners in 1902, and 155,672 centners in 1901. Of these amounts the re-export of imported spirit after refining was only 1 centner in 1903, as against 54 in 1902, and 7,297 in 1901. The exports of actual German spirit for the past 10 years is shown in the following table:—

Year.	Amount in Centners.	Year.	Amount in Centners.
1894	76,987	1899	159,662
1895	167,652	1900	154,322
1896	182,108	1901	148,375
1897	28,201	1902	313,448
1898	60,250	1903	232,796

The spirit exported, including the small amounts re-exported after refining, went chiefly to the countries mentioned in the following table:—

——	1903.	1902.	1901.
	Centners.	Centners.	Centners.
Great Britain	55,713	92,106	57,803
Switzerland	51,012	29,555	35,424
Holland	22,412	15,754	8,219
Italy	15,134	14,845	2,741
Austria-Hungary	14,323	16 217	2,819
Hamburg (free port)	11,395	2,510	3,133
Turkey in Europe	9,053	17,198	6
„ Asia	8,602	9,780	1,099
British West Africa	5,006	7.252	7,503

The import of spirit in casks into the German customs union amounted to 8095 centners in 1903, as against 3415 centners in 1902, and 9980 in 1901. Of these amounts, 7813 centners were destined for re-export after refining, in 1903, 3238 in 1902, and 9685 in 1901, and thus the amounts imported for consumption in Germany were 282 centners in 1903, 177 in 1902, and 295 in 1901.—A. S.

SHERRY IN SPAIN; PRODUCTION OF ——.

U.S. Cons. Rep., No. 1875, *Feb.* 12, 1904.

The production of sherry is confined to the district of Jeres. Since 1890 the vintage has decreased so enormously that unless the new vineyards planted with American vines in the last few years prove a success, the existence of this great industry is near its end. In 1890, there were produced 6,000,000 gallons in the district of Jeres. The vintage has fallen off from year to year, until the product of 1903 only amounted to 145,848 galls.

XVIII. A.—FOODS.

FOODS AND DRUGS; U.S. "STANDARD DEFINITIONS" OF PURE ——.

Bd. of Trade J., Feb. 25, 1904.

A Bill, now before the United States Senate, fixes "standard definitions" of pure foods and drugs, and defines what are to be considered adulterations or misbrandings of the same. A copy of the Bill may be seen at the Commercial Intelligence Branch of the Board of Trade, 50, Parliament Street, S.W.

XIX.—PAPER, PASTEBOARD, Etc.

WOOD PULP; EXPORT DUTIES ON ——, IN SWEDEN.

Bd. of Trade J., Feb. 25, 1904.

By a Law passed by the Swedish Parliament during the Session of 1903, export duties were imposed on wood pulp at the following rates:—

——	Rates of Duty.	English Equivalent.
Wood pulp—	Öre.	*s.* *d.*
Dry—		
Chemically prepared, per ton	50	0 6¾
Mechanically „ „	30	0 4
Wet, per ton	Half the rates imposed on dry.	Half the rates imposed on dry.

Patent List.

N.B.—In these lists, [A.] means "Application for Patent," and [C.S.], "Complete Specification Accepted."

Where a Complete Specification accompanies an Application, an asterisk is affixed. The dates given are (i) in the case of Applications for Patents, the dates of application, and (ii) in the case of Complete Specifications Accepted, those of the Official Journals in which acceptances of the Complete Specifications are advertised.

Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

T. Fairley, 17, East Parade, Leeds.

Notices.

JUBILEE OF Dr. H. CARO.

On February 13th a celebration took place at Mannheim in honour of the 70th birthday of Dr. H. Caro, one of the original members of this Society. On that date the President and Dr. Messel, acting on behalf of the Council, sent to him a telegram of congratulation, of which the following s a copy :—

"Dr. H. Caro, Mannheim.

"The Society of Chemical Industry, proud of the grand achievements of its member, sends its sincerest congratulaions on your 70th birthday, and hopes that you may long be spared to your family and to your admiring friends.

(Signed) Ramsay, President.
Messel, Vice-President."

To this Dr. H. Caro has sent the following reply :—

'Dear Sir William, Mannheim, 1 March 1904.

"I never feel more my inability to make words meet with my feelings than at the present moment, when I am bout to undertake the task of expressing to you, as the President of the time-honoured Society of Chemical ndustry, and to Dr. Messel, as the Vice-President thereof, my heartfelt thanks for the great honour and distinction which your Society has bestowed upon me by its congratuations to my 70th birthday, framed in words honouring he generous sender not less than the deeply thankful eceiver. May I then be allowed, dear Sir William, to ask ou, kindly, to complete your noble mission and to convey he expression of my sincerest and never-dying gratitude o the Society of Chemical Industry. I have never forgotten he happy time of my younger days when I became aprenticed to English manufacturing chemistry, when I earned to make my first steps in chemical investigation, nd when, above all, I was led to love and appreciate the true greatness of your noble country and your generous-hearted ountrymen. To be honoured by my British fellowhemists in the manner done by you, dear Sir William, by Dr. Messel, and the Society of Chemical Industry, is to my mind the crowning of my entire life, and the most recious gift presented to my 70th birthday.

Believe me, dear Sir William,
Yours ever faithfully,
(Signed) Dr. H. Caro.

To Sir William Ramsay, K.C.B., Ph.D., F.R.S.,
President of the Society of Chemical Industry,
London."

THE MEDAL.

At a meeting of the Council of the Society held on March 23rd last, it was unanimously resolved to present he Society's medal for 1904 to Prof. Ira Remsen, President f the Johns Hopkins University, Baltimore, Md., U.S.A., r conspicuous services rendered by him to Applied hemistry.

NNUAL GENERAL MEETING, NEW YORK, 1904.

The Annual General Meeting will be held in New York ity on Thursday, Sept. 8th, and following days. Members ho contemplate attending are requested to communicate ith the General Secretary as soon as possible, in order hat suitable travelling arrangements may be made. A vised programme appears in this issue of the Journal.

ST. LOUIS EXHIBITION, 1904.

The St. Louis Chemical Society has established a Bureau Information for the benefit of members of foreign hemical societies who may visit the World's Fair. Any embers of such societies who desire information in regard the Exhibition are invited to write to the Secretary, rof. E. H. Keiser, Washington University, St. Louis, Mo.

COMMUNICATIONS.

Authors of communications read before the Society, or any of its Local Sections, are requested to take notice that under Rule 43 of the Bye-laws the Society has the right of priority of publication for three months of all such papers. Infringement of this Bye-law renders papers liable to be rejected by the Publication Committee, or ordered to be abstracted for the Journal, in which case no reprints can be furnished to the author.

List of Members Elected

23rd MARCH 1904.

Appleby, Joseph, 35, Pembroke Road, Bootle, Liverpool, Flour Miller.

Bayly, Harold G., 65, Fulham Park Gardens, London, S.W., Analytical Chemist.

Bleakley, Wm., Phœnix House, Swinton, Lancashire, Cotton Mill Manager.

Brown, Frederick W., 470, Lenox Avenue, New York City, U.S.A., Chemist.

Buchanan, J. L., 27, Birch Road, Lower Bebington, Cheshire, Analytical Chemist.

Burton, Thos. R., c/o Scott, Greenwood, and Co., 19, Ludgate Hill, London, E.C., Technical Journalist.

Chubb, H. M., Wharfedale Villas, Tadcaster, Yorks. Brewery Chemist.

Clark, Ernest, Royal Technical Institute, Salford, Assistant Lecturer in Chemistry.

Cooke, W. Ternent, Chem. Dept., University College, Gower Street, London, W.C., Research Student in Chemistry.

Dixon, Fred. J., 5, Prospect Terrace, Harrogate, Yorks., Civil Engineer.

Elliott, Philip, c/o Lanosoap, Ltd., Marion Street Works, Bradford, Yorks., Works Chemist.

Everitt, Walter, 83, The Grove, Ealing, W., Analyst.

Garnar, G. Lestor, Monticello, Sullivan Co., N.Y., U.S.A., Superintendent (Leather Works).

Gerard, Thos. A., Messrs. Gerard Bros., Ltd., Nottingham Soap Manufacturer.

Hochstetter, Henry, Ault and Wiborg Co., Cincinnati, Ohio, U.S.A., Chemist.

Jessup, Alfred E., c/o U.S. Consul, Tientsin, China, Assayer.

Keddell, H. Hewes, 2, Lime Street Square, London, E.C., Merchant.

Korte, Dr. Reinold F., Clydach, R.S.O., Glamorganshire, Works Chemist.

Lawson, Jos. H. S., Worsley Street Mills, Hulme, Manchester, Salesman.

Lowenstein, Arthur, c/o Nelson, Morris, and Co., U.S. Yards, Chicago, Ill., U.S.A., Chemist.

Mather, J. Cecil, 15, The Holloway, Runcorn, Cheshire, Works Chemist.

Muckenfuss, Anthony Moultrie, State University, Fayetteville, Arkansas, U.S.A., Professor of Chemistry.

Newgass, Solomon, 257, W. 132nd Street, New York City, U.S.A., Student (Columbia School of Mines).

Payne, Allen G. C., 89, Rokeby Street, West Ham, E., Assistant Works Chemist.

Peyser, Horace F., 68, West 47th Street, New York City, U.S.A., Chemist.

Pollitt, George P., Ferndale Villa, Rectory Road, Stanford-le-Hope, Essex, Chemist.

Reinherz, Otto, 9, Heaton Grove, Bradford, Yorks., Chemist.

Richards, Adelbert H., c/o General Metals Co., Colorado Springs, Colo., U.S.A., Chemist.

Schoeller, Walter R., 169–170, Shoreditch High Street, London, E.C., Analytical Chemist.

Stanffacher, W., 64, Oberwilerstrasse, Basle, Switzerland, Manager (Chemical Works).

Strange, Edward Halford, 7, Staple Inn, Holborn, London, Technical Research Chemist.

Swindells, Seth, Craiglea Villa, Kidsgrove, Stoke-on-Trent, Chemist.

Thornley, Thomas, Cross Chemical Co., Ltd., Camelon, Falkirk, N.B., Chemical Manufacturer.

Zimmermann, Henry D., c/o American Ether Co., Richmond, Va., U.S.A., Chemist.

Changes of Address.

When notifying new addresses, members are requested to write them distinctly, and state whether they are temporary or permanent. Multiplication of addresses is also to be avoided as tending to create confusion. When sending subscriptions, the use of the form attached to the application helps in the verification of addresses, on which the safe delivery of the Journal depends.

Baxter, J. G.; Journals to McEvoy and Holt's Cement Works, Northfleet, Kent.

Meeting held at the University, Liverpool, on Wednesday, January 27th, 1904.

MR. FRANK TATE IN THE CHAIR.

DESTRUCTIVE BACTERIA IN MANUFACTURING OPERATIONS.

BY H. B. STOCKS, F.I.C.

To those engaged in the manufacture of organic products from animal and vegetable sources the study of bacteria is of the utmost importance. Our rapidly increasing knowledge of this subject, though of recent date, has shown that many of our largest industries depend either entirely or partly upon bacterial action, and that in others these minute organisms are responsible for many changes, either beneficial or otherwise, which occur at various stages of manufacturing processes. The changes directly due to bacteria come within the scope of the chemist, and it may be a part of his duty to deal with them.

There are stages in many manufactures where bacteria do a considerable amount of damage, and there are few stages where the conditions are so unfavourable that bacteria cannot increase or at least exist if they find an entry. There exist several species of bacteria whose spores can withstand a temperature of boiling water for several hours and afterwards develop under favourable conditions: there are many bacteria which flourish at moderately high temperatures, and others which may be frozen and yet multiply. Some can withstand moderately strong alkalis or acids, and there exist quite a number that are not checked at all by the usual antiseptic methods of treatment such as weak solutions of phenol or mercuric chloride.

The sources of infection are the materials used, the air or the water used; and bacteria may also be introduced by careless or uncleanly methods of working. If the conditions are at all favourable bacteria will multiply at an enormous rate, and pass from one stage of the process to another, finally appearing in the more or less damaged finished product. Especially is this the case in intermittent work, when the plant is only in use for a portion of each day; the material left in the apparatus then becomes a breeding ground for germs, and the vats, filter presses, pipes, and pumps containing it have to be thoroughly cleansed before they can be used again.

The first precaution to be observed is thorough cleanliness. All apparatus should be cleansed or disinfected i such a manner that it may be used without any fear o contamination to the material that may be in process o manufacture.

It was shown in 1878 by Downs and Blunt (Proc. Roy Soc., **26**, 188) that the development of bacteria and othe putrefactive organisms is arrested under the influence o sunlight and oxygen. Most bacteria shun the light putrefactive bacteria flourish under anærobic conditions Efficient ventilation is therefore absolutely necessary in factory.

Waste water should be treated in some way, or run directly into the sewer. Other waste materials should be sterilised, destroyed, or carried right away while they are quite fresh.

It should always be remembered that bacteria require water for their growth, so that a waste product should be brought into a dry condition, if possible.

Other methods of treatment will depend upon the nature of the material operated upon. In dealing with food products, sterilisation by heat is largely practised, and, if the material will bear a high temperature, it is heated to 100° C. or slightly above, as in the preservation of meat, meat extracts, &c.

The preservation of substances not intended for food is usually insured by the addition of preservatives or antiseptics, which may be added during the manufacture or to the finished product, but it is essential for proper working to get them in as soon as possible to prevent, if possible, even incipient signs of decomposition.

The preservatives mostly used are phenol, cresols, thymol, salicylic acid, formaldehyde, formic acid, lactic acid, zinc chloride, borax, boric acid, sulphurous acid, sodium and calcium sulphites and bisulphites, hydrofluoric acid and alkali fluorides and silicofluorides.

The application of some of these to foods is also to a certain extent practised, but this should be severely dealt with; though of great benefit to the manufacture, it is far from beneficial to the consumer, and no doubt leads to the working-up of a lot of material that would otherwise have to be destroyed or converted to some meaner use.

In the brewing of beer, in the distillery, and in wine manufacture, a considerable amount of trouble is caused by bacterial action. In bread making, the general surroundings of a bakery ought to be carefully looked into, and any source of infection quickly put a stop to. A new Act came into force in January, which deals with the question, and no new bakehouses will be allowed below ground. In the manufacture of sugar and starch destructive bacteria are especially numerous, and cause a great amount of trouble. The leather industries are dependent upon the action of bacteria; the various soaks used contain immense numbers of bacteria which act upon the skins in such a way as to better fit them for the subsequent tanning operation; these bacteria may, however, become destructive, and cause a loss of weight or strength in the finished material.

In the manufacture of gum tragasol from the locust beans as carried out at the Gum Tragasol Works, we noticed, during the extraction of the gum from the milled beans, soon after the commencement of operations, isolated black patches disseminated through the gum. On examining these with the microscope, it was found that they contained a large number of spores, and, though the temperature was very high, *i.e.* about 88° C., they were evidently developing. These black patches were eventually traced to the mill. The machines for grinding include two sets of small millstones enclosed in cast-iron casings. During the grinding of the beans considerable friction is experienced, and heat is generated in the mills which drives out the moisture contained in the beans; this collects upon the inside of the iron covers, and is quickly coated with fine dust produced during the grinding, which also passes into this space; the water and dust together form a soft pulp, which accumulates until it touches the revolving stones, and forms a layer half an inch or more in thickness. During the period of grinding there is a current of air passing down through the feed opening in the upper stone, between the stones, and out through the delivery spout, this air being heated to a temperature of about 35° C. while it is passing through. The spores contained in the volume of air passing through these mills must be considerable, and many of them are held back by the coating of dust and water lying upon the iron plates; the temperature being very suitable, and the necessary organic matter plentiful, they develop, the bacteria multiply very rapidly, and soon the pulp is swarming with them.

The bacteria thus introduced generate acids which attack the iron casings, while the iron thus dissolved combines with the tannin of the dust from the husk forming a black lake or ink, and imparts to the material a black colour. The acidity of the moist material equals 0·46 per cent., calculated as acetic acid. After a time this black material dries up and breaks away from the iron casings; it falls into the grading machines along with the beans, and any pieces which may have broken up to about the same size as the beans pass with them through the remainder of the grinding machines, becoming rounded, hardened, and polished in the process. About half an ounce or less of this material may be found in 100 lb. of beans, but the number of spores in this quantity must be so great that its absolute weight gives no idea of the destruction these spores may do when they develop. In the manufacture of the gum the black particles very rapidly swell and liberate the spores into the gum, and if allowed to develop these cause a considerable amount of trouble. Attempts were made to cultivate these bacteria by inoculation into agar-agar, but they did not develop; they will, however, grow readily by simply warming these black particles with water and allowing them to remain for a few days in a warm place. The organisms which appear to be most common, are a short rod-shaped bacterium, with well-developed spore at one end; in very sour material this becomes about twice as long; and a short bacterium, under favourable conditions developing into a very long chain, and a diplococcus. Some of these bacteria act upon the gum in such a way as to render it quite fluid, and this action becomes so powerful that a very small quantity of the fluid gum added to a large quantity of fresh gum will cause it to become fluid in about half an hour; this action is no doubt due to enzymes excreted by these bacteria, as the organisms alone could not, in so short a time, destroy so much material. This emphasises what I said in my opening remarks, that all old material should be removed, as it is often very destructive.

In the preparation of flour for sizing purposes two methods are pursued; either the material is used in its fresh state after the addition of a preservative, or it is allowed to ferment for several weeks. In conjunction with Mr. Graham White I have studied the changes which take place when flour ferments, and as they are of a destructive character they may be of interest here. When flour and water are mixed together and allowed to stand, a fermentation commences in about three days and continues for a long period. This fermentation may be due entirely to bacteria, or partly to bacteria and wild yeasts, or partly also to the ordinary forms of moulds according to which organisms get the upper hand; but the changes appear to be of a similar character in different fermentations. The figures given in the table refer to a fermentation carried out on a fairly large scale, the atmospheric temperature varying between 64° and 72° F. Samples for analysis were taken from the bulk at 2, 4, 6, and 8 weeks, and corrections made accordingly:—

Fermentation of Flour at 64° to 72° F.

Samples taken from Bulk.

——	Fresh.	Fermented 2 weeks.	Fermented 4 weeks.	Fermented 6 weeks.	Fermented 8 weeks.
Albuminoids:					
Soluble in water	3·96	9·76	9·25	7·27	7·29
Insoluble in water ..	7·68	1·43	1·62	2·50	2·50
Total.........	11·64	11·19	10·87	9·77	9·79
Sugars................	3·62	0·54	..	..	..
Acidity in parts NaHO per 100 of flour	0·35	2·25	2·59	4·85	5·90
Ammonia.............	0·018	0·102	0·120	0·250	0·234
Nitrogen:					
In soluble albuminoids	0·632	1·516	1·481	1·164	1·167
In insoluble „	1·233	0·275	0·260	0·406	0·400
As ammonia	0·015	0·084	0·099	0·206	0·193
Total	1·880	1·875	1·840	1·770	1·760
Soluble albuminoids ppt. by tannin and sodium chloride:					
In acid solution...	..	..	..	..	4·03
In neutral „ ...	..	..	..	..	4·74

If we compare the figures obtained after two weeks' fermentation with those obtained when the flour was fresh we find that a great change has taken place: most of the albuminoids have become soluble, nearly all the sugar has been removed, the acidity has considerably increased, and some ammonia has been produced. The changes after the second week are of a similar character but much slower, and it is evident that the greater part of the work is done at an early period. There is a gradual loss of nitrogen, and a large increase in acidity, and also a slight increase in insoluble albuminoids owing to the large increase in bacteria and yeasts which are themselves nitrogenous. The acids generated appear to be to a certain extent preservative, for putrefactive fermentation does not set in for a long period, an unusual occurrence in presence of such a quantity of albuminous matter. The amount of soluble albuminoids and peptones at the eighth week is shown to be fairly large by the precipitate obtained with tannic and sodium chloride. The time at my disposal will not allow of a full account of the work done. The following are the most interesting points:—After the eighth week ethyl alcohol was found to be present in the liquid to the extent of 0·6 per cent.; volatile acids, principally acetic acid, were also found equal to 0·313 per cent.; and non-volatile lactic acid 0·504 per cent., besides other products. When the necessary corrections were made and the weights of these constituents calculated on 100 grms. of the original flour, the amounts were as follows: —

	Grms.		Grms.
Alcohol	6·13	containing carbon	3·20
Acetic acid	3·20	„	1·28
Lactic acid	5·15	„	2·06
		Carbon.........	6·54

The sugar in the original flour amounting only to 3·62 per cent., and containing 1·44 per cent. of carbon, it is evident that a portion of the other carbohydrates dextrin and starch must have been destroyed, and this is borne out by the fact that the starch granules are much shrunk and eroded. There is no doubt a good deal of starch lost in this process.

It appeared to be of interest from a sizer's point of view to determine whether the albuminoids or gluten could be brought into solution without the long and wasteful process of fermentation, and for this pupose three experiments were tried:—

By acting upon flour with—

(1) 10 times its weight of cold water.

(2) „ „ ½ per cent. acetic acid.

(3) „ „ ½ per cent. of lactic acid.

On analysis these mixtures gave the following results:—

—	Soluble.	Insoluble.	Total.
	Albuminoids.	Albuminoids.	
1	2·50	7·81	10·31
2	7·69	2·62	10·31
3	8·56	1·75	10·31

proving that the albuminoids of flour are very largely soluble in these weak acids.

With regard to the pollution of water supply a good deal might be said, but the following example, which has come under my own notice, will suffice.

The Gum Tragasol Co. derive the water for boiler purposes partly from pits or ponds in an adjacent field and partly from the mains; in one of the pits, which is nearest the works, changes have been going on of a rather unusual kind. The pond water is derived from rain, drainage from fields, more or less waste effluent draining through the soil, and water blown through the boilers; in consequence of the latter the temperature of the water in this pond is 5 or 6° higher than that of other ponds in the neighbourhood. I have had this pond under observation for a considerable time, and the following is an outline of these observations:—In January 1902 the water was quite clear, and a well-defined gray layer could be seen about a foot from the edge toning off into yellow as it neared the shallower water, this was found to consist largely of diatoms: beyond this layer the mud was black. Early in April the water became quite turbid, and of a creamy white colour, and a loose flocculent material was gathered thickly upon the water weeds, the lower part of the weeds and the mud being black: sulphuretted hydrogen was evolved when the latter was stirred.

On April 7th a portion of the black mud was dried in a current of coal gas, and the following determinations made:—

	Per Cent.
Matter soluble in hot benzene	3·09
Containing free sulphur	0·37
Iron.... } in combination as FeS.............	3·28
Sulphur } in combination as FeS.............	1·87
Iron as Fe_2O_3	1·33

A microscopical examination of the black mud revealed besides the presence of the black ferrous sulphide and other mineral matter, many active monas, and reddish brown cells in shape and size resembling protococcus, many species of infusoria, and greyish flocculent matter made up very largely of bacteria.

On April 28th, when the water appeared to be very turbid, 2¼ litres of it were warmed and filtered. The weight of the precipitate was only about 0·1 grm., but it contained 0·0055 grm. of free sulphur, or 0·22 part per 100,000 of the water. At this period the water had exactly the same appearance as sulphuretted hydrogen water which has been exposed to the air for a time and in which an incipient precipitation of sulphur has taken place; it also evolved sulphuretted hydrogen on warming, and there appears to be no doubt that a great part of the turbidity is due to the separation of finely-divided sulphur formed by the oxidation of dissolved sulphuretted hydrogen produced from the mud. The formation of sulphides, sulphuretted hydrogen and free sulphur in this water are due to the same changes that occur in sewage and wherever sulphates and decaying organic matter are exposed together (Quart. Journ. Geol. Soc., Vol. LVIII., 1902 pp. 46—58; this J., Vol. XXI., p. 52) that is, under anaerobic conditions the following changes take place:—

$$CaSO_4 + 2C = 2CO_2 + CaS.$$

$$CaS + CO_2 + H_2O = CaCO_3 + H_2S.$$

$$Fe_2(OH)_6 + 3H_2S = 2FeS + 6H_2O + S.$$

and under limited aerobic conditions:—

$$H_2S + O = H_2O + S.$$

The bacteria producing these changes are readily cultivated in a solution containing meat extract peptone, $Ca\,SO_4$, and $Fe_2(OH)_6$, and in three or four days the same reaction is perceived by the blackening of the latter, if after inoculation, the liquid is sterilized by heat there is no change whatever, showing conclusively that bacteria are necessary to bring about these reactions.

Besides the sulphide organisms there are also present in the mud numerous active spirillæ, Fig. 5, which cultivated in a solution of citrate of iron and ammonia precipitate the whole of the iron as hydrate in a short time, no doubt absorbing the organic acid and probably the ammonia; these organisms are present in peat and peaty waters, and they may be the cause of similar troubles to the other iron organisms, *e.g.* Crenotherix and Cladothrix.

Reverting to the pond water again: during the whole time of the observations bacteria were swarming, but a very large kind seemed to become prominent when the water was turbid, it was in the form of long rods or of filaments and contained refractive granules which may be sulphur; whether this organism helps in the oxidation of the sulphuretted hydrogen and absorbs the sulphur in the same way as Beggiatoa alba does I should not like to affirm, but that they were prominent at this time was evident.

On 29th April a thick yellowish-white greasy scum appeared upon the surface of the pond. On examining this the following results were obtained:—

	Per Cent.	
Oil	28·61	Soluble in benzene.
Free sulphur	12·14	
Insoluble in HCl	19·42	
Fe_2O_3	8·53	
CaO	4·10	
MgO	0·76	

The lime and magnesia were probably present as carbonates; organic matter, water, and carbonic acid make up the remainder; the most interesting point about this scum was the presence of over 12 per cent. of free sulphur.

On June 13th the pond evolved a strong odour of sulphuretted hydrogen, and the air over the water blackened paper moistened with lead acetate; the water itself gave a black precipitate with lead acetate solution and a white flocculent precipitate with hydrochloric acid.

The sulphur present as hydrogen sulphide equalled 1·81 parts per 100,000, and the sulphur precipitated by hydrochloric acid 0·6 part per 100,000.

A few of the constituents were determined as follows:—

CaO	18·00	parts per 100,000
MgO	8·24	„
SO_3	10·09	„
Total solids	88·20	„

The water changed from a black tint (when hydrogen sulphide was evolved) to a turbid white colour (in which state there was no free hydrogen sulphide) several times, the changes evidently being due to alternate periods of reduction and oxidation.

The alkalinity of the water was determined several times with Methyl Orange and standard hydrochloric acid, and attempts were made to estimate the carbon dioxide present in the free state and as bicarbonate by means of baryta water and hydrochloric acid, but these last were not successful, as it was found that a carbonate of an alkali was also present.

On May 7th the alkalinity calculated as $CaCO_3$ was 42·0 parts per 100,000, and the apparent CO_2 only 0·176 part.

On June 13th the alkalinity equalled 45·5 parts $CaCO_3$ per 100,000, and the apparent CO_2 only 2·68 parts per 100,000.

On July 2nd the alkalinity equalled 50·2 parts $CaCO_3$ per 100,000. And on this day there was apparently no free CO_2, the water, after addition of baryta was more alkaline than the blank test, in fact the water both before and after boiling gave a pink colour with phenolphthalein showing unmistakably the presence of an alkali carbonate.

On July 2nd 500 c.c. of the water was boiled and the precipitate filtered off, dissolved in N/2 HCl, and titrated back with NaOH; this equalled 36·25 parts $CaCO_3$ per 100,000 (some MgO would be present in this). The filtrate was titrated with N/10 HCl and Methyl Orange, and the alkalinity was found to be equal to 12·72 parts Na_2CO_3 per 100,000.

If the Na_2CO_3 be calculated as $CaCO_3$, we get the following results:—

Temporary alkalinity as $CaCO_3$	36·25
Permanent alkalinity due to Na_2CO_3 calculated as $CaCO_3$	12·00
Total alkalinity calculated as $CaCO_3$	48·25

which is approximately the same as the total alkalinity directly determined. The water was evidently in a state of unstable equilibrium, as there was not enough carbonic acid present to form bicarbonates both of soda and lime. The sodium carbonate present in this water must have been produced from sodium sulphate by the same reactions as are given for calcium carbonate, for no sodium carbonate was present in any of the waters draining into the pond. The steam from this water had given a good deal of trouble when used in open coils for boiling purposes owing to the odour it imparted, but finally the water boiled with it contained an appreciable quantity of sulphuretted hydrogen, and for this reason the supply was cut off.

I am indebted to the directors of the Gum Tragasol Co., Ltd., for permission to give the results of the work which I have described in this paper.

ERRATA.

THE MANUFACTURE OF SULPHURIC ACID FROM ARSENICAL PYRITES.

BY W. ROSCOE HARDWICK.

Discussion (this Journal, 1904, 220—221).

London Section.

Meeting held at Burlington House, on Monday, March 7th, 1904.

MR. WALTER F. REID IN THE CHAIR.

PRESENTATION TO MR. A. R. LING.

The CHAIRMAN said that their late Secretary, Mr. Ling, after working for them for some years had been obliged by pressure of business to resign the office of Honorary Secretary and many of them wished to give him some testimonial of their appreciation of his services. He then read the following letter from their late Chairman, Mr. Otto Hehner:—

Dear Mr. Chairman,

As I am unfortunately prevented from attending the meeting to-night, I must do by letter what I wished to have done personally, namely, to say that I have been in almost daily communication with our late secretary, Mr. Ling, while I presided over the section and know, therefore, better than most other members how much he has done for the section, how with an utter disregard of his personal interests, he thought and slaved for us, yet always kept himself modestly in the background.

We cannot repay him for his services; his repayment must consist in his own knowledge that he has done well and that each member of the section thinks of him as a friend. But we want him to have a visible token of our affection and gratitude, and of our good wishes for his health and prosperity.

Sincerely yours,
OTTO HEHNER.

The way in which the sentiments expressed by Mr. Hehner had been echoed by the meeting, showed how entirely they all agreed with him, and he was quite sure they all regretted that Mr. Ling had found it necessary to resign his post, but in order that he might retain some tangible mark of their appreciation they had in the first instance had an illuminated testimonial prepared bearing the following inscription:—

"Presented to A. R. Ling as a token of recognition of his untiring energy and zeal as Honorary Secretary and Treasurer of the London Section of the Society of Chemical Industry during the years 1898—1903.

"Signed on behalf of the Members and Committee:

BOVERTON REDWOOD, Chairman, 1898—1900.
OTTO HEHNER, Chairman, 1900—1902.
WALTER F. REID, Chairman, 1902—1904.
JULIAN L. BAKER, Hon. Local Sec.

March 7th, 1904."

Those words expressed the obligations which Mr. Ling had conferred upon them, and they were glad to know that he would still remain an active member not only of the London Section but of the Committee. He felt sure that the services he had rendered in the past were not the only ones he would render to the section. The Committee entrusted with the selection of this testimonial had chosen a silver tea service which they trusted would meet with the approval of Mr. Ling and of his family.

In addition to that there was a cigar case for Mr. Ling himself. He hoped that however their ways might diverge in future he would always think as kindly of his old friends in the Society of Chemical Industry as they would of him.

Mr. **Ling**, in reply, said he was much touched by the kind words of the Chairman. His feelings of gratitude were mingled with a certain amount of regret at leaving the Secretarial Office. It was, in fact, most reluctantly, and only after mature consideration, that he asked the Committee to accept his resignation. The secretaryship involved a certain amount of work, and it had always been a great pleasure to him to carry it out; in fact, he took it as a privilege to have been able to further in any way the ends of that great Society of Chemical Industry. He hoped to be associated with the work of the London Section and with the Society as a whole for many years. Turning to the beautiful illuminated address, on which were inscribed the signatures of the Chairmen he had served under—Dr. Boverton Redwood, Mr. Otto Hehner, and Mr. Reid—he could only say that it had been an honour to be associated with any one of them. With regard to this as well as to the very handsome plate he might say on behalf of his wife as well as himself that they could not have selected a more acceptable token of their appreciation of his services.

OBSERVATIONS ON COTTON AND NITRATED COTTON.

BY H. DE MOSENTHAL, F.I.C.

The effect of solvents on cellulose and nitrocellulose, and their so-called *gelatinisation*, has found so many applications in the arts, that anything which adds to our knowledge of this subject must be of interest. I have for some years endeavoured to ascertain the structural changes which celluloses and nitrocelluloses undergo when acted upon by solvents, and in this connection I have also studied starches and nitrostarches. Mr. Lindsay Johnson, F.R.C.S., has kindly placed his great manipulative skill at my disposal, and assisted me in the preparation of microscopic specimens both with and without the microtome, and in obtaining microphotographs for illustration.

On this occasion, my remarks will be limited to cotton and nitrocotton, for in the manufacture of articles based on gelatinised cellulose, cotton is generally used, and supplies the cellulose which, when nitrated, is used for explosives and artificial silk, as well as for most celluloids. An investigation into the solubility of cotton or nitrocotton required, in my opinion, a knowledge of—

1. *The Minute Structure of the Cotton Fibre.*—The most recent work on cotton is that of Heinrich Kuhn.[*] As regards the structure, however, he relies on the work of O'Neill, Crum, and Bowman. In fact, the book published by the latter in 1881,[†] in which Crum's work is fully referred to, seems to be the source from which subsequent writers have chiefly taken their data as to the histology of the cotton fibre. Hugh Monie, jun.'s, book, published in 1890,[‡] deals mainly with the differences between cottons of different origin, although a good deal of useful information regarding the structure of the fibre in general can be gathered from it.

The cotton fibre is usually described as a single elongated cell, the mature fibre having the form of a hollow tube twisted many times throughout its length, the outer surface being striated or corrugated. The fibre or tube consists of an outside membrane or outer cuticle, and an inner membrane or inner cuticle between which lies the intercuticular substance. The cuticles are harder than the intercuticular substance which constitutes 85 per cent. to 90 per cent. of the fibre. Hugh Monie says that the inner cuticle is harder than the outer. I have not succeeded in differentiating them.

The statement that the intercuticular substance constitutes 85 per cent. to 90 per cent. of the fibre, rests on experiments made with cuprammonium (Schweitzer's reagent), which dissolves the intercuticular substance before it attacks the cuticles. I have tried to repeat the experiments, but could not make sure that the minute supernatant cuticles were all collected and free of intercuticular substance and copper. I, therefore, think that the percentage estimation must be regarded as approximate, and 10 per cent. as a maximum for the cuticles. That the intercuticular substance dissolves in cuprammonium more readily than the cuticles, points to the celluloses being different. Hugh Monie terms the cellulose of the intercuticular substance the real cellulose; he means, no doubt, to draw a distinction between the cuticular and intercuticular cellulose, similar to that which is made between the amidose and granulose in starches.

The intercuticular substance, which, as remarked, constitutes the bulk of the fibre, consists, according to my observations, of minute spherical granules of nearly uniform size (about 1 μ). I attempted to see them *in situ* by obtaining longitudinal sections of the cotton fibre. The difficulty of obtaining such sections was very great, due to the resistance of the cotton, which was liable to be struck by the knife and dragged through the substance in which it was embedded. I have, however, succeeded in obtaining longitudinally cut fragments, some of which had one of the cuticles removed revealing the intercuticular substance (see Fig. 4). The intercuticular granules lie closely packed, kept in position by the cuticles, and it is only when the tension of these is sufficiently relaxed that the granules can escape.

The well known fact that cotton depolarises and shows, when examined by polarised light, brilliant colouring, seems due to differences in the relative tension or strain of the layers. Longitudinal sections through the cotton fibre still show depolarisation, except where the knife has torn off fragments of either of the cuticles. In fact as long as the two cuticles remain in position the full effect of depolarisation is visible. Precipitates of cotton and nitrated cotton from filtered solutions do not depolarise. The differences of appearance in polarised light observed when the cotton fibre is treated in various ways, including nitration, must no doubt be ascribed primarily to a change in the relative tension or strain of the layers. I mean a similar condition to that which causes annealed glass to depolarise and show differences of colour according to the strain.[*] The optical properties of cotton and nitrated cotton, the appearances in polarised light, their rotatory power, and the refractive index, form a subject so large that it cannot be discussed within the limits of this paper.

It is to osmotic action of the cuticles in conjunction with the capillary action of the tube, that the penetration of dyestuffs into the fibre is ascribed. This theory, which seems to be generally accepted, was originated by Walter Crum, F.R.S. He points out, however, that the most powerful microscopes did not reveal any pores in the cotton fibre (J. Chem. Soc., Vol. I., p. 409). He seems to have seen a difficulty in admitting that the mordants and dyes penetrated the intercuticular substance passing through a non-porous membrane. Now I find that the cuticle is extremely porous. It has pores in addition to what appear to be minute stomata, which latter are frequently seen in oblique rows as if they led into oblique lateral channels.

Many of the corrugations, striations, and indentations which the microscope reveals in the cotton fibre, can, with proper preparation of the slides and with high magnification be resolved into pores and oblique rows of stomata. (See Figs. 1, 2, 3.) Once observed with high magnification, the pores and stomata can be seen with somewhat lower powers as is often the case in microscopy: the knowledge of that which can be seen assisting the eye. The pores and stomata can be seen with more or less distinctness in any

cotton fibre—every fibre varying somewhat in this respect—with a homogeneous oil immersion objective and a × 6 ocular. They are more distinctly seen if the fibre is stretched or strained on the slide, staining or dyeing does not seem to render them more prominent; the only method by which I have been able to bring them out more distinctly is by treatment with nitrate of silver.

Fibres digested with pepsin and tripsin did not show the pores and stomata more plainly, nor did treatment with hydrofluoric acid materially assist me. In mercerised cotton the pores and stomata are somewhat more distinct, and digestion with alum or tannic acid seems to enlarge the former to some extent. When the fibre is nitrated the pores frequently become larger. In fragments of cuticle obtained from solutions in cuprammonium, as explained later, the pores and stomata can be seen (see Fig. 5, in which the stomata are marked *a*).

It may here be stated—as I have not seen it recorded—that according to my observation single isolated cotton fibres have no capillary action; several fibres must be in contact before the liquid will rise. The liquid seems to rise between the fibres and then to enter the fibre through its pores. I have experimented with various aniline dyes and also with vanadic chloride, potassium bichromate, and permanganate.

2. *The Minute Structure of the Nitrated Cotton Fibre.*—Nitration produces in the cotton fibre but little apparent structural change. The tube collapses and the corkscrew twists flatten down to such an extent as to be unrecognisable, so that the nitrated fibre presents, as a rule, a tape-like appearance with rugosities there where the twists occurred. The outer cuticle appears still more wrinkled (see Fig. 5). The intercuticular substance remains practically unchanged, unless it be that the granules are somewhat larger. It is extremely difficult to verify this, as I have not been able to measure the granules of either cotton or nitrated cotton *in situ*, but only when precipitated from solutions.

That the relative tension of the layers decreases materially is seen in the marked difference in the appearance in polarised light, the nitrated fibre appearing dull as compared with the brilliant colours shown by the natural cotton fibre. Cotton and nitrated cotton which has been pulped, shows, when examined by the microscope in ordinary light, that the pulping partially opens the fibre. This is especially the case with the nitrated fibre, the granules frequently becoming visible at the ends.

A. *Solutions of Cotton.*—Before considering the question of solubility, it may be permissible to refer to the question of cotton considered as a seed-hair. A considerable amount of study has been devoted to ascertaining the changes which cotton undergoes during growth, reference to which will be found in the above-mentioned books, but no satisfactory explanation seems so far to be given to the change which the proteid contents of the cells undergo in order to become cellulose. Evidently the granular intercuticular substance s a modification of the granular contents of the cell which Mann* has referred to as *cytoplasm* and Heidenhain has termed *microsomes*; they probably correspond to that which Dippel terms the *intercellular substance* of the fibre cells.†

Text books on botany contain but few references to seed hairs, beyond stating generally that their object is to waf he seed, and enable it to be carried by the wind until it finds a suitable resting place. My attention has been drawn to the part which the hygroscepicity of cellulose may play in the utility of the seed hairs, and the suggestion has been made that when the weather is moist the seed hairs become limp and prevent the seed from being blown away and deposited on the wet soil, because it is essential hat the seed should settle on dry ground and enter the earth without exposure to the damaging action of moisture.

Cross and Bevan, in their classical work on Cellulose,‡ state that cellulose is insoluble in all simple solvents; in he presence of certain metallic compounds, however, it combines rapidly with water, forming gelatinous hydrates which finally disappear in solution. There are three such solvents for cellulose—(1) zinc chloride in concentrated aqueous solution which requires heating; (2) zinc chloride and hydrochloric acid which dissolves cellulose in the cold; and (3) ammoniacal cupric oxide, or Schweitzer's reagent. The process of dissolution of cellulose is ascribed by these authors to the presence in the cellulose molecule of OH groups of opposite functions, basic and acid, the compounds formed with the solvents being, according to them, of the nature of double salts.

A distinction should, I think, be made between solutions in zinc chloride with or without the addition of hydrochloric acid and those in cuprammonium. With the former a clear solution cannot be obtained from which the cotton can be regained quantitatively, whilst with the latter it can. I have found a distinct difference between cotton regained from solutions in zinc chloride or zinc chloride and hydrochloric acid as compared with that from solutions in cuprammonium. Zinc chloride both with and without the addition of hydrochloric acid destroys the structure, and neither the granules of the intercuticular substance nor fragments of the cuticle can be found in the restored cellulose. In the cotton regained from a cuprammonium solution the granules are preserved and the fragments of cuticle are present.

Dr. Lottermoser, in a recent publication on colloids,* after mentioning the hydrosols obtained by Graham with sugar and metallic hydroxides, and the colloids obtained by Grumaux (Comptes rend., **98**, 1485), by means of organic compounds containing hydroxydes and alkaline solutions of metallic hydroxydes, refer specially to Grumaux's (Comptes rend., **98**, 1540), investigations on cuprammonium as follows:—

"In dialysing Schweitzer's reagent the excess ammonia together with a considerable amount of blue salts passes into the water. After six or seven days no copper can be found in the latter. The dialyser contains a blue fluid which will not pass through the membrane, and from this copper hydrate can be precipitated by adding water freely, and it gelatinises on the addition of acids and a number of salts, with the exception of sodium chloride and sodium nitrate. The fluid which remains in the dialyser is really the solvent for cellulose. If cellulose is dissolved in Schweitzer's reagent and dialysed, blue salts likewise go over with the ammonia, and the colloid remaining in the dialyser is much lighter in colour and contains all the cellulose. The cellulose is precipitated by the addition of water, but enters into solution again on the addition of a few drops of ammonia."

I have repeated Grumaux's experiment and examined the dialysed cotton, after freeing it from copper by means of acetic acid. I find that I can distinguish the granules and fragments of the cuticles. I also find the granules and fragments of cuticle in precipitates from cuprammonium solutions of cotton. When hydrochloric acid is used to neutralise the cuprammonium and remove the copper, the granules are frequently seen embedded in a white transparent stellate or nodular crystalline mass, which I have identified micro-chemically as cuprous chloride. It may be that this led Gibson† (Chem. Centralbl., 1893) to state that cellulose may be crystallised from its solution in cuprammonium. He used hydrochloric acid.

If acetic acid is used to precipitate the cotton and to remove the copper, the precipitate, when washed, shows the granules and cuticles without any crystalline nodules, acetic acid removing the copper more thoroughly than hydrochloric acid. This is no doubt why Pauly in his patent (Eng. Pat. 28,631 of 1897) indicates the use of acetic acid in the manufacture of artificial silk by means of a cuprammonium solution of cotton. The slightest trace of copper would adversely affect the dyeing of the yarn. In order to wash the very flocculent precipitate I found it easiest to allow it to settle, and to decant the supernatant liquid, adding water and acid; repeating this until all the copper

† See Cross and Bevan: "Cellulose." p. 12.

was removed. A centrifuge expedites the operation. It is very difficult to distinguish the granules and cuticle fragments in the dried precipitate. I leave the precipitate in suspension, draw off the water with the suspended particles by means of a pipette, and allow a few drops to dry slowly on the slide.

If cotton fibres in course of dissolution in cuprammonium are freed from copper and washed, it will be seen on microscopic examination that the granules gradually become freed and washed out as the cuticles yield to the swelling of the fibre. The fibre swells and bursts, thus liberating the granules, and it takes some time before the cuticles themselves break up into minute fragments and enter into solution.

All my solutions were filtered through glass-wool, as particles of spun glass are easily recognisable in the microscopic preparation, which would not be the case if a fibrous substance were used, as, for instance, asbestos. Moreover, most of the filtering media which suggest themselves have the disadvantage of depolarising, vitiating results when polarised light is used.

B. *Solutions of Nitrated Cotton.*—Acetone seems to be the only solvent for all nitrated cottons without distinction. It has been referred to as the *universal* solvent in contradistinction to the *selective* solvents which dissolve only certain nitrated cottons. I have watched the patent literature carefully for years and obtained a list of solvents, which I have been able to extend through the courtesy of Mr. Oscar Guttmann, who has placed a list of his own at my disposal. It will be found appended to this paper.

The effect of some of the solvents mentioned seems very doubtful, and there is moreover in many cases a distinct difference between the pure and the commercial material. I have tested but few and have no evidence of the efficiency of the majority beyond that they are mentioned in a patent. The manner in which cotton has to be nitrated in order to be soluble in a given solvent has in each case to be closely investigated. In consequence of the very large number of selective solvents, and the different varieties of nitro-cellulose on which they act, it is quite impossible to establish any general rule as to the method to be followed in order to obtain suitable nitrated cotton. Moreover the solubility in any given solvent is no index of the solubility in another. We can, however, say with certainty to-day that the solubility is not a function of the degree of nitration. Cotton can, within certain limits, be nitrated to the same degree of nitrogen contents to be either soluble or insoluble in a given solvent.

The terms soluble and insoluble require qualification, as the nitrated cotton is as a rule neither entirely soluble nor entirely insoluble. A specification for nitrated cotton should give the percentage of nitrogen desired and the degree of solubility required, and should indicate the solvent. The viscosity should also be stated, as it varies materially with the method of nitration, being independent of the degree of nitration.

The classification of nitrated cottons according to their solubility in ether-alcohol is fallacious, as cottons can be nitrated to the same percentage of nitrogen to be either soluble or insoluble in ether-alcohol.[*]

There is a prevailing idea that the gradual changes in the conditions of nitration cause immediate transitions in the degree of nitration, thus justifying the distinction between di-, tri-, tetra-, &c., nitrocellulose, and attempts have been made to isolate such entities. But this discontinuity has now been proved to be non-existent.[†]

My experiments have been carried out with acetone, but I have, for comparison, made observations on solutions of suitably nitrated cottons in ether-alcohol, amyl-acetate, and acetic-ether.

If a solution of nitrated cotton, carefully filtered through glass-wool, is allowed to evaporate on glass, the resulting film appears granular under the microscope. I have prepared solutions ranging from 1 in 10,000 to 5 in 100, and found that the ½ per cent. solution (0·5 grm. of nitrated cotton in 100 grms. acetone) showed the granules most distinctly. They are arranged in strings or clusters which tend to mat together, and occasionally some isolated granules are seen. Focussing down, I can distinguish fragments of the cuticles, which, therefore, evidently settle first being, no doubt, heavier. Fig. 7 represents the appearance of the granules obtained by the evaporation of ½ per cent. solution. If the solution is more dilute the granules are more straggling and isolated, and many preparations have to be examined before cuticle fragments can be found. If the solution is more concentrated the clusters of granules lie so closely fused together as to make it difficult to identify them. In solutions of over 2 per cent. it is not possible to obtain a single layer.

With a little practice the dissolution of nitrated cotton can be watched with the microscope. I prefer an 8 mm. objective and a × 12 ocular on account of the longer working distance. I use a small open cell into which I place a little nitrated cotton, so as to fill the cell to about one-quarter of its capacity, and squirt a few drops of acetone into the cell by means of a fine long pipette fitted with a rubber ball. I must then rapidly focus upwards. If this is done, it will be seen that the acetone, so to say, washes the granules out of the fibre, and these granules float about in the fluid at a very great rate, seemingly attracting and repelling each other, turning round on their axes, and ultimately settling in strings and clusters. The movements of these granules are analogous to Brownian movements, for even when the stage of the microscope is considerably inclined, they travel upwards as well as downwards and laterally. The manner in which the granules settle varies with the nature of the solvent, and is dependent on the rate of evaporation. The stratification of the granules and cuticles, therefore, varies with the solvent. This may account for the great difference between smokeless nitrocellulose powders in the manufacture of which different solvents have been used.

Whenever a solution of nitrated cotton is filtered through a dense medium, the remnant which remains in the filter and will not pass is of greater viscosity than the original solution. A 1 per cent. to ½ per cent. solution, according to the nature of the nitrated cotton as regards viscosity, can to a considerable extent (about 80 per cent.) be drawn through a Pasteur filter. When then is done the filtrate will be found to contain granules only; all the cuticle fragments, as well as a portion of the granules, remaining in the more viscous remnant. Considering that the granules in the filtrate measure very nearly 1 μ, it is difficult to see how they can pass through a Pasteur filter. It was suggested to me at the Pasteur Institute in Paris that this was only possible on the assumption that the granules, yielding to pressure, elongate, and pass through with a considerably reduced diameter.

It is well known that water precipitates nitrated cotton out of solutions, and that the resultant precipitate frequently assumes so fibrous an appearance that, to the unaided eye, the cotton fibre seems to have been restored to its original form. I have carefully examined these precipitates microscopically, and find that they show a felting of the cuticle fragments to which the granules adhere. Remarkable to say, the precipitates obtained from solutions of unpulped nitrated cotton in water seem more fibrous and much more like the original cotton to the naked eye than those obtained from nitrated cotton which has been pulped. The microscope shows differences in the size of the cuticle fragments. Precipitates from solutions of 2 per cent. or under of cotton nitrated at high temperatures scarcely coalesce or felt at all; they are flocculent or are thrown down as a fine powder. The reason for this is evidently that the acids having disintegrated the fibre to a much greater extent, the cuticles break up in the solution into much more minute fragments than is the case with cottons which have been nitrated at lower temperatures. When solutions which have passed through a Pasteur filter, and which, as we have seen, contain granules only, are thrown into water, the precipitate comes down as a fine powder.

When dried, all felted precipitates cake and harden, and are then so friable that it is difficult to examine them microscopically with transmitted light. They must, there-

---

[*] See Dr. Dupré's remarks on p. 22 of H.M. Inspectors of Explosives Report. 1898.

[†] Dr. Will: "Der Fortschritt der Sprengtechnik," Ber., 37. 1904.

fore, be teased out while wet, preferably in glycerin. Precipitates obtained by means of water from solutions of suitably nitrated cottons in ether-alcohol and acetic-ether do not differ materially from those obtained from acetone, except in the rate at which they coalesce. When the solvent is not miscible with water, as in the case of amyl acetate or nitrobenzene, for instance, the precipitate coalesces with great difficulty.

It would seem as if this felting of nitrated cotton from solutions is one of the reasons why it has been found more suitable for certain industrial purposes than other celluloses. This felting appears to be a function of the cuticles. Cotton partially dissolved in cuprammonium will felt like paper. The fact that the original condition of the nitrated cotton influences the final product, and that unpulped nitrated cotton shows more fibrous felting than pulped, may account for the fact that unpulped nitrated cotton is used in the manufacture of artificial silk to ensure greater tensile strength.

A great deal of work has recently been done on hydrosols, both organic and inorganic. Graham and others have studied colloids of inorganic substances in organic menstrua, but I cannot find any investigations on a colloid in which both the solute and the solvent are organic, as in the case of solutions of nitrated cotton, all the solvents for which are organic.

The difficulties of the present investigation are increased by the fact that we are dealing with a substance the structure of which is apparently partially retained in solution. The solid solution of nitrated cotton in camphor still further adds to these difficulties. I have so far been unable to detect any structure in nitrated cotton extracted from celluloid.

Are we to regard these solutions as colloids, as suspensions of finely-divided particles? The microscopic examination of films and precipitates certainly points in that direction. That no particles can be seen in the solutions does not, I think, militate against that view. It is true that according to Lottermoser particles must be smaller than 0·5 μ to be microscopically invisible in solution and our particles are much larger. But surely the detection of minute particles in a liquid does not only depend upon their size, but also on the relative refractive indices of the suspended matter and the liquid. In our case, the liquid soaking into the particles of nitro-cellulose influences the relative refractive indices, decreasing the likelihood of visibility. Moreover, even in a ½ per cent. solution of nitrated cotton which has been filtered by a Pasteur filter, a slight turbidity can be seen with proper illumination and a sufficient thickness of layer, as, for instance, in the 20 cm. tube of the polarimeter.

On the other hand, we must not forget that the solutions can be filtered through dense media, but I have not yet attempted dialysis. It was Tyndall who first pointed out that a ray of light, concentrated by means of a lens, if allowed to pass through a colloid, and examined with a single Nicol prism, will be found to be polarised. A test for colloids has been based on this fact, but there are some exceptions. I find that solutions of nitrated cotton in acetone, ether-alcohol, or acetic-ether do not polarise the ray.

I may further mention that no separation occurs when solutions of nitrated cotton are placed in a centrifuge of the milk separator type, neither does this occur with a solution of cotton in cuprammonium. Evidently the question cannot be decided without further research.

Solvents for Nitrocellulose mentioned in Patents.

Nitric acid at 80° C.

Sulphuric acid.

Methyl, ethyl, propyl, butyl, isobutyl, and amyl alcohols.

Methylal, acetal, isovaleric aldehyde, and its derivatives, and other aldehydes; acetone, diethyl ketone, propione, dibutyl, dipentyl, methyl-ethyl, methyl-propyl, methyl-butyl, methyl-amyl, ethyl-butyl ketones.

Ethyl ether at low temperatures (−100°, below freezing point of 95° alcohol), amylidene-dimethyl, and amylidene-diethyl ethers. Methyl-amyl ether.

Glacial acetic acid, butyric acid.

Alkyl sulphuric acid, hydrochloric and nitric esters, amyl nitrate, nitrates of methyl and amyl.

Nitroglycerin, nitromannite.

The methyl, ethyl, propyl, butyl, and amyl esters of the following acids:—Formic, acetic, butyric, valerianic, lactic, oxalic, succinic, sebacic, tartaric, citric, and their nitro, chloro, bromo, chloronitro and bromonitro, acetyl and benzoyl derivatives.

Alkyl esters of acids acting on fats and oils, and their soaps.

Alkyl esters of adipic, pimelic, suberic, azelaic, and glyceric acids.

Acetine, chloracetate of chloramyl.

Glycerides of acetic and hydrochloric acids, such as acetodichlorhydrin, and diacetochlorhydrin.

Ammonia dissolved in ethyl ether.

Methyl, ethyl, propyl, butyl, isobutyl, and amyl alcohols mixed with any of the following:—

(*a*) Methylic, ethylic, propylic, butylic, amylic ether.
(*b*) Aldehydes, such as acetaldehyde, and their compounds with alcohol, such as methylal, acetal, &c.
(*c*) Acetic, lactic, levulinic, oxalic, tartaric, citric acids.
(*d*) The esters of the acids mentioned under (*c*).
(*e*) The salts of the acids mentioned under (*c*), also the salts of hydrochloric or alkylsulphuric acid, with ammonium, sodium, potassium, magnesium, calcium, strontium, barium, aluminium, and zinc, provided the salt is soluble in alcohol.

Polyhydric alcohols, such as glycol and glycerol, mixed with the esters of acetic, lactic, levulinic, oxalic, tartaric, and citric acids.

Palmitone and stearone in alcoholic solution.

Impregnation with alcohol, then dissolving in caustic alkalis, or sulphides of sodium, potassium, or ammonium.

Benzine.

Wood naphtha, distilled over calcium, zinc, or manganese chloride.

Ozonised methyl alcohol, fusel oil, acetone, acetal, ethyl amyl ether.

Methyl alcohol, amyl alcohol, benzine and acetic acid, distilled together.

Benzol, aniline, pyridine.

The nitro, chloro, bromo, chloronitro, and bromonitro derivatives of aromatic hydrocarbons.

Acetylated and benzoylated secondary aromatic amines.

Solid ketones (methylnaphthylketone, dinaphthylketone, and the corresponding derivatives of naphthol, or the ethers of these ketones).

Benzylidene acetone.

Paranitrobenzaldehyde.

Phthalic and phthalonic acids and their anhydrides.

Coumarin.

Benzicine.

Phenol and naphthol esters of inorganic acids.

Methyl, ethyl, propyl, butyl, and amyl esters of:—Benzoic, toluic, mesitylenic, hippuric, and phthalic acids, and the nitro, chloro, bromo, chloronitro, and bromonitro derivatives thereof, and their acetyl and benzoyl derivatives.

Esters of the nitrophenols.

Phenolic esters and derivatives of mono- and poly-valent aliphatic acids, such as carbonic, formic, propionic, tartaric, and citric acids. (Diphenylcarbonic ester, naphtholpropionic ester, dinaphthylcarbonic ester, diacetyl resorcinol, acetylnaphthol, acetylchloronaphthol, acetylnitronaphthol are mentioned.)

Phosphoric acid esters of halogen or similar derivatives of the phenols, cresols, and naphthols. Thiophosphoric acid esters of the phenols, cresols, naphthols, and their substitution products. (Triphenyl and trinaphthylphosphate, monochlortricresylphosphate, tetranitrotrinaphthylphosphate, tricresylthiophosphate, dichlorodiphenylthiophosphate, dinitrotrinaphthylthiophosphate are mentioned.)

Esters of phthalic and phthalonic acids.

Glycerides of benzoic and hippuric acids.

Anilides and their homologues (formanilide, acetanilide, acetotoluidide, acetoxylidide).

Acidyl derivatives of secondary amines, containing only aromatic radicles. (Formyldiphenylamine, acetyldiphenylamine, acetylphenyltolylamine, acetylphenylnaphthylamine are mentioned.)

Alpha and beta naphthol, and anthraquinone in alcoholic solution.

Creosote.

Camphor.

Nitro, chloro, bromo, chloronitro, and bromonitro derivatives of camphor.

Thujone.

Pulegone (oil of pennyroyal).

Oil of camphor.

Ozonised oil of turpentine, oil of camphor, and oil of caraway seed.

Artificial camphor (terpenes in alcohol).

Nitrated resin oils and resins.

Camphor dissolved in sulphurous acid, carbon bisulphide, carbon tetrachloride, hydrocarbons, alcohol, and ether.

Methyl, ethyl, propyl, butyl, isobutyl, and amyl alcohols mixed with—

(*a*) Aldehydes, such as benzaldehyde, and their alcohol derivatives.
(*b*) Nitrophenols, aminophenols, and hydroxybenzoic acids.
(*c*) Nitroderivatives of aromatic hydrocarbons which are soluble in alcohol.
(*d*) Pyridine, quinone, and their homologues.

Acetone oils mixed with benzaldehyde.

Mixed esters and anilides of phosphoric acid from alcohol, or anilide radicles and phenol, cresol, or naphthol.

Note.—Since reading the paper I have succeeded in dialysing a 5 per cent. solution of nitrated cotton. After 24 hours a sufficient quantity had passed through the parchment diaphragm into the external acetone to show a film on glass and give a water precipitate.—H. de Mosenthal.

Discussion.

Sir William Ramsay said the phenomenon of Brownian motion always took place with excessively small particles, but they might conceivably be too small to be visible, and yet be revealed by the polarisation of light. But, going a stage further, it was possible to imagine particles still smaller and not able to polarise light, owing to their minuteness, but still giving rise to very rapid Brownian motions. The question of the passage of such a solution through the Pasteur filter was a very curious one indeed. Messrs. Linder and Picton, in their laboratory, had made a number of experiments on the passage of various dyes through a Pasteur filter. A blue dye of very high molecular weight would not pass through the filter, the molecules being too large; a kind of separation was made of substances according to their molecular weights, some of which would pass and others would not. In this case, evidently, the cotton must have a sufficiently small molecule—curious as it might appear—to pass through the filter; or else, conceivably, the particles must deform themselves and glide through as worms, reverting to the shape of balls on the other side, which did not seem likely. Another possible means of investigation would be by measuring the osmotic pressure. Of course there was no possibility of measuring it by means of lowering the freezing point of the solvent, but it could be measured directly; the difficulty would be to keep the temperature perfectly constant, for the instrument acted as a thermometer. Still, *faute de mieux*, some method of this kind might perhaps be useful in further experimenting.

Dr. Robertson said he could confirm the statement made by the author, namely, that great differences in viscosity could be obtained with nitrocottons of the same nitrogen content and the same solubility, according to the method of nitration employed. Using a viscosimeter differing from the one with which the author had worked, and in which the dilute solution in acetone was passed through a very fine aperture in a pipette, and measuring the time of discharge, he observed that nitrocotton containing 13·2 per cent. of nitrogen and having a solubility of 3 or 4 per cent. made by two different processes varied in viscosity to as great a degree as 1 to 6.

Dr. Silberrad said that he could not agree with the author in his view that nitrocellulose was not a mixture of *definite compounds*. In support of his view the author referred to the fact that the viscosity constants of various samples of nitrocellulose, prepared under different conditions, differed even though the percentage of nitrogen were the same in both samples; he also referred to the property of selective solvents, as ether-alcohol, pointing out that they would dissolve one sample but not another, even though both had the same nitrogen content. Both facts were equally well explained on the assumption that the nitrocellulose was a mixture of definite compounds. In the case of the sample soluble in ether-alcohol they were all of approximately the same degree of nitration. From experiments he had recently carried out on heating nitrocellulose under such conditions that the active mass and the volatile catalysers were maintained at a minimum, he had found that the inherent velocity of decomposition at a high temperature for a sample of medium nitration soluble in ether-alcohol was peculiar to itself, whereas the results obtained with the insoluble sample coincided very closely with those obtained from a sample of the same nitrogen content made by mixing together samples of very low nitration and very high nitration, both of which were insoluble in ether-alcohol. Thus he deduced that the sample soluble in ether-alcohol was a mixture of nitrocelluloses of nearly the same degree of nitration, whilst the sample insoluble in the selective solvent consisted of a mixture of high and low nitrated cottons.

Prof. Hodgkinson did not consider that they were quite in a position to discuss the nitration problem at present. He did not know really whether he believed that there were definite stages of nitration (that is, definite nitrates), or whether this went on, as Prof. Will said, gradually, so that any intermediate stage or degree of nitration could be arrived at. As the result of some recent experiments he was rather inclined to Will's idea.

Mr. Oscar Guttmann pointed out that there was no definite stage of nitration, but a gradual merging of the percentage of nitrogen from low to high. This statement was made first by himself in the Chem.-Zeit. of 1901, and Prof. Will referred to it in a footnote. It had, however, been disputed by Dr. Silberrad. He would only say that there was quite as much evidence, and in fact far more, the other way, namely, that the nitrates of cotton were not mixtures. The fact mentioned by Mr. de Mosenthal that there could be nitrocelluloses of the same percentage of nitrogen, one completely soluble and the other completely insoluble, pointed distinctly to the impossibility of their being a mixture. With regard to the dissolving action of a certain number of solvents, he was in the same position as Mr. de Mosenthal. He had not tried nearly a quarter of those mentioned, and he had to take them on trust. But the facts mentioned with regard to the different solubilities of pulped and unpulped cotton and the use of the latter for making artificial silks had been strikingly illustrated to those who had had the opportunity of seeing that manufacture. When they saw how the fibrous nitrocellulose was dissolved by merely tumbling it about in the solvent, and that, in spite of the solution being fairly clear, there could be filtered out through special filters a large quantity of material which would otherwise obstruct the very fine apertures of the so-called silkworm, namely, the glass tube which served for spinning, they would find that the solution, however carefully made, and however powerful the solvent might be, was never quite a perfect one. In fact, he doubted whether in filtering through a Pasteur filter a 2 per cent. or even a ½ per cent. solution it would not be possible by repeated filtering to still retain further fibres. When it was considered that solutions made for the purpose of artificial silk were much stronger, so strong, indeed, that considerable pressure had to be applied to drive them through the filter, it could be seen that this became a very intricate problem.

Mr. Cross said that cellulose was a substance which combined in a very definite way with negative groups, giving, *e.g.*, the tetracetate, trinitrate, and dibenzoate; not only very wide chemical variations from the original sub stance, but each was convertible into a regular solid of controlled dimensions, threads, and films, the physical constants of which could be definitely measured. Such comparisons constituted a scientific basis of investigation of the first order. He might mention one fact. Bronnert (Rev. Gen. Màt. Col., 1900) took a skein of cotton of certain dimensions and measured its breaking strain. After being fully nitrated the gross breaking strain had scarcely altered. In other words, the cellulose had combined with 70 or 80 per cent. of a highly negative residue, such as the NO_2 group, and still had not sensibly altered its visible structure, nor, in a sense, the fundamental structure and properties of the substance itself. This was true also of the acetate. Cellulose could be combined with 80 or 90 per cent. of acetyl, and the resulting acetate retained the properties of the original cellulose. Similarly, the water soluble forms of cellulose, for example, the xanthate, were convertible into regular solids. The instance of a substance like cellulose, combining with 80 per cent. of nitric acid, without fundamental structural change, might be contrasted with the case presented by an inorganic basic hydroxide of colloidal character, where the immediate result of combination with nitric acid was an entire structural change and an alteration of the whole internal constitution. On the other hand, the cellulose, under similar conditions, retaining all its structural properties unchanged, would appear to show that they were independent of hydroxyl groups, and depended on some aggregate, which was probably a high aggregate of the carbon atoms of the cellulose, and that was retained or persisted, throughout cycles of chemical actions of severity, such as in the production and decomposition of the xanthate. The author had dealt with the subject from his point of view in an extremely practical and suggestive way, and he only hoped that he would extend his work on the lines that he had laid down with regard to nitrates, to the acetates, benzoates, and other derivatives, and would associate himself with those who were endeavouring to bring this very important scientific problem within the range of modern methods.

Dr. GOLDSMITH said all workers in nitrocellulose would be indebted to the author for this paper. It would be impossible to pass in review the large number of solvents he had compiled, but they differed greatly in their solvent power. For instance, camphor dissolved in carbon bisulphide was not a solvent for nitrocellulose. With regard to the viscosities of colloid solutions, Prof. Quincke had been determining this property, and found it varied in the first few hours after the solution was prepared, before it obtained a constant value. The colloid solutions he was referring to, gelatin and water, and also albumin and water, behaved really as though there were two solutions with mutual surface tensions against each other, and also as if there were threads of a thick solution swimming in a thinner one. He referred also to the fact, which seemed to be universal with colloids, that at the beginning of solution there were two solutions actually visible; the more concentrated solution containing perhaps 90 per cent. of the solid colloid and 10 per cent. of the solvent, and a thin solution containing 10 per cent. of the solid colloid and 90 per cent. of the solvent. In the celluloid industry there were experiments recorded where the nitrated cotton fibre had entirely disappeared for months and then reappeared again. The nitrated cotton might have been dissolved and passed into a perfectly transparent sheet, but under the conditions of these experiments, one saw after some months ghosts of nitrated cotton fibres, which gradually materialised more and more, and finally the sheet became quite opaque from intersecting fibres of precipitated nitrated cotton. A subsequent examination showed that there was a great alteration in their properties. For instance, this precipitated nitrated cotton did not depolarise. With regard to examining the solutions of nitrated cotton in different solvents, an apparatus might be found very useful which was exhibited at the Deutsche Naturforscher-Versammlung last year by Zgismondy, and described as "an apparatus to render ultra-microscopic particles visible."

Dr. JOHNSON said he had had a very small share in assisting his friend Mr. de Mosenthal in his work, and it was rather in self-defence he should like to make a few remarks. The chemist was apt to regard the cotton fibre as an agglomeration or collection of molecules of cellulose which were more or less structureless and which became fused together to form the cotton fibre, but from a physiologist's point of view the case was very different. No doubt they recognised in the illustrations that a certain number of small apertures to which they had given the name stomata were to be seen, but some people might be inclined to challenge the assertion that they were stomata, and ask what evidence there was that they were holes at all and not minute specks of dirt on the specimen. That remark might have had great force a great many years ago at the time when Schleiden and Van Baer discovered the cell, and that all organic bodies, vegetable or animal, consisted of a great accumulation or agglomeration of cells. About 1874 it was discovered that the cell—so far from being what physiologists had previously thought, a simple collection of inorganic particles, a mere mass of protoplasm or cellulose or albumin—was an extremely complex body, and it was on these lines that Mr. de Mosenthal thought that with extreme care and by examination with the microscope he could find some differentiation in the cotton cell. In fact they were both quite prepared to find such stomata, or at any rate to find some differentiation of structure in the fibre, and from having seen these stomata in wood fibres, in every case they naturally concluded it might be quite possible to find them in the cotton fibre, and were not at all surprised when they saw them in many specimens. He did not think they had ever been seen before, but they had both of them seen them in so many specimens that there could be no doubt that cotton fibre did contain a very large number of stomata. He should not be at all surprised if Mr. de Mosenthal were to find that the fibre revealed even other things quite as interesting as the stomata.

Dr. DIVERS said with regard to the question of the nitration of cellulose not consisting in the formation of definite compounds, he could not see the force of the arguments brought in favour of its being a continuous process. No doubt, as Mr. Cross pointed out, cellulose was such a remarkable substance, and of such very great interest to chemists and others from its nature, that it was very dangerous to generalise about it; but still the facts brought forward by the author, and confirmed by others, that there could be obtained by different kinds of treatment the same cotton nitrated to the same extent, and yet quite different in its chemical behaviour with regard to solvents, &c., were almost decisive proof that both nitro-cottons were mixtures of differently nitrated cellulose, one being a mixture of highly nitrated with very low nitrated cellulose, and the other being a mixture of nitrocelluloses that more nearly approached each other. He did not see how otherwise there could be an explanation of that fact. He gathered that Sir William Ramsay hardly believed in the possibility of these microscopic granules of cellulose passing through the pores of a Pasteur filter by elongating themselves. But it seemed to him the most natural thing that under pressure they would thus elongate and pass through. Many of them knew that the leucocytes of the blood did pass in that way through the membrane of the capillaries without there being any visible pore by which they did so. It was possible to see them pass by that system of elongation under the microscope, and he thought that was almost the only explanation of the passage of these cellulose granules through the Pasteur filter. He asked whether the author really believed that his cellulose structures did enter into solution in the zinc or copper solvents. According to Mr. de Mosenthal, what had once been cuticle became dissolved, ceased to have any structure, and then was precipitated as cuticle. That seemed to him utterly impossible. He thought the particles must only have become transparent and invisible, owing to the refrangibility of the solvent, and the substance being practically identical. All the solutions exhibited were quite distinctly opalescent, in spite of their wonderful clearness, considering what solutions they were, and he thought the experiments and the photographs which had been shown only served to support the position for which he contended, that the cellulose did not enter into a true solution.

Mr. ARTHUR MARSHALL pointed out that the experiments in which cellulose was precipitated from solution in a fibrous state could be repeated with other colloids, which originally possessed no fibrous structure. For instance, if gutta-percha was dissolved in chloroform or benzene, and the solution poured into alcohol, the gutta-percha would be precipitated in a fibrous state, which might not be exactly the same as that of the cellulose exhibited by Mr. de Mosenthal, but certainly was not very dissimilar. No doubt the same result could be obtained with other colloids, showing that these substances have a tendency to form strings or fibres under these conditions. The interesting phenomenon that guncotton, which had been subjected to different physical treatment, gave solutions of different viscosities, also had its parallel with other colloids. If indiarubber were worked too much upon the rolls, many of its valuable properties were destroyed, although its chemical composition remained the same, as far as could be judged. It was evident then that these were properties of colloids in general rather than of cellulose in particular.

Prof. Mills said that when experimenting a number of years ago (1881): "On the Ascent of Hollow Glass Bulbs in Liquids," he had observed that the state of ascent was inverse to the diameter of the cylinder used for the experiment. In his own case the rule ceased to apply at a diameter of four inches. Tubes of one inch in diameter, like those used by the author, would give results much too high for the very viscous liquids he used, and were probably five inches too small, though they might not be without a certain value comparatively. As bearing on the question of viscosity itself, he might mention that castor oil did not immediately regain its viscosity after heating, but, in his experience, took about 24 hours to recover it. It was also a known fact that when guncotton was dissolved in ether-alcohol for the purpose of making collodion, months were required before the substance dissolved became properly associated with the solvent. Differences in viscosity would depend on variations in the method of preparation, on the antecedent temperature, and on the time given to a solution to "ripen."

The Chairman congratulated Mr. de Mosenthal on his success in finding the stomata which had so long been overlooked by the many who had investigated nitrocellulose. He should much like to know how the photographs were obtained, for it was by no means an easy matter to observe a translucent substance such as cotton fibre; but perhaps it was dyed. With regard to the function of cellulose in nature, that went rather beyond their subject, but it was a very interesting one. He was rather inclined to think that instead of cellulose being nature's first material it was one of nature's final or waste products, and came as the derivative of many others. He thought they were wrong from the very beginning in treating it as a chemical entity as had been done in that room the whole evening. He never considered it one, but believed it was a compound substance of complicated structure. They had not determined the chemical constitution of cellulose, and until they did so they would not be able to explain the compounds produced from it. In certain circumstances they got, as Mr. Cross had shown, compositions of certain regularity; but on the other hand they had this remarkable fact, as had been ably pointed out, that they could get nitrocellulose not only of almost any stage of nitration between the limit terms, but in those stages varying degrees of viscosity could be obtained, showing that the substances dealt with were totally different, although the total nitrogen might be the same. They also knew that cellulose from various sources, although considered to be pure cellulose, still behaved very differently indeed when nitrated. The interesting disappearance of the twist in the fibre when nitrated was, he thought, due to the action of the acid and not to the nitration. There would be an important paper in a forthcoming number of the Journal by Professor Pope and Mr. Hübner, in which they showed that after mercerisation the natural twist of the fibre was lost and a straight fibre resulted when the concentration of the acid or alkali went beyond a certain percentage. He asked Mr. de Mosenthal why he did not use as a test of viscosity the rate of flow of the solution from an orifice. For many years he had used that method and always found it satisfactory; if dealing with an extremely thick liquid it was a different matter, but there were very few solutions that could not be diluted.

Mr. de Mosenthal remarked that many members had spoken about cellulose, while he had spoken about cotton; it was impossible in one paper to deal with the various forms of cellulose. He had made experiments with wood cellulose, hemp, and various other celluloses, and he thought it would be possible to show that there was a certain number which behaved in a very different way when acted upon by solvents. He considered from the first that he was dealing with a suspended substance so finely divided that it looked like a clear solution. But there were a number of points, as for instance the fact that the ray of light was not polarised, which led him to ask himself whether he was dealing with a real solution or with a pseudo solution. The question could no doubt be settled by dialysis and osmotic pressure, and he was obliged to Sir William Ramsay for indicating the manner in which this could be carried out. His difficulty, however, was to determine the osmotic pressure at a constant temperature when he was dealing with volatile solvents. He had tried to construct an apparatus, but had not so far succeeded, and he should be very grateful for any suggestion. The question of nitration, which had been mentioned by so many speakers—namely, whether these were mixtures or not—he was not prepared to go into at present. With regard to viscosity, he might observe that this again raised difficult problems, because after all it was believed that viscosity was directly connected with the size of the molecule. If they considered that by mechanical as well as chemical differences in the manufacture the viscosity was affected the question of the constitution of the molecule would arise. An investigator on this subject had recently said to him "We are much further away from the constitution formula of cellulose than we are from that of albumin."

THE PRODUCTS AND RELATIVE TEMPERATURE OF COMBUSTION OF SOME SMOKELESS POWDERS.

BY W. MACNAB, F.I.C., AND A. E. LEIGHTON.

Having had occasion to examine a number of smokeless powders, chiefly sporting, it is hoped that a short statement of the results obtained may be of interest to members of this society.

The sporting powders were purchased from a well known firm of gun makers. All the samples were analysed. The calorimetric determinations were made in a Berthelot bomb,

nd the products of combustion, measured and analysed s described in a paper published in the Proc. Roy. Soc., 6, 8 (see this J., 1894, 973). In all cases when deteriining the calories and products of combustion, 4 grms. of ach explosive were fired in the exhausted bomb, the apacity of which was 488 c.c. When the explosive ontained inorganic compounds the solid products of ombustion were not analysed. The relative temperature eached during combustion was determined by means of ie method described in the Proc. Roy. Soc., 65, 221 (see iis J., 1900, 466).

Briefly described, this method is a modified application f the thermo-electric pyrometer developed by the late ir W. C. Roberts-Austen, and consists in exposing a hodium-platinum couple in the interior of the bomb aring the combustion of the explosive, and by means of galvanometer, to which the couple is connected, ieasuring the deflection of a spot of light on a falling photographic plate. The deflection is directly proportional to the temperature to which the couple is heated. Although it is not claimed that the actual temperature developed during the explosion can be determined, yet a reliable comparison of the temperatures produced by the combustion of different explosives can in most cases be obtained. Before firing, the spot stands at the base line *a*; immediately after firing, the spot is deflected till the maximum is reached at *b*, when it slowly returns to its original position. The measure of the temperature is the distance *a b* from the base line to the highest point of the curve. The curve is the result of the combined movement of the spot of light and the falling photographic plate.

In the temperature experiments, 4 grms. of each explosive were fired in the bomb full of air, the same couple, 0·028 in. diameter, being used in each case. The following table gives the composition of the different explosives examined.

In regard to the sporting powders, they may be broadly ivided into two classes—those containing and those ithout metallic nitrates. The chief constituent of those owders is nitrocellulose, either in the form of nitrocotton : nitrolignin, and in the case of the first five on the table considerable quantity of metallic nitrates is present; nnonite contains a much higher percentage of nitrootton with a small amount of nitrate, shotgun rifleite is early pure nitrocotton with a small quantity of dinitrotoluene, walsrode is a pure nitrocotton powder, and sporting ballistite is composed of nitrocotton and nitroglycerin. The sample marked "Cordite" has the composition originally employed by the Government, while that marked "Cordite, M.D.," has the composition recently adopted in which the proportions of nitrocotton and nitroglycerin are practically reversed. The following table gives the calories, the quantity, and composition of the gases evolved :—

Name.	Calories per grm.	Permanent Gas c.c. per grm.	Aqueous Vapour c.c. per grm.	Total Volume of Gas calculated at 0 and 760 mm.	Percentage composition of Permanent Gas.

The powders have been arranged in the order of the mount of heat evolved, and it is worthy of note how omparatively similar are the results of the first six. As ie amount of nitrocotton increases the heat evolved also icreases, and a large increase takes place when nitrolycerin is present. In the case of the cordites the effect f the nitroglycerin from the point of view of the heat volved is greatly reduced by the introduction of vaselin. t will be noticed that as the heat increases the quantity of arbon dioxide also increases and the carbon monoxide nd hydrogen decrease, and a larger quantity of aqueous apour is formed. The table on next page shows the powders rranged in the order of the temperature developed. The ieasurements are in millimetres.

It will be seen from the table that the order of the powders according to the temperatures is, broadly speaking, the same as when they are arranged according to the calories. It was observed in these and other experiments that when the powder left no residue, either carbonaceous or mineral, the results were more uniform (see Walsrode, the Cordites and Sporting Ballistite), whereas in the case of shotgun rifleite there was a large carbonaceous, and in the other cases a considerable mineral residue, and as is seen the results are much less uniform; but in these experiments the order is practically the same whether the maximum or the mean figures are taken.

In the temperature experiments, the sporting powders were fired in the form of grain as supplied, but the two cordites were ground and sieved to the size as prescribed for the heat test, which gave grains of about the same size as the other powders.

A series of experiments, to study the effect of size of grain or form of the explosive on the temperature measurements, is in progress, and some interesting results have been already obtained, which it is hoped will form the basis of a future communication.

In conclusion we desire to express our thanks to Mr. T. P. Middleton for valuable assistance in carrying out these experiments.

Discussion.

Prof. **Hodgkinson** said the diagrams showed the quantity of carbon dioxide, carbon monoxide, nitrogen, and hydrogen, but he did not see any mention of oxides of nitrogen. Was any oxide of nitrogen noticed in these experiments?

Mr. **Guttmann** said it was remarkable that sporting ballistite should show a higher percentage of nitrogen than cordite, seeing that the former contained less nitroglycerin.

Dr. **Silberrad** said that the importance of estimating the pyrometric value of propellants with accuracy could scarcely be over-estimated, as undoubtedly their erosive properties depended to a very large extent thereon. Consequently as the method described by Mr. Macnab gave a ready way of comparing powders, it was of great value. It must, however, not be lost sight of that the method was purely empirical and measured the product of the temperature of the flame by the time of burning of the explosive under the conditions of the experiment, since the explosion was never of sufficient duration to raise the thermo-junction up to the temperature of the flame. Hence, it was necessary that the conditions of the experiment, the quantity of explosive, and its time of burning, should always be kept constant in order to obtain truly comparative results. He had carried out a large number of experiments on the pyrometric values of powders of all sizes, from small arms powders up to those used in 12-in. guns, and could not agree with Mr. Macnab on this point; he found that the effect of the size of grain had very little influence on the absolute pyrometric value. The products of combustion were the same and the maximum time taken for combustion was less than $\frac{1}{50}$th of a second for the largest size ammunition used in the largest guns fired under gun pressures. Then the question of pressure raised another point. His experiments, which had been carried out at pressures from 10—30 tons to the sq. in. (1,500—7,500 atmospheres), had indicated that pressure had a very marked influence, both on the nature of the gases produced on explosion and also on the pyrometric value of the powder; hence, to obtain really useful results pyrometric values should be determined at gun pressures. The practical value of this method, however, was doubtless far greater than one which necessitated very long and elaborate experiments, even if thereby one ultimately obtained absolute results.

Dr. **Robertson** asked if Mr. Macnab found any relation between his results and the absolute values, and if the latter were in accordance with the values deduced by using the most recent determinations of Mallard and Le Chatelier for the variation of the specific heat of gases at high temperatures, based on Sarrau's figures. He had recently worked with a bomb of much stronger material than that Mr. Macnab used, namely of gun steel $1\frac{1}{4}$ in. in thickness. He obtained very similar figures as regards the number of calories from cordite and cordite, M.D.; for example, at $\Delta = 0{\cdot}1$, 1,249 cal., for cordite, Mark I., and for cordite, M.D., 1,020 cal. By means of the figures of Mallard and Le Chatelier certain absolute pyrometric values could be deduced. One would like to get a confirmation of such values by some method on the basis of Mr. Macnab's elegant apparatus, if only it could be made absolute.

The **Chairman** asked if the vaselin had been identified in the composition of the powders in every case; he understood that in some of these powders the substance was not altogether vaselin, but other things were added. With regard to the method in general, they did get practical results with it no doubt, and they were extremely valuable and could be compared one with another; but, as Dr. Silberrad had pointed out, there were some difficulties when the results were compared with those obtained in practice; in the barrel of a gun or ordnance there was a gradually increasing space, whereas with the calorimetric bomb there was not. Again, with regard to the explosion, when air was present in the bomb a different result must be obtained than in a vacuum. Had Mr. Macnab compared the two conditions to see what the actual difference of temperature might be? In one case air was compressed by the gases produced, and in the other only the gases themselves were compressed.

Mr. **Macnab**, in reply, said that under the conditions in which the experiments were carried out they never found any trace of oxides of nitrogen, all the nitrogen appearing in the free state. Mr. Guttmann asked about the nitrogen in sporting ballistite being higher than in cordite. That came from the large amount of carbon monoxide and dioxide, due to the vaselin which diluted the gas. What Dr. Silberrad said about pressure was perfectly true. One knew the results obtained in the comparatively low pressure under which they worked in the Berthelot bomb were considerably modified when the explosive was fired under heavy pressure. Vieille had made a number of experiments showing how the amount of carbon dioxide in the total volume of gas increased and that of carbon monoxide decreased when fired under greater pressure, and there was no doubt that the temperature would be very much higher as measured by the pyrometer. With regard to the size of the grain, Dr. Silberrad said it did not seem to affect the pyrometric result. In certain conditions he found it had a very great effect, but he could not say more on that point at present. Dr. Robertson spoke about the absolute temperature. That of course was the object with which he was trying to work, but a great many unforeseen difficulties had arisen. All he could say was that he believed he was getting nearer to a solution of the problem, so that one would be able to say with some show of accuracy that the temperature was so many thousand degrees. It was certainly much to be desired that one could have some definite statement to make, but one could only work away and hope to get accurate results. With regard to the vaselin, they got a body which had all the appearance of vaselin, and one could safely call it a mineral jelly. The presumption was so strong it was vaselin that it was put down as such.

New York Section.

Meeting held at Chemists' Club, on Feb. 19th, 1904.

DR. VIRGIL COBLENTZ IN THE CHAIR.

GRAPHITIC ACID OR OXIDE.

BY FREDERIC S. HYDE.

The preparation of the yellow insoluble substance termed "graphitic acid," which has been described by Brodie, Berthelot, Staudenmaier, and others, and to which the ormula $C_{11}H_4O_5$ has been given (Mendeleeff's Principles of Chemistry), is, perhaps, one of the best illustrations of the derivation of an organic compound directly from elementary carbon—a link, as it were, between the organic and inorganic worlds. It is not only a characteristic derivative of graphite in distinction from other forms of carbon, but it is also noted for its peculiar instability, or power of deflagrating when subjected to a temperature just below a red heat, leaving a black, buoyant, sooty residue known as "pyrographitic acid," $C_{22}H_2O_4$ (Tidy's Handbook of Modern Chemistry).

Notwithstanding the somewhat indiscriminate use of the erms "acid" and "oxide," the expression "graphitic oxide" is usually applied to the grass-green substance obtained as an intermediate product during the transformaion of the graphite to the yellow acid. This "green oxide" likewise possesses the power to deflagrate when dry. It also represents a critical step in the transormation, its colour being indicative of the presence of graphite.

Staudenmaier's method of preparation evidently depends on he use of "puffed up" or expanded graphite (aufgeblähten Graphit); otherwise the operation might be prolonged for days, or even weeks. According to Staudenmaier, graphitic acid may be prepared in quantity in a short time, 24—48 hours (Chem. Centr., 1896, **69**, 258, and Ber., **31**, 1481—1487), without danger of explosion from chlorine dioxide, by mixing in a shallow porcelain dish at the ordinary emperature 1 litre of crude concentrated sulphuric acid and $\frac{1}{2}$ litre nitric acid (sp. gr. 1·4), and stirring into this mixture 25 grms. "puffed up" or expanded graphite ollowed at intervals by portions of dry potassium chlorate, 450 grms. in all. After testing with permanganate and acid to obtain a bright yellow colour, the whole is poured nto an excess of water, allowed to settle, and decanted. The green residue is thoroughly washed and heated with a solution of 7 grms. potassium permanganate in 120 c.c. water, o which, after cooling, 90 c.c. of dilute sulphuric acid (1:5) s added. The product, no longer green, is transferred to a porcelain dish and heated on the water-bath until the red coloration disappears, and then treated with hydrogen peroxide, stirring the mass occasionally, and allowing to stand awhile. The graphitic acid is washed with dilute nitric acid (1·28 sp. gr.), then with alcohol and ether, and dried. For small quantities it is suggested that 30 grms. of potassium chlorate be stirred into a mixture of 40 c.c. sulphuric acid and 20 c.c. nitric acid at a temperature of 20° C., and when nearly dissolved 1 grm. of graphite added and thoroughly stirred. It is stated that in five minutes it becomes bluish and greenish, and in about an hour it is sufficiently transformed to become yellow immediately with permanganate.

On trying this method the writer found that direct treatment of Ceylon graphite (200 mesh fine and 90 per cent. pure) failed to give satisfactory results, until the graphite itself had been subjected to a preliminary treatment to obtain the "puffed up" or Brodie's form; and even then it required 10—12 hours to become dark greenish, and (after renewing the chlorate mixture) two days before it was sufficiently transformed to yield the yellow product with permanganate and acid.

It is recommended not to oxidise more than 20—25 grms. graphite in the same dish at the same time, at a temperature above 20° C., especially in summer—simply a precaution against local overheating and collection of explosive gases in bulky solutions.

For rapid oxidation, Staudenmaier suggests a preliminary treatment of the graphite, using 300 c.c. crude concentrated sulphuric acid, 100 c.c. concentrated nitric acid (1·4 sp. gr.), 50 grms. pulverised Ceylon graphite, stirring in at intervals 100 grms. potassium chlorate, and allowing to stand several hours at the ordinary temperature. After thorough washing with water, the graphite so treated is heated to a glow in a large metal dish, so that it expands or "puffs up." When cool, the "puffed up" mass is stirred in water, and the floating portions taken for further oxidation. The writer found this treatment quite satisfactory, and far preferable to Brodie's dangerous method, in which sulphuric acid and chlorate alone are employed.

The general method adopted by Staudenmaier for preparing graphitic acid deserves consideration because of the substitution of potassium permanganate, sulphuric acid, and hydrogen peroxide to complete the oxidation. His method is, however, somewhat tedious and uncertain, and is also characterised by the excessive amounts of potassium chlorate required to produce the green oxide—nearly a pound of chlorate to every ounce of graphite oxidised. The fumes evolved on stirring the acid mixture are copious and very disagreeable, and even in small quantities seem to exert a depressing effect in spite of precautions for ventilation.

Staudenmaier's objection to Moissan's method consists mainly in the difficulty of preparing anhydrous nitric acid (monohydrate) in sufficient quantity to yield large amounts of graphitic acid. But it is quite evident that anhydrous nitric acid, once obtained, fully repays the pains taken in its preparation, even if necessary to conduct several separate distillations at once to obtain the requisite quantity.

Brodie, who is credited with being the first to discover that graphite could be oxidised to graphitic acid, and Berthelot, who investigated methods for distinguishing various forms of carbon, evidently depended on the use of strong nitric acid and chlorate of potash at low temperatures. Berthelot states that with a mixture of potassium chlorate and red fuming nitric acid graphite is oxidised to graphitic acid (Chem. Centr., 1896, **67**, 466). This may be true with certain amorphous graphites, but as a rule the ordinary fuming nitric acid, as obtained from the dealer, is not concentrated enough for the reaction.

Probably, one of the most simple and satisfactory methods (a combination of Berthelot's and Staudenmaier's) is that described by Fitzgerald (this J., 1901, 443—445).

Instead of heating over the ordinary water bath, as in Fitzgerald's case, the writer prefers a beaker containing water at 60° C., in which the test tube is inclined, the temperature being maintained by placing the beaker on top of a radiator or hot air bath. Above 70° C., explosions varying in intensity from the "toot" of a small whistle to the noise of a fire cracker are liable to occur, rendering close observation hazardous. Excessive amounts of potassium chlorate are unnecessary. The acid used should be especially prepared by distilling a mixture of equal parts C.P. concentrated sulphuric and nitric acids, so as to obtain one-third its bulk of distillate.

After obtaining the grass-green oxide, it should be washed with water, and heated on the water bath with about 150 c.c. N/50 permanganate solution to which dilute sulphuric acid has been added. The substance should assume a yellow colour, and the permanganate show signs of reduction. Hydrogen peroxide is then added to destroy the permanganate and "clear up" the solution. The yellow crystalline product may be washed by decantation successively by dilute nitric acid, alcohol, and ether; but generally two or three washings with absolute alcohol on a filter will suffice, after which it should be dried at the odinary temperature.

Ceylon graphite of 90 per cent. or more purity seems to produce the best results. The green oxide is formed more readily from Ceylon graphite than from artificial graphite; and not at all from ordinary coke, or charcoal, or carbon black. As a rule, ordinary carbon or carbonaceous matter simply passes into solution, imparting a dark brown colour to the oxidising mixture, such solubility forming a basis of separation from graphite. Charcoal dust may he almost completely dissolved in twenty-four hours, yielding the usual coffee-coloured solution and a whitish residue which dissolves on dilution, imparting a yellowish-brown coloration. This is not necessarily true, however, with gas retort carbon, which is more or less inert, and may give an unmistakable green solution, as if it were partially graphitised and required only a strong electric current to complete the graphitisation.

Some of the low grade amorphous graphites respond readily to the test, while others, like Bohemian and Mexican, are uncertain. With the American flake variety, the action is slower than with Ceylon, yielding a darker shade of "green oxide." Occasionally, the writer has obtained the final product as a dark brown powder, which deflagrated more readily than the yellow form. Very often the yellow acid seems to retain the flaky structure of the original graphite.

That graphitic "oxide" may be produced more readily from natural than from artificial graphite is no criterion of the refractory powers of the latter, since, gram for gram, the best Ceylon lump, after proper milling, resists oxidation by fire much longer than artificial graphite of the same carbon content and degree of fineness and under same conditions. Apparently the more perfect the graphitisation, the more readily is the graphitic oxide formed, although a hard crystalline structure in itself might retard the reaction.

Whether or not natural graphite is the result of the decomposition of plant life; or the destructive distillation of hydrocarbon gases; or the metamorphosis of charred residues from prehistoric forest fires, it is, nevertheless, quite evident that differences in physical structure are usually accompanied by differences in behaviour with oxidising agents. Ceylon plumbago, occurring in massive form and yielding an ash more or less granular, should not be classed with the American flake varieties having a micaceous structure, nor with the amorphous compact forms containing argillaceous matter.

The use of the chlorate oxidising mixture to distinguish graphite from other forms of carbon through production of insoluble graphitic acid and soluble humic acids has claimed more or less attention from time to time (Berthelot, Comptes rend. 1869, **68**). The Staudenmaier mixture has already been recommended by Fitzgerald for testing carbon electrodes to determine whether they are composed entirely of amorphous carbon or partially of graphite (Electrochemical Industry, Oct. 1902, page 68). Of course, graphite itself may exist in the amorphous state and produce the usual grass green oxide.

While approximate separations may be made with simple mixtures of graphite and charcoal dust or ordinary coke, the results are hardly satisfactory with hard gas retort carbon for reasons previously stated.

THE IODINE ABSORPTION OF SPIRITS OF TURPENTINE.

BY R. A. WORSTALL.

Little has been published concerning the analysis of turpentine and the detection of adulterants, which have consisted chiefly of petroleum distillates, rosin spirits, and rosin oil. Burton (Amer. Chem. J., **12**, 102) detected petroleum products by oxidising the sample with fuming nitric acid, pouring into water, and extracting the unchanged paraffins with ether. Armstrong (this J., 1882, 478) detected heavy petroleum products by distilling the sample in steam, only the heavy paraffins remaining behind. Naphtha and gasoline he determined by first polymerising the terpenes with sulphuric acid, and then distilling in steam, the distillate containing only the volatile paraffins. Hinsdale (Chem. News, **63**, 161) claimed to be able to detect petroleum fractions by evaporating ten drops of the sample in a watch glass at 77 C. In seven minutes all was evaporated save the petroleum. This is evidently a crude method. Aignan (Comptes rend., **109**, 944) detected rosin oil by the decrease it caused in the rotation. Baudin (J. prakt. Chem., **23**, 279) tested for petroleum by the grease that it left when the sample was evaporated spontaneously on filter paper. Zune (Monatsh. f. Chem., **2**, 794), employed the increased index of refraction to denote rosin oil. Evers (Zeits. öffentl. Chem., **4**, 211) stated that equal volumes of spirits of turpentine and fuming hydrochloric acid (1·19) when shaken together gave a definite rise in temperature, and used a qualitative test with bromine to distinguish between genuine and imitation spirits of turpentine. Schreiber and Zetzsche (Chem.-Zeit., **23**, 68) have also made use of the latter test.

The preceding, while not a complete bibliography of the subject, comprises most that has been published concerning the detection of adulteration in spirits of turpentine. Usually the determination of specific gravity, which should be 0·865; the flash point, which should be 92—94 F.; and the distillation test—pure spirits should begin to distil at 150 C., and 90 per cent. should pass over before 165—are sufficient to denote any considerable adulteration with petroleum products or rosin spirits. But since the development of the yellow pine distillation industry and the appearance on the market of various grades of "wood turpentine," from straw colour to water white, the problem has become more difficult. "Wood turpentine," as might be expected from its method of production, possesses characteristics both of spirits of turpentine and of wood alcohol, and seems to consist both of terpenes and of alcoholic bodies. In its general properties it closely resembles true spirits of turpentine, and its strong odour can be largely removed by refining. It is not equal to genuine "spirits" in any way, however, and hence must be classed as an adulterant.

Some two years ago, feeling that the methods in use for the analysis of spirits of turpentine were both slow and unsatisfactory, the author determined to try to substitute for them some method at once quicker and more reliable. The specific gravity test, the distillation test, and the flash test, while easily carried out require time, and are not absolutely sure indications of purity. Upon looking into the literature upon the subject, it was found that R. H. Davies (Pharm. J. and Trans., 1889, 821) had determined the iodine absorption of a large number of essential oils, using the Hübl method, and that with the exception of two or three rare and costly essential oils, none gave nearly as high figures as did spirits of turpentine, whose absorption he found to be 377 per cent. After a few preliminary tests the following method was adopted for carrying out the determination, and is still in use. About 0·1 grm. of the sample is weighed out from a dropping bottle into a glass stoppered bottle, 10 c.c. of Hübl's solution added, and the tightly stoppered bottle set away over night. The excess of iodine is then titrated back as usual. For more than two years this method has been the chief test employed in this laboratory for spirits of turpentine, and the results have been most satisfactory.

The average iodine absorption of 55 samples of spirits of turpentine of undoubted purity, examined during the first six months of 1903, had been 384 per cent. As a rule, three times the total quantity of iodine necessary for complete saturation had been added, and 18 hours had usually been allowed. $C_{10}H_{16}$ would be converted into $C_{10}H_{16}I_4$ by complete addition, and this would require theoretically 373 per cent. iodine.

The first point investigated was the rapidity of the reaction. The spirits of turpentine, of undoubted purity, was weighed from a dropping bottle into glass stoppered bottles, a definite volume of Hübl's solution added, and the tightly stoppered bottles placed in the dark for definite periods of time, when the excess of iodine was titrated back in the usual way with thiosulphate. The following table shows the results :—

Time.	Absorption.	Time.	Absorption.
Hours.	Per Cent.	Hours.	Per Cent.
½	314	5	378
1	335	6	379
2	348	7	380
3	365	18	380
4	374	24	389

It would appear from these figures that absorption is complete in from four to six hours, given a large excess of iodine, and that if the time be greatly prolonged, substitution or other secondary reactions ensue. The influence of a large excess of iodine, and the proper amount of the same necessary to ensure complete saturation, was next studied, with the following results :—

Time.	Excess of Iodine.	Absorption.
Hours.		Per Cent.
18	0·0456	316
18	0·0881	332
18	0·1428	357
18	0·2098	366
18	0·3583	378
18	0·5749	392
18	1·0123	402

It would follow from these results that if 18 hours be allowed for the reaction, twice as much iodine must be added as is necessary for complete reaction; and if 12 hours be allowed, three times the quantity of iodine should be added; also that a very great excess of iodine or unduly prolonged time for the absorption each result in secondary reaction, which increase the apparent absorption.

The most common adulterants of spirits of turpentine, and in fact about the only possible and profitable ones are kerosene, 63° naphtha, or other petroleum distillates; rosin spirits or rosin oil, and wood turpentine. The iodine absorption of each of these was determined from samples on hand:—Rosin spirits, 185; rosin oil, 97; kerosene, 0; naphtha, 0; refined wood turpentine, 212; water white, 328 per cent. Evidently any adulteration, even in very small proportions, with petroleum distillates should be easily detected by the consequent decrease in the iodine absorption. Mixtures of pure turpentine and kerosene were made, and the iodine number determined, with the following results:—

	Absorption after 18 hours. Per Cent.
Pure turpentine	391
5 per cent. kerosene	360
10 ,, ,,	350
20 ,, ,,	313
40 ,, ,,	238
100 ,, ,,	0

Another test was made with resinous mixtures containing refined wood turpentine as the adulterant, with the ollowing results:—

	Absorption after 12 hours. Per Cent.
Pure turpentine	375
5 per cent. wood-turpentine	360
10 ,, ,, ,,	355
20 ,, ,, ,,	313
50 ,, ,, ,,	278
100 ,, ,, ,,	212

It would, no doubt, be more difficult to detect the addition f 5 per cent. of such a wood-turpentine as the sample hich gave an iodine value of 328 per cent., but no such dulteration is likely to be encountered. The cost of such an xtra-refined article is so little below that of genuine pirits of turpentine that if used as an adulterant for the tter it would have to be in the proportion of 25 to 0 per cent. to be profitable, and such adulteration would asily be shown by the decreased iodine number. In the econd place, it is extremely doubtful if the addition of 0 per cent. of this water-white wood-turpentine would be t all detrimental. It has been so well refined that nearly ure terpenes are left.

The author believes that the iodine absorption can thus e applied to spirits of turpentine as a positive and reliable est of purity. Kerosene and wood-turpentine were taken s the extremes—in iodine absorption—of possible adulerants, and what is true of them applies equally well to esin spirits, resin oil, naphtha, or any other adulterant. rovided the test be carried out with the proper precautions s to time and excess of iodine, any sample which shows n iodine absorption of less than 370 per cent. can certainly e condemned; and, given the fact that its iodine absorption too low, the nature of the adulterant can be determined y any of the methods now in use.

A METHOD FOR THE DETERMINATION OF CERTAIN ALDEHYDES AND KETONES IN ESSENTIAL OILS.

BY SAML. S. SADTLER.

In a paper read before the Chemical Section of the Franklin nstitute in Philadelphia, on October 15th, 1903, I described a general way a method for the quantitative estimation aldehydes of both the aliphatic and aromatic series, based upon the assumed fact that, when neutral sulphites react with aldehydes, caustic alkali is separated. I have since that time experimented on several applications of the method, and read a short paper before the Philadelphia Section of the American Chemical Society on January 21st, 1904, on the determination of formaldehyde. Very recently, however, I received word from Dr. Clemens Kleber to the effect that he had been working along the same lines, and had sent a paper on the subject of formaldehyde assay to one of the journals for publication. In view of that fact I have left that field to Dr. Kleber, and have devoted what time I could to experimenting upon some essential oils. I wish to acknowledge my indebtedness for the receipt of most of the samples used in this work to Dr. F. D. Dodge and Messrs. Fritzsche Bros.

The subject of this reaction has been treated upon at considerable length by the late Prof. Tiemann (Ber., **31**) Dodge (Amer. Chem. J., 1890, 55), and Heusler (Ber., **24**). Tiemann and Dodge used the reaction to obtain citral from lemon-grass oil, and Heusler used it in connection with cinnamic aldehyde. Tiemann says that many organic compounds containing double linkings add the elements of sulphurous acid, forming sulphonic acids. He pointed out that the reaction occurred readily with unsaturated aldehydes, such as acrolein, croton aldehyde, &c. Heusler pointed out the reaction with cinnamic aldehyde, as follows:—

$$C_6H_5.CH:CH:COH + Na_2SO_3 + H_2O =$$
$$C_6H_5.CH.(SO_3Na).CH_2.COH + NaOH,$$

but said, however, that the resulting alkali, in a certain concentration, exercises a decomposing action upon the sulphonate formed, and has to be neutralised by acids.

Prof. Tiemann has shown in the case of citral that, besides the bisulphite compound, three hydrosulphonic acid compounds exist. The normal bisulphite compound is obtained by the action of sodium bisulphite, preferably containing a little free sulphurous acid. It is completely decomposed by soda, regenerating citral. When this compound is steam-distilled from water, half of the citral contained passes over and the other half is converted into the sodium salt of the so-called "stable" citral dihydrodisulphonic acid; thus:—

$$2C_9H_{15}CH(OH)SO_3Na = C_9H_{15}COH, C_9H_{17}(SO_3Na)_2COH.$$

This compound is readily soluble in water, without being reconverted into citral, by means of sodium carbonate or hydrate. He shows that the aldehydic group is still intact.

The second compound is the so-called "labile" citral dihydrodisulphonic acid, and results when citral is agitated with an aqueous solution of neutral sulphite, the formula, unless written stereo-chemically, being the same. The reaction is—

$$C_9H_{15}COH + 2Na_2SO_3 + 2H_2O$$
$$C_9H_{17}(SO_3Na)_2COH + 2NaOH.$$

He stated that this compound was quantitatively decomposed by the action of sodium hydroxide, forming citral and neutral sodium sulphite. In other words, the reaction is reversible, and the laws of mass action should apply

A third compound is the mono-hydro-sulphonate Tiemann further points out that the decomposition of this "labile" compound may be prevented by the addition of an acid salt, such as acid sulphite, bicarbonate of soda, or a weak acid, such as acetic acid.

I came to the conclusion that if the alkali formed were neutralised with measured quantities of standard acid the reaction should complete itself, and the measure of the amount of the reacting substances be determined at the same time; and, as in experiments with acidified solutions, I got low results, which tend to show that if the sulphite solution is acidified the bisulphite addition compound is likely to form.

With regard to the applicability of the reaction, Tiemann seemed to hold that it only related to unsaturated compounds, such as acrolein, crotonic aldehyde, cinnamic aldehyde, and citral. This does not seem to me to be the case, as it reacts apparently quantitatively, with the formation of two molecules of alkali hydroxide, with formaldehyde. It seems also to react with acet aldehyde; to a certain limited, yet definite extent with condensed aldehydes, like para-formaldehyde and paraldehyde; and in the aromatic series, besides unsaturated aldehydes, it seems to react with benzaldehyde and vanillin, and even in the class of ketones I have found it to react, carvone, as will be seen later, reacting quantitatively. A strong qualitative test was also obtained with purified acetone and some constituent of honey, possibly laevulose. It seems to me, therefore, that the reaction must be considered either, as Tiemann has pointed out, as taking place with unsaturated aldehydes according to our reaction, and reacting in a different way, almost certainly affecting the aldehydic group itself, in the other cases mentioned; or, as seems more reasonable, as a purely aldehydic reaction, primarily affecting the oxygen atom of the $-CHO$ group, with a molecular rearrangement in certain cases, such as citral and cinnamic aldehyde. I believe double bondings and other groupings affect the reaction, as the position and character of substitution groups affect the activity of groups in the aromatic series. For example, carvone reacts, while its isomer, Japan camphor ($C_{10}H_{16}O$), does not react, with neutral sulphite.

Although my method of citral assay, outlined in the advance sheets of the Journal of the Franklin Institute, seems to be fairly clear, inasmuch as Kremens and Brandel, in a very recent publication, entitled "The Citral Assay of Volatile Oils," obtained very concordant results, and state that the figures obtained show "that, even without experience, fairly good results may be obtained by this method;" still I would like to add some precautions and discuss results to some extent, and will here give the method with such revision as I believe desirable. The method is apparently applicable to oils containing aldehydes or ketones which are found to react. The only differences in procedure that I have found are in the amounts of different oils taken. The use of bicarbonate and acetic acid to take up the caustic soda as formed, I have not found beneficial in any case which I have investigated. Either phenolphthalein or rosolic acid may be used as an indicator; I have generally used the latter, as it is less affected by sulphurous acid, and, although the end point is not as deep in colour, it does not fade, which is an advantage, as it is well to let the flasks stand all night to see if any additional alkali forms, indicating incompleteness of reaction. I have used normal and semi-normal hydrochloric acid for titrating, but have also tried weaker acids, such as oxalic, acetic, and sulphurous acids, to prevent any decomposition of sulphite, but, as I do not add the acid after the red or pink colour of the indicator has been discharged, I found no advantage in the change.

With oils of lemon, 10 grms. are weighed into an Erlenmeyer flask, 10 c.c. of water and four drops of rosolic acid (or phenolphthalein) indicator solution added, and N/10 potassium hydroxide solution added until just alkaline, to remove free acid which, to a greater or less extent, is present in all essential oils. Then 25 c.c. of a 20 per cent. sodium sulphite solution is added, measuring out an equal amount for a blank test. On agitation, a pink colour forms, and this is discharged by adding N/2 hydrochloric acid from a burette. The agitation (effected by inserting a well-fitting cork in the neck of the flask and shaking violently) and neutralising are carried out repeatedly, being careful not to let the solution become strongly alkaline at any time. When no more alkali is liberated, the flask is heated on the water bath, the shaking and neutralising being still carried out successively. Several tests may be made at once, a separate burette with the standard acid being reserved for each test. When the pink colour no longer forms, the flask is allowed to cool; the pink colour, if any, in the blank test is also discharged with N/2 hydrochloric acid, and both are then titrated with N/2 sodium hydroxide until the pink colour begins to form. The algebraic sum of the c.c. of acid and alkali of the blank experiment (those of sodium hydroxide being minus) are subtracted from those of the test, and the c.c. of N/2 hydrochloric acid are calculated into citral by considering one molecule of citral as equivalent to two molecules of hydrochloric acid; this, divided by the weight of oil taken, gives the percentage of citral. The following results were obtained by this method:—

Lemon Oils.

	Per Cent.
Sanderson's oil of lemon.	4·49 and 4·31
Dodge and Olcott sample	4·13 „ 4·31
Expressed oil of lemon	3·08, 3·09 „ 3·20
Oleo resin of lemon (California)	5·24 „ 5·29

Lemon-grass Oil (using about 1 *grain of Sample and* 10 *c.c. of Kerosene as a Diluent).*

	Per Cent.
Oil of lemon-grass, I.	75·13 and 76·04
„ „ II. (71 per cent.)	71·24 „ 72·74
Sample of citral	93·43

A polymerisation effect appeared to have taken place to a certain extent with citral, as a residue neutral to this reaction was noticed. Probably more water should have been used, and the alkali neutralised more promptly. But the result is close enough to show the correctness of the general reaction.

Before leaving the subject of citral, I would again refer to the paper of Kremers and Brandel, and call attention to the results which they obtained with mixtures of citral and limonene.

These results were as follows:—Calculated, 5 per cent. Found, 5·2, 5·04, 5·5, 5·2, by one experimenter; 4·7, 4·9, 5·0, by a second experimenter; 5·1, 5·09, by a third. They were very satisfactory. It is, however, in the determinations with cinnamic aldehyde where my results differ from those of Tiemann.

Oils of Cinnamon and Cassia (same amount used and Kerosene added as with Oil of Lemon-grass).

	Per Cent.
Oil of Cinnamon, I.	70·11 and 70·94
„ „ II. (64 per cent.)	62·37 „ 62·59
„ cassia (82 per cent.)	84·35, 79·7 „ 76·2
Pure cinnamic aldehyde	93·2 „ 94·5

(In the case of the Cassia the samples probably stood too long with the free alkali.)

Oil of Carraway (1 grm. and used Kerosin).

	Per Cent.
Oil of carraway (50-60 per cent.)	55·10
Carvone (97 per cent.)	91·3

Benzaldehyde and oils of bitter almonds were tried and gave results varying about one-third of the theoretical. They showed, however, that other than unsaturated aldehydes react with neutral sulphites. It is possible that acids salts or acids might control this reaction satisfactorily, but I have not as yet had success with the use of bicarbonate or acetic acid, as I tried the samples of citral, carvone, and cinnamic aldehyde, using an excess of N/2 acetic acid, but obtained the following results respectively, 88·31, 87·1, and 86·5. It seems likely to me that some bisulphite compound formed as well as the dihydro-disulphonate, as these results are lower than those obtained in neutral solutions.

Oil of citronella gave a small amount of free alkali, which would correspond to a few per cent. of citral.

Oil of fennel was tried in order to see whether fenchone reacted as well as carvone.

The applicability of this reaction is at least twofold. To serve as a convenient assay method of several constituents of essential oils, notably citral, cinnamic aldehyde, and carvone, and to be a means of learning more about the constitution of substances, especially aldehydes and ketones, of doubtful composition.

The close agreement in most cases shown here between this and other methods seems to show very clearly that with the aldehydes investigated two molecules of sulphurous acid are attached not only to aldehydes containing two double bonds like citral, but the same number were found to be taken up by cinnamic aldehyde, which has but one double bond, and furthermore two molecules were found to be taken up by aldehydes with no double bonding, such as formaldehyde, benzaldehyde, and vanillin, and also by a ketone, a body of distinctly different composition.

I would, therefore, provisionally write the general reaction for aldehydes, thus—

$$\mathrm{R.CHO + 2Na_2SO_3 + 2H_2O = R.CH:(NaSO_3)_2 + 2NaOH + H_2O.}$$

and for ketones—

$$\mathrm{R'.CO.R' + 2Na_2SO_3 + 2H_2O = R'_2:C:(Na_2SO_3)_2 + 2NaOH + H_2O.}$$

Meeting held at Chemists' Club, on March 25th, 1904.

DR. VIRGIL COBLENTZ IN THE CHAIR.

ACETIC ACID IN ACETATE OF LIME.

BY ALBERT G. STILLWELL.

The estimation of acetic acid by means of the distillation method is of growing importance, and it seems to the writer that a uniform method of analysis should be adopted.

A large amount of acetate of lime is manufactured each year, in factories scattered throughout the United States, a large amount of which is exported, while the rest finds a ready market at home.

A short description of the method in use in this laboratory should prove of interest to manufacturer and consumer alike. The following method has been in use for some time, with very satisfactory results.

Method.—The sample is drawn from bags as shipped, by means of tryers 14 ins. long, having a bevelled edge, mouth $1\frac{1}{2}$ ins. inside diameter, and expanding to 2 ins. at the handle end. The sample should be kept in tight cans or glass jars, as acetate of lime absorbs moisture very rapidly in wet weather, and loses it just as rapidly in dry. On reaching the laboratory the sample is rapidly passed through a $\frac{1}{4}$ in. sieve. The moisture in this sample is determined, and constitutes the original moisture. An average sample (about 6 oz.) is now passed through a 14-mesh sieve. This is the working sample, and the moisture in this should also be determined. From this fine sample 2 grms. are weighed out on balanced aluminium foils, and very carefully brushed into a round bottomed flask of 300 c.c. capacity, and having a neck 4 ins. long, great care being taken not to lose any of the fine dust. 15 c.c. of syrupy phosphoric acid are now added, and all drops carefully washed down from the neck with about 25 c.c. of water. 30 c.c. of standard soda solution are measured out by means of a pipette and run into a 12-oz. Erlenmeyer flask, and the flask placed under the delivery tube of the apparatus.

The flame is now lighted, and distillation carried on for $1\frac{1}{4}$ hours; the Erlenmeyer is now removed and a small beaker substituted; the distillate in the Erlenmeyer is neutralised by standard soda, drawn from a burette (10 c.c. capacity, and measuring about 12 ins. long, divided into tenths).

The distillation is carried on for 15 minutes longer, and the distillate in the beaker added to that in the Erlenmeyer; if the colour is discharged more soda is added and the distillation carried on 15 minutes longer. Usually the distillation is completed in $1\frac{1}{2}$ hours.

During the distillation the volume of liquid in the flask is kept as near 40 c.c. as possible, by means of the inlet or water controlled by screw as per cut.

The standard soda employed is of such a strength that 1 c.c. equals 0·0175 grm. of acetic acid when 2 grms. of sample are used.

When the acetic acid in the working sample is found, a simple calculation back to the original moisure will give the amount in the original sample.

It is perhaps superfluous to say that in standardising the soda phenolphthalein should be used as indicator, as well as in the final distillation.

If the water supply at hand contains much carbonate, distilled water should be used, as the carbon dioxide liberated by the phosphoric acid during the distillation will (by use of phenolphthalein) be reckoned as acetic acid.

In order to save calculation, the table given on the preceding page is used, the figures reading per cent. when 2 grms. of sample are taken.

Apparatus.—The condensing tank is of copper with glass tubes running through it as shown.

The water supply for the flasks is drawn from a small brass pipe by means of rubber tubes, and flow controlled with screw clamps.

The flasks are supported on a galvanised strip with holes cut in it, these holes being just a little smaller than the bottom of the flask.

MR. J. T. WOOD IN THE CHAIR.

NOTE ON THE DETERMINATION OF THE IODINE VALUE BY IODO-BROMIDE.

BY L. ARCHBUTT, F.I.C.

In the Hanus method of determining iodine values, a solution of iodine monobromide in acetic acid is used, which is somewhat more easily and cheaply made than the Wijs solution, and for this reason it has been adopted by some analysts. Results which have been published in this J. by Hunt (1902, p. 455) and by Harvey (1902, p. 1439) have shown that iodine values determined by means of the Hanus solution are lower than those obtained by the Wijs solution, the difference being greater the higher the iodine value, and these observations are confirmed by the following values which have been obtained in my laboratory. The difference in the case of turpentine oil is very marked. Duplicate tests by the Hanus solution do not agree so closely as duplicates obtained by the Wijs method, and it seems a pity that the latter process, which is so excellent, should be discarded in favour of a less perfect process.

DISCUSSION.

Mr. HARVEY said he could thoroughly support Mr. Archbutt's opinion as to the superiority of the Wijs method, over that of Hanus and others. Dr. Wijs had shown that theoretical results were obtained with pure unsaturated fatty acids, and that the reaction was practically instantaneous, earth-nut oil absorbing in one minute 99 per cent. of the total halogen finally absorbed, and linseed oil 98 per cent.

The CHAIRMAN said Mr. Archbutt's figures seemed to confirm what Mr. Harvey had said about this method. He asked Mr. Archbutt if he had any comparative figures for cod liver oil.

Mr. ARCHBUTT replied in the negative, but expressed the opinion that the results would be similar to those obtained with linseed oil.

DR. L. DOBBIN IN THE CHAIR.

THE CHEMICAL AND MECHANICAL TESTING OF PORTLAND CEMENT.

BY G. H. GEMMELL, F.I.C., F.C.S.

The Cement Trade Section of the London Chamber of Commerce, in a report issued in 1897, defined Portland cement to be a mixture of two or more suitable materials, intimately and artificially mixed in the requisite proportions, and afterwards properly calcined and ground, to which nothing has been added during or after calcination, excepting that an addition not exceeding 2 per cent. of gypsum is permissible for the purpose of regulating the setting. That if any material whatever, excepting an amount not exceeding 2 per cent. of Gypsum, be added to the Portland cement clinker, during or after calcination the article so produced shall not be sold as Portland cement but under some other distinctive name. This definition is practically the same as that adopted by the German and Austrian Association of Portland cement makers. Made in the manner described, however, Portland cement is not a substance of definite chemical composition. According to Le Chatelier, the essential and valuable ingredients are tricalcium silicate and tricalcium aluminate, but associated with these compounds of definite chemical composition there are various impurities and the ultimate composition of samples of cement varies within the following limits :—

	Per Cent.
Lime, CaO	60 to 65
Iron and alumina oxides	7 to 14
Alkalis	Traces to 3
Sulphuric anhydride, SO_3	Traces to 3
Silica	20 to 26
Magnesia	1 to 3
Loss on ignition	3 to 5

A mixture of the pure tricalcium silicate and tricalcium aluminate, $3CaO.SiO_2$, $3CaO.Al_2O_3$, would have the percentage composition :—

	Per Cent.
Lime, CaO	67·4
Silica, SiO_2	12·1
Alumina, Al_2O_3	20·5

Messrs. Newberry, of America, after a very careful investigation, arrived at conclusions somewhat different from Le Chatelier (see this J., 1897, page 1035). They prepared from pure materials the tricalcium silicate, and agreed with Le Chatelier that to this ingredient is due the hardening properties of cement, though it sets very slowly. A cement containing $2\frac{1}{2}$ molecules of lime to one of alumina was not sound, but one containing 2 of lime to 1 of alumina set quickly, showed constant volume and soundness, and good hardening properties. A mixture of pure tricalcium silicate and dicalcium aluminate, $3CaOSiO_2$ $2CaOSiO_2$, would have the per-centage composition :—

	Per Cent.
Lime, CaO	63·4
Silica, SiO_2	13·5
Alumina, Al_2O_3	23·1

A chemical analysis indicates whether a cement has a proportion of ingredients within these limits, but in other espects fails to give much information of its true value.

A report of a sub-committee of the New York Section of our Society was published in this Journal in 1902, on "Uniformity in Analysis of Materials for the Portland Cement ndustry." Admirable and full of details as that report is, t appears to me that the results obtained were not of such value as to warrant the expenditure of so much time and rouble. Further, some of the more important determinaions, and those in which there is doubt as to the most suitable method, were omitted altogether. I refer more especially to the determination of insoluble silica and clay, free lime, blast urnace slag, and other adulterants.

I fail to appreciate the necessity of drawing up a uniform cheme for the chemical analysis of cement, and the stimation of silica, lime, magnesia, &c.; but when we conider the mechanical and physical tests to which Portland ement should be submitted, I am strongly of opinion that a efinite and uniform method of procedure should be adopted. These tests are purely of an arbitrary and empirical character.

There is general agreement that in addition to a chemical nalysis the specific gravity, fineness, time of set, tensile trength and soundness, is required to enable a reliable udgment to be passed on a cement but it is in the method f carrying out these tests that chaos reigns. The determination of the specific gravity is simple.

Fineness.—This test is one of great importance and is ncluded in most specifications.

Though coarse particles have a certain value, fine grinding argely increases the adhesive power of cement, because of s greater covering power and the possibility of using a elatively larger proportion of sand. In finely ground ement, water attacks the free lime more readily and there less liability to unsoundness. The cement is also made uicker setting, but more thorough aeration will counteract his. There is no general agreement as to the sieves to be sed in testing for fineness. The American Society of Civil ngineers recommend three sieves 50 by 50 (2500), 76 by 6 (5776), and 100 by 100 (10,000), and while many ngineers are satisfied with a residue of not more than per cent. on a 76 by 76 some makers guarantee no residue o a sieve of this mesh and 15 per cent. on a 180 by 180. ttention has frequently been drawn to the gauge of the ire used in making the sieve but as yet no general greement has been arrived at. On the continent and in merica, the standard agreed upon is that the diameter of he wire should be half the width of the meshes. Thus a eve having 76 holes to the inch should be made with ire, one-third of a seventy-sixth of an inch, or 0·0044 in. = No. 41 standard wire gauge, and the holes should be qual to 0·0088 in.

Tables have been prepared showing the number of holes er linear or square inch, No. of British standard wire auge, size of wire, and size of hole. As there is no trouble n obtaining reliable sieves made according to this standard here is no reason why this method should not be universally dopted.

Soundness.—The tendency in cement to "blow" is attriuted to the presence of uncombined lime, and no reliable method has yet been devised of distinguishing the free from he uncombined. Fresenius attempted to measure it by an estimation of the alkalinity of water after being shaken with the cement, but the limits prescribed were abandoned after some years trial by the Association of German manufacturers as valueless.

Cement is entirely decomposed by repeated shakings with large quantities of water and ultimately the greater proportion of the lime can be dissolved in this way. In looking into this matter some time ago with a view to devising, if possible, a method for estimating free lime, a series of trials were made with glycerin. This liquid has a slight solvent action on calcium oxide and can be obtained free from water. An objection to its use is its great viscosity and the difficulty of filtering. The method of procedure adopted was as follows: 0·5 grm. of finely ground cement was dried and placed in a dry wide mouth stoppered bottle. To this 50 c.c. of glycerin was added and the bottle and contents heated to 40° C. for seven days shaking twice a day, on the seventh day 50 c.c. of 90 per cent. alcohol was added and the solution filtered, using a hot water jacketed funnel. The residue was washed with 90 per cent. alcohol, dried and weighed. The solution was diluted with water, a few drops of ammonia added, and the lime precipitated by ammonium oxalate in the usual way.

The results do not give much promise that the method is a satisfactory one by which to estimate free lime with any degree of accuracy, and it is, I fear, much too long and troublesome to be of general use.

Another of the methods of attempting to measure the free lime indirectly is by the rise of temperature on addition of water, but this rise is due to the crystallisation and setting of the mass, and the higher the proportion of lime, up to the limit of 63·5 per cent., which is in chemical combination with silica and alumina the more rapidly this will proceed, and the higher the temperature will rise—but this does not necessarily mean that the cement is a dangerous one to use. Experiments have shown that the rise of temperature varies also with the degree of fineness. A fine, quick-setting cement will show a marked rise of temperature in a very short time, due to rapid crystallisation, while a slow setting cement will only show a slight rise over a period of time, though the heat evolved may possibly be equal in both cases. In fact, at the present time there are no satisfactory chemical tests for free lime, and indication of its presence from rise of temperature is quite unreliable, so that we must have recourse to one of the methods in use for soundness to determine this factor. Here again the number of tests recommended are bewildering in their variety. In my opinion the boiling test is unduly severe. A cement which passes it—and there are many—can certainly be relied upon, but on the other hand it has been known to condemn cements which in after practice have proved entirely satisfactory.

By the Faija test a cement is put to a very severe trial and for all purposes is sufficient. It has been practised for more than 20 years, and is probably held in higher esteem now than ever.

The Deval test is probably worthy of more extended use in this country. After a long series of experiments he concluded that cold tests were no criterion of soundness, but that good cement briquettes with one to three of sand and immersed at 80° C. for two and seven days should be equal in strength to similar briquettes kept at the ordinary temperature for seven and 28 days. A cement containing any appreciable quantity of free lime would not stand this test. It is claimed that the temperature used in the Faija apparatus at 115° to 120° F., imparts an artificial age to briquettes, and it would be interesting and suggestive to know the results of tests of sand briquettes made with various cements kept at 120° F., for two and seven days with those tested in the usual way.

Tensile Strength.—While it is true that cement is used where resistance to compression is more important than resistance to tension, still the tensile strength is the test most in favour. This probably arises from the fact that such tests are much more easily carried out by simple and inexpensive machines, and that the resistance to compression is approximately ten times that of the tensile strength. Of all the methods in use to ascertain the value of cement, the manner in which this is carried out is most unsatisfactory. Considerable latitude is permissible as to the percentage of water, and the manner in which the briquettes are made, and two individuals using the same cement will often get greatly varying results, while a set of six briquettes made together by the same person will vary 100 lb. in 500.

To eliminate all question of the personal element, I am strongly in favour of the Arnold system of making briquettes, and that standard rules be prescribed as to the method of carrying it out. Every cement and every briquette is then tested under precisely the same conditions.

The method of using this process is as follows:—135 grms. of cement are weighed and placed in the mould on a tray; with the handle of a palate knife press down the cement and expel the air, level it off, gently tap it on the table to consolidate the mass, place the die in the mould, and submit to pressure till the top of the die is on a level with the top of the mould; this is usually done in a screw press. This manner of compressing the briquette is the least satisfactory feature of this method; by it, cements of low sp. gr. get a greater pressure than those of higher gravity, and are tested under more favourable conditions. It has been suggested to me that by means of a weighted lever all briquettes could be subjected to the same pressure and this would entirely do away with the difficulty. The section of the briquette would vary slightly, but, before breaking, this can be accurately measured and allowed for by calculation. After making the briquette, water at 60° F. is filled into the tray containing the mould. In 20 to 30 minutes the briquette is set and may be removed, but I have always allowed it to remain one hour in water. Under these conditions the cement will take up the exact quantity of water it requires, and no more. After the removal of the briquette from the mould it is weighed, and the percentage of water absorbed calculated The briquette is then placed in a moist atmosphere for 24 hours, and in water for six days or longer. I have always made it a rule to make three briquettes by this method of each cement sent to me, in addition, to hand-gauged briquettes. The results are more uniform, though usually lower than when hand-gauged and rammed, but not lower than when thumb-pressed. Briquettes made in this way undoubtedly "blow" more readily than when hand-gauged, and, with unsound cements, give less favourable results. As an example of the plan of working, I give an extract taken from the laboratory note-book:—

Number of Mould.	1.	2.	3.
Weight of cement taken in grms. pressed and kept in mould one hour	135	135	135
Weight when taken from mould ...	156·7	156·7	156·7
Water absorbed per cent.	16·07	16·07	16·07
Weight when taken from water ...	159·2	159·3	159·4
Water absorbed per cent.	17·9	18·0	18·1
Tensile strain in lbs., seventh day..	487	487	470

Briquettes made with the same cement gauged with 20 per cent. of water, broke at 381 lb.; gauged with 18 per cent. of water, the average of three broke at 487 lb.; gauged with 17 per cent. of water, which was the correct quantity, broke at 552 lb.

With another quick-setting cement, three briquettes each were made as follows:—Briquettes made by hand-gauging and rammed with the handle of the trowel, with 22 per cent. of water, average result, 387 lb.

Briquettes pressed in with thumbs, gauged with 22 per cent. of water, average 249 lb.

Briquettes made by Arnold method: water absorbed, 17·6 per cent., 460, 459¼, 452; average, 454.

A third cement: briquettes made by ramming gave an average test of 1,110 lb., but thumb-pressed only 905 lb.

Where such discrepancies are possible, and no indication is given in the specification as to how the briquettes are to be made, a uniform system of testing is much to be desired. In Germany, the sand test is always specified, and is much to be preferred to the neat test, which gives the cohesive power of the cement only, whereas the sand test indicates its adhesive or cementing value, and also the presence of adulterants.

There is, undoubtedly, a strong suspicion abroad that much cement adulterated with slag is sold, and that considerable quantities are put on the market with a large percentage of ragstone.

The use of ragstone is defended by certain manufacturers, who maintain that such addition increases the tensile strength; but it has been conclusively shown by the researches of Messrs. Stanger and Blount (this J., 1897, p. 853), that ragstone is not a cementitious substance, and a sound cement is weakened by its addition, though unsound cement may be temporarily improved by its addition. Most users of cement accept this view and are desirous of some means whereby the presence of an adulterant can be detected. Side by side with an analysis of cement is here placed the composition of the commoner adulterants:—

—	Portland Cement.	Ragstone.	Hassock.	Blast Furnace Slag.
Silica	20 to 26	4 to 10	62·6	30 to 35
Iron and alumina oxides	7 ,, 14	1·5 ,, 3	1·4	30 ,, 35
Lime	60 ,, 65	45 ,, 50	16·3	24 ,, 30
Water and carbon dioxide	1 ,, 3	36 ,, 40	11·7	..
Magnesia	1 ,, 3	0·5 ,, 1	0·5	..
Specific gravity	3·1 ,, 3·2	2·5 ,, 2·7	2·36	2·85

Experiments have shown that admixture with such an adulterant materially reduces the strength of the sand briquettes, but here also it is not possible to state absolutely whether any admixture is the cause, and, if so, to what extent. It was thought that if some rapid and fairly accurate method for the separation and estimation of ragstone could be devised it would prove useful to the trade. The most successful method of detecting adulteration with ragstone has been by a microscopic examination, but during an investigation into this matter it occurred to me that a method based upon the difference of the sp. gr. of ragstone and cement might possibly be devised. It is well known that a very complete separation of the various mineral constituents of rocks can be made by agitating the finely-ground material with a fluid of a less gravity than the heavier constituent, and a greater gravity than the lighter ones. The sp. gr. of a Portland cement should not be less that 3·1, while that of ragstone is 2·6 to 2·7. If then a mixture of these two substances be agitated in a fluid of a density intermediate between these figures a separation should be effected. It was not only necessary that the liquid be of suitable gravity but that it would not dissolve or react on the cement, and after consideration the fluid selected was bromoform, sp. gr., 2·853. This was tried, but on agitating violently in a test tube, it was found that no satisfactory separation took place, much of the material remaining suspended in the fluid even after long standing. It was thought that this might be owing to the presence of moisture, so the experiment was repeated with perfectly dry material, but with no better result.

With a view to assist the separation it was thought that "whirling" in a centrifugal might be of use. Small quantities of known mixtures of finely-powdered ragstone and cement were placed in a sediment tube with a measured volume of bromoform, and, after thorough agitation, whirled for a short time; as this appeared to give promise of satisfactory separation, systematic experiments on these lines were instituted. Samples of mixtures of known proportions of three ragstones marked, respectively, R., G., and B. were then made with a cement.

Each were carefully ground together, passed through a 90 by 90 sieve, again ground and dried. They were then shaken up with bromoform and whirled for three minutes. The mixture separated quite readily, at the bottom of the tube was a compact layer of cement, then a nearly clear layer of bromoform, and finally the ragstone floating on the surface. This was decanted on to a small filter, the bromoform after filtration being ready for use again. The filter paper and contents were dried over a low argand flame, the paper burned off, and the ragstone weighed. The first series of results were all too low, some of the ragstone being apparently carried down by the heavy cement, it was therefore decided to try the effect of whirling three times, decanting off the ragstone after each whirling, shaking up with clear bromoform, and whirling again. The following were some of the results obtained per cent. :—

Cement.	Ragstone.	Ragstone recovered.

70	30	30·0
95	5	6·5

With mixtures of 10 per cent. or less of ragstone there appeared to be a proportion of cement carried up with it. It was thought advisable, therefore, to try a number of experiments with cements of guaranteed purity, and this was done with the following results :—

Cement 1.	Per cent. of floating matter	3·4
„ 2	„ „	2·2
„ 3	„ „	2·2
„ 4	„ „	3·1
„ 5	„ „	5·3
„ 6	„ „	5·0
		per Cent.
Ragstone		94·9
		94·4

Many other trials were made, all cements showed a small quantity of floating matter, but ragstones and hassock floated entirely. These losses are apparently due to particles of the ragstone adhering to the side of the tube, and probably a slight loss on ignition. A sample of cement said to be adulterated was tried with the following results :—Floating matter per cent., 16·9, 15·4, 16·5. This floating matter was tested and found to contain 16 per cent. of carbon dioxide. As this was too low for ragstone it appears probable that the separated material contained an admixture of cement.

To determine whether this was so or not a number of the tests were repeated with known proportions of cement and ragstone, and a partial analysis made of the floating matter. The following is a typical result :—

—	Cement.	Ragstone.	Floating Matter.
	80 parts.	20 parts.	22·5 parts.
Silica	22·80	6·35	11·5
Iron and alumina oxides	11·70	1·40	3·3
Lime	61·40	49·50	51·2
Loss on ignition	0·44	40·20	31·8

The results confirm those previously made, and the general conclusions to which I have arrived are that all cements contain a proportion of inert matter which may readily be estimated in this way, but which should not exceed 5 per cent.

By it an approximate estimation or separation can also be made of added substances such as ragstone, and the adulterent can be collected, weighed, and submitted to partial analysis to ascertain the composition. So far experiments have been made with only one liquid, bromoform, but I propose to continue them with liquids of greater density, 3·0 to 3·05, and, if possible, make a more complete analysis of the separated products.

Yorkshire Section.

Meeting held at the Midland Hotel, Bradford, on January 25th, 1904.

MR. JAS. E. BEDFORD IN THE CHAIR.

ESTIMATION OF CANE SUGAR, LACTOSE, &c., IN MILKS, &c.

BY F. W. RICHARDSON AND ADOLF JAFFÉ.

The disaccharide or biose known as lactose or milk-sugar, manifests some very peculiar properties when its solutions are examined in the polarimeter. When freshly dissolved in water at 20° C. the lactose anhydride gives a rotation of +88° to the polarised ray ; in 24 hours the rotation sinks gradually to the normal degree +52·53°. A, B, and γ forms give respectively +88°, +25·3°, and +36·2°. The very abnormal "γ" modification can be made by quickly evaporating a 20 per cent. to 30 per cent. solution of the ordinary "A" form, and drying the residue at 98° C., till quite free from water of crystallisation. The analyst finds it very necessary to make himself acquainted with these multirotative properties of lactose. The ordinary, or "B" form, is the stable variety with which the chemist has to deal, and may be produced by mere boiling of the solutions of milk sugars, or by allowing them to remain at the ordinary temperature for 24 hours.

Nine eminent observers have given as many different values for the rotatory power of lactose. As extremes we may mention Hoppe-Seyler's 51·18°, and Pogginle's 54·20°. The average figure of the nine is 52·65°. Schmoeger seems to us to have given the correct degree, +52·52° for lactose hydrate, $C_{12}H_{22}O_{11}. + OH_2$, as we obtain an average of 52·5° for the purest crystalline lactose we can procure.

A remarkable, and to the analyst a very satisfactory feature of lactose is the scarcely perceptible change its polarimetric powers undergo when its concentrated solutions are diluted. Strength of solution is a most important factor with carbohydrates generally, and with nearly all bodies which exercise a rotative influence upon polarised light. We confirm Schmoeger that the $[\alpha]_D$ of lactose at 20° C. is 52·5 for solutions of 2·5 to 12·5 per cent. concentration. As we employ 86° C. in the method to be described we have determined the $[\alpha]_D$ of lactose at this degree and find it to be 49·0—a result in harmony with Landolt's temperature formula —

$$A_T = A_{20} \times \frac{1020 - T}{1000}$$

(Landolt's "Das Optische Drehungsvermögen," &c., 1898, p. 533), which gives 49·04.

In general our conclusions as to copper methods are :—

(1) Despite all its defects no other metallic solution gives results at all as comparably good as Fehling's.

(2) Ost's copper solutions are altogether too unsatisfactory.

(3) Glycerine may replace Rochelle Salt in Fehling's solution with some very slight advantage.

(4) Wein's mode of applying Fehling's copper solution, *i.e.*, short boiling in porcelain dishes, gives better results than Brown, Morris, and Millar's process of heating in covered beakers in the water bath for 12 minutes.

(5) Collection of the cuprous oxide on asbestos, and reduction by hydrogen in tubes is open to several objections, and at the best gives no better results than our own modified method of receiving the oxide on double Swedish filters washing well and then using 25 c.c. of a one-tenth per cent. solution of tartaric acid, finally incinerating directly and weighing the cupric oxide.

(6) Pavy-Fehling's solution is altogether too weak, 1 c.c. being equivalent to only half a milligram of dextrose, and gives too erractic results with lactose and inverted sucrose solutions ; Messrs. Stokes and Bodmer (Analyst, 1885, p. 82, &c.) notwithstanding. With as much as 100 c.c. of

Pavy-Fehling solution should 25 c.c. of the sugar solution be required for reduction, and less should not be used if reasonable accuracy is required, one would have to use only a one fifth per cent. solution of the reducing sugar.

Apart from the question of excessive dilution, Pavy-Fehling's copper solution mostly gives an end reaction not easily discernible and often misleading.

(7) Fehling's copper solution gives very unreliable results when applied *volumetrically*, even when the colour of the solution does not interfere with the application altogether.

(8) Fehling's copper solution applied gravimetrically never gives data sufficiently accurate to meet with the requirements of theory, and mostly supplies only roughly approximate approximate results.

The reasons for these obliquities are not far to seek, and we may summarise them in brief :—

(*a*) Unstable equilibrium of organic solutions in alkaline copper solution.

(*b*) Powerful action of caustic alkalies, particularly in boiling solutions, upon carbohydrates, producing saccharic and mucic acids and other oxidation products.

(*c*) Necessity of using a known strength of the reducing sugar solution. Wein's and other chemists tables show how concentration affects copper reducing power.

(*d*) Disturbing influence of non-reducing organic substances, *e.g.*, sucrose, upon the copper reducing power of a sugar. (Wein's tables for mixture of sucrose and invert in varying proportions prove this).

(*e*) Influence of temperature; time required to heat to 212° F., and for boiling the mixture.

(*f*) Great variations due to the use of differing amounts of copper.

For our experiments we used Merck's purest dextrose and lactose which were found to be 92 per cent. and 98½ per cent. pure respectively by combined polarimetric and copper-reducing methods, associated with the results of fermentation. With these sugars our own experiments show :—

Ratio of CuO precipitated to CuO added as "Fehling."	Dextrose actually present.	Dextrose found.
	Per Cent.	Per Cent.
1 : 5·15	92·0	104·00
1 : 2·93	92·0	92·10
1 : 1·56	92·0	89·10
	Lactose actually present.	Lactose found.
1 : 6·60	98·5	104·24
1 : 3·34	98·5	94·70
1 : 1·75	98·5	92·30

For the estimation of lactose and sucrose in the presence of each other, one is advised to get the copper reducing value before and after inverting with 2 per cent. of citric acid, boiling for 10 minutes.

Unfortunately lactose and invert sugar when present in mixtures do not react in the aggregate towards alkaline copper as one might assume from the sum of the sugars present. Doubtless one might work out the value of any particular mixture and construct some sort of a table; but the need of such a procedure proves the unsatisfactory character of the general method.

It may be necessary to estimate starch sugar in condensed milk; one must be therefore prepared to determine dextrose in the presence of lactose. We have made mixtures of these sugars and have compared the results with those obtained under the same conditions with the same strength and same volume of lactose and dextrose solutions taken separately, using similar amounts of Fehling's copper solution.

Our results prove that the mixtures do not give the same weights of CuO as the sum represented by the reducing powers of the constituents would occasion us to assume. The differences appear small, but they are really large enough to vitiate the accuracy of the analysis to a very marked extent. When sucrose was added the weight of copper oxide obtained was large enough to render the data quite useless.

We wish to protest strongly against the arbitrary fixation of copper reducing powers for sugar. If we turn to standard works on chemistry and analysis we find the copper oxide value of lactose given as 1·736 per grm., while 2·20 has been fixed for dextrose.

Wein's tables show us that the copper oxide values may vary from 1·632 to 1·746 for lactose, and from 2·06 to 2·460 for dextrose. It would not be difficult to show the utter absurdity of relying upon any such fixed factors for calculating the composition of a mixture of reducing sugars.

Having failed to find a really reliable chemical method we turn to polarimetry to help us out of our difficulty. To our Schmidt-Haensch instrument we have added a water-jacketed 2-dcm. observation tube; by means of this and a vessel of water and a thermo regulator, we can readily ascertain the rotatory power of our carbohydrate solutions at any degree from 0° C. to 100° C.

When sucrose, *i.e.*, saccharose (pure cane or beet sugar), is heated at 70° C. in solution with an addition of 10 per cent. of the volume of pure hydrochloric acid for seven minutes, complete inversion is effected. We have often confirmed this method of Herzfeld—

$$\underset{\text{Saccharose.}}{C_{12}H_{22}O_{11}} + OH_2 = \underset{\text{Lævulose.}}{C_6H_{12}O_6} + \underset{\text{Dextrose.}}{C_6H_{12}O_6}$$

average of—

$$\frac{-92{\cdot}9 + 52{\cdot}5}{2} = 20{\cdot}2$$

for "invert sugar" in this manner 1 part of sucrose furnishes 1·0528 grms. of a mixture of equal parts of lævulose and dextrose with a rotatory power of − 20·2, under specified conditions of temperature and concentration of solution. If the temperature be raised from 20° C. to 86° C., the polarimetric reading of invert solution becomes nil. For every elevation of one degree centrigrade lævulose loses about seven-tenths of a degree of rotatory power and at 86° C. the minus reading sinks until it is equal to the plus reading of the dextrose. For the analysis of a pure solution of sucrose and invert sugar, we have, therefore, a twofold polarimetric method based upon the following determinations :—Reading of the original solution at 20° C. and at 86° C., and reading of the inverted solution at 20° C. We find that at 86° C. the $[\alpha]_D$ of sucrose is 63·05 instead of 66·5 at 20° C. Therefore any *plus* reading of the original solution at 86° C., divided by 0·6365, at once gives the amount of sucrose. We find that in 10 per cent. solutions at 20° C., the rotatory power of invert sugar is uniformly − 20, a convenient figure to work with and remember.

One grm. of pure sucrose furnishes 1·053 grms. of invert with a reading therefore of − 0·20 × 1·053 = − 0·2106. The 1 grm. of sucrose has disappeared, and with it a plus reading of 0·665: therefore, every grm. of sucrose on inversion occasions a reduction in rotatory power of − 0·2106 + − 0·665 = − 0·8756.

Any diminution of the plus reading affected by Herzfeld's inversion process is divided by 0·8756 to obtain the percentage of sucrose. Knowing this and the rotatory value of the original solution it is easy to calculate the percentage of sucrose and invert.

The following are a few results obtained by us from the use of the latter method :—

—	Present.	Found.
Sucrose	3·41 3·96 4·92	3·27 3·81 4·96
Invert	12·69 12·60 3·32	12·32 12·60 3·19

Working at a temperature of 86° C. the process gave even more satisfactory results, and it will be admitted that these percentages are as accurate as we have any reason to desire, *i.e.*, in commercial or industrial analysis.

Having obtained such good results with mixtures of invert and sucrose at 86° C., we applied the same process to solutions containing sucrose and lactose. As an example of the method and the calculation we submit the following: 25 c.c. + 0·5 c.c. of strong hydrochloric acid heated to 187° F. gave 20·0° in a 2-dem. tube.

$$\frac{25 \cdot 5}{25 \cdot 0} \times 20 = 20 \cdot 4$$

for the original solution, or 10·2° in 1-dem. tube. 10·2° × 0·3466 = 3·537 $[\alpha]$. 3·537 $[\alpha]$ ÷ 0·49 (factor for lactose hydrate at 187° F., as above stated) = 7·22 per cent. lactose. Reading of the original solution in 2-dem. tube at 20° C. = 62·5 = 31·25 in 1 dem. = 10·84 $[\alpha]$.

$[\alpha]$ of original solution at 20° C.	10·84
$[\alpha]$ of lactose found, 7·22 × 0·525 at 20° C...	3·79
$[\alpha]$ of sucrose in original solution at 20° C.	7·05

7·05° ÷ 0·665 = 10·6 per cent.

——	Present.	Found.	Error.
Sucrose......................	10·58	10·60	+ 0·02
Lactose......................	7·10	7·22	+ 0·12
	17·68	17·82	+ 0·14

These results leave little to be desired.

How to apply the process to milks and condensed milks was the next question. Milk albumin in various solvents has a lævo-rotatory power of −76 to −91. It is therefore essential that these albumens should all be removed before taking the polarimetry of the serum. Wiley has tried several albuminoid precipitants and coagulating substances, but has decided in favour of a solution of mercury in nitric acid. Basic-lead acetate in excess causes a decrease of the rotatory power. Wiley found, as we are also surprised to find, that excess of the acid mercury nitrate solution has not the slightest effect on the readings.

Wiley uses an ingenious double-dilution method to dispose of the volume of the mercury precipitate. If the same weight of milk, after precipitation with mercury nitrate, is made up to 100 c.c. and 200 c.c. respectively, the rotatory powers of the filtrates should furnish the necessary data for the calculation of the volume of the mercurial precipitate, on the basis of $(200 - X):(100 - X)::a:b$. Where X = volume of precipitate, and a = reading of the single dilution, and b = reading of the double dilution. The correct reading according to Wiley = $\frac{ab}{a-b}$.

H. D. Richmond and L. K. Boseley have severely criticised Wiley's formula. Certainly numerous results of our own throw considerable doubt upon the correctness of $\frac{ab}{a-b}$.

Dr. P. Vieth assumes that the proteids in milks rarely ever vary more than from 3·5 to 4·0 per cent., and finds that for these the volume of the mercury precipitate is approximately 3 c.c.

Richmond and Boseley use Vieth's estimate and determine the percentage of fat (which may be calculated with sufficient accuracy from the gravity and total solids): an operation easily affected by one of the many modifications of Babcock's centrifugal process. Every per cent. of fat gives 1·11 c.c. volume of precipitate plus 3 c.c. for the proteids; therefore to every 100 c.c. one should add 3 c.c. of mercury nitrate solution and 4½ c.c. of water. The filtrate should give a reading reasonably representative of that of the milk itself.

We find that the acid mercury nitrate solution completely inverts sucrose when the solution is heated to 86° C.; it is therefore only necessary to place some of the filtrate in the 2-dem. jacketed tube and get readings at 20° C. and 86° C. to enable one to estimate the lactose and sucrose. If to a solution of sucrose one adds 2 per cent. of citric acid and heats to boiling for 10 minutes (as recommended by Stokes and Bodmer) or heats in a boiling water bath for 30 minutes (as advised by E. W. T. Jones) complete inversion results. Under the same conditions lactose remains quite unaffected. We have abundantly proved the accuracy of these statements.

Our method is simpler, as one has only to take the readings at 20° C. and 86° C. in the water-jacketed tube.

Lactose, Sucrose, and Glucose (Dextrose) in Milks, &c.—As starch-sugar is now so extensively used and is such a cheap commodity it is quite probable that it may be found in condensed milks; we should then have to deal with a mixture of three sugars and possibly some dextrins; we say "possibly" because we have met with starch-sugars quite free from dextrins, as proved by the alcohol test. Unfortunately the osazone process is not of much service; for although lactosazone is more soluble than glucosazone, the difference is not sufficiently great to allow of a quantitative separation.

We have shown that with mixtures of lactose and glucose in the presence of sucrose the copper methods are quite unreliable. The process we are perfecting is based upon the very different changes which the three sugars exhibit when heated in solutions containing 10 per cent. of the volume of hydrochloric acid. After three hours at 100° C. the glucose has suffered a little change, owing to the formation of mannose and other substances. The reading has increased for the lactose solution as the molecule has split up into galactose and dextrose. With $[\alpha]$ 80·21 for galactose and 52·9 for dextrose we obtain an average of $[\alpha]$ 66·55 for the mixed sugars; as 1 grm. of lactose produces 1·0528 grms. of these carbohydrates on hydrolysis it should produce an equivalent $[\alpha]$ of 1·0528 × 66·55 = 70·0. We find only 64·0, as similar changes to those occurring in the case of glucose have no doubt occurred.

Sucrose solutions when boiled with 10 per cent. hydrochloric acid first produce invert sugar, of which the levulose portion soon commences to carbonise. With sufficient boiling all the levulose disappears and only glucose remains; indeed, after three hours, we find this change has taken place. Unfortunately the results so far have been wide of what theory would assume For the sucrose used + 15·1 $[\alpha]_D$ was found instead of + 26·45 $[\alpha]$ the figure expected. We are trying to obtain constants for the three sugars; even should these not be in harmony with theory; with such constants we could readily calculate the composition of the solution containing the three sugars. Other workers may possibly offer elucidation of this subject.

Our best thanks are due to Mr. Donald Levy and also to Mr. Walter Mann for conducting a number of the experiments upon which our conclusions are based.

Discussion.

The Chairman referred to the practical importance of the paper, in which the question was attacked by both chemical and optical methods, of which the optical method appeared to have the great advantages of rapidity and cleanliness. The purity of certain foods and especially of the different varieties of condensed milks, were dependent on researches such as those of Mr. Richardson and his colleagues.

Mr. Fairley referred to the great advantage a physical method possessed when only a small quantity of the substance was available for analysis, as in many cases no destruction of the material took place.

A member suggested that the "blueing" of the filter paper was brought about by the paper becoming mercerised with strong caustic soda, then taking up and combining with a portion of the copper, and that the washing with tartaric acid according to Mr. Richardson's method decomposed any compound thus formed, and enabled the paper to be more thoroughly washed.

Mr. Richardson said that ordinary filter papers were practically pure cellulose and a fine texture was necessary to obtain a clear filtrate. To carry out the process a large excess of copper was necessary, and he had not found any filter paper which did not turn blue.

Meeting held at Leeds, on February 22nd, 1904.

MR. JAMES E. BEDFORD IN THE CHAIR.

THE TREATMENT OF SEWAGE BY BACTERIA.

BY W. J. DIBDIN, F.I.C., F.C.S., ETC.

In responding to the invitation of the Yorkshire Section of the Society of Chemical Industry to introduce a discussion on the present position of the important question of the disposal of sewage by bacterial agency, I do so with much pleasure, especially as in no other district has the question been more ably or enthusiastically taken up with the view to ascertain the most economical and reliable means of applying this now generally recognised method of sewage purification.

From the work which has been done in the past it is perfectly clear that there is no difficulty in obtaining effluents of excellent quality by the final treatment of the partially purified sewage on either bacteria or "contact" beds, or on trickling filters on which the liquid is distributed by one of the various forms of rotating sprinklers. By either method or by various modifications of these the final work may be equally well accomplished. The great desideratum is an equally effective and simple method of primary treatment of the raw sewage in such a manner as will effectually and economically meet the sludge difficulty. In the following observations I propose to confine myself to this point.

When the original bacterial installation on working lines was started at the Northern Outfall Works of the London County Council under my direction in 1892 the sludge was first removed from the sewage by preliminary treatment with lime and iron in the proportions of about 4 grs. of lime to 1 gr. of ferrous sulphate per gallon of sewage, followed by settlement in tanks.

When I introduced the coarse-bed treatment at Sutton as a preliminary to the second or fine bed, it was with the object of ascertaining how far the bacterial agency was capable of disposing of the suspended organic matters and thereby avoiding the necessity of chemical treatment. The result was that the organic matters were so far destroyed or altered in character that they no longer formed the foul abomination denominated sludge, and that the resulting effluent was in many cases sufficiently pure for direct treatment either on land or for discharge into streams having a sufficient flow, while, if passed through the second or fine bed the effluents were sufficiently pure to be passed direct into any inland brook.

The difficulty experienced with the ordinary coarse, or "first contact" bed, in those cases where the crude sewage was turned direct on to it, was that the interstices between the particles of coke or clinker, &c., became filled with the finely divided matter in the sewage and the carbonaceous residuum from the bacterial action on the organic matters.

I have always felt that notwithstanding the expense entailed in turning over the material in the coarse bed from time to time and occasionally changing it for a standbye quantity which had been weathering, the coarse bed system does indeed go further to solve the problem of the inoffensive disposal of the sludge than any other known method.

Take a case in point, at Alton, Hants, where about 33 per cent. of the dry weather flow is brewery refuse. The filling material in the coarse beds had to be changed after three years' work. The cost of labour was 1*s.* 2*d.* per sq. yd. or, say, 5*d.* per yard per annum. The fine beds, equal to 830 sq. yds., had treated 160,000 gallons daily plus subsoil water. This quantity is equal to over 200,000 gallons per yard, so that five yards would have treated one million gallons, the cost for which for renewing the material in the beds from a reserve supply would be 5*s.* 10*d.*

The adoption of a grit or detritus tank for the purpose of intercepting the mineral matters and those of a more resistant organic character has been very successful in prolonging the life of the coarse bed, while the septic tank, introduced by Mr. Cameron at Exeter, is undoubtedly effective in this connection.

Unfortunately, however, both these contrivances still leave a quantity of sewage sludge to be disposed of. The septic tank especially, whilst the effluent from this tank does undoubtedly give rise to objectionable emanations, and no little evidence is forthcoming to the effect that it is better to prevent, if possible, the sewage undergoing putrefactive decomposition before passing it on to the grass land, or on sprinkling filters. These experiences entirely support the view that I have always held, and do still hold most strongly, viz., that the sewage should never be allowed to undergo putrefaction, but should be collected and treated in as fresh a condition as possible. I admit at once that the tank methods are convenient at first sight as they may save a little trouble. Let there be a grit or detritus tank to prevent the mineral matters going on the beds, but I submit that the moment putrefaction starts in this tank it should be cleaned out.

The question next arises as to what can be done to either prevent the putrefactive action in the tank whether "septic" or "grit," or to increase the efficiency of the coarse or first contact bed. On turning to the two admirable reports by the Corporations of Manchester and Leeds we find the question as to causes of loss of capacity of contact beds fully discussed. Summarising these, it is found that the chief causes of loss of capacity are the following:—

(*a*) Settling together of the material.
(*b*) Growth of organisms.
(*c*) Impaired drainage.
(*d*) Insoluble matter entering bed.
(*e*) Breaking down of material.
(*f*) More organic solids entering the bed than it can can digest.
(*g*) Soluble matters being rendered insoluble by the action of the beds, as for instance, iron salts.

After reviewing these points the Leeds report continues: "If, therefore, contact beds are to be used for Leeds sewage in future the problem will be—

"1. To find a material of perfectly even size not liable to degradation.

"2. To reduce as far as possible the solid matters put on to the rough bed.

"3. To exclude and treat separately the iron liquors. Another point suggests itself, whether it would be possible to construct a bed in such a way that the undigested or indigestable solids shall be expelled from the beds with the effluents."

We have here the question fully set out. With a view of suggesting how the various points may be successfully met and inviting discussion thereon, I submit the following considerations:—In the case of a coarse bed filled with coke or clinker, &c., we have a number of solid particles presenting only an outer surface, the interior of the particle occupying space to no purpose. On consideration it occurred to me that this interior space could be utilised by employing a material of hollow form so that it would present an interior as well as an exterior surface on which the bacteria could grow, whilst the interior space would largely increase the water content, or working capacity of the bed. These considerations induced me to think of agricultural drain pipes as suitable, but the cleansing of the interior of the pipes presented a difficulty. Then the obvious question followed, What is a pipe but a bent plate? Cut your pipe down its length and the thing is done. At once we have the interior and exterior surface, facilities for cleansing, and the working content of the bed increased as desired. With this view I requested Mr. Hamblet, of West Bromwich, to make me some trial tiles having ridges on their under surface so as to separate them from each other. According to the depth of these ridges, so will be the water capacity of the bed. Thus, if they were 1 inch deep and the thickness of the tile half an inch, the water capacity will obviously be two-thirds or 66 per cent. In the case of a new coarse coke bed the initial water capacity will be about 50 per cent., which soon becomes reduced to about 33 per cent., by one or more of the causes mentioned above, particularly to the breaking down and settling of the material together, inducing impaired drainage, which would be entirely avoided by the use of suitable flat plates supported at intervals.

As an alternative to the use of tiles I may instance an experimental installation at Devizes in which waste slate *débris* is used under the sanction of the Local Government Board. The slates vary in size from about 1 ft. to 3 ft. super., and average about $\frac{1}{4}$ inch thick. They are supported about 1 in. apart by small slate blocks. This arrangement gives no less than 80 per cent. of water capacity to the beds, thereby doubling their effective working capacity as compared with coke, &c. In fact the bed at Devizes is exactly one-half the size of the fine bed into which it discharges, with the result that the cost of construction of an installation is reduced 50 per cent. The slate *débris* from the hard slate refuse at Blaenau Festiniog, in North Wales, is obtainable in practically unlimited quantity and a great variety of sizes. By the use of such tiles or slates or other similar material the chief causes of loss of capacity are overcome. To take these seriatim as before—

(*a*) The material will not settle together.

(*b*) The growth of organisms will take place on both surfaces of the slates or tiles and will not choke the spaces between as in the case of coke, &c.

(*c*) The drainage cannot be impaired.

(*d*) The insoluble matter (grit, &c.) can be kept off the bed by the use of a grit tank, or, if it gains access, can be removed from such surfaces by flushing, &c.

(*e*) The material will not break down.

The accompanying diagrammatic plan and section shows the arrangement proposed for the disposition of the slates or tiles. The top layer should be laid overlapping in such a manner that it forms an automatic screen by the junction of the edges through which the finer divided matters can pass to the under layers. The fibrous and coarser matters being retained on the top layer of slates, may from time to time be swept to the further end of the bed, which is raised above the water level, where they may thoroughly drain before removal. The wide channel receiving the sewage will act as a grit chamber as in the Carlisle installation which I designed in 1899. The sewage will flow over the weir-lip of this channel on to the slates and thereby become aerated.

Another point is that as the sewage gradually fills the bed films of air will be retained on the under surface of each plate. If this film is only one-fiftieth of an inch thick and the intervals between the plates 1 in., the quantity of oxygen so retained will be sufficient to thoroughly aerate the sewage, for instance, each gallon of sewage will dissolve about 2 cb. in. of oxygen, which will be contained in 10 cb. ins. of air. Two cubic feet of bed capacity of 50 per cent. will contain $6\frac{1}{4}$ galls., which will accordingly have to be supplied with $62\frac{1}{2}$ cub. ins. of air. The plates in 2 cub. ft. of such a bed will present a total underneath area of 144 × 24 = 3,456 ins. super. If the film of air retained under this surface be only of an average depth of one-fiftieth of an inch the total film of air so retained will be equal to 69 cb. ins. This quantity is in addition to that which will be already dissolved in the sewage and mechanically held in suspension as the water flows over the weir on to the plates.

The following analyses of samples of sewage put on to a slate bed in which the layers of slate are about 2 ins. apart, and of effluents obtained therefrom, will serve to indicate the nature of the work accomplished :—

Slate Bed with Layers 2 ins. apart.

No. of Filling.	Sewage. Alb. NH_3.	Effluent. Alb. NH_3.	Percentage Purification effected.	Suspended Matters in Effluent.
	Grains per Gallon.	Grains per Gallon.		
2	0·804	0·668	17	None.
4	0·675	0·546	19	,,
5	0·910	0·740	19	,,

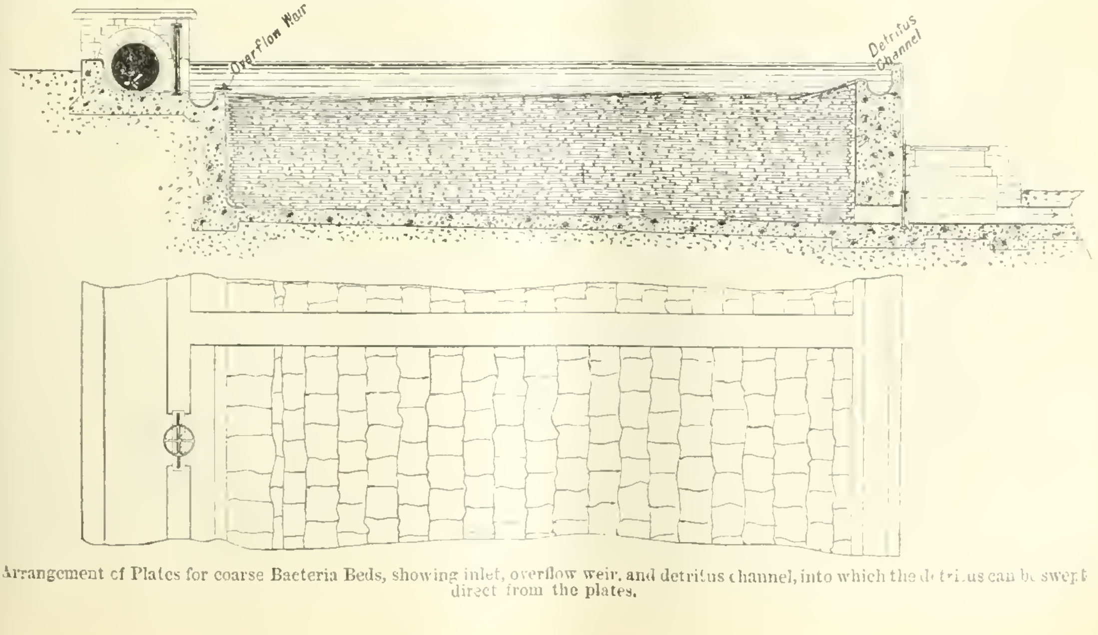
From these results it will be seen that as the deposit of sewage matters became more thoroughly charged with bacteria, the efficiency of the bed increased until it was fully equal to that of a coke bed in regard to the effect on the nitrogenous matters of the sewage, whilst the capacity of the bed was equal to double that of a coke bed of similar size.



Arrangement of Plates for coarse Bacteria Beds, showing inlet, overflow weir, and detritus channel, into which the detritus can be swept direct from the plates.

Discussion.

The Chairman said he considered that the principle of the process a good one, because it found use for slate which would otherwise be wasted. The area occupied by these beds was only one-half of that required for the usual installations, and this was another important point which favoured the method described. The whole subject of sewage purification was of great importance, especially to a town situated as Leeds was, with a river flowing through it containing unpurified sewage from towns higher up the stream. Authorities ought to be compelled to remove objectionable matter from sewage before allowing it to pass into a stream.

Mr. Jones (Yorkshire Fisheries Board) mentioned a case of contamination which was going on through the circulation of unpurified sewage. It was only one instance of many similar cases, and he was sorry that his board had not been able to deal with the responsible authorities in a proper manner.

Dr. H. Maclean Wilson (West Riding Rivers Board) said that it was now recognised that any kind of sewage could be purified by one or other of the several bacterial methods which were in use. He agreed with the author of the paper that there was no need to allow putrefaction to take place in the sewage before its application to the bacteria beds. Although the bacteriological treatment of sewage was first looked upon with some reserve, it was now admitted to be one of the best methods of purification. At the Knostrop Sewage Works they were able to produce a pure effluent 20 minutes after the sewage arrived at the works, thus showing the rapidity of the purification by bacteria. An ideal contact bed is one that offers the largest amount of surface of material with the largest water capacity. The beds described by Mr. Dibdin possessed this advantage, and this commended them to him. He thought it necessary to have detritus tanks, although the lecturer did not use them.

Dr. Cheetham (M.O.H., North Riding of Yorkshire) thought that some inexpensive method of treatment would be appreciated by authorities which were unable to expend large sums of money on sewage works. Mr. Dibdin's method had the advantage of being more economical than other processes.

Dr. Evans (M.O.H., Bradford) asked what kind of sewage had been used in the experiments at Devizes.

Mr Oscar J. Kirkby supported the use of septic tanks. When the sewage putrefies, one half of the work of purification is done.

Mr. E. W. Dixon (Harrogate) thought that although the water capacity in a bed made of slate slabs was greater than in one of honeycomb slag, yet the surface available for oxidising was greater in the latter case. He asked whether the sediment which deposited on the slabs of slate interfered with the action of the bacteria on that surface. He also inquired what was the relative superficial area of a slate bed compared with a coke bed.

Dr. J. Spottiswoode Cameron (Medical Officer of Health, Leeds) said if the slate bed got rid of the difficulties of the present coarse bed on the contact system and the septic tank could be got rid of altogether, he thought that it would be an advantage. He asked the lecturer if the slate bed could be used with a sprinkler. He congratulated Mr. Dibdin upon the improved prospect of his contact beds. This matter was, however, rather an engineering one. He had hoped to have heard something more upon the chemistry of the effluent. He was anxious to know what became of the bacterial products in the effluent. It was an interesting inquiry whether products of an alkaloidal nature, allied to the ptomaines which they were accustomed to in the body, were not generated by the bacteria in the tanks, and whether they did not pass away in the effluent. Some of them might naturally be of a poisonous character, and he rather hoped that this matter would have been dealt with. Even typhoid germs themselves might pass through bacterial beds with comparatively little change. He congratulated the Society upon having secured a paper from Mr. Dibdin, who, although a chemist, had like another distinguished chemist (M. Pasteur), largely discarded chemistry for biology. The success of the bacterial process of sewage treatment was largely due to Mr. Dibdin.

Mr. T. Fairley pointed out one great advantage of this method of treatment which previous speakers had overlooked. This was the easy way in which a slate bed could be cleaned when necessary and restored to its original condition, the only expenditure incurred being the cost of labour to carry out the cleansing. This would be the only cost for the maintenance of the bed.

Mr. W. J. Dibdin, in replying, said that he did not wish to deny the value of septic tanks where they were found to be useful, but personally he did not approve of them. One great disadvantage was the production of objectionable odours. He could not say that ptomaines were produced during the putrefaction of the organic matter; this, however was avoided by using aerobic bacteria beds. He did not wish to say that the use of detritus tanks was unnecessary. The channels around the beds described acted as such, so long as the rate at which the sewage was flowing was not too great. The kind of sewage with which he had experimented varied very considerably, at times absorbing 10 and even 13 grains of oxygen per gallon, but at other times it could be considered normal for a residential district. A coke bed was liable to break down, so that, although the area of surface in a new bed might at first be slightly greater than in a slate bed, it diminished considerably, whereas the area of a slate bed was practically constant. The question was not as to relative area in regard to mechanical contact, but to relative bacterial efficiency and working capacity.

In answer to the question regarding a deposit of sewage on the upper surface of the slate, bacterial action went on at the surface of the deposit on the slate just the same as underneath a slate. The film of bacteria was the active agent, and so long as this was present, purification must go on. There were two methods of cleaning the beds: (1) By taking up each slate separately, cleaning it, and relaying the bed. (2) When laying the bed in the first place it could be so arranged that, by the removal of the slates down the centre of the bed, a hose pipe might be introduced to wash away the deposit on the slates on either side of the opening.

Replying to Dr. Cameron, he had not yet tried a slate bed with a sprinkler, but hoped to try it on a new bed which he was about to put down. If any typhoid germs were present in the sewage before treatment, they were practically all destroyed by the action of the bacteria in the beds and the effluent. The effluents from these beds retained and maintained over 50 per cent. of dissolved oxygen, and would not undergo putrefaction, and fish were able to live in the effluents. These he considered sufficient tests for the purity of the water, but he agreed that the standards proposed by the Mersey and Irwell Joint Committee and the West Riding of Yorkshire Rivers Board were good standards.

Obituary.

VLADIMIR MARKOWNIKOFF.

Professor of Chemistry in the University of Moscow.

Vladimir Markownikoff was born in 1839. He entered the University of Kazan in 1856 and studied under Professor Ketara, at a later date becoming the assistant of Prof. Butlerow. He shortly afterwards obtained his degree, and then the Chair of Chemistry in the University of Kazan. Here Markownikoff continued his work until about 1872, when he was elected to the Chair of Chemistry in Moscow University, with which institution he was connected with so much distinction up to the time of his death, which took place on Feb. 11th. Markownikoff's researches were especially directed to the inquiry into the nature of the hydrocarbons of Caucasian petroleum. It is now nearly twenty-five years since Mr. Ragosine approached him with regard to the investigation of

Baku petroleum, in the utilisation of the hydrocarbons and other products of which the former was greatly interested, extensive works having been erected by him at Konstantinoff and Balakhany. Markownikoff's investigation of this subject, in conjunction with Ogloblin, appeared in the Journal of the Russian Phys. and Chem. Soc. in 1883 (see this J., 1883, 166). He discovered the naphthenes, and later on practically confirmed the views of Beilstein and Kurbatow, to the effect that the hydrocarbons of Caucasian petroleum, of the general formula C_nH_{2n}, are hydrogen addition products of aromatic hydrocarbons, and are not identical with the hydrocarbons of American petroleum of the same general formula, which occur along with those of the C_nH_{2n+2} series. His remarkable work on the naphthenes and terpenes, published in 1893, and on the so-called petroleum acids, is sketched in this J., 1893, 32—33. There is not the least doubt that the researches of Markownikoff have furnished the means whereby the most important improvements have been introduced in the refining of Russian petroleum. In conjunction with Reformatsky, in 1894, he investigated the Bulgarian oil of roses (this J., 1894, 272).

atent Specifications may be obtained by post by remitting as follows:—

English.—8*d.* each, to the Comptroller of the Patent Office, C. N. Dalton, Esq., Southampton Buildings, Chancery Lane, London, W.C.

United States.—1*s.* each, to the Secretary of the Society.

French.—1 fr. 25 c. each, to Belin et Cie., 56, Rue des Francs-Bourgeois, Paris (3e).

.—PLANT, APPARATUS, AND MACHINERY.

English Patents.

Air and other Gaseous Fluids; Apparatus for Liquefying ——. H. Knudsen, London. Eng. Pat. 23,646, Oct. 29, 1902.

The air, under a pressure of about 2,000 lb. per sq. in. nd sufficiently cooled, passes into a separator consisting of a comparatively small inlet pipe leading to near the bottom of a comparatively large surrounding pipe, in which moisture and other impurities, *e.g.*, oil, are deposited. The air then passes through an after-cooler consisting of coils of pipe, in which any remaining moisture is frozen out. A spare after-cooler is provided so that the coils can be leaned without interrupting the process. The compressed ir passes from the after-cooler to the liquefier, in which t is cooled sufficiently to cause liquefaction of any arbon dioxide present. It then enters the top of the entral tube of the liquefier, which is provided with xternal and internal baffles, and from the bottom of he central tube passes to the nozzles of a turbine having a "Pelton" wheel. The cold compressed air impinges upon the buckets of the Pelton wheel, expands, and is partially liquefied, the liquid portion being tapped off from the motor casing. The unliquefied portion is led back first to the spaces surrounding the tubes in the liquefier, then to the after-cooler, thereby cooling the incoming compressed air, and is finally returned to the air-compressor.—A. S.

Retort Furnace, and method of Charging the Retort. C. Westphal, Berlin. Eng. Pat. 3331, Feb. 12, 1903.

See Fr. Pat. 329,008 of 1903; this J., 1903, 990.—T. F. B.

Drying Apparatus; Impts. in ——. H. Diedrich, Paris. Eng. Pat. 4173, Feb. 21, 1903.

A horizontal cylinder, mounted on rollers, is provided with blades shaped to lift up the material and deposit it slightly further on, to be taken up by the following blade, and thus pass it through the cylinder. The cylinder is heated by passing the furnace gases round it. The drying is effected by passing air through winged or corrugated tubes in which it is heated by the furnace gases and then through the cylinder in the opposite direction to the material. Part of the air, after passing through the cylinder and a dust-depositing chamber, is returned to the furnace to support combustion.—W. H. C.

Drying Apparatus; Impts. in ——. H. J. Haddan, London. From The Edison Reduction Machinery Co., Cleveland, Ohio, U.S.A. Eng. Pat. 25,060, Nov. 17, 1903.

The drying chamber surrounds a central shaft furnished with radial stirring arms. It consists of two end-pieces, between which are a number of cast-iron annular cylindrical sections, provided with projecting flanges, by means of which they are bolted together. The sections can be adjusted circumferentially, and are provided with ports by which the annular space between the inner and outer walls of one section communicates with the corresponding space between the walls of the next section. Steam, enters through a port in one of the end-pieces of the chamber and passes successively through the spaces between the walls of the different sections, condensed water being drained off. One or more of the cylindrical sections are provided with pipe connections for the introduction and discharge of the material to be dried, all vapour escaping through the feed-opening.—A. S.

Centrifugal Separating Apparatus; Impts. in ——. J. M. Adam, Glasgow. Eng. Pat. 4612, March 2, 1903.

The improvements consist in arranging the centrifugal dust separator described in Eng. Pat. 14,302 of 1897, in an outer casing, which acts as a balance chamber to equalise any intermittent suction. Also a trap is provided for the inlet to the separator, fitted with a perforated screen to intercept any bulky matter.—W. H. C.

Centrifugal Machines; Impts. in ——. A. R. Robertson, Glasgow. Eng. Pat. 8114, April 8, 1903.

The strainer or lining of the revolving basket of a centrifugal machine is arranged as an annular piece or ring made of a material, preferably "Liebermann gauze," either itself elastic and perforated, or porous, or it is made of parts capable of expanding, and thus of bearing against the inner surface of the basket when the machine is in operation.—A. S.

Concentrating Liquids; Apparatus for ——. A. J. J. Waché, Paris, and E. F. G. E. Locoge, Douai. Eng. Pat. 5770, March 12, 1903.

See addition of Dec. 24, 1902, to Fr. Pat. 283,758 of 1898; this J., 1903, 899.—T. F. B.

Moulding or Briquetting; Process and Apparatus for preparing Pulverulent Materials for ——. B. J. B. Mills, London. From The Zwoyer Fuel Co., New York. Eng. Pat. 541, Jan. 8, 1904.

The material is fed in at one end of a horizontal chamber mounted on a longitudinal shaft, which is provided with blades and driven at a high speed. The binding material is blown in at the other end, by an atomiser, either as spray or powder. Means are provided for passing hot gases through the chamber. The mixture passes from the chamber to the briquetting or moulding machine. A vertical arrangement is also claimed for letting the material fall through the chamber whilst the binding material is being sprayed upwards from the side and hot gases passed up.—W. H. C.

United States Patent.

Muffle. J. Carter and A. G. Carter, Malden, Mass. U.S. Pat. 752,438, Feb. 16, 1904.

The claim is for a cylindrical muffle having a central vertical cylindrical flue, as well as a surrounding external flue. The dome covering the muffle has a central opening opposite this flue, provided with an adjustable cover, which can be operated from without, by means of a chain and pulley, or other mechanism.—W. H. C.

French Patent.

Extraction Apparatus. E. Bataille. Fr. Pat. 328,185, Dec. 24, 1902.

The apparatus consists of an extraction chamber superposed on an evaporation chamber and connected with a condenser. The filtering medium in the extraction chamber surrounds the material to be extracted, upward or downward extraction being employed. There is also direct communication with the evaporator, which can be controlled from without by means of a valve and rod. The evaporator is heated by a water bath, and steam from the latter for blowing out the solvent, is conveyed to the evaporator and delivered by means of silent heaters. The water-bath can be heated by direct fire. The condenser coil is in two parts, with a separator between, so that the hot solvent can be directly applied. The condenser communicates with a receiver placed below and from which a reflux condenser, cooled by the incoming water to the main condenser, serves to complete the condensation of the solvent.—W. H. C.

II.—FUEL, GAS, AND LIGHT.

Cyanogen; Extraction of —— from Coal-Gas. W. Feld. J. f. Gasbeleuchtung, 1904, **47**, 132—136, 157—159, 179—184.

The author has investigated Bueb's process of cyanogen-extraction (this J., 1900, 999; 1903, 204, 356; 1904, 111), in which the ammonia of the gas is utilised as the alkali required, along with a solution of ferrous sulphate. Instead of all the cyanogen being arrested as insoluble ammonium-ferrous ferrocyanide, he finds that the cyanide mud contains only one fourth of it in that form, one half existing as soluble ammonium ferrocyanide, and the remaining fourth as insoluble iron cyanide. According to the amount of oxygen present in the gas, there is a loss of cyanide through formation of sulphocyanide (thiocyanate); hence the process cannot be applied to coke-oven gases. The working up of the cyanide mud is a difficult matter, unsuitable for gas-works practice; and, as the recovery of the ammonia is also troublesome, the profit from the process is less than in the case of other wet methods of extraction. (See this J., 1903, 16.) Where this process is employed it is preferable to work with a weaker (14—18 per cent.) solution of ferrous sulphate than that recommended by Bueb: in this way the absorptive power of the iron salt is fully utilisable, and the cyanogen is retained almost wholly as soluble ammonium ferrocyanide. From such a liquor the ammonia and cyanogen can be readily recovered.—H. B.

Luminous Arcs in Metal [Mercury, &c.] Vapours. E. Weintraub. XI. A., page 326.

English Patents.

Peat; [Electrical] Process and Apparatus for removing Water from ——. B. Kittler. Eng. Pat. 126, Jan. 2, 1904. XI. A., page 326.

Carbon Monoxide; Producing ——. R. Pearson, London. Eng. Pat. 3347, Feb. 12, 1903.

Gases from a lime kiln are passed over incandescent coke. —E. S.

Gas-Generator Furnaces with Inclined Retorts. A. G. Brookes, London. From Stettiner Chamotte-Fabrik A.-G. vormals Didier, Stettin. Eng. Pat. 3852, Feb. 18, 1903.

In gas generator furnaces with inclined retorts, to facilitate the production of a uniform temperature in the retorts, the combustion chamber of the furnace is divided by means of vertical partitions into a number of separate compartments, each communicating with the generator through apertures controlled by dampers. The air supply to the combustion chamber is heated by flowing through zig-zag passages in the furnace pillars.—H. B.

Gas Generating Apparatus or Gas-Producers; Impts. in ——. W. P. Thompson, London. From Schweizerische Lokomotiv- und Maschinen Fabrik, Winterthur. Eng. Pat. 5798, March 12, 1903.

A gas-generator, worked by suction, is provided at the upper end of the furnace with a hollow, annular water-vaporiser, which is connected to a water reservoir. A diaphragm within the latter is attached to the outlet valve and acts automatically by admitting to the vaporiser, at each suction stroke, the required quantity of water. The air supply for the generator is drawn through the vaporiser, and the mixture of air and steam is led to the grate of the furnace down a pipe round which the hot generator gases circulate. The apparatus is provided with charging devices, a scrubber, and a fan for starting the furnace.—H. B.

Gas Furnaces ; Impts. in Regenerative ——. F. Siemens, London. Eng. Pat. 5866, March 13, 1903.

The claim is for an improved type of Siemens' regenerative furnace, in which the gas-regenerative flues (constructed of checker brickwork) expand towards the furnace, and are heated by radiant heat from it. The flues are built so as to have no direct communication with the chimney, and may be surrounded wholly or in part by air-passages between the furnace and air-regenerators. Before the final combustion of the gases takes place in the furnace, they may be mixed in a chamber interposed between the gas- and air-flues and the furnace, and in order to enrich poor gas, oil may be admitted into the mixing chamber. The waste heat of the products of combustion may be utilised by passing them through a heating flue in a boiler.—L. F. G.

Gas ; Manufacture of ——. A. J. Boult, London. From J. E. Goldschmid, Frankfort-on-the-Maine. Eng. Pat. 7770, April 3, 1903.

Coal is first partially coked in a lighting-gas retort, through which a current of water-gas is passed, and is then treated in a water-gas generator for the production of the water-gas. If the gas produced is too rich for the purpose in view, it may be diluted by mixing with the water-gas the carbon dioxide generated during the blast period.
—H. B.

Oil-Gas of High Combustible Value ; Process for Making an ——. H. Blau, Augsburg, Germany. Eng. Pat. 10,527, May 8, 1903.

See Fr. Pat. 322,115 of 1903 ; this J., 1903, 1190.—T. F. B.

Generators for Power Gases ; Impts. in ——. E. Catier, Boussois, France. Eng. Pat. 19,929, Sept. 16, 1903.

The invention relates to improvements in various details of construction of a suction-generator for use with a gas-engine.—H. B.

Water-Gas ; Manufacture of ——. A. J. Boult, London From W. A. Köneman, Chicago. Eng. Pat. 28,761, Dec. 31, 1903.

See U.S. Pat. 749,302 of 1904 ; this J., 1904, 247.—T. F. B.

Carburetting or Enriching Coal Gas ; Apparatus for ——, *and for like purposes.* The Gas Economising and Improved Light Syndicate, Ltd., London, and J. McColl, Barking. Eng. Pat. 622, Jan. 9, 1904.

Improvements are described in Eng. Pats. 14,111 of 1886, 14,031 of 1889, and 18,082 of 1891 (this J., 1892, 898), these comprising an arrangement of valves for controlling the flow of gas to the chamber, means for preventing the deposition of naphthalene round the valves by the preliminary introduction of oil, and devices for bringing the gas more completely into contact with the carburetting liquid.—H. B.

Gas Washers. J. E. Bousfield, London. From H. Gerdes, Berlin. Eng. Pat. 9733, April 29, 1903.

The washer is built up of a number of superimposed horizontal circular chambers, having a central vertical shaft which carries, within each chamber, a centrifugal device for atomising the washing liquor. The liquor flows down through the apparatus, entering each chamber through the top, near the circumference, and leaving it through a central orifice in the bottom, while the gas flows in the reverse direction.—H. B.

French Patents.

Peat Briquettes ; Process and Apparatus for Making ——. F. White and G. A. Griffin. Fr. Pat. 336,151, Aug. 14, 1903.

See Eng. Pat. 17,514 of 1903 ; this J., 1903, 1237.—T. F. B.

Aluminium Alloys ; Manufacture of ——, *with a view to the production of Hydrogen more or less Carburetted, and Pure Hydrogen.* N. A. Hélouis, L. Mauclaire, and E. Meyer. Fr. Pat. 335,954, Sept. 25, 1903. X., page 325.

Air-Gas ; Apparatus for Making ——. E. Pichegru. Fr. Pat. 336,036, Oct. 17, 1903.

Compressed air is admitted from a reservoir, by way of a reducing valve, into a carburetter consisting of a chamber containing a number of superimposed trays, charged with gasoline. The air is caused to pursue a tortuous course in its passage up between the trays, to the outlet.—H. B.

Generator for Poor Gas, free from Tar. L. Boutillier. Third Addition, Oct. 30, 1903, to Fr. Pat. 331,014, April 7, 1903.

Various modifications are described of the apparatus mentioned in the principal patent, in which the gases from the freshly charged fuel are freed from tarry matters by passage through a body of fuel free from tar.—H. B.

Gas ; Continuous Process for Manufacturing ——. F. Clauss. Fr. Pat. 336,397, Nov. 2, 1903.

See Eng. Pats. 1090 and 1091 of 1903 ; this J., 1903, 1342
—T. F. B.

Electrodes for Arc Lamps ; Mineralised ——. Soc Française d'Incandescence par le Gaz (Système Auer). Fr. Pat. 328,180, Dec. 20, 1902.

The addition of borate or fluoride of barium, magnesium, aluminium or strontium, with or without alkali borates, to carbons containing calcium compounds is claimed (see Blondel's Fr. Pat. 323,924 ; this J., 1903, 487).—H. B.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM AND MINERAL WAXES.

Ammonia [Recovery from Coal Gas] ; Notes on ——. F. E. Sheriff. J. Gas Lighting, 1904, **85**, 2130.

The author advocates the use of rotary scrubbers instead of towers, both for absorbing ammonia from the coal-gas and for the final production of liquor ammoniæ, claiming as advantages the use of a smaller quantity of water the removal of a greater amount of impurities from the gas, and the production of a much stronger crude liquor. It is stated that by the use of rotary scrubbers for washing the gas, 47 per cent. of the carbon dioxide, 33 per cent. of the sulphuretted hydrogen, and 99·8 per cent. of the ammonia can be removed from the gas ; and that crude liquor containing 6 per cent. of ammonia can be produced.
—A. S.

Petroleum ; Neutral Sulphuric Ester in Commercial ——. F. Heusler and M. Dennstedt. Zeits. angew. Chem., 1904, **17**, 264—265.

Several years back the authors discovered in commercial petroleum sold in Bonn, the presence of a sulphuric ester resembling that formed during the acid refining of lignite tar (see this J., 1895, 558), and a series of tests since performed has revealed the same (neutral) compound in all the oil in the storage tanks at Hamburg. The presence of the aforesaid ester is said to increase the tendency of the burning oil to carbonise the lamp wick.—C. S.

Aniline ; Direct Hydrogenation of ——. *Syntheses of Cyclohexylamine and of two other New Amines.* P. Sabatier and J. B. Senderens. XXIV., page 341.

English Patent.

Gas Liquor; Treatment of ——. C. G. Moor, London. Eng. Pat. 4988, March 4, 1903.

The gas liquor of small works, not having plant for sulphate making, is mixed with acid sodium sulphate, and after separation of the precipitate formed, is evaporated. Ferrous sulphate may be added during the concentration to prevent the evolution of hydrogen sulphide. The product may be used as a manure, or as a source of ammonia.—E. S.

United States Patent.

Organic Acids [from Petroleum]; Process of making ——. N. Zelinsky, Moscow. U.S. Pat. 752,744, Feb. 23, 1904.

See Fr. Pat. 326,665 of 1902; this J., 1903, 807.—T. F. B.

French Patent.

Asphalt; Process of making Artificial ——. Aktieselskabet Venezuela-Asfalt Komp. Fr. Pat. 336,020, Oct. 6. 1903.

See Eng. Pat. 21,799 of 1903; this J., 1903, 1343.—T. F. B.

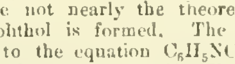
IV.—COLOURING MATTERS AND DYESTUFFS.

Diazotisation of Nitrobenzene. E. Bamberger and A. Wetter. Ber., 1904, **37**, 629—630.

If a paste of sodamide with light petroleum spirit be added to nitrobenzene in a freezing-mixture, traces of normal benzene-sodium diazotate are formed and can be detected by means of an alkaline α-naphthol solution. Finally some iso-diazotate is also formed. The formation of the normal diazotate probably takes place according to the equation $C_6H_5.NO_2+H_2N.Na = C_6H_5(N_2ONa)+H_2O$. If the mixture be warmed iso-diazotate alone is formed, but only in small traces. In presence of β-naphthol the yield of diazo-compound is considerably improved, though even in this case not nearly the theoretical amount of benzene-azo-β-naphthol is formed. The reaction takes place according to the equation $C_6H_5NO_2 + Na.NH_2 + C_{10}H_7OH = C_6H_5.N_2.C_{10}H_6.OH + NaOH + H_2O$. Aniline, sodium nitrite, β-naphthol, and nitrobenzene, when mixed together in absence of moisture form no benzene-azo-β-naphthol, even in a week, and therefore the dyestuff formation in the above experiment cannot be due to the formation of aniline and sodium nitrite from sodamide and nitrobenzene.—E. F.

α-Naphthylmagnesiumbromide. S. F. Acree. Ber., 1904, **37**, 625—628.

α-Bromonaphthalene reacts almost quantitatively with magnesium to form α-naphthylmagnesium bromide. This compound reacts readily on carbon dioxide, ketones, benzoyl chloride, and other substances. With ketones it forms carbinols according to the equation—$R_2:CO + C_{10}H_7.MgBr = R_2:C(OMgBr)(C_{10}H_7)$. The products form the corresponding carbinols on pouring into dilute sulphuric acid. On adding small quantities of diphenyl-α-naphthyl-, methylphenyl-α-naphthyl-, or phenyl-α-naphthyl-carbinol to concentrated acids, the solutions show intense coloration, which disappears on dilation with water, the carbinol being then precipitated unchanged. The corresponding methanes do not show this reaction. The author considers it to be probably due to the formation of quinonoid salts of the type—



$$C_6H_4\left\langle\begin{array}{l}CH(SO_4H).CH\\ \qquad\qquad\quad\;\; \ddot{}\\ C(CR_2) — CH\end{array}\right.$$

which would be hydrolysed by water and would then at once revert to the ordinary carbinol form. α-Naphthoic acid may be prepared by acting on α-naphthylmagnesium bromide with dry carbon dioxide in ethereal solution, and pouring the product into dilute sulphuric acid. The yield is almost quantitative.—E. F.

Anthraquinone-α-monosulphonic Acid. C. Liebermann and B. Pleus. Ber., 1904, **37**, 646—648.

The presence of the α-sulphonic acid in commercial anthraquinone monosulphonic acid was established by Liebermann and Bischof in 1880. They obtained from anthraquinonemonosulphonic acid, an anthracene sulphonic acid, which when distilled with potassium ferrocyanide and hydrolysed gave a mixture of two isomeric carboxylic acids which were separated by means of the different solubilities of their barium salts. The acid from the soluble barium salt was found to be identical with the α-carboxylic acid previously obtained by Liebermann and v. Rath, whilst the acid from the insoluble salt formed the greater portion of the mixture. Liebermann and Bischof demonstrated from the results of their investigations, that the carboxyl group in the new anthracene-carboxylic acid occupies the same position as the hydroxyl in hydroxyanthraquinone. That the formation of the acid from the soluble barium salt is due to the presence of alpha acid in commercial anthraquinone-monosulphonic acid, is now proved by the production of anthracene-carboxylic acid from the sodium salt of anthraquinone-α-monosulphonic acid.—D. B.

Dibenzalacetone and Triphenylmethane. A. Baeyer and V. Villiger. Ber., 1904, **37**, 597—612.

In a former communication the authors described an anhydride, containing no oxygen, of p-aminotriphenylcarbinol. They now find that this anhydride is bimolecular, and that the compound $(C_6H_5)_2:C:C_6H_4:NH$, which may be supposed to be first formed, polymerises. They have also prepared the anhydride of p-phenylaminotriphenyl carbinol, and find it to be monomolecular. It was obtained by converting the chloride of diphenyl-p-anisyl carbinol into the corresponding anilide, and heating this with benzoic acid, acetic acid, or other organic acids, the reaction proceeding according to the equation:—

$$(C_6H_5)_2(CH_3O.C_6H_4).C.NH.C_6H_5 = C_6H_5.N:C_6H_4:C:(C_6H_5)_2 + CH_3OH.$$

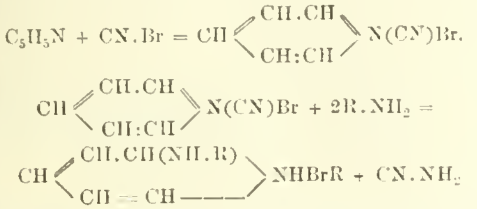
The product is purified by converting it successively into the picrate and the sulphate, treating with dilute aqueous ammonia solution, and shaking out with ether. It forms red crystals and readily combines with alcohols, aniline, and water to form colourless addition products of the carbinol type. With acids it forms deeply coloured quinonoid salts.—E. F.

Diphenyl- and Triphenylmethane Dyestuffs; Basic ——. J. v. Braun. Ber., 1904, **37**, 633—646.

Malachite Green does not react smoothly with cyanogen bromide, but on acting on leuco-Malachite Green with the same compound, s-dimethyldicyanodiaminotriphenylmethane, $[(CN)(CH_3)N.C_6H_4]_2:CH.C_6H_5$, was obtained. This was oxidised with permanganate to the corresponding carbinol. This compound does not dissolve in dilute mineral acids, but in concentrated acids it dissolves to deep red solutions, whereas the salts formed from ordinary Malachite Green are green. The anther concludes from the difference in colour of the salts that they are essentially different in structure. The only important difference in chemical character of the two compounds is that, whereas the dimethylamino groups of Malachite Green are capable of forming ammonium groups by the addition of acid, cyanomethylamino groups are incapable of conversion into ammonium groups. Therefore the conclusion to be drawn is that the green salts of tetramethyldiaminotriphenyl carbinol are ammonium compounds of the quinonoid type as usually formulated.—E. F.

Dyestuffs derived from Pyridine; New Class of ——. W. König. J. prakt. Chem., 1904, **69**, 105—137.

When mixtures of 1 mol. of pyridine, 2 mols. of an aromatic amine, and a suitable diluent are acted upon by cyanogen bromide or cyanogen chloride, dyestuffs are formed, almost quantitatively, with elimination of 1 mol. of cyanamide. The dyestuffs as obtained are almost chemically pure. They crystallise well and vary from yellow, through orange and red, to violet, and dye silk in shades showing beautiful fluorescence. Some of the dyestuffs show marked affinity for unmordanted cotton. They are, with difficulty, soluble in water, but are usually more soluble in warm alcohol and in acetic acid, also in pyridine. The pyridine may be replaced by α-picoline (α-methylpyridine), but collidine (α-α¹-dimethyl pyridine) does not react. The dyestuffs are also formed by first acting on pyridine with cyanogen bromide and then treating the addition product so formed with 2 mols. of an aromatic amine. The reactions probably take place according to the following equations :—



$$C_5H_5N + CN.Br = CH\left\langle\begin{matrix}CH.CH\\ CH{:}CH\end{matrix}\right\rangle N(CN)Br.$$

$$CH\left\langle\begin{matrix}CH.CH\\ CH{:}CH\end{matrix}\right\rangle N(CN)Br + 2R.NH_2 =$$

$$CH\left\langle\begin{matrix}CH.CH(NH.R)\\ CH = CH\text{———}\end{matrix}\right\rangle NHBrR + CN.NH_2$$

The shades which some of the dyestuffs from various amines produce on silk are :—Aniline, orange, with yellow fluorescence ; ψ-cumidine, fiery orange ; β-naphthylamine, rose-red, with yellow-red fluorescence ; sulphanilic acid, orange, with green fluorescence, not fast to boiling water ; aminoazobenzene, heliotrope; *p*-aminosalicylic acid, brown ; dehydrothiotoluidine, red ; benzidine, violet.—E. F.

Phenolphthalein ; Constitution of ——. A. G. Green and A. G. Perkin. Proc. Chem. Soc. 1904, **20**, 50.

The authors have found that a solution of phenolphthalein, decolorised by an excess of caustic alkali, can be entirely neutralised, without any return of the colour taking place, by careful titration at a low temperature with dilute acetic acid. If, however, the colourless neutral solution is boiled, the red colour returns in its full intensity, whilst at the same time the solution becomes alkaline. If the solution is acidified and either left for some time or heated, a precipitation of free phenolphthalein occurs, which also dissolves in aqueous alkalis to a red solution. The point at which neutrality occurs in the titration with acetic acid corresponds with the presence in the colourless solution of the carbinolcarboxylic acid salt—

$$C_6H_4(CO_2M).C(OH)(C_6H_4.OH)_2.$$

These observations do not agree with the electrolytic dissociation hypothesis, but are simply explained by the quinonoid theory if the colour changes are attributed to a variation of type from a quinonoid to a benzenoid form and *vice versâ*, due to hydration and dehydration. Thus, the first action of an alkali on the free phenolphthalein (lactone) would probably be the replacement of the phenolic hydrogen by the alkali metal. This salt being unstable may be supposed to undergo immediate transformation into the coloured quinonoid salt—

$$C_6H_4(CO_2K).C(C_6H_4.OH){:}C_6H_4{:}O,$$

by direct transference of the metal from the phenolic to the carboxylic group. With excess of caustic alkali, this coloured salt is converted, by assumption of KOH, into the colourless carbinol salt—

$$C_6H_4(CO_2K).C(OH)(C_6H_4.OH).C_6H_4.OK,$$

and this product, when neutralised with acetic acid, gives $C_6H_4(CO_2K).C(C_6H_4.OH)_2{\cdot}OH$, which is also colourless. Caustic potash is set free on boiling the latter salt, and the actone—

$$CO\left\langle\begin{matrix}-O-\\ C_6H_4\end{matrix}\right\rangle C(C_6H_4.OH)_2,$$

which is produced is simultaneously converted into the coloured quinonoid salt by the liberated alkali. A similar xplanation is offered in the case of quinolphthalein, the behaviour of which is found to be exactly similar to that of phenolphthalein.

English Patents.

Dyestuffs [Anthracene Dyestuffs] of the Anthraquinone Series ; Manufacture of Green ——. O. Imray. From Farbw. vormals Meister, Lucius und Brüning, Hoechst-on-Maine. Eng. Pat. 7353, March 30, 1903.

1.4.5.8-leuco-tetrahydroxyanthraquinone is heated with aromatic amines, when it forms dialphylaminodihydroxyanthraquinones. The products are easily sulphonated and then dye wool in clear yellowish-green shades.—E. F.

Anthracene Colouring Matters and Intermediate Products ; Manufacture of ——. J. Y. Johnson. From the Badische Anilin- u. Soda Fabrik, Ludwigshafen-on-Rhine. Eng. Pat. 7394, March 30, 1903.

A new polyhydroxyanthraquinonesulphonic acid is obtained by acting on anthraquinone-β-sulphonic acid with concentrated sulphuric acid, and either mercury or a mercury salt, in presence of nitrous acid and of either arsenic acid or phosphoric acid. This new purpurin-sulphonic acid dyes unmordanted and alumina-mordanted wool in bluish-red, and chrome-mordanted wool in bluish-brown shades. On treatment with aromatic amines, such as aniline, *o*- or *p*-toluidine, xylidine, *p*-phenylenediamine, benzidine, or α- or β-naphthylamine, with or without a condensating agent, dyestuffs are obtained. The product obtained with aniline dyes unmordanted wool violet, and chrome mordanted wool dark blue.—E. F.

Anthracene Colouring Matters [Dyestuffs] ; Manufacture of ——. J. Y. Johnson. From the Badische Anilin und Soda Fabrik, Ludwigshafen-on-Rhine. Eng. Pat. 20,151, Sept. 18, 1903.

The polyhydroxyanthraquinonesulphonic acid described in Eng. Pat. 7394 of 1903 (see preceding abstract) is condensed with sulphonic acids of aromatic amino-compounds, such as sulphanilic or metanilic acids either in the presence or absence of water, and with or without a condensing agent. The products dye unmordanted wool in bluish-red, chrome-mordanted wool in reddish-blue, and alumina-mordanted wool in violet shades.—E. F.

Tetrazo-dyestuffs [Azo-dyestuffs] with aid of 2 : 5 : 1 : 7-Aminonaphtholdisulphonic Acid ; Manufacture of new ——. O. Imray. From the Society of Chem. Ind. in Basle. Basle. Eng. Pat. 28,033, Dec. 21, 1903.

One mol. of the tetrazo-derivative of an aromatic *p*-diamine of the diphenyl series is combined either with 2 mols. of 2 : 5 : 1 : 7-aminonaphthol-disulphonic acid, or with 1 mol. of this acid and 1 mol. of an aromatic amine, a phenol or a naphthol, or a sulphonic or carboxylic derivative of any of these compounds. The products dye unmordanted cotton in violet to blue tints. When diazotised on the fibre and developed with β-naphthol, they yield indigo blue shades, very fast to washing.—E. F.

Mono-azo Colouring Matter [Dyestuff] ; Manufacture of ——. J. Y. Johnson, London. From Badische Anilin und Soda Fabr., Ludwigshafen. Eng. Pat. 7396, March 30, 1903.

See U.S. Pat. 737,445 of 1903 ; this J., 1903, 1125.—T. F. B.

Mono-azo Dyestuffs ; Manufacture of Mordant Dyeing ——. C. D. Abel, London. From Act.-Ges. f. Anilin Fabr., Berlin. Eng. Pat. 8406, April 11, 1903.

See Fr. Pat. 331,121 of 1903 : this J., 1903, 1126.—T. F. B.

Sulphur [Sulphide] Dyestuffs derived from Indophenol ; Manufacture of ——. C. D. Abel, London. From Act.-Ges. f. Anilin Fabr., Berlin. Eng. Pat. 8405, April 11, 1903.

See U.S. Pat. 736,403 of 1903 ; this J., 1903, 1041.—T. F. B.

United States Patents.

Dyestuff ; Sensitising —— *[for Photographic Purposes].* R. Berendes, Assignor to Farbenfabr. of Elberfeld. U.S. Pat. 752,323, Feb. 16, 1904. XXI., page 337.

Azo Dye [Dyestuff]; Red ——. P. Julius, Assignor to Badische Anilin und Soda Fabrik, Ludwigshafen-on-Rhine. U.S. Pat. 752,562, Feb. 16, 1904.

See addition, of Feb. 27, 1902, to Fr. Pat. 315,573 of 1901; this J., 1902, 1451.—T. F. B.

FRENCH PATENTS.

p-p'-Diaminoformyl-(acetyl)-diphenylamine; Manufacture of ——, *and its Conversion into p-p'-Diamino-diphenylamine.* Cie. Paris. Coul. d'Aniline. Fr. Pat. 328,201, Dec. 31, 1902.

See Eng. Pat. 543 of 1903; this J., 1903, 1343.—T. F. B.

Azo-Dyestuffs from 1.8-Azimino-naphthalene Sulphonic Acid; Process for Preparing ——. Cie. Paris. Coul. d'Aniline. Fr. Pat. 336,389, Jan. 14, 1903.

See Eng. Pat. 953 of 1903; this J., 1904, 16.—T. F. B.

V.—PREPARING, BLEACHING, DYEING, PRINTING AND FINISHING TEXTILES, YARNS, AND FIBRES.

Bleaching; Cost of Electrolytic ——. Fraass. Färber-Zeit., 1904, **15**, 69—70.

The cost of bleaching by electrolysing a solution of sodium chloride in which the goods are placed is discussed. 500 kilos. of goods can be bleached in the usual way by 2,000 litres of a solution containing 2·5 to 2·7 grms. of available chlorine per litre. According to the system and apparatus of Schuckert, this amount of chlorine may be produced by the electrolysis of a 10 per cent. sodium chloride solution giving a liquor containing 20 grms. of available chlorine per litre. 29 kilos. of salt are required for this, costing, at 2·2 M. per 100 kilos., 0·64 M.; the power necessary is 40 ampères, at 110 volts, for 8—9 hours, *i.e.*, 39·6 kilowatt hours, costing, say, 1·98 M.; wear and tear and insurance on the apparatus are calculated at 1·16 M. per day, and the sulphuric acid required (2 litres at 5·2 pf.), 0·10 M., making a total cost of 3·88 M., which compares favourably with the cost of 2,000 litres of bleach solution of $1\frac{1}{2}^{\circ}$—$1\frac{3}{4}^{\circ}$ B., or 12 kilos. of 32 per cent. bleaching powder and 10 litres of sulphuric acid required for the same quantity of goods by the usual method.—T. F. B.

Viscose in Printing; Application of ——. R. Haller. Zeits. Farb. u. Text. Chem., 1904, **3**, 81.

On account of its instability, viscose solution has had but little application in printing. By the addition of sodium amalgam the author has obtained a viscose solution which will remain unaltered for 22 days. Viscose solution is not altogether suitable as a thickening agent, the alkaline sulphides it contains blackening the copper rollers. It can, however, be used with success in fixing certain sulphur dyestuffs. On printing with 500 grms. of viscose solution 1 : 1, and 40 grms. of Immedial Blue C (paste), then passing through a "Mansarde" and once through a small Mather-Platt, washing with hot water, passing in open width through a soap solution and then drying, a good indigo shade is obtained which possesses an excellent fastness to light and soap. Aniline black or other steam-developed colours can be used in the same way. Other immedial dyestuffs cannot be fixed on the fibre in this way; the viscose solution on mixing with the aqueous dyestuff solution becomes gelatinous and in consequence unfit for printing. Viscose can also be used for printing with mordant dyestuffs which are fixed with chromium acetate, as follows:—700 grms. of viscose solution 1 : 1, 50 grms. of Alizarin Viridin F F (paste), 20 grms. of chromium acetate at 20° B., and 150 c.c. of distilled water. After printing, the goods are steamed, washed hot, soaped and dried as before. Shades are obtained in this manner which are somewhat duller than when gum or starch thickening is used, this being due to cellulose precipitated on the fibre. On the addition of metallic salts to viscose solution, coloured xanthates are formed. The tin salt is coloured a dark red-brown and is the best for printing. To fix this metallic salt on cotton, the goods are padded in a 5 per cent. tin chloride solution and dried in the hot flue at the lowest temperature possible; they are then printed with a dilute viscose solution (1 : 5), the tin xanthate is formed and is fixed on the fibre by passing through a "Mansarde" at 50° C. In this manner colours of unusual fastness to soap and light are stated to be obtained.—R. S.

Cellulose Nitrate; An Unstable ——. E. Knecht. XIX., page 335.

ENGLISH PATENTS.

Carbonising or destroying Cotton or Silk in Woollen Rags. S. Roberts and J. H. Crossley, Liversedge. Eng. Pat. 24,641, Nov. 13, 1903.

The material is impregnated with commercial hydrochloric acid, then squeezed or hydro-extracted to remove surplus liquid, and finally dried in a drying machine or stove in order to destroy the cotton, silk, or vegetable fibres present, without affecting the wool.—A. B. S.

Soaps developing active Oxygen and having an Antiseptic and Bleaching effect; Manufacture of Non-Caustic ——. H. Giessler and H. Bauer. Eng. Pat. 22,580, Oct. 19, 1903. XII., page 327.

FRENCH PATENTS.

Vegetable or Animal Fibres, or mixtures of these; Process for Obtaining Extra-fast Shades on ——, *with certain Colours, and particularly with Blue.* G. Caux. Fr. Pat. 328,182, Dec. 23, 1902.

See Eng. Pat. 1 of 1903; this J., 1903, 738.—T. F. B.

Textile Dyeing; Apparatus for ——. A. Henuchert and E. Lepers. Fr. Pat. 335,830, Oct. 8, 1903.

This apparatus consists essentially of two similar rectangular vessels, which open at the side and can be hermetically closed. The material to be dyed is placed on perforated plates a little above the bottoms of the vessels and pressed down by other perforated plates held in position by central rods passing air-tight through the tops of the vessels. Pipes for the supply of dye-liquor enter the vessels under the lower perforated plates and are connected together, and also to the main supply tank, by means of a three-way cock. These connections are steam jacketted. The supply tank is placed at a higher level and furnished with heating coils. A pipe for the entry of compressed air is fitted to the top of each vessel, through which also passes a pipe reaching to any required depth and fitted with a float valve. When the material is in position, the dye-liquor is allowed to flow into both the vessels up to a certain level, after which the two vessels are placed in communication. Compressed air is then turned on into one of the vessels, whereby the liquid is forced over into the other vessel. As soon as the liquid in the first vessel sinks low enough to open the float valve, the compressed air escapes through the pipe mentioned above and acts on a special piston arrangement which cuts off the compressed air from the first vessel and turns it into the second vessel, where the whole process is repeated. —A. B. S.

Dyeing Apparatus; Automatic ——. L. Mascelli. Fr. Pat. 335,949, Sept. 23, 1903.

This apparatus consists of two vessels placed one above the other, the upper one being connected with the lower by means of a central pipe which passes almost to the bottom of the latter, and is furnished with a valve operated from outside. The lower vessel is furnished with a closed steam coil at the bottom and also with a perforated spiral pipe at the top, which serves either for steam or water. If the material is to be dyed in the loose form, it is placed in a cage with a central perforated pipe; this is placed in the upper vessel and screwed down on to the opening of the central pipe; if cops or bobbins have to be dyed, they are placed on perforated spindles, which are also connected with the central pipe. The lower vessel is fitted with pipes for introducing dye-liquor, &c., and for letting out air. When the material is in position, the valve in the central pipe is shut and the dye-liquor is run in until the lower vessel is full; the inlet valves are then shut, the central one opened, and the dye-liquor is forced up the central pipe and through the material by blowing steam through the upper perforated spiral. The central valve is then closed and the lower vessel filled with dye-liquor as before from a higher tank. The inlet valve being again shut, the central one is opened and steam is also turned on in the closed coil. The hot dye-liquor is forced up the central pipe into the upper vessel, and when it reaches a certain level in the latter, it acts on a float which by a suitable arrangement shuts off the steam in the lower coil. As the lower vessel cools, a vacuum is formed, and part of the liquid in the upper vessel runs back, releasing the float and opening the steam valve again.—A. B. S.

Etching [Designs on] Metals, and especially Printing Cylinders. J. A. Déjey. Fr. Pat. 335,941, Sept. 18, 1903. XI. B., page 327.

Textile Printing; New Arrangement for ——. R. H. D. Mills. Fr. Pat. 336,061, Oct. 15, 1903.

A machine for printing both sides of a material, in which one of the pressure cylinders has a smaller diameter and also a smaller number of printing rollers than the other is claimed. The relative positions of the two cylinders can be altered for use as single printing machines if required. —A. B. S.

Lustering of Vegetable Fibres in Thread or Tissue by means of Viscose; Method for ——. J. R. Subrenat. Fr. Pat. 328,179, Dec. 20, 1902.

The textile material is impregnated with viscose (xanthate of cellulose). This can also be produced from the fibre itself by impregnating with caustic soda, and then exposing to the vapour of carbon bisulphide. The material prepared by either of the above methods is then dried carefully in a hot flue at a temperature which must not be higher than 50°—60° C., and next slightly moistened in order to dissolve the superficial layer of viscose, and then lustred either by calendering, brushing, &c. After this is finished the material is steamed at a high pressure or else passed through boiling concentrated solutions of ammonium sulphate or chloride or some other suitable salt, in order to convert the soluble viscose into the insoluble hydrated cellulose. The latter retains the lustre of the viscose.—A. B. S.

VI.—COLOURING WOOD, PAPER, LEATHER, Etc.

English Patent.

Leather; Method of Dyeing —— with Sulphur Colours. R. B. Ransford, Upper Norwood. From L. Cassella and Co., Frankfort-on-Maine. Eng. Pat. 7954, April 6, 1903.

See Addition of March 30, 1903, to Fr. Pat. 322,605 of 1902; this J., 1903, 1084.—T. F. B.

French Patent.

Leather: Process of Dyeing —— by means of Sulphide Dyestuffs. Manuf. Lyon. Mat. Col. Second Addition, dated Oct. 24, 1903, to Fr. Pat. 322,605, June 28, 1902. (See this J., 1903, 363 and 1084.)

If leather be treated with formaldehyde before dyeing, or even during the tanning process, alkali sulphides have no detrimental effect during the dyeing with sulphide dyestuffs. A suitable method consists in immersing the leather in a formaldehyde solution for about an hour, and then adding the dyestuff solution to the formaldehyde bath.—T. F. B.

VII.—ACIDS, ALKALIS, AND SALTS.

Potassium-Magnesium Carbonate. F. Auerbach. Zeits. Elektrochem., 1904, **10**, 161—169.

As the double salt $MgCO_3.KHCO_3.4H_2O$ plays an important part in the potash industry at Stassfurt, the author has investigated the conditions of its formation and decomposition. Determinations of the solubility of $MgCO_3.3H_2O$ in potassium bicarbonate solutions of increasing concentrations at 15°, 25°, and 35° C., showed that at any given temperature the magnesium-content of the solution was a function of the potassium-content, and that in the graphic representation, with magnesium-contents as ordinates and potassium-contents as abscissæ, each isothermal was an ascending straight line cut by the lower part of a convex curve representing the double salt content at the same temperature. At the point of intersection the individual carbonates are in equilibrium with a solution of definite composition. By applying the principle of mass action and by making certain simplifying assumptions, the equations of the isothermals were deduced, and then verified. As the solution of $MgCO_3.3H_2O$, and also the formation and separation of the double carbonate proceed with evolution of heat, the decomposition of the latter is attended by absorption of heat. Hence, as the temperature rises its formation becomes more and more difficult. The aqueous solution of the double salt is unstable under ordinary conditions, $MgCO_3.3H_2O$ separating out.—E. H. T.

Sodium Nitrite; Action of Carbon Dioxide on ——. L. Meunier. Comptes rend., 1904, **138**, 502—503.

Marie and Marquis (this J., 1904, 252) described certain experiments from which it was concluded that nitrous acid is liberated from solutions of sodium nitrite by the action of carbon dioxide. The author contends that the results obtained in the first two experiments (*loc. cit.*) were due to the presence of the potassium iodide. This is proved by saturating a solution of sodium nitrite with carbon dioxide and adding potassium iodide to one half of it, leaving the other half blank. The solution containing the iodide shows a gradual separation of free iodine, whereas the blank solution when "spotted" on iodide and starch test paper fails to show the slightest trace of free nitrous acid. The result of the third experiment (*loc. cit.*) is explained by the presence of traces of halogen salts as impurities which act in the same way as iodides. It is therefore concluded that carbon dioxide does not liberate nitrous acid from pure solutions of sodium nitrite.—J. F. B.

Cadmium Arsenide. A. Granger. Comptes rend., 1904, **138**, 574.

When cadmium is heated to bright redness in presence of arsenic vapour, combination proceeds rapidly, and a cadmium arsenide, Cd_3As_2, condenses, in the form of brilliant red octahedra, of sp. gr. 6·21; this product is similar to that obtained by Spring by subjecting the two constituents to hydraulic pressure. Like most arsenides, it is soluble in nitric acid, and is decomposed by halogens, oxidising agents, &c.—T. F. B.

Fluorine Compounds; Preparation and Physical Characters of new ——. O. Ruff and W. Plato. Ber., 1904, **37**, 673—683.

The principle of the method is the decomposition of the corresponding chlorine compounds by heating them with anhydrous hydrofluoric acid. The acid is prepared from potassium hydrogen fluoride, which is first thoroughly dried by heating for 24 hours or more to 150° C *in vacuo* in presence of fused potassium hydroxide, the salt being freshly powdered and the potassium hydroxide remelted every 6 or 8 hours. The dry salt is then introduced into the platinum retort shown in Fig. 1, which is connected with the platinum condensing tube, and this by the copper connexion *a* with the copper vessel C, of some 500 c.c. capacity, immersed in a freezing mixture, and *b*, a guard tube with calcium chloride. The joints between platinum and platinum are made good, where necessary, with sulphur; those between platinum and copper with platinum foil. The retort, not more than two-thirds full, is heated very gradually, and the operation is ended when the bottom is red-hot. Screw caps *m* (Fig. 2) are used to close C, and the acid can be kept for any length of time.

Titanium Tetrafluoride.—The acid is distilled by means of a water-bath at 25° C. into the retort A as shown in

Fig. 2. The copper-tubes pass through a lead stopper, and are luted with sulphur. The horizontal tube contains calcium chloride, and A is immersed in a freezing mixture. The tared retort is re-weighed; half the calculated quantity of titanium tetrachloride is cooled and added to the acid drop by drop, the stopper and guard tubes are put in, and the whole left for some hours; then the retort is connected with the condenser, and heated in an oil-bath to 200° C. till all the hydrofluoric acid is distilled off. Now the condenser is removed, the copper vessel E (Fig. 3) fitted to the retort beak, and the whole retort kept hot by a flame till the titanium tetrafluoride has condensed in E, which is cooled by a lead worm coiled round it. The tetrafluoride forms a loose white sublimate, b. pt. 248° C., sp. gr. 2·798/20°, 2·833/11° C., vapour density 129 (theory 124·1).

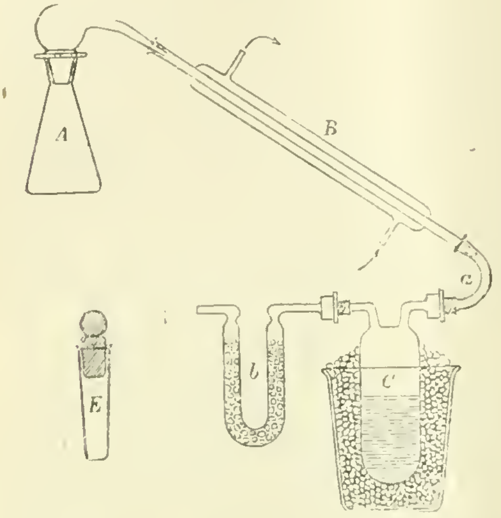


Fig. 3.

Fig. 1.

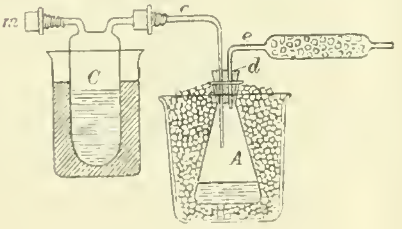

Fig. 2.

Antimony Pentafluoride.—Prepared similarly, but the mixed pentachloride and hydrofluoric acid must be heated by a water-bath at 25° C. under reflux condenser till hydrochloric acid ceases to be evolved (about 3 days). Then, after distilling off the excess of hydrofluoric acid the temperature is raised to 155° C., and the antimony fluoride distilled over. Colourless, viscous, oily liquid, solidifying when cooled; b. pt. 155° C., sp. gr. 2·993/22·7° C. Corrodes the skin; dissolves paraffin and other organic substances; absorbs moisture from the air to form the hydrate, $SbF_5.2H_2O$; dissolves in water without decomposition.

Antimony Penta- and Trifluorides.—When these fluorides are mixed, reaction occurs, and on distillation substances varying in composition, according to the proportions in the mixture, pass over. These substances thus obtained have a composition varying between $SbF_5.2SbF_3$ and $SbF_5.5SbF_3$, and are probably mixtures of these. The first of these two compounds, a colourless crystalline mass, boils at 390° C., and has a sp. gr. of 4·188/21° C.; the second is a colourless liquid, b. pt. 384° C.

Tin Tetrafluoride.—Prepared like antimony pentafluoride. After distilling off the hydrofluoric acid, tin tetrachloride passes over from 130° to 220° C. in quantity, showing that $SnCl_4.SnF_4$ had been formed. When the tetrafluoride has all passed over, a stopper with thermometer is substituted by another of plaster of Paris, carrying a thin brass spiral cooled by water, and the flask heated to redness. At 750° C. the tetrafluoride distils, and condenses on the spiral in radiating crystalline masses. It is very hygroscopic, soluble in water, and the solution, slowly at the ordinary temperature, more rapidly on heating, deposits stannic oxide. The sp. gr. of the tetrafluoride is 4·780, its b. pt. 705° C.—J. T. D.

Carbon from Carbides [*Metallic*]; *Separation of* ——, *and the formation of Graphite.* H. Ditz. Chem.-Zeit., 1904, **28**, 167—171.

Among the processes for preparing amorphous or crystalline carbon from (calcium) carbide is that devised by Frank (this J., 1900, 545). It is interesting to notice that a suitable carbide is also able to withdraw the carbon from a carbonate, *e.g.*, $3BaCO_3 + BaC_2 = 4BaO + 5CO$, whilst, if the base employed be changed to calcium, magnesium, or an alkali metal, a larger quantity of carbon is recovered in the free state. Again, one of the reactions in the Frank process shows that the decomposition of calcium oxide by carbon, which is employed to yield calcium carbide, is a reversible reaction. According to Rothmund (this J., 1902, 761) the temperature of reversion in the equation $CaO + 3C \rightleftarrows CaC_2 + CO$ is 1620° C. This reversibility has hitherto only been proved to occur in the specific case of calcium carbide, but the author believes a similar occurrence is to be found in the case of other carbides, and, if so, it may throw some light on the mechanism of Acheson's method of making artificial graphite from coal. When an Acheson furnace is opened and its contents are cut through, surrounding the central core is a mass of black crystals having the shape of carborundum (silicon carbide), but actually consisting of graphite with an amount of ash varying from 10 per cent., the ordinary commercial limit of purity (Pietrusky), down to practically nothing. This graphite cannot be produced from the amorphous carbon of the charge by the mere heat of the furnace, for, were that the case, all the carbon might be "graphitised." Such a view, too, fails to explain why a pure carbon, such as petroleum coke, yields hardly any graphite, whereas a carbon contaminated with ash, like bituminous coal or American anthracite (5 to 15 per cent. of ash), gives much. According to a recent suggestion, carbides are first produced, a purely catalytic action then taking place, the ash behaving as the active substance. (The finished graphite may contain up to 10 per cent. of ash constituents, and only very small quantities of amorphous carbon.) It is hence quite probable that the crystallisation occurs whilst the carbon still contains the bulk of the mineral matter. With regard to the nature of the foreign matter in Acheson graphite, Acheson has found that an addition of metals to the furnace charge (or of their sulphides or other salts) assists in graphitisation; but, for various reasons, it is preferable to use oxide. On the other hand, if a process of simple catalysis were alone involved, the active oxides of the original charge should be found again in the finished graphite; and, besides, it would not be comprehensible why a raw material must be taken so impure that the graphite may contain 10 per cent. of ash. Tentatively, therefore, the author puts forward a hypothesis based on the above-mentioned behaviour of carbon monoxide. The amorphous carbon, it may be imagined, first reacts with its ash oxides to yield the corresponding carbides (of Si, Fe, Al, Ca, &c.), carbon monoxide being liberated. Some of this is retained among the material of the furnace, and, if the other carbides behave like that of calcium, acts upon those carbides to form oxides again, with separation of graphite. These two reactions may go on indefinitely, always leaving metallic oxides among the carbon, until, as the temperature of the furnace rises, a larger or smaller proportion of them is driven away as vapour. Part of the carbides, perhaps, simply dissociate, the metal volatilising, and the carbon appearing as graphite. A separation of crystalline carbon on dissociation is already known to occur with calcium carbide (Moissan) as well as in the case of barium and manganese carbides (Gin and Leleux, Comptes rend., 1898, **126**, 749). The reactions of calcium carbide or acetylene with carbon bisulphide (Sandmann, this J., 1902, 932) and certain other organic sulphur compounds, whereby free carbon and sulphuretted hydrogen or calcium (penta-) sulphide are formed, seem likely to develop into processes for removing sulphur from benzol, oils, and, possibly, coal-gas.—F. H. L.

English Patents.

Sulphate of Copper; Manufacture of ——, *by the direct Sulphurisation of the Ores.* G. Gin, Paris. Eng. Pat. 5230, March 6, 1903.

Sulphur ores of copper are roasted until the copper is oxidised, partly into sulphate and partly into oxide. The ore is then transferred to the floor of a cooling passage into which the sulphurous gases from the furnace, with air, are directed, whereby the copper oxide and ferric oxide are transformed into sulphates, the temperature being adjusted as most suitable to the formation of sulphuric anhydride, whereby the change is mainly effected, whilst the formation of ferrous sulphate is prevented. The mass is lixiviated, and the solution digested with roasted and oxidised ore, so that the basic ferric sulphate may act upon the copper oxide to form copper sulphate, with separation of ferric oxide. See also Fr. Pat. 328,801, of 1903; this J., 1903, 1002.—E. S.

Aluminium Sulphate; Manufacture of ——. H. Spence and Peter Spence and Sons, Ltd., Manchester. Eng. Pat. 6458, March 20, 1903.

See Fr. Pat. 331,836 of 1903; this J., 1903, 1195.—T. F. B.

Carbon Monoxide; Producing ——. R. Pearson. Eng. Pat. 3347, Feb. 12, 1903. II., page 316.

Gas Liquor; Treatment of ——. C. G. Moor. Eng. Pat. 4988, March 4, 1903. III., page 318.

United States Patents.

Sulphuric Anhydride; Contact Apparatus for the Production of ——. W. Hasenbach, Assignor to Ver. Chem. Fab., both of Mannheim, Germany. U.S. Pat. 752,165, Feb. 16, 1904.

See Fr. Pat. 323,491, of 1902; this J., 1903, 495.—E. S.

Bromine; Process of "Fractioning" ——, *apart from Chlorine.* H. H. Dow, Assignor to the Dow Chemical Co., both of Midland, Mich. U.S. Pat. 752,286, Feb. 16, 1904.

Brine containing bromine is oxidised, and the pure bromine first liberated, is blown out by a limited quantity of air, the remainder being blown out (without further oxidation) by a large quantity of air. Both portions of bromine thus expelled are received in suitable absorbents. Or the purest portion, that first expelled, is absorbed by means of sodium carbonate solution, the final portion by natural brine. See also the two following abstracts.—E. S.

Bromine; Process of Fractioning —— *from Chlorine.* H. H. Dow, Assignor to the Dow Chemical Co., both of Midland, Mich. U.S. Pat. 752,331, Feb. 16, 1904.

Brine containing bromine is oxidised to "excess of its bromine contents"; bromine, and mixtures of bromine and chlorine in various proportions, are obtained by passage through the oxidised brine, first, of a limited amount, and then of a larger amount of air, the fractions being separately absorbed, the pure bromine by sodium carbonate, and the mixed gases by a natural brine. See also preceding and the next following abstracts.—E. S.

Bromine; Process of Manufacturing —— *from natural Brines.* H. H. Dow, Assignor to the Dow Chemical Co., both of Midland, Mich. U.S. Pat. 752,332, Feb. 16, 1904.

In the process conducted substantially as described in the two preceding abstracts, the first and second fractions of the bromine liberated are conducted for absorption into sodium hydroxide solution; the later fractions, containing chlorine with the bromine, being passed into natural brine. Suitable apparatus for carrying out the process is shown. Compare U.S. Pats. 733,466, 733,467, and 741,637, of 1903; this J., 1903, 908, and 1243.—E. S.

French Patents.

Hydrosulphites; General Method for Preparing ——. L. Descamps. Fr. Pat. 328,191, Dec. 29, 1902.

See Eng. Pat. 6933 of 1903; this J., 1903, 950.—T. F. B.

Active Oxygen; Salts of Acids containing easily liberated ——, *Preparation of.* G. F. Jaubert. Fr. Pat. 336,062, Oct. 14, 1903.

An acid, such as boric, sulphuric, or acetic acid, is caused to react upon an alkali- or alkaline-earth peroxide, to obtain a permanent solid product from which "active" oxygen may be readily set free. For example, a mixture of 248 parts of boric acid with 78 parts of sodium peroxide is added by small portions to 2,000 parts of cold water, with agitation. The crystals which form on cooling are washed with alcohol, and dried at from 50° to 60° C. A permanganate may be used when it is desired to set the oxygen free. See Fr. Pat. 325,627 of 1902, and Addition to the same, of 1903; this J., 1903, 743 and 1318.—E. S.

VIII.—GLASS, POTTERY, ENAMELS.

Solubility of Glass; Electro-chemical Determination of ——. F. Haber and H. Schwenke. XI. A., page 326.

French Patents.

Porcelain; Manufacture of ——. Comp. Générale de Constructions Electriques. First Addition, of Oct. 16, 1903, to Fr. Pat. 332,912, of May 9, 1903.

In order to remove rapidly the water added during the mixing, the moulded article, before burning, is placed in a receiver, from which the air is exhausted, at first gently, and then very strongly.—A. G. L.

Muffle for burning the Enamel on Porcelain and for similar applications. E. Jouannaud. Fr. Pat. 336,274, Oct. 27, 1903.

The muffle is characterised by having its walls fitted with a number of pierced and arched baffle-plates, which also divide it into three independent parts, each one of which can be heated separately. At the rear of the muffle a double flue is provided, which receives the gases from all three parts.—A. G. L.

IX.—BUILDING MATERIALS, CLAYS, MORTARS AND CEMENTS.

English Patents.

Plaster of Paris; Manufacture of ——. W. Brothers, Prestwich. Eng. Pat. 3225, Feb. 11, 1903.

See Fr. Pat. 333,858 of 1903; this J., 1904, 20.—T. F. B.

Bricks, Artificial Stone, and the like; Manufacture of ——. F. W. Jenkins, Herne Hill. Eng. Pat. 3378, Feb. 12, 1903.

See Fr. Pat. 329,346 of 1903; this J., 1903, 998.—T. F. B.

Brick Kilns and the process of burning Bricks. J. W. D. Pratt, Oldbury. Eng. Pat. 28,103, Dec. 22, 1903.

The process of burning is carried out in three stages, the usual air-drying of the "green" bricks being omitted, a drying in a separate chamber by heat radiated from a chamber containing burnt bricks cooling down being substituted. After this drying, the bricks are further heated by the hot products of combustion from a kiln actually burning, and are then burnt in a kiln, the flues and dampers of which are so arranged that the hot gases are not directly impeded in their passage by dampers, thus preventing leakage of hot gases or entrance of cold air around the damper slots. —A. G. L.

Pipes or Conduits, or other articles; Manufacture of ——, for use underground, or in other situations where they are subject to electrical or corrosive action. J. Y. Johnson, London. From L. A. Brown and D. Tredway, both of St. Louis, Mo. Eng. Pat. 1279, Jan. 18, 1904.

The articles, *e.g.*, pipes, are made with a metallic body and an adherent coating of insulating material, consisting, *e.g.*, of 55 per cent. of sand, 35 per cent. of sulphur, and 10 per cent. of cement. The composition is made by melting the sulphur at about 280° F., mixing it with the cement, and then stirring in the sand, previously heated to about 500° F. The mass is then allowed to cool to 300° F., when it becomes sufficiently viscid to be applied to the metal.—A. G. L.

United States Patent.

Timber-treating Process. P. F. Dundon, San Francisco, Cal. U.S. Pat. 753,052, Feb. 23, 1904.

The timber is first exposed to steam-heat, moisture, and pressure in order to open the pores and expel the sap. It is then dried, and treated under heat and pressure with a "limpid mineral oil," which fills the pores. This is followed by treatment under heat and pressure with a bituminous pitch, which enters into the pores of the outer stratum only, and so forms an impervious coating for the conservation of the interior substance.—A. G. L.

French Patents.

Stone and similar substances; Process for Colouring or Hardening —— throughout its mass. Chem. Techn. Fabr. Dr. Alb. R. W. Brand and Co. Fr. Pat. 328,193, Dec. 29, 1902.

See Eng. Pat. 5594 of 1903; this J., 1904, 188.—T. F. B.

Furnace; Continuous —— for Bricks, Tiles, Cement, &c. Scheidt et Cie., Belgium. Fr. Pat. 336,166, Oct. 7, 1903.

The flues and valves of a horizontal furnace are so arranged that the temperature may be regulated at every part of each chamber.—H. B.

X.—METALLURGY.

Iron Ores; Briquetting ——. A. Weiskopf. Stahl u. Eisen., 1904, 24, 275—281.

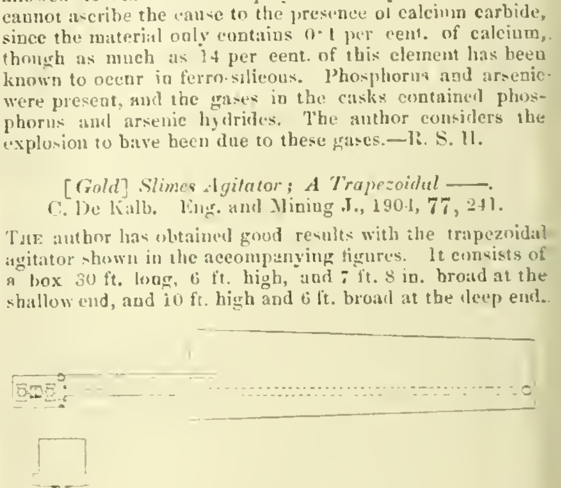
The methods devised may be grouped as those—1*a*. With inorganic binding substances (*e.g.*, clay, lime, water-glass, slags, waste liquors from certain manufactures, &c.). Some of these yield briquettes of good quality, but low in iron and high in silica and alumina. 1*b*. With organic binding substances (*e.g.*, tar, petroleum residues, rosin soaps, coal-dust, liquors from cellulose or sugar manufacture, &c.). The mixture is made with the aid of suitable machinery, the briquettes being subsequently hardened by exposure to the air, with or without compression, or by heating to sintering, with or without previous compression. The percentage of iron is not lowered so much as in 1*a*, but most of the briquettes so formed are liable to crumble in the furnace. 2. Without binding substance, the briquettes being subjected to high pressure, and hardened by exposure to air or with the aid of heat, or being hardened by heat alone (sintering) without previous application of pressure. The author considers that the problem of producing, sufficiently cheaply, briquettes which shall be mechanically resistant to the shocks of transport and the pressure in the furnace, shall stand the weather, shall not crumble at a high temperature, and shall be sufficiently porous, is not yet solved. Especially an efficient, cheap, and non-injurious binding substance is wanted. The advantages of briquettes, to be counted against the cost, are, saving of carriage of moisture, and lessening of loss in transport, saving in coke, increased production through greater regularity in working, lessened repairs to lining, lessened amount of dust in the waste gases, and consequent economies in the use of these gases.—J. T. D.

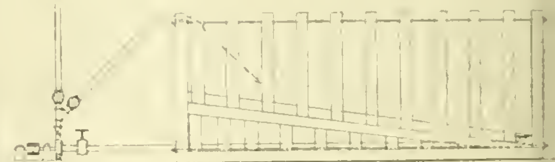
Ferro-Silicon; An Explosion of high-grade ——. G. Watson Gray. Paper read before the Faraday Soc. Electrochemist and Metall., 1904, 3, 501—503.

The author has investigated a series of explosions at Liverpool of recently imported ferro-silicon which had been allowed to stand on the quay for nearly a month. He cannot ascribe the cause to the presence of calcium carbide, since the material only contains 0·1 per cent. of calcium, though as much as 14 per cent. of this element has been known to occur in ferro-silicons. Phosphorus and arsenic were present, and the gases in the casks contained phosphorus and arsenic hydrides. The author considers the explosion to have been due to these gases.—R. S. H.

[Gold] Slimes Agitator; A Trapezoidal ——. C. De Kalb. Eng. and Mining J., 1904, 77, 241.

The author has obtained good results with the trapezoidal agitator shown in the accompanying figures. It consists of a box 30 ft. long, 6 ft. high, and 7 ft. 8 in. broad at the shallow end, and 10 ft. high and 6 ft. broad at the deep end.





A 6-in. pipe leads from near the centre of the deep end to a centrifugal pump placed 11 ft. in front of the shallow end of the box. The discharge pipe of the pump is fitted with a 45° Y-pipe, the inclined branch of which leads to just over the edge of the box. The pulp pumped from the box is discharged through this pipe at such an angle that it impinges on the surface of the pulp in the box at a distance of 10 in. from the nozzle. The pump works at an average rate of 460 revolutions per minute, and in consequence of the low "head," the pulp is discharged at a high velocity. Agitation is stated to be complete in 4½ hours, and the pulp is then forced through the vertical branch of the Y-pipe to the distributing box, and thence to the settling tanks. Detailed results obtained with this apparatus are quoted, and it is stated that the total extraction of gold and silver has increased from an average of 67·04 per cent. when agitation was effected with compressed air in the settling tanks, to an average of 74·27 per cent. with the apparatus described.—A. S.

Aluminium Powder and the Oxidation of Aluminium. E. Kohn-Abrest. Bull. Soc. Chim., 1904, 31, 232—239.

A sample of aluminium powder examined by the author had the following composition:—Metallic aluminium (including iron), 91·20; alumina, 5·80; silica, 1·30; "graphitoidal" and insoluble silicon (determined indirectly), 0·40; carbon, 0·23; moisture, loss, &c. (by diff.), 1·07 per cent. Aluminium powder in contact with alumina or aluminium hydroxide becomes oxidised, the action being especially rapid in an ammoniacal medium. If aluminium hydroxide be precipitated from a chloride solution by ammonia, and then aluminium powder be added, the latter is soon completely converted into a white gelatinous mass, probably a suboxide of aluminium.—A. S.

Arsenic and Antimony in Nickel Speiss; Determination of ——. H. Nissenson and A. Mittasch. XXIII., page 338.

Alumina [in Metallurgical Products]; Method for the direct Determination of ——. C. E. Rueger. XXIII., page 339.

English Patents.

Steel; Manufacture of ——. H. W. Lash, Cleveland, Ohio. Eng. Pat. 8026, April 7, 1903.

Low-grade iron ore is smelted in a blast furnace, and the greater part of the crude metal produced is treated in a Bessemer converter until it is partially oxidised; the remainder of the impure metal (containing metalloids) is conveyed whilst molten to a basic-lined open-hearth furnace; "basic materials" may then be added, together with the refined Bessemerised molten metal containing iron oxides. When chemical action has subsided, the refined mass is drawn off.—E. S.

Steel Armour Plates, or other Plates of Steel with a Hardened Face; Manufacture of ——. T. J. Tresidder, Sheffield. Eng. Pat. 8299, April 9, 1903.

Steel plates composed of stated proportions of iron, carbon, manganese, nickel, and tungsten are manufactured without, at any stage, "heating said plates to different temperatures in different parts of the plate at the same time." Such a plate is cemented or "supercarburised" on one side, and whilst hot, is re-forged or rolled, quenched, then uniformly heated and gradually cooled (after bending when necessary) and is again heated and quenched until the uncemented portions are in good fibrous condition. The plates are then uniformly heated and chilled. Plates so treated have "a smooth glass-hard face and a fibrous body or back." See Fr. Pat. 333,582, of 1903; this J., 1903, 1353.—E. S.

Iron and Steel; Production of —— by the Direct Reduction of Iron Ores in Crucible Furnaces. C. J. L. Otto, Dresden, Germany. Eng. Pat. 9346, April 24, 1903.

Within a portable, covered furnace, supported on trunnions for tilting, is arranged a covered crucible having a central tube (conveying fire-gases), open at the top and bottom, carrying a circular plate fitting to the sides of the crucible near its top, in which plate are tubular projections admitting passage of gases from within into the surrounding air space. The crucible is charged with a little charcoal at the bottom, and is then filled with crushed ore, in some cases mixed with scrap iron. The space around the crucible is filled with fuel, by the combustion of which the crucible is heated, without contact between the ore and the ashes of the fuel. The reduction of the ore takes place under a pressure of about two atmospheres from an air-blast. There is an air chamber about the lower part of the furnace, the air-blast supplying which, is heated by means of the fuel gases, and there are numerous passages through the walls of the furnace from the air chamber into the space filled with fuel.—E. S.

Precious Metals; Extraction of —— from Ores. C. H. Webb, Dorking, Surrey. Eng. Pat. 24,417, Nov. 7, 1902.

The crushed ore is treated with a solvent solution in a revolving vat having at either or both ends, and along its sides, continuously or at intervals, gratings covered with a suitable cloth or other filtering material. The filtering devices are so arranged within the vats that a space is left behind them, and such spaces are connected with pipes leading outside, whereby the liquid, as it filters through, is led away. The filtration is carried on under a difference of pressure between the feeding and delivery sides of the filtering devices, effected by the use of an air-pump, adapted for either compression or exhaustion, or for both alternately; or a separate suction pump may be provided.—E. S.

Blast-Furnace Tuyères or Injectors; Impts. in ——. E. Bertrand and E. Vorbach, of the Prager Eisenindustrie Ges., Kladno, Bohemia. Eng. Pat. 26,037, Nov. 28, 1903.

A hollow core is arranged in the longitudinal axis of the tuyère, so that it may be pushed forward or withdrawn by suitable mechanical means, thereby regulating the free section for the passage of the blast into the furnace. Through the action of the blast a depression of pressure is caused inside the core; this may be measured by means of a gauge, and then affords information as to the quantity of air passing. The core may be provided with an opening at its rear end, through which ore, flux, or combustibles may be sucked, and blown into the furnace by the action of the blast.—L. F. G.

Lithographic Stones [Metallic Substitute]; Manufacture of Substitutes for ——. G. Bower, St. Neots, and F. W. Gauntlett, London. Eng. Pat. 6155, March 17, 1903.

The substitutes for lithographic stones consist in metallic plates, the surfaces of which are covered with one or more metallic oxides. Thus a coating of iron oxide may be obtained on a steel plate by exposing it to heat and steam, but preferably to the action of superheated steam containing a little oil vapour, which removes any free oxygen present in the steam, so that only magnetic oxide is formed on the steel plate. Coatings of copper, tin, or zinc oxides may also be employed.—A. G. L.

United States Patents.

Iron and Steel; Process of treating ——. E. Engels, Düsseldorf. U.S. Pat. 752,054, Feb. 16, 1904.

See Eng. Pat. 25,932 of 1903; this J., 1904, 118.—T. F. B.

Metals; Extraction of —— from complex Ores. J. B. de Alzugaray, Bromley. U.S. Pat. 752,320, Feb. 16, 1904.

See Fr. Pat. 334,272 of 1903; this J., 1904, 24.—T. F. B.

French Patents.

Aluminium Alloys; Manufacture of ——, with a view to the production of Hydrogen more or less carburetted, and pure Hydrogen. N. A. Hélouis, L. Mauclaire, and E. Meyer. Fr. Pat. 335,954, Sept. 25, 1903.

Alloys of aluminium with barium, sodium, zinc, and other metals are obtained, preferably, by the aluminium-thermic process. If it be desired to obtain a carburetted hydrogen, a mixture of barium dioxide, powdered aluminium, and carbon, in stated proportions, is ignited in a magnesia-lined crucible. The product is broken up, and after several days is treated, first with water, and lastly with soda solution, to obtain the gas. If pure hydrogen be required, the alloy of aluminium-barium is produced from the described mixture except that the carbon is omitted, and that the aluminium is in granules or filings. An aluminium-sodium alloy may be similarly formed from a mixture of sodium dioxide with aluminium. On treating the product with water to obtain hydrogen, a strong solution of sodium aluminate remains as a by-product. Various applications for the pure and carburetted hydrogen thus obtained are described and claimed. Compare Fr. Pats. 333,724 and 333,725 of 1903; this J., 1903, 1347.—E. S.

Cadmium; Alloy of ——. G. Chaudoir, jun. Fr. Pat. 335,838, Oct. 9, 1903.

To form an alloy offering resistance to rupture at high temperatures nearly equal to that offered at ordinary temperature, from 1 to 3·5 parts per cent. of cadmium are melted with copper, bronze, or brass. An alloy containing

92 parts of copper, 4·5 parts of tin, and 3·5 parts of cadmium, is especially recommended. Reference is made to Eng. Pat. 10,197 of 1897 and to Ger. Pat. 97,141. —E. S.

Ores; Treatment of —— in a Furnace having a chamber to receive melted products. I. Sanfilippo. Fr. Pat. 336,069, Oct. 5, 1903.

Besides the furnace chamber proper, the furnace is provided with a second, relatively shallow chamber underneath the hearth, inclined towards a guarded opening for the outflow of melted metal or metalloid (such as sulphur), the dividing floor or partition being supplied with numerous holes or slits for passage of melted matter from the upper to the lower chamber. One means of access, or more, to the chimney is provided from the subsidiary chamber, whereby gases, such as sulphur dioxide, formed in roasting the ore, may be drawn into or through it; or the direction of the gases may be reversed.—E. S.

Air for Blast Furnaces or Converters; Process and Apparatus for removing the Moisture from ——. J. Gayley. Fr. Pat. 336,065, Oct. 15, 1903.

See Eng. Pat. 19,933 of 1903; this J., 1904, 22.—T. F. B.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

(*A.*)—ELECTRO-CHEMISTRY.

Electro-chemical Industries. F. B. Crocker and M. Arendt. School of Mines Quarterly, 1903, **25**, 1—20.

The subjects treated by the authors include: The electrolytic refining of copper; the electrolytic manufacture of aluminium, caustic soda, and potassium chlorate; electrolytic bleaching; manufacture of calcium carbide, barium compounds, alkali cyanides, carborundum, and artificial graphite; electric smelting (iron, steel, aluminium bronze); and the manufacture of ozone and of oxides of nitrogen.—A. S.

Luminous Arcs in Metal Vapours [of Mercury, &c.]. E. Weintraub. Philos. Mag., **7**, 95—124. Chem. Centr., 1904, **1**, 628.

A long arc can be readily produced in mercury vapour, with a continuous current at 100—200 volts, if a supplementary electrode be placed in the neighbourhood of the cathode, in order to render the latter active. The anode cannot be rendered active in this way. An arrangement is described in which the anode is of iron or graphite, whilst near the mercury cathode, a supplementary cathode, also of mercury, is placed. By electro-magnetic means, an iron core can be raised, whereby the film of mercury which connects the two cathodes is removed and a small arc is produced. By the ionising action of the arc on the mercury vapour, the main cathode is rendered active, and if no foreign gases be present, the main arc is produced almost instantaneously. If, however, the containing vessel or lamp has not been completely evacuated, *e.g.*, if the pressure of foreign gases (air, hydrogen, oxygen) exceed 0·01 mm., the supplementary cathode does not act so well. In such cases, a thin carbon filament may be used extending from the anode to near the cathode. The main arc extends first to the carbon filament, and then, rapidly, to the anode. Similar effects can be produced with alkali metals and amalgams in place of mercury.—A. S.

Solubility of Glass; Electrochemical Determination of ——. F. Haber and H. Schwenke. Zeits. f. Electrochem., 1904, **10**, 143—156.

The authors have worked out a rapid and simple method for determining the corrosive or solvent action of water on glass bottles such as are used for wine and beer. The method of examination recommended by the authors, consists in heating the glass bottle containing pure distilled water to 80° C. during five hours; a current of air (free from carbon dioxide) being bubbled through the water. Two small platinum electrodes are dipped into the water and the strength of current obtained by 10, 20, and 30 volts is noted every hour. From these measurements the specific conductivity of the water is obtained, and by the increase of this value, which is noted, the solubility is calculated. Comparison of the results with those obtained with previously examined bottles enables one to form an opinion of the quality of the glass of the vessel under examination.—R. S. H.

English Patent.

Peat; [Electrical] Process and Apparatus for removing Water from ——. B. Kittler, Memel, Germany. Eng. Pat. 126, Jan. 2, 1904.

In the removal of water from peat by electro-osmotic action, the peat is warmed, kept in motion, and subjected to a vacuum. The peat is contained in a cylindrical sieve or strainer, which acts as the negative pole, and which is arranged with an outer casing carried on a central hollow shaft provided with hollow stirring blades, arranged helically around the shaft so as to act as conveyers; the shaft and stirring blades form the positive pole. Hot air is passed through the hollow shaft, and the outer casing is provided with an outlet for removal of the water and is connected with an air-pump. It is claimed that great efficiency is obtained with a small consumption of current, and that incrustation on the positive pole and short circuiting are prevented.—A. S.

United States Patents.

Electrically Heating Articles; Process of ——. E. F. Price, Niagara Falls, N.Y., Assignor to Union Carbide Co., Niagara Falls, N.Y. U.S. Pat. 752,357, Feb. 16, 1904.

The carbon articles, to be heated or baked, are arranged end to end in proximity to and around a resistance-conductor, and within or between, and in proximity to, layers of a separate material which is normally a poor conductor of electricity. The electric current is passed directly through the resistance-conductor, which is interposed between the electrodes or terminals, and the articles are heated and the layer of material is converted by the heat into a better conductor. The material thus allows the current to pass directly through it, and supplies a further quantity of heat to the articles sufficient to bake them. —B. N.

Heating Articles by Electricity; Process of ——. E. F. Price, Niagara Falls, N.Y., Assignor to Union Carbide Co., Niagara Falls, N.Y. U.S. Pat. 752,358, Feb. 16, 1904.

The process is similar to the one described in the preceding abstract of U.S. Pat. 752,357, with an additional arrangement for mechanically directing the electric current through the articles after they have been partially heated, so as to bring them to the desired temperature. It is claimed that the process is suitable for electrically baking carbon electrodes, the latter being arranged in a number of superposed or concentric layers.—B. N.

(*B.*)—ELECTRO-METALLURGY.

Steel; Examination of ——, with regard to its Electrica Conductivity. J. A. Capp. Amer. Inst. Mining Eng. New York, 1903.

The specific resistance of 45 samples of steel varied a about 20° C. between 11 and 22·7 microhms, or between 6·4 and 13·2 times that of copper. Seven samples o wrought iron showed at 25° C. a specific resistance of from 10·8 to 13·8 microhms, or 6·12—7·82 times that of copper

Curves are given showing the influence of impurities on the resistance of steel. Manganese is the element which exerts the greatest influence, and it is stated that commercial steel rails contain more manganese than is necessary to obtain the best results. For a good rail-steel having a resistance (13·8 microhms) eight times that of copper, not more than 0·15 per cent. of carbon, 0·30 of manganese, 0·06 of phosphorus, 0·06 of sulphur, and 0·05 per cent. of silicon should be present.—A. S.

French Patents.

Metals ; Manufacture of New Combinations of ——, *by Ionisation.* A. Nodon. Fr. Pat. 335,907, Oct. 14, 1903.

The electro-negative metal is fused and used as the cathode in an electric furnace, the anode being a non-attackable substance, and the electrolyte a fusible and only slightly volatile halogen compound of the more electro-positive metal. The passage of the current effects an ionisation, effecting the combination of the metals and the liberation of the halogen. To incorporate other metals, the electro-affinity of each of the new metals is first determined, and these are added to the electrolyte as halogen compounds. The proportions are regulated by the composition of the alloy to be obtained, and the liberation of the metals is effected successively by the aid of electro-motive forces proportional to the electro-affinities of the metals of the electrolyte.—B. N.

Etching [*Designs on*] *Metals, and especially Printing Cylinders.* J. A. Dejey. Fr. Pat. 335,941, Sept. 18, 1903.

The present process differs from that described in Fr. Pat. 334,499 of 1903 (this J., 1904, 67) in that the metallic reserve is tin instead of lead, and the deposition of the tin on the prepared surface is effected electrolytically from a hot bath, preferably constituted of two parts of sodium pyrophosphate to one part of stannous chloride, dissolved in distilled water. The other processes remain substantially as described in the former patent. Reference is made to Fr. Pat. 301,227 of 1900. See Addition to Fr. Pat. 301,054 of 1901 ; this Journal, 1902, 51.—E. S.

XII.—FATTY OILS, FATS, WAXES, AND SOAP.

Oleic Acid ; Solidifying ——, *with Sulphuric Acid.* K. Hartl, jun., Vienna. Ger. Pat. 148,062, Jan. 20, 1903. Zeits. angew. Chem., 1904, **17**, 277.

Oleic acid and fatty acids in which it is contained are solidified by first submitting them to distillation with superheated steam—to remove organic impurities liable to be carbonised by sulphuric acid—and then treating the distillate with concentrated sulphuric acid in the usual manner.—C. S.

"Extraction Beeswax" ; Characteristics of ——. W. Hirschel. Chem.-Zeit., 1904, **28**, 212—213.

In the preparation of beeswax, the bulk of the wax is first separated by treatment with hot water and straining from dead bees, &c., and the residue pressed in layers with straw in a filter-press. The pressed residue is again boiled and pressed, yielding the so-called "expressed wax," and this final residue in the press is extracted with benzine to recover the 10—15 per cent. of wax that it still contains. The "extraction wax" is frequently contaminated with the material of artificial combs. The author has analysed three specimens of genuine "extraction wax" as obtained directly from the residue, previous to the partial bleaching and refining that it undergoes before being put upon the market. The crude wax was a dark brown soft mass, greasy to the touch and of unpleasant odour. In each case it was boiled with water before analysis to remove a yellow colouring matter. The filtered waxes gave the following results :—Acid value, 23·3 to 27·1 saponification value, 92 to 94·5 ; "ratio," 2·46 to 2·95 ; Buchner's acid value, 11·9 to 13·2 ; iodine value, 31·2 to 39·6 ; m. pt., 61·3 to 62·5 ; and sp. gr. at 15° C., 0·953 to 0·957. With the exception of the specific gravity and melting point these values differ greatly from the figures for normal beeswax, and particularly in the case of the iodine value and Buchner's acid value. All three specimens gave faint reactions in the tests for rosin, and in Weinwurm's test for paraffin behaved as though containing about 5 per cent. of that substance. In Fehling's test for stearic acid only a faint milkiness was obtained. Six commercial samples of "extraction wax" in a semi-bleached condition gave the following results :—Acid value, 21·9 to 53·3 ; saponification value, 91·5 to 122·2 ; "ratio," 1·29 to 3·24 ; Buchner's acid value, 10·1 to 27·9 ; m. pt., 69° to 72·5° C. ; and sp. gr. at 15° C., 0·970 to 0·984. All the samples gave more or less pronounced reactions with Fehling's stearic acid test.—C. A. M.

Wood Oil [*Tung Oil*] ; *Treatment of* —— *to form Products especially useful in the Manufacture of Linoleum and the like.* A. H. Dewar. From The Linoleum Manufacturing Co. Eng. Pat. 5789, March 12, 1903. XIII. B., page 328.

Sewage Sludge and like matters ; Treatment of [*Extraction of Fatty Matters from*] ——. H. Spence and P. Spence and Sons., Ltd. Eng. Pat. 8348, April 11, 1903. XVIII. B., page 334.

Soaps developing Active Oxygen and having an Antiseptic and Bleaching Effect ; Manufacture of Non-Caustic ——. H. Giessler and H. Bauer, Stuttgart. Eng. Pat. 22,580, Oct. 19, 1903.

Ordinary soap is mixed with a suitable proportion of "sodium or ammonium perborate," NH_4BO_3 or $NaBO_3$, or "sodium percarbonate," Na_2CO_4, either in the form of powder or as a paste with lanolin, vaselin, &c. Claim is also made for protecting such salts from the action of the carbon dioxide of the air by enveloping them in soaps, spermaceti, vaselin, paraffin-wax, &c.—C. A. M.

French Patents.

Oils and Fats ; Enzymic Decomposition of ——. M. Nicloux. Fr. Pat. 335,902, Oct. 14, 1903.

Crushed castor (or other) seeds are triturated with castor oil from a previous operation, and the oily extract filtered and subjected to centrifugal force. The deposit consists of aleurone and the active enzymic substance, and amounts to about 7·5 per cent. of the original non-decorticated seeds. As separated it still contains about 80 per cent.

of oil. It is stated that 10 kilos. of this active deposit are able to effect nearly complete decomposition of 1,000 kilos. of fats and oils in 24 hours.—C. A. M.

Solvent; Separation of —— from substances from which the Fat has been extracted. E. Bergmann. Fr. Pat. 335,964, Oct. 12, 1903.

The solvent is displaced by a liquid having a greater affinity for the substance but without chemical action on the solvent, *e.g.*, water, with or without the addition of an acid, alkali or salt, which additions may in certain cases be made to the substance before the extraction.—C. A. M.

XIII.—PIGMENTS, PAINTS; RESINS, VARNISHES; INDIA-RUBBER, Etc.

(*A.*)—PIGMENTS, PAINTS.

Alkaline Earths [Pigment]: Mangani-manganates of the ——. V. Auger and M. Billy. Comptes rend., 1904, **138**, 500—502.

The compounds prepared by the fusion of manganese dioxide with a mixture of an earthy base and its nitrate or chlorate never possess the composition of manganates but always have a deficiency of oxygen as compared with the general formula MnO_4M''. The authors regard such compounds as mangani-manganates, the barium salt having been introduced as a pigment under the name of Cassel green. This compound is best prepared by evaporating a clear solution of baryta to a pasty consistency in a large flask, incorporating with the mass a mixture of equimolecular proportions of potassium and sodium nitrates to the extent of about five times the dry weight of the baryta and introducing powdered potassium permanganate in the proportion of 1 mol. to 4 mols. of barium oxide. The whole is then heated in an air bath in presence of a current of dry air to remove the water and is then maintained at a temperature of about 280° C. until the mass becomes green and ceases to evolve oxygen. After cooling, the green mass is thoroughly washed with boiled water and dried in the desiccator. The green pigment had the following composition:—MnO 19·9, BaO 70·8, available oxygen 6·98, H_2O (by difference) 2·4 per cent. This composition indicates an excess of barium over that required by the theoretical formula $Mn_2O_8Ba_3H_2O$, but the ratio of available oxygen to manganese corresponds exactly to the formula $O_3:Mn_2 = 48:110$.—J. F. B.

English Patent.

Paint Composition. W. A. Hall, New York.
Eng. Pat. 26,903, Dec. 8, 1903.

A water-resisting and more or less elastic paint is produced by mixing a mineral base, such as talc (200 parts), a vegetable oil, *e.g.*, tung oil (25 parts), potassium oxalate (2 parts), and water (50 parts), and adding to the mixture 100 parts of a binding composition consisting of casein (20 parts), ammonia (1 part), formaldehyde (2·5 parts), boric acid (2 parts), creosote (1 part), and water (170 parts).—T. F. B.

French Patents.

Medium for Oil Paints; Manufacture of a ——.
J. E. Kellinger. Fr. Pat. 336,317, Jan. 10, 1903.

See U.S. Pat. 738,456 of 1903; this J., 1903, 1096.—T. F. B.

Pigment, and Process of Manufacturing same. W. J. Armbruster and J. Morton. Fr. Pat. 33 ,222, Oct. 23, 1903. Under Internat. Conv., Jan. 30, 1903.

See U.S. Pat. 743,802 of 1903; this J., 1903, 1300.—T. F. B.

White Paint; Manufacture of a ——. J. E. Kollinger. First Addition, dated Oct. 23, 1903, to Fr. Pat. 328,114, Oct. 23, 1902; this J., 1904, 69.

The pigment obtained from dolomite containing 20—50 per cent. of magnesia is superior to that from a purely calcareous limestone. Magnesia may be added to a limestone, but the result is less satisfactory than when it is naturally present.—M. J. S.

(*B.*)—RESINS, VARNISHES.

Colophony; Constituents of ——. W. Fahrion.
Zeits. angew. Chem., 1904, **17**, 239—241.

In a former communication (this J., 1902, 127) the author asserted that the chief constituent of American colophony was an acid (or isomeric acids) of the formula $C_{20}H_{30}O_2$, which readily underwent spontaneous oxidation with the formation of a product insoluble in petroleum spirit. His views were opposed by Tschirch and Studer (this J., 1903, 1250). The author now replies to Tschirch and Studer, and concludes that his former theory of the "autoxidation" of colophony is completely justified by observations made.
—C. A. M.

Rosin and Rosin Oil; Practical Uses of ——. S. v. Rela-Stanislawski. Chem. Rev. Fett- u. Harz-Ind., 1904, **11**, 8—9.

The cheaper qualities of sealing-wax contain up to 40 per cent. of rosin, in addition to shellac, accaroid resin, thick turpentine, Manila copal, and colouring and weighting materials; whilst ordinary packing sealing-wax contains as much as 60 per cent. of rosin. Mixtures of heavy rosin oil and mineral oil are used as "saturation oils" in the sugar industry. Effront (see Eng. Pat. 19,354 of 1902, and Fr. Pat. (addition) 321,124 of 1902; this J. 1903, 223, 1061; also this J. 1903, 876) has described a method of improving the fermentation of molasses for the manufacture of spirit by adding rosin, rosin acids, or rosin soaps to the mash, wort, or pitching yeast. An addition of 20 to 100 grms. of rosin to 100 litres of mash increases the yield of alcohol, whilst abnormal molasses are rendered readily fermentable by treatment with rosin acids at a higher temperature. Cheap substitues for shellac have been prepared from accaroid resin, rosin, and a saponifiable wax, whilst in some cases Manila copal is present. For certain purposes these preparations give as good results as shellac. Rosin and rosin oil are added to inferior asphaltum varnishes to improve their lustre and elasticity, whilst rosin varnishes are mixed with benzene solutions of rubber, and used as insulating varnishes.—C. A. M.

Copal Resin and Kino, New; obtained respectively from the Fruit and Bark of Dipteryx Odorata, Willd. E. Heckel and F. Schlagdenhauffen. Comptes rend., 1904, **138**, 430—432.

The red secretion product contained in the bark of *Dipteryx odorata*, and probably in all trees of the genus *Dipteryx*, presents very close analogies with previously known kinos. The flowers contain a copal resin and the berries are rich in coumarin.—T. H. P.

English Patent.

Wood Oil [Tung Oil]; Treatment of —— to form products especially useful in the manufacture of Linoleum and the like. A. H. Dewar, Staines; and the Linoleum Manufacturing Co., Ltd., London. Eng. Pat. 5789, March 12, 1903.

Tung oil polymerised by heat is mixed with "solidified" (oxidised) linseed oil, yielding a product that melts at a lower temperature than the polymerised oil (300° C.). Resins, oils, siccatives, or the like may also be added, or blown castor oil, rosin oil, &c., may be added at about 180° C. instead of the solidified linseed oil.—C. A. M.

(*C.*)—INDIA-RUBBER.

Indiarubber; Valuation of ——. C. O. Weber.
Gummi-Zeit., 1904, **18**, 461.

The method of fractional precipitation (this J., 1903, 885) for the valuation of india-rubber must be used with caution in the case of rubbers not well known, and it is as well to supplement it by an elementary analysis of the original rubber, and also of each fraction, and a determination of bromine in the bromine-addition product. The author gives an instance of Uganda ball, which had all the appearance of a good rubber. The nitroso product appeared normal, but the bromide on analysis only yielded 60·27 per cent. of bromine (instead of 70·17 per cent.). The rubber itself contained no less than 32 per cent. of oxygen; yet by the Schneider method (*loc. cit.*) it yielded 92 per cent. of α-caoutchouc and 8 per cent. of resin.—J. K. B.

English Patents.

Rubber; Process of Vulcanising ——. A. O. Bourn, Bristol, R.I., U.S.A. Eng. Pat. 28,353, Dec. 24, 1903.

The object of the process is to ensure a uniform temperature in all parts of the vulcanising chamber, whether the heating be done by a steam-jacket or by coils inside the chamber. This is achieved by mechanically circulating the vulcanising medium (air or other gas) by means of suitably arranged pipes connected to a fan or pump.—J. K. B.

Adhesive Solution for sticking all kinds of Leather, Rubber, Cloth, and the like. H. E. Dancer, East Finchley. Eng. Pat. 7313, March 30, 1903.

A suitable solution for sticking together leather, rubber, cloth, &c., consists of gutta-percha (about 1 lb.) dissolved in methylated ether (1 lb.) and carbon bisulphide (4 lb.). —T. F. B.

United States Patents.

Rubber-like Gum. M. G. Brownell, Denver, Col. U.S. Pat. 752,951, Feb. 23, 1904.

A plastic, rubber-like, waterproof gum is prepared from the plant *Picradenia floribunda utilis* by grinding the plant to a pulp and treating this pulp with a volatile hydrocarbon solvent, such as light petroleum spirit, in which the gum is soluble, and separating the gum from the extract by evaporation.—J. F. B.

Rubber-like Gum. M. G. Brownell, Denver, Col. U.S. Pat. 752,952, Feb. 23, 1904.

A plastic, rubber-like body, consisting essentially of the gummy particles contained in the plant *Picradenia floribunda utilis*, separated and agglomerated into a coherent mass, insoluble in water, but soluble in light hydrocarbons is claimed. The plant is ground to a pulp with water, and the pulp is subjected to a compressive, rubbing action, whereby the gummy matter is separated from the fibre. —J. F. B.

Rubber-like Material. R. A. Leigh, Assignor to the Western Rubber Co., both of Denver, Col. U.S. Pat. 752,988, Feb. 24, 1904.

The agglomerated gummy matter obtained from *Picradenia floribunda utilis* is mixed with sulphur or sulphur compounds, rolled into sheets, and vulcanised by heating under pressure.—J. F. B.

French Patent.

Caoutchouc, Artificial; Manufacture of ——. L. L. A. Seguin and J. F. G. de Roussy de Sales. Fr. Pat. 336,206, Oct. 21, 1903.

The "caoutchouc ferment" mentioned in Fr. Pat. 334,833 (this J., 1904, 122) is prepared in the following manner. A solution of natural caoutchouc in "benzine" is exposed to daylight in a closed bottle, and the thick deposit produced is redissolved by heating at 50° C. The solution is then poured into double its volume of alcohol, the liquid decanted from the precipitate obtained, and the latter scattered on the surface of a mixture of coal-tar with boric acid, which is then kept at 50° C., in an atmosphere of oxygen. After some time, the cover and the walls of the containing vessel become coated with a brownish-grey powder, which is stated to be a very active ferment.—M. J. S.

XIV.—TANNING; LEATHER, GLUE, SIZE.

English Patents.

Cement [Glue Composition] for uniting pieces of Wood. J. H. J. Bartels, Liverpool. Eng. Pat. 4154, Feb. 21, 1903.

Ordinary animal glue is dissolved in milk of lime, and 1 to 2 parts of linseed meal are added to the glue solution so obtained (9 pints) and also about 1 part of commercial silicate of soda. The sheets to be united are coated thinly with the cement, and then brought together, and submitted to pressure and heat.—J. K. B.

Adhesive Solution for sticking all kinds of Leather, Rubber, Cloth, and the like. H. E. Dancer. Eng. Pat. 7313, March 30, 1903. XIII. C., col. 1.

French Patent.

Leather; Grained ——, *and Process of making same.* The Universal Leather Co. Fr. Pat. 336,256, Oct. 26, 1903.

See Eng. Pat. 22,872 of 1903; this J., 1904, 27.—T. F. B.

XV.—MANURES, Etc.

Phosphoric Acid in Crude Phosphates; Rendering the —— *soluble, for Manuring Purposes.* A. Ystgaard. Teknisk Ugeblad, Christiania, 1903, **50**, 329. Chem.-Zeit., 1904, **28**, Rep., 56.

If powdered apatite be fused with carnallite, reaction takes place according to the equation:—$Ca_3P_2O_8 + 3MgCl_2 = Mg_3P_2O_8 + 3CaCl_2$. The product can be easily pulverised, and of its total phosphoric acid, about 80 per cent. is soluble in 2 per cent. citric acid. The best results are obtained by using 1½ times the theoretical amount of carnallite, and fusing at about 700° C. for not longer than 10—30 minutes. The process is more economical if the carnallite be partly substituted by kieserite. The best mixture consists of 100 parts of apatite, 200 parts of carnallite, and 100 parts of kieserite; and the product, after being lixiviated with cold water, yields a residue containing from 26—30, sometimes as much as 34, per cent. of phosphoric acid soluble in 2 per cent. citric acid. Comparative vegetation experiments with the product obtained and with Thomas meal gave results favourable to the new product.—A. S.

English Patents.

Gas Liquor; Treatment of ——. C. G. Moor. Eng. Pat. 4988, March 4, 1903. III., page 318.

Brewers' and Distillers' Yeast: Treating and Drying —— *for use as a Manure.* J. L. Baker. Eng. Pat. 7921, April 6, 1903. XVII., page 333.

XVI.—SUGAR, STARCH, GUM, Etc.

Beetroot Juice; Determination of the purity of ——. H. Pellet. Bull. de l'Assoc. des Chim. de Sucr. et de Dist., 1904, **21**, 762—766.

The author agrees with Hermann (this J., 1904, 28) that the determination of the purity of beetroot juice in the analysis of the juice obtained by pressing chopped slices gives only inexact and variable results from which nothing definite can be deduced. It is sufficient to determine the quotient of the diffusion juice and the sugar content of the beetroot. The tabulation of the richness of beetroots from 7 to 20 per cent. with the corresponding purity of the diffusion juice shows that for normal roots these are strictly related when average figures are used. Roots from irrigated lands, as in Persia, Spain and Egypt, contain, according to the author's experience, a greater quantity of salts in proportion to sugar than usual. Beetroots also which have lain long on the ground after vegetation is complete are abnormal in character.—L. J. de W.

Beetroot Juice; Action of Lime on certain Nitrogenous Matters in ——. E. Sellier. Bull. de l'Assoc. des Chim. de Sucr. et de Dist., 1904, **21**, 760—762. See this J., 1903, 969.

The author criticises the method used by Andrlik (this J., 1903, 1202) for determining that portion of the nitrogen of raw juice that can be set free as ammonia by distilling with lime after clarification. It is not stated how the clarification is to be effected, nor is the proportion of lime given. Basic lead acetate would eliminate albuminoids, properly so-called, but the separation of their products of degradation is less certain. It is not known what bodies other than ammoniacal compounds and amino-acids give off ammonia when distilled with lime. There is a presumption that albuminoids are decomposed, but the proof is wanting. Glutamine forms a precipitate with basic lead acetate, which increases on standing, and the optical character of the solution changes. If part of the amino-acids are precipitated by the clarification, the determination of the ammoniacal nitrogen is rendered inexact.—L. J. de W.

Evaporation and Heating; Transmission of Heat in ——. H. Claassen. Bull. de l'Assoc. des Chim. de Sucr. et de Dist., 1904, **21**, 800—808.

The coefficient of transmission of heat increases with the fall of temperature, and does not vary much per degree within the limits of experiment, except for very steep falls, when the injurious effect of an intense evaporation at the heating surface makes itself increasingly felt. The coefficient of transmission increases with rise of temperature of the heating steam and boiling liquid. Heating-steam at temperatures above and below 100° C. in particular, seems to act very differently. The coefficient diminishes when the column of liquid on the heating surface is increased. In the evaporation of solutions, the nature of the dissolved substance and the concentration of the solution have great influence. Salt solutions have co-efficients equal to or above that of water. For solutions of sugar, and probably of all organic matters, the coefficient diminishes with the increase in concentration. The condition of the heating surface (not only incrustation and rust, but also the composition of the metallic surface) has a marked influence on the transmission of heat. Any superheating of the steam diminishes the coefficient of transmission, and at a rate increasing greatly with that of the superheating.—L. J. de W.

Sugar; Inversion of ——. L. Lindet. Comptes rend., 1904, **138**, 508—510.

It is recognised that the inversion of saccharose by boiling with pure water is due to the very feeble acid properties of the sugar; inversion is intensified by the presence of invert sugar, the acidity of the constituents of which is greater than that of the saccharose. If the electrical conductivity of distilled water "be taken as unity," that of cane sugar is 1·3, fructose 3·7, and glucose 5·1. The addition of 1 part of invert sugar to 3,000 of saccharose doubles the degree of inversion. The author's experiments were carried out by boiling a 10 per cent. solution of sugar for four hours. The nature of the vessel in which the boiling is conducted has a great influence on the inversion. With new glass vessels the inversion is retarded or even inhibited by the alkalis extracted from the glass, which neutralise the acidity of the sugar. This influence of the glass decreases with repeated use, and the proportions of reducing sugar formed, increase with each operation until the glass becomes indifferent. The maximum degree of inversion can be attained at once if the glass be first extracted with boiling water or dilute acid. With copper or aluminium vessels the inversion is considerably intensified. The author was therefore led to investigate the influence of shavings of various metals on inversion in previously extracted glass vessels. Copper, lead, tin, and bismuth considerably intensified the inversion; aluminium and antimony had a weaker intensifying effect; nickel, chromium, arsenic, gold, platinum, silver, and mercury were indifferent; cobalt, iron, zinc, cadmium, and magnesium had a retarding influence. These effects are due to the acid or basic nature of the oxides of these metals. The influence of metals on the inversion of saccharose is greater the smaller the heat of formation of their compounds, and the greater their tendency to chemical dissociation. Further, these metals intensify the inversion of sugar more powerfully the less the liability of their compounds to electrolytic dissociation, the less the heat evolved by their ionisation, and the lower their electrolytic solution-pressure. —J. F. B.

Sugar; Various methods of Refining ——. A. Aulard. Zeits. Ver. deutsch. Zuckerind., 1904, 143—186.

In a review of the progress in the sugar refining industry in the last three years, the author deals with the composition of molasses; formation of invert sugar; refinery value of raw sugars; defecation with baryta and ammonium phosphate; Roux's process for the complete drying down under vacuum of refinery massecuites; specification of complete plant for sugar refineries; sugar-grinding and cube-forming machinery; sugar-loaf and slab-forming machines with centrifugal claying; plant and working statistics of a French refinery; description of the "Perfect" sand filter for syrups. Many of the descriptions are accompanied by illustrations.—J. F. B.

Potato Starch; Composition of ——. A. Fernbach. Comptes rend., 1904, **138**, 428—430.

By determining the proportions of phosphoric anhydride in the small, light granules and in the large, heavy granules of samples of potato starch, the author arrives at the conclusion that small starch granules consist of a nucleus relatively rich in phosphorus on which are gradually superposed, so as to form larger and larger granules, layers of starch free from phosphorus. The latter element does not seem to belong entirely to the nitrogenous organic matter present, as the starch examined contained only small proportions of nitrogen.—T. H. P.

Invertase; Influence of Electrolytes on the Action of ——. S. W. Cole. J. of Physiology, **30**, 281—289.

The invertase solution was prepared from a solution of commercial invertase by dialysis with distilled water in presence of chloroform. The following table shows the amount of sugar inverted in solutions containing 21·4 per

Sugar Solution containing	Percentage of Sugar Inverted after 24 Hours.	Percentage of Sugar Inverted after 42 Hours.
Without any addition............	20·0	26·2
Sodium chloride..................	11·6	12·4
Ammonium chloride............	37·3	53·7
Barium chloride..................	10·6	11·4
Potassium sulphate............	10·1	10·8
Ammonium sulphate............	41·2	58·6
Magnesium sulphate............	9·5	10·4
Sodium-potassium tartrate......	10·6	12·0
Ammonium tartrate	63·6	73·6

cent. of sugar, the concentration of the individual salts o the mixture corresponding in each case to a N/9 solution; the temperature was 40° C.

The results show that in general the retarding action of the cations of the salts preponderates over the acceleratng influence of the anions. A comparison of the results obtained with sodium, ammonium, and barium chlorides, and with potassium, ammonium, and magnesium sulphates shows that the retarding influence of salts increases with he strength of the base contained in it. In the case of ammonium salts, the retarding influence of the weak NH_4-ion is so slight that it is easily overcome by the accelerating influence of the anions, the result being that ammonium salts have a remarkable stimulating effect on nvertase. The greater acceleration of the inversion by ammonium tartrate than by ammonium chloride and sulphate s due to the fact that the proportion of injurious hydrogen ons is greater in the solutions of the inorganic salts. A small addition of hydrochloric acid (up to a concentration of N/3000), causes a remarkable increase in the action of nvertase on cane sugar. In a solution containing 23·73 per cent. of sugar, in 51 hours at 39·5° C., 4·96 per cent. of he sugar was inverted by invertase alone, 59·58 per cent. by invertase + 0·0012 per cent. of hydrochloric acid (= N/3000), and 3·24 per cent. by 0·0012 per cent. of hydrochloric acid alone. With larger proportions of acid, he amount of sugar inverted by the acid alone increases, but that inverted by invertase + acid decreases. The nfluence exerted by electrolytes on ferment action is due o an action on the ferment itself, not on the nutritive medium.—A. S.

Enzymes. H. Johnson. J. Fed. Inst. Brewing, 1904, 1, 13—27.

Proteolytic Enzyme of Malt.—When ground malt is digested with water at suitable temperatures, the acidity of the infusion increases on standing for about six hours, his being due to the production of soluble amides, peptones, and albumoses by the action of the proteolytic enzyme. The most favourable temperatures for this action lie between 105° and 130° F.; no increase of acidity takes place at temperatures above 155° F. Increase of acidity occurs to the same extent in the presence of chloroform, so that it is not attributable to bacterial activity. It takes place either at the expense of or under the influence of some of the nsoluble constituents of the malt, since a filtered infusion of malt, when tested under the same conditions, shows no ncrease of acidity. From these facts, it follows that the acidity of a sample of malt must be determined by extraction at temperatures above 158° F. The acidity of a sample of malt is a rough measure of the soluble nitrogenous bodies; excessive acidity indicates "forced" growth. In warm top fermentations the yeast is generally allowed to digest most of its own food, and high mashing temperatures are generally employed. But for cool bottom fermentations pre-digested food must be supplied, and low initial mashing temperatures are required. Any degeneration of he yeast owing to deficient nutrition can generally be corrected by slightly lowering the initial temperature of mashing, thereby favouring the activity of the proteolytic enzyme in the malt.

Liquefying Diastase. — Malt-starch which has been modified by germination, is very readily attacked and saccharified in the mash tun, but the starch of raw grain should be digested with 20 per cent. of malt for half an hour at 75° F. before treatment in the converter.

Invertase of Yeast.—Invert sugar may be prepared for brewing purposes by dissolving raw sugar in the proportion f 144 lb. per barrel, adding 3 lb. of liquid yeast per cwt. of sugar, and digesting at 133° F. for 1½—2 hours; the olution can then be used in the copper without separating he yeast.

Influence of Enzymes on Attenuation.—The various types f saccharomyces are arranged in the following order:— . apiculatus, Saaz, Frohberg, Burton, Logos—produce increasing degrees of attenuation in malt worts, owing to the ction of the different enzymes secreted by them upon the extrins. It is suggested that primary fermentation might e carried out by a low attenuating type, whilst a more powerfully attenuating yeast could be sown afterwards for conditioning.—J. F. B.

Malt; Extraction of the Nitrogenous Matters of ——. L. Pierre. Monit. Scient., 1904, 18, 190—193.

Interaction between Potassium Phosphates and Certain Calcium Salts.—Solutions of calcium bicarbonate and calcium sulphate are treated at various temperatures with primary and secondary potassium phosphates and with a mixture of the two, and for each temperature acidity and alkalinity were determined after filtration, also the quantities of lime and phosphoric acid in the precipitates. In all cases the precipitates produced above 60° C. contained calcium carbonate. In the case of a mixture of primary and secondary phosphates with calcium bicarbonate solution (a medium corresponding with the mashing liquor in the brewery), the acidity was greater than in the case of primary phosphate alone, owing to the action of the carbon dioxide liberated upon the secondary phosphate. For this reason the neutralisation of the acidity of malt by calcareous water always requires more calcium bicarbonate than is indicated by theory. The presence of primary phosphate considerably retarded the precipitation of lime and phosphoric acid. The influence of the nature of a water upon the acidity and alkalinity of a malt wort will be greater or less for a given percentage of phosphoric acid, according to whether the malt is richer in primary or in secondary phosphate. In the cold, the solutions of calcium bicarbonate with the mixed phosphates showed the highest acidities, but above 35° C. the solutions of calcium sulphate were more acid.

Cold Infusions of Malt.—When infusions of malt were prepared with distilled water at the ordinary temperature, the acidity showed that the proportion of primary phosphates increased with the duration of infusion. From the results obtained from infusions made with pure water, with solutions of tannin and with solutions of neutral potassium fluoride, the author concludes that the increase of acidity with the duration of infusion is due to the action of the bacteria occurring on the surface of the grain, and not to the extraction of acid substances or to the influence of an enzyme.

Influence of Potassium Phosphates on Extraction of Nitrogenous Matters.—Infusions were made on a scale of ascending temperatures, with pure water, with a solution of primary phosphate and a solution of secondary phosphate. The presence of primary phosphate considerably increased the extraction of nitrogenous matter; secondary phosphate had a similar but weaker effect. At temperatures below 50°C. a portion of the increase included coagulable matters.

Influence of Certain Salts on the Extraction.—The increase of acidity and non-coagulable nitrogenous matter with increasing temperature was much less rapid with calcium bicarbonate than with pure water; the quantity of non-coagulable nitrogen was always less in presence of calcium bicarbonate than with pure water. In presence of calcium sulphate there was more non-coagulable nitrogen extracted below 50° C. and less above 50° C. than with pure water at the same temperatures. Water containing sodium chloride showed the greatest extractive power for non-coagulable nitrogen at all temperatures. In all cases the acidity and extraction of nitrogen rose to a maximum at a temperature of 57°—60° C.

Influence of the Method of Mashing.—Worts prepared by the decoction process were less acid and poorer in coagulable and non-coagulable nitrogen than worts prepared at similar saccharification temperatures by infusion, except in the case of the calcium bicarbonate mash. This result is attributed to the partial sterilisation and fixation of the nitrogenous matters brought about by decoction of a portion of the mash.—J. F. B.

Malt; Percentage of Moisture in ——. A. Vogel. Zeits. ges. Brauw., 1904, 27, 163—165.

The author entirely confirms the views expressed by Windisch (this J., 1904, 261). The effect of long storage begins to show itself especially in the summer and autumn. Excessive moisture is frequently due to the old practice of storing the malt without removing the culms, which are exceptionally hygroscopic. Fries has shown that it is quite possible to preserve malt until the autumn so that the moisture shall not exceed 4—5 per cent. in the bulk. After six months' storage in a suitable bin, he found that the moisture in the malt at a depth of 10 ins. below the surface was less than 5 per cent., whilst at a depth of 2 ft. the effect of six months' storage was scarcely perceptible. Storage in silos is equally efficient. In default of such means the malt should be covered with cloths, hop-bagging, &c.; an uppermost layer of malt culms has been found advantageous for protecting the malt from the atmospheric moisture. The malt store should be ventilated with due regard to the temperature and humidity of the air admitted. Malt in which the moisture has increased to 7 per cent., will have suffered internal deteriorations which cannot fail to produce their effect on the flavour, character, and even the keeping qualities of the beer: beers of poor quality are for this reason far more common in the autumn than at any other season.—J. F. B.

Lactic Acid Bacteria; Effect of certain species of —— and of a species of Acetic Acid Bacterium on the Fermentation of Grain Mashes [Harmful Lactic Acid Bacteria]. W. Henneberg. Zeits. Spiritusind., 1904, **27**, 83—85.

In many distillery fermentation tuns the wood is found to be infected with various species of "wild" lactic acid bacteria, as distinguished from the culture species, *B. Delbrücki*, which is used for the acidification of the mashes. Some of these "wild" species are harmless, whilst others have a harmful effect upon the yeast and the yield of alcohol. The species of acetic acid baterium isolated did not grow in presence of yeast during fermentation. But all the 17 different species of lactic acid bacteria found, grew well and produced acid in presence of yeast at a temperature of 27·5°—30° C.; *B. Delbrücki* produces very little acid at so low a temperature. Those species of lactic acid bacteria which do not set up fermentation (*i.e.* with production of alcohol, carbon dioxide, and acetic acid) in mashes do no harm to the yeast or to the attenuation. It is not desirable, however, to employ them for acidifying the mashes, as the relatively low temperature at which they develop permits the growth of harmful competing bacteria. Those species which produce volatile acids (together with alcohol and carbon dioxide) in mashes, injure the yeast and the yield of alcohol. Such species are frequently found in badly attenuating potato mashes. The restriction of the attenuation by these harmful species of lactic bacteria is proportional to the quantity of volatile acid produced by them; the presence of *B. Hayducki*, *B. panis fermentati*, and *B. brassicæ fermentatæ* is for this reason especially harmful. If the harmful species, in a debilitated condition, be added simultaneously with the yeast (infected yeast), they are suppressed by the latter. If healthy bacteria and yeast be sown at the same time, both develop powerfully for 24 hours, after which the acidity does not increase unless the bacteria, in virtue of their production of volatile acid, are of such a nature as to be able to harm the yeast. Seed yeast so infected will give bad attenuations. If the yeast be first allowed to set up a vigorous fermentation in a pure condition, subsequent infection, even with healthy harmful bacteria, will have no ill effect. Many harmful species, *e.g. B. Buchneri*, when sown together with the yeast are almost completely suppressed by the latter. If the yeast be sown 24 hours after the lactic acid bacteria, the latter will continue to produce acid, and the final acidity will be greater than if no yeast were present. In practice the yeast is sown 24—48 hours after the acidifying bacteria; in this case, if acidification has been effected spontaneously or by too low a proportion of cultivated *B. Delbrücki* at too low a temperature, many harmful species of lactic bacteria will be present, and the attenuation will be even worse than in the case of infected yeast. In these experiments no appreciable differences were noted whether many or only a few bacteria were sown along with the yeast.—J. F. B.

Beer; Sarcina Disease of ——, and the Organisms which cause it. N. H. Claussen. Zeits. ges. Brauw., 1904, **27**, 117—121 and 137—142.

Sarcina disease in beer is caused by the development of certain species of pediococcus, pure cultures of which have been made by the author from single tetrads isolated from the diseased beers. These beer-pediococci are very easily separated from large quantities of yeast, and from most other organisms which accompany them by the selective antiseptic action of dilute solutions of acid ammonium fluoride, the pediococci surviving whilst the yeast, &c. perish. At least two species or groups of pediococci are concerned in the production of sarcina sickness in beer. *P. damnosus* as a rule imparts an unpleasant flavour and odour to the beer, but does not produce any notable turbidity. *P. perniciosus* makes the whole liquid turbid in addition to spoiling the flavour and taste. *P. perniciosus* produces a higher degree of acidity in unhopped wort than *P. damnosus*. One and the same pure culture of pediococcus causes through its growth in the same kind of beer always the same kind of symptoms. The author sees no reason for assuming the existence of virulent and non-virulent forms of the same organism in the same kind of beer. But certain kinds of beer exist which, owing to their composition, can withstand the development of *P. damnosus* in considerable quantities without showing any symptoms of disease. Beer-pediococci grow in hopped wort and other neutral or acid brewery culture liquids, but the presence of a small quantity of free alkali is sufficient to stop their development entirely. Ammoniacal yeast-water, which has been recommended as a favourable culture medium, is entirely unsuitable for the cultivation of pediococci in the brewery. At moderate temperatures in suitable culture media, such as wort, the beer-pediococci appear to be perfectly indifferent to the presence or absence of oxygen. Cultures of beer-pediococci are completely sterilised by the action of alcohol (50—93 per cent.) or of "antiformin" in less than 15 minutes. Bisulphites also appear to have a powerful antiseptic effect. Tartaric acid is relatively feeble, whilst fluorides and fluosilicates have a very weak action in destroying growths of pediococci.—J. F. B.

Beer; Albuminoid Turbidity in ——. F. Schönfeld. Woch f. Brau., 1904, **21**, 124—126.

On examining some bottled lager beer which had developed intense turbidity, and formed a dense deposit a week after being sent out from the brewery, no yeast or bacteria could be found, but on warming the bottles, every trace of turbidity and deposit disappeared, and the beer became quite bright; the precipitated matter consisted of resin and albuminoids. Trouble of this nature is avoided by placing the beer, immediately after filtration, in a moderately warm room (8°—10° C.), and keeping it there until sent out for consumption. New filters often cause difficulty in the direction of after-turbidity of the beer. The best way to cope with this, is to allow the filter to stand under beer for a day or so before using, and then to retain the first few barrels which pass through the filter and filter them again later; it is sometimes necessary to several times fill the filter with beer and allow to stand for a day. Experiments made by the author show that the longer beer is kept moderately warm after filtration, the quicker and greater will the formation of turbidity be when it is subsequently cooled to the temperature of the lager cellar; such turbidity mostly disappears on warming. The author supposes that the changes taking place are molecular transformations, and that, at a certain temperature, and possibly under the influence of living enzymes in the beer, the albuminoid substances assume other configurations, and then exhibit behaviour at low temperatures different from that of the original compounds.—T. H. P.

Beer; Albuminoid Turbidities in —— caused by Metals. F. Schönfeld. Woch. f. Brau., 1904, **21**, 133—135. (See also this J., 1904, 263.)

Working with a pale beer brewed by the high temperature short mashing process, the author added various small quantities of tin chloride to the beer. The addition of 0·0001 grm. of tin chloride per litre of beer produced no turbidity even after long standing, but with 0·0005 grm per litre a heavy turbidity was produced after 24 hours. With increasing proportions of tin, increased turbidities were observed, these turbidities not increasing on prolonged standing. Metals in the form of strips were immersed in the beer for a period of seven days. Aluminium, lead, copper, brass, nickel, and antimony produced no turbidity under these conditions; iron caused a precipitate of rust but not a true albuminoid turbidity; tin alone caused the characteristic albuminoid turbidity, which appeared first after 24 hours and which increased as the time of contact was prolonged. Tinned metals caused a still more intense turbidity than pure tin, and in a much shorter time. A second series of experiments of the same nature was made with two strips of different metals, so as to produce galvanic couples. At the ordinary temperature after seven days' contact, no turbidities were produced by any of the following couples:—Iron-lead, iron-copper, aluminium-copper, aluminium-brass, lead-antimony, copper-antimony, nickel-antimony. When the same tests were subsequently cooled to 2°—3° C., turbidities appeared in the following cases:—Aluminium-copper, aluminium-brass, and lead-antimony showed very faint turbidities; antimony-copper and antimony-nickel showed considerable turbidities, but to nothing like the extent of those produced by tin. Tin is the only metal which can take part in the production of these turbidities on the practical scale, and the use of tinned metallic surfaces in any part of the brewery plant is unsafe.—J. F. B.

Beer Filtration; Turbidities caused by ——. C. Sellenscheidt. Woch. f. Brau, 1904, **21**, 144—145.

The author states that all metals are inimical to beer, the worst being zinc and lead; most filter-makers use tinned-brass; the tin is generally alloyed with lead, since a coating of pure tin is difficult to apply. The Enzinger filters are constructed of pure tin with fittings of tinned brass; no filter is absolutely indifferent to beer. Corrosion of the metal by the beer may be either direct or galvanic. The best means for protecting a new filter from direct corrosion is to leave it full of waste beer for a day or two, and afterwards to clean it only with hot or cold water. The most sensitive are the immature beers containing a large proportion of carbon dioxide. The denser the metal the less the liability to corrosion, since the surface pores become more readily protected. Galvanic is far more serious than direct action in causing turbidities; aluminium is especially liable to galvanic corrosion. The author has selected pure tin as the material for the bodies of the filters, because it is the densest metal available, and because it gives rise to the fewest complaints from galvanic corrosion. Copper is too soft and silver-plated brass too expensive. Cleansing with soda, and especially with "antiformin," is a certain cause of turbidity, but such cleansing is occasionally necessary; the filter must then be treated in the same way as a new filter. The danger of turbidities is increased by the use of pressure regulators and counter-pressure bottling machines, which are also made of metal. The use of a cheap, insufficiently purified asbestos pulp for filtration may cause a characteristic bluish "clay" turbidity which is very difficult to remove.—J. F. B.

Cane Molasses; Quantity of unfermentable Sugar in ——. H. Pellet and G. Meunier. Bull. de l'Ass. Chim. de Sucr. et Dist., 1904, **21**, 797—800.

Cane molasses leaves, in practice, about 3 per cent. of the molasses unfermented in the form of reducing bodies. The determination of these reducing principles gives invariably higher results after inversion, but the difference is ess in proportion as the fermentation is more complete.
—L. J. de W.

Fermentation in the Distillery. H. Alliot. Bull. de l'Ass. Chim. de Sucr. et Dist., 1904, **21**, 783—785.

According to Effront's method, the yeast is acclimatised o substances foreign to the composition of distillery worts —hydrofluoric acid and fluorides—and the whole of the yeast and contents of the vats are rendered antiseptic, whilst by the author's method the yeast is accustomed to he presence of volatile principles, toxic to the yeast, pro-uced in the body of the molasses itself and driven off by he process of denitration. A yeast is thus prepared capable f living and developing in a wort of raw molasses which as not been boiled and to which, in the bulk, no antiseptics ave been added.—L. J. de W.

Wines, Natural and Grape Stones; Organic Phosphorus compound in ——. J. Weirich and G. Ortlieb. Chem.-Zeit., 1904, **28**, 153—154.

Analysis of a sweet wine, prepared only from the must of grapes from the island of Thera, showed that it contained 0·095 per cent. of phosphoric anhydride, whilst wines from other localities contained proportions of phosphoric anhydride varying from 0·02 to 0·060 per cent. It is found that this phosphorus exists in organic combination and has its origin in compounds of the lecithin type contained in the grape stones. The proportion of nitrogen contained in a wine varies almost directly with that of the phosphorus. Thus, a Greek wine contained 0·0535 per cent. of phosphoric anhydride and 0·025 of nitrogen; and two wines from Thera grapes—(1) 0·092 of phosphoric anhydride and 0·05 of nitrogen, and (2) 0·095 of phosphoric anhydride and 0·057 of nitrogen. It is to this presence of lecithin, which has an advantageous physiological action, that strong, natural, southern wines owe their superority over distilled alcoholic liquors, and in estimating the value of a wine for invalids, its phosphorus content, and especially that of its organically-combined phosphorus, is of the highest importance; in fortified wines the proportion of the latter is always low. In order to render wine more stable, it is often pasteurised, or else the must is heated and fresh yeast subsequently added. Neither of these methods is to be recommended, as they both lead to the destruction of the most important constituent of the wine, namely, the lecithin, which undergoes decomposition at slightly above 50° C.—T. H. P.

Brewers and Distillers Yeast; Treating and Drying ——, *for use as a Manure.* J. L. Baker, London. Eng. Pat. 7921, April 6, 1903.

The yeast is heated in a steam-jacketed vessel, provided with an agitator, with a small proportion of sulphuric acid or of an alkali acid sulphate. Calcium carbonate is then added, but in such proportion as to leave the mixture acid. The mass becomes porous from escaping carbon dioxide, and may be readily dried. According to a second process, the yeast is mixed with a mineral phosphate, and is then heated and stirred with the proper proportion of sulphuric acid to constitute superphosphate. Or yeast, after being treated as first described, is mixed with a superphosphate and calcium carbonate, leaving the mass acid so as to avoid loss of ammonia.—E. S.

Distillers' Wash or Dregs and other noxious organic effluents; Process of treating ——. R. Anderson. Eng. Pat. 7658, April 2, 1903. XVIII. B., page 334.

Wine Vinegar; Ferment for the Manufacture of ——. C. Chotteau and E. Disse, Paris. Eng. Pat. 23,066, Oct. 24, 1903.

Fresh brewers' yeast, 2 parts, and sugar, 25 parts, are pounded, mixed, and compressed into a block, which is then wrapped in a thin shaving of beech-wood wound on itself. This ferment can be kept indefinitely in the dry state, and when placed in wine sufficiently aerated, it converts the wine into vinegar in a few days.—J. F. B.

French Patent.

"*Œnophile Vegetale*"; *Preparation for preserving wines and liquids poor in alcohol.* C. Gros. Fr. Pat. [illegible], Oct. 24, 1903.

Œnophile vegetale is prepared from the flowers, wood, bark, fruits, roots, leaves, seed, or pulp of plants belonging to the families of the gentianaceæ, citraceæ (bitter orange), rubiaceæ (cinchona), cruciferæ (cresses and mustard), papilionaceæ (chick pea), rutaceæ (guaiacum), *lauraceæ* (cinnamon and laurel), and *viniferæ* (vines). The preparation may be used in the form of a liquid extract (70—80 c.c. of extract per hectolitre of wine) or of a dry powder (45—50 grms. per hectolitre of wine). The preservative is mixed with the wine in the tuns, and is said to prevent decomposition for several years and otherwise to improve the quality.—J. F. B.

XVIII.—FOODS; SANITATION; WATER PURIFICATION, & DISINFECTANTS.

(*A*.)—FOODS.

Butter-Fat; Interdependence of the Physical and Chemical Criteria in the Analysis of ——. T. E. Thorpe. J. Chem. Soc., 1904, **85**, 248—256.

The general relations between the analytically important chemical and physical constants of butter-fat, as disclosed by a study of the average values of these constants determined on 357 samples of butter-fat of known origin, are set out in a number of curve diagrams showing the variation of (1) specific gravity, (2) saponification equivalent, (3) Zeiss refractometer value, (4) percentage of soluble fatty acids, (5) percentage of insoluble fatty acids, and (6) mean molecular weight of insoluble fatty acids—all with Reichert-Wollny value.—A. S.

French Patent.

Milk; Desiccation and preservation of ——. J. R. Hatmaker. First Addition, dated Oct. 2, 1903, to Fr. Pat. 324,913, Oct. 2, 1902. (See this J., 1903, 645.)

In order to preserve the casein unchanged by desiccation, sodium phosphate is added to the milk, and, in order to preserve the fat unchanged, caustic soda is added. For 100 litres of separated milk 315 grms. of crystallised sodium phosphate are added, and, for 100 litres of full-cream milk, 16 grms. of caustic soda are employed. Sugar, farinaceous matter, and other matters unaffected by the heat of the drying process may be added to the milk if desired.
—J. F. B.

(*B*.)—SANITATION; WATER PURIFICATION.

English Patents.

Distillers' Wash or Dregs and other noxious Organic Effluents; Process of treating ——. R. Anderson, Edinburgh. Eng. Pat. 7658, April 2, 1903.

Finely ground sphagnum moss and calcium sulphate are added to the crude effluent, which is then filtered or allowed to settle. By preference a succession of filter-beds made up of sphagnum moss and calcium sulphate, is employed. In the case of brewers' dregs, the comparatively clear filtrate is again treated with sphagnum moss and calcium sulphate and then neutralised by the addition of sodium hydroxide. The precipitate is allowed to settle.—W. P. S.

Sewage Sludge and like matters; Treatment of ——. H. Spence and P. Spence and Sons, Ltd., Manchester. Eng. Pat. 8348, April 11, 1903.

When sewage sludge is precipitated by ferric or aluminic compounds and curdled by heat (Eng. Pat. 12,124 of 1900; this J., 1901, 830), the fatty matters subsequently extracted from the dried sludge are liable to contain iron and alumina in combination. This is prevented by treating the precipitated sludge with a limited proportion of a mineral acid, heating the treated sludge, and removing the liquor before extracting the fatty matters.—J. F. B.

French Patent.

Water and Sewage; Purification of ——. F. Jean. Fr. Pat. 335,979, Oct. 15, 1903.

Ferrous and manganous oxides are added to the water or sewage, and then oxidised by aeration or oxidising agents. The precipitate formed, carries down with it the organic impurities present in the water.—W. P. S.

(*C*.)—DISINFECTANTS.

English Patent.

Soaps developing active oxygen and having an antiseptic and bleaching effect; Manufacture of non-caustic ——. H. Giessler and H. Bauer. Eng. Pat. 22,580, Oct. 19, 1903. XII., page 327.

French Patent.

Sulphur Baths; Preparation of a Substance suitable for Preparing ——. W. Matzka. Fr. Pat. 336,278, Oct. 28, 1903.

See Eng. Pat. 20,548 of 1903; this J., 1903, 1306.—T. F. B.

XIX.—PAPER, PASTEBOARD, Etc.

Paper Machine; Cleaning the wire cloth of the ——. Wochenbl. f. Papierfabl., 1904, **35**, 538.

The following method is recommended for cleaning the wire cloth of the paper machine:—A dilute solution of caustic soda is sprayed along one of the lower guide rolls of the wire; the upper couch roll having been removed, the wire is run round two or three times, whereby the caustic soda is distributed to all parts of the wire as it passes the roll on which the solution is being sprayed. The water sprays are then opened in order to remove the excess of soda remaining on the wire before the couch roll is replaced. By this treatment all the particles of slime and dirt which are so difficult to remove by ordinary means, are either dislodged or so loosened as to be readily removable by means of a wire brush.—J. F. B.

Paper; Resistance of —— *to Moisture.* Winkler. Papier-Zeit., 1904, **29**, 675.

In testing the suitability of papers for covering cartridges or for electrical insulation, the relative resistance to absorptio

No.	Sort of Paper.	Composition.	Grms. per Sq. Metre.	Increase of Weight.	Sizing.
				Per Cent.	
1	Wrapping paper I	Pine wood cellulose, a little rag pulp	125	13·1	Hard.
2	„ „ II.	Rags, a little pine wood cellulose, and jute	103	14·1	Moderately hard.
3	„ „ III.	Cotton, mechanical wood, a little wood cellulose, and jute	111	12·8	Soft.
4	Filter paper	Cotton	75	10·2	Unsized.
5	Cellulose wrapping paper	Pine-wood cellulose	105	12·0	„
6	Printing paper (news)	Mechanical wood, 80 per cent., pine cellulose 20 per cent.	74	9·2	Soft.
7	Normal deed paper	Linen and cotton	86	9·7	Very hard.
8	Wrapping paper IV.	Pine-wood cellulose, a little mechanical ordinary leafed wood and pine-wood	105	11·4	Hard.

f moisture was determined. The papers were placed in a oistened atmosphere, with a humidity of 90 per cent. t 20° C. for 96 hours, and the increase of weight was etermined, with the results shown in the following table. he results of these tests were apparently unaffected by e sizing, but depended on the composition, and the egree of beating. Other tests were made with the wrapping apers by floating them on the surface of water for three inutes and removing the excess by blotting-paper. No. 1 bsorbed 30 per cent.; No. 2, 45 per cent.; No. 3, 76 per ent.; and No. 8 only 22 per cent. of water; this test epends on the sizing. "Wet beaten" papers, such as nitation parchment, always contain a high proportion of oisture; at normal humidity (65 per cent.) such papers ontain 19 per cent. of moisture, as against 7—8 per cent. ith other varieties. In an atmosphere at 90 per cent. umidity they may contain as much as 20 per cent. of oisture.—J. F. B.

Cellulose Nitrate; Unstable ——. E. Knecht.

Ber., 1904, **37**, 549—552.

Vhen pure cotton is immersed in nitric acid of sp. gr. ·415, it assumes gelatinous appearance, which disappears n washing and drying; the cotton has then a normal ppearance, but has shrunk about 13 per cent. in length, is ronger, contains more moisture, and shows greater affinity r certain dyestuffs than ordinary cotton—*i.e.*, it exhibits e properties of mercerised cotton in a modified degree. If, ter treatment with nitric acid, the cotton be pressed and ried over lime *in vacuo*, a product is obtained which fumes damp air, and which gives, on treatment with water, itric acid and a cellulose hydrate. When heated to 100° C. a partial vacuum, nitrous fumes are evolved, and a roduct is obtained which is most probably identical with e oxycellulose obtained by treating cellulose with excess f nitric acid.

The appended table shows the amounts of nitric acid of arious strengths combining with cellulose, and the contrac- on produced.

Specific Gravity of Nitric Acid.	Nitric Acid Combined.	Shrinkage.
	Per Cent.	Per Cent.
1·1	3·0	1·0
1·3	3·8	1·0
1·325	7·1	1·0
1·375	7·5	1·0
1·38	10·8	2·5
1·4	27·3	10·0
1·415	35·8	13·0

Treatment with nitric acid of higher sp. gr. than 1·415 esults in the formation of nitrocellulose. The product is robably cellulose nitrate, $C_6H_{10}O_5$, HNO_3, possibly—

$$CH_2(CHOH)_4.C(O.NO_2)(OH),$$

hich requires 37·2 per cent. of nitric acid, the deficiency ound being due to the instability of the product.—T. F. B.

Celluloid; Solubility of ——. H. Flemming.

Chem.-Zeit., 1904, **28**, 213—214.

experiments with nitrated paper the author found that ly about 2 per cent. was dissolved by hot amyl acetate, hilst dichlorhydrin dissolved 10 times as much. In the tter case a clear solution was readily obtained on warm- g, but a solution containing 19 grms. of the nitrocellu- se in 50 grms. of solvent underwent some decomposition hen heated, giving off nitrous fumes and becoming more quid. The solution could be diluted with alcohol. A milar partial denitrification of celluloid was observed. hen finely-cut pieces of celluloid were warmed with 0 grms. of dichlorhydrin, solution readily occurred at 0° C. When 9 grms. of celluloid were present (tempera- re 140° C.) red fumes were evolved, which increased til 27 grms. had been added, and subsequently decreased. the concentration of the solution increased, the colour came darker, but the temperature should be kept below boiling point of dichlorhydrin (176° C.). A concen- ted solution (100 grms. in 100 grms.) solidified instantly on the addition of amyl acetate, benzene, or epichlorhydrin, and was readily miscible with linseed oil fatty acids. The addition of alcohol to the solution caused a separation of the celluloid.—C. A. M.

English Patents.

Paper for manifolding copying processes; Method of preparing —— *and printing surfaces therefrom with self-contained ink or colour supply.* W. H. Hutchinson, Shanklin. Eng. Pat. 24,532, Nov. 8, 1902.

Soft-sized paper is impregnated with melted fat, *e.g.*, with a mixture of stearic and oleic acids and paraffin wax. The excess of fat is removed by means of heated rollers at a temperature of 200°—250° F. to such an extent that the paper will not grease off at lower temperatures than that of the rolls. This treated paper is placed on a moderately soft surface, and the desired writing or design is impressed thereon with a pen, style, or die, in such a way that it stands up on the back of the paper in distinct ridges, without perforation of the paper. A special ink composed of glycerin, alcohol, and aniline dyestuff, is spread upon the positive side of the paper, which is then reversed on an inking pad. When the negative side of the paper is treated with an "inducting fluid," composed essentially of alcohol, the ink is enabled to penetrate through the paper only in those places which have been compressed by the pen; these penetrable places, standing in high relief, constitute the printing surface for taking manifold copies.

—J. F. B.

Paper and Pulp Machines; Impts. in ——. S. Milne, Edinburgh. Eng. Pat. 2420, Feb. 2, 1903.

In machines working on the principle of the cylinder paper-making machine, the endless wire sieve, instead of being carried on the walls of a cylinder revolving in a vat, is caused to dip obliquely or vertically into the vat and out on the other side. The wire in the vat is guided by a number of rolls, carried by end-pieces which make a watertight connection between the edges of the wire and the walls of the vat. In this way the wire makes a central compartment inside the vat, the pulp being outside, and the waste water inside this compartment. The pulp is caused to adhere to the wire, either by a difference of level between the liquid outside and that inside the wire, or by pumping off the water from the inside by suction boxes applied at a certain point.—J. F. B.

"Carton Pierre" [Decorative Moulding]; Preparation of ——. E. G. Jackson, London. Eng. Pat. 6703, March 23, 1903.

"Carton pierre" is prepared, in a liquid condition, by mixing 1 part of pulped paper, 2 parts of glue, 20 parts of water, 10 parts of whiting, and 10 parts of boiled plaster of Paris together, and adding to the mixture 0·05 part of sulphuric acid immediately before it is introduced into the moulds. Such a composition sets readily without shrinkage, and takes the pattern more sharply than the usual plastic composition.—J. F. B.

French Patent.

Paper and Cardboard; Process of Sizing ——. F. Dobler. Fr. Pat. 328,178, Dec. 19, 1902.

The paper is soaked in a solution or emulsion containing rosin soap, to which animal size may be added if desired. The rosin is then precipitated in the sheet of paper by treating the latter with a solution of alum, which at the same time has an astringent action on the gelatin, the sized paper being subsequently dried.—J. F. B.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

Bismutho-protocatechuic Acid. P. Thibault. Bull. Soc. Chim., 1904, **31**, 176—178.

The author has prepared this compound by the interaction of anhydrous or hydrated bismuth oxide and protocatechuic acid in water. It is a microcrystalline powder, formula $C_7H_5O_5Bi$, the bismuth being attached to the phenolic hydroxyls. The sodium, potassium, and ammonium salts and the anilide were prepared and analysed.—F. S.

Papaverinium Bases. H. Decker and O. Klauser. Ber., 1904, **37**, 520—531.

The authors discuss the constitution of the papaverinium bases and their decomposition products, and describe the formation of the *N*-methyl, *N*-ethyl, and *N*-benzyl derivatives of *iso*-papaverine, a base isomeric with papaverine, and of 6.7-dimethoxy- and 6·7-dihydroxy-2-benzyl-1-*iso*-quinolone, oxidation products of *N*-benzyl-*iso*-papaverine. —A. S.

Terpenes and Essential Oils. **65.** O. Wallach. Annalen, 1904, **331**, 318—333.

In the present communication the author describes the properties of *campherphorone*, an isomer of pulegenone; its decomposition by water in presence of alkali into acetone and 1.2-methylcyclopentanone; and a comparison of campherphorone and pulegenone with other cyclic ketones, both saturated and unsaturated.—A. S.

Camphor Synthesis. Schindelmeiser. J. Soc. Phys. Chim. Russ., 1903, 954. Chem. and Druggist, 1904, **64**, 379.

The author finds that the most favourable temperature for the production of borneol by the action of oxalic acid on pinene (see this J., 1904, 75, 266) is 110° C., and that the greatest yield obtainable is 70 grms. of borneol from 350 grms. of pinene. He points out that this small yield, apart from further loss in converting the borneol into camphor, is against the remunerative production of synthetic camphor. Moreover, borneol can be obtained more economically from the oil of *Abies siberica* (see this J., 1903, 879), which contains from 36 to 50 per cent. of bornyl acetate.—A. S.

Rare Earths; Contribution to the knowledge of the ——. W. Biltz. XXIV., page 341.

Acetanilide; Two New Reactions of [Distinction from Phenacetin] ——. E. Barral. XXIII., page 339.

Phenacetin; New Colour Reactions of ——. E. Barral. XXIII., page 339.

Cinchona Succirubra; De Vrij's Liquid Extract of, Determination of Cinchotannates in ——. J. Warin. XXIII., page 341.

English Patent.

Cream of Tartar; Manufacture of ——. U. Roux, Malaga, Spain. Eng. Pat. 7363, March 30, 1903.

See Fr. Pat. 328,713 of 1903; this J., 1903, 1011.—T. F. B.

United States Patents.

Organic Acid Compounds [Anhydrides]; Process of Making ——. W. Bauml, Assignor to Badische Anilin und Soda Fabr., Ludwigshafen. U.S. Pat. 752,947, Feb. 23, 1904.

See Eng. Pat. 24,255 of 1902; this J., 1903, 1147.—T. F. B.

[Adrenalin] Glandular Extractive Compound. J. Takamine, New York. U.S. Pat. 753,177, Feb. 23, 1904.

The compounds claimed are the salts of the extract of the suprarenal glands ("adrenalin," "suprarenin," "epinephrin," this J., 1901, 746, 1903, 818, and 1904, 213) with halogen acids, which are stable in aqueous solution, and possess all the physiological and therapeutic properties of the uncombined extract.—T. F. B.

French Patent.

Pinene Hydrochloride; Production of Pure ——. Chem. Fabr. Uerdingen, Lienau and Co. Addition, dated Dec. 19, 1902, to Fr. Pat. 328,009, June 27, 1902. See this J., 1903, 1101.

Concentrated sulphuric acid, while resinifying the impurities associated with pinene hydrochloride, does not materially decompose or dissolve the hydrochloride itself, even at fairly high temperatures. The crude hydrochloride may, therefore, be agitated with an equal volume of concentrated sulphuric acid, and the product cooled by ice and distilled with steam. Or the impurities may be removed as far as possible by saponification, as in the principal patent, and the product treated with concentrated sulphuric acid in a centrifugal separator, and the hydrochloride purified by sublimation.—T. F. B.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Development and Fixing; Combined ——. T. T. Baker. Phot. J., 1904, 1—6.

Although Lumière and Seyewetz have found that traces of thiosulphate in the developer give rise to "dichroic fog" (this J., 1903, 759), it appears that, by the use of a suitable solution, plates may be developed and fixed simultaneously, giving a negative quite free from "dichroic fog," even when 25 per cent. of thiosulphate is present. Although development is more rapid at first, the whole time required for development is considerably increased, and to obtain a negative of good density it is essential that the image shall appear very rapidly, as otherwise fixation will proceed too rapidly. The developer used must be one which, when used in the usual way, has very little tendency to fog, and must contain alkali hydroxide; "edinol" and quinol (hydroquinone) were found to give the best results. The following is a typical example of the combined solution:—Edinol, 2 grms; potassium metabisulphite, 3 grms.; sodium sulphite, 10 grms.; sodium carbonate, 20 grms.; sodium hydroxide, 1 grms.; thiosulphate 40—50 grms.; water, 200 c.c.; the addition of small quantities of bromide was found to give negatives of increased contrasts with the solution mentioned, whilst the exposure necessary is less than that required when an ordinary developer is used.—T. F. B.

Carbon Tissue; Sensitising ——. H. W. Bennett. Phot. J., 1904, **44**, 7—9.

The sensitising solution used consists of potassium bichromate, 4 parts; citric acid, 1 part; water, 200 parts; and "ammonia," about 3 parts; the amount of ammonia may vary with different tissues. Papers prepared in this way require about 50 per cent. longer for printing than the ordinary tissues.—T. F. B.

Silver Halides; Photo-chemical Behaviour of Unemulsified ——. K. Schaum and W. Braun. Zeits. wiss. Phot through Phot. J., 1904, **44**, 13.

An image which can be developed is formed by the action o light on silver bromide, precipitated from dilute solutions the plates are also susceptible to "ripening" to a certai extent, the gradation being increased considerably thereby "Solarisation" is clearly marked. Röntgen rays affec silver halides directly, and not owing to the fluorescenc of the support, and "solarisation" was observed afte 80 minutes exposure.—T. F. B.

Pyrogallol Developer; Properties of the ——, *and a caus of the production of "Fog."* W. Vaubel. Chem.-Zeit 1904, **28**, 213, 232—234.

The rate of absorption of oxygen by alkaline pyrogallol greatest when sodium hydroxide solution of about 3 pe cent. strength is employed. The amount of oxygen al sorbed is greatest (3—3½ atoms of oxygen per mol.

yrogallol) with a concentration of alkali of from 0·5 to ·3 per cent. With a higher concentration of alkali, the mount of oxygen absorbed, decreases. The oxidation roducts formed vary according to the nature and concen ation of the alkali. Among them are hexahydroxydihenyl (see Harries. Ber., 1902, **35**, 2954), the compounds $C_4H_4O_3)_n$ and $C_{20}H_{20}O_{16}$ (see Berthelot, this J., 1898, 603, nd Comptes rend., 1898, **126**, 1459), and a compound, ${}_{20}H_{15}O_7(OH)_3$ isolated by the author. The production f "fog" on photographs which have been treated with a yrogallol developer is in most cases due to the formation f larger or smaller amounts of oxidation products of yrogallol insoluble in alkali, but can be completely or lmost completely prevented by the addition of sodium ulphite to the developer.—A. S.

English Patents.

ellulose Acetate [for Photographic Films, &c.]: Manufacture of ——. H. E. Newton, London. From Farbenfabr. vorm. F. Bayer & Co., Elberfeld. Eng. Pat. 7346, March 30, 1903.

ee Addition of Jan. 30, 1903, to Fr. Pat. 317,007 of 1901; is J., 1903, 1015.—T. F. B.

ollodion Emulsions; Method for the Preparation of Durable —— for all Colour Rays of the Spectrum, suitable for the production of Negatives for half-tone in natural colours. F. Nusch, London. From the Franklin Tarsulat, Budapest. Eng. Pat. 14,073, June 24, 1903.

ollodion emulsions are treated with di-iodofluorescein, c., or with "sensitive salts or solutions." The emulsions hus prepared may be treated with suitable dyestuffs (free rom silver) to increase their sensitiveness for particular ays.—T. F. B.

richromatic Photography. B. Jumeaux and W. N. L. Davidson, Brighton. Eng. Pat. 3730, Feb. 17, 1903.

hree negatives are prepared as usual by using red, blue, nd green light filters. A silver chloride print (or transarency) is prepared from the negative taken through he red screen, and is toned blue; thin films of bichroated gelatin are exposed under the other two negatives, nd immersed in dilute acid. The film from the negative aken through the green screen is now stained red and uperimposed on the blue print already made, and that rom the negative taken through the blue screen is stained ellow and superimposed on the red film, and the whole astened together.—T. F. B.

hotographs and Photo-Mechanical Prints: Process and Apparatus for the Production of Coloured ——. A. A. Gurtner, Berne. Eng. Pat. 7924, April 6, 1903.

ee U.S. Pat. 730,454 of 1903; this J., 1903, 820.—T. F. B.

hotographic Printing Paper or the like; Process for Preparing ——. I. Hoffsümmer, Düren, Germany. Eng. Pat. 25,390, Nov. 21, 1903.

rior to being coated with the emulsion, paper is treated ith "zapone" or similar substance, *i.e.*, a solution of elluloid in amyl alcohol, amyl acetate, acetone, &c.; it is aid that the emulsion is not absorbed by paper thus repared, but adheres strongly to it.—T. F. B.

United States Patents.

yestuff; Sensitising —— [for Photographic purposes]. R. Berendes, Elberfeld, Assignor to Farbenfabr. of Elberfeld Co., New York. U.S. Pat. 752,323, Feb. 16, 1904.

y treating with sodium hydroxide the compound obtained y the action of diethyl sulphate on quinaldine, a dye-stuff obtained which is soluble in water, alcohol, and chlororm, giving a violet solution, and which has the property of imparting greater sensitiveness to photographic emulsions for "distinct colours of the spectrum."—T. F. B.

Photographic Emulsion; Sensitive ——. A. Eichengrün, Elberfeld, and A. Braun, Mülhausen, Assignors to Farbenfabr. of Elberfeld Co., New York. U.S. Pat. 752,388, Feb. 16, 1904.

See Fr. Pat. 326,468 of 1902; this J., 1903, 820.—T. F. B.

French Patent.

Photographic Emulsions; Process for "Optically Sensitising" ——, by means of Dyestuffs. Soc. Anon. Prod. F. Bayer et Cie. Fr. Pat. 336,298, Oct. 29, 1903.

Emulsions suitable for the preparation of panchromatic plates, films, and papers are prepared by emulsifying with collodion, gelatin, &c., freshly precipitated silver halides which have been previously stained by means of a solution of a suitable dyestuff. For instance, silver bromide is stained by a five minutes immersion in a 0·01 per cent. solution of Erythrosin, washed until the washings are colourless, and emulsified with a 4 per cent. gelatin solution in the usual manner.—T. F. B.

XXII.—EXPLOSIVES, MATCHES, Etc.

Paper [for Cartridges]; Resistance of —— to Moisture. Winkler. XIX., page 334.

English Patents.

Nitroglycerin; Manufacture of ——. F. L. Nathan, J. M. Thomson, and W. Rintoul, Waltham Abbey, Essex. Eng. Pat. 3020, Feb. 9, 1903.

The object of the invention is to prevent the formation and separation of nitroglycerin in the waste acids after the nitroglycerin initially formed in the nitrating vessel has been separated and removed. It has been found that if a relatively small quantity of water be added to the waste acid, all further separation of nitroglycerin is prevented, and the strength of the waste acids is so slightly reduced that their separation and re-concentration are not affected. "After-separation" is thus done away with, and the nitroglycerin plant simplified and its output increased. The operation may be carried out in the apparatus described in Eng. Pat. 15,983 of 1901 (this J., 1902, 927). After nitration, separation is commenced at a temperature such that when all the displacing acid has been added, and the separation of the nitroglycerin is complete the temperature of the contents of the nitrating vessel shall not be lower than 15° C. A sufficient quantity of displacing acid is then run off through the waste-acid cock, to allow of the remaining acids being air-stirred without splashing over the top. A small quantity of water (from 2 per cent. to 5 per cent., according to strength of acid and temperature) is now slowly added through the separation cylinder, and the contents of the nitrator are air-stirred, but not cooled, the temperature being allowed to rise slowly and regularly as the water is added—usually about 3° C. for each per cent. of water added. When air-agitation has been stopped, the acids are kept at rest for a short time, in order to allow of any small quantity of initially formed nitroglycerin adhering to the coils and sides of the vessel rising to the top. When this has been separated by displacement, the acids are ready for denitration, or can be safely stored without further precaution.
—G. W. McD.

Guncotton; Manufacture of ——. J. Selwig, Brunswick. Eng. Pat. 6409, March 19, 1903.

See Fr. Pat. 327,803 of 1902; this J., 1903, 963.—T. F. B.

Explosives. J. Wetter, London. From Westfälisch-Anhalt. Sprengstoff Act.-Ges., Berlin. Eng. Pat. 8898, April 2, 1903.

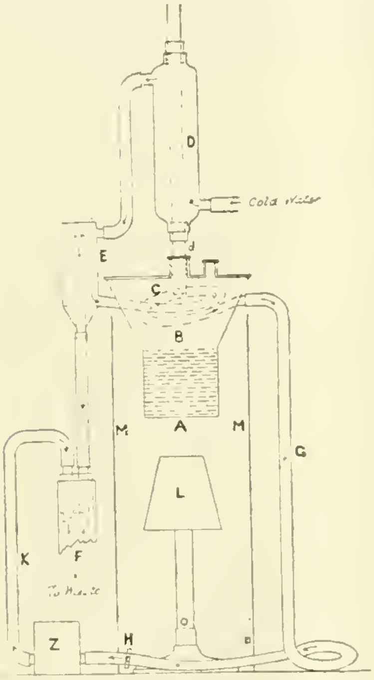
See Fr. Pat. 329,031 of 1903; this J., 1903, 1015—T. F. B.

XXIII.—ANALYTICAL CHEMISTRY.

APPARATUS, ETC.

Thermostat for Use in connection with the Refractometric Examination of Oils and Fats; Simple ——. T. E. Thorpe. J. Chem. Soc. 1904, **85**, 257—259.

In examining oils and fats in the Zeiss butyro-refractometer, it is generally necessary to allow a current of water of constant temperature to flow through the apparatus for some little time before making the readings. By means of the device shown in the figure, it has been found possible to secure a steady current of water not varying more than about 0·1° C. in temperature throughout the day. In the figure, A is a metallic cylindrical vessel, 5 cm. in diameter and 5 cm deep, containing about 100 c.c. of water, &c., for generating the heating vapour. B is a conical vapour chamber in which is suspended the coil C of copper or "compo." tubing, 25—30 cm. long, and with an internal diameter of about 3 mm. The cover of C has a diameter of 10 cm. D is a reflux condenser. E is an arrangement for maintaining a constant head of water at the point of entrance to the coil, so as to reduce variations in the pressure of the current of water. F is a stout glass tube acting as a "tell-tale" to indicate whether or not the overflow and the current of water through the instrument Z are running properly. G and K are pieces of thick-walled caoutchouc tubing, H a screw-clamp for regulating the flow of water, and M a metal cylinder to reduce loss of heat by radiation from the walls of the vapour generator.—A. S.



INORGANIC—QUANTITATIVE.

Sulphuric Acid; Determination of ——. R. Silberberger. Monatsh. Chem., 1904, **25**, 220—248.

The inaccurate results obtained in the determination of sulphuric acid as barium sulphate, in the presence of iron, chromium, aluminium, and potassium salts, are stated to be due to the co-precipitation of complex barium salts. Sulphuric acid in the presence of iron, aluminium, and chromium can, however, be accurately determined by precipitation with strontium chloride in alcoholic solution, and the method is especially suitable for the rapid determination of the sulphur in pyrites. About 0·5 grm. of the pyrites is decomposed by 20 c.c. of *aqua regia*, evaporated several times with hydrochloric acid, the residue treated with hot hydrochloric acid and filtered. In the filtrate the sulphuric acid is precipitated by alcoholic strontium chloride solution and 100 c.c. of alcohol are added. The precipitate is digested at a moderate heat for 1 hour, allowed to settle in the cold, and the clear solution poured off through a filter. The precipitate is stirred with 2 c.c. of hydrochloric acid (2:1) and 50 c.c. of alcohol, allowed to settle, the clear solution again poured off, and the precipitate washed with alcohol, three times by decantation, and finally on the filter. The precipitate filters well and is free from chlorine. The results are concordant and are 0·89 per cent. higher than those obtained by Lunge's method and 0·53 higher than those obtained by Küster's method (Zeits. anorg. Chem. **19**, 100).—A. S.

Arsenic; Rapid determination of —— *in Sulphuric and Hydrochloric Acids.* N. G. Blattner and J. Brasseur. Chem.-Zeit., 1904, **28**, 211.

The method is based on the conversion of the arsenic into arsenic tri-iodide, as in Seybel and Wikander's qualitative method (Chem.-Zeit., 1902, **26**, 50)—

$$As_2O_3 + 6HCl + 6KI = 2AsI_3 + 6KCl + 3H_2O \text{ or}$$
$$As_2O_5 + 10HCl + 10KI = 2AsI_5 + 10KCl + 5H_2O \text{ and}$$
$$AsI_5 = AsI_3 + I_2.$$

The arsenic tri-iodide is nearly insoluble in hydrochloric acid or sulphuric acid, and is filtered off through cotton wool or glass wool, and converted into arsenious acid $2AsI_3 + 3H_2O = As_2O_3 + 6HI$. The arsenious acid is neutralised with sodium bicarbonate and the resulting sodium arsenite titrated with a standard solution of iodine.

Hydrochloric Acid.—50 c.c. of the acid, preferably of 20° to 22° B. (if necessary strengthened with pure sulphuric acid) are mixed with constant stirring with 5 c.c. of a 30 per cent. solution of potassium iodide, and the liquid filtered after one minute through a Soxhlet's tube containing cotton-wool or glass-wool, the beaker being washed out with a few c.c. of pure strong hydrochloric acid containing 10 per cent. of the potassium iodide solution. The precipitate is then dissolved off the filter by water, and the aqueous solution rendered slightly alkaline with pure sodium bicarbonate and titrated with N/10 iodine solution. Twice the number of c.c. used, multiplied by 0·00375 and divided by the specific gravity of the acid, gives the percentage of arsenic.

Sulphuric Acid.—In this case the concentration of the acid should be about 45° B. With a strength above 50° B. some iodine is liberated from the potassium iodide, whilst an acid below 45 B. dissolves some of the arsenic tri-iodide. The disturbing effect of chlorine on the reaction, as also of ferric chloride, or selenium in hydrochloric or sulphuric acid is prevented by the addition of a few drops of a concentrated solution of stannous chloride. Although arsenic is also precipitated by stannous chloride the reaction does not take place for some time. Lead in sulphuric acid also gives a precipitate with potassium iodide, but the addition of sufficient strong hydrochloric acid prevents the precipitation of lead or tin. In the determination, 25 c.c. of the sulphuric acid (brought to about 45° B.) are mixed with 25 c.c. of pure hydrochloric acid, and treated with potassium iodide solution as described above. Four times the number of c.c. of iodine solution used multiplied by 0·00375 and divided by the specific gravity of the acid gives the percentage of arsenic in this acid of 45 B. The whole determination can be made in about 10 minutes, and is stated to give very accurate results with acids containing as little as 0·001 per cent. of arsenic. When the amount exceeds 0·2 per cent. a smaller amount of acid should be taken for the test and made up to 50 c.c. with pure concentrated hydrochloric acid.—C. A. M.

Arsenic and Antimony in Nickel Speiss; Determination of ——. H. Nissenson and A. Mittasch. Chem.-Zeit., 1904, **28**, 184—186.

The following modification of the Györy method (for determining antimony in lead) is recommended (see this J., 1903, 967): 0·5 grm. of the substance is digested at 300°—400° C. with 8 c.c. of concentrated sulphuric acid until the mass is nearly or quite white. After cooling it is heated to boiling with a little water, to dissolve any basic salts, and treated with sulphuretted hydrogen to throw down arsenic, antimony, and copper. The precipitate is filtered and washed with a little acidified sulphuretted hydrogen water, after which it is heated with 7 c.c. of concentrated sulphuric acid to dissolve the sulphur compounds. The cooled solution is made up to about 100 c.c. with water, strongly heated and titrated with decinormal potassium bromate, in presence of three drops of a sulphuric acid solution of indigo as indicator, preferably added towards the end of the operation. To separate the arsenic and antimony the solution is treated with an excess of potassium bromate, a portion is then evaporated, treated with ½—1 grm. of tartaric acid when cold, then rendered alkaline with ammonia and treated with 30 c.c. of magnesia mixture. After standing several hours the precipitate is filtered off, washed with a little ammoniacal water, the filtrate concentrated, acidified with sulphuric acid, and the antimony and copper precipitated with sulphuretted hydrogen. Finally, the treatment with sulphuric acid and titration with potassium bromate are repeated, the arsenic being estimated by difference.—C. S.

Gold; Electrolytic Analysis of ——. F. M. Perkin and W. C. Prebble. Paper read before the Faraday Soc. Electro-Chemist and Metall., 1904, **3**, 490—494.

The authors propose the use of ammonium thiocyanate in place of the potassium cyanide which is generally recommended. With a current density of 0·2 ampère per q. dcm. the deposition of 0·05 to 0·08 grm. of gold is omplete in five to six hours in the cold, and with 0·4 to 0·5 ampère in 1½ to 2 hours. The solutions employed ontained 5 grms. of ammonium thiocyanate in 120 to 50 c.c., the gold chloride solution which was used for the ests being added in measured volume. The deposit of gold is redissolved from the platinum by use of potassium yanide and an oxidising agent, *e.g.*, hydrogen peroxide. The completion of deposition is judged by testing a sample f the electrolyte with stannous chloride after the thioyanate has been decomposed with sulphuric acid. For most of the determinations the gauze flag electrodes esigned by one of the authors (this J., 1903, 1064) were employed; a suitable form of stand for platinum asins, as also a heating bath to keep the temperature onstant at from 55° to 60° C., are described.—R. S. H.

Alumina [in Metallurgical Products]; Method for the direct determination of ——. C. E. Rueger. Eng. and Mining J., 1904, **77**, 357.

The following modification of a method proposed many ears ago by Wöhler, based on the precipitation of alumina om a slightly acid solution by sulphur dioxide, is stated to e sufficiently accurate for technical purposes. The precipitate of aluminium and iron hydroxides obtained in the usual manner is washed, dissolved in hydrochloric acid, the solution nearly neutralised with sodium carbonate, and sodium sulphite added till a precipitate begins to form. The precipitate is redissolved in a slight excess of hydrochloric acid, and the solution boiled vigorously till all the sulphur dioxide is expelled. The precipitated alumina is stated to be compact and granular; it is filtered off, washed, redissolved in hydrochloric acid, and precipitated again in the same manner as before. The precipitate is finally ignited and weighed as alumina. The results are stated to be accurate within 0·3 per cent. Zinc, manganese, nickel, and copper have no influence on the results, but the latter are affected by the presence of titanium, phosphorus, lead, arsenic, and antimony.—A. S.

ORGANIC—QUALITATIVE.

Edible Fats; Analysis of ——, *particularly the Detection of Cocoa-nut Oil in Butter and Lard.* A. Juckenack and R. Pasternack. Zeits. Untersuch. Nahr. Genussmittel, 1904, **7**, 193—214.

The author shows that on subtracting 200 from the saponification value and further subtracting the result from the Reichert-Meissl value, a figure is obtained which, in the case of pure butter, varies from − 4·14 to − 3·39, whilst with cocoanut oil the figure lies between − 47·0 and − 50·7. Again, the mean molecular weight of the volatile, water-soluble fatty acids of butter is stated to be from 95·0 to 99·0, and that of the non-volatile insoluble fatty acids is from 259·5 to 261·0. The volatile soluble fatty acids of cocoanut oil have a mean molecular weight of 130·0 to 145·0, and the non-volatile insoluble acids 208·5 to 210·5. The phytosteryl acetate test affords the most certain means of detecting cocoanut oil, or other vegetable oil, in butter and lard. The melting point of the acetate after the fifth re-crystallisation never exceeds 115° C., if vegetable oils be absent. When the melting point is 117° C. or higher, vegetable oil is certainly present. In the determination of the Reichert-Meissl value of cocoanut oil only about 37 per cent. of the total volatile fatty acids are found in the distillate, whilst in the case of butter, about 80 per cent. pass over during the distillation. If further successive quantities of water be added to the distillation flask and the boiling continued, distillates are obtained containing the remainder of the volatile acids. In the case of butter, the fifth distillate is practically free from volatile acids, but with cocoanut oil, even the eighth distillate still contains an appreciable quantity of volatile acids, requiring 0·45 c.c. of N/10 alkali for their neutralisation. The results of numerous analyses and experiments are given, and are summarised in the following table:—

Fat.	Reichert-Meissl Value (*a*).	Saponification Value (*b*).	"Difference" *a*−(*b*−200).	Butyro-Refractometer.	Phytosteryl-Acetate Test. M.P.	Mean Molecular Weight of Insoluble Fatty Acids.

Acetanilide; Two new Reactions of [Distinction of —— *from Phenacetin].* E. Barral. J. Pharm. Chim. 1904, **19**, 237.

Phosphomolybdic acid reagent, added to a solution of cetanilide, gives a bright yellow precipitate, soluble on warming. Phenacetin gives a similar precipitate which emains insoluble when heated.

Mandelin's reagent (1 grm. of ammonium vanadate in 00 grms. of sulphuric acid) gives a red colour, rapidly changing to greenish brown, with acetanilide. With phenacetin the colour at first is olive green in the cold, becoming reddish brown when warmed.—J. O. B.

Phenacetin; New Colour Reactions for ——. E. Barral. J. Pharm. Chim. 1904, **19**, 237—238.

Sodium persulphate produces a yellow colour when warmed with phenacetin; this deepens to orange on prolonged boiling.

Bromine water, when heated with a few crystals of phenacetin, colours them rose; the liquid becomes orange yellow, and, on cooling, a brown precipitate is gradually formed.

Millon's reagent (1 part of mercury treated with its own weight of strong nitric acid and heated to about 60° C. for solution. Two vols. of water are added, the liquid let stand, and the clear liquid decanted for use) heated with phenacetin gives a yellow colour passing to red; nitrous fumes are given off and a yellow precipitate is formed.
—J. O. B.

p-Nitrophenylhydrazine and p-Dinitrodibenzylhydrazine; Some Hydrazone Derivatives of —— [Detection of Acetone or of Wood Spirit in denatured Alcohol]. A. van Ekenstein and J. J. Blanksma. Zeits. Ver. deutsch. Zuckerind. 1904, 190—194.

p-Nitrophenylhydrazine can be utilised for the detection of wood spirit in denatured alcohol, in virtue of the acetone contained therein. A quantitative determination of acetone in alcohol is performed by mixing a solution of 5 c.c. of the spirit in 15 c.c. of water with a solution of 400 mgrms. of the hydrazine in 5 c.c. of 30 per cent. acetic acid. The *p*-nitrophenylhydrazone of the acetone, m. pt. 148° C., separates almost immediately, and after standing for 30 minutes, is collected on a tared filter, washed with a little 20 per cent. alcohol, and dried at 105° C. Any aldehyde originally present must first be destroyed by caustic potash. *Glucose* yields two isomeric *p*-nitrophenylhydrazones. One of these is obtained by heating 2 grms. of glucose in 30 c.c. of strong alcohol for 10 minutes on the water-bath with 2 grms. of the *p*-nitrophenylhydrazine. This hydrazone melts at 185° C., $[\alpha]_D = +21 \cdot 5°$; it is sparingly soluble in alcohol. The other is obtained at ordinary temperatures from a solution of 3 grms of glucose in a little water, 3 grms. of *p*-nitrophenylhydrazine and 30 c.c. of glacial acetic acid. It melts at 195° C., $[\alpha]_D = -128 \cdot 7$. Both these hydrazones yield the same osazone, m. pt. 257° C., $[\alpha]_D = -21 \cdot 1°$. In the same way *mannose* yields two hydrazones, m. pt. 190° C. and 202° C. respectively, the latter being produced in presence of acetic acid. The following sugars yield only one *p*-nitrophenylhydrazone respectively: *fructose*, m. pt. 176° C., $[\alpha]_D = +16°$ (osazone identical with that from glucose); *galactose*, m. pt. 192° C., $[\alpha]_D = +45 \cdot 6°$; *xylose*, m. pt. 156° C., readily soluble in alcohol; *rhamnose*, m. pt. 186° C., $[\alpha]_D + 21 \cdot 4°$; *arabinose*, m. pt. 168° C., $[\alpha]_D + 48 \cdot 3$; *maltose* and *milk sugar* do not react in alcoholic solution. The *p*-nitrophenylhydrazones are readily decomposed by heating with the calculated quantity of benzaldehyde, regenerating the sugars.—J. F. B.

ORGANIC—QUANTITATIVE.

Sugar; Analysis of ——. K. Abraham. Zeits. Ver. deutsch. Zucker-Ind., 1904, 187—188.

It is proposed that in the analysis of a white sugar the following determinations shall be made:—Moisture = W; ash = A; difference between the alkalinity of the sugar and alkalinity of the ash = D; organic non-sugar (empirical coefficient = 3) = 3D; invert sugar = I. The saccharose is then calculated as equal to 100—(W + A + 3D + I) and the result is said to be more accurate than by polarisation. Any raffinose which may be present is shown by the difference between the polarisation and the calculated percentage of saccharose.—J. F. B.

Sugar Analysis; Dry Defecation in optical ——. W. D. Horne. J. Amer. Chem. Soc., 1904, 26, 186—192.

In determining the polarisation of a raw sugar, an error is introduced, owing to the fact that a precipitate is formed by the lead subacetate added to the solution of the normal weight of sugar before making up to 100 c.c. In order to obviate this error, the author recommends defecating in such a way that the normal weight of sugar shall remain dissolved in 100 c.c. of the solution. This is done by making the solution of the normal weight up to 100 c.c. and then adding small quantities of powdered, anhydrous lead subacetate until the impurities are all precipitated. Some refinery solutions, notably such as have been subjected to the influence of bone-black, have a tendency to coat the grains of lead salt with insoluble adherent crusts and so prevent the solution of the interior portions; this difficulty may be overcome by adding coarse dry sand, with the lead salt, to the solution before shaking. Comparison of the numbers yielded by this method of working with those obtained by the old method and making allowance for the volume occupied by the lead precipitate, show that it gives good results.—T. H. P.

Nitrogenous Substances soluble in Water; Determination of —— in Barley and Malt. Guiness Research Lab. Trans., 1903, 1, 61—78.

Standard conditions have been determined under which the soluble nitrogenous matters may be extracted from barley and malt in such a way that the changes which take place in these substances during germination may be ascertained. In order to compensate for the changes in the weight of the grain which occur during malting, advantage is taken of the fact that the dry weight of 1,000 corns always represents an average sample for statistical purposes, whereby the altered grain can be referred to the original. In performing the actual extractions it was found that the time of digestion and the ratio of grain to water employed had a considerable influence on the results, owing in the one case to proteolysis and in the other to the influence of the concentration of mineral salts present on the solubility of certain proteids like the globulins. A standard concentration was therefore selected, whether in dealing with barley or malt, such that the total final volume (extract + residue) always represented the equivalent of 20 grms. of the dry original barley per 100 c.c. The volume of the mixture during the extraction proper was always taken at three-quarters of the total final volume, the deficit being adjusted at the end of the process. The finely ground sample was mixed with water in a flask in the proportions indicated, the flask was then agitated by mechanical means for a standard time of six hours; the volume was then adjusted and the extract filtered. The nitrogen was determined in the filtrate, direct and after the removal of the substances coagulated by boiling; the volume of the dried residue being then calculated from its weight and specific gravity, the results were all finally expressed in terms of the dry original barley. Preliminary determinations showed that, in the case of barley, a period

Solvent.	Percentage of Nitrogen Extracted in Six Hours from Dry Barley and its Equivalent Weight of Malt (concentration 20 grms. of Barley or its Malt Equivalent per 100 c.c.).			Nitrogen Extracted per Cent. of Total Amount present in Original Barley (Dry).		
	Total.	Coagulable.	Non-coagulable.	Total.	Coagulable.	Non-coagulable.
Barley.						
Water	0·251	0·090	0·161	14·7	5·3	9·4
5 per cent. salt solution ...	0·388	0·128	0·260	22·8	7·5	15·2
Malt.						
Water	0·523	0·142	0·381	30·7	8·3	22·4
5 per cent. salt solution...	0·669	0·212	0·457	39·3	12·5	26·8

of six hours was necessary for complete extraction of the soluble nitrogenous matters. When extraction was prolonged beyond 12 hours, a slight proteolytic action was observed, whereby the non-coagulable matters were increased at the expense of the insoluble proteids of the grain, the coagulable soluble proteids being unaffected. In the case of malt, extraction was probably complete in less than six hours; when it was further prolonged, a noticeable proteolysis occurred, just as in the case of the barley except that in this case the coagulable soluble proteids were attacked. The effect of doubling the proportion of water to grain was shown, in the case of barley, by a marked decrease in the quantity of nitrogenous matter extracted, whereas in the case of malt there was no difference. Extraction with a 5 per cent. solution of sodium chloride instead of water, caused a considerable increase in the quantity of nitrogenous matter dissolved. The addition of salicylic acid to the extraction mixture had no influence in restricting proteolysis during prolonged periods of extraction. In the foregoing table are shown the results obtained with a sample of good Wiltshire barley and the kiln-dried malt prepared from it. A few experiments with air-dried malt indicated that with such malt, proteolysis during extraction for prolonged periods was distinctly more active than with kiln-dried malt; it is, therefore, somewhat doubtful whether the standard period of six hours is perfectly safe in such cases.—J. F. B.

Cinchona Succirubra, De Vrij's Liquid Extract of ——; *Determination of Cinchotannates in* ——. J. Warin. J. Pharm. Chim., 1904, **19**, 233—236.

The author has previously shown (this J., 1903, 569) that evaporation *in vacuo* as prescribed by De Vrij for the preparation of the fluid extract of *cinchona succirubra* is unnecessary. Criticism is now directed to the method of De Vrij for determining the amount of alkaloïdal cinchotannates in the fluid extract and to the modification of that process at present official in the supplement to the Dutch Pharmacopœia, 1902. The latter reads as follows:—"10 grms. of the liquid extract are mixed with 2 grms. of sodium acetate and 10 c.c. of water. The reddish-brown precipitate is collected on a filter, washed with a little water, dried, and weighed." It is found, not only that this washing with water removes a notable amount of alkaloids, but that, even without washing, the whole of the alkaloids are not precipitated by the acetic acid set free in the process. When the precipitate was merely collected and dried without washing, the weight from 10 grms. of fluid extract was 1·03 grm., and the filtrate yielded 0·1473 grm. of alkaloids. Where the precipitate from the same amount of fluid extract was washed with 5 c.c. of water, its weight when dried was 0·990 grm., and the washings, collected apart, gave 0·062 grm. of alkaloids. A third similar quantity, precipitated as before, but the cinchotannates washed with 10 c.c. of water, gave only 0·825 grm., and the washings contained 0·0868 grm. of alkaloids. Increasing the amount of sodium acetate employed was not found to materially affect the results. The addition of 5 per cent. of acetic acid to the wash-water was tried, but this menstruum was found to remove more alkaloids than water alone. The method is therefore condemned, since more than 20 per cent. of the total alkaloids present are not precipitated, the washing with water removes yet more, and the results obtained have but little definite value. In valuing the fluid extract of cinchona, the determination of the total alkaloids, by precipitation as such, is preferable. If it be desired to determine the cinchotannic acid, this can be done in the ammoniacal mother-liquor, after shaking out the bases with ether, in the usual manner.—J. O. B.

XXIV.—SCIENTIFIC & TECHNICAL NOTES.

Rare Earths; Contribution to the Knowledge of the ——. W. Biltz. Annalen, 1904, **331**, 334—358.

The author describes the preparation and properties of the acetylacetonates of thorium, didymium, praseodymium, neodymium, samarium, cerium, lanthanum, and aluminium, and also experiments on their application to the determination of the valencies of thorium and the cerite earth metals, and of the atomic weight of thorium.—A. S.

Magnetic Oxide of Iron; Formation of —— *by heating Metallic Iron in a current of Carbon Dioxide.* J. Donau. Monatsh. Chem., 1904, **25**, 181—187.

By heating metallic iron in the form of very fine wire in a current of carbon dioxide, at 1100°—1200° C., protosesquioxide of iron is produced, identical in appearance, hardness, density, and magnetic properties with natural magnetite. The presence of a small amount of moisture in the carbon dioxide has a favourable effect on the crystalline condition of the oxide produced.—A. S.

Light; Chemical Action of ——. G. Ciamician and P. Silber. Phot. J., 1904, **44**, 12.

o-Nitrobenzaldehyde, in alcoholic, benzene, &c., solution, is converted by light into *o*-nitrosobenzoic acid. A colourless compound of the composition $C_9H_9O_3N$ was also obtained.
—T. F. B.

Aniline; Direct hydrogenation of ——. *Synthesis of Cyclohexylamine and of two other new Amines.* P. Sabatier and J. B. Senderens. Comptes rend., 1904, **138**, 457—460.

When the vapours of aniline, together with an excess of hydrogen, are passed over reduced nickel maintained at a temperature of about 190° C., a considerable absorption of the gas takes place, and a liquor with an ammoniacal odour is collected by condensation. This liquor contains cyclohexylamine, together with two other bases hitherto undescribed, dicyclohexylamine and cyclohexylaniline.

Cyclohexylamine, $C_6H_{11}NH_2$, is a very powerful base, boiling without decomposition at 134° C. It has an ammoniacal odour: its density, $0°/0° = 0·87$. It turns litmus blue, and absorbs carbon dioxide from the air with great avidity, forming a well crystallised carbonate; the hydrochloride melts at 206° C.

Dicyclohexylamine, $(C_6H_{11})_2NH$, is produced by the union of two molecules of cyclohexylamine with elimination of ammonia. It boils with slight decomposition at 250° C.; its density, $0°/0° = 0·936$. It is a fairly strong base, alkaline to litmus, and yields a crystalline carbonate which dissociates in presence of dry air. The hydrochloride is very sparingly soluble in ether. It is a secondary amine, possessing characters similar to those of the amines of the fatty series, and does not yield colour reactions with oxidising agents.

Cyclohexylaniline, $C_6H_5NH.C_6H_{11}$, results from the partial decomposition of dicyclohexylamine. It boils at 275° C. with considerable decomposition and formation of diphenylamine and hydrogen. It is only slightly soluble in water; its density $0°/0° = 1·016$; its hydrochloride crystallises in tufts of fine needles, which, when exposed to the air, turn grey, and finally green. It turns red litmus blue, but does not form a solid carbonate. Owing to the presence of a benzene nucleus this amine yields colour reactions analogous to those of diphenylamine.—J. F. B.

Dibenzalglucosides and Benzalmethylglucosides. A. van Ekenstein. Zeits. Ver. deutsch. Zuckerind., 1904, 188—190.

The sugars condense with benzaldehyde in exactly the same manner as with formaldehyde. Sugar, 2 parts, is treated with freshly distilled benzaldehyde, 3 parts; phosphorus pentoxide, 3 parts, is then added with continued stirring. After standing for half-an-hour, the product is diluted with ice-cold water, and the precipitate is dissolved in methyl alcohol. Only the pentoses yield well crystallised products, the hexoses giving uncrystallisable syrups. The constitution of the products is analogous to that of the corresponding formaldehyde derivatives. The carbonyl group having disappeared, the derivatives do not reduce Fehling's solution; they contain two benzal residues. The pentose derivatives contain no hydroxyl group, but the hexose derivatives still contain one free hydroxyl. *Dibenzalarabinose*, m. pt. 154° C., $[\alpha]_D = +27°$ (in methyl alcohol), *dibenzalxylose*, m. pt. 130° C., $[\alpha]_D = +37·5$,

and *dibenzalrhamnose*, m. pt. 128° C., $[\alpha]_D = +56°$ are described. The glucosides react with benzaldehyde far more readily than the sugars; derivatives are obtained by boiling the glucosides for a few hours with benzaldehyde in presence of a little aqueous sodium sulphate. The monobenzal derivatives of α and β-methylglucoside and of methylmannoside, and the dibenzal derivative of the last are well defined, crystalline, optically active products.
—J. F. B.

Mannamine: New Base derived from Mannose.
E. Roux. Comptes rend., 1904, **138**, 503—505.

When mannose-oxime is reduced by sodium amalgam according to the general method adopted for the preparation of glucamine (this J., 1901, 605, 817) a base exactly analogous to the latter is obtained, to which the name of *mannamine* is given. According to Maquenne's notation mannamine is amino-1-hexanepentol $^{4.5.}_{2.3.}.6$.

$$NH_2.CH_2[CH(OH)]_4CH_2OH$$

The mannose oxime is readily prepared from the crude syrup obtained by the hydrolysis of ivory nuts, and the mannamine is separated, after reduction of the oxime, in the form of the oxalate. Mannamine resembles glucamine very closely in its general properties. It occurs as a colourless crystalline mass, very soluble in water, and fairly soluble in alcohol; it melts at about 139° C., and possesses a caustic and sweet flavour. In 10 per cent. solution its rotatory power $[\alpha]_D = -2°$. It precipitates nickel sulphate and yields a white amorphous product with mercuric chloride, insoluble in excess of the base.—J. F. B.

New Books.

The Textile Technical Schools and Development of the Textile Industries: Germany. Foreign Office Miscellaneous Series, No. 602. Eyre and Spottiswoode. Price 5*d*.

List of schools giving instruction in textile manufactures. Plan of instruction of the course in textile industry at the Brunswick Technical University. Detailed descriptions of various schools established in Germany to provide instruction in dyeing, spinning, weaving, &c. Examination of the present extent and importance of German textile industries. Tables showing value of imports and exports of raw materials for textile industry, and of exports of textile goods to other countries. Factors which have aided the development of the German textile industry.

Mineral Tables, for the Determination of Minerals by their Physical Properties. By Arthur S. Eakle, Ph.D., Asst. Prof. of Mineralogy, University of California. John Wiley and Sons, New York. Chapman and Hall, Ltd., London. 1904. Price 5*s*. 6*d*. nett.

8vo volume, containing introduction, 7 pages of physical properties, an analytical key and 59 pages of tables, each grouped under the following columns:—"Name," "Composition," "Colour," "Streak," "Lustre," "System," "Cleavage or Fracture," "Common Structure," and "Observations." At the close there is an alphabetical index. In the preliminary chapter, "Physical Properties," definitions are given of the precise intent of each column heading just referred to. A list is also furnished of the very simple apparatus needed for utilising the tables mentioned for the purpose set forth.

Directions for Laboratory Work in Physiological Chemistry. By Holmes C. Jackson, Ph.D. 2nd Edition. John Wiley and Sons, New York. Chapman and Hall, Ltd., London. 1903. Price 5*s*. 6*d*. nett.

8vo volume, containing preface, 142 pages of subject-matter, and the alphabetical index. The following subjects are treated of in the book:—I. Carbohydrates. II. Fats. III. Proteids. IV. Muscular Tissue. V. Bone. VI. Nervous Tissue. VII. Salivary Digestion. VIII. Gastric Digestion. IX. Pancreatic Digestion. X. Intestinal Putrefaction. XI. Bile. XII. Blood. XIII. Milk. XIV. Urine. XV. Sediments.

Anleitung zur Quantitativen Bestimmung der organischen Atomgruppen. Von Dr. Hans Meyer. 2te, vermehrte und umgearb. Auflage. Julius Springer's Verlag, Berlin. 1904. Price M. 5.

8vo volume, containing prefaces, table of abbreviations, introduction, 198 pages of subject-matter with 23 illustrations, and an alphabetical index. The subject is treated under the following heads:—I. Determination of the Hydroxyl Group; II. of the Carboxyl Group; III. of the Carbonyl Group; IV. of the Alkyl Oxide Group; V. of the Methylene Oxide Group; VI. of the Primary Amine Group; VII. of the Imino Group. VIII. Quantitative Determination of the Typical Hydrogen of the Amines. IX. Determination of the Nitrite Group; X. of the Methyl- and Ethylimino Group; XI. of the Acid-amino Group; XII. of the Diazo Group; XIII. of the Azo Group; XIV. of the Hydrazine Group; XV. of the Nitroso Group; XVI. of the Nitro Group; XVII. of the Iodo and Iodoso Groups; XVIII. of the Active Oxygen of the Peroxides and Peracids. XIX. Determining the Double Linkage and the Triple Linkage.

The figures do not in all cases represent the total roduction of the minerals for the year. Large quantities f several important minerals, such as iron ore, limestone, andstone, slate, clay, &c., are obtained from quarries under he Quarries Act, and from other open workings, the returns rom which are not yet available. The totals for coal, and he ores of copper, lead, and zinc may, however, be egarded as substantially complete. The total mineral utput of the United Kingdom, including the returns from uarries, &c., will appear in Part I. of the General Report.

Germany; Tariff Modifications.

Bd. of Trade J., March 10, 1904.

The following are some recent modifications in the tariff lassification of Germany :—

Half- and wholly-tanned skins, with the hair on, of calves, attle, seals, and reindeer, are to pay duty as leather under No. 21 of the tariff.

Artificial sweetening substances, having a greater sweetening power than refined cane or beet sugar, but of less nutritive value are to be admitted duty free under No. *5m* of the tariff, permission to import such substances being first obtained.

In addition to the foregoing, the duty payable on certain articles has been fixed as follows :—

	Mks. per 100 kilos.
Lime-sandstone (artificial stone made of a mixture of lime and sand) :—	
In the form of bricks (ebenflächig)	Free
Other kinds, including figured (profilirt)—	
Imported by sea...........................	Free
" land	1 00
Rolled films of celluloid	200·00

New York Chemical Imports.

Chem. and Druggist, March 5, 1904.

Among the imports at New York in 1903, were 49,369 lb. of bismuth, 940,662 lb. of barium sulphate, 67,480 tons of crude chalk, 642,616 lb. of precipitated chalk, 15,139 tons of china clay, 66,687 lb. of cobalt oxide, 3,103 tons of fullers' earth, 637,184 lb. of lithopone, 346,200 lb. of mica, 8,062,051 lb. of ochre, 979,829 lb. of ozokerite, 3,765,083 lb. of potassium carbonate, 198,432 lb. of potassium permanganate, 1,793,876 lb. of potassium ferrocyanide, 112,154 lb. of sodium hyposulphite, 298,886 lb. of sodium nitrite, 5,239,448 lb. of talc, 1,048,976 lb. of ceresin, and 1,396,310 lb. of zinc oxide. Great Britain and Germany furnished the bulk of these imports.

Egyptian Market for Chemical Products and Manures.

Ch. of Comm. J., March 1904.

The French Consul at Cairo calls attention to the increased importation into Egypt of chemicals, notably of disinfectants, refrigerants, and preparations used in electrical and photographic processes. The principal shipments consist of sulphuric, citric, and hydrochloric acids, sal ammoniac, alum, sulphate of iron and sulphate of magnesia, corrosive sublimate, soda crystals, caustic soda, carbolic acid, and aniline dyes. Italy and Germany are becoming dangerous competitors, owing to the lowness of their prices. It is noteworthy as regards the consignments of chemical manures that France took first place in 1902, displacing the United Kingdom. A group of Egyptian agriculturists are promoting the use of chemical manures. Experiments are being undertaken by various landowners who recommend the establishment of experimental stations under the auspices of the Agricultural Union of Alexandria. This society will keep in touch with the chemical manure manufacturers. The principal product cultivated in Egypt, namely cotton, requires phosphate as dominant together with potash ; maize, potash as dominant together with phosphate of lime ; and barley and wheat, nitrogen. From the foregoing it will be observed that manufacturers of chemical products may do well to make themselves acquainted with the requirements of the Egyptian market.

VII.—ACIDS, ALKALIS, Etc.

Sodium Sulphite : U.S. Customs Decision.

Jan. 13, 1904.

A shipment of sodium sulphite containing sodium sulphate as an impurity was held by the Board of General Appraisers to be dutiable at 25 per cent. *ad valorem* under paragraph 3 of the present Tariff Act. The claim of the importer that it was dutiable at 12 cents per hundred lb. as "salt," under paragraph 284, was contradicted by analysis and was overruled.—R. W. M.

Lead Sulphate ; Impure —— : U.S. Customs Decision.

Jan. 25, 1904.

Merchandise invoiced under the above name was assessed for duty at 25 per cent. *ad valorem*, as a "chemical compound," under paragraph 3 of the present Tariff Act. Analysis showed it to contain selenium, iron, silica, water, free sulphuric acid and lead sulphate. The sample contained 52·80 per cent. of lead sulphate, and the sample was a residue from sulphuric acid chambers. Following a previous decision, the Board of General Appraisers held the article to be dutiable at 10 per cent. *ad valorem*, as "waste," under paragraph 463.—R. W. M.

Barium Peroxide : U.S. Customs Decision.

Jan. 21, 1904.

The Board held that barium peroxide was properly assessed for duty at 25 per cent. *ad valorem* as a "chemical salt" under paragraph 3 of the present Tariff Act, and overruled the claim of the importer that it was dutiable at 5·25 dols. per ton as "manufactured barytes" under paragraph 44.—R. W. M.

Barium Sulphate ; Artificial —— : U.S. Customs Decision.

Jan. 19, 1904.

An importation of goods invoiced as barium sulphate was assessed for duty at ½ cent per lb. as "artificial sulphate of barytes" under paragraph 46 of the present Tariff Act. The Board of General Appraisers affirmed the assessment of duty and overruled the several claims of the importer that it was dutiable at 25 per cent. *ad valorem* as a "chemical salt" under paragraph 3, or at 75 cents per ton under paragraph 44 as "barytes, unmanufactured," or at 5·25 dols. per ton as "manufactured barytes" under the same paragraph, or at 20 per cent. *ad valorem* as a "manufactured article unenumerated" under section 6.
—R. W. M.

X.—METALLURGY.

Spelter Production ; The World's ——, in 1903.

H. R. Merton and Co. Eng. and Mining J., Feb. 25, 1904.

The following figures approximate closely to the details of the world's spelter production in 1903 ; the figures for 1902 are added for comparison.

——	1902.	1903.
	Tons.	Tons.
Belgium, the Rhine, and Holland	200,140	215,690
Silesia........................	115,280	116,835
Great Britain.........................	39,610	43,415
France and Spain....................	27,030	27,920
Austria and Italy...............	8,460	9,025
Poland	8,150	9,745

Pig Iron Production of Canada in 1903.

Bd. of Trade J., March 3, 1904.

The American Iron and Steel Association, has received direct from the manufacturers the statistics of the production of all kinds of pig iron in Canada in the year 1903. They show a decrease of 54,139 tons, or nearly 17 per cent., as compared with 1902, but an increase of 20,442 tons as compared with 1901.

The total production in 1903 amounted to 265,418 tons, against 319,557 tons in 1902, and 244,976 tons in 1901. Of the total production in 1903, 247,905 tons were made with coke and 17,513 tons with charcoal. Nearly one-half of the total production was basic pig iron, namely, 126,892 tons. Less than 1,000 tons of Bessemer iron were made. Spiegeleisen and ferromanganese have not been made since 1899.

The following table shows the total production of all kinds of pig iron (including spiegeleisen and ferromanganese) in Canada from 1899 to 1903 :—

	Tons.
1899	94,077
1900	86,090
1901	244,976
1902	319,557
1903	265,418

The un-sold stocks of pig iron in Canada on 31st December, 1903, amounted to 19,168 tons.

XII.—FATS, FATTY OILS, Etc.

OLIVE OIL PRODUCTION OF SOUTH AUSTRALIA.

Bd. of Trade J., March 3, 1904.

In the prefatory report on the agricultural and livestock statistics of South Australia for the year ended 31st March, 1903, it is stated that olive cultivation has for many years been carried on in that State, the climatic conditions, nature of the soil, and the introduction of the best varieties all tending to the success of a highly remunerative industry in the production of fruit and oil of the best quality. The number of trees returned for the period under review is 78,642, against 66,852 in 1901–02, and the quantity of oil expressed 12,422 galls., as against 11,327 galls. in 1901–02.

CARNAUBA WAX.

Pharm. Weekblad, 4, 78, 79 ; *through Pharm. J.*, 1904, 72, 246.

About 1,000 tons of Carnauba wax are exported annually from Brazil, chiefly to Hamburg. The greater portion of the wax is collected along the banks of the Jaquariba, in the provinces of Ceará and Parahyba. The leaves of the plant which yield the wax are left to dry in the sun for two or three days and the wax brushed or scraped from the surface. It is then melted in hot water, skimmed off, and allowed to solidify, when it forms a yellow or pale greenish wax of sp. gr. 0·995, and m. pt. 84° C.—A. S.

CHINESE WOOD OIL.

U.S. Cons. Reps., Feb. 24, 1904.

Wood oil is rapidly becoming an important article of export from China. During the past season there has been over 1,890,000 dols. worth of it shipped from Hankow. There are two kinds of this oil—one yellow, the other a dark colour. Only the former has been exported, being considered of a higher quality than the latter. The price of the yellow variety during the past season has varied from 4·92 dols. to 6·05 dols. per picul (133⅓ lb.). The price at this date is about 5 dols. gold. The oil is brought to the port in bamboo baskets lined with oiled paper, each basket containing about 1 picul of oil.

SOAP TREE OF ALGERIA.

U.S. Cons. Rep., March 1, 1904.

German papers report that steps are being taken in Algeria to manufacture natural soap on a large scale from a tree known as "*Sapindus utilis*." This plant, which has long been known in Japan, China, and India, bears a fruit of about the size of a horse-chestnut, smooth and round. The colour varies from a yellowish green to brown. The inner part is of a dark colour and has an oily kernel. The tree bears fruits in its sixth year and yields from 55 to 220 lb. of fruit, which can easily be harvested in the fall. By using water or alcohol the saponaceous ingredient of the fruit is extracted. The cost of production is said to be small.

YELLOW GREASE : U.S. CUSTOMS DECISION.

Jan. 14, 1904.

A hard yellow grease was assessed for duty at 20 per cent. *ad valorem* as a "manufactured article unenumerated" under section 6 of the present Tariff Act. The Board of General Appraisers, on examining the sample, held it to be properly dutiable at ½ cent per lb. as "wool grease," under paragraph 279.—R. W. M.

XIII. B.—RESINS, VARNISHES, Etc.

GUAIACUM RESIN : U.S. CUSTOMS DECISION.

Jan. 25, 1904.

Resin guaiacum was decided to be dutiable at ¼ cent per pound and 10 per cent. *ad valorem*, under paragraph 20 of the present Tariff Act, as a "gum advanced in value," and not free of duty as a "crude drug" under paragraph 548.
—R. W. M.

"MIXTION CLARIFIÉ": U.S. CUSTOMS DECISION.

Jan. 22, 1904.

Merchandise described on the invoice as above, and according to analysis consisting of turpentine oil, drying oils, and resinate of lead, was decided to be dutiable at 35 per cent. *ad valorem*, as "varnish," under paragraph 53 of the present Tariff Act, and not at 20 cents per gallon, as "linseed oil oxidised," under paragraph 37.—R. W. M.

XIV.—TANNING; LEATHER; GLUE, Etc.

TANNING INDUSTRY IN BURMA.

Bd. of Trade J., March 3, 1904.

In its issue of 6th February, "Indian Engineering" calls attention to the fact that the Forest Department at Rangoon are working a tanning factory, which may be the means of introducing a new industry into the province of Burma, whose forests and coasts supply tanning material in abundance.

GROUND SUMACH : U.S. CUSTOMS DECISION.

Jan. 27, 1904.

Sumach leaves, ground and containing 15 per cent. of lentisco leaves also ground, were assessed for duty at 20 per cent. *ad valorem*, as a "manufactured article unenumerated," under section 6 of the present Tariff Act. The Board of General Appraisers sustained the claim of the importer that they were dutiable at 0·3 cent. per pound, as "ground sumach," under paragraph 85, the evidence showing that such was their commercial designation.—R. W. M.

XVI.—SUGAR, STARCH, Etc.

SACCHARIN AND SIMILAR SUBSTANCES ; IMPORT OF ——, INTO SPAIN.

Bd. of Trade J., March 10, 1904.

The regulations which have been issued for giving effect to the law governing importation of saccharin, &c., into Spain (this J., 1904, 143), provide that the importation of saccharin and similar products is to be effected only through the Custom-houses of Irun, Port Bou, Barcelona, Seville, Bilbao, and Grao de Valencia, and only in the name and for account of certificated apothecaries. Until the Ministry of the Interior has fixed the quantity of saccharin, &c., which is to be considered as the maximum necessary for the pharmaceutical purposes of each importer, the amount of each consignment is not to exceed 2 kilos.

SUGAR EXPORTS OF BRITISH GUIANA.

Bd. of Trade J., March 3, 1904.

The following figures are taken from official sources, and give the destination of the exports of sugar from British Guiana for the years ending March 31st :—

Year.	United Kingdom.	United States.	Canada.
	Tons.	Tons.	Tons.
1898–9	17,612	78,609	218
1899-1900	15,931	68,422	331
1900–1	16,902	76,216	1,588
1901–2	12,868	85,099	7,774
1902–3	16,326	89,805	13,777

For the period from 1st April to 3rd November 1903, the sugar exports to Canada reached a total of 32,683 tons.

XVII.—BREWING, WINES, SPIRITS, *Etc.*

WINE PRODUCTION IN ITALY IN 1903.

Bd. of Trade J., March 10, 1904.

The following table, showing the amount of wine produced in Italy in 1903, as compared with the productions of 1902 and 1901, has been compiled from official figures published in the *Gazzetta Ufficiale* of 25th February :—

Districts.	1901.	1902.	1903.
	Hectols.	Hectols.	Hectols.
Piedmont	6,130,000	5,370,000	2,800,000
Lombardy	2,250,000	1,995,000	1,550,000
Venetia	3,000,000	2,270,000	1,920,000
Liguria	420,000	370,000	200,000
Emilia	4,940,000	3,415,000	3,230,000
Umbria	4,500,000	3,945,000	3,000,000
Tuscany	4,985,000	4,210,000	3,100,000
Lazis	1,150,000	1,600,000	1,440,000
South Adriatic	7,200,000	9,370,000	6,430,000
South Mediterranean	3,500,000	4,100,000	5,060,000
Sicily	4,155,000	3,180,000	3,960,000
Sardinia	1,950,000	1,615,000	2,410,000
Totals	44,180,000	41,440,000	35,100,000

SPIRIT DRAWBACK.

At a meeting of the Associated Chambers of Commerce held at the Whitehall Rooms, W.C., on Thursday, March 10, on the motion of Mr. Ivan Levinstein, seconded by Mr. Thos. Tyrer, the following resolution was passed :—

Having regard to the great advantages resulting from the extensive employment of untaxed alcohol for industrial purposes, and for the generation of power abroad, this Association is convinced that the retention of the existing duty on alcohol for such purposes is a very serious obstacle to the progress of British industry, and that a letter be forthwith addressed to the Chancellor of the Exchequer asking him to receive a deputation on an early date for the purpose of demonstrating to him the importance and urgency of exempting from duty alcohol for industrial uses.

WINE PRODUCTION OF SOUTH AUSTRALIA.

Bd. of Trade J., March 3, 1904.

Vine growing in South Australia is becoming one of the most important industries, the production of wine having increased fourfold during the past decade. In 1893 there were 15,418 acres, with 4,206,880 vines in bearing and 4,545,737 non-producing. In 1903 the area had increased to 21,692 acres, the number of productive vines to 10,067,139, and 1,723,787 vines not in bearing, aggregating nearly 12,000,000 vines.

The future of the vine industry must depend more and more on extraneous demand, especially from consumers in Great Britain. The consumption of Australian wine in the United Kingdom was in 1860 only 951 galls.; in 1870, 36,147 galls.; in 1880, 55,000 galls.; in 1890, 314,401 galls.; and at the close of the century, 822,503 galls.

XVIII. C.—DISINFECTANTS.

"SACARBOLATE": U.S. CUSTOMS DECISION.

Jan. 12, 1904.

An article described as sacarbolate, which on analysis was shown to be a preparation of soap containing phenolic compounds and pyridine bases, was assessed for duty, as a "medicinal soap," at 15 cents per lb. under paragraph 17 of the present tariff. The evidence showed that it was principally used for disinfecting railway cars and refrigerators, and was not suited for use on the human body. The claim of the importer that it is properly dutiable at 20 per cent. *ad valorem* as "soap not specially provided for," under paragraph 72, was sustained by the Board.

—R. W. M.

XX.—FINE CHEMICALS, *Etc.*

QUININE EXPORTS FROM JAVA DURING 1903.

Chem. and Druggist, March 5, 1904.

The exports of quinine from Java from Jan. 1 to Dec. 31 were as follows :—

	Cases.
1899	1,600
1900	1,921
1901	2,255
1902	1,986
1903	1,917

ENFLEURAGED GREASES, CONCRETE ESSENCES, AND OILS: U.S. CUSTOMS DECISIONS.

Jan. 27, 1904.

The Board held that concrete essence of violet, concrete essence of cassie, and pomade lily are "enfleurage greases," and free of duty under paragraph 626 of the present Tariff Act; and oil of jasmine also free under same paragraph, by specific designation. Articles described as oil of gardenia, oil of muguet, and oil of thyme were held to be dutiable either "as essential oils," under paragraph 3, at 25 per cent. *ad valorem*, or at 60 cents per lb. and 45 per cent. *ad valorem*, under paragraph 2, as "alcoholic compounds," according to the presence or absence of alcohol. It was also held that certain concrete essences and oils, described as concrete clover blossoms, oil of jasmin, oil of chypre, solid carnation pink, concrete rose, concrete violet, concrete May lily, concrete tuberose, concrete fleur-orange, and solide oeillet are also free of duty, under paragraph 626 as "efleurage greases." In another case, decided Feb. 10, concrete essences, fleur d'oranges, cassie, heliotrope, rose, tuberose, reseda, violette de parme, and jasmine were also decided to be free of duty, as above, while glycine, gardenia, and lilas blanc were held to be dutiable at 25 per cent. *ad valorem* as "essential oils" under paragraph 3, as being compounds of essences. In a further case, decided Feb. 15, essence naturelle pure violette and essence naturelle concrete mimosa were held to be dutiable at 25 per cent. *ad valorem* as "essential oils."—R. W. M.

GUAIACOL CARBONATE AND PIPERAZINE: U.S. CUSTOMS DECISION.

Feb. 8, 1904.

The Board of General Appraisers held guaiacol carbonate and piperazine to be "medicinal preparations in the preparation of which alcohol is used" and dutiable at 50 cents per lb. under paragraph 74 of the Tariff Act.—R. W. M.

ARISTOL: U.S. CUSTOMS DECISION.

Feb. 8, 1904.

Aristol, derived from thymol and iodine, was found to be non-alcoholic in character and dutiable at 25 per cent. *ad valorem* as a "medicinal preparation" under paragraph 76 of the Tariff Act.—R. W. M.

Patent List.

N.B.—In these lists, [A.] means "Application for Patent," and [C.S.], "Complete Specification Accepted."

Where a Complete Specification accompanies an Application, an asterisk is affixed. The dates given are (i) in the case of Applications for Patents, the dates of application, and (ii) in the case of Complete Specifications Accepted, those of the Official Journals in which acceptances of the Complete Specifications are advertised.

Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

[A.] 5955. Sellars. Extraction and recovery of by-products from shales, coal dust, or other bituminous or carbonaceous matters. March 11.

[C.S.] 8596 (1903). Bengough. Process for the production of highly sulphuretted hydrocarbons. March 9.

IV.—COLOURING MATTERS AND DYESTUFFS.

[A.] 4997. Johnson (Badische Anilin und Soda Fabrik). Manufacture of azo colouring matters. Feb. 29.

,, 4998. Johnson (Badische Anilin und Soda Fabrik). Manufacture of colouring matters of the anthracene series. Feb. 29.

,, 5303. Imray (Basle Chemical Works). Manufacture of indoxyl, its homologues and their derivatives. March 3.

[C.S.] 8905 (1903). Imray (Meister, Lucius und Brüning). Manufacture of dyestuffs of the anthracene series. March 9.

,, 9598 (1903). Imray (Meister, Lucius und Brüning). Manufacture of cyanine dyestuffs. March 9.

,, 10,074 (1903). Newton (Bayer and Co.) Manufacture of new derivatives of the anthraquinone series. March 9.

,, 11,004 (1903). Abel (Act.-Ges. f. Anilinfabr.) Manufacture of red monazo dyestuffs. March 9.

,, 11,717 (1903). Newton (Bayer and Co.). Manufacture of dyestuffs of the anthraquinone series. March 9.

,, 2738 (1904). Imray (Basle Chemical Works). Manufacture of new basic dyestuffs. March 9.

V.—PREPARING, BLEACHING, DYEING, PRINTING, AND FINISHING TEXTILES, YARNS, AND FIBRES.

[A.] 5247. Goddard. Apparatus for dyeing warps for weaving and otherwise treating them with liquids. March 3.

,, 5585. Sunderland and The Bradford Dyers' Association, Ltd. Production of colour or other effects on textile fabrics. March 7.

,, 5782. Newton (Bayer and Co.). Printing. March 9.

[C.S.] 9849 (1903). Fielding. Rendering permanent embossed and like effects on woven goods. March 16.

,, 23,310 (1903). Muntadas y Rovira. Continuous bleaching, washing, dyeing, and like apparatus. March 9.

VII.—ACIDS, ALKALIS, AND SALTS.

[A.] 5067. Lee. Manufacture of cyanide of potassium. March 1.

[A.] 5101. Bloxam (Gibbs). Manufacture of salts of oxy-acids of chlorine and salts of chromic acid. March 1.

,, 5173. Ashcroft. *See under* XI.

,, 5194. Kenyon. Process and apparatus for extracting nitrogen from atmospheric air. March 2.

,, 5195. Kenyon. Manufacture of nitrogenous compounds. March 2.

,, 5293. Pearce and Couchet. *See under* XI.

,, 5360. Woltereck. Process for producing hydrocyanic acid. March 4.

,, 5540. Pauling and Pauling. Process for the production of nitric acid from air. March 7.

,, 5603. Lennard. Improvements in and apparatus for the manufacture of carbonate of ammonia. March 7.

[C.S.] 5649 (1903). Lévy. Process for the separation of gases from gaseous mixtures, particularly oxygen and nitrogen from atmospheric air, and apparatus therefor. March 16.

,, 8478 (1903). Swan and Kendall. Apparatus to be employed in the manufacture of cyanides. March 9.

,, 768 (1904). Stevens and Timmerman. *See under* XI.

,, 2284 (1904). Lake (Fallows). Production of phosphoric acid. March 16.

VIII.—GLASS, POTTERY, AND ENAMELS.

[C.S.] 297 (1904). Imray (Window Glass Machine Co.). Methods of and apparatus for drawing and annealing glass. March 9.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

[A.] 4940. Seaton-Snowdon. Flame-preventing compositions. Feb. 29.

,, 4986. Wouldham Cement Co., 1900, Ltd., and Fennell. The linings of rotary kilns or furnaces. Feb. 29.

,, 5487. Curry. Manufacture of refractory bricks. March 5.

,, 5648. Stringfellow. *See under* X.

,, 5711. Bidtel, Bidtel, and Nutz. Magnesia cement composition, and process for making artificial stone from the same.* March 8.

,, 5712. Shedlock. Manufacture of artificial asphalt or like composition. March 8.

,, 5853. Brothers. Manufacture of plaster of Paris, and apparatus therefor. March 10.

,, 5913. Törno. Process of manufacturing artificial marble or artificial stone.* March 10.

,, 6007. Steger. Manufacture of artificial stone, blocks, or bricks.* March 11.

,, 6112. Robinson and Sons, Ltd., and Smith. Plasters. March 12.

[C.S.] 388 (1904). Gogler and Seinfeld. Process for manufacturing white cement. March 16.

X.—METALLURGY.

[A.] 4973. Trezel and Comte de Monthy. Alloy for and process of soldering and brazing aluminium and alloys containing aluminium. Feb. 29.

,, 4975. Moore and Heskett. Manufacture of iron and steel from ferruginous ore.* Feb. 29.

,, 5011. Moore and Heskett. Apparatus for treating ferruginous ore for the manufacture of iron and steel therefrom. March 1.

,, 5276. Alzugaray. The refining of iron, steel, and other metals. March 3.

,, 5349. Bower. Oxidising metallic surfaces. March 4.

,, 5361. Proctor and Jackson. Method of soldering aluminium. March 4.

[A.] 5591. Alton and Ramsay. Treatment of zinc ore or zinciferous flue dust. March 7.

,, 5648. Stringfellow. Treating blast-furnace slag, and utilising the products thereof. March 8.

,, 5649. Wheatley. *See under* XI.

,, 5671. Lake (Bassett, Parker, and Strout). The brazing of metals, and fluxes for use therein.* March 8.

,, 6046. Wemyss-Just and Hurry. Metallic alloy. March 11.

[C.S.] 5683 (1903). Prescott and E. Green and Son, Ltd. Manufacture of metallic alloy. March 16.

,, 768 (1904). Stevens and Timmerman. *See under* XI.

,, 912 (1904). Matzek. Method of filling up cavities produced in steel blocks during casting or cooling. March 16.

,, 2460 (1904). Cadotte. Case-hardening compound. March 9.

,, 3235 (1904). Schulte-Steinberg. Manufacture of briquettes from friable ores. March 16.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

[A.] 5173. Ashcroft. Production of metals of the alkali group by electrolysis. March 2.

,, 5193. Macaulay. Device for collecting gases which are driven or given off electrical furnaces. March 2.

,, 5293. Pearce and Couchet. Electrolytic process for manufacturing nitrites. March 3.

,, 5297. M. I. P. Electrical Syndicate, Ltd., and Blackman. Electric accumulators or secondary batteries. March 3.

,, 5528. Brindle. Composition for insulating and other purposes. March 7.

,, 5649. Wheatley. Plating aluminium or its alloys with a metal or alloy by electrolysis. March 8.

,, 5683. Johnson (Badische Anilin und Soda Fabrik). Apparatus for producing reactions in gases by means of electricity. March 8.

[C.S.] 10,251 (1903). Wokes and Street. Apparatus for purifying air and generating ozone by electricity. March 16.

,, 11,276 (1903). Roderbourg. Manufacture of electrodes for secondary batteries. March 9.

,, 768 (1904). Stevens and Timmerman. Furnaces for extracting metals, and making carbides and similar compounds. March 16.

XII.—FATTY OILS, FATS, WAXES, AND SOAP.

[A.] 5,000. Kirton. Soap or compound applicable for cleaning gloves and the like. Feb. 29.

,, 5399. Taylor. *See under* XVIII A.

,, 5609. Fearnhead. Apparatus for the manufacture of candles, &c. March 8.

,, 6028. Rÿk. Absorbent for lubricants, and method of lubricating with the aid thereof. March 11.

,, 6080. Slater and Slater. Manufacture and subsequent treatment of soap. March 12.

[C.S.] 8954 (1903). Finlay. Preparation of soap and other commodities liable to evaporation. March 9.

,, 10,324 (1903). Delahaye. Manufacture of artificial wax. March 16.

,, 1303 (1904). Parziale. Soap. March 16.

XIII.—PIGMENTS, PAINTS; RESINS, VARNISHES; INDIA-RUBBER, Etc.

(*A.*)—Pigments, Paints.

[C.S.] 8335 (1903). Strange and Graham. Manufacture of improved paint vehicles. March 16.

[C.S.] 28,800 (1903). Armbruster and Morton. Pigments, and processes of making the same. March 9.

(*B.*)—Resins, Varnishes.

[A.] 5186. Hannay. Anti-fouling compositions for ships' bottoms. March 2.

,, 5292. Charlesworth and Gray. Medium for colouring or staining purposes. March 3.

[C.S.] 6823 (1903). Blumer. Synthetical production of resinous substances. March 9.

XIV.—TANNING; LEATHER, GLUE, SIZE, Etc.

[A.] 5475. Richardson. Treating leather to adapt it for being united to other material. March 5.

[C.S.] 5305 (1903). Zacharias. Manufacture of leather. March 16.

,, 9944 (1903). Banham and Co., Ltd., and Sagar. Impregnating woven belting and other fabrics with balata, gutta-percha, &c. March 9.

,, 11,625 (1903). Jensen (Maetschke). Process of manufacturing a limpid solution of agar agar. March 9.

XV.—MANURES, Etc.

[A.] 6101. Crone, Taylor, and Williams. Manufacture of fertilisers. March 12.

XVI.—SUGAR, STARCH, GUM, Etc.

[A.] 5574. Kantorowicz. Manufacture and production of starch materials. March 7.

XVII.—BREWING, WINES, SPIRITS, Etc.

[A.] 4974. Squire, Squire, and Squire. Manufacture of yeast for bakers' use. Dec. 29.

,, 5263. Dymond. Kilns for drying brewers' grains, &c., and machinery and apparatus therefor. March 3.

,, 5272. Kenneth and Murray. Method of manufacturing alcohol. March 3.

,, 5445. Frew and Dempster. Fermented beverages. March 5.

XVIII.—FOODS; SANITATION, WATER PURIFICATION; & DISINFECTANTS.

(*A.*)—Foods.

[A.] 4974. Squire. *See under* XVII.

,, 5102. Van Dalfsen. Production of an article of food from sweet cassava.* March 1.

,, 5399. Taylor. Preparation and preservation of cream and similar fatty substances or emulsions. March 4.

,, 5789. Leetham. Process for bleaching, conditioning, or sterilising flour, milk, and other food products or fermentable materials. March 9.

,, 5790. Leetham. Process for bleaching or sterilising, and apparatus therefor. March 9.

,, 5946. Butler. Manufacture of milk in the form of milk powder, also applicable to the treatment of other solutions containing fatty matter. March 10.

[C.S.] 12,045 (1903). Daseking and Paradies. Treatment of milk for purifying and preserving same. March 9.

(*B.*)—Sanitation; Water Purification.

[C.S.] 4759 (1903). Nesfield and Crerar. Sterilisation of water and other liquids and of alimentary substances to render same potable or edible. March 9.

XIX.—PAPER, PASTEBOARD, Etc.

[A.] 4996. Jackson. Manufacture of paper pulp from printed paper. Feb. 29.

,, 5126. Voigt. *See under* XXII.

,, 5277. Alzugaray. Manufacture of paper. March 3.

,, 5280. Ortmann. Manufacture of celluloid. March 3.

,, 5286. Howorth (Soc. Franc. de la Viscose). Apparatus for treating viscose. March 3.

,, 5730. Howorth (Soc. Franc. de la Viscose). Apparatus for the treatment of viscose. March 8.

,, 5994. Greening. *See under* XX.

[C.S.] 4863 (1903). Schmerber and Morane. Manufacture of celluloid. March 9.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

[A.] 5549. Richardson. Manufacture of camphors. March 7.

,, 5994. Greening. Method of producing artificial camphor and rendering same a solvent for nitrocellulose forming celluloid. March 11.

[C.S.] 10,095 (1903). Zimmerman (Chem. Fabrik auf Actien vorm. E. Schering). Manufacture of methylene hippuric acid. March 9.

,, 11,138 (1903). Imray (Meister, Lucius und Brüning). Manufacture of esters of trimethylcyclohexenone carboxylic acid. March 9.

,, 1180 (1904). Evers. Process for obtaining liquorice juice from partly or completely dried liquorice root. March 9.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

[A.] 4941. Heskiel. Colour photography. Feb. 29.

,, 4994. Imray (Meister, Lucius und Brüning). Manufacture of coloured photographic images or prints and of sensitive surfaces therefor. Feb. 29.

,, 5814. Bennion-Booth. Photographic printing process resembling mezzotint. March 9.

,, 5917. Spitzer. Process for producing etchings from negatives or diapositives of any kind. [German Appl., Oct. 29, 1903.]* March 10.

XXII.—EXPLOSIVES, MATCHES, Etc.

[A.] 5126. Voigt. Processes for manufacturing nitrated celluloses.* March 1.

[C.S.] 10,836 (1903). Brock. Explosive for blasting, signalling, and other purposes. March 16.

,, 11,990 (1903). Christensen. Manufacture of matches. March 16.

,, 23,472 (1903). O'Donnell (Frank). Process of manufacturing a safety explosive. March 9.

Printed and Published by Eyre and Spottiswoode, East Harding Street, London E.C. for the Society of Chemical Industry.—P 9416.

JOURNAL OF THE Society of Chemical Industry.

A RECORD
FOR ALL INTERESTED IN CHEMICAL AND ALLIED MANUFACTURES.
ISSUED TWICE A MONTH.

No. 7.—Vol. XXIII. **APRIL 15, 1904.** No. 7.—Vol. XXIII.

Subscription of Members 25/- per annum;
Entrance Fee 21/-;
Election by the Council.

Notices.

THE MEDAL.

At a meeting of the Council of the Society held on March 23rd last, it was unanimously resolved to present the Society's medal for 1904 to Prof. Ira Remsen, President of the Johns Hopkins University, Baltimore, Md., U.S.A., for conspicuous services rendered by him to Applied Chemistry.

ANNUAL GENERAL MEETING, NEW YORK, 1904.

The Annual General Meeting will be held in New York City on Thursday, Sept. 8th, and following days. Members who contemplate attending are requested to communicate with the General Secretary as soon as possible, in order that suitable travelling arrangements may be made. A revised programme appeared in the March 31st issue.

COMMUNICATIONS.

Authors of communications read before the Society, or any of its Local Sections, are requested to take notice that under Rule 43 of the Bye-laws the Society has the right of priority of publication for three months of all such papers. Infringement of this Bye-law renders papers liable to be rejected by the Publication Committee, or ordered to be abstracted for the Journal, in which case no reprints can be furnished to the author.

Changes of Address.

When notifying new addresses, members are requested to write them distinctly, and state whether they are temporary or permanent. Multiplication of addresses is also to be avoided as tending to create confusion. When sending subscriptions, the use of the form attached to the application helps in the verification of addresses, on which the safe delivery of the Journal depends.

Meeting held at Ottawa, on February 18th, 1904.

PROF. W. R. LANG IN THE CHAIR.

NOTE ON THE FRACTIONAL CONDENSATION OF AIR, WITH A VIEW TO THE COMMERCIAL PRODUCTION OF OXYGEN.

BY ERNEST A. LE SUEUR, B.SC.

The problem of the cheap preparation of oxygen, or of an atmosphere rich in oxygen, has long been recognised as a technically important one. The number of uses to which a really cheap oxygen could be put is exceedingly large. Hitherto, for almost all purposes requiring oxygen, air has had to be used. In the case of the combustion of fuel, for instance, for every ton of coal burnt at least ten tons of inert nitrogen are loaded into the flame. This dilution, or some of it, may be advantageous for certain purposes, as in the case of steam boiler work, but for practically all metallurgical operations it is highly objectionable, and for some it is even fatal, as in the case of the direct production of calcium carbide in a blast furnace. In industrial chemical operations, also, there are many processes demanding oxygen and, as in the cases of the Deacon and Mond chlorine processes, receiving air to their great prejudice.

The development in late years of methods of liquefying air has led to an active investigation as the practicability of producing cheap oxygen by purely mechanical means. Parkinson took out a patent (Eng. Pat. 44,418, 1892 ; this J., 1893, 545) for a method of refrigerating air until the oxygen (which has the higher boiling point) liquefied. This was impracticable owing to the fact that the two gases, oxygen and nitrogen, invariably liquefy together in a mutual solution. Some eight or nine years ago, Prof. James Dewar, of the Royal Institution, investigated the relative proportions in which oxygen and nitrogen liquefy when a mass of air is exposed to partial liquefaction. Unfortunately he arranged matters so that the only possible result was a complete liquefaction of a fraction of the air instead of a fractional liquefaction from the whole of it. That is to say, the mass of air as a whole was not only not chilled to the liquefying point, but, save for the portion withdrawn, was maintained at ordinary temperatures, while the separated portion was not only chilled below the point at which the most condensible constituents liquefied, but far below the condensing point of nitrogen itself. Naturally, the air exposed to this treatment liquefied in its entirety, and the conclusion was drawn that air, in its initial stages of condensation, could only deposit a liquid of its own composition. This conclusion seems to have been accepted throughout that section of the scientific world which has interested itself in this field of investigation. One result of this has been that, if a liquid, and subsequently a gas, rich in oxygen was desired to be obtained through the agency of liquefaction, it was considered necessary to liquefy air as a whole and then subject it to fractional distillation, when an atmosphere weak in oxygen would leave the liquid and a residue rich in oxygen remain behind. Carl Linde developed, in addition, a process in which he prepared liquid air under great pressure and at a comparatively high temperature, and then, by relieving the pressure, obtained a fractional distillation due to ebullition which accompanied the drop in pressure and temperature. An additional feature of his process consists in the further concentration in oxygen strength by fractional distillation induced on the regenerative principle. His process is undoubtedly the cheapest at present publicly known for preparing atmospheres rich in oxygen. There remains yet, however, much to be desired in Linde's process owing to the great power consumption, and labour and repair charges required when working at the pressures of between 100 and 200 atmospheres.

The following will serve to indicate the lines along which a remarkably cheap and efficient method has been developed. To begin with, in order to attain anything approaching efficiency in the use of a gas such as air (as distinct from a vapour, liquefiable by pressure alone, like ammonia) as the working fluid of the refrigerative cycle, it is imperative that the power represented by the drop of pressure of the gas should be abstracted from it as far as possible in the act of expansion. This fact has long been recognised, and Sir W. Siemens made application of it in the attempt to liquefy air by expanding previously cooled compressed air through an engine. His apparatus, however, was entirely inadequate to attain the extremely low temperature required for his purpose.

Now, inasmuch as it is required to develop power from our compressed gas, the latter must not be in the liquid condition. In the second place, any oxygen separated can only be secured by being first in the liquid condition. Thirdly, if we resort to a partial liquefaction of air so as to get oxygen from the liquid and power from the expansion of the unliquefied gaseous residue, and if, as Dewar believes, the portion liquefied is of the same composition as air, the method presents no notable advantages. Fortunately Dewar was wrong in his conclusions, and the device of working a motor with the unliquefied portion of the compressed air, thereby developing chilling effect, and of using the liquid rich in oxygen as a source of gaseous oxygen, is an excellent one.

A simple experiment suffices to determine the fact that air partially liquefied under a comparatively low pressure is rich in oxygen. I immersed in a boiling mixture of oxygen and nitrogen, richer in oxygen than air is, the lower end of an empty, unstoppered, test tube. After immersion for some minutes, examination showed the tube to contain a small quantity of a decidedly blue liquid, and this, on analysis, turned out, of course, to be a mixture of oxygen and nitrogen rich in oxygen. I say "of course" because, since the temperature of the boiling bath was higher than that of boiling liquid air (because it was richer in oxygen than air), it was impossible for liquid air to exist (at atmospheric pressure) under so high a temperature, and the liquid had therefore to be something which could be condensed out of the atmosphere and exist at atmospheric pressure at the temperature in question. It could not be oxygen, because oxygen and nitrogen invariably condense from air together in a mutual solution; in fact, I found on analysing it that the precipitation was a mixture of oxygen and nitrogen approximating in composition to, but slightly richer in oxygen than the boiling bath itself. I found that no liquefaction occurred at all when the oxygen strength of the bath rose to 50 per cent., because then the atmosphere boiling away from the bath was richer in oxygen than was air, and, obviously, the bath's temperature must be above that at which air can precipitate any portion of itself as a liquid under atmospheric pressure.

In the light of the recent publication of certain results by M. Georges Claude which appear to be along somewhat the same line, it may be proper to mention that I established theoretically the necessity for the occurrence of the above phenomena in 1889, and took steps at that time to make certified disclosures to that effect with certain authorities in Washington.

THE IMPROVEMENT OF BOILER-FEED WATER.

BY A. McGILL, M.A., F.R.S.C.

Part I.—Introductory.

The great demands made upon the modern locomotive have intensified the importance of using soft water in steam production. Rossel* states that the best water for boiler use would be pure distilled water rendered slightly alkaline. All naturally occurring water contain matter in solution. The carbonates, sulphates, chlorides, and silicates of lime, magnesia, soda, iron, and alumina are most usual; and organic matter must often be taken into consideration. In 1900 the Lancashire and Yorkshire Railway instituted an inquiry into methods of feed purification as then in use by the different railways of the world (Proc. Inst. Civil Eng., Lond., 1901, 68). Reports from eleven countries show that 25 out of a total of 58 roads used some system of water softening. The mean cost of treatment was 6½ cents. per 1,000 gallons. It is safe to say that the practice of softening boiler feed water has increased ten-fold during the past four years. Only one American road reported in 1900. I know of 27 American railways that have systematic treatment in use to-day. Evidence of the attention given to this matter is afforded by the fact that this Journal for 1902 contains abstracts of 24 patents, taken out in England in that year, for apparatus only.

It was formerly the custom to attempt treatment in the boiler. For valuable opinions on this subject see Maignen (this J., 1886, 224), Fisher,† and other high authorities.

The problem of making hard water soft is not a problem of pure chemistry. It is a practical problem, which must be solved subject to many limitations. These have reference to cost of reagents, of plant, of skilled labour. They include complexity of process and apparatus, time required in treatment, potability of the resultant water. In general the reactions must be carried out in cold dilute solution, while at the same time economy precludes the use of reagents in excess. The problem is not that of producing perfectly pure water, but of achieving the best possible result under given conditions of limitation.

We recognise three respects in which natural waters may be objectionable or impracticable for steam making:—(1) They may be corrosive; (2) They may foam or prime; (3) They may form scale. Corrosive waters of natural recurrence are rare. Air as dissolved by water contains 35 per cent. of oxygen, instead of 21 per cent. as in the atmosphere; but the corrosive action of dissolved air can only be held as proven in the absence of free carbon dioxide. Moist carbon dioxide, especially at boiler temperatures, acts strongly on iron, which is dissolved as ferrous carbonate. This is oxidised to the ferric salt by the dissolved air: the iron is precipitated as oxide and the carbon dioxide set free to make a fresh attack on the boiler plate; so that a small quantity of carbon dioxide is enabled, by this regenerative action, to effect very serious corrosion. It

---

* Report to the Swiss Steam Users Association, 1888.

† "Die Chemische Technologie des Wassers," p. 278.

is true that the oxygen dissolved plays a part in this process, but it is as auxiliary to carbon dioxide in solution. It has further been demonstrated (Petit, Comptes rend., 1896, 1278; this J., 1897, 128) that while sodium chloride attacks iron even in the absence of carbon dioxide, the corrosive action is much intensified by its presence. Pfeifer (this J., 1894, 134) recommends that the feed pipe be placed near low water level, so that the feed water may meet the hottest layers, and air be immediately expelled with the steam.

Corrosion undoubtedly results from the use of acid waters (alum springs, mine waters, or streams receiving the waste from chemical manufactures), as well as from waters containing notable amounts of magnesium salts (sea water, western prairie waters, &c.) In the latter case dissociation occurs, basic salts are precipitated, and the liberated acid attacks the boiler plate. Cribb (Analyst, **22**, 169) has shown that magnesium chloride undergoes marked dissociation in solution, when distilled under high pressure. Bailey (this J., 1899, 456) finds that hydrochloric acid does not appreciably volatilize with the steam until a concentration of 1 per cent. is reached. Hence injury to boiler plate will occur long before any acidity is apparent in the steam.

Corrosive qualities can generally be counteracted by the judicious use of soda; but, unless care is taken, there may result a foaming water, nearly or quite as impracticable as the original. Each case of this kind must be studied by itself.

Foaming waters are much more common, and frequently present problems of great difficulty to the chemist. Plateau (Pogg. Ann., 141, 44) has established the fact that foaming is due to increase of viscosity and decrease of surface tension, as well as to the property which he has named "superficial viscosity." It is closely allied to the power of forming emulsions. I have approached the subject from the empirical side, with the object of getting practical guidance in the treatment of feed waters, and have recently published an account of apparatus (Can. Elect. News, Jan. 1904). The following synopsis of results may be given here:—

1. The first general condition which causes foaming is the sudden superheating of the water in the boiler, due to reduction of boiler pressure by drawing off steam.

2. With distilled water, foaming does not result under the conditions named.

3. With a clear space of 1 inch between the water surface and the safety-tube, foaming does not occur with distilled water, even on addition of 500 mgrms. of powdered chalk.

4. When sodium carbonate is in solution in the proportion of 1 grm. per litre, the escaping steam is charged with much water, even though the water in the boiler is quite free from particles of solid matter in suspension.

5. When sodium carbonate is present to the extent of 0·25 grm. per litre, the steam is distinctly wet, but no great amount of water is thrown out.

6. On addition of powdered chalk to the last-named solution, very violent projection of water occurs.

7. All sodium salts that I have tried produced foaming waters, even when the water is clear, when present to the extent of 1 grm. per litre.

8. Sodium salts seem to produce intensity of foaming in the following (decreasing) order:—stearate, carbonate, silicate, sulphate.

9. The presence of solid particles in suspension invariably increases the violence of the foaming.

10. Saturated solution of caustic lime does not foam violently; but the addition of a minute trace of any saponifiable fatty matter causes violent foaming.

11. Fatty matter, in a certain amount, will produce foaming, even if added to distilled water; but a mere trace, having no appreciable effect in the case of a neutral water, causes violent foaming if the water be alkaline either with lime or with soda, but more markedly with the latter.

12. Pectous matter (swamp waters), if at all concentrated, produces foaming, and especially when solid particles are present.

13. Tannin, in small amount, does not seem to cause foaming.

The following practical inferences may be drawn:—

First. The content of sodium salts must be kept down to a minimum. Marked foaming takes place, under 10 lb. pressure, when the soda (Na_2O) reaches 1,500 parts per million. At 200 lb. pressure it is presumable that the foaming limit will be reached at a much lower concentration. Practical men have assured me that no water containing 300 parts of Na_2O per million is fit to make steam with. A concentration of 5 : 1 would bring such a water up to 1,500 parts per million.

Second. Caustic lime in excess will cause foaming in presence of saponifiable fats, which are always present, in traces, in boiler concentrates. Hence the necessity of avoiding excess of lime in water treatment. Of course, this applies still more strongly to the case of caustic soda in excess.

Third. Solid matter in suspension predisposes to foaming. It is impossible that boiler concentrates should be free from suspended matter, but care should be taken to provide a feed water which is clear at first and is of such a character as to deposit a minimum of solid matter on being boiled.

Hillyer's recently published work on soap solutions (J. Amer. Chem. Soc., **25**, 511) corroborates these conclusions.

Since caustic lime and soda are amongst the most available reagents for softening hard waters, it is important to fix a limit of causticity for the resultant water, as well as a limit for its content of sodium salts. I propose the following maxima for causticity (basicity due to free alkali):—

Causticity due to	Limit.	Reasons.
Soda............	10°	Economy of reagent and danger of saponifying fats.
Lime	50°	Same reasons.
Baryta..........	0°	Same, with additional one of preventing poisonous water.

Note.—Degrees of causticity express the causticity to phenolphthalein, in terms of CaO per million.

It is rather a matter for surprise that the quality of foaming in boiler water has received so little attention. Driffield, in 1887, used the following language (this J., 1887, 178): "that tallow be not used for lubricating engine cylinders, if the exhaust steam from the cylinders be used directly to heat the feed water." It is probable that the author had in mind the formation of a special kind of scale, rather than the production of foaming qualities, by saponification. As a matter of fact, a trace of saponifiable fat, incapable of giving trouble in a merely mechanical way, will cause serious foaming in the presence of alkaline water under 200 lb. pressure, and a temperature of 380° F. —the condition usually obtaining in locomotive boilers.

Numberless analyses of boiler scale have been published. These exhibit wide differences of composition, depending upon the character of the water supply, the rate of evaporation, the pressure carried, the attention given to the boiler as regards frequency of blowing-off, cooling before blowing-off, and other conditions. But they all contain calcium and magnesium as sulphate, carbonate, or oxide, to form by much the largest constituents. Silica, iron, alumina, and organic matter make up the balance; although exceptional scales contain small amounts of chlorine and metallic bases. In the sequel I shall consider the conditions under which calcium and magnesium salts can be removed from the water. In their removal, other scale-forming substances are either incidentally got rid of, or are rendered harmless.

With regard to silica, I may say that in the analysis of 130 samples of water, chiefly from the Canadian North-West, the highest dissolved silica I have found is 70 parts per million; and this is altogether exceptional. The usual amounts vary from 10 to 30 parts per million. Headden (Amer. J. Science, 1903, 169) has found the water of mountain streams to be highly charged with silica, derived from the action of carbon dioxide and organic acids on the weathered feldspars of the gathering ground. This silicic acid is removed from solution by combination with lime and magnesia of the lower levels. The following maximum amounts of silica, cited by him, are interesting—

Source.	Total dissolved Solids.	Silica as percentage of Solids.	Silica per million.

Part II.—Methods of Analysis.

In the light of ionisation theory, it is incorrect to speak of salts in solutions, in the ordinary sense. What is really of importance to us, for present purposes, is not the way in which acids and bases are combined in solution, but in what combinations they separate out, under the conditions of steam-making, or of softening processes. The form given to his report by an analyst, should be that which most clearly and simply lends itself to calculations for treatment. On this subject it is interesting to read the comments of such authorities as Fresenius,* Leffmann and Beam,† and A. H. Allen (this J., 1888, 799).

Since lime is now, and is likely to remain, the chief agent in treatment, there can be no difference of opinion about choosing the form in which we handle this article, as the basis of notation. But if we express lime as CaO we must represent the acid radical as the difference between the base and the salt. This requires us to write sulphuric acid as SO_3, &c. Lime is not only the most important substance used in softening water, but is also the most important substance to which hardness is due. For this reason it naturally constitutes the unit in which the hardness of a water should be stated. The German unit is 1 part of CaO per 100,000. The English unit of hardness is 1 part of calcium carbonate per 70,000 (*i.e.*, 1 grain per gallon). It has a historical interest, dating from 1841, when Clark published his celebrated process, together with his soap test for determining hardness. The most convenient unit of hardness, as conforming with our use of metric measures and weights; and further, as avoiding the necessity of using decimal points, is the mgrm. litre unit, or 1 part CaO per million. This is the unit which I employ throughout the following paper. Its magnitude is 1/10th of the German and 1/8th of the English unit.

Although hardness is expressed in terms of lime, it may in reality be due to magnesia. If it be desired to express it in terms of magnesia (MgO) the factor 5/7ths may be used.

If a water which reacts alkaline to phenolphthalein be titrated to neutrality (with this indicator), using decinormal hydrochloric acid, and operating on 100 c.c. of the sample, the required number of c.c. of N/10 acid, multiplied by 28, gives, in terms of CaO per million, what I call the "causticity" of the sample. The fact implied by the term "causticity" need have no reference to lime. It may be due to soda or magnesia, or to the mono-carbonates of these, or other, bases. Owing to the limited solubility of some of these substances, it cannot exceed a certain maximum in their case. Thus the maximum causticity for magnesium hydroxide is 20° (Macnab and Beckett, this J., 1886, 267); for calcium hydroxide is about 1,800°; for magnesium mono-carbonate is about 175°, and for calcium mono-carbonate about 30° (Thorp, this J., 1888, 804). Magnesium carbonate is much more soluble than the hydroxide. If, however, calcium be present as hydroxide, magnesium cannot be present as carbonate; so that the maximum causticity due to magnesia, in the presence of lime, is 20°. Soda, in a similar way, is incompatible with magnesium carbonate. If, therefore, lime is absent, and the causticity exceeds 20°, the excess must be due to soda, f soda is present.

The analysis of water for purposes of softening is, of course, to be distinguished from analysis for strictly scientific purposes. Pfeifer (Zeits. Angew. Chem., 1902, 193) has ridiculed certain elaborate analytical results, which nevertheless, failed to furnish him with the data he wanted for calculating treatment. When the general character of a supply is known, very simple analytical operations suffice for guidance in treatment. Seasonal changes are to be looked for; but these are more likely to involve variations in the absolute, than in the relative amounts of substances in solution. It is quite unusual for a supply rich in lime at one period of the year to become decidedly magnesian at another period.

In the first examination of a water sample, it is, however, desirable to learn all that we can about it.

Hardness.—This determination has quite recently been discussed by Procter (this J., 1904, 8). The soap test, originally described by Clark in 1841, has now passed into ancient history; although I find that Winckler (Zeits. anal. Chem., 1901, 82), has described a modernised form of it, using pure potassium oleate, instead of ordinary soap. Grossman (Chem. News, 1879, 258), Hehner (Analyst, **8**, 77), Allen (this J., 1888, 796), Leeds, and many others have demonstrated its shortcomings.

Hehner (*loc. cit.*) was one of the first to suggest a more rational method of determining hardness. Before describing this method, in its present form, it is necessary to consider the modes in which carbon dioxide exists in water.

Carbon Dioxide.—This exists in most natural waters in three conditions, viz., fully-bound, half-bound, and free. By fully-bound, is meant that which is combined with bases to form normal or mono-carbonates. Thus 62 Na_2O; 56 CaO; 40 MgO or 153 BaO combine with 44 CO_2 to form respectively 106, 100, 84, and 197 parts of the corresponding mono-carbonate. The solubility of the bases named is increased by excess of carbon dioxide, except in the case of soda. The maximum solubility of the other three is reached when for 56 CaO, 40 MgO or 153 BaO, 88 parts CO_2 is present. The bicarbonate is then said to be in solution. These bicarbonates have not been obtained other than in solution, except in the case of soda.

All the monocarbonates react alkaline to phenolphthalein, and, although with the exception of sodium carbonate they are only soluble in very limited amount, the reaction is easily appreciable. The bicarbonates are neutral to phenolphthalein. Towards certain indicators, such as Methyl Orange, Erythrosin (this J., 1891, 856), &c., they react more or less like the free base. The monocarbonates are quite permanent as solids, as well as in solution, under ordinary conditions. Bicarbonates in solution are by no means stable. If the solution is violently shaken, more or less carbon dioxide goes off and a corresponding amount of monocarbonate is formed. If this is in excess of the solubility of the monocarbonate, the excess is precipitated. The solubility of the carbonates in question is approximately as follows:—

Substance.	Parts per million.	
	Monocarbonate.	Bicarbonate.
Sodium carbonate	200,000	90,000
Calcium „	*30	900
Magnesium „	175 +	1,320 +
Barium „	70	?

* Thorp.—This J., 1888, 804.

Archbutt (this J., 1891, 515) prepared a solution of magnesium bicarbonate containing 4,890 parts of magnesia per million. Such a solution could only be kept constant under pressure, or under a continuous current of carbon dioxide.

It follows that in a solution of carbonates which reacts neutral to phenolphthalein only bicarbonates can be present. The combined carbon dioxide exists half in the fully-bound, and half in the semi-bound state. By titrating 100 c.c. of

---

* "Quantitative Analysis" (Grove's Transl.) Vol. II., 171.
† "Examination of Water, &c." p. 70.

such a water with decinormal acid in presence of an indicator not affected by carbon dioxide, the amount can be determined.

If v = c.c. N/10 acid used in titrating 100 c.c. sample to neutrality (phenolphthalein).

If w = c.c. N/10 acid used in titrating 100 c.c. sample to neutrality (methyl orange) after phenolphthalein.

(17) CO_2 in monocarbonate = 22 v. Formula 17.

(18) „ „ bicarbonate = 44 w. Formula 18.

(19) Total combined $CO_2 = 22\ (v + 2\ w)$. Formula 19.

Besides the carbon dioxide which is combined with bases as mono- or bi-carbonates, most natural waters contain it in the free state. Although carbon dioxide constitutes only four parts in 10,000 of our atmosphere, it is much more soluble than the other constituents.

This dissolved carbon dioxide is even more readily expelled from solution than the half-bound, so that if a carbonated water is vigorously shaken, it will lose the whole of its free acid. When shipped for analysis, unless especial care has been taken to quite fill the container, and to properly cork it, the free carbon dioxide is lost through the shaking incident to transportation. The only safe way to estimate free carbon dioxide in water is, therefore, to make the determination on the spot.

Direct estimation by use of decinormal sodium carbonate solution was suggested by Leeds (J. Amer. Chem. Soc., 1891, 98). The process has lately been examined and favourably reported on by Ellms and Beneker (J. Amer. Chem. Soc. 1901, 405). Vignon and Meunier (this J., 1899, 865) describe a somewhat similar method, in which they use alcohol, and work to a standard depth of colour. An indirect method, described by Forbes and Pratt (J. Amer. Chem. Soc., 1903, 747), and ascribed to Dr. Brown, depends upon the separate estimation of total and fixed carbon dioxide.

So far as my observation goes, the free carbon dioxide in natural waters varies from a trace to about 300 parts per million. I have also found that, although excellent duplicates may be obtained at the time, the amount found in solution at intervals of a few weeks, varies greatly. It is certain that in the case of sparkling waters, the amount of free carbon dioxide held in solution is influenced by rainfall, temperature, and other conditions. I am convinced that the unsatisfactory results so often observed in water treatment, are largely due to a failure to take account of the part played by free carbon dioxide.

The earliest mention of free carbon dioxide as affecting treatment, I find in a paper by Macnab and Beckett (this J., 1886, 267). The authors say: "An excess of carbonate of soda must be used, because of free carbon dioxide in the water. The resultant water contains excess of alkali, which is objectionable for many purposes." They recommend the use of caustic soda, which takes up this free carbon dioxide, and then acts as sodium carbonate in softening the water. Lawrence (this J., 1891, 624) patented this same reaction in 1890, as a means of providing sodium carbonate to reduce permanent hardness. Koyl (this J., 1901, 830) recently obtained a patent in England, covering the use of lime in excess, as a means of neutralising the free carbon dioxide in water.

Free carbon dioxide is so easily got rid of by mere agitation—as by paddles, or by blowing air or steam through—that the addition of chemicals cannot be justified. The addition of lime produces unnecessary sludge, while the use of soda produces carbonate, which we have seen to be a main cause of foaming. If the water be of a kind to which sodium carbonate must be added for reduction of permanent hardness, it might, at first sight, seem plausible to urge that the carbonate produced in this way could be utilised for precipitation of calcium sulphate. But when we consider the prices at which caustic soda and sodium carbonate are sold, the speciousness of the plea is apparent.

The best and cheapest way of getting rid of free carbon dioxide is by agitation. For this purpose the mixing apparatus, needed in any plant, will suffice. The resultant water is in carbon dioxide equilibrium, and the proper quantities of reagents can be calculated with certainty.

Hardness.—A water is said to be hard when it contains more than 7 grains of mineral matter per gallon (Maignen, this J., 1866, 324), that is, 100 parts per million. The terms permanent and temporary have reference to whether or not the hardness persists after boiling the water. Permanent hardness is generally due to the presence of calcium or magnesium sulphates, or to magnesium carbonate. Temporary hardness is due to calcium bicarbonate. Sodium sulphate or chloride may be quite largely present in either kind of hard water. Sodium bicarbonate may exist along with temporary, or with some forms of permanent, hardness, but, although it may exist in cold solution along with calcium sulphate, these salts are not generally found together in natural waters. Flow over stones, change from higher to lower pressure, rise of temperature, and other causes, bring about loss of carbonic dioxide, and the resulting sodium carbonate enters into reaction with calcium sulphate, so that finally sodium sulphate is found in solution, and calcium carbonate is precipitated. Magnesium carbonate is fairly soluble, and is not precipitated by sodium carbonate; but experience shows that when magnesia and soda are both present in natural waters, these contain high sulphates or chlorides, or both sulphates and chlorides, and the soda remains in solution, when the water is concentrated by boiling, combined as sulphate or chloride.

In the following table, which gives analytical data for natural waters high in sodium salts, the waters of Group I. contain but little scale-forming material, and the soda remains, at least partly, in solution as carbonate, on concentration.

Waters of Group II., containing high sulphates and low chlorides, yield solution of sodium sulphate on concentration. Those of Group III. give sodium chloride under similar conditions.

Determination of Temporary Hardness.—On titrating 100 c.c. with N/10 hydrochloric acid, the number of c.c. of acid used (Methyl Orange as indicator) is a measure of the bases existing as carbonates, and may be interpreted in terms of lime (CaO). This number is called the "alkalinity" of the sample.

$$(2)\ \text{"Alkalinity"} = A = 28\,(w + v).\quad \text{Formula 2}$$

(see table at end of paper, page 357, and page 354.)

In the absence of sodium carbonate this number is identical with the temporary hardness. If the sodium carbonate is present, it will be included in the alkalinity, and this number will be correspondingly larger than the true temporary hardness.

The true temporary hardness (Ht) is obtained by subtracting the permanent hardness (Hp) from the total hardness (H): $Ht = H - Hp$.

Total Hardness.—After titrating with N/10 hydrochloric acid, the whole of the bases exist as permanent hardness. If a proper precipitant is now added, in sufficient quantity, the lime and magnesia may be thrown out of solution, up to their limit of solubility. The most convenient reagent for this purpose is a decinormal solution of soda, in which half the soda is present as carbonate and half as hydroxide. It is advisable to use it in distinct excess of the theoretical quantity required. The solution is only one-twentieth normal from the point of view of precipitating either lime or magnesia since the object is to throw down the first as carbonate and the second as hydroxide. It is also of importance to remember that the carbon dioxide liberated in the "alkalinity" determination must be boiled off, before adding this carbonate-hydroxide mixture (of which I shall hereafter speak as "soda-reagent"), as otherwise the hydroxide in it will be more or less fully converted into carbonate.

The following equations explain the action of the "soda-reagent." The terms "neutral" and "alkaline" have reference to behaviour with Methyl Orange:—

$$(1)\ \underset{\substack{\text{neutral}\\ 56,\ 80}}{\mathrm{CaO, SO_3}} + \underset{\substack{\text{alkaline}\\ 62,\ 44}}{\mathrm{Na_2O, CO_2}} = \underset{\substack{\text{neutral}\\ 62,\ 80}}{\mathrm{Na_2O, SO_3}} + \underset{\substack{\text{precipitated}\\ 56,\ 44}}{\mathrm{CaO, CO_2}} \qquad \text{Alkalinity lost.}$$

$$(2)\ \underset{\substack{\text{neutral}\\ 40,\ 80}}{\mathrm{MgO, SO_3}} + \underset{\substack{\text{alkaline}\\ 62}}{\mathrm{Na_2O}} = \underset{\substack{\text{neutral}\\ 62,\ 80}}{\mathrm{Na_2O, SO_3}} + \underset{\substack{\text{precipitated}\\ 40}}{\mathrm{MgO}} \qquad \text{Alkalinity lost.}$$

$$(3)\ \underset{\substack{\text{neutral}\\ 56,\ 88}}{\mathrm{CaO\ (CO_2)_2}} + \underset{\substack{\text{alkaline}\\ 62}}{\mathrm{Na_2O}} = \underset{\substack{\text{alkaline}\\ 62,\ 44}}{\mathrm{Na_2O, CO_2}} + \underset{\substack{\text{precipitated}\\ 56,\ 44}}{\mathrm{CaO, CO_2}} \qquad \text{Alkalinity unchanged.}$$

$$(4)\ \underset{\substack{\text{neutral}\\ 40,\ 88}}{\mathrm{MgO\ (CO_2)_2}} + \underset{\substack{\text{alkaline}\\ 2\,\times\,62}}{\mathrm{2NaO_2}} = \underset{\substack{\text{alkaline}\\ 2\,(62\,+\,44)}}{\mathrm{2\ Na_2O, CO_2}} + \underset{\substack{\text{precipitated}\\ 44}}{\mathrm{MgO}} \qquad \text{Alkalinity unchanged.}$$

The first and second equations show that when the "soda-reagent" is added to a neutral solution of lime or magnesia as sulphates (or chlorides) the earthy bases are precipitated, and a proportional loss of basicity appears. The operation is conveniently performed on 100 c.c., and the liquid boiled. It is then cooled, made up to 200 c.c., and 100 c.c. of the filtrate is titrated back. From the loss of basicity the bases (lime and magnesia) are calculated as follows:—

If Q^1 = volume of "soda-reagent" added
and r^1 = c.c. of N/10 acid used in titration

$$(3)\ H = 28\,(Q^1 - 2\,r^1).\quad \text{Formula 3.}$$

Equations (3) and (1) show that when "soda-reagent" is added to a neutral solution of lime or magnesia as bi-carbonates, the whole of the lime or magnesia is precipitated, but the alkalinity remained unchanged. In this case the caustic soda component of "soda-reagent" is alone affected: and for each equivalent of caustic soda that disappears, an equivalent of carbonate of soda is formed, which last behaves like caustic soda towards Methyl Orange.

Permanent Hardness ($= Hp$) is directly determined by treating 100 c.c. of the sample (neutral to phenolphthalein) with an excess of "soda-reagent," boiling a few minutes; cooling; making up to 200 c.c., and titrating back to 100 c.c. If Q^2 represent the volume of "soda-reagent" used and r^2 the volume of N/10 acid used in titrating back, then—

$$(4)\ Hp = 28\,(Q^2 - r^2).\quad \text{Formula 4.}$$

True temporary hardness ($= Ht$) is the difference between total hardness (H) and permanent hardness—

$$(20)\ Ht = H - Hp.\quad \text{(Formula 20.)}$$

In most natural waters this quantity is identical, or nearly so, with the "alkalinity." Where "alkalinity" exceeds "temporary hardness," this is due to the presence of carbonate of soda—

$$(21)\ \underset{\substack{\text{(naturally}\\ \text{present)}}}{\mathrm{Na_2CO_3}} = \frac{53}{28}\,(A - Ht).\quad \text{(Formula 21.)}$$

From equations on page 20, it may be seen that (working on volumes of 100 c.c.) we need 0·07 c.c. "soda-reagent" for each 1 part per million of lime; 0·10 c.c. "soda-reagent" for each part magnesia existing as sulphate (or chloride); 0·20 c.c. "soda-reagent" for each part magnesia existing as bi-carbonate. In practice we must allow about 50 per cent. excess of "soda-reagent"; and duplicate estimations, using different volumes of "soda-reagent," should always be made.

Lime and Magnesia.—The number for total hardness gives us the sum of lime and magnesia, expressed in terms of CaO. Several methods of distinguishing the amount of each base are in use.

First Method.—Pfeifer (Zeits. angew. Chem., 1902, 193) adds a standard lime water in excess. This precipitates magnesia, with corresponding loss of alkalinity and phenolphthalein, since an equivalent of lime is precipitated as carbonate.

Second Method.—Depends (d'Auseline, Bull. Soc. Chem., **29**, 14) upon the fact that ammonium chloride prevents the precipitation of magnesia by "soda-reagent."

Third Method.—Depends upon the precipitation of lime only, by standard solution of oxalate of ammonia. The excess of this solution is determined by a back titration with standard permanganate.

Fourth Method.—I prefer to precipitate the lime with ammonium oxalate; to wash the precipitate with boiling water till free from oxalic acid; dissolve it from the filter with sulphuric acid, heat and titrate with N/10 permanganate. I have checked this mode of working, and find it quite accurate. If the operation is performed on 250 c.c. of the sample, and k = c.c. N/10 permanganate used—

$$\mathrm{CaO}\ \text{(per million)} = 11{\cdot}2\,k.\quad \text{(Formula 19.)}$$

Soda.—The most convenient way of estimating the total soda is the sulphating of the residue obtained by evaporating to dryness a known volume of the sample in platinum. The method (recommended by Fresenius) has been adversely criticised by Rössing (Zeits. Anal. Chem., **36**, 359), but the critic himself points out that by using ammonium carbonate in the solid state, the excess of sulphuric acid may be got rid of without entailing serious loss. If notable amounts of silica, iron, or alumina are present, suitable modifications must be made, but for ordinary waters the sulphated residue may be considered as normal sulphates of lime, magnesia, and soda.

Sulphuric Acid.—A volumetric method for determining sulphuric acid in presence of benzidine chloride has been described by Wolf Muller (Ber., 1902, 1587), and is highly spoken of by Procter (this J., 1904, 8). The gravimetric method, as barium sulphate, is the only one that I can recommend from experience.

Hydrochloric Acid.—Is easily determined by the silver nitrate method, with chromate indicator, or by the method of Volhard.

Methods for determination of silica, iron, alumina, and organic matter, when necessary, are too well known to need description here.

In order to learn fully the nature of a new supply, a full analysis must be made. When the general character is known, and a decision as to treatment made, very simple analytical operations suffice to furnish data for the calculations as to quantity of reagents.

Part III.—Treatment.

So long as lime was the only reagent used in softening water, the silver test described by Clark in 1841 answered the purpose of fixing the minimum of lime to be added, and gave an approximate indication for a maximum. Modern methods of treatment generally involve the use of at least two reagents, and simple tests for carrying out treatment are not available. Makers of apparatus for effecting treatment on the large scale frequently supply elaborate testing vessels, guaranteed to furnish the workmen with all needful information as to the progress of the softening. I have had opportunity of examining some of these, and find them quite misleading. If sufficiently delicate to give any useful information, they require greater nicety of manipulation than can be expected from ordinary labourers; and, if sufficiently strong to meet this requirement, their indications are too vague to have any value. Their most important failure, however, results from the assumption that the changes we aim at producing in the water take place immediately, and that the character of the water as it will be fed to the boiler is identical with that which it possesses a few minutes after the reagents are mixed with it. The fact is that in dilute and cold solutions the chemical changes desired are very slowly brought about, and time is a most important factor in treatment.

A compound treatment can best be carried out by adhering as closely as possible to a prescription, resulting from careful study of the supply. It is possible from time to time, by means of simple tests, to ascertain the quality of the resultant water; and such tests should be applied as often as convenient. Every natural supply undergoes periodic changes, and some supplies suffer cataclysmic change. This is specially true of small supplies. But these variations soon come to be well known, and can even be predicted, as statistics accumulate. Determinations of causticity, alkalinity, and total hardness are simple and easy, and I know of no simpler or more practical way of learning the satisfactory character of water in process of treatment.

Mono-carbonate of lime is soluble in water to the extent of 20 parts CaO per million, *i.e.*, 20°. Magnesia is soluble to the extent of 17°. Since these are the forms in which lime and magnesia are precipitated, we need not expect to reduce the lime hardness below 20°, nor the magnesia hardness below 17°. Where both these bases are present, the minimum hardness will be about 37° (= 4·5 English degrees).

Schierholz asserts (Chem. Centralbl., 1901, 139) that an excess of 50—80 parts of lime per million, and 100—200 parts of soda ash, effect a still more complete removal of lime and magnesia. Of course, the extra costs of reagents would prohibit the employment of such excess, even if the resultant causticity of the water were unobjectionable.

Reagents.—The following list of substances which have been proposed for use in softening water makes no pretence to completeness; still less is it intended to concede any high degree of efficiency to many of them. The fact that their cost makes it impossible to use them on the large scale is sufficient to make them unimportant for our purpose.

The reagents, which on the ground of cheapness and efficiency, are available for our purpose, are quick-lime, soda-ash, and caustic soda. It is sincerely to be hoped that barium, as hydroxide or oxide, may become available in the near future, as it would supply a real need. Many natural waters, especially those of our western prairies, contain so much soda that the further addition of this substance produces a foaming water. These waters are at the same time high in lime and magnesia sulphates. The United Barium Company of Niagara Falls, is, I believe, prepared to supply barium oxide, of 90 per cent. purity, at 3 cents a pound. The high combining weight of barium makes the article too costly to be extensively used at this figure.

Caustic Lime.—When made from calcite, may contain 95 per cent. of lime, or even more; but most limestones contain silica, magnesia, and other impurities, so that it is not unusual to find samples containing less than 70 per cent. of real lime. It deteriorates appreciably on exposure to air, absorbing water and carbonic acid. It is applied either in solution as lime water, or, in the dry state, is weighed in.

Lime Water.—Water dissolves from commercial lime only such portion as is valuable for softening water; the magnesia, clay, and unburnt carbonate remaining undissolved. On this account, as well as because a saturated solution of lime has (theoretically) a definite composition, the employment of this reagent in the form of saturated lime water, would seem to be far away preferable to the method of weighing in. In practice, however, difficulties occur which counterbalance apparent advantages. The chief difficulty is in saturating the lime water, or in so conditioning it as to produce a lime water of constant strength.

According to Wittstein, a saturated solution, at ordinary temperatures, should contain 1,040 parts of lime per million. Macnab and Beckett (this J., 1886, 267) claim for the Stanhope purifier, that it furnishes a solution containing 1,000 parts of lime per million. The Devereux apparatus is claimed (Zeits. angew. Chem., 1902, 206) to produce a solution containing 1,100 parts of lime per million. Vignon and Meunier state (this J., 1899, 865) that a saturated lime water should contain 1,360 of lime per million. I prepared nine solutions by shaking water with excess of lime for three hours (mechanical shaking), and obtained solutions containing from 1,120 to 1,344 parts of lime per million. In most of the automatic apparatus, the lime water is made by causing a small stream to flow continuously through a long cylinder in which slaked lime is suspended. Since the rate of flow varies, the strength of the solution must vary, and it can never be truly saturated.

Another obvious advantage of the use of lime water is the fact that the lime is applied in true solution. The importance of this condition cannot be over-estimated, and when lime is applied in any other way than as clear lime water, we must furnish means of ensuring true solution in the water being treated. This means, of course, vigorous and prolonged agitation, either by paddles, or by a current of air or steam.

Weighing-in.—Owing to the uncertainty of the strength of lime water made by any continuous process, as well as to the large and costly apparatus needed for its preparation and use, the weighing-in method of working has much in its favour. Of course the workman in charge must know the real strength of his lime. This may be furnished to him by the chemist, or he may himself determine it very easily by the following apparatus.

A stock bottle containing hydrochloric acid of 1:8 strength, to which phenolphthalein has been added, is fitted with a burette reading centimetres. The burette should be attached to the bottle, and arranged so as to be filled by pressing a rubber bulb. The upper end of the burette is loosely covered by a glass cap. Acid of the strength given is such that 100 c.c. exactly suffice to neutralise 5 grms. of lime. An apothecary's scale and a 5-grm. weight are wanted, together with a few boiling flasks and a lamp; this s the whole outfit, although it may be well to furnish a mortar and a sieve for use in preparing the sample.

If the chemist has reported the lime to contain 85 per cent. of lime, and it is desired to know whether any deterioration has taken place, the workman runs 85 c.c. of he acid into a boiling flask, dilutes and adds 5 grms. of his (properly prepared) sample. On prolonged boiling, to complete solution, the red colour of phenolphthalein should persist. If it does not do so the sample has deteriorated, and the operation is repeated with 84 c.c. or less, until the colour persists. The number of c.c. used in the final est, gives directly the percentage strength of the sample.

The lime furnished to a given station is usually obtained from a single source, and the relative content of magnesia s once for all determined by the chemist, but need not be known to the workman, who uses his lime on a basis of its causticity.

Uses of Lime.—Lime is used to neutralise the half-bound carbon dioxide in bi-carbonates, thus causing the precipitaion of all lime existing as carbonate, except 30 parts per million, and of all magnesia existing as carbonate, except 175 parts per million; these numbers representing the solubilities of the mono-carbonates in pure water. Under special conditions, lime may be used to precipitate magnesia as oxide (hydrate), but caustic soda is a more efficient precipitant. Lime is often used, along with soda ash, to effect the liberaon of caustic soda *in sitû.* In this case the lime is recipitated as mono-carbonate, and is added to the sludge. The only reason for working with carbonate of soda and me, instead of with caustic soda directly, is cheapness. Caustic soda is now quoted in Montreal (on a basis of 90 per cent. oxide) at 4 cents a pound (Na_2O), and soda ash on the same basis) at 2 cents. Against this first cost must e set the facts (1.) that more sludge has to be removed 2.) that the reaction between soda ash and lime is never mplete in the cold (Macnab and Beckett, this J., 1886, 267), whence results a waste of soda ash, an incomplete precipitation of magnesia, and an undesirably caustic water. When all is considered, it may be that less real difference of cost exists than would at first appear.

Soda Ash.—Seems to have been known as an efficient softener of hard water since 1823, when Muspratt established the soda industry in England. Soda ash is used to precipitate lime from compounds like the sulphate and chloride; and also to furnish caustic soda, by interaction with caustic lime, as already explained.

Caustic Soda.—This is the best precipitant for magnesia. It is available for neutralising the half-bound carbon dioxide, but is less desirable for this purpose than lime, by reason of its greater cost and the fact that it leaves carbonate of soda in solution. When this substance (carbonate of soda) is required for reduction of permanent hardness, it is cheaper to supply it as soda ash than to produce it by the carbonating of caustic soda.

Occasions, however, do arise in which the use of caustic soda is preferable to any other treatment. These must be regarded as exceptional. Schreif (Zeits. angew. Chem., 1892, 514) asserts that a slight excess of caustic soda does no harm to the boiler.

Barium hydrate has not found extensive application, by reason of its cost. At 3 cents a pound, for 90 per cent. purity, it is three and a half times as expensive as caustic soda at 4 cents. It is to be hoped that improvements in manufacture, may reduce the cost to about 1 cent. per pound. Its special advantage is in the fact that hardness can be reduced without increasing the content of soda salts in the supply. Some experimental work with a view to determining the most economical way of applying barium oxide (or hydrate) is given in the fourth part of this paper.

A supplementary treatment with carbon dioxide has been recommended by Archbutt and Deeley (this J., 1891, 511) for the purpose of converting colloid hydrate of magnesia into carbonate. This colloid substance, they state, is immediately deposited when the water enters the boiler, choking the nozzle of feed-pipe or injector. By carbonating the water (for which purpose the authors have patented a special apparatus) this objection is successfully met. A carbonating device has more recently been patented by Lawrence (this J., 1893, 171). I have no knowledge of the difficulty complained of, and find that efficient agitation ensures a satisfactory precipitation of magnesia.

Formulas for use in calculating treatment are readily deducible from the equations already given. Comprehensive formulas, intended to be of general applicability, have been published by Kalmann (this J., 1890, 1065), Pfeifer (Zeits. angew. Chem., 1902, 193), and others. It is evident that no formula can be universally applicable if best results are sought. The real difficulty is less in finding how much lime or soda is wanted to effect a given reaction than in deciding what reactions should be brought about in a given case.

No.	Wanted.	Given.	Formula.	No.
1	"Causticity" = a	v	$a = 28\,v$.	1
2	"Alkalinity" = A	w, v	$A = 28\,(w + v)$.	2
3	Total hardness = H	Q^1, r^1	$H = 28\,(Q^1 - 2\,r^1)$.	3
4	Permanent hardness = H_p	Q^2, r^2	$H_p = 28\,(Q^2 - 2\,r^2)$.	4
5	Lime (CaO) to neutralise free CO_2 = C	C	$CaO = 1{\cdot}273\,C$.	5
6	Lime (CaO) to neutralize the half-bound CO_2	c	$CaO = 0{\cdot}637\,c$.	6
7	Lime (CaO) equivalent of the magnesia	M	$CaO = 1{\cdot}4\,M$.	7
8	Lime (CaO) to reduce H_t	G, $\frac{1}{2}\,c, m$	$CaO = 1{\cdot}273\,(C + \frac{c}{2}) + 1{\cdot}4\,m$.	8
9	" " " H_t	A, a, m	$CaO = 28\,(A - a) + 1{\cdot}4\,m$.	9
0	Caustic soda (Na_2O) to replace CaO in treatment	CaO	$Na_2O = 1{\cdot}107\,CaO$.	10
1	Soda ash (Na_2CO_3) to precipitate magnesia (must be used with lime as in P. 7).	M	$Na_2CO_3 = 2\,65\,M$.	11
2	Soda ash, to reduce the permanent hardness	H_p	$Na_2CO_3 = 1{\cdot}893\,H_p$.	12
3	Baryta (BaO) to precipitate sulphuric acid	SO_3	$BaO = 1{\cdot}912\,SO_3$.	13
4	Carbon dioxide in monocarbonates	v	$CO_2 = 22\,v$.	14
5	" " bicarbonates	w	$CO_2 = 44\,w$.	15
6	Total combined CO_2	v, w	$CO_2 = 22\,(v + 2\,w)$.	16
7	True temporary hardness	H, H_p	$H_t = H - H_p$.	17
8	Sodium carbonate (Na_2CO_3) naturally present	H, H_t	$Na_2CO_3 = \frac{53}{28}\,(A - H_t)$.	18
9	Lime present, per million	k	$CaO = 11{\cdot}2\,k$.	19

The following formulas give the number of parts per million for the reagents named. They may be interpreted as pounds per 1000 galls. by moving the decimal point two places to the left.

a = "causticity" (*i.e.*, alkalinity to phenolphthalein) as CaO.

A = "alkalinity" (*i.e.*, alkalinity to methyl orange) as CaO.

$(A - a)$ = bi-carbonates, in terms of CaO. (In normal waters $a = 0 \therefore (A - a) = A$.)

H = total hardness in terms of CaO.

H_p = permanent, in terms of CaO.

$(H - H_p) = H_t$ = temporary, in terms of CaO.

C = free carbonic acid, in terms of CO_2.

c = combined carbonic acid, in terms of CO_2.

$\frac{1}{2}c$ = fully-bound = half-bound, in terms of CO_2.

v = c.c. N/10 acid used in titrating 100 c.c. to phenolphth.

w = c.c. N/10 acid used in titrating 100 c.c. to methyl orange, after making neutral to phenolphth.

M = total magnesia, in terms of MgO.

m = magnesia of temporary hardness.

$(M - m)$ = magnesia of permanent hardness. (Where H_p is large, $m = 0 \therefore (M - m) = M$.)

Q^1 = c.c. "Soda Reagent" used with 100 c.c. sample in determination of H (see p. 21).

Q^2 = c.c. "Soda Reagent" used with 100 c.c. sample in determination H for H_p (see p. 21).

r^1 and r^2 = c.c. N/10 acid used in titrating back 100 c.c. from a total volume of 200 c.c (see p. 21).

K = c.c. N/10 permanganate in CaO estimation (as on p. 22).

MR. J. T. WOOD IN THE CHAIR.

THE SOLUBILITY OF ATMOSPHERIC OXYGEN IN SEA-WATER AND IN WATER OF DIFFERENT DEGREES OF SALINITY.

BY FRANK CLOWES, D.Sc., AND J. W. H. BIGGS.

Introductory.—It is usual to measure the injurious effect produced by sewage and by other deoxidising refuse liquids upon the water of rivers, of estuaries and of the sea, by ascertaining the extent to which the dissolved atmospheric oxygen of the water has become reduced in amount by the action of these foreign liquids. The reduction in the amount of dissolved oxygen is not only a measure of the proportion of reducing matters present in the water, but also a measure of the extent to which the pollution is dangerous in restricting or preventing the respiration of fish.

The amounts of dissolved oxygen found in polluted water are usually calculated as percentages of the maximum possible under the conditions of the determination.

The determinations, the results of which are recorded in this paper, were made with the view of establishing standard percentages of aeration for estuary waters of varying salinity. The standard for sea-water is well known to be about 20 per cent. lower than that for distilled water under similar conditions; but it does not appear that determinations have been made for water intermediate in salinity between sea-water and fresh water.

Method of Determination.—The method selected for determining the aeration of the water was that of Winkler ("Die Bestimmung des im Wasser gelösten Sauerstoffes"; Ber. der deutschen Chem. Gesellsch., 1888, p. 2851). This method is more easily carried out than those of Bunsen and of Schutzenberger, and is free from the inaccuracies of the original method of Mohr.

In collecting the sample of water, care must be taken to avoid agitating it and exposing it for any length of time to the air. It is transferred with similar precautions by siphoning to a stoppered bottle of known capacity which can contain about 300—400 c.c. About 1 c.c. of strong manganous chloride solution (containing about 40 grs. $MnCl_2.4H_2O$ per 100 c.c.) is added, followed by 2 c.c. of a solution containing 33 per cent. of alkaline hydroxide and 10 per cent. of potassium iodide. The bottle, which must be full of liquid, is now closed with the stopper without including any air-bubble, and the liquids are mixed by several times inverting the bottle. The manganous hydroxide precipitate which forms will be more or less discoloured by higher hydroxide according to the proportion of oxygen which was dissolved in the water sample. Since the oxidation of the manganous hydroxide is not immediate, and the action of light influences the result, the bottle is put by in the dark for about 15 minutes; its contents are then acidified with from 2 to 3 c.c. of strong, pure hydrochloric or sulphuric acid. The acid causes the precipitate to disappear, and leaves the liquid coloured with dissolved iodine. The iodine is titrated with standard thiosulphate, of which the oxygen value should be known so as to give the amount of oxygen directly. It is usual, however, when possible, to determine the amount of thiosulphate required in the above process by the same volume of the fully aerated unpolluted water of similar character or of distilled water, and then to calculate the percentage of the possible amount of oxygen present in the polluted water directly from the amounts of thiosulphate which equal volumes of the two samples require.

It is noteworthy that the manganous chloride used in the process must be free from iron. All reagents must also be free from nitrite, and accordingly the alkaline solution when mixed with starch solution and potassium iodide must not yield an immediate blue colour when it is acidified with the strong acid. Probably potassium hydroxide is more frequently free from nitrite than sodium hydroxide.

Amounts of Atmospheric Oxygen dissolved by mixtures of distilled with Sea-water, stated as approximate percentages of the amount dissolved by distilled Water under similar conditions.

Sea-water	78·7	1,950	81·1	1,950	82·2	1,950

Results obtained with waters of different salinity, distilled water being the standard.—The early experiments showed that the following procedure was the most simple for avoiding errors from differences of temperature, from super-saturation with oxygen and from suspended air bubbles. Both samples were allowed to attain the temperature of the laboratory, and were then saturated with atmospheric oxygen by frequent agitation with fresh portions of air; they were then allowed to stand overnight at the laboratory temperature in a cool incubator, to cause the suspended air bubbles to separate completely; this interval was especially necessary in the case of sea-water, which froths when it is shaken. Three determinations were made of each water sample, and they showed fair agreement. Thus in a particular case the three separate estimations in the same sample of sea-water gave the following percentages of the oxygen dissolved by distilled water under the same conditions, 83·3, 82·9, 82·9.

The amount of oxygen dissolved in sea-water shows a gradual increase for some time when the same sample is repeatedly shaken with air at intervals of some days. The natural inference is that the sea-water contains either oxidisable matter or organisms which remove oxygen, and that its maximum power of solution is therefore only attained when these deoxidising agencies are removed. The results tabulated indicate the extent to which this deoxidation occurs, since by further prolonging the period no higher aeration was attained. The same sea-water was used throughout these experiments, and a fresh portion was diluted for each test.

It will be seen that the approximate percentage of sea-water in the mixture of distilled water with sea-water is stated in the first column, and that the amount of chlorine as chloride was also determined in each mixture.

These results show that the solubility of atmospheric oxygen diminishes regularly with the proportion of sea-water present.

An experiment was made by dissolving sufficient sodium chloride in distilled water to give chlorine approximately equivalent to that present in sea-water, and the amount of atmospheric oxygen dissolved both by the original distilled water and by the salt solution under similar conditions was then determined. The salt solution with a chlorine content of 1,930 per 100,000 dissolved 82·9 per cent. of the amount of oxygen dissolved by the distilled water; the corresponding percentage for sea-water containing 1,950 parts of chlorine was 82·2. From this result it would appear that the sodium chloride in the sea-water is he constituent which determines its power of dissolving tmospheric oxygen.

Discussion.

Mr. F. R. O'**Shaughnessy** said he took it that the modified results were not the outcome of chemical action bsolutely but were chiefly owing to a physical one. At Birmingham the greatest variation was found in the amount f dissolved oxygen in effluents and river water. He hought that the case of sea-water was an extreme one, nd that the results obtained from effluents of the river as odified by the amount of saline matter present must be a egligible quantity.

Dr. **Caven** said it was interesting to note that the presnce of inorganic salts reduced the solubility of oxygen. t was the inorganic matter rather than any possible organic atter, which prevented the full complement of oxygen eing present.

Mr. **Ward** said that the amount of carbon dioxide ssolved in water was very considerably affected by the esence of salts. Was the salt used in the distilled water a salt or common salt?

Dr. **Clowes** said that the aeration experiments were rried out on the lower reaches of the Thames, and were tended into the North Sea. He was surprised to find at when they entered the estuary the water samples never owed 100 per cent. aeration as compared with distilled ter. He was quite certain that this water had not been oxidised by any sewage pollution. In the open sea nilar results were obtained. In working with salt water it was found impossible to get 100 per cent. aeration when distilled water was the standard. In working with common river water, however, unless it was largely salted by the sea, they were able to get 100 per cent. aeration. As regards the nature of the reducing matter present in sea water he had evaporated some years ago samples of sea water and made an organic combustion of the residue in order to determine the amount of carbon and nitrogen which it contained, and he was surprised at the high results obtained. The carbon and nitrogen might have been derived from either living or dead organic matter, possibly it was the de-aerating matter.

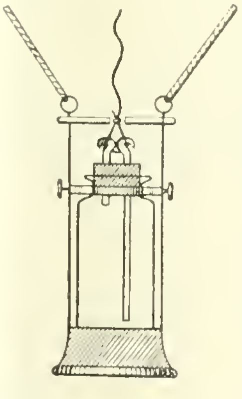
It was a well-known fact that the solution of alkali chloride in water increased its power of dissolving carbon dioxide; this might be attributed to chemical change; but it was not so easy to put down chemical change as the cause of decreased solubility of oxygen in water when sodium chloride was in solution.

NUMBER OF BACTERIA IN THE WATER OF THE NORTH SEA, AND THE EFFECT OF SEA AND RIVER WATER AND OF BIOLOGICAL TREATMENT ON THE NUMBER OF BACTERIA PRESENT IN SEWAGE.

BY FRANK CLOWES, D.Sc.

Opportunity has been recently afforded me to determine the total number of bacteria in the water of the North Sea, of the Thames estuary, and of the lower reaches of the Thames. The samples were collected from the deck of the steamship "Burus," Captain Vivlash, one of the large sludge-steamers of the London County Council. The steamer was itself converted into a bacteriological laboratory, the saloon being utilised for putting down cultivations, and roomy quarters being equipped with the necessary incubators. By this arrangement the samples could be put down for cultivation immediately after collection, and no question could arise regarding increase in the number of organisms between the time of the collection of the sample and its treatment in the laboratory.

Samples of water were collected from the surface, from the bottom, and in some places from the intermediate depths. In many places samples of the sea-bottom itself were also secured.



The surface samples were taken by dipping in a clean metal pail.

The samples from the bottom were obtained by sinking a heavily weighted glass bottle, which was closed by a rubber stopper carrying two glass tubes; one tube terminated immediately beneath the stopper and served for egress of the air displaced by the entrance of the water through the other tube which extended nearly to the bottom of the bottle. Both glass tubes terminated above the stopper in recurved capillaries, which were sealed at their ends; a loop of strong twine was slipped over these hooked capilliaries. The twine was held by the hand with plenty of slack, while the bottle was being lowered from the ships rail by two oblique lateral cords. By this arrangement the bottle was readily lowered in a vertical position to the sea bottom, and a jerk of the twine then served to break off the closed capillaries, and allowed the bottle to become filled in about three minutes with bottom-water.

The samples from intermediate depths were collected by lowering over the side of one of the ship's boats a known length of stout canvassed rubber tube weighted at the end and pumping up the water into a clean metal pail. These methods of collection were devised by Mr. J. W. H. Biggs.

For the purpose of collecting samples of the sea-bottom itself a strong canvas bag attached round its mouth to a heavy iron ring was suspended by a chain and lowered to the bottom. By steaming ahead, a sample of the sea-bottom was picked up in the bag, and this was raised by the steamer's steam-winch. This arrangement was devised by the captain. A washing, obtained from this bottom material by means of sterilised water, was also subjected to cultivation, and the total number of bacterial "colonies," as well as the colonies of *B. coli communis* and of *B. enteriditis sporogenes*, were counted as in the direct cultivations of the water samples.

The sample which was actually subjected to cultivation was usually an average sample; it was obtained either by mixing equal volumes of the water samples collected at one particular spot, or in the case of a dredged sample of the sea-bottom by mixing the matter brought up.

Effect of Sea Water on Bacterial Life.—It appeared desirable to ascertain by preliminary experiments whether bacterial life was prejudicially affected by sea water as compared with fresh water. This was determined in the following way.

Two series of parallel experiments were started by mixing one cubic centimetre of clarified sewage with a litre of sterilised distilled water, and another c.c. of the clarified sewage with a litre of sterilised sea water. One cubic centimetre of each of these liquids was at once mixed separately with 10 c.c. of gelatine medium, poured into Petri-dishes, and then incubated at 65° F.: this process was repeated with the inoculated waters at the intervals stated below, and the total number of "colonies" which developed in each culture were counted. The following results were obtained :—

Date. 1903.	Interval since Inoculation.	Period of Cultivation in Gelatine.	Number of Colonies per c.c.	
			In the Inoculated Sea Water.	In the Inoculated Distilled Water.
March 13	None	72 hours	8,748	7,100
„ 16	3 days	43 „	281,000	288,360
„ 18	5 „	45 „	531,000	421,200
„ 19	6 „	48 „	348,000	113,000

It is evident that the organisms were rapidly decreasing in number after the fifth day, probably on account of deficient nutrition.

A further similar series of experiments was made by incubating cultivations, put down at stated intervals, of ordinary sea water, and of the same sea water inoculated with clarified sewage in the proportion of 750 to 1. The following results were obtained :—

Date. 1903.	Interval of Standing.	Period of Cultivation.	Number of Colonies per c.c.	
			In Natural Sea Water.	In Inoculated Sea Water.
March 27	None	96 hours	1,115	11,000
„ 28	1 day	96 „	94,250	238,000
„ 30	3 days	96 „	230	1,976,000
April 1	5 „	48 „	109	2,373,000

A consideration of the results of these experiments leads to the conclusion that sea water exerts no inhibitory effect upon the life and multiplication of bacteria, and that the organisms thrive in sea water in much the same way as in water free from dissolved saline matter. It will be noted that inoculation of the sea water with sewage enabled the organisms to increase for a longer period, probably owing to the introduction of their nutriment in the sewage.

Number of Bacteria in the Water of the North Sea.—A bacterial examination was made of the water of the North Sea by collecting samples of the surface water in the neighbourhood of the Galloper light-ship, which is stationed about 25 miles seaward of the sea end of the Barrow deep, and is therefore in the open sea.

Samples of water were collected every five minutes for two hours, and equal volumes of the samples taken during each half hour were mixed together to constitute one average sample. In this way four average or compound samples were produced and were subjected to cultivation in the manner already described. The following results were obtained :—

	Number of Colonies per c.c.
High water, 11th April, 1903, 11.40 p.m. ……	373
5.5 a.m. to 5.35 a.m. ……	215
5.35 a.m. to 6.5 a.m. ……	191
6.5 a.m. to 6.35 a.m. ……	357
6.35 a.m. to 7.5 a.m. ……	298

Tests were made for *bacillus coli* and for *bacillus enteriditis sporogenes*; neither organism was detected in 1 c.c. of the water.

The results indicate that the open sea water contained a small number only of bacteria, an average of 287 per c.c.: and that what are ordinarily considered organisms of intestinal origin were absent.

Bacteria in Sewage "Effluent" and in Sewage "Sludge."—Before giving the results of the bacterial examination of the river water below the points at which the effluent from the settled sewage from London is discharged into the Thames, the results of the bacterial examination of the sewage effluent itself may be stated. And similarly the bacterial condition of the "sludge," or matter separated from the sewage by sedimentation, may be stated before the bacterial examination of the estuary water into which the sludge is discharged is referred to.

A comparison of the bacterial condition of the sewage effluent and sludge with that of the water of the lower river and of the estuary will then indicate the reduction in the number of bacteria effected by dilution and by other means after the discharge of these organisms has taken place.

Number of Bacteria in 1 c.c. of "Sludge" at both Outfalls.

Barking. 1903.	Bacteria which grow at 20° C.	Bacteria which grow at 37° C. (Blood-heat).	Spores.
April 29…	121,000,000	60,000,000	6,250
May 2…	126,000,000	74,200,000	8,100
„ 4…	119,500,000	45,000,000	10,550
„ 5…	131,000,000	64,000,000	11,800
„ 6…	135,000,000	70,000,000	11,400
Average…	126,500 000	62,640,000	9,620

Crossness, 1903.	Total Number of Bacteria.	Number of *Bacillus Coli Communis.*	Number of *B. Enteriditis Sporogenes.*
June 8…	118,000 000	At least 1,000,000	At least 10,000, but not 1,000,000
„ 9…	57,000,000	At least 10,000, but not 1,000,000	„ „
„ 10…	149,000,000	At least 1,000,000	„ „
„ 11…	163,000,000	„ „	„ „
„ 12…	132,000,000	„ „	„ „
„ 13…	177,000,000	„ „	„ „
Average…	132,666,666	..	..

The average number of bacteria in the sludge is therefore 129,583,333 per c.c.

The total number of bacteria in the sewage effluent ischarged at both outfalls is as follows :—

Date and Outfall.	Bacteria which grow at 20° C.	Bacteria which grow at 37° C. (Blood-heat).	Aerobic Spores.	Number of Estimations.
Barking, March, 1903	8,585,714	5,100,000	234	Average of 7 samples.
Crossness, June, 1903	6,300,000	..	..	Average of 6 samples.
Average	7,442,857	..	..	..

The average for both outfalls is therefore 7,442,857.

Reduction in Number of Bacteria by passage down River.—The samples were taken from the surface water y dipping, and were collected at low water in mid-stream nd near either shore. The average of the results obtained rom six series of samples collected on the 3rd, 4th, 5th, nd 6th of March, 1903, are stated below :—

Locality.	Approximate Distance in Miles from Crossness.	Average Number of Bacteria per c.c.
Mucking light	21·3	4,837
Hole haven	24·3	3,431
Chapman light	27·0	1,662
Tantlet creek	29·5	711
Southend pier	31·5	379
Garrison point	33·5	381
Nore light	35·8	186
Below the Nore	39·3	145

It will be seen that the average number of 7,442,857 bacteria per c.c., which were present in the sewage effluents discharged from the Barking and Crossness outfalls, have become reduced by the action of the river water to 4,837, at a distance down-stream 21 miles from Crossness, and hat off Southend, 31 miles from Crossness, a further eduction to 379 has taken place. When the Nore lighthip is reached, the bacteria number only 186 per c.c.

Each water sample was further examined for gasorming bacteria, which are generally considered to be hose of intestinal origin. Out of 45 samples examined, nly seven contained such bacteria, and these seven amples were all of them collected between the Mucking nd the Chapman lights. No gas-forming bacteria were ound in the water below the Chapman light. Hence it ppears that the intestinal bacteria in the sewage effluent ad disappeared from the river 27 miles below the point t which they had been introduced into the stream.

Reduction in Number of Bacteria per c.c. introduced to the Estuary Water by Sewage Sludge.—Several series examinations have been undertaken at different times ith the view of ascertaining the bacterial content of tuary water into which sewage sludge is constantly being troduced, and very many samples have been subjected examination. The following statement briefly summarises e results obtained :—

On April 2nd and 3rd, 1903, surface samples were llected throughout the length of the Barrow deep in the tuary immediately after the fleet of sludge steamers had posited their sewage sludge. The average number of cteria found in the water was 1,940 per c.c., as compared th 129,583,333 contained in the discharged sludge.

On the 9th and 10th April 1903 the surface water wing from the Barrow deep into the river during an coming tide was examined. This represented the estuary ter which had been mingled with sludge in the estuary. mples were taken every five minutes throughout the e of rising tide. The average number of bacteria per . found was only 458.

During September, 1903, further experiments were made h the view of ascertaining whether the diminution in number of bacteria was due to sedimentation or to eral diffusion by dilution. Immediately after the dark-coloured sludge had been discharged, a drifter, which was suspended from a float, and was cross-shaped and 8 sq. ft. in area, and which remained 10 ft. beneath the surface (the depth at which the sludge is discharged from the bottom of the steamers), was immersed in the discoloured water. This enabled a boat to be kept in the middle of the area of discharge for the purpose of taking samples at different depths. The examination of these samples furnished the following results. Samples were taken every five minutes, and those collected during each hour were mixed to produce an hourly average sample.

Date, 1903.	Interval after Discharge of Sludge, at which Sample was Collected.	Total Number of Bacteria per c.c. found at following Depths.		
		Surface.	10 Feet.	40 Feet, or Bottom.
Sept. 28th	None	940,000	13,000	140
	One hour	32,700	2,910	690
	Two hours	1,470	790	320
	Three „	340	140	130
	Four „	380	220	..
„ 29th	None	8,000	2,000	..
	One hour	21,400	580	..
	Two hours	6,200	700	..
	Three „	5,800	610	..
	Four „	5,300	610	..
	Five „	1,700	500	..

These results seem to indicate that the number of bacteria per c.c. is not reduced by the sinking of the organisms to lower levels in the water, but by a lateral diffusion or mingling.

The final series of samples, bacterially examined, consisted of water taken at different depths in the different channels of the estuary, of the bottom materials, and of the sands which were exposed at low water. In no case were bacteria found to be present in any considerable number.

Reduction in number of Sewage Bacteria occurring during the Biological Purification of Sewage.—Observations were made for some time with the object of ascertaining how the total number of bacteria present in the final effluent from the bacterial treatment of sewage compared with the number present in the corresponding sewage before it had undergone the treatment.

Two classes of sewage in different localities were placed under careful observation, the cultures for counting the colonies which developed being put down at the time and place of collection of each sample.

One sewage was of purely domestic origin, being that derived from the residents in Christ's Hospital, Horsham. The sewage flowed into a settling tank, its passage through which occupied about 24 hours. The effluent from the tank passed through coke-beds contained in shallow tanks which were alternately allowed to stand full of effluent and full of air. The bacterial action taking place in the settling tank disposed of all the settled suspended solid matters, and the subsequent bacterial action in the coke-beds removed all putrescible dissolved matters.

The other sewage which was placed under observation was the average sewage delivered to the Northern Sewage Outfall Works from the sewers of North London. This sewage had been roughly screened, then mixed with small proportions of chemicals in order to expedite the subsequent sedimentation during its slow passage through settling channels, and the effluent from these channels constituted the feed to an intermittently worked coke-bed which was similar to that at Horsham. The feed to this bed, and the effluent from it, were subjected to systematic bacterial examination.

It should be stated that the lower part of the coke-bed at the northern outfall consisted of somewhat fine and compacted material, which may to some extent have mechically reduced the number of bacteria. It should also be explained that while the screened London sewage contained only finely comminuted fæcal matter, because it had been subjected to the process of pumping and a flow of many miles, the Horsham sewage contained comparatively unbroken fæces, since it had flowed by gravitation only for a short distance. This would probably tend to diminish the number of bacteria found in the Horsham sewage, since the sample was collected by dipping the liquid from a collecting chamber outside the settling tank. Both sewages were, however, clarified by passage through a filter-paper before they were subjected to cultivation.

The results obtained are summarised in the following tables :—

Average Horsham Samples taken quarter-hourly during maximum flow of Sewage.

Date of Collection, 1903.	Total Number of Bacteria per c.c. (average of Cultivations).		
	Crude Sewage.	Effluent from Settling Tank.	Effluent from Coke-beds.
June 9th	7,390,000	13,650,000	8,750,000
„ 12th	9,800,000	10,850,000	9,500,000
„ 16th	9,000,000	5,750,000	6,650,000
„ 19th	8,750,000	9,800,000	8,050,000
„ 23rd	12,700,000	8,200,000	5,100,000
July 8th	16,150,000	3,650,000	3,000,000
„ 14th	23,450,000	21,700,000	18,200,000
Average numbers	12,492,857	10,514,285	8,464,285
Percentage decrease in numbers ...	..	15·8	32·2

It is necessary to calculate the decrease in bacteria from the average results, since the samples of effluent obtained on the same day cannot altogether correspond to that day's discharge of untreated sewage.

It may be noted that the results obtained from each of these samples when put down at once for cultivation were compared with the results obtained by putting down the same sample 21 hours after its collection. The average percentage increases in the number of bacteria counted, after keeping the samples 21 hours before cultivation, were 106 in the case of the sewage, 60 in the effluent from the tank, and 54 in the effluent from the coke-bed. As might have been anticipated, the highest rate of increase occurred in the more largely polluted liquid, and this indicates the necessity of not delaying cultivation of impure liquids which are under bacterial examination. It was found that a delay of 21 hours not unusually occurs between the collection of a sample and its arrival at and cultivation in the laboratory. This delay evidently leads to results which, in certain cases at least, do not correspond with those which would be yielded by the sample at the time of its collection, and in series of samples, such as those taken above, the delay very seriously affects the ratio between the numbers of bacteria found in the different series.

In the case of the London sewage, samples were taken every ten minutes during the filling and emptying of the coke-bed, and the samples of the sewage and of effluent for each date were mixed to form the average samples for examination for the day. The following results were obtained :—

Average Samples from the Barking Coke-bed.

Date, 1903.	Total Number of Bacteria per c.c.	
	Settled Sewage.	Coke-bed Effluent.
May 9th	8,000,000	70,000
„ 13th	11,500,000	814,000
„ 14th	5,300,000	829,000
„ 16th	10,000,000	1,180,000
„ 19th	10,800,000	Lost.
„ 20th	6,600,000	1,070,000
„ 27th	7,900,000	1,675,000
Average number	8,585,714	939,667
Percentage reduction in the number of bacteria		89

The average numbers at the foot of the table form a fairer means of judging the extent of reduction in the number of bacteria than the daily numbers do, since the effluent and feed of the bed on the same day are not precisely corresponding liquids.

It will be seen that in the case of both sewages a marked reduction in their bacterial content takes place. As far as the effluent from bacteria beds is concerned it is therefore not right to consider the bed as a means of increasing the number of bacteria; the bacteria rather appear to carry out their active functions in the bed, and to pass away in large numbers in the effluent in a lifeless condition.

The large amount of experimental work upon which the above results and conclusions are founded, involving the collection and examination of several thousand samples, has been carried out by Messrs. J. W. H. Biggs and E. B. Pike under my general direction.

Discussion.

The Chairman said he had always looked upon it that the salts in the sea water acted as nutriment for bacteria, and asked Dr. Clowes what media were used for cultivations.

Mr. S. R. Trotman said that, having frequently to make bacteriological examinations of water from a distance, he had found an ice-box to answer perfectly well for transportation of samples. Had Dr. Clowes any experience of this?

Mr. Golding, after referring to the preservation of milk by simply getting rid of the oxygen, asked how much salt was added to Dr. Clowes's medium in which the organisms germinated. He further asked if many fluorescent bacteria were found in the sea water.

Mr. O'Shaughnessy said Birmingham sewage was very deficient in organic life, which was something more than 400,000 organisms per c.c. The number of bacteria present in the land effluent was about the same. One must be struck by the fact that it was not the absolute number of bacteria present in the liquid which was alone the question of prime importance. One must consider the potentialities of the liquid itself. He maintained that the method of estimating the number of bacteria was distinctly an arbitrary method, but was agreed that the medium in which the organisms were determined ought to approximate in some way with the natural conditions.

Mr. Thorp asked if Dr. Clowes regarded the action of the coke bed as dependent upon some substance which possessed the physical action of absorption.

Dr. Clowes in reply drew attention to the results obtained by Dr. Dunbar, who had found that fragments of coke or other material were able, when in contact with sewage, to produce an oxidising effect; and he stated that this purifying action was exerted before any bacterial growth had formed on their surfaces. It seems, therefore, to be certain that these fragments retained on their surface absorbed oxygen which exerted an active oxidisation. Possibly the reason why putrefaction of meat took place with greater rapidity in fresh water than in salt water was in part due to the fact the fresh water contained less dissolved oxygen than sea water did. The action of putrefactive organisms was in abeyance as long as they were in the presence of oxygen or of dissolved oxygen in water. The bacteria which he had been dealing with were not putrifying bacteria; they were bacteria which were carrying on their changes without the production of any smelling gases. The medium used in cultivations was stated in the paper, and this had not been varied in the case of salt water.

In reply to Mr. Trotman, he recognised the difficulties of transport and remarked that he had repeatedly tried ice when conveying bacteria from long distances to the laboratory, but he had not made comparative experiments to ascertain whether any advantage resulted from using ice. He agreed with Professor Frankland that no results could pretend to be absolute if the cultivations were not put down on the spot. So far as fluorescent organisms were concerned they had not made any special observations with the view of detecting them. He was astonished to hear from Mr. O'Shaughnessy that Birmingham sewage contained only 400,000 organisms per cubic centimetre. This was possibly accounted for by the introduction of large quantities of acid chemicals into the sewage.

In the water of the upper part of the lower river, the amount of sodium chloride did not vary much. Pollution could be measured by de-aeration in the lower river, but no appreciable indication could be obtained out in the estuary.

There was no medium quite so efficient as coke for bacteria beds.

Filters; Impts. in ——. W. B. Smith, Perth Amboy. Eng. Pat. 3938, Feb. 19, 1903.

An outer perforated tube is slipped over an inner perforated tube, closed at its upper end by a suitable cap, and fixed with its lower extremity in a socket. Round the outer tube is wrapped a filter-cloth, extending inside the outer tube, and enclosing the inner tube when slipped over it. The liquid to be filtered enters the inner tube from below, and percolates through two layers of filtering material before reaching the outside of the outer tube. This filtering may take place in the reverse direction. Any number of these tube filters may be arranged in a tank. —L. F. G.

Concentrating Liquids; Apparatus for ——. P. Kestner, Lille. Eng. Pat. 6372, March 19, 1903.

See Addition, of Nov. 15, 1902, to Fr. Pat. 315,973 of 1901; this J., 1903, 788.—T. F. B.

Evaporators for Distilling or Concentrating Liquids, or for Generating Steam or Gas; Impts. in ——. J. W. Gordon, London. From C. Licardie, Guatemala. Eng. Pat. 27,621, Dec. 16, 1903.

The liquid enters at the highest point of a continuous coil arranged in a furnace, whilst the residuum is discharged from the lowest point. At various points of the coil, side tubes are placed as outlets for the vapours, whilst baffles extend across the interior of the coil to retard the flow of the liquid. If the coil is to be used as a steam or gas generator, all these outlet pipes are connected together. If the apparatus is intended for use as a still, the pipes can be led separately to condensers, thus enabling products of different boiling points to be continuously collected. —W. H. C.

Centrifugal Separating Apparatus; Impts. in ——. E. Seger, Stockholm. Eng. Pat. 458, Jan. 7, 1904.

The separation of a mixture of solids and liquids, without the use of a gauze or other straining medium, is effected by means of bucket wheels, rotating in cases placed in an outer rotating cylinder. The bucket wheels rotate in consequence of the centrifugal force produced by the rotation of the outer casing acting on the mixture to be separated. Means are provided for drawing off the solid and liquid separately. The bucket wheels may be set vertically or horizontally in the outer casing.—W. H. C.

Rotary Furnaces; Impts. in ——. N. M. Hansen, Berlin. Eng. Pat. 11,119, May 15, 1903.

Between the outer metal casing of the furnace and the inner lining of firebricks or other refractory material there is placed a layer of asbestos or material which is not only refractory but also a bad conductor of heat, the object being to prevent loss of heat by radiation from the shell of the furnace.—W. H. C.

Furnaces; Impts. in ——. J. Ritz, Schw. Gumend. Eng. Pat. 27,613, Dec. 16, 1903.

The grate bars of the furnace are inclined, so that the fuel, which is fed in at the upper end, gradually slides down towards the clinker hole placed at the bottom. From underneath, a "poking appliance" is periodically set to work to remove the clinker as it is formed, and rake it into the clinker hole. To prevent the clinker from caking on to the masonry of the furnace, the grate bars are protected at the side by an iron ledge of suitable design.—L. F. G.

Briquette Machine. F. Meyer, Chicago. Eng. Pat. 2137, Jan. 28, 1904. Under Internat. Conv., Jan. 29, 1903.

This machine consists of a mould, or series of moulds, arranged in a frame, with a conveyor to supply the material to be compressed. There is a series of plungers, each acting in the same mould and compressing the material to successively varying degrees. Means are provided for bringing the mould or moulds successively opposite the various plungers and for expelling the briquette when formed. Claim is also made for a type of mould in which the compression is effected by two plungers, and for means of operating the plungers, &c.—W. H. C.

United States Patents.

Cooling Tower. C. F. Hettinger, Boston. U.S. Pat. 753,573, March 1, 1904.

An enclosed water-cooling tower is provided with air and water shafts, the latter being divided into several compartments by horizontal perforated partitions. Fans are provided at the bottom, and the air is driven horizontally across the falling spray of liquid towards the air-exhaust shaft. Means are provided for supplying the liquid to be cooled in the form of spray, for regulating the supply of air, and for collecting the cooled liquid in a tank at the base of the tower.—W. H. C.

Drying and Calcining Kiln. C. E. Pickett, Bayonne. U.S. Pat. 753,624, March 1, 1904.

The kiln consists of two concentric horizontal cylinders with external means for rotating. There is a hopper and worm-conveyor for feeding the material to be treated, and means are provided for heating the annular space between the cylinders and for drawing off the gases from the annular space and from the inner cylinder separately. The outlet end of the cylinder is closed by a movable end-piece with arrangements for oil-burners for heating, and for removing the dried or roasted material.—W. H. C.

Centrifugal [Separating] Machine. J. H. Ostrander, Ticonderoga. U.S. Pat. 754,796, March 15, 1904.

Through a vertical tank passes an upright shaft carrying a perforated bowl with a flanged upper edge extending over the top of the tank. Surrounding the upper parts of the bowl and tank is a casing, which is provided with a drain pipe and with an opening, through which a feed-pipe passes into the interior of the perforated bowl. Inside the perforated bowl is fixed a vertical worm conveyor, arranged to discharge material from the bowl into the casing.
—L. F. G.

French Patents.

Supersaturator for Solutions [Brine] which are to be Concentrated. J. L. Gauthier. Fr. Pat. 336,138, Oct. 20, 1903.

The apparatus is specially adapted for the concentration of common salt solutions. The evaporating pan is surrounded by an annular chamber containing the fresh salt solution, which is heated by the waste furnace gases from the fire, and by a pipe lying throughout the length of the chamber, through which pass the hot vapours escaping from the evaporating pan. The liquid in the annular chamber gets heated up to 85° or 90° C., and is then siphoned off into the evaporating pan, where it discharges on to the surface of the concentrated, and therefore specifically heavier, salt solution, and readily gives up its water. A drain-cock is provided for the condensed water in the pipe serving to heat up the annular chamber.—L. F. G.

Gummy Substances, Rapid Process for Drying ——. Maschinenfabrik St. Georgen b. St. Gallen Ludwig von Süsskind. Fr. Pat. 336,230, Oct. 23, 1903.

The substances, in the form of small pieces, are placed on a series of horizontal sieves, arranged in a chamber open at the top. Compressed air is blown in from below, the rate of escape of the air being regulated by means of dampers fixed to the cover of the chamber.—L. F. G.

Receptacles containing Highly Inflammable Liquids; Device for Preventing Explosions in ——. Fabr. Explosionssicherer Gefässe. Fr. Pat. 336,757, Nov. 17, 1903.

See Eng. Pat. 25,547 of 1903; this J., 1904, 110.—T. F. B.

II.—FUEL, GAS, AND LIGHT.

Water-Gas; Introduction of —— into the Carbonising Retorts. H. Croissant. J. Gasbeleucht., 1904, **47**, 219—222.

The passage of water-gas through the retorts during the carbonising period is a process which requires careful supervision, but is attended with advantages that outweigh the extra trouble involved. The water-gas inlet pipes are apt to become stopped, and require to be frequently cleaned, and the removal of graphite from the retorts demands the same attention as before. A manometer attached to the inlet tube affords a useful control of the pressure within the retorts. The quality of the gas produced is subject to serious fluctuations unless the introduction of the water-gas be limited to the first two hours or so after charging the retorts, otherwise the gas of low grade, which distils off during the later period of the carbonisation, becomes so highly diluted that the mixture in the gas-holder does not become homogeneous, and consequently the gas does not burn well. If considerable proportions of water-gas are to be mixed with the coal-gas (say 40—50 vols. of the former to 100 vols. of the latter, the mixture being carburetted with benzol so as to have a calorific value of 5100—5300 cal.), it is necessary to provide air-regulating collars to the incandescent burners fed with the gas, otherwise lighting back is apt to occur. One of the advantages of the process is the relatively large yield of gas from the coal used, the gain in heating value amounting generally to from 7 to 12 per cent. If the introduction of the water-gas be properly regulated, stoppages of the ascension pipes, otherwise so frequent, are almost entirely prevented, and the tar is appreciably more fluid. The carburetted mixed gas costs from 0·75 to 1 pfennig less per cubic metre than pure coal-gas. The result of carburetting the gas with benzol is to almost entirely prevent the deposition of naphthalene in the gas mains, so that a lower supply pressure suffices.—H. B.

Calcium Carbide; New Mode of Formation of ——. H. Moissan. XXIV., page 388.

English Patents.

Gas; Manufacture of ——. W. R. Jones, Beckton. Eng. Pat. 5781, March 12, 1903.

Illuminating gas is obtained by mixing crude coal-gas from the retorts with water-gas at a high temperature, and then superheating the mixture, whereby the hydrocarbons become fixed and incondensable.—H. B.

Gas Retort Mouth Pieces; Impt. in Inclined ——. G. B. A. Gibbons, Lower Gornal, and C. J. McEwen, Liverpool. Eng. Pat. 7251, March 28, 1903.

One or more holes are made in the lower part of the retort mouth-piece or its lid, each hole being provided with a valve or stopper. By this means the tar which accumulates at the lower end of the retort can be run off from time to time.—H. B.

Gas Retorts. W. Angus and C. McPherson, Birmingham. Eng. Pat. 8135, April 8, 1903.

The patent relates to methods of attaching to the door the coal stop employed in an inclined retort, so that the use of intermediate joints between the door and the stop can be dispensed with.—H. B.

Gas [from Wood]; Apparatus for the Generation of —— W. H. Brooks, Adelaide. Eng. Pat. 2481, Feb. 1, 1904

Gas obtained by the carbonisation of wood, &c., in a retort is passed through a series of horizontal pipes arranged i the furnace flue, and then successively through a condense a washer, a gas-holder, and scrubbers. By means of branc pipes the gas may be drawn directly from the scrubbers or may be passed through an enricher. All the pipes are straight, and all the unions are made rectangular, being provided with screw-plugs, to facilitate cleaning.—H. B.

Arc Light Electrodes. O. Vogel, Berlin. Eng. Pat. 11,442, May 19, 1903.

In arc-lamp electrodes, which may or may not contain light-emitting additions, there are provided one or more centrally-placed passages or tubes of pure carbon, into which are introduced substances (*e.g.*, peroxide of barium, chlorate of potash) capable of liberating free oxygen when exposed to the heat of the arc.—H. B.

United States Patents.

Coke Oven. H. Koppers, Essen-on-the-Ruhr. U.S. Pat. 753,146, Feb. 23, 1904.

The coke oven, besides the usual coking chambers and heating flues, has "nozzles at the bottom for the admission of a vertically ascending gas column," and "inclined channels connecting the air conduits with the base part of the heating flues, the inclination being out of line with the ascending gas-column in order to leave it undisturbed, and circulate around it." See also Eng. Pats. 18,159 and 23,278 of 1901; this J., 1902, 1127 and 762 respectively.—E. S.

Retort for making Gas and Coke. A. C. Kloman, Assignor to J. Scott, both of Pittsburg. U.S. Pat. 754,459, March 15, 1904.

A series of coke retorts are placed in battery, each retort having a bottom inclined in both directions from a middle ridge, and discharge openings, which can be closed by doors, at the ends of this bottom. The retorts have arched flues, which are connected at one end to a common combustion chamber placed transversely, and at the other end to a stack-flue, and are provided with gas eduction pipes leading to a gas-main, and can be suitably heated.—L. F. G.

Gas; Method of Producing ——. P. Naef, New York. U.S. Pat. 753,294, March 1, 1904.

See Eng. Pats. 20,658 and 20,659 of 1899; this J., 1900, 1094 and 1095.—T. F. B.

Gas; Method of Making ——. P. Naef, New York. U.S. Pat. 753,295, March 1, 1904.

ee Eng. Pat. 20,660 of 1899; this J., 1900, 1095.—T. F. B.

Gas Producer. J. M. Wight and H. Hyatt, Cleveland. U.S. Pat. 753,340, March 1, 1904.

hrough the centre of the top of the producer a water-ooled coal-supply tube extends down to the fire. The atter rests on a rotating conical grate, carried by a rotating nnular water-pan, and having a feed-screw at its apex xtending up into the tube. The blast-pipe opens under he grate, and over the latter are fixed water-cooled pokers. —H. B.

French Patents.

oal and Minerals; Process for Enriching ——. F. Blanc. Addition, dated Jan. 16, 1903, to Fr. Pat. 317,908, Jan. 18, 1902.

e Eng. Pat. 14,328 of 1902; this J., 1903, 287.—T. F. B.

riquettes; Process for Increasing the Calorific Power of ——. C. Melhardt. Fr. Pat. 336,235. Oct. 24, 1903.

he coal dust from which the briquettes are to be made is ated in a closed vessel with compressed air, containing y or fatty substances in a state of fine division. —L. F. G.

al [Small] and like Matters; Simultaneously Washing nd Sorting ——. Schüchtermann and Kremer. Fr. Pat. 36,241, Oct. 24, 1903.

e small coal is delivered on to a wire mesh stretched oss a trough, below the top, such mesh allowing passage fragments of less, say, than 10 mm. diameter. Such fine ff, passing the sieve, accumulates in the bottom of the trough, whence it may be subsequently discharged from a suitable outlet, and treated apart. The larger fragments, of, say, from 10 to 80 mm. diameter, above the screen, separate, during the washing, into a lower layer of the heavier shale, which is caught in a side channel having a bent-over top or cover, and is discharged thence by action of an endless screw, and an upper layer of coal fragments, which flow off from the top down an inclined sluice, and are washed in the usual way in a second trough.—E. S.

High Temperatures; Process and Apparatus for Production of —— *by Means of Combined Chemical and Electrical Energy.* R. Schnabel. Fr. Pat. 326,452, Nov. 5, 1903. XI. A., page 377.

Power-Gas; Process and Apparatus for Production of —— *by Continuous Combustion under High Pressure.* S. Wigelius and P. L. Laurell. Fr. Pat. 336,450, Nov. 5, 1903.

Air is pumped at high pressure into the annular space between two concentric cylindrical vessels, and enters the inner cylinder at the bottom, where it meets with a regulated supply of "petrol." Combustion takes place continuously and completely. The heat generated raises the air to a high temperature before it reaches the "petrol." The gas produced by the combustion, at very high pressure, is led from the inner cylinder to the motor, where it is utilised directly, in the same way as steam is used.—H. B.

Gas Producer. E. Hovine and H. Breuillé. Fr. Pat. 336,786, Nov. 19, 1903.

The producer consists of two compartments in open communication with each other; the one, forming the producer proper, being supplied with superheated steam and a hot-air blast, and having a bed of fuel of but little depth, which is always kept incandescent, and the other, acting merely as a regulator of the composition of the gas, being filled with fragments of coke or anthracite, through which the gas produced in the first chamber is drawn down by a fan. The steam and air supplies for the first chamber are led through heating boxes, arranged beneath the grate of the second chamber in the path of the gas produced. In certain cases, the second chamber may contain, instead of fuel, merely pieces of flint, or the like, when the carbonaceous deposit forming on the flint is sufficient to regulate the composition of the gas.—H. B.

Sulphur; Extracting —— *from Residues of Gas Purification, and from Poor Ores.* E. Vaton and A. Zuaznavar. Fr. Pat. 336,661, Nov. 14, 1903. VII., page 371.

Carbons for Arc Lamps; Manufacture of Cored ——. F. von Hardtmuth. Fr. Pat. 336,748, Nov. 17, 1903.

The carbon paste is extruded through a draw plate, in the centre of which is a helicoidal steel core, mounted so as to rotate on a support. The rifled carbon tube thus obtained is then filled with a paste to form the core.—H. B.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM, AND MINERAL WAXES.

English Patent.

Hydrocarbons; Process for the Production of Highly Sulphuretted ——. J. E. W. Bengough. Eng. Pat. 8596, April 15, 1903. XX., page 383.

United States Patents.

Wood; Apparatus for Distilling ——. W. C. Douglas, Raleigh. U.S. Pat. 753,376, March 1, 1904.

The retorts are arranged in two rows, a short distance apart, and the furnace is situated centrally for the retorts. Each pair of retorts is connected by three or more pipes, and all these cross pipes are connected by pipes running the length of the apparatus. These longitudinal pipes are connected by a single vertical pipe, from which discharge pipes lead the vapours away. All the pipes are heated and protected from draughts, so as to keep the temperature above the condensing point of the lighter vapours. A stack leading from the furnace is situated at one end of the still, between the two rows of retorts, "closing the space between the retorts and preventing atmospheric draught therebetween."—T. F. B.

Wood Distillation Apparatus. C. M. Palmer, New London. U.S. Pat. 754,232, March 8, 1904.

A vertical retort or still is provided with a horizontal grate or perforated partition on which the wood rests; the vapours are conveyed from the top of the retort by means of a pipe, which is provided with a tar trap and a creosote trap between the retort and the condenser; the tar trap is connected with a pipe, which conveys the tar and heavy distillates back to the retort, which it enters below the grating. On leaving the condenser, the distillates are passed through filters into receiving tanks. Provision is made whereby the warm water from the condenser is introduced into the discharge-pipes of the condenser, mixing with the distillates and passing through the filters with them.—T. F. B.

Petroleum; Apparatus for Refining Crude ——. J. M. O'Neall, Dallas, Assignor to British American Power Co. U.S. Pat. 754,687, March 15, 1904.

The oil is passed through a narrow pipe which is coiled around a pipe of larger diameter, through which hot furnace gases pass; the whole is surrounded by a pipe or vessel, through which steam is blown. The portions of the oil pipe outside the steam pipe are insulated by suitable means. Means are provided "for forcing the vapour into a liquid and a condenser consisting of a series of pipes of different diameters and connected at different angles."—T. F. B.

IV.—COLOURING MATTERS AND DYESTUFFS.

2.6-Dibromo-p-phenylenediamine; Action of Bromine on ——. C. L. Jackson and D. F. Calhane. Amer. Chem. J., 1904, **31**, 209—220.

By the action of an ethereal solution of bromine on an ethereal solution of 2·6-dibromo-*p*-phenylenediamine, a green precipitate was obtained, which showed all the properties of the hydrobromide of a base, which was most probably 2.6-dibromo-*p*-phenylenedi-imine. 1 mol. of bromine was found to react with two mols. of dibromo-*p*-phenylenediamine. The base could not be isolated owing to its instability, but its hydrobromide was converted into dibromoquinone on treatment with bromine and water. On treating *p*-phenylenediamine in ethereal solution with bromine, a blue substance was obtained, similar in properties to that from the dibromo compound, and reacting like the hydrobromide of *p*-phenylenedi-imine.—T. F. B.

Amino- and Aminohydroxydiphenylamines [for Blue Sulphide Dyestuffs]. R. Gnehm and H. Bots. J. prakt. Chem., 1904, **69**, 161—175.

Dimethyl-*p*-amino-*p*-hydroxydiphenylamine was prepared both by the action of dimethyl-*p*-phenylenediamine on quinol and by reduction of the corresponding indophenol by means of zinc dust and dilute acetic acid. The latter method yields the best results. The product yields diacetyl and dibenzoyl derivatives, and combines with 1 mol. of alkyl iodide. On nitrating the diacetyl compound a tetranitro derivative of the mother substance is obtained. On melting dimethyl-*p*-amino-*p*-hydroxydiphenylamine with sodium polysulphide at 110° C. for 24 hours, a leuco compound of a blue sulphide dyestuff is obtained. The dyestuff is isolated by dissolving in dilute acetic acid, filtering, making alkaline with caustic soda, oxidising by means of a current of air, and precipitating with hydrochloric acid. The composition of the dyestuff is represented by the formula $C_{14}H_{12}N_2S_3O_2$. It forms salts of silver and zinc soluble with difficulty in water, and with sodium bisulphite yields an addition product, $C_{14}H_{12}N_2S_3O_2 + NaHSO_3 + 2H_2O$, which forms orange-yellow needles. By the action of stannous chloride and acetic anhydride the sulphide dyestuff is converted into the diacetyl derivative of its leuco compound, from which the original dyestuff is regenerated on boiling with solution of a caustic alkali. *p*-Aminotolyl-*p*-hydroxydiphenylamine was prepared by reduction of the corresponding phenol (from *o*-toluidine and *p*-aminophenol) with sodium sulphide. It can be acetylated. The thiosulphonic acid of dimethyl-*p*-amino-*p*-hydroxydiphenylamine was obtained by oxidation of equimolecular proportions of dimethyl-*p*-phenylenediamine-thiosulphonic acid and *p*-aminophenol, and reduction of the dyestuff so obtained by means of sulphuretted hydrogen.—E. F.

Benzidine Transformation. A. F. Holleman and J. Potter Van Loon. Konink. Akad. Wetenschappen, Amsterdam, 1902, 377—378; 1903, 262—267. Chem. Centr., 1904, **1**, 792—793.

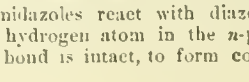
The authors have examined quantitatively the transformation of hydrazobenzene into benzidine and diphenyline (*p*-*p*- and *o*-*p*-diaminodiphenyl). At the ordinary temperature, 84 per cent. of the hydrazobenzene is converted into benzidine by means of N/10 hydrochloric acid, and 90 per cent. by means of N/1 hydrochloric or hydrobromic acid. At 100° C., N/10 hydrochloric, nitric, sulphuric, and hydrobromic acids effect the transformation of 66·4, 67·3, 63·1, and 65·8 per cent. respectively of the hydrazobenzene into benzidine. At 25° C. the velocity of the reaction increases with, but more rapidly than the concentration of the acid. The course of the reaction is altered by the use of a solvent. For example, if the hydrazobenzene be employed in ethyl or methyl alcoholic solution, the proportion of benzidine produced is less, and that of diphenyline is greater.—A. S.

Gallorubin. W. Feuerstein and K. Brass. Ber., 1904, **37**, 827—831.

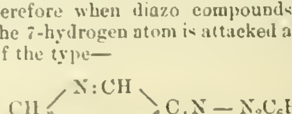
For the preparation of Gallorubin 14·7 grms. of isatin and 16·6 grms. of dihydroxycumarone are dissolved in 150 c.c. of water and heated for one hour at 100° C. with 450 grms. of hydrochloric acid. From the resulting hydrochloride the dyestuff is separated by treatment with hot water. It crystallises from alcohol in reddish-brown needles, melting at 300° C., and dyes brownish-violet shades on mordanted cloth. When Gallorubin (2 grms.) is boiled with aniline (15 grms.) for a short time, the red solution assumes a greenish-yellow colour with formation of anilinodihydroxygallorubin according to the equation: $C_{16}H_9NO_5 + C_6H_5.NH_2 = C_{22}H_{16}N_2O_5$. It crystallises in greenish-yellow laminæ, melting at 257° C., and yields brownish to greenish-yellow shades according to the mordant used.—D. B.

Diazoamino Compounds of Imidazoles and Purine Substances. R. Burian. Ber., 1904, **37**, 696—707.

Substituted imidazoles react with diazo compounds if there is a free hydrogen atom in the *n*-position, and the amidine double bond is intact, to form compounds of the type—



The relations in the purine group are quite analogous. In a similar manner purine compounds react with diazo-bodies unless the imino hydrogen atom (7) of the imidazole nucleus is substituted or the amidine double bond broken down. Thus theophylline, which is 1.3-dimethylxanthine reacts with diazo compounds, whereas theobromine (3.7-dimethylxanthine) and caffeine (1.3.7-trimethylxanthine) do not. Therefore when diazo compounds act on purin derivatives, the 7-hydrogen atom is attacked and diazo-amin compounds of the type—



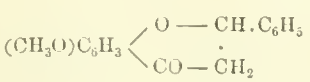
are formed. They are obtained by adding a diazo solutio to an alkaline solution of a purine compound and hav marked tinctorial properties. Those obtained from tetrazo-compounds dye vegetable fibres directly from an alkaline bath.—E. F.

2-Hydroxyflavonol ; Synthesis of ——. S. v. Kostanecki and V. Lampe. Ber., 1904, **37**, 773—778.

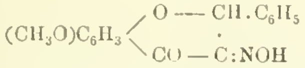
Quinacetophenone-monomethylether—

$$C_6H_3(OH)(COCH_3)(OCH_3)[1:2:4]$$

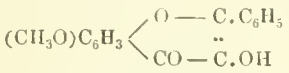
and benzaldehyde are condensed to 2-methoxyflavonone—



This is converted by nitrous acid into its iso-nitroso derivative—



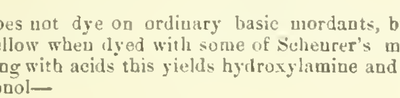
which does not dye on ordinary basic mordants, but gives a fine yellow when dyed with some of Scheurer's mordants. On boiling with acids this yields hydroxylamine and 2-methoxyflavonol—



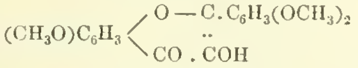
This substance gives rather weak yellow dyeings on alumina-mordanted cotton. The dyeings on iron mordant are very weak. On boiling with strong hydriodic acid it yields 2-hydroxyflavonol, which shows similar dyeing properties to its ether.—E. F.

Fisetin ; Synthesis of an Isomer of ——. S. v. Kostanecki and S. Kugler. Ber., 1904, **37**, 779—781.

3.4 - Dimethoxybenzaldehyde (veratric aldehyde) is condensed with quinacetophenonemonomethyl ether (see previous abstract) to form 2.3′.4′-trimethoxyflavanone—



With nitrous acid this yields an isonitroso compound, which, on boiling with acids, yields 2.3′.4′-trimethoxyflavonol—



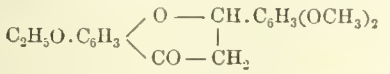
On de-methylation with hydriodic acid this yields 2.3′.4′-trihydroxyflavonol, which is an isomer of fisetin. It dyes strongly on basic mordants, orange-yellow on alumina and olive-brown on iron mordant.—E. F.

Fisetin ; Synthesis of ——. S. v. Kostanecki, V. Lampe, and J. Tambor. Ber., 1904, **37**, 784—791.

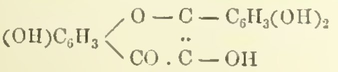
2′-Hydroxy-4′-ethoxy-3.4-dimethoxychalkone—

$$C_2H_5O.C_6H_3(OH).CO.CH:CH.C_6H_3(OCH_3)_2,$$

prepared by condensing resacetophenonemonoethyl ether with methylvanillin (Ber., 1899, **32**, 2257), is boiled with dilute mineral acid, and the product so obtained is converted by boiling with absolute alcohol into 3-ethoxy-3′.4′-dimethoxyflavanone—



With nitrous acid this yields an isonitroso compound, which is converted by boiling with acid into 3-ethoxy-3′.4′-dimethoxyflavonol. This can be de-methylated with hydriodic acid, yielding fisetin, which is 3.3′.4′-trihydroxyflavonol—



—E. F.

2.4′-Dihydroxyflavonol ; Synthesis of ——. S. v. Kostanecki and M. L. Stoppani. Ber., 1904, **37**, 781—784.

The substance is prepared in a manner analogous to that by which 2.3′.4′-trimethoxyflavonol is obtained (see previous abstracts), the veratric aldehyde being replaced by anisaldehyde. It dyes bright yellow on alumina, weak brown on iron-mordant.—E. F.

2.3′-Dihydroxyflavonol ; Synthesis of ——. S. v. Kostanecki and A. Ottmann. Ber., 1904, **37**, 957—960.

2.3′-Dimethoxyflavanone is obtained by condensing quinacetophenonemonomethylether with *m*-methoxybenzaldehyde. It is converted into 2.3′-dihydroxyflavonol by methods described in the preceding abstracts for the preparation of 2.3′.4′-trihydroxy- and 2.4′-dihydroxyflavonol. The dyeing properties of this substance are similar to those of 2.4′-dihydroxyflavonol.—E. F

Nile Blue Base ; Some Properties of ——. L. Michaelis. Pflüger's Arch., **101**, 183—190 ; Chem. Centr., 1904, **1**, 834.

The author, in reply to Heidenhain (this J., 1904, 183), maintains his previously expressed view that the properties of Nile Blue are best explained by the assumption that the free base exists in two modifications, one red, the other blue.—A. S.

English Patents.

Cyanine Dyestuffs [for Sensitising Photographic Emulsions] ; Manufacture of ——. O. Imray. From Meister, Lucius und Brüning. Eng. Pat. 9598, April 28, 1903. XXI., page 384.

Anthraquinone Series ; Manufacture of New Derivatives of the —— *[Anthracene Dyestuffs].* H. E. Newton, London. From Farbenfabr. vorm. F. Bayer and Co., Elberfeld. Eng. Pat. 10,074, May 4, 1903.

See Fr. Pat. 331,616 of 1903 ; this J., 1903, 1126.—T. F. B.

Dyestuffs of the Anthraquinone Series ; Manufacture of —— *[Anthracene Dyestuffs].* H. E. Newton, London. From Farbenfabr. vorm. F. Bayer and Co., Elberfeld. Eng. Pat. 11,717, May 22, 1903.

See Fr. Pat. 332,261 of 1903 ; this J., 1903, 1192.—T. F. B.

Monazo Dyestuffs ; Manufacture of new Red ——. C. D. Abel, London. From Act.-Ges. f. Anilinfabr., Berlin. Eng. Pat. 11,004, May 14, 1903.

See Fr. Pat. 332,145 of 1903 ; this J., 1903, 1192.—T. F. B.

Basic Dyestuffs ; Manufacture of New —— *[Pyrone Dyestuffs].* O. Imray, London. Assignor to the Basle Chemical Works, Basle. Eng. Pat. 2738, Feb. 3, 1904.

Red dyestuffs suitable for dyeing cotton, silk, and wool, are obtained by heating the Rhodamine-bases with derivatives of halogenised fatty acids either alone or in presence of some diluent, such as alcohol, glycerin, &c. The products are easily salted out from their solutions in water. All the Rhodamine-bases of the phthalic acid series and also of the succinic acid series may be used, and analogous dyestuffs are obtained by heating them with chloracetamide, dimethyl chloracetamide, ethyl chloro-acetate or similar derivatives of other fatty acids.—A. B. S.

United States Patents.

Trisazo Dye [Azo Dyestuff]. A. Israel and R. Kothe, Elberfeld, Assignors to Farbenfabr. of Elberfeld Co., New York. U.S. Pat. 748,076, Dec. 29, 1903.

See Fr. Pat. 334,140 of 1903 ; this J., 1904, 16.—T. F. B.

Anthraquinone Dye [Anthracene Dyestuff], and Process of Making same. O. Bally, Mannheim, Assignor to Badische Anilin und Soda Fabr., Ludwigshafen. U.S. Pat. 749,918, Jan. 19, 1904.

See Eng. Pat. 20,151 of 1903; this J., 1904, 319.—T. F. B.

Anthracene Dyestuff, and Process of Making same. O. Bally, Mannheim, Assignor to Badische Anilin und Soda Fabr., Ludwigshafen. U.S. Pat. 753,657, March 1, 1904.

See Eng. Pat. 20,719 of 1900; this J., 1901, 1205.—T. F. B.

Anthracene [Indanthrene] Derivative, and Process of Making same. R. Bohn, Mannheim, Assignor to Badische Anilin und Soda Fabr., Ludwigshafen. U.S. Pat. 753,659, March 1, 1904.

See Addition, of Oct. 26, 1903, to Fr. Pat. 319,018 of 1902, next column.—T. F. B.

Azo Dyestuff, and Process of Making same. P. Julius and E. Fussenegger, Assignors to Badische Anilin und Soda Fabr., Ludwigshafen. U.S. Pat. 754,315, March 8, 1904.

See Eng. Pat. 5689 of 1903; this J., 1904, 183.—T. F. B.

Azo Dyestuff; Red-Violet ——. A. Dorrer, Assignor to Badische Anilin und Soda Fabr., Ludwigshafen on Rhine. U.S. Pat. 754,856, March 15, 1904.

See Eng. Pat. 20,000 of 1902; this J., 1903, 903.—T. F. B.

Anthraquinone Dyestuffs; Manufacture of [Blue] ——. E. Hepp and E. Wolpert, Assignors to Farbwerke vorm. Meister, Lucius und Brüning, Höchst-on-the-Maine. U.S. Pat. 754,768, March 15, 1904.

Blue dyestuffs, dyeing mordanted or unmordanted wool in blue shades, distinguished by their fastness to light, acids, and alkalis, are produced by condensing 1.4.5.8-leucotetrahydroxyanthraquinone with the sulpho-acids of primary aromatic amines such as aniline.—A. B. S.

French Patents.

Monazo Dyestuff for Wool; Process for Preparing a Pure Blue ——. Cie. Paris. Coul. d'Aniline. Fr. Pat. 336,423, Jan. 15, 1903.

See U.S. Pat. 739,118 of 1903; this J., 1903, 1126.—T. F. B.

Phenylglycine-o-Carboxylic Acid; Manufacture of —— *[Indigo Dyestuffs].* Cie. Paris. Coul. d'Aniline. Second Addition, dated Jan. 19, 1903, to Fr. Pat. 306,302 of Dec. 15, 1900.

The alkali salts of o-chlorobenzoic acid and of glycocoll are heated together in equimolecular proportions in aqueous solution in presence of an alkali carbonate and of copper powder or copper salts. The presence of copper or its salts greatly facilitates the reaction.—E. F.

Azo Dyestuffs ranging from Clear Yellow to Deep Brown; New ——. Soc. Anon. des Mats. Colorantes et Prods. Chim. de Saint-Denis. Fr. Pat. 336,559, Jan. 20, 1903.

Sulphanilic acid, 1.3.6-*α*-naphthylaminedisulphonic acid, *m*-sulphanilic acid, disulphanilic acid, sulphonated *m*-nitraniline, *p*-amino-*o*-sulphophenol, *p*-amino-*o*-sulphodiphenylamine, *p*-amino-*p*-nitro-*o*-sulphodiphenylamine, the naphthionic acids, aminonaphtholdisulphonic acid H, aminonaphtholsulphonic acid *γ*, *o*-amino-*o*-nitro-*p*-sulphophenol, 1.2.4-*o*-aminophenol-*p*-sulphonic acid, 1.2.4.6-*o*-aminophenoldisulphonic acid, 1.2.4-*o*-aminophenol-*p*-carboxylic acid, *m*-aminobenzoic acid, or *p*-aminosalicylic acid are diazotised and coupled with *m*-aminophenol in neutral, acid, or alkaline solution. The products dye wool from an acid bath. The shade of the product varies according to the acid or alkaline nature of the medium in which it was produced. The products produced from components which yield mordant dyeing dyestuffs, such as *o*-amino-*o*-nitrosulphophenol, dye in shades which vary with the mordant employed.—E. F.

Sulphide Dyestuff dyeing Unmordanted Cotton Blue-Black; Preparation of ——. Cie. Paris. Coul. d'Aniline. Fr. Pat. 336,630, Jan. 22, 1903.

2.4-dinitro-3′.5′-dichloro-4′-hydroxydiphenylamine, obtained by the condensation of 1-chloro-2.4-dinitrobenzene with 2.6-dichloro-4-aminophenol, is heated with an alkali sulphide and sulphur. The product dyes unmordanted cotton in blue-black shades, which turn to reddish-blue on treatment with hydrogen peroxide.—E. F.

Anthracene Dyestuffs; Production of ——. Badische Anilin und Soda Fabrik. First Addition, dated Oct. 26, 1903, to Fr. Pat. 319,018 of Feb. 24, 1902 (this J., 1902, 1451).

According to the main patent a blue dyestuff is obtained by acting on indanthrene with chlorine. It is now found that a chlorinated product dyeing cotton in blue shades, perfectly fast to chlorine, is obtained by the action of sulphuryl chloride on either pure or crude indanthrene. A similar product, also perfectly fast to chlorine, and dyeing in greener shades than indanthrene, especially suitable for printing on cotton, is obtained by acting on pure or crude indanthrene with a mixture of fuming nitric and fuming hydrochloric acids and reducing the product, for instance, with sodium hydrosulphite.—E. F.

Lakes [from Azo Dyestuffs]; Process for Preparing ——. Soc. Anon. Prod. F. Bayer & Co. Fr. Pat. 336,433, Oct. 20, 1903.

Bluish red lakes are obtained from dyestuffs resulting from coupling the diazo derivative of aminoazobenzenedisulphonic acid with various naphtholsulphonic acids, of which the following are mentioned:—naphtholmonosulphonic acids 1.4, 1.5, 2.8; naphtholdisulphonic acids 1.3.8, 1.4.8, 2.3.6, and 2.6.8; and naphtholtrisulphonic acid 2.3.6.8. An aqueous solution of the azo dyestuff is added to a suspension of aluminium hydroxide in water, the dyestuff being precipitated by means of a 5 per cent. solution of barium chloride.—T. F. B.

V.—PREPARING, BLEACHING, DYEING, PRINTING, AND FINISHING TEXTILES, YARNS, AND FIBRES.

Benzine; Spontaneous Inflammation of —— *[in Dry Cleaning].* G. Just. Zeits. Elektrochem., 1904, **10**, 202—204.

In the cleaning of fabrics with "benzine" (petroleum spirit) it sometimes happens that the goods suddenly burst into flame when withdrawn from the bath. M. M. Richter, in 1893, showed this to be due to electrification, caused by the friction between fabric and benzine, and stated that the addition of 0·02—0·05 per cent. of magnesium oleate renders the benzine incapable of spontaneous inflammation. By determinations of the conductivity of benzine with and without the addition of magnesium oleate, the author found that the inhibiting action of the oleate depends upon its neutralisation of the electric charges by conduction, and so preventing sparks. The author has examined a number of other substances in this connexion, but finds none so effective as magnesium oleate.—W. A. C.

Blue-Red Prints with Paranitraniline. G. v. Block. Zeits Farben- u. Textil-Chem., 1904, **3**, 102—103.

According to the method of Pluzanski, a basic blue dyestuff is printed on the material and developed by steaming and passing through tartar emetic. The printed material is then padded with *β*-naphthol solution and developed with diazotised paranitraniline. This blue is very fast to soaping, but not easy to manufacture. A new and shorter method is is to first prepare the goods with *β*-naphthol, then to print Nitroso Blue in the usual way, and, after steaming, &c., to develop with diazotised paranitraniline. The goods must only pass for a very short distance through the diazo solution, and then at once in the open width through squeezing rollers into the tartar emetic solution.—A. B. S.

Sizing of Textiles; Recent Developments in ——. H. B. Stocks and H. G. White. J. Soc. Dyers and Colourists, 1904, **20**, 55—62.

A starch which is likely to be much used in future for sizing purposes is obtained from the cassava root, which grows in Central America. The roots contain only about 25 per cent. of starch, but the yield of roots per acre is very large. The fermentation of flour is of great importance in sizing. A change takes place during the first two weeks. Most of the albuminoids become soluble in water, nearly all the sugar is destroyed, and the acidity is largely increased. After two weeks the changes are much slower, and there is a slight increase of insoluble albuminoids, due probably to the growth of moulds and bacteria. By acting on fresh flour with ½ per cent. solution of acetic or lactic acid, it was found that most of the albuminoids were converted into the soluble form. It is, therefore, possible to effect one of the chief aims of fermentation without its defects and without loss of time. Lactic acid is a very powerful preservative, a 1 per cent. solution being better than a 3 per cent. solution of zinc chloride, sp. gr. 1·5, in preventing growth of mould. (See also this J., 1903, 4.)—A. B. S.

Cellulose; Constitution of ——. A. G. Green.
XIX., page 382.

English Patents.

Impregnating Woven Belting and other Fabrics with Gutta-percha, Balata, and like Substances; Impts. in ——. G. Banham and Co., Ltd., and C. R. Sagar. Eng. Pat. 9944, May 2, 1903. XIII. C., page 378.

Bleaching, Washing, Dyeing, and like Apparatus; Continuous ——. M. Muntadas y Rovira, Barcelona. Eng. Pat. 23,310, Oct. 27, 1903. Under Internat. Conv., Sept. 29, 1903.

See Addition, of Sept. 29, 1903, to Fr. Pat. 327,931 of 1902; this J., 1904, 251.—T. F. B.

Hydrosulphite Compounds; Manufacture of ——, *and Methods of Dyeing and Printing with their Aid.* O. Imray, London. From Farbwerke vorm. Meister, Lucius und Brüning, Hoechst-on-the-Maine. Eng. Pat. 5867, March 13, 1903.

Double compounds of hydrosulphurous acid or hydrosulphites and aldehydes (particularly formaldehyde) are produced by the action of hydrosulphurous acid on aldehydes or their derivatives, or by the action of sodium bisulphite (or sulphurous acid and zinc) and an acid on the bisulphite compounds of aldehydes, or by the action of sodium sulphite, sodium bisulphite, zinc, and acid on aldehydes. For instance, 450 grms. of "solid, concentrated sodium hydrosulphite" are mixed with 250 grms. of 40 per cent. formaldehyde. On cooling, the compound separates in the form of white needles. Or, 210 grms. of sodium bisulphite solution (38° B.) are mixed with 180 grms. of 25 per cent. formaldehyde; 50 grms. of zinc dust, 210 grms. of 38° B. sodium bisulphite solution and 75 grms. of sulphuric acid (52° B.) are introduced into the solution, which is cooled. After standing, the compound is salted out and filtered. These compounds are suitable for use as discharges in dyeing, padding, and printing. At moderate temperatures they have no reducing action, but are decomposed by steam heat or by bisulphites, hydrosulphurous acid being liberated.—T. F. B.

French Patents.

Cellulose and Fibres difficult to Bleach; Liquid for the Preparation of ——. A. Braun, jun. Fr. Pat. 336,594, Jan. 21, 1903.

The material is heated under a pressure of from 4 to 10 atmos., for from 10 to 24 hours with a neutral solution of ammonium sulphite. The latter is prepared by passing ammonia into a weak aqueous solution of sulphurous acid until it is completely neutralised. The ammonia is recovered. —A. B. S.

Textile Materials; Apparatus for the Treatment —— *of with the Aid of the Circulation of Liquids, Especially Applicable to the Maceration of Silk Waste and other Silky Fibres.* V. Mazzucchelli. Fr. Pat. 336,280, Oct. 28, 1903.

The material is placed in a carriage which fits into a horizontal cylindrical boiler. This latter is connected by means of cocks with a pump and with inlet and outlet pipes for liquids, which are contained in reservoirs in which they can be heated by indirect steam. The boiler can first be evacuated if desirable, and the liquids are then introduced at any desired temperature and pressure.—E. F.

Dyeing; Apparatus for ——. Soc. Colell and Bentner. Fr. Pat. 336,215, Oct. 22, 1903.

The apparatus consists of a vat for dyeing loose textile fibres. The material to be dyed is placed between perforated horizontal plates, and there are arrangements for pumping the liquid up and down alternately through the vat, so that the material in each compartment is pressed against the upper and lower perforated plate alternately. —E. F.

"Bleeding" in Dyed or Printed Tissues; Process for the Prevention of ——. Comp. Parisienne de Couleurs d'Aniline. Fr. Pat. 336,113, Jan. 5, 1903.

In order to prevent "bleeding" of the dyestuff in the processes of fulling, rinsing, soaping, and other cleansing operations, a hydrosulphite is added to the bath. This destroys any small quantity of dyestuff removed from the fibre, and so prevents it from staining the white portions of the fabric.—E. F.

Finishing of Textiles; Process for ——. E. X. Béranger. Fr. Pat. 336,482, Nov. 7, 1903.

The fabric is rolled on a perforated cylinder. Steam is forced into this cylinder by means of a pipe which is in communication with a receptacle containing the finishing liquid. The latter is under pressure and is forced into the steam pipe, and so carried with the steam through the perforations of the cylinder, and thus into the cloth. The process is especially used for finishing with fatty or other substances such as glycerin, which give the fabric a soft feel.—A. B. S.

Metallisation of Fibrous Substances generally, Process for the ——. A. Forster. Fr. Pat. 336,451, Nov. 5, 1903.

See Eng. Pat. 24,289 of 1903; this J., 1904, 184.—T. F. B.

VI.—COLOURING WOOD, PAPER, LEATHER, Etc.

French Patent.

Furs and Hides; Machine for Dyeing and Preparation of ——. C. et E. Chapal Frères et Cie. Fr. Pat. 336,714, Nov. 14, 1903.

The skins to be treated are made to pass by a system of clips, round a revolving cylinder. The latter can be stopped automatically as desired. Under the cylinder is placed a brush, which is partly immersed in a bath of the dye-liquor or other liquid to be applied; the upper end of this brush is in contact with the skin, and applies the liquid to it by capillary action. Next to this is placed a brush with a to and fro motion, which rubs the liquid into the skin to a depth which can be regulated by altering the pressure of the brush. A third brush smoothes the fur and removes excess of liquid.—A. B. S.

VII.—ACIDS, ALKALIS, AND SALTS.

Sodium Nitrite; Action of Carbon Dioxide on Solution of ——. C. Marie and R. Marquis. Comptes rend., 1904, **138**, 694—696.

The authors uphold, against Meunier (this J., 1904, 321), their conclusion (this J., 1904, 252) that carbon dioxide

decomposes sodium nitrite solution. They have substituted for potassium iodide and starch as a reagent, an aqueous solution of a mixture of β-naphthylamine and sulphanilic acid, decolorised, if necessary, by means of zinc. This is coloured orange-red by a trace of nitrous acid, and gives a red precipitate of azo-dyestuff if the quantity of nitrous acid be a little greater. The experiments quoted in the former paper give the same results with this reagent as with iodide and starch. These results are indicated by theory—for sodium nitrite solution containing NO_2-ions and Na-ions, and carbonic acid containing HCO_3-ions and H-ions, a mixture of the two contains simultaneously NO_2-ions and H-ions, that is, nitrous acid. Though the amount of nitrous acid thus liberated is very small, yet even if it be destroyed, it is renewed; and many reactions can be carried out with it—as, *e.g.*, the authors' synthesis of nitroprussides by the action of nitrous acid liberated from sodium nitrite by carbonic acid on alkali ferrocyanides, or Meunier's preparation of diazoaminobenzene, by acting with carbonic acid on a solution of sodium nitrite and aniline (this J., 1904, 56).
—J. T. D.

Chlorides; General Method for the Preparation of Anhydrous ——. C. Matignon and F. Bourion. Comptes rend., 1904, **138**, 631—633.

A CURRENT of dry chlorine is passed through a vessel containing sulphur chloride heated to a suitable temperature, the mixed vapours are then conducted over a layer of the oxide of the metal in a glass tube, which, in most cases, is preferably heated to dull redness. The chlorides produced are isolated by distillation and condensation either of the metallic chloride, if volatile, or of the excess of the chlorinating vapours if the reverse. Chlorides have been prepared from silica, alumina, thoria, the oxides of praseodymium, neodymium, and samarium, and from vanadic anhydride.
—J. F. B.

Nitrogen Oxides from Air; Yield of —— *by the Flame Discharge. Influence of Length of Flame and Temperature.* F. v. Lepel. XI. A., page 376.

Carbon Dioxide; Determination of —— *in presence of Chlorine.* M. Schlötter. XXIII., page 386.

English Patents.

Receivers, Condensers, and similar Vessels, such as are used in connection with Nitric Acid and other Chemical Manufacturing Plants, and for analogous Purposes. W. Round, Birmingham. Eng. Pat. 9182, April 23, 1903.

RECEIVERS, condensers, and the like are made in two separable parts. The upper part of the lower section is in the form of an annular channel, of which the outer wall is of greater height than the inner wall, such channel being adapted to receive the mouth or lower edge of the crown or top section, for forming a liquid or mercury seal.—E. S.

Cyanides; Manufacture of ——, *and the Recovery of By-Products.* Grossmann's Cyanide Patents Syndicate and J. Grossmann, Manchester. Eng. Pat. 4513, Feb. 26, 1903.

A SATURATED solution of potassium ferrocyanide is heated by live steam, with a slight excess of dilute sulphuric acid (or other suitable acid or acid sulphate), in a partial vacuum. The hydrogen cyanide evolved is collected in a solution of an alkali hydroxide; or in milk of lime, if it be desired to obtain calcium cyanide. Or the gas may be absorbed by a solution of potassium or sodium sulphate with lime.

The Everitt's salt remaining in the still after the distillation, is boiled with solution of a suitable ferric salt in the presence of free acid, and the Prussian blue thus produced is separated by filtration or otherwise from the ferrous salt in solution. The ferrous salt (or other suitable corresponding salts of low oxidation) may be utilised for the conversion of another portion of Everitt's salt into Prussian blue in acid solution with injection of air. The Prussian blue is converted into a soluble ferrocyanide by boiling with an equivalent quantity of caustic alkali. See Fr. Pat. 331,331, and Eng. Pat. 36, both of 1903; this J., 1903, 1130 and 1194.—E. S.

Cyanides; Apparatus to be employed in the Manufacture of ——. J. W. Swan and J. A. Kendall, London. Eng. Pat. 8478, April 14, 1903.

THE reaction vessel is a horizontal closed cylinder of nickel or cobalt, supported within a jacket, hydrogen being admitted to the space thus formed. A contracted continuation of the cylinder within the jacket space is joined to an outlet steel tube traversing a plate, against the outer face of which a removable box is supported, so as to obstruct too free access of air to the cyanide which flows down the outer surface of the plate into a receptacle. A nickel or cobalt tube is autogenously soldered at one end to an opening in a highly heated part of the cylinder, the tube passing through the hydrogen-filled space to the front of the apparatus, to enter the bottom of a closed nickel vessel in which an alkali hydroxide is melted, a device being arranged whereby graduated portions of the molten hydroxide may be delivered through the tube into the carbon-charged cylinder.—E. S.

Alumina and By-Products; Processes of Making ——. L. R. Keogh and B. Broughton, Hamilton. Eng. Pat. 23,918, Nov. 4, 1903.

SEE U.S. Pat. 744,765 of 1903; this J., 1903, 1347.—T. F. B.

United States Patents.

Sulphuric Acid; Making ——. N. Heinz and H. Hegeler, Lasalle. U.S. Pat. 752,677, Feb. 23, 1904.

THE invention consists in returning nitrogen compounds from any part of the system, in the "Glover process" of manufacture, and introducing and mixing them with the sulphurous gases entering the Glover tower.—E. S.

Aluminium Sulphate; Process of Preparing ——. H. F. D. Schwahn, St. Louis. U.S. Pat. 752,927, Feb. 23, 1904.

ALUMINOUS materials containing iron and silica are subjected to the action of a chlorinating agent, to convert the iron into ferric chloride, and the mass is heated to a temperature sufficient to volatilise the ferric chloride, and then to a higher temperature to render the silica insoluble in acids, but below the point at which aluminium compounds become insoluble. The resulting product is treated with sulphuric acid, in portions of successively gradually increasing strength, simultaneously with the injection of hot air. The aluminium sulphate solution is then separated from insoluble matters, and is concentrated.—E. S.

Sulphate of Aluminium; Process of Making [*Basic*] —— H. Spence, Manchester. U.S. Pat. 754,824, March 15, 1904.

SEE Fr. Pat. 331,836 of 1903; this J., 1903, 1195.—T. F. B.

Nitrogen Compounds [*Cyanides*]; *Making* ——, *from Atmospheric Nitrogen.* H. Mehner, Steglitz. U.S. Pat. 754,474, March 15, 1904.

A CLOSED chamber, having a hopper inlet on one side of its top, and at the opposite side of its bottom an outlet into a "separator," is charged with fragments of carbon. A molten, white hot alkaline silicate is caused to percolate downwards through the carbon, whilst near the middle of the side of the chamber air is admitted in such manner as to diverge within the mass into an upward, and a weaker, downward current, in both burning the carbon, but in the upward current forming carbon dioxide, and in the downward current, carbon monoxide "preventing the reaction being disturbed by the presence of carbon dioxide." As this fluid reaches the reservoir, alkaline matter is added to it, and it is again run through the apparatus, and so on successively. The cyanides and other nitrogen compounds which are said to collect in the reservoir, are separated, and decomposed into ammonia and an "alkaline compound," which latter is utilised with the alkaline silicate as described.
—E. S.

Cyanides and Nitrates; Process of Making ——. W. E. Everette, Tacoma. U.S. Pat. 754,647, March 15, 1904.

"Pulverised material containing carbon" is cooled by means of liquid air, and is then immediately rendered "incandescent by exposure to a source of intense heat, whereby cyanides, nitrates, &c., are formed by the union of the nitrogen of the air with the disrupted elements" occurring on the explosion.—E. S.

Lead Salts; Process of Making ——. W. Mills, London, Assignor to A. O. Granger, Cartersville. U.S. Pat. 754,667, March 15, 1904.

Substances containing lead are treated with hydrofluosilicic acid; the solution of lead silicofluoride formed is treated with a nitrate to form lead nitrate, and the latter acted upon by the proper reagent to form the lead salt desired.—E. S.

Ammonium Nitrate; Process of Making ——. W. Mills, London, Assignor to A. O. Granger, Cartersville. U.S. Pat. 754,668, March 15, 1904.

A mixture of lead or of a compound containing lead with hydrofluosilicic acid "of about 1·80 sp. gr." is heated, a nitrate is added to the solution of lead silicofluoride thus formed, and the lead nitrate is decomposed by ammonium fluoride.—E. S.

French Patents.

Sulphurous Acid; Recovery of —— from Mixed Solutions of Monocalcium Phosphate and Calcium Sulphite. Rheinische Gelatinwerke G. m. b. H., and R. Arens. Fr. Pat. 336,507, Nov. 9, 1903.

The solution containing calcium sulphite and calcium monophosphate (such as is obtained on dissolving tricalcium phosphate in sulphurous acid) is run into a solution of calcium monophosphate heated to 90° C., whereby sulphurous acid is set free, and is recovered, whilst dicalcium orthophosphate is formed.—E. S.

Barium Hydroxide; Process of Making ——. Harrison Bros. and Co., Incd. Fr. Pat. 336,657, Nov. 14, 1903. Under Internat. Conv., Feb. 2, 1903.

See U.S. Pat. 741,920 of 1903; this J., 1903, 1347.—T. F. B.

Copper Sulphate; Manufacture of ——. G. Gin and the Soc. Anon. la Métallurgie Nouvelle. Addition, dated Sept. 25, 1903, to Fr. Pat. 328,800, Jan. 26, 1903. See this J, 1903, 996.

Mattes or ores derived from cupreous sulphides, are subjected to an oxidising roasting, and after powdering, are digested with moderately diluted sulphuric acid in an autoclave, heated by steam to from 155° to 170° C., and provided with means of discharge. The iron present is thus mainly separated as a basic, insoluble salt, or as ferric hydroxide. Copper sulphate crystals, obtained from the liquor of a second crystallisation, may be digested in solution with a precipitate obtained by adding to a separate part of the solution a small proportion of sodium carbonate. Any iron salt remaining with the copper salt is thus eliminated.
—E. S.

Supersaturator for Solutions [Brine] which are to be Concentrated. J. L. Gauthier. Fr. Pat. 336,138, Oct. 20, 1903. I., page 364.

Reduction of Compounds of Substances which are Reduced and Volatilised at nearly the same Temperature [Silicon]; Process and Apparatus for the ——. F. J. Tone. Fr. Pat. 336,469, Nov. 6, 1903.

See U.S. Pat. 745,122 of 1903; this J., 1903, 1356.—T. F. B.

Sulphur; Extracting —— from Residues of Gas Purification and from Poor Ores. E. Vaton and A. Zuazuavar. Fr. Pat. 336,661, Nov. 14, 1903.

The residues or other materials are dried by exposure to air and to carbon dioxide, and are then heated in retorts, to which series of condensers are so connected that only vapours (not molten sulphur) may reach them. The first in order of the condensing chambers is of such dimensions as to maintain a temperature greater than 150° C. and under 440° C., so that only pure sulphur is condensed therein.
—E. S.

Nitrogen and Oxygen, Atmospheric; Apparatus for Separating ——. R. P. Pictet. Addition, dated June 27, 1903, to Fr. Pat. 322,600, June 28, 1902. See this J., 1903, 364.

The apparatus is a large rectangular metal case divided into two unequal vertical compartments, the larger of which is intended for the accumulation of nitrogen, and the smaller for oxygen. The lower portion of the first compartment contains a bath for liquid air divided into sections and provided with immersed coils for passage of cooled compressed air, which latter in liquefying, causes ebullition, and the nitrogen passes off, first into the upper part of the compartment in which is a serpentine acting as an exchanger. The liquid air, now enriched in oxygen, passes by a U tube in the bottom of the compartment into the smaller, oxygen compartment, in which is an exchanger similar to that in the first compartment. Air liquefied in the second compartment is, after filtering off the frozen carbon dioxide, made to spray on to a series of shelves in the first compartment, where it aids in the refrigeration, and also parts with nitrogen, which escapes, nearly pure, from an outlet tube in the top of the compartment. From a corresponding outlet in the lesser compartment, oxygen gas finds exit.—E. S.

VIII.—GLASS, POTTERY, ENAMELS.

English Patents.

Plate Glass; Apparatus for Manufacturing ——. H. Mielisch, Doebern. Eng. Pat. 18,339, Aug. 25, 1903.

The liquid glass is forced out of a closed hopper by air pressure, emerging between two adjustable rollers rotating in opposite directions, from which it is deposited in a layer of adjustable thickness upon a travelling table. No further rolling is required.—A. G. L.

Glass; Methods of and Apparatus for Drawing and Annealing ——. O. Imray, London. From The Window Glass Machine Co., Pittsburg. Eng. Pat. 297, Jan. 5, 1904.

The glass is drawn upwards from a bath which is protected, at the point at which the glass is drawn, from the surrounding heat by means of shields. The glass passes into a drawing chamber, designed to prevent breakage, mechanism being provided to hold the edges of the sheet and prevent its narrowing in width. Warping or bowing is prevented by supplying heat to the drawing chamber in such a way that the intermediate parts of the sheet are cooled in advance of the edges. When it has reached the desired length, the lower end of the sheet is severed from the bath, and then passes into a leer, where it is annealed and cooled.—A. G. L.

Muffle Furnaces or Kilns [for Pottery, &c.]; Impts. in Continuous ——. L. L. Grimwade, Stoke-on-Trent. Eng. Pat. 26,712, Dec. 7, 1903.

This is an improvement on Eng. Pat. 1805 of 1899 (this J., 1900, 146), and consists essentially in arranging two concave tracks on the floor of the kiln to retain the balls (on which the endless or rotating table moves) in position. The bottom of this table is provided with flat plates underneath of sufficient width to allow some lateral motion without permitting the balls to get away from the flattened portion. Friction wheels are placed in the side wall of the muffle to act as guides.—W. H. C.

French Patent.

Glass in Sheets; Process and Apparatus for Making ——. J. Hirst. Fr. Pat. 336,695, Oct. 20, 1903. Under Internat. Conv., June 12, 1903.

See Eng. Pat. 21,782 of 1903; this J., 1904, 63.—T. F. B

Kaolin ; Process to Separate —— from Rocks by Levigation. R. Frugier. Fr. Pat. 336,490, Nov. 9, 1903.

The rock to be treated is charged into the annular space formed between a central cylindrical cage of open-work and the walls of the containing vessel. Water passes upwards into the cage, where it is agitated by a suitable stirrer, and flowing through the perforations of the cage, disintegrates the rock and becomes charged with kaolin and sand. The kaolin remains in suspension sufficiently long to pass with the water into another outer vessel, from which it is carried to settling tanks. The heavier sand, on the other hand, falls down a sloping channel under the cage, through which the water is introduced, and is carried away by means of a mechanical lift, on the endless chain principle.
—A. G. L.

IX.—BUILDING MATERIALS, CLAYS, MORTARS AND CEMENTS.

English Patents.

Building Materials ; Artificial ——. B. J. B. Mills, London. From A. Seigle, Lyon-Monplaisir. Eng. Pat. 4048, Feb. 20, 1903.

See Addition, of June 4, 1903, to Fr. Pat. 323,666 of 1902; this J., 1903, 1294.—T. F. B.

Brick Kilns ; Impts. in ——. W. Morris, Oldbury. Eng. Pat. 26,751, Dec. 7, 1903.

The kilns are arranged in a series and connected at both ends by a main flue with the chimney, so as to enable them to be worked in either direction. The hot products of combustion from one kiln are made to pass into the next one through the ash-hole, fire-hole, and fire-bags on one side, being exhausted on the opposite side through louvres in a steam-flue running the length of the kiln. The use of side flues is obviated by using a separate inlet flue to each ash-hole. All the dampers used are set obliquely to the flues, so as to press by their own weight against their slides and more effectually to prevent leakage of hot gases or entry of cold air.—A. G. L.

Cement ; Bituminous —— chiefly for Marine Purposes. W. Briggs, Dundee. Eng. Pat. 4907, March 3, 1903.

Seventy parts of crushed or ground asphalt, natural or artificial, are mixed with 20 parts of powdered calcined magnesite. The mixture is made into a paste with 10 parts of magnesium chloride dissolved in sufficient water to give a solution of sp. gr. 1·2, and the whole is then mixed with five parts of sodium silicate previously dissolved in water.
—A. G. L.

United States Patent.

Portland or other Hydraulic Cements ; Process of Maturing ——. H. A. Gerdes, Assignor to F. W Cappelen, A. H. Elftman and J. B. Cull, all of Minneapolis. U.S. Pat. 753,385, March 1, 1904.

The cement is matured by subjecting it to a temperature of 360° F., and to a current of air charged with moisture and carbon dioxide.—A. G. L.

French Patents.

Refractory Products ; Process of Manufacturing extremely ——. J. Bach. Fr. Pat. 336,518, Nov. 10, 1903.

See Eng. Pat. 24,041 of 1903 ; this J., 1904, 64.—T. F. B.

Distemper ; Manufacture of a powdered ——. H. Beissier. Fr. Pat. 336,539, Nov. 12, 1903.

The distemper is prepared by mixing 7 parts of dry powdered casein, 20 parts of slaked lime, 100 parts of covering material (calcium carbonate, ochre, barium sulphate), 8 parts of dextrin, 8 parts of powdered soap and suitable colouring matters. The powder is mixed with water for use, and when applied to walls forms a surface impervious to moisture.—W. P. S.

X.—METALLURGY.

Cast-Iron ; Recent Investigations and Discoveries in ——. A. E. Outerbridge. J. Franklin Inst., 1904, **157**, 121—136.

By alternately heating and cooling cast-iron, a considerable increase in the volume of the metal takes place. The greatest increase is produced by heating to about 1450° F. (788° C.). On heating a bar, $14\frac{13}{16}$ in. long by 1 in. square, 27 times at 1450° F. for one hour each time, an increase of $1\frac{11}{16}$ in. in length and $\frac{1}{8}$ in. in cross-section was observed, *i.e.*, an increase in volume of over 40 per cent. The metal, after the repeated heating and cooling, suffers a loss of strength, sometimes of more than 30 per cent. Among the technical applications of this property of cast-iron are mentioned the enlargement of small castings and of a piston which had become too small through wear.—A. S.

Cast-Steel ; Mechanical Properties of —— at High and Low Temperatures. C. Bach. Zeits. Ver. Deutsch. Ing., 1903, **47**, 1762—1770, 1812—1820. Science Abstracts (B), 1904, **7**, 205.

Three samples of steel marked O, K, and M respectively, were tested at temperatures ranging from 20° C. to 500° C., with the following results :—

——	O.	K.	M.
Tensile strength in kilos. per sq. cm. :—			
At 20° C.	4,285	3,953	3,788
At 300° C.	4,788	4,242	4,319
At 500° C. (after ½ hour)	2,691	2,043	2,274
At 500° C. (after 8—12 hours)	..	1,561	1,911
Extension per cent. :—			
At 20° C.	25·5	29·0	27·2
At 200° C.	7·7	17·7	15·2
At 500° C.	33·3	51·3	26·1
At 500° C. (long heating)	..	41·4	19·5
Sectional contraction :—			
At 20° C.	50·4	56·1	48·7
At 300° C.	15·8	49·4	34·7
At 500° C.	44·6	75·7	42·1
At 500° C. (long heating)	..	57·0	31·1

In general it may be stated that the tensile strength decreases steadily as the temperature rises. Minimum values for the extension and contraction are shown at about 200° C. The results show that the ordinary mechanical tests of boiler plates, &c., should be supplemented by others made at higher temperatures.—A. S.

Carbon Tool Steel ; Tempering ——. H. Le Chatelier. Rev. de Metall., 1904, **1**, 184—187.

The author has determined the conditions of quenching and annealing, under which tool steel of the best quality is obtained. The best temperature at which to quench, is one just above the transformation point of the steel, and this temperature may be accurately ascertained in the following manner, without the use of a pyrometer. The pieces of steel are introduced successively at equal intervals of time into a muffle heated to a temperature a little above the transformation point of the steel. If, after a certain time, the pieces be taken out in the reverse order, they will at first show progressively increasing degrees of brightness, but afterwards there will be a certain number of pieces all showing the same degree of brightness, these pieces being at the transformation point. When the transformation point is passed, the pieces again rapidly acquire a brightness superior to that of their neighbours, and should then be immediately quenched. The best temperature for annealing is about 220° C., the melting point of a mixture of equivalent quantities of sodium and potassium nitrates. The bath containing the fused salts is heated to about 30 higher than the melting point of the mixture, and the piece of cold steel introduced. The latter becomes coated with a solid crust, which gradually melts as the steel becomes hot. The steel is removed from the bath when this crust has completely disappeared. It is stated that by this method of annealing, the life of a tool may be increased by 50 per cent.—A. S.

Chrome Steels. L. Guillet. Rev. de Metall., 1904, **1**, 155—183.

Two series of chrome steels were investigated, the first containing only from 0·043 to 0·464 per cent. of carbon; and the second from 0·741 to 0·973 per cent. of carbon. These alloys are divided into three classes, as follows :—

Class.	Structure.	Percentage of Chromium.	
		Series 1.	Series 2.
1	Perlite, like that of ordinary carbon steel	0— 7	0— 5
2	Martensite	7—20	5—18
3	Special, due to a double carbide of iron and chromium	> 20	> 18

The second class may be further subdivided as follows :—In the first series of alloys, those containing from 7—8 per cent. of chromium show a structure of *α*-iron and martensite; from 10—13 per cent. of chromium, pure martensite; and from 13 to 20 per cent. of chromium, martensite and the double carbide of iron and chromium. In the second series of alloys, those falling in the second class may also be subdivided into three kinds showing a structure of *α*-iron and martensite, martensite and troostite, and martensite, troostite, and the double carbide, respectively. With regard to mechanical properties, the breaking strength, elastic limit and hardness of the alloys with a perlite structure, increase with the percentage of chromium; the elongation and contraction are high, and the resistance to shock depends chiefly upon the content of carbon. The mechanical properties of these alloys are considerably modified by quenching at 850° C., the effects being similar to those observed in the case of ordinary carbon steels, except that with the alloys containing only a small percentage of carbon, the breaking-strength and elastic limit are increased, and the elongation and contraction diminished to a much greater degree than with steels containing no chromium. In the alloys showing a structure of martensite or troostite, the breaking strength, elastic limit and hardness are high, the elongation and contraction low, and the brittleness depends upon the content of carbon. These alloys are slightly softened by annealing and by quenching. The alloys showing the structure of a double carbide of iron and chromium have a somewhat high breaking strength and elastic limit, a somewhat low elongation and contraction, and are very brittle. They are softened by quenching at 850° C., and to a still greater degree by quenching at 1,200° C., owing to the disappearance, at least in part, of the double carbide. Annealing produces a similar effect.
—A. S.

Silver Trial-Plates; Constant Standard ——. E. Matthey. Proc. Roy. Soc., 1904, **73**, 124—127.

ᴛʜᴇ author has previously (this J., 1894, 889) shown that lates of sterling silver of an average weight of 4—5 kilos., nd of a uniform standard could be obtained by casting rom thin castings. Having regard to the difficulty experienced at the Royal Mint in obtaining large silver plates of onstant standard, the author has made further experiments. le finds that by sufficiently rapid cooling, liquation can be lmost completely prevented, which is the direct converse f the view hitherto accepted, viz., that a uniformity of andard is best attained by slow and uniform cooling. By asting the melted silver into a cold mould furnished with a ate, so that the metal entered the mould proper from the ottom, a plate was produced which, when rolled till it was mm. thick, measured 75 cm. × 90 cm., weighed 7·87 los., and showed a constant proportion of silver (925 parts r 1,000) nearly all over the plate.—A. S.

opper Losses in Blast-Furnace Slags. W. A. Heywood. Eng. and Mining J., 1904, **77**, 395.

Fig. 1 the ratio of the amount of copper in the slag from e blast-furnace to that contained in the matte produced at the same time is shown. 2,500 assays, extending over a period of 2½ years, were made, and as it was found that the percentage of copper in the slag was considerably influenced by the amount of silica also present, the results were plotted to form a number of curves representing slags containing varying percentages of silica. The ore smelted was heap-roasted pyrrhotite containing only from 10—20 per cent. of silica, and the deficiency of silica was made up by the addition of quartz. The copper was determined by the cyanide method, after precipitation with aluminium. The insoluble matter in the slag was represented as silica, the results obtained in this way being from 1·5 to 2 per cent. higher than those obtained by direct determination of the silica. The average composition of the slag produced during one month was :—Silica, 31·04; ferrous oxide, 51·40; alumina, 4·84; lime, 6·30; magnesia, 1·37; sulphur, 1·36; zinc, 2·01; manganese, 0·51; and copper, 0·45 per cent. The curves in Fig. 2 represent the actual losses of copper in slags containing different percentages of silica, allowance being made, in the case of the more silicious slags, for the increased amount of slag produced from the additional quartz added.—A. S.

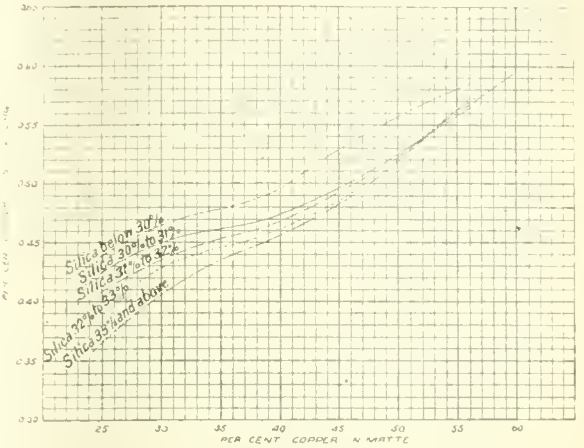

Fig. 1.

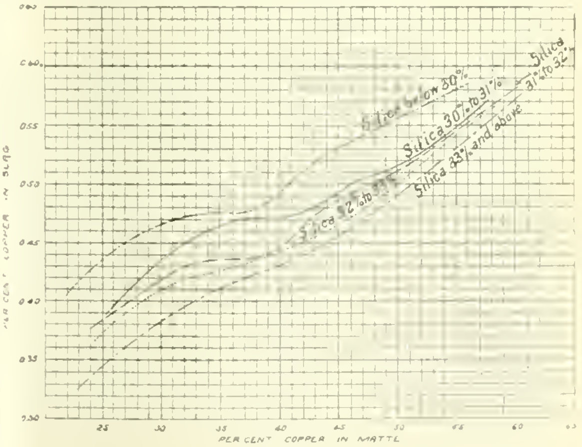

Fig. 2.

Zinc Retorts; Changes Produced in —— during use. O. Mühlhaeuser. Zeits. angew. Chem., 1903, 277.

ᴛʜᴇ flying ash constituents of the bituminous coal used in the furnace attack the clay substance of the retorts and form a continually thickening glaze, whilst on the inner side zinc spinel and tridymite are formed. When the wet charge is inserted, a network of cracks is formed on the outer surfaces, and these become filled with the glaze produced, which may even penetrate right through the walls and corrode the material. At the same time similar cracks are formed on the inside, these in turn filling up with fused slag which attacks the surrounding material and increases its density, the resulting inequalities in expansion easily inducing fracture. The same result ensues from the difference in temperature to which the mouth and body of the retort are exposed. The influence of the life of a retort on its usefulness is shown by the fact that the loss of zinc in a new retort is over 32 per cent. on the first day, but falls to 8·3 per cent. by the seventh day.—C. S.

Silicon; Solubility of ——, in Zinc and in Lead. H. Moissan and F. Siemens. Comptes rend., 1904, **138**, 657—661.

The results obtained by the author were as follows:—

Lead dissolves		Zinc dissolves	
At temp.	Per cent. Si.	At temp.	Per cent. Si.
° C.		° C.	
1,200	trace	600	0·06
1,250	0·024	650	0·15
1,330	0·070	730	0·57
1,400	0·150	800	0·92
1,450	0·210	850	1·62
1,550	0·780		

—J. T. D.

Metals; Crystalline Structure of ——. S. Kalischer. Phys. Zeits., 1903, **4**, 854—856. Science Abstracts (B), 1904, **7**, 204.

The author states that the crystallisation of hot platinum recently described by Holborn and Henning was observed by him in 1882, as also were similar changes in silver and gold. Zinc becomes crystalline above 150° C. The crystalline structure of the following metals is greatly developed by heating:—Rolled cadmium (at 200°—250° C.), rolled tin (200° C.), iron, copper, brass, alloys of copper, zinc and tin, tombac, bronze, and German silver.—A. S.

Density of certain Bodies (Metals); Diminution of —— by Strong Pressure. W. Spring. Bull. Acad. roy. Belg., 1903, 1066—1082. Chem. Centr., 1904, **1**, 776—777.

By the action of a very strong pressure (over 10,000 atmospheres) on a number of metals, and on certain other substances, a diminution of density (from 1·773 to 1·750 in the case of ammonium sulphate) instead of an increase is caused. The author considers that bodies composed of particles which are not perfectly spherical, have a tendency to "flow" when under the influence of strong pressure acting on all sides, the substance, in consequence, undergoing an alteration of molecular structure ("pseudofusion"), involving a diminution of viscosity. This hypothesis is in agreement with the fact that there is a connection between the phenomenon described above and the alteration of the volume of a substance on fusion. Metals like tin, lead, cadmium, and silver, which expand when fused, have their density increased when subjected to strong pressure; but bismuth, which contracts when fused, has its density diminished by pressure. Wires were prepared from different metals by forcing them through narrow openings. The fact that the bismuth wire was quite pliable at first, and only reverted to the brittle condition when it had been bent several times, was regarded as a confirmation of the view that the strong pressure had caused the particles of the metal to "flow." Each of the wires was divided into two portions, of which one was heated to near the melting point, causing the metal to revert to its normal condition. When the two portions of the wire prepared from each metal were now immersed in a solution of a salt of the metal, a weak electric current was set up, the cathode being the portion of the wire just as prepared, in the case of tin, lead, cadmium, and silver; but the portion which had been heated or "annealed," in the case of bismuth. In the following table the density of some metals at 16° C. after various treatments is shown:—

Metal.	Density of the Metal after the particles have been caused to "Flow."	Density of the Rolled Metal.	Density of the "Annealed" Metal.
Lead........	11·3351	11·3348	11·3410
Tin.........	7·3011	7·3016	7·3137
Cadmium...	8·6558	8·6603	8·6633
Silver.......	10·2485	10·2531	10·2596
Bismuth ...	9·8522	..	9·8354

It is stated that a distinction must be drawn between the "true" solid condition, in which a metal can suffer no notable deformation, and the "apparent" solid condition, which is characterised by loss of crystalline structure, and the capacity of "flowing." Certain substances (plastic metals) have the power of easily passing into this "apparent" solid state, whilst others have the power in very small degree or not at all. Substances of the latter class (coal, sand) are composed of particles which will not cohere and form a single mass even when subjected to strong pressure.—A. S.

English Patents.

Cast-Steel Ingots; Process of Perfecting ——. R. W. Hunt, Chicago. Eng. Pat. 23,821, Nov. 3, 1903.

The invention has for its object the prevention of blowholes and "pipes" in cast-steel ingots, and particularly in such as are intended to be made into rails. The molten steel is poured into a suitable ingot mould, which is allowed to stand until a substantial crust is formed upon it; then, immediately before stripping the mould from the ingot, a bar of steel, preferably of a higher quality than that of which the ingot is made, is driven into its central molten portion by appropriate mechanism. This is effected beneath a stripping machine, which, after driving in the bar, draws off the mould, and thus the "probable cavity" within the ingot is filled, and the quality of its axial portion is improved.—E. S.

Steel and Armour Plates; Process for Treating ——. E. Engels, Düsseldorf. Eng. Pat. 1842, Jan. 25, 1904.

The steel plates are heated to redness in a closed furnac in presence of oxygen, or of an oxygen-yielding substance then cooled in molten lead; mechanically treated by rolling &c.; again heated to redness in presence of carbides, t which substances decomposing these at a red heat hav been added; hardened in oil or the like; and then heate to a lower temperature than before in a furnace or met bath, and finally rolled and pressed. Or the plates ma be at once heated with carbides as described, withou undergoing the preliminary process, and after hardening i oil, be again heated, but to a lower temperature than befor Reference is made to Eng. Pat. 25,932 of 1903; this J 1904, 118.—E. S.

Furnaces; Puddling and similar Melting and Reheatin ——. J. Jones, Tipton. Eng. Pat. 4894, March 3, 190

A puddling or reheating furnace is constructed wi double walls, between which air passages proceed fro the chimney end of the furnace to the front of the fi chamber, where they meet in a common space. The a heated by traversing these passages, after passing throu perforations in the inner walls at the front end separatin the space in front from the fire chamber, issues throu the open top of the said chamber, and thus suppo combustion and obviates smoke.—E. S.

Crucible Furnaces. J. B. De Alzugaray, London. —— Eng. Pat. 9689, April 29, 1903.

The crucible rests on a pedestal, concentric with which an inner and an outer or main wall, in the annular spa between which the fire-bars are placed. A shallow annu trough beneath the grate contains water, the steam fr which mingles with the fire-gases above. The annu space between the inner wall and the pedestal, forms a down-flue for products of combustion, into a horizontal passage beneath, leading to the chimney. The furnace is covered by a dome, and a passage to the combustion chamber is provided for the fuel. The crucible has a tapping hole near the bottom. A modified form of furnace, in which the crucible is directly heated by the fuel, and in which a chimney may be dispensed with, is also claimed.—E. S.

Bronze and the like Metallic Powder; Production of ——. L. Lauer, Nürnburg. Eng. Pat. 9064, April 22, 1903.

The metal is melted, and caused to flow into a receptacle in a thin film, or rain, whilst being exposed to the action of a current of air, or of a non-oxidising gas, compressed or otherwise. Or a jet of water may be caused to impinge against the metal films falling in a uitable receptacle. The process may be modified in a ariety of ways, the object being, in any case, to produce he bronze as leaves, foil, or the like, to be then reduced to owder.—E. S.

Case-hardening Compound. J. Cadotte, Suncook. Eng. Pat. 2460, Feb. 1, 1904. Under Internat. Conv., April 16, 1903.

See U.S. Pat. 748,842 of 1904; this J., 1904, 118.—T. F. B.

United States Patents.

Steel; Process of Manufacturing ——. O. Massenez, Wiesbaden. U.S. Pat. 754,154, March 8, 1904.

See Fr. Pat. 329,132 of 1903 and addition thereto; this J., 1903, 1002 and 1353.—T. F. B.

ron or Steel; Cleansing and Improving the Quality of ——. F. C. Weber, Chicago. U.S. Pat. 754,262, March 8, 1904.

The process consists in adding to iron or steel, in a molten tate, "soluble binary metallic borides decomposable in olution under heat, furnishing nascent atoms for cleansing he metal, and a titanium alloy, whereby impurities and ccluded nitrogen will be eliminated by chemical reaction, nd the radical metals of the crystalline borides and titanium lloy will be united with the iron or steel."—E. S.

Steel Projectiles or other Articles; Manufacture of Hardened ——. R. A. Hadfield, Sheffield. U.S. Pat. 754,301, March 8, 1904.

ee Eng. Pat. 6089 of 1901; this J., 1902, 410.—T. F. B.

Gold [and Platinum]; Extracting —— from Rebellious Ores. E. C. Broadwell, Chicago, Assignor to J. A. Lyons, Chicago, and Sarah A. Starring, Springfield. U.S. Pat. 753,822, March 1, 1904.

he powdered ore is mixed with an alkali or alkaline-earth ypochlorite solution, and to the mixture is added "a salt e.g., copper sulphate) of a heavy metal having an acid ature, precipitable by hydrogen sulphide from its acid olution, and capable of acting with the alkali hypochlorite give the hypochlorite of the heavy metal."—E. S.

Metallurgical Furnace. F. Kepp, Brooklyn. U.S. Pat. 753,712, March 1, 1904.

he furnace includes a vertical discharge flue, a melting amber, of which the hearth has an inclined table and a shed portion or crucible, and a superposed initial heating amber or set of chambers communicating independently ith the flue at their rear ends. Each chamber has a fire-x at its front end, separate controllable air flues and parate heaters. A vertical shaft having a cover passes om each of the superposed heating chambers to the elting chamber beneath, admitting flow of molten metal om one to the other. The melting chamber is supplied th air by a valved "diving flue"; a pair of intersecting ches extends conjointly from the front of the fire-box to e front of the discharge flue, constituting the top wall, e arches having their point of intersection above the ucible, so as to deflect the flames downwards against the olten metal therein, and subsequently against the charge metal supported by the inclined table.—E. S.

Roasting Furnace. S. D. Craig, G. E. Kelly, and W. Turner, Laharpe. U.S. Pat. 754,194, March 8, 1904.

The furnace comprises a long casing, having a floor inclined downwards, on which track rails extend, carrying a carriage-agitator, on which is a swinging frame, having on each side two sets of scraper plates, the plates of the series at the ends being at reverse angles, and the plates at one end being at reversed angles to the plates of the other end, with means for holding the sets of plates in reversed position as to elevation. The material being roasted is thus forced, as the agitator traverses the furnace, successively towards and away from the centre rail. The furnace has a series of arched roof-plates, some of which form the bottom walls of a flue. The side walls have openings with removable doors. Fire-boxes communicate with the interior of the furnace, the ends of which latter have swinging doors. —E. S.

Blast Furnace. J. W. Pack, Berkeley. U.S. Pat. 754,337, March 8, 1904.

A slag-chamber and crucible are located in the lower part of a vertical stack, the slag-chamber being surrounded by a water-jacket. In the narrowest part of the furnace, above the slag-chamber and horizontally coinciding with the outer water-jacket, is an interior hollow water-jacket, having an interior open chamber, and the upper portion converging toward the bosh or neck of the furnace, to form inclined walls, which support and arrest the ore on its passage through. Oil burner pipes open through the interior water-jacket into the ore chamber, and through the outer jacket into the slag-chamber.—E. S.

Zinc; Process of Obtaining ——. E. H. Hopkins, London. U.S. Pat. 754,141, March 8, 1904.

See Eng. Pat. 12,859 of 1902; this J., 1903, 701.—T. F. B.

Zinc Blende; Separating Iron Pyrites from ——. K. Danziger, Kattowitz. U.S. Pat. 754,643, March 15, 1904.

Zinc blende containing iron pyrites is subjected "to the action of air, moisture, and heat," and the ferrous salt thus formed is washed out by water.—E. S.

Ores, Mattes, &c.; Treating ——. J. A. Potter, New York. U.S. Pat. 754,159, March 8, 1904.

A furnace, the bed of which is separated into two pockets by a transverse central elevation of the bed, is so supported that either end may be sufficiently elevated to allow flow of the melted contents of the elevated pocket into the depressed pocket. A molten metallic bath is formed in one of the pockets, and a separate charge of solid materials is "preheated" in the other pocket; the molten charge is then, by tilting the furnace, caused to flow over the solid material; a portion of the combined mass is then tapped out, and another charge of solid material is "preheated" in the pocket from which the molten charge was poured. Compare U.S. Pat. 710,300 of 1902; this J., 1902, 1333. —E. S.

Ores; Process of Separating —— from Magnetic Gangue. T. A. Edison, Llewellyn Park. U.S. Pat. 754,756, March 15, 1904.

A magnetic ore, such as "pyrrhotite" associated with a relatively small proportion of a non-magnetic ore (a nickel ore for instance) is ground to a fineness sufficient to free the non-magnetic particles, and is mixed with a larger bulk of a coarser non-magnetic material. The mixture is then treated in a magnetic separator, and the non-magnetic tailings are screened to separate the added coarse material from the nickel ore.—E. S.

Matters in Fusion [Metals, &c.]; Process of Treating —— [with Sodium]. P. L. Hulin, Clavaux. U.S. Pat. 754,566, March 15, 1904.

See Fr. Pat. 327,982 of 1902; this J., 1903, 1052.—T. F. B.

Tins; Method of Printing on ——. I. Kitsee, Philadelphia. U.S. Pat. 753,144, Feb. 23, 1904.

A metal is printed on with an ink containing a second metal in solution; and the printed-in parts are subjected to the action of a sulphur compound. Tins or tin cans may be printed on with an ink containing an acidulous compound of copper, thickened with gum, followed by application of a sulphur compound.—E. S.

French Patents.

Steel; Process for the Deoxidation and Desulphurisation of ——. Soc. Electro-Métallurgique Française. Fr. Pat. 336,705, Nov. 2, 1903.

Calcium carbide, together with silica or other flux for lime, is added to the scoria associated in the furnace with molten steel. The scoria thus deoxidised, reacts on the metal to deoxidise or desulphurise it, as the case may be. The process is stated to be particularly applicable in an electric furnace. Reference is made to Fr. Pat. 320,682 of 1902; this J., 1903, 148. See also U.S. Pat. 724,770 and Fr. Pat. 328,350, both of 1903; this J., 1903, 557 and 955; and Add. to Fr. Pat. 328,350 and Eng. Pat. 8101 of 1903; this J., 1904, 25 and 118.—E. S.

Cementation Furnace. A. Gueur, H. Mertens, and J. Lalemant. Fr. Pat. 336,116, Oct. 19, 1903.

The furnace is adapted to receive on its hearth a covered case containing the iron, and the cementation is effected by exposure to the heat of the fire-gases entering from centrally and laterally arranged flues, through openings in the bottom of the sole, and through the sides of the chambers. The loaded case, placed on a truck, travels on rails to the front of the furnace, and arrangements are provided for drawing the case inwards to its place on the hearth, on opening a counterpoised sliding door, which is afterwards closed.—E. S.

Solder for Aluminium or Aluminium Alloys. M. Forest. Fr. Pat. 336,354, Jan. 13, 1903.

The solder consists of foil, sheet, bar, wire, or the like, of zinc, or of a zinc alloy, coated with a layer of nickel.—E. S.

Alloy for Soldering Aluminium. A. A. Bancal and A. Sturm. Fr. Pat. 336,297, Oct. 29, 1903.

The solder is obtained by melting together in stated order and with certain precautions, magnesium, 20 parts; borax, 50 parts; zinc, 1,000 parts; zinc phosphide, 40 parts; tin, 260 parts; and powdered copper sulphate, 250 parts. The proportions may be varied to suit special requirements. The introduction of magnesium in any convenient proportion is claimed as a characteristic feature of the invention.—E. S.

Mineral Briquettes; Furnace for making ——. G. Gröndal. Fr. Pat. 336,605, Oct. 27, 1903.

See Eng. Pat. 23,764 of 1903; this J., 1904, 118.—T. F. B.

Lead Ores; Desulphurising ——. A. Savelsberg. Fr. Pat. 336,540, Nov. 12, 1903.

Fuel, alternating with layers of limestone fragments, is ignited at the bottom of an ordinary converter, into which air is blown, and well moistened lead ore is added in successive layers, and at intervals between layers of limestone, &c., the proportion of the latter used being usually from 15 to 20 per cent. of the weight of the lead ore treated. The ore is wetted, not merely to prevent occurrence of dust, but also to increase the proportion of sulphuric acid formed in the process. The final product is a silicate containing lead oxide, which admits of ready treatment in a cupola furnace.—E. S.

Zinc and Lead, and generally all Metals having less Affinity for Sulphur than Copper; Extracting ——, *from their Sulphides.* A. H. Imbert. Fr. Pat. 336,660, Nov. 14, 1903.

The process consists in heating the sulphide ore with granulated copper, and, if necessary, a flux. The copper sulphide produced, after separation of the reduced metal, is treated for recovery of the copper in a Bessemer converter.—E. S.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

(A.)—ELECTRO-CHEMISTRY.

Nitrogen Oxides from Air; Yield of —— *by the Flame Discharge. Influence of Length of Flame and Temperature.* F. v. Lepel. Ber., 1904, **37**, 712—719. (Compare this J., 1903, 303 and 636.)

When the discharge occurs between a copper wire anode and a carbon cathode, the poles are clearly differentiated, both by the naked eye and by the spectroscopic appearance of the flame; and this difference is also shown in the chemical effects of the discharge, for the gases drawn from the immediate vicinity of the cathode contain a much larger proportion of nitric oxide than those taken close to the anode. Receding from anode and cathode, however, the proportions respectively increase and decrease, so that at 5 mm. from the anode, the air surrounding the flame is richer in nitric oxide than at 20 mm. from the cathode. Naturally the highest total yield of nitrogen oxide is got by taking the air surrounding the flame along its whole length. The author considers that the formation of nitrogen oxides is due to direct electrical action, and is not solely thermal, as Muthmann and Hofer suppose. In experiments in which the voltage and current in the primary were kept constant, the temperature of the air at a certain distance from the flame (and hence presumably that in the flame itself) rose as the speed of rotation of the anode was increased from zero, and also as the length of the flame was increased. The yield increased with the temperature (to a quickly reached maximum) only when the anode was fixed. The best yield was always obtained with a medium temperature. The frequency of the interrupter was also varied, but moderate frequency was found to give the best results: a Wehnelt interrupter is not suitable. The yield is increased by soaking the cathode in various salt solutions, such as potassium hydroxide, copper sulphate, or titanium chloride. The solution of nitrate and nitrite obtained by neutralising with sodium carbonate the aqueous solution of the nitrous gases produced by the process can be used as manure, and is apparently as efficient as Chili saltpetre, so that for this purpose the conversion of the nitrite into nitrate is not necessary.—J. T. D.

Calcium Carbide; New Mode of Formation of ——. H. Moissan. XXIV., page 388.

English Patents.

Lead Peroxide on Plates of Electric Accumulators; Impts in forming ——. J. Diamant, Hungary. Eng. Pat 6954, March 25, 1903.

Lead peroxide is formed on the surface of plates of larg superficial area for accumulators by adding to the electrolyte about 0·1 per cent. of a sulphonic acid or hydroxy sulphonic acid derivative of methane, or a mixture of thes substances.—B. N.

Coating and Impregnating Porous Materials [Insulatin Materials] with Oils, Varnishes, or the like; Method of ——. E. A Carolan, London. From Gen. Elec. Co New York. Eng. Pat. 7134, March 27, 1903.

The fabric is saturated with a volatile liquid, such gasolene, and then immediately dipped into an insulatin substance, such as linseed oil or varnish, which is soluble i the gasolene, and preferably heated. The sheets are drie and subjected to pressure at a high temperature.—B. N.

Electrodes for Secondary Batteries; Manufacture of — C. Roderbourg, Hagen. Eng. Pat. 11,276, May 18, 1903

Nickel compounds are applied as a paste to a suital support, and the pasted electrodes are first suspended in alkali so as to form a layer of nickel hydroxide on t surface, and then subjected to the oxidising action of electric current so as to form highly-oxidised nickel oxide —B. N

Solutions for Use in the Cells of Galvanic Batteries; Impts. in ——. W. H. Wheatley, London. From the Atwood Electric Co., Boston. Eng. Pat. 28,057, Dec. 21, 1903.

The positive or carbon electrode is immersed in a solution repared as follows:—7 lb. of sodium nitrate are added to 6 lb. of nitric acid, 30° B., and the mixture poured into ½ lb. of sulphuric acid, 25° B. Sulphuric acid is added to 4 galls. of water till the sp. gr. reaches 1·2, and the two iquids are then mixed. The negative or zinc electrode is mmersed in a solution prepared thus:—Sulphuric acid is dded to 30 galls. of water till the sp. gr. is 1·2, and 1½ lb. f ammonium carbonate, 10 oz. of sodium carbonate, and 0 oz. of mercury bisulphate are then added, the liquid eing afterwards diluted with 6 parts of water.—B. N.

United States Patents.

lectrodes for Storage-Battery Cells; Process of Preparing ——. O. Frank, Assignor to L. J. Lennox and Michigan Storage Battery Co., all of Detroit. U.S. Pat. 753,383, March 1, 1904.

HE lead electrodes are first immersed in an electrolyte onsisting of "95 per cent. of water, 5 per cent. of sodium ulphate, and 0·7 per cent. of potassium chlorate," and an lectric current of one ampère is passed through the elecrodes for 50 hours at a temperature of about 20° C. The lates are removed, washed with distilled water, and the ositive plates placed in a weak solution of sulphuric acid. hese positive plates are used as the negative electrodes, nd sheets of lead as the positive, and a current of two mpères is passed for 50 hours; the plates are removed, ydrochloric acid extracted by thorough washing with dislled water, and the electrodes dried at a temperature of 00° C., preferably in a current of air charged with lead mes.—B. N.

lectrodes; Process of Preparing ——. G. J. Atkins, Tottenham. U.S. Pat. 754,114, March 8, 1904.

French Patent.

lectrodes. G. Cornaro. Fr. Pat. 336,817, Oct. 15, 1903.

HE electrodes are made from one or more powdered tals or non-metals, pure, or mixed together, or mixed h carbon, metallic or non-metallic oxides, oxygen salts, .—B. N.

ectrodes for Accumulators; Process of Producing Plates f Active Material for use as ——. Pflüger Accumulaorenwerke A.-G. Fr. Pat. 336,549, Nov. 12, 1903.

E plates of lead or lead alloy, furnished with active terial in the usual manner, are heated to a temperature ve the melting point of the metal employed to form grids; the metal melts and runs off, but leaves a porous allic pellicle on the surface of the active material, and s maintains the latter intact.—B. N.

vement of Liquid during Electrolysis; Process and pparatus for Producing ——. Soc. Consortium für lektrochem. Ind. G. m. b. H. Fr. Pat. 336,213, Oct. 22, 903.

T electrolyte is circulated from the anode to the cathode o the surface of the diaphragms, so as to remove by s tion the cathode liquid which is travelling by diffusion t ards the anode. Two forms of diaphragms are described, t first made up of wedge-shaped pieces of material p ed one above the other, and the second of pieces disp d like bricks in a wall, the interstices being enlarged b ronves so as to admit of a better circulation of the li d.—B. N.

High Temperatures; Process and Apparatus for the Production of ——, by means of Combined Chemical and Electrical Energy. R. Schnabel. Fr. Pat. 336,452, Nov. 5, 1903.

This invention relates to a process and apparatus for electrically heating a gas, or other combustible matter, before or during combustion. The gas passes first into a hollow vertical positive carbon electrode, and then, by means of small openings below, into an annular space between the two electrodes, this space being filled with high-resistance material. In an alternative form, the outer cylindrical negative electrode is surrounded by a space into which the gas passes, small openings at the base serving to conduct the heated gas into the annular space containing high-resistance material. The air or oxygen in this case is conveyed by a tube nearly to the top of the hollow positive electrode, and as before, into the annular space, so as to be mixed with the gas; or the mixture of gases may be carried by a porcelain tube from the annular space surrounding the negative electrode to the inside of the positive electrode, and thence to the annular space containing the resistance material. In a second form, the gas is heated by being passed through the hollow vertical positive electrode of an electric arc, two or more horizontal electrodes forming the negative pole. The former is filled with fragments of carbon to increase the heating surface, or may contain a rod of carbon so placed as to form an annular space around the rod, which is filled with high-resistance material. The current passes through the latter from the rod, and the gas is subjected to the combined heating effect of the arc and resistance material. Water-gas may be used, or this may be produced by passing steam over the carbon forming the resistance material, the products of decomposition being afterwards heated and burnt.—B. N.

Ozonising Apparatus. G. Labille. Fr. Pat. 336,530, Nov. 11, 1903.

The dielectrics are made of agglomerated mica, and between these is placed a vessel of metal, such as aluminium, which is not easily oxidised, and through which a current of cooled conducting liquid is circulated. A space is left between the dielectrics and the metal vessel, and through this space air or oxygen is circulated, the joints being made gas-tight with asbestos. Into the liquid in the metal tube is plunged a glass vessel containing a conducting liquid, with suitable connections, so as to act as a condenser for producing oscillating discharges.—B. N.

(B.)—ELECTRO-METALLURGY.

United States Patents.

Iron Alloys; Electrical Manufacture of ——. G. Gin, Paris. U.S. Pat. 753,875, March 8, 1904.

See Eng. Pat. 12,702 of 1902; this J., 1903, 872.—T. F. B.

Furnace; Electric ——. C. A. Keller, Paris. U.S. Pat. 754,656, March 15, 1904.

See Eng. Pat. 24,234 of 1901; this J., 1902, 354.—T. F. B.

French Patents.

Furnace; Electric —— with Induced Currents. A. Fauchon-Villeplée. Fr. Pat. 336,313, Oct. 30, 1903.

An electric furnace, in the form of a retort or crucible, in which the material to be treated, instead of being placed in an annular trench surrounding the core of the transformer, is intercalated in the circuit of the armature. The lines of force pass from one pole to the other through the armature and return through the material, the induced currents in the latter raising the material to the desired temperature. —B. N.

Furnaces; Impts. in Electric ——. C. A. Keller. Fr. Pat. 336,403, Nov. 2, 1903.

The electrodes of different polarity are disposed in separate cavities, communicating below by a space which contains the material to be treated, and through which the whole of the current must pass. The electrode spaces are separated by a hollow dome of non-conducting material, closed by a plug which permits of access to the material, or of the introduction, if necessary, of a current of air.—B. N.

Iron Sand and other Refractory Ores; Method of and Apparatus [Electric Furnace] for Treating ——. D. R. S. Galbraith and W. Steuart, New Zealand. Fr. Pat. 336,726, Nov. 16, 1903.

Iron sand, or other refractory powdered ore, with or without addition of carbon or a flux, is showered down in a vertical electric furnace, in the lower part of which (in one form of the furnace) are set transversely a number of resistance rods, which may be provided with shields or screens, either surrounding them or protecting their upper surfaces. These incandescent resistance bodies are set in such alternate order, row below row, as to deflect the falling grains from side to side, and to bring them successively into contact with such bodies in the zone of greatest heat, whilst meeting an upward current of a previously heated redneing gas or vapour, such as the vapour of a mineral oil injected into a closed chamber through an electrically heated side passage, into which chamber the treated mineral passes through an outlet in the bottom of the furnace; this chamber is provided with outlets for the slag.—E. S.

Iron Sand, Iron Oxides, and other Refractory Ores; Process and Apparatus [Electric Furnace] for the Reduction of ——. D. R. S. Galbraith and W. Steuart, New Zealand. Fr. Pat. 336,727, Nov. 16, 1903.

The process described in the preceding abstract is modified in certain details, and especially in respect to the heating zone of the furnace, in which series of non-conducting screens, having electrical conductors touching their ends, are arranged in similar order to the resistance bodies described in the former patent. The grains of ore are showered upon these screens through perforations in V-shaped troughs, and on reaching them they complete the electric circuit and become incandescent, and similarly, as they fall from screen to screen, always against an upwardly passing current of a heated reducing gas or vapour.—E. S.

Nickel from Garnierite and other Minerals; Electric Process for the Extraction of ——. Soc. Elec. Metall. Française. Fr. Pat. 336,376, Oct. 30, 1903.

A mixture of a mineral of nickel with a flux and carbon is treated in an electric furnace with suitable metals, so as to obtain nickel free from sulphur and silicon. The alloy may be refined by oxidation, and a product richer in nickel is obtained, the slag being returned to the reducing furnace. With iron, nickel, and cobalt an alloy known as "electric nickel" is obtained, which is useful in the manufacture of nickel steel. The crucible has a base of refractory material covered with metal, and the walls are of a non-reducible mineral and are kept cool.—B. N.

XII.—FATTY OILS, FATS, WAXES, AND SOAP.

Bears' Fat; Characteristics of ——. P. N. Raikow. Chem.-Zeit., 1904, **28**, 272—273.

Fresh bears' fat is white and very similar to lard in appearance. The flare fat is softer and more transparent than the kidney fat, and its odour recalls that of fresh bacon. Bears' fat differs from the fats of the dog, fox, and cat in having a lower specific gravity, a very low melting point, and a fairly high iodine value. The specimens examined by the author gave the following results:—

Origin.	Sp. Gr. at 15°/15° C.	M. Pt. of Insol. Fatty Acids.	Acid Value.	Ester Value.
		° C.		
Flare fat....	0·9209	32—32·25	2·2	192·6
Kidney fat..	0·9211	30·5—31	2·2	198·1—198·3

Origin.	Iodine Value.	Reichert-Meissl Value.	Refractometer Reading.	
			at 25° C.	at 40° C.
Flare fat....	98·5	1·66	61·2	53·0
Kidney fat..	106·5—107·4	1·15	61·2	53·0

The author points out that these iodine values do not confirm the statement of Henriques and Hansen, that the iodine value decreases with the nearness of the fat to the interior of the body.—C. A. M.

English Patent.

Brewers' and Distillers' Yeast; Utilisation of —— in the Manufacture of Artificial Manures. W. Wardle, Burton-on-Trent. Eng. Pat. 10,581, May 9, 1903.

A mixture is made of about 2 parts of yeast with 1 part of sodium chloride and 5 parts of calcium sulphate, by weight, for use as a manure. Pure or impure yeast, or yeast previously treated for the extraction of a portion of its constituents, may be used, and the gypsum may be replaced by other "earthy substances of a like non-corrosive nature." See Eng. Pat. 6971 of 1901; this J., 1902, 183.—E. S.

XVI.—SUGAR, STARCH, GUM, Etc.

Maltose and Dextrin; Hydrolysis of —— by Dilute Acids, and the Determination of Starch. W. A. Noyes and others. J. Amer. Chem. Soc., 1904, **26**, 266—280.

In all the experiments the hydrolysis proceeded more slowly towards the end of the reaction, and never followed the course of a normal mass reaction. The authors have found that, whilst the cupric-reducing power of glucose was scarcely affected by heating with hydrochloric acid of 2·5 per cent. strength, that of the products formed by the hydrolysis of maltose decreased after reaching a maximum after about one hour at 100° C.; the maximum reducing power corresponded to a hydrolysis of 96—98 per cent., which is 98—99 per cent. of the cupric-reducing power which would be attained on complete hydrolysis. The hydrolysis was more complete in solutions containing 2—4 per cent. of maltose than in 0·5 per cent. solutions. The rate of hydrolysis for dextrin (prepared by malt) was about one-half of that for maltose. The hydrolysis reached 90 per cent. in one hour, and rather less than 95 per cent. in two hours at 100° C. The mixed products of the conversion of starch by malt, containing 74—78 per cent. of apparent maltose, gave a maximum reducing power at 100° C. after about one hour, the copper oxide reduced by a 2 per cent. solution being 97·1 per cent. of the quantity corresponding o complete hydrolysis. By the direct treatment of maize starch with 2·5 per cent. hydrochloric acid, a hydrolysis of 17 per cent. was attained in one hour, and 98 per cent. in four hours at 100° C. in 0·5 per cent. solution; in this case no decrease of cupric-reducing power occurred on prolonged heating. For the determination of starch, the solution obtained by conversion with malt should be treated, after iltration, with 10 per cent. by volume of hydrochloric acid, p. gr. 1·125. The solution should be heated up in a boiling water bath and subsequently maintained at that emperature for one hour. The solution is then cooled and reated with caustic soda sufficient to neutralise 90 per cent. f the acid present; it is then made up to a definite volume nd filtered if necessary, the cupric reducing power being etermined by Fehling's solution, previously standardised with pure glucose; 100 parts of glucose may then be taken o represent 93 parts of starch in the original material.

French Patent.

Sugar Juice; Process and Apparatus for Crystallising ——. H. Mathis. Fr. Pat. 336,796, Nov. 19, 1903.

The syrups are concentrated to a high degree of supersaturation so as to contain 6—8·5 per cent. of water, the formation of fine grain being prevented by gradually increasing the temperature to a high degree. The syrup is then transferred to a closed vessel provided with stirrers and an external heating jacket, the temperature being maintained between 92° and 100° C., whilst a vigorous agitation is kept up and a current of high-pressure steam or air is introduced into the mass through a longitudinal slit in the bottom of the vessel. Subsequently, the crystals produced are increased in size by a slow process of evaporation, by aspirating a current of heated air across the surface of the mass and adding from time to time small quantities of suitably diluted molasses, the stirrers being kept in motion.—J. F. B.

XVII.—BREWING, WINES, SPIRITS, Etc.

Barley; Germination of ——. A. Nilson. J. Amer. Chem. Soc., 1904, **26**, 289—294.

The author contends that enzymes are not the primary cause of the germination of grain, but that they only play their part when germination has been fully started, their appearance being rather the result than the cause of growth. He suggests that the real starting agents of germination are the lactic acid bacteria, always present on the surface of the grain. These develop acid under the hulls of the corn during steeping, at the expense of the ready-formed sugars. The lactic acid produced, then dissolves the insoluble albumin, thus in some way starting the liberation of enzymes which carry on the metabolism. If barley be steeped in a decinormal solution of sodium hydroxide for 24 hours, it turns a dark brown colour, and a condition is established under which any enzymes, if present, would be absolutely paralysed. But if the steeped grain be transferred to a germinating tray, pale spots gradually appear on its surface; subsequently rootlets are formed and the corn regains its natural colour. On the other hand, if the grain be steeped in solutions which are inimical to bacteria but harmless towards enzymes, no growth will take place. Such a result occurs if barley be steeped for 24 hours in toluene-water, even if the steeped grain be subsequently thoroughly washed with water. If, however, germination be started in the ordinary way, the sprinkling of the growing seedling with toluene-water has no effect. Unlike sodium hydroxide, a N/20 solution of ammonia so debilitates the lactic acid bacteria that barley, when steeped in this reagent, will not germinate. Since the ammonia has no effect upon the putrefactive bacteria, these soon obtain the upper hand.—J. F. B.

Steely Malt in Modern Brewing, and the Filter-Press. C. B. Davis. Amer. Brewing Inst.; through Brewers' J., 1904, **40**, 184—185.

The effect of steely corns in reducing the yield of extract is shown by determining the quantity of extract in worts made by mashing the fine meal and coarse grist respectively, the difference between the two results being proportional to the percentage of steely corns. In preparing the grist in the brewery, the steely corns are merely cracked by the grinding rolls, and the starch is largely protected from the action of the diastase. It must be borne in mind, however, that the portion of mash withdrawn for the decoction (about 23 per cent. of the total) is completely converted, and yields the whole of its extract in the mash-tun, whether the corns are steely or not. The loss of extract due to insufficient sparging is estimated at about 5 per cent. In working the filter-press method, the malt is ground to flour, and the proportion of steely corns does not affect the yield. With steely malt, a portion of unconverted starch may pass into the wort, causing turbidity, or at least an excessive acidity due to lactic fermentation, which is liable to upset the normal composition of the proteid constituents, thus causing "albuminoid" turbidities. The wort from such grists also does not "run off"

rapidly, and does not show a normal "break." New malt, straight from the kiln, is also liable to cause turbidities; the malt should always be kept in store for 2—3 weeks. Lastly, turbidities may occur even with well milled malt, if the temperature of the sparging water exceed 67°—68° C.
—J. F. B.

Wort: Determination of Colour of ——. Comparison between the New Style (Berlin Congress) and the Old Style of Expressing the Colour-type of Malt. H. Hanow. Woch. Brau., 1904, **21**, 153—154.

Referring to the new method of expressing the colour-type of a malt in terms of the number of c.c. of N/10 iodine per 100 c.c. of water required to match the colour of the standard laboratory wort as prepared for analysis (see this J., 1903, 1205), the author amplifies the table there given for comparing the results found by the new method with that hitherto in use. The numbers given in the second, third, fourth, and fifth columns of the table (*loc. cit.*) represent the colour-types expressed according to the old style, employing N/100 iodine and calculating the results per cent. of extract in the malt. In the present article, an extended table relating only to the paler types of malt, yielding worts of colour values between 0·13 and 0·75 (new style) is given, showing the equivalents of these grades for worts of gravities between 7·5° and 8·8° Balling in terms of the old style of colour-types, *i.e.*, the number of c.c. of N/100 iodine per 100 c.c. of water required to match the colour of 100 grms. of malt extract.—J. F. B.

Beer; Causes of the "Head"-retaining Property of ——. O. Mohr. Woch. Brau., 1904, **21**, 149—150.

From experiments on the "head"-retaining power of a solution of commercial peptone, before and after filtration, and after the addition of 0·005 per cent. of zinc sulphate to the filtered solution, the author concluded that the "head"-retaining properties of beer are absolutely independent of its viscosity, but are caused by the presence of suspended particles of colloidal bodies in an infinitely minute state of division, such as can only be detected by the "ultramicroscope." This instrument has shown that solutions of colloidal substances are made up of such particles, the shape of which depends on the nature of the colloid; such observations applied to beer should reveal the nature of the particles which impart the "head"-retaining properties. It is known that any influence which tends to agglomerate these fine particles to form larger ones, *e.g.*, turbidity caused by chill, also detracts from the permanence of the "head."—J. F. B.

Wines: Turbidities of Sparkling ——. L. Mathieu. Bull. Assoc. Chim. Sucr. et Dist., 1904, **21**, 854—872.

The subject is treated under the following headings:—I. Classification of forms of turbidity. II. Mineral matters. III. Organic salts. IV. Amorphous organic matters. V. Coagulation by metallic salts. VI. Coagulation by oxidation. VII. Turbidity from various causes. VIII. Dead organised matters. IX. Living micro-organisms. X. *Saccharomyces ellipsoideus.* XI. Maladies caused by microbes. XII. Various micro-organisms. XIII. Special turbidity of gassed wines.—L. J. de W.

Oak-Wood; Extractive Action of Spirit of Various Strengths on ——. Gelatin; Solubility of —— in Spirit. G. Heinzelmann. Zeits. Spiritusind., 1904, **27**, 95—96.

Shavings were taken from new oak-wood staves of Hungarian and Russian origin; these were treated with spirit of 95, 90, and 86 per cent. strength (by volume) respectively for 10 days, and the non-volatile extractive matter absorbed by the spirit was determined. Both samples of Hungarian wood yielded more extract than the Russian; the quantity of extract dissolved increased as the strength of the spirit was decreased; the first extracts were considerably heavier than subsequent extracts, but distinct quantities were found even after four extractions; in the later extracts the differences between the behaviour of the different strengths of spirit disappeared. It is concluded that the solid wood in the form of casks would yield extractive matter even after the casks had been in use for a considerable time. Previous extraction of the wood with boiling water for 2—6 hours failed to remove the resinous extractive matters, but appeared to facilitate the complete exhaustion of the wood when subsequently treated with spirit. Experiments with gelatin, such as is employed for glazing the interior of casks used for rectified spirits, showed that the gelatin was quite insoluble in 95 per cent. spirit, but 90 per cent. spirit dissolved 0·1 grm. and 86 per cent. spirit dissolved 0·25 grm. of gelatin per litre. When the spirit contained tannin matters extracted from previous contact with wood, the gelatin removed some of the tannin matter from 90 per cent. and 86 per cent. spirit; in presence of 95 per cent. spirit the reaction between gelatin and tannin did not take place. On account of the solubility of gelatin in spirit it is not advisable to use glazed casks for crude spirits, in order to protect them from the wood, unless their strength is above 90 per cent.—J. F. B.

Enzyme Action; Studies on ——. I. Correlation of the Stereoisomeric α- and β-Glucosides with the corresponding Glucoses. E. F. Armstrong. XXIV., page 388.

Malt; Determination of Moisture in —— by Hoffmann's Apparatus. J. H. Schulze and G. Marienhagen. XXIII., page 386.

ENGLISH PATENT.

Brewers' and Distillers' Yeast; Utilisation of —— in the Manufacture of Artificial Manures. W. Wardle. Eng. Pat. 10,581, May 9, 1903. XV., page 379.

UNITED STATES PATENT.

Honey; Process of Fermenting ——. A. V. Kouba, Milligan. U.S. Pat. 754,461, March 15, 1904.

Honey is dissolved in water to a saccharometer gravity of 21°, the solution is boiled and skimmed, chalk is added in the proportion of 40 lb. per 100 galls. of liquid, boiling and skimming are continued, animal charcoal in the proportion of 50 lb. per 100 galls. is added and the liquid is cooled allowed to settle, and drawn off clear. A suitable ferment is added consisting of 15 lb. of wine yeast, 6 oz. of ammonium phosphate, 15 oz. of ammonium tartrate, 25 oz. of potassium bitartrate, 11 oz. of tartaric acid, and 6 oz. of magnesium sulphate per 100 galls. of liquor.
—J. F. B.

FRENCH PATENTS.

Brewing; Saccharifying and Filtering Apparatus for ——. L. Dacier. Fr. Pat. 336,477, Nov. 7, 1903.

The mash tun is provided with agitating rakes mounted on vertical and horizontal shafts and moving in different directions. The strong wort is drawn off clear by a pipe situated at some distance from the bottom of the tun; the thick residues of the mash are then discharged from the bottom into a special filter-press composed of alternate filter-plates and spacing frames. The frames are provided with agitators, which can be operated from the outside to prevent the mass clogging the cloths. The filter-plates are divided by corrugated partitions into two compartments, one to each filtering surface. The washing waters can be caused to flow in two directions, to discharge on either side of the cakes. The first compartments of the filter may, if desired, be closed by valves, which are opened one by one after the further compartments have been filled.—J. F. B.

Alcoholic Liquids; Purification of ——. F. Verbièse and E. Darras. Fr. Pat. 336,795, Nov. 19, 1903.

Crude alcoholic liquids, distillery phlegms, &c., are treated with peroxides or dioxides of alkalis or alkaline earth before rectification, in proportions calculated from the acidity of the liquor, and varying generally between 1 and 50 grms. per hectolitre of phlegms. The base liberated by the decomposition of the peroxide serves to neutralise the free acidity of the phlegms.—J. F. B.

XVIII.—FOODS; SANITATION; WATER PURIFICATION, & DISINFECTANTS.

(A.)—FOODS.

Formaldehyde; Action of —— on Milk. A. Trillat. Comptes rend., 1904, **138**, 720—722.

Milk, to which formaldehyde in varying quantity had been added, was curdled with rennet; and casein from freshly curdled milk was also suspended in vessels of water containing varying amounts (1/10,000—1/20,000) of formalin. All were then subjected to digestion with pepsin, along with untreated casein from the same source. The undigested residues were in the first series 5—6 per cent., in the second 30 per cent. greater than those from the untreated casein. It is proved, then, that formalin, even in these small doses, impairs the digestibility of milk. Moreover, formalin added to milk is there as formalin as long as the milk remains unaltered, so that the absorption of formalin-treated milk implies the absorption of the whole dose of formalin added. Both by its action on the gastric mucous membrane and from its rendering casein less digestible, formalin in small daily doses is thus at least a possible danger to health, and its use, like that of other preservatives, should be prohibited. —J. T. D.

Cooked Vegetable Foods; Chemical Composition of ——. Katharine I. Williams. J. Amer. Chem. Soc., 1904, **26**, 244—252.

The chemical composition was determined of various vegetable foods cooked in the usual manner, except that no salt or flavouring substances, sugar, &c., were added. The results are shown in the following table :—

——	Price per lb.	Refuse.	Used for Cooking.	Composition of the Edible Portion of the Cooked Foods.							
				Water.	Ash.	Protein (N × 6·25).	Woody Fibre.	Cellulose.	Fats.	Starch.	Undetermined.

'eeding Stuffs; Yield and Components of Bodies called "Fibre" and "Carbohydrates" in ——. P. Schweitzer. J. Amer. Chem. Soc., 1904, **26**, 252—262.

n a comparative investigation of the [American] Official gric. Chem. method, the chlorate method, and the bromine ethod of preparing the "crude fibre" in cattle foodstuffs, was found that the O.A.C. method gave the lowest yields f fibre, but that the chlorate method, on the average, gave ields not very different; the bromine method, on the other and, gave considerably higher yields, owing to the fact iat the pectose is not removed from the fibre by this agent. The different "crude fibres" were separated into rce portions by extraction with Schweitzer's reagent, the llowing being the average proportions of the three groups components in the fibres prepared from the green foods udied :—

——	O.A.C. Method.	Chlorate Method.	Bromine Method.
	Per Cent.	Per Cent.	Per Cent.
bre undissolved by Schweitzer's reagent	14·07	2·29	3·28
luble, and reprecipitated by acid	75·61	83·57	71·76
rmanently soluble (hydrolysed)	10·32	14·14	24·95

The table in which the results of the author's analyses e summed up includes the following determinations for samples of cattle foods :—"Crude fibre," by O.A.C. thod; "carbohydrates," by difference; "true fibre," , the "crude fibre" *minus* the pentosan contained in it; ibro-pentosan," from the furfural yielded by "crude re"; "pectose," *i.e.*, the "crude fibre" by the bromine thod *minus* the "crude fibre" by the O.A.C. method; ecto-pentosan," from the difference between furfural determinations in "crude fibres" by bromine and O.A.C methods; "pentosan," from difference between total furfural in foodstuff and furfural in "crude fibre" by bromine method (this "pentosan" is mainly associated with the "indefinite carbohydrates"); "sugar"; "starch"; "indefinite carbohydrates" of unknown composition, by difference.—J. F. B.

Wheat Flour; Determination of Gliadin in ——, by means of the Polariscope. H. Snyder. XXIII., page 387.

Cocoanut Oil in Butter; New Method for Determining ——. E. Polenske. XXIII., page 387.

English Patents.

Water and other Liquids and Alimentary Substances; Sterilisation of ——. V. B. Nesfield and A. Crerar. Eng. Pat. 4759, Feb. 28, 1903. XVIII. B, page 382.

Liquid Extracts [Coffee, &c.]; Apparatus for the Production of ——. E. H. Schofield, Atlanta, and L. C. Cole, Bowling Green. Eng. Pat. 11,450, May 19, 1903.

The apparatus consists of a horizontal cylinder, heated preferably by steam or hot water. The solvent enters at one end, and the body to be extracted, packed in suitable permeable cartridges or cases, is introduced at the other end. Arrangements are provided for pushing forward, rotating, and discharging the cartridges.—W. H. C.

Milk; Process of Purifying and Preserving ——. Marie Daseking and H. Paradies, both of Hanover. Eng. Pat. 12,045, May 26, 1903.

The milk is heated to a temperature of about 85° C. for 20 minutes, then subjected to centrifugal action while still hot, and finally cooled to a temperature of 3° C., in an open cooler.—W. P. S.

Edible Fats and Process of Making same. N. N. Cronholm, Chicago. Eng. Pat. 27,449, Dec. 15, 1903.

A MIXTURE of edible fats of suitable consistency, *e.g.*, "oleo-oil," 5 parts, neutral lard, 7 parts, and butter, 1 part, is mixed with albuminous "batter," 4 parts, with the addition of 1 part of salt as a preservative. If the albuminous constituent be composed of the whites and yolks of eggs beaten to a foam, the product will have the consistency and colour of butter. The molten fats are added to the egg-"batter," and the whole is stirred at a temperature sufficient to produce coagulation of the albumin (150°—200° F.); the mass is then cooled gradually with continuous stirring, and the salt is worked in.—J. F. B.

UNITED STATES PATENT.

Centrifugal Liquid [Milk] Separator. T. H. Springer, Washington. U.S. Pat. 754,909, March 15, 1904.

THE apparatus is cylindrical in form, with a screwed-on conical top, provided with a cylindrical neck containing an opening for the cream, and a central feed-tube for the whole milk. The lower end of the feed-tube is enlarged conically, and above this end are fitted a number of concentric deflecting discs inclined downwards and pierced by vertical openings near the central tube, and having a series of bent pipes leading from their outer periphery through the neck of the apparatus and outwards.—L. F. G.

FRENCH PATENT.

Cream in Milk; Apparatus for Determining ——. F. Billet. Fr. Pat. 336,788, Nov. 19, 1903. XXIII., page 386.

(*B.*)—SANITATION; WATER PURIFICATION.

ENGLISH PATENT.

Water and other Liquids and Alimentary Substances; Sterilisation of ——. V. B. Nesfield and A. Crerar, both of London. Eng. Pat. 4759, Feb. 28, 1903.

THE water is treated with chlorine, the latter being afterwards destroyed by the addition of a suitable reagent. The chlorine may be added to the water either in the liquid form enclosed in glass tubes, or in the shape of tablets composed of mixtures of bleaching powder with tartaric acid or sodium bicarbonate. The neutralising reagent which is afterwards added consists of sodium sulphite or thiosulphate, and may be enclosed or embedded in the tablet. It is separated from the chlorinating material of the tablet, by surrounding it with a layer of soluble substance, such as gelatin or sugar. Alimentary substances are sterilised by subjecting them to the action of the chlorinated water.—W. P. S.

FRENCH PATENT.

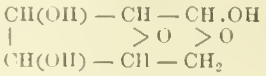
Sterilisation of Water by means of Ozone; Apparatus for the systematic Treatment of Liquids with Gases, applicable especially to the ——. A. Schneller and D. Koeleman. Fr. Pat. 336,614, Nov. 10, 1903.

THE apparatus consists of a cylindrical vessel in which are placed a number of horizontal partitions of fine metallic gauze, which reach nearly across the whole cylinder, but leave a part free, preferably always on alternating sides, and end in a number of vertical perforated partitions which extend nearly to both the next higher and lower horizontal partitions. The liquid to be treated is fed in at the top of the apparatus, flows on to the first horizontal partition, over the vertical one, then on to the next horizontal one, and so on, whilst the gas is led in at the bottom, and forces its way up through the perforations, passing through the liquid in doing so.—A. G. L.

XIX.—PAPER, PASTEBOARD, Etc.

Cellulose; Constitution of ——. A. G. Green. Zeits. Farben- u. Textil-Chem., 1904, 3, 97—98.

THE formula of cellulose is usually considered to be some multiple of $C_6H_{10}O_5$, chiefly from the supposed existence of intermediate nitrates, and also from the fact that cellulose is a colloid. The latter is no proof of high molecular weight since silica and alumina both form colloidal hydrates, and yet are given a simple formula. The author prefers the $C_6H_{10}O_5$ formula, and suggests the following structure:—



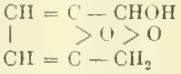
$$\begin{array}{l} \mathrm{CH(OH) - CH - CH.OH} \\ | \qquad\qquad\qquad\quad > \mathrm{O} \quad > \mathrm{O} \\ \mathrm{CH(OH) - CH - CH_2} \end{array}$$

This formula represents cellulose as an inner anhydride of glucose, and easily explains its conversion into the latter by simple hydrolysis. It also demonstrates the possibility of formation of a tri-nitrate and a tri-acetate. The formation of a tetra-acetate is doubtful, and can only be explained by a previous partial hydrolysis of the cellulose (one of the central O atoms being converted into an OH group). The fact that cellulose itself does not contain CO groups, but apparently does so after a simple hydrolysis, can be explained thus:—

$$\begin{array}{l} \text{The } \mathrm{-CH-OH} \text{ group is converted first into } \mathrm{-CH(OH)_2} \\ \qquad\quad > \mathrm{O} \qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad \mathrm{-CH_2(OH)} \\ \qquad \mathrm{-CH_2} \qquad \text{and then into } \mathrm{-CHO} \\ \qquad\qquad\qquad\qquad\qquad\qquad\quad \mathrm{-CH_2OH} \end{array}$$

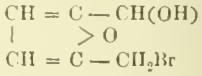
The behaviour of cellulose on mercerisation with caustic soda is explained by the conversion of the central O atoms into ONa groups, and then into OH groups. The suggested formula also explains Fenton's formation of bromomethylfurfural by treatment with hydrobromic acid gas. The compound I is possibly formed first by dehydration, and this absorbs HBr and gives II.:—

I.



$$\begin{array}{l} \mathrm{CH = C - CHOH} \\ | \qquad\quad > \mathrm{O} > \mathrm{O} \\ \mathrm{CH = C - CH_2} \end{array}$$

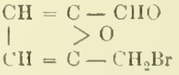
II.



$$\begin{array}{l} \mathrm{CH = C - CH(OH)} \\ | \qquad\quad > \mathrm{O} \\ \mathrm{CH = C - CH_2Br} \end{array}$$

Bromomethylfurfural III. is formed from II. by the separation of one molecule of water:—

III.



$$\begin{array}{l} \mathrm{CH = C - CHO} \\ | \qquad\quad > \mathrm{O} \\ \mathrm{CH = C - CH_2Br} \end{array}$$

The substance I. has the empirical formula of lignone, and is possibly related to it. The other reactions of cellulose can also be explained in a simple way by this formula.

—A. B. S.

ENGLISH PATENTS.

Pulp water; Regulating the Supply of ——, *to Pulp catchers or Savers in the Manufacture of Paper.* R. Dietrich, Merseberg. Eng. Pat. 4378, Feb. 24. 1903.

BETWEEN the circulation tank, in which the "backwaters" from the machine are collected, and the pulp-catchers are interposed suitable distributing tanks, which maintain a constant supply of "backwater" to the pulp-catchers, by means of valves operated by floats, in spite of any irregularities in the level of water in the circulation tank. These distributing tanks are fed by a trumpet-shaped overflow pipe in the circulation tank, pierced with holes, which increase in area towards the top of the overflow pipe. A trumpet-shaped overflow pipe is also provided in the first distributing tank, in order to remove any scum or floating impurities. The chamber in which the pulp-catching cylinder revolves is fed with "backwater" from below, in order to catch the fibres as they ascend.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

Euquinine [Quinine Ethyl Carbonate] and Salicylic Acid; Compound of ——. P. Cesaris. Boll. Chim. Farm., **43**, 11—12. Chem. Centr., 1904, **1**, 732.

On mixing together solutions of 3·96 grms. of euquinine, $CO(OC_2H_5)(OC_{20}H_{23}ON_2)$, and of 1·38 grms. of salicylic acid in about 100 grms. of absolute alcohol, crystals of a compound of the two substances separate after a few minutes. After recrystallisation from boiling alcohol, the new product melts at 195°—196° C.; it is almost insoluble in water at 15° C., soluble in 600 parts of boiling water, in 10 parts of boiling alcohol, slightly in ether, carbon bisulphide, and benzene, and easily in chloroform.—A. S.

Artemisia; Essential Oil of ——. E. Grimal. Comptes rend., 1904, **138**, 722.

From the Algerian *Artemisia herba alba*, which is a plant of some medical renown among the indigenous population, the author has extracted about 0·3 per cent. of a greenish-yellow essential oil, having a pleasant aromatic odour and a camphor-like taste. It contains lævo-camphene, eucalyptol, lævo-camphor, and the caprylic and capric esters of an undetermined terpenic alcohol.—J. T. D.

Liquorice Root; Obtaining "Juice" from partly or completely dried ——. F. Evers, Düsseldorf. Eng. Pat. 1180, Jan. 16, 1904.

100 kilos. of coarsely ground liquorice root are boiled with about 300 litres of water, and the aqueous extract is pressed out. The extract is mixed with 0·25 kilo. of iron oxide and boiled down to about 100 kilos. Subsequently a quantity of sodium carbonate (about 1 kilo. of the anhydrous carbonate) sufficient to dissolve the iron compound is added, and the liquid is concentrated to any desired consistency. The iron oxide combines with the "free vegetable acids," forming compounds which are soluble in alkaline liquids. Instead of iron oxide, manganese oxide or metallic iron or manganese may be used. The "juice" so prepared is equivalent to that made from the fresh roots.—J. F. B.

United States Patents.

Aromatic Esters, and Process of Making same. E. Ritsert, Frankfort-on-Maine. U.S. Pat. 748,101, Dec. 29, 1903.

Aromatic aminocarboxylic esters are combined with aromatic sulphonic acids or their salts, thus forming the salts of the aminocarboxylic esters. For instance, *p*-amino-benzoic acid ethyl ester combines with phenol-*o*-sulphonic acid (1 mol.), or with benzene-*m*-disulphonic acid (2 mols.). The compounds or salts thus produced are soluble in water and alcohol, but insoluble in ether; they are considered to be suitable for use as anæsthetics, and are said not to give rise to injurious effects. —T. F. B.

Chloroform; Process of Making ——. A. W. Smith, Cleveland. U.S. Pat. 753,325, March 1, 1904.

Carbon tetrachloride, prepared by heating carbon bisulphide with sulphur chloride, is purified by treatment with sulphur chloride and sulphur, and distilled. It is then subjected to the action of iron and water, whereby chloroform is produced.—T. F. B.

French Patent.

Arsenic and Iron; Extracting Soluble Compounds of —— *[for Therapeutic Use]*. Chem. Werke Hausa G. m. b. H. Fr. Pat. 336,127, Oct. 19, 1903.

Natural mineral waters, containing arsenic and iron, are evaporated without access of air, and preferably whilst passing a feeble current of an indifferent gas through the liquid. If the waters contain bicarbonates, carbon dioxide should be passed through during the evaporation. The dry compound of arsenic and iron thus obtained is stated to be soluble, and to possess a high therapeutic value. The mineral waters of Levico, Austria, are said to be suitable for use as described.—E. S.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Three-Colour Photography; Sensitisers for ——. E. König. Phot. Mitt., 1904, **41**, 81.

Among sensitisers for use in the modern form of three-colour photography, where only one plate is exposed, Ethyl Red gives a good result over the green and yellow part of the spectrum up to the orange; Orthochrome T is, however, better for red; while the new dyestuff, Pinachrome, answers even better still. When incorporated with the emulsion, Orthochrome and Pinachrome give less rapid plates than when the bromide films are prepared by dipping; but this greater rapidity is not due to the presence of ammonia, because Orthochrome, used as a bath, is equally effectual in neutral solution. To prepare the bath, 1 grm. of either dyestuff is dissolved in 100 c.c. of warm alcohol, and then diluted with 500 c.c. of alcohol and 400 c.c. of water; this forms a stock solution, which may be kept indefinitely in the dark. The actual bath is composed of 4 c.c. of the solution, 2 c.c. of ammonia, and 200 c.c. of water—a quantity which is sufficient for not more than two 13 × 18 cm. plates. The plates are immersed for three or four minutes, washed well for two or three minutes, and then dried rapidly in perfect darkness. If the drying be not too slow, the plates will keep a month or more. When two ordinary plates, one of which is 10 times as sensitive as the other, are dipped in these baths, the ratio of exposure to any particular portion of the spectrum does not remain as before, but the slower plate becomes relatively more rapid. In red light, the slow plate mentioned will only require three times the exposure of the more rapid one. Nevertheless, it is not advantageous to dip slow plates for practical work, because, when exposed to mixed light, they still remain less sensitive than rapid ones.—F. H. L.

Development; Separation of ——, into Primary and Secondary Actions. J. Sterry. Phot. J., 1904, **44**, 50—57.

Development of a photographic image may be considered as consisting of two actions: the primary action, or reduction of the silver halide; and the secondary action, or intensification of the reduced portions of the image. This secondary action appears to be diminished or entirely removed by treating the plates, &c., before development, with some substance which tends to counteract the effects of the developer, *e.g.*, a dilute solution of potassium bichromate, chromic acid, &c. The effect of this treatment is not to destroy the image entirely, but the gradation of the resulting negative is entirely altered, and depends on the strength of solution used and the time of immersion. Normal gradation can as a rule be obtained, after such treatment, on much over-exposed plates.—T. F. B.

English Patents.

Agar-agar; Process of Manufacturing a Limpid Solution of —— [for Photographic Purposes]. P. Jensen, London. From M. Muetschke, Berlin. Eng. Pat. 11,625, May 21, 1903.

See Fr. Pat. 330,595 of 1903; this J., 1903, 1102.—T. F. B.

Cyanine Dyestuffs [for Sensitising Photographic Emulsions]; Manufacture of ——. O. Imray, London. From Farbwerke vorm. Meister, Lucius und Brüning, Hoechst-on-the-Maine. Eng. Pat. 9598, April 28, 1903.

The dyestuffs are obtained by heating with alkali hydroxide in a suitable solvent, *e.g.*, alcohol, (1) a mixture of an alkyl halide of quinoline, or of quinoline substituted in the *m*- or *p*-position by alkyl, or alkyloxy radicles, with an alkyl halide of quinaldine, similarly substituted, or (2) a mixture of an alkyl halide of quinoline substituted as above and an alkyl halide of quinaldine. For example, 30 grms. of *p*-toluquinaldine methyl iodide and 58 grms. of *p*-toluquinoline methyl iodide, dissolved in 800 c.c. of alcohol, are heated with 5·6 grms. of potassium hydroxide. Dyestuffs obtained in this way are said to render photographic plates twice to four times as sensitive to red as quinaldine-quinoline cyanine.—T. F. B.

United States Patent.

Photographic Plate. A. A. Gurtner, Bern. U.S. Pat. 753,977, March 8, 1904.

A plate suitable for carrying out the process described in U.S. Pat. 730,454 (this J., 1903, 820) consists of two "carriers," one holding an orthochromatic film containing silver bromide, and the other holding a film containing silver chloride, and stained with Aniline Orange, thus forming a colour filter for red rays; the two films are fixed in contact by means of binding strips fastened to the "carriers."—T. F. B.

French Patent.

[Sensitive] Film Cards or Papers for Photographic Purposes; Process for Making ——. Soc. Anon. Plaques et Papiers Photographiques. A. Lumière et ses fils. Fr. Pat. 336,533, Nov. 11, 1903.

A substitute for dry plates may be prepared by "enamelling" a card or paper with a coating of gelatin, &c.; the card is then immersed in water or a dilute solution of gum, sugar, or any substance "capable of increasing or reducing the adhesive power of the enamelled surface." The sensitive film is then fixed by pressure to the card thus prepared, and can be easily removed from its support, after development, by mechanical means.—T. F. B.

XXII.—EXPLOSIVES, MATCHES, Etc.

Explosion of Nitroglycerin; Circumstances attending an —— which occurred in the Precipitating and Final Washing Houses of the Factory of the National Explosives Co., Ltd., at Upton Towans, Hayle, Cornwall, on Jan. 5, 1904. By Capt. J. H. Thomson, H.M. Chief Inspector of Explosives.

In this explosion, which was attended by loss of life, 4,200 lb. of nitroglycerin were involved. The probable cause of the explosion is considered to be the dropping of the lid of a tank into which a charge of nitroglycerin was flowing. The lids were constructed of wood, covered on the under side with lead, and, owing to their weight and shape, would give a heavy glancing blow if allowed to fall. Captain Thomson considers "that no movable article of uncovered metal other than aluminium need be present in any nitroglycerin building." As the explosion was communicated from the precipitating house to the final washing house by means of the charge of nitroglycerin running down the leaden gutter, it is recommended that the difference of level between buildings thus connected should be such as to shorten, as much as possible, the time occupied in running down a charge. Gutters should also be washed with clean water after each charge has passed down, and not more than one charge should be running to or from any one building at one time.

—G. W. McD.

Safety Explosives for Fiery Mines. Mém. des Poudres et Salpêtres, 1903–4, **12**, 7—30.

Explosives with Ammonium Nitrate as a Base.—An examination of the relative merits of paraffined paper and tinfoil of 0·03 mm. thickness as waterproof wrappers for cartridges when embedded in damp sawdust showed that, with the former, cartridges absorbed 0·19 per cent. of moisture in ten days, and 5·8 per cent. in 120 days, while with tinfoil the figures were 0·07 per cent. and 4·03 per cent. respectively. The paraffined paper cartridges could be subjected to fairly rough usage without breaking—a fact not true in the case of cartridges covered with tinfoil. Detonation in the open is transmitted much more readily between cartridges wrapped in paraffined paper than in those covered with tinfoil. The minimum quantity of fulminate necessary to detonate a 50 grm. cartridge of certain explosives is shown as under:—

	Composition.	Minimum Quantity of Fulminate.
(A)	Ammonium nitrate, 95·5 per cent. ..... Trinitronaphthalene, 4·5 per cent......	0·40 grm.
(B)	Ammonium nitrate, 90·5 per cent. ..... Collodion cotton, 9·5 per cent.	0·25 grm.
(C)	Ammonium nitrate, 88 per cent. ...... Nitroglycerin, 12 per cent.	0·20 grm.

No appreciable difference could be detected in transmission of detonation in the open in these three explosives. The addition of potassium chlorate (5 to 10 per cent.), potassium bichromate (2 per cent.), potassium permanganate (2 per cent.), barium nitrate (2 to 5 per cent.), lead nitrate (2 to 5 per cent.), and aniline nitrate (2 to 5 per cent.)

separately to these explosives, made no difference either in sensitiveness or transmission of detonation.

Explosives with Ammonium Perchlorate as a Base.—Specimens of the following composition were investigated :—(D) Ammonium perchlorate (94 per cent.), collodion cotton (6 per cent.). This compound is non-hygroscopic, does not burn in the open in thin layers, and gives results similar to explosive B, mentioned above, in the borehole, and also as regards sensitiveness to and transmission of detonation. B exploded after 9½ hours' heating at 110° C., whereas D was heated for 87 hours without exploding. (E) Ammonium perchlorate (89 per cent.), nitroglycerin (11 per cent.). This compound was heated for 30 hours at 100° C. without appreciable decomposition, but detonates by shock, and is more sensitive in every respect than D. The addition of some 40 per cent. of saltpetre to these explosives was also investigated; but in a damp atmosphere the cartridges were found to be extremely hygroscopic, owing to the formation, by double decomposition, of ammonium nitrate. Since, further, D and E produce free hydrochloric acid on explosion, they are not suitable for use in mines. Cartridges of explosive C separated in the borehole by discs of cardboard up to 9·6 mm. thick, were still found to be completely detonated, and miss-fires are to be traced chiefly to absorption of moisture by the cartridge. Explosive A, when containing 3 per cent. to 4 per cent. of moisture, would not detonate with less than 2·5 grms. of fulminate, but 1·5 grms. of fulminate was found to be sufficient when supplemented by a primer of the non-hygroscopic explosives D and E. An explosive of the following composition was investigated :—(F) Nitroglycerin (31·35 per cent.), collodion cotton (1·65 per cent.), potassium nitrate (67 per cent.) Both in the bomb and the borehole (with fulminate) the residue obtained contained from 38 to 54 per cent. of undecomposed potassium nitrate, thus pointing to very incomplete decomposition.

—G. W. McD.

Dynamite No. 0; Modification of ——. M. Lheure. Mém. des Poudres et Salpêtres, 1903–4, **12**, 46—47.

The explosive consisted of nitroglycerin (68·6 per cent.), collodion cotton (1·4 per cent.), dry wood-meal (30 per cent.). When submitted to continual exposure to damp and alternate freezing and thawing, the explosive, while slightly increasing in bulk, showed no sign of exudation of nitroglycerin. When heated continuously for 24 days at 40° C. no exudation could be detected nor any development of acid products, and the explosive was consequently authorised for manufacture.—G. W. McD.

Dynamite; Four New Types of ——. M. Lheure. Mém des Poudres et Salpêtres, 1903–4, **12**, 51—54.

The following compositions were investigated :—

——	4.	5.	6.	7.
Nitroglycerin	59·00	48·00	39·50	29·00
Collodion cotton	1·50	1·00	..	..
Sodium nitrate	25·00	36·30	43·00	50·35
Cellulose	14·00	14·00	17·00	11·00
Sodium carbonate	0·35	0·45	0·30	0·50
Ochre	0·15	0·25	0·20	0·15
Wheat flour	..	..	..	9·00

When submitted to the tests detailed in the previous abstract, hese explosives were found to be satisfactory. There were, iowever, slight traces of exudation of nitroglycerin, but iot sufficient to prevent authorisation for manufacture.

—G. W. McD.

English Patents.

itrated Cellulose; Manufacture of ——. G. J. Atkins, Tottenham. Eng. Pat. 7058, March 27, 1903.

otton-seed waste (consisting of the husk of the seed and ifts of cotton) is boiled with alkali and bleached "with a olution of a mixture of chloride and oxychloride of sodium r potassium." After purifying and drying, the bleached ellulose material is ready for nitration in the ordinary way.

—G. W. McD.

Nitrocellulose; Manufacture of ——. F. L. Nathan, J. M. Thomson, and W. T. Thomson, of Waltham Abbey. Eng. Pat. 7269, March 28, 1903.

In order to replace the water (left in nitrocellulose after washing) by alcohol, without the use of pressure and in such a manner that a very small amount of dilution of the alcohol with water takes place, the nitrocellulose is first covered with water so that practically all air is excluded. Alcohol is then quietly run down the sides of the vessel so as to form a layer on the surface of the water. A cock at the bottom of the vessel is slightly opened, so that the water slowly flows away at a rate of fall of level in the vessel of half an inch to one inch per hour. The alcohol flows in and replaces the water in the interstices of the nitrocellulose, the treatment being continued until all the water has been displaced by alcohol. When dehydration has thus been completed, the excess of alcohol is removed by pressing or centrifuging.—G. W. McD.

Nitrocellulose Gunpowder; Manufacture of a ——. O. Schmidt, Hassloch. Eng. Pat. 116, Jan. 2, 1904.

Cellulose material is ground to a paste with water under edge runners, and granulated through sieves, the grains being rounded off in a polishing cask and then dried. These grains are converted into nitrocellulose by soaking them in strong nitric acid until they swell and become transparent, after which they are immersed in strong sulphuric acid. After neutralising, purifying, and drying in the ordinary way, the powder is ready for use without the aid of solvents.—G. W. McD.

Explosive; Process of Manufacturing a Safety ——. J. P. O'Donnell, London. From C. W. Frank, Melbourne. Eng. Pat. 23,472, Oct. 29, 1903.

See Fr. Pat. 327,721 of 1902; this J., 1903, 924.—T. F. B.

United States Patents.

Nitrated Carbohydrate. A. Hough, Dover. U.S. Pat. 751,076, Feb. 2, 1904.

The claim is for a highly nitrated carbohydrate, containing about 16·5 per cent. of nitrogen, and having a constitution corresponding to the formula $C_{12}H_{12}(NO_2)_8O_{10}$. Dry finely-powdered maize starch is injected below the surface of a mixture containing 3 parts of nitric acid, 2 parts of sulphuric acid (98 per cent.), and sufficient Nordhausen sulphuric acid (containing 40 per cent. of SO_3) to "bring the nitric and sulphuric acids to 100 per cent. concentration," and leave an excess of 2—3 per cent. of free sulphuric anhydride. A further quantity of the Nordhausen acid is added during the process to maintain the strength of the nitrating liquid. The temperature is maintained at 45°—50° F. The nitrated starch is separated by filtration, and freed from lower nitro-derivatives by treatment with hot dilute ammonia. The finished explosive is an orange-coloured powder, soluble in ether-alcohol. (See also this J., 1902, 1471.)—G. W. McD.

Smokeless Powder, Rod or Grain, and Process of Making same. H. Maxim, New York. U.S. Pat. 753,994, March 8, 1904.

See Eng. Pat. 10,071 of 1899; this J., 1900, 376.—T. F. B.

Match Composition. J. A. Wendel, Milwaukee. U.S. Pat. 754,265, March 8, 1904.

The composition consists of potassium chlorate, 20 parts; antimony sulphide, 10 parts; lead nitrate, 10 parts; amorphous phosphorus, 5 parts; vegetable carbon, 5 parts; potassium bichromate, 3 parts; and glue.—G. W. McD.

French Patents.

Explosive [Slow-burning] for Fuses and the like. W. T. Unge. Fr. Pat. 336,266, Oct. 26, 1903.

For the purpose of rendering fuse powder, &c., less hygroscopic and more elastic, so that discontinuities are not present, the grains of the composition are coated with a very thin layer of a non-volatile oil or fat. In the case of black powder, 0·1—0·3 per cent. of oil or fat is said to be sufficient.

—G. W. McD.

Safety Explosive. E. Steele. Fr. Pat. 336,783, Nov. 18, 1903.

The explosive is prepared by mixing nitrophthalic acid or a nitrated mixture of resin and starch with an alkali chloride, and subjecting the mixture to a feeble gelatinisation by allowing it to fall through the vapour of wood-spirit or ether.—G. W. McD.

XXIII.—ANALYTICAL CHEMISTRY.

APPARATUS, ETC.

Shaking and Stirring Apparatus. J. W. Brühl. Ber., 1904, **37**, 918—924.

An apparatus is described by means of which flasks carrying reflux condensers can be shaken and their contents stirred whilst they are being heated.—A. S.

French Patent.

Cream in Milk; Apparatus for Determining ——. F. Billet. Fr. Pat. 336,788, Nov. 19, 1903.

The apparatus consists of a glass cylinder having a mark about half its height, and a second mark a little above the first. The milk is added up to the lower mark, and then water up to the second. The amount of water thus added is about one fourth the volume of the milk, and causes the cream to rise more quickly. The tube is graduated between the two marks, in percentages of cream on the undiluted milk. A vertical blue strip in the side of the cylinder aids the reading of the meniscus.—W. P. S.

INORGANIC—QUALITATIVE.

Hydroxylamine Salts in Qualitative Analysis. N. Tarugi. Gaz. chim. ital., **33**, 449—454. Chem. Centr. 1904, **1**, 836—837. (Compare this J., 1904, 131.)

The author points out further defects in the method proposed by Knoevenagel and Ebler (this J., 1902, 1296). Platinum salts are not reduced to metallic platinum by an ammoniacal solution of hydroxylamine hydrochloride. In dilute solutions, no insoluble compound is produced, whilst in concentrated solutions, the precipitate formed consists of a mixture of different platinum compounds and has a composition varying with the conditions under which the precipitation is effected.—A. S.

INORGANIC—QUANTITATIVE.

Carbon Dioxide; Determination of ——, in Presence of Chlorine. M. Schlötter. Zeits. angew. Chem., 1904, **17**, 301—302.

If a gaseous mixture containing carbon dioxide and free chlorine be shaken with a solution of a hydrazine salt, the chlorine and hydrazine interact to produce hydrochloric acid and free nitrogen, the volume of the latter being half that of the original chlorine. 100 c.c. of the mixtures are collected in a Bunte burette, and after running out the water, hydrazine sulphate solution is introduced and the whole well shaken. More hydrazine solution is run in and the apparatus again shaken. This is continued until no further diminution in volume takes place. The decrease in volume having been read off, the carbon dioxide is determined. This method should be useful in the analysis of electrolytic chlorine.—E. H. T.

Mercury; Determination of Small Quantities of ——. T. W. Richards and S. K. Singer. J. Amer. Chem. Soc., 1904, **26**, 300—302.

A coil of copper wire about 1·5 mm. in diameter, previously polished and cleansed by alkali, acid and water successively, is immersed in about 15 c.c. of the solution containing the mercury, preferably in the form of nitrate. It is advantageous to take out the bulk of the mercury by one coil and to collect the last traces, which are precipitated very slowly, by the immersion of a second similar coil. The best results would probably be obtained by immersing the first coil for 4—5 hours and the second coil for 20 hours. When the precipitation is complete, the coils are washed with water and then with alcohol and dried over calcium chloride. After weighing, the coils are heated in a current of hydrogen at a temperature not much above 350° C., until the mercury is volatilised, and then weighed again.—J. F. B.

ORGANIC—QUANTITATIVE.

Starch Syrups; Examination [Analysis] of ——. A. Rössing. Zeits. öffentl. Chem., **10**, 1—7. Chem. Centr., 1904, **1**, 757.

For the determination of dextrose and dextrin in starch syrups, the following process is recommended. 50 c.c. of a solution containing 40 grms. of the sample per litre, are made up to 250 c.c., and with 25 c.c. (= 0·2 grm.) the direct cupric-reducing power is determined by Allihn's method. 50 c.c. of the original solution (= 2 grms.) are treated with 100 c.c. of a cold saturated solution of barium hydroxide, made up to 200 c.c., well shaken, and allowed to stand for two days in a closed flask at the ordinary temperature. 100 c.c. of the solution are then precipitated with sodium carbonate solution, made up to 200 c.c., filtered, and the reducing power determined with 25 or 50 c.c. of the filtrate. For inversion, Sachsse's method was found to give low results and the following procedure is recommended. 50 c.c. of the original solution are treated with 50 c.c. of water and 15 c.c. of hydrochloric acid of sp. gr. 1·19, and the mixture heated on a boiling water bath for two hours in a flask fitted with a reflux condenser. After cooling, the solution is made nearly neutral, diluted to 250 c.c., and the reducing power determined with 25 c.c. From the diminution of reducing power, *r*, before and after the treatment with baryta water, the percentage of dextrose, D, in the sample is calculated by the following formula, the decrease in the case of pure dextrose being taken as 11·7 per cent. (see this J., 1903, 886)—

$$D = \frac{100\,r}{11{\cdot}7}.$$

The total dextrose after inversion minus D gives the dextrose produced from dextrin, and this multiplied by 0·93 gives the percentage of dextrin in the sample.—A. S.

Malt; Determination of Moisture in ——, by Hoffmann's Apparatus. J. H. Schulze and G. Marienhagen. Woch. Brau., 1904, **21**, 165—166.

Owing to the occasionally anomalous behaviour of malt, when treated in Hoffmann's apparatus for the determination of its moisture (this J., 1902, 1088 and 1903, 655), the following improved procedure is prescribed:—500 c.c. of petroleum are placed in the distillation flask, 100 grms. of whole malt are added thereto and thoroughly agitated, the cooling vessel is then screwed on, filled with cold water, with an asbestos screen between the boiler and condenser, and the measuring tube is placed in position. 25 c.c. of oil of turpentine are placed in the stoppered funnel, and the thermometer is adjusted so as to clear the bottom of the boiler by 1 cm. The temperature is raised to 170° C. in 10 minutes, at first with a large flame, so that 120° C. is reached in three minutes, and subsequently with a small flame. In order to assist the circulation, the flame must not impinge on the centre of the bottom of the boiler, but must be placed to one side, immediately below the dropping funnel. A temperature of 170° C. is maintained for five minutes. The turpentine is then admitted from the funnel, and the temperature is raised to 185°—190° C. in 2—3 minutes. The distillate must be caused to flow in a continuous stream. The volume of water is read off immediately as indicated (*loc. cit.*). For pale malts the volume of water is increased by 0·2 c.c., for dark malts no correction is made, for medium malts 0·1 c.c. is added to the volume of water. For steeped barley the procedure is the same as for raw cereals (*loc. cit.*), but for green malt, after the grain has begun to sprout, the treatment is the same as for pale malt, except that 50 grms. of the sample are taken. Before use, the whole apparatus is rinsed several times with turpentine; all joints are well covered with lubricating oil.—J. F. B.

Alcohol in Dilute Solutions; Determination of ——, by Nicloux's Method. M. E. Pozzi-Escot. Bull. Assoc. Chim. Sucr. et Dist., 1904, 21, 872—876.

The determination of alcohol by the method of Nicloux (this J., 1897, 473 and 941) gives not only ethyl alcohol but aldehyde and all fermentation alcohols, and the author shows that there is doubt as to the precise stage of oxidation reached in the reaction. These results indicate that the method has only a restricted application.

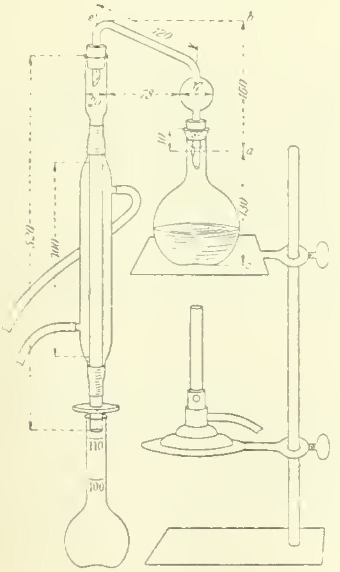
—L. J. de W.

Wheat Flour; Determination of Gliadin in —— by means of the Polariscope. H. Snyder. J. Amer. Chem. Soc., 1904, 26, 263—266.

From 85 to 90 per cent. of the total proteids of wheat flour occur in the form of gliadin and glutenin, the former predominating. Gliadin is soluble in dilute alcohol and glutenin in dilute alkalis. The specific rotatory power of gliadin, $[\alpha]_D = -92°$. The proportion of sugars and optically active non-gliadin proteids extracted by 70 per cent. alcohol is so small as not to interfere with the determination of gliadin by the polariscope. 15·97 grms. of flour are treated with 100 c.c. of 70 per cent. alcohol, and the mixture is shaken moderately at intervals of half an hour for two or three hours; the alcohol is left in contact with the flour for 12—18 hours at a temperature of about 20° C. The solution is then filtered and polarised in the 220 mm. tube. The reading on the sugar scale, when multiplied by the factor 0·2, gives the approximate percentage of gliadin nitrogen in the flour; the results correspond accurately with those of the Kjeldahl method. The results obtained indicate that wheat flour of good quality should contain about 12 per cent. of total proteids (N × 6·25) or 11 per cent. of protein (N × 5·70), of which 55—65 per cent. should be in the form of gliadin.—J. F. B.

Cocoanut Oil in Butter; New Method for Determining ——. E. Polenske. Zeits. Untersuch. Nahr. u. Genussm., 1904, 7, 273—280.

The method proposed depends upon the determination of the volatile insoluble fatty acids which distil over in the ordinary Reichert-Meissl process. The distillation must be carried out under the conditions described; the apparatus employed is shown in the illustration.



Five grms. of the filtered fat are saponified in the usual ay with 20 grms. of glycerol and 2 c.c. of 50 per cent. dium hydroxide solution. An alcoholic solution should t be used, as traces of alcohol may find their way into e filtrate. The soap is then dissolved in 90 c.c. of iled water, acidified with 50 c.c. of dilute sulphuric acid (25 c.c. of acid in 1 litre of water), a few particles of pipeclay or pumice are added, and the distillation proceeded with. The flask holds 300 c.c. The flame should be so regulated that 110 c.c. of distillate are collected in from 19 to 21 minutes, and the condenser water should have a temperature between 18° and 22° C. As soon as 110 c.c. of distillate are obtained, the receiver is removed and replaced by a 25 c.c. cylinder. Without mixing its contents, the receiver is placed in a bath of water at a temperature of 10° C., for 10 minutes, the surface of the water being about 3 mm. above the 110 c.c. mark. The insoluble fatty acids contained in the distillate collect in the neck of the flask. In the case of pure butter they solidify to form white, opaque granules, whilst with pure cocoanut oil, clear oily drops are obtained. Mixtures containing more than 10 per cent. of cocoanut oil also yield oily drops. The contents of the receiver are now mixed, passed through a filter 8 cm. in diameter, and the Reichert-Meissl value determined on the filtrate. The filter is washed three times with 15 c.c. of water, this water being also previously used for washing out the condenser, cylinder, and the receiver. The insoluble fatty acids are then dissolved by pouring three successive quantities of 15 c.c. of 90 per cent. alcohol on the filter. The alcoholic solution obtained is titrated with barium hydroxide solution, using phenolphthalein as indicator. The number of c.c. of N/10 barium hydroxide solution required is termed the "new Butter-value" of the sample of fat under examination. Thirty-one various samples of butter, having Reichert-Meissl values between 23·3 and 30·1, gave "new Butter-values" varying from 1·5 to 3·0, whilst four samples of cocoanut oil, with Reichert-Meissl values from 6·8 to 7·7, yielded "new Butter-values" from 16·8 to 17·8. A considerable number of analyses of mixtures of these two fats are also given, and it is seen from the results that butters giving Reichert-Meissl values between 23 and 27, have "new Butter-values" from 1·6 to 1·9, or, in other words, a rise of 1·0 in the former, causes the latter to increase by 0·1. With Reichert-Meissl values of 28, 29, and 30, the "new Butter-value" increases more rapidly, viz.: 2·2, 2·5, and 3·0. By taking into account the Reichert-Meissl value of the sample, a determination of the "new Butter-value" affords a simple means of detecting the presence or absence of cocoanut oil.—W. P. S.

Aldehydes and Ketones; Determination of —— in Essential Oils and Allied Substances. H. E. Burgess. Analyst, 1904, 29, 78—84.

The method adopted is that described by the author for the determination of citral in lemon oil (this J., 1901, 1176—1182); this method is found to give equally good results with most essential oils containing aldehydes or ketones, and depends on the formation of soluble sulphonates from aldehydes and ketones with neutral sodium sulphite solution. Oils containing a high percentage of aldehyde or ketone are utilised directly, whilst those, like lemon oil, containing small amounts, are subjected to fractionation (*loc. cit.*).

—T. F. B.

Aldehydes, Aromatic and Fatty; Basic Reaction for Detection and Determination of ——. S. S. Sadtler. J. Franklin Inst., 1904, 157, 231—234.

Tiemann has found (see this J., 1899, 169, 1901, 1178) that alkali is liberated by the action of sodium sulphite on an aldehyde, the reaction in the case of citral being expressed by the equation—

$$C_9H_{15}COH + 2H_2O + 2Na_2SO_3 = C_9H_{17}COH(NaSO_3)_2 + 2NaOH.$$

The author proposes to determine aldehydes by titrating the free alkali with N/2 hydrochloric acid. For the determination of citral in lemon oil, from 5 to 10 grms. of the sample are made neutral, if necessary, treated with 25 or 50 c.c. of a 20 per cent. solution of normal sodium sulphite (which has been previously heated on the water-bath), and neutralised by means of N/2 hydrochloric acid in presence of rosolic acid as indicator. The red colour due to free alkali which is produced is discharged with N/2 hydrochloric acid, and the mixture kept hot and well agitated, the titration with acid being continued as long as the red colour is re-formed. Reaction is complete in about half an hour. The reaction is also available for the determination of vanillin, piperonal, and other aldehydes. The phenolic hydroxyl of the vanillin is first neutralised with a little caustic soda, using rosolic acid as indicator, the sodium sulphite added, and the titration with N/2 hydrochloric acid performed in the hot solution. The reaction is complete and immediate with the fatty aldehydes. It will detect a dilution 1 : 1,000,000 of formaldehyde with water. The presence of acetone in wood spirit, and of acetaldehyde in grain spirit may be similarly detected. Acetone and the higher ketones also react with sodium sulphite.—J. O. B.

XXIV.—SCIENTIFIC & TECHNICAL NOTES.

Mineral containing Radium in the Province of Quebec; Note on ——. J. Obalski. Eng. and Mining J., 1904, **77**, 411.

About 10 years ago the author obtained from a white-mica mine, in the province of Quebec, a specimen of cleveite weighing 375 grms. and containing 70·71 per cent. of uranium oxide. On further examination, the mineral has been found to contain an amount of radium comparable with that contained in the richest pitchblende. Rutherford found that the specimen has a radioactivity "equal to four or five," and that it contains 0·1 mgrm. of radium. Associated with this mineral was a non-coking bituminous coal, the ash of which contains 35·43 per cent. of uranium oxide.—A. S.

Platinum Black; Mechanism of the Catalytic Action of ——. R. Vondráček. Zeits. anorg. Chem., 1904 **39**, 24—40.

From experiments on the decomposition of ammonium nitrite solution in presence of platinum black, the author concludes that the reaction is a periodic one, and that a distinction must be drawn between ordinary platinum black which contains oxygen, and platinum black free from oxygen. In the first stage of the reaction, the ammonia of the ammonium nitrite is oxidised by the platinum black containing oxygen, and in the second stage the platinum black now free from oxygen effects the reduction of the nitrous acid; nitrogen is evolved in both stages of the reaction. (See also this J., 1902, 257; 1903, 1246.)—A. S.

Hydrate of Potassium Hydroxide, $KOH.2\frac{1}{2}H_2O$; A Peculiar Formation of the ——. H. Ditz. Oesterr. Chem.-Zeit., **7**, 53—54. Chem. Centr., 1904, **1**, 709.

On allowing solid caustic potash to remain in contact with purified ether containing water, well-defined crystals of the hydrate $KOH.2\frac{1}{2}H_2O$ form on the bottom of the containing vessel.—A. S.

Zinc Chloride; Specific Gravity of ——. G. P. Baxter and A. B. Lamb. Amer. Chem. J., 1904, **31**, 229—235.

Dry zinc chloride was prepared by heating the pure double zinc ammonium chloride $ZnCl_2, 3NH_4Cl$, first in a current of dry hydrochloric acid, then in nitrogen, and lastly in air. The specific gravity was determined in a modified form of pyknometer by means of toluene, in which zinc chloride is insoluble. The mean value found for the specific gravity of zinc chloride was 2·907.—T. F. B.

Calcium Carbide; New Mode of Formation of ——. H. Moissan. Comptes rend., 1904, **138**, 661—663.

While carbon will only reduce lime and form calcium carbide when the lime is melted (this J., 1904, 185), calcium will combine with finely-divided carbon at a dull red heat. Calcium chloride, fused in a graphite crucible which serves as anode, and electrolysed by a current of 10—15 ampères at 120 volts, with a graphite rod as cathode, yields metallic calcium containing a notable amount of carbide. A better electrolyte is obtained if the calcium chloride be mixed with one-fourth of its weight of calcium fluoride, and the yield of carbide is increased by adding to the bath some coarsely-powdered petroleum coke.
—J. T. D.

Metal Ammoniums; Action of Carbon Dioxide on the ——. E. Rengade. Comptes rend., 1904, **138**, 629—631.

When dry carbon dioxide is passed through sodium-ammonium or potassium-ammonium at temperatures below −50° C., the compound is rapidly whitened, with the production of sodium or potassium carbamate and evolution of hydrogen, $CO_2 + NH_3Na = NH_2CO_2Na + H$. At temperatures above −50° C. there is produced at the same time the formate of the alkali metal at the expense of the nascent hydrogen produced in the above reaction. The quantity of formate produced increases as the temperature is raised above − 50° C.—J. F. B.

Enzyme Action; Studies on ——.—I. Correlation of the Stereoisomeric α- and β-Glucosides with the corresponding Glucoses. E. F. Armstrong. Trans. Chem. Soc., 1903, **83**, 1305—1313.

By the hydrolysis of α-methylglucoside by means of maltase and of β-methylglucoside by means of emulsin, the corresponding stereoisomeric glucoses are formed, the α-compound (the ordinary crystalline glucose) having a high, and the β-compound a low rotatory power. Both α- and β-glucose are unstable in solution, and the changes which take place in a solution of glucose—slowly in simple aqueous solution, but instantaneously in the presence of a small quantity of alkali—are due to the conversion of one form into the other, until a condition of equilibrium is attained. The α- and β-glucoses have a lactonic structure and are identical with the labile α- and γ-glucoses isolated by Tanret (see this J., 1896, 365), whilst the latter's stable β-form of glucose is a mixture of the two labile modifications in the proportions in which they are in equilibrium.

Experiments on the hydrolysis of maltose by means of maltase, and of cane sugar and raffinose by means of invertase, are also described.—A. S.

Glucose; Bi-rotation of ——. R. Behrend and P. Roth. Annalen, 1904, **331**, 359—382.

By a study of the acetyl derivatives of the two modifications of glucose with a high and low optical rotation respectively, the authors confirm the conclusions arrived at by Armstrong (see preceding abstract).—A. S.

Saccharose; Combinations of —— with certain Metallic Salts. D. Gauthier. Comptes rend., 1904, **138**, 638—639.

In 1871 (J. Chem. Soc., **9**, 269) Gill described a compound of saccharose with sodium iodide to which he assigned the formula $2C_{12}H_{22}O_{11}, 3NaI. 3H_2O$. The author has prepared this compound in the same way, obtaining it in the form of prismatic crystals of a large size. His analysis, however, shows that the compound possesses the formula $C_{12}H_{22}O_{11}, NaI, 2H_2O$, thus corresponding with the analogous compounds obtained with potassium and lithium iodides. In a similar manner the author has prepared well crystallised compounds of one molecule of saccharose with one molecule of the thiocyanates (sulphocyanides) of each of the following metals: ammonium ($1·5 H_2O$), potassium ($1H_2O$), sodium ($1H_2O$), and barium ($2H_2O$).—J. F. B.

Aldehydes; General Synthesis of ——. F. Bodroux. Comptes rend., 1904, **138**, 700–701.

The author has greatly improved the yield in his synthesis of aldehydes by the reaction of ethyl orthoformate on aromatic organo-magnesium compounds, by using toluene and other hydrocarbons of the benzene series as solvents for the organo-magnesium compounds—

$$R.MgBr + C_2H_5O.CH.(OC_2H_5)_2 = C_2H_5O.MgBr + R.CH(OC_2H_5)_2$$

$$R.CH.(OC_2H_5)_2 + H_2O + HCl = R.CHO + 2C_2H_5OH + HCl.$$

The organo-magnesium compound is prepared in ethereal solution; toluene is added and the ether distilled off. To the hot liquid ethyl orthoformate is very gradually added. After half an hour, dilute hydrochloric acid is added, the upper layer decanted, washed, and dried, the toluene removed, the residue boiled with dilute sulphuric acid to destroy any acetal, and the aldehyde isolated by means of bisulphite. The following yields have been obtained :—

From	Aldehyde.	Yield per Cent. of Theory.
Benzyl chloride	Phenylacetic	55
α-Bromonaphthalene	α-Naphthoic	70
p-Dibromobenzene	*p*-Bromobenzoic	60
p-Chlorobromobenzene	*p*-Chlorobenzoic	64
Propyl bromide	Butyric	75
Isobutyl bromide	Isovaleric	66

—J. T. D.

yclohexanol [*and Ketohexamethylene*]; *Preparation of* ——. A. F. Holleman. Königl. Akad. Wiss. zu Amsterdam, 1903, 201—293. Chem. Centr., 1904, **1**, 727.

By passing a mixture of phenol vapour and excess of hydrogen over finely-divided nickel heated to 140°—160° C., the author obtained a good yield of cyclohexanol. The latter, by treatment with chromic acid mixture at a low temperature, is oxidised to ketohexamethylene.—A. S.

New Books.

Die Chemie und Technologie der Natürlichen und Künstlichen Asphalte. Ein Handbuch der gesammten Asphalt-Industrie für Fabrikanten, Chemiker, Techniker, Architekten und Ingenieure. Von Dr. Hippolyt Köhler. Friedrich Vieweg und Sohn, Braunschweig. 1904. Price M. 15.

8vo volume, containing preface, table of contents, and ubject-matter filling 417 pages and containing 191 illustrations. The following is a sketch of the contents :—Part I.—I. History, Occurrence, Properties, Formation, and Composition of the Natural and Artificial Asphaltums and Asphalts. II. Occurrence of Asphaltums. III. Views as to the Origin of Bitumens and Asphaltums. IV. The Physical and Chemical Properties, Composition, and Con-tituents of Asphaltums. V. Artificial Asphalt, its Origin, Properties, and Composition. Part II.—Natural Asphal-um, and its Use in Industry, &c. VI. Preparation of Asphalt Powder, and its Use for Mechanical Stamping. VII. Manufacture of Asphalt, Tar, &c., and its employ-ent for Molten Asphalt Work. VIII. Utilisation of Pure sphaltum for other Purposes. Part III.—Artificial sphaltum, and its Use in Industry. IX. Tars, Lacs, astics, and Cements from Artificial Asphaltum. X. and I. Manufacture and Use of Roofing Felt and Tiles, &c. II. Other Uses of Artificial Asphaltum. Part IV.—emical Investigation of Natural and Artificial Asphaltums sphalts), and the Chemico-Technical Testing of Asphalt terials.

ilinschwarz und seine Anwendung in Färberei und Zeugdruck. Von Dr. E. Noelting und Dr. A. Lehne. Zweite, völlig umgearbeitete Auflage. Julius Springer's Verlag, Berlin. 1904. Price M. 8.

o volume, containing 174 pages of subject-matter, with illustrations, the alphabetical index of subjects and hors, and four sheets of dyed specimens. The entire ject is dealt with under the following heads :—I. The mation of Aniline Black : 1. Historical ; 2. Theory of mation ; and 3. Greening of Aniline Black. II. Use Aniline Black in Calico Printing : 1. Aniline Black in vder ; 2. Formation of Aniline Black on the Fibre. Aniline Black on Wool and Silk. IV. Use of Aniline k in Dyeing. V. Investigation of the most important Materials.

Trade Report.

I.—GENERAL.

Annual Meeting of the Association of Chambers of Commerce of the United Kingdom.

At the 44th annual meeting of the Association of Chambers of Commerce, held on March 8, 9, and 10, the following were among the resolutions carried :—

Railway Rates (*Birmingham*).—1. That the trading interests of Great Britain are injuriously affected by the discrepancy between the railway rates for the carriage of goods from foreign towns to the sea, and the rates charged by railway companies in this country ; and that this injury is increased by the advantage given by our railway companies to foreign producers for the conveyance of goods from the outports to the great centres of distribution at lower rates than from the seats of home production.

2. That a memorial be addressed to the President of the Board of Trade praying that he will be pleased to receive a deputation from this Association to urge upon him the desirability of moving for the appointment of a Select Committee to inquire into the question, and to recommend some means for removing the present grievance, either by a readjustment of the railway rates, or by the development of our canals, or by both.

Railway and Canal Traffic (*Leicester*).—That in the opinion of this Association it is desirable that a special department of the Board of Trade should be appointed, with an official who shall have power to initiate inquiries into, and jurisdiction to deal with, complaints against railway and canal companies in reference to rates and conditions affecting traffic, and that a cheaper and more expeditious tribunal for dealing with such complaints on the part of traders should be substituted for the Railway Commission, the local county courts being suggested for this purpose.

Canal Development (*Manchester*).—In view of the heavy disability imposed upon the industries and commerce of the United Kingdom by the excessive cost of inland transport, and of the neglect into which the waterways of the country have fallen, this Association earnestly calls upon His Majesty's Government to take steps for the purpose of the full utilisation, the co-ordination, and the extension of British and Irish canals, either by the establishment of public canal trusts or by some other method of creating an efficient national system of cheap inland water transportation.

Minister of Commerce (*Bradford*).—That this Association expresses its satisfaction at the appointment of a departmental committee "to consider the position and duties of the Board of Trade and the Local Government Board, and to report whether any, and, if so, what alterations should be made in the constitution and status of these bodies; also whether, in the interests of administrative efficiency, any rearrangement of duties between these Departments and other Government Departments is desirable," and trusts that the deliberations of the committee will result in the organisation of a suitable Department to deal with the commercial and industrial interests of this country, such Department to be presided over by a Minister of Commerce, whose position shall be equal to that of His Majesty's Secretaries of State, as has been repeatedly urged by this Association for upwards of 30 years.

Philosophical and Scientific Apparatus for Colleges, &c. : U.S. Customs Decisions.

An exhaustive decision was rendered by the Board of General Appraisers, January 12, 1904, on a large variety of articles imported by societies or institutions incorporated solely for religious, philosophical, scientific, or literary purposes, as specified in paragraph 638 of the present Tariff Act. After noting the principal decisions of the United States courts on this subject, and the fact that many articles formerly used exclusively for scientific purposes now find extended use in trades and commerce, a review of the various provisions of all the tariffs of the United States is presented. Beginning in 1790 with the first American Congress, it was enacted that philosophical apparatus specially imported for any seminary of learning should be free of duty. The Act of 1792 continued this exemption, while the next general Act of 1816 widened the field of free importation, while the Act of 1824 extended the privilege to schools and colleges. The Acts of 1841 and 1842 enumerated the classes of articles on which no duty was to be levied, while the same broad policy was observed in all subsequent tariff acts since enacted, with exceptions only in those of 1846 and 1864, at the time of the Mexican and Civil War, when the needs of the Government were great. In 1894 the word "utensil" first appears in the law, which covers many articles not strictly scientific in character.

The Board held that a number of laboratory articles specified in the decision were free of duty when imported according to the regulations of the Treasury Department. —R. W. M.

II.—FUEL, GAS, AND LIGHT.

Gas, Coke, Tar and Ammonia Products in America in 1902.

Eng. and Mining J., March 10, 1904.

In making its annual canvass of the coal-mining and coke making industries for 1902, the United States Geological Survey has extended its inquiries in order to cover all plants producing gas and coke from coal and covering tar and ammonia. The final report will appear in "The Mineral Resources" for 1902, and the following is an abstract of some of the more important data in advance of its publication :—

In 1902 the returns from 533 companies, including the operations of 1,665 by-product coke-ovens, show that 5,015,511 tons of coal were carbonised, which yielded 30,764,625,332 cb. ft. of gas. Of this product 29,079,073,555 cb. ft. were sold, leaving 1,685,551,777 cb. ft. lost or unaccounted for. About 2,000,000 tons of the total coal carbonised were used in by-product ovens.

The aggregate value of all the products obtained from the distillation of coal in gas works or retort ovens in 1902 was 43,869,440 dols. About two-thirds of this amount, or 29,342,881 dols., represented the value of the gas produced. The value of the coke produced was 11,267,608 dols., while the tar was worth, at the works, 1,873,966 dols. Most of the ammonia produced was sold in the form of ammoniacal liquor. The total quantity sold was 49,490,609 galls., and was worth, at the works, 1,065,300 dols. In addition to this there was an actual production of 11,276,502 lb. of sulphate, which sold for 319,685 dols.

Comparatively little progress in the manufacture of chemical products from coal-tar has been made in America. The coal-tar produced in 1902 was worth at first hand 1,873,966 dols. In the fiscal year ended June 30, 1902, the coal-tar products imported into the United States were worth, at points of shipment, 7,494,340 dols. Including duty, freight, and other costs, their value in the wholesale markets of America probably amounted to about 12,000,000 dols. in all.

Coke : U.S. Customs Decision.

Feb. 5, 1904.

Coke is not free of duty under the Act of Congress approved January 15, 1903, which makes free of duty "all coal of every form and description," since coke is not coal, but a distinct article prepared therefrom.—R. W. M.

Wood Charcoal ; U.S. Customs Decision.

Feb. 29, 1904.

Wood charcoal is dutiable at 20 per cent. *ad valorem* under section 6, as "a manufactured article unenumerated," and not at 35 per cent. *ad valorem* as an "article composed of carbon," under paragraph 97.—R. W. M.

III.—TAR PRODUCTS, PETROLEUM, Etc.

Creolin Pearson : U.S. Customs Decision.

Jan. 19, 1904.

Following a decision of the United States Circuit Court, it was held that creolin pearson is dutiable at 20 per cent. *ad valorem* under paragraph 15 of the present Tariff Act, as a "preparation of coal tar not a colour or dye and not medicinal." The assessment of duty at 25 per cent. *ad valorem* as a "medicinal preparation" under paragraph 68 was overruled.—R. W. M.

Bleacher's Blue : U.S. Customs Decision.

Certain liquid blue was assessed for duty at 30 per cent. *ad valorem* as a "coal tar," under paragraph 15 of the present tariff. This action was sustained by the Board of General Appraisers. On appeal to the United States Circuit Court this decision was reversed and the claim of the importer that it was dutiable at 20 per cent. *ad valorem* under the same paragraph as a "preparation of coal tar not a colour or dye" was sustained.—R. W. M.

Petroleum Field in Russia.

Eng. and Mining J., March 17, 1904.

Explorations have been carried on for some time in the district of Berkeh, about 250 kilometres from Baku, and as they have been attended with success, active production is expected in the near future. It is intended to ship the crude oil to Baku for refining.

IV.—COLOURING MATTERS, Etc.

Indigo Crop of India.

U.S. Cons. Rep., No. 1893, *March* 5, 1904.

The season in Bengal opened unfavourably in the seven indigo-growing districts, the rainfall being very insufficient, but later good rain fell, and thenceforward conditions were favourable. The area continues to contract, the estimate for the year being 249,700 acres, compared with 255,500 acres sown last year. The exports in each of the last three years have been :—

From	1900 1.	1901 2.	1902 3.
	Cwts.	Cwts.	Cwts.
Calcutta	71,637	55,038	29,403
Madras	18,745	25,056	32,242
Bombay	5,322	3,015	2,295
Karachi	6,593	6,297	1,437

Alizarin Blue : U.S. Customs Decision.

Feb. 29, 1904.

The Board of General Appraisers held the following dyestuffs to be free of duty as "dyes derived from alizarin or from anthracene," under paragraph 469 of the present tariff :—Alizarin Blue S A E, Alizarin Blue B A, Alizarin Blue E A, Alizarin X.—R. W. M.

VII.—ACIDS, ALKALIS, Etc.

Nitrate Deposits in Tunis.

Eng. and Mining J., March 17, 1904.

What is believed to be an extensive deposit of a good quality of nitrate of soda, fit for mining, has been discovered east of Timimum, near the Feggaguira oasis. Other discoveries of equal importance have been made lately in the so-called south oasis of the Sahara in Tunt, Gurara, and Tidikelt, by military attachés. Unfortunately these deposits are remote from adequate transportation facilities that would make them of commercial value. It is intimated, however, that the completion of the Trans-Senegal Railway, now being constructed along the Zousfana river, may aid materially in developing the nitrate beds.

CRYOLITE: U.S. CUSTOMS DECISION.

Feb. 4, 1904.

Artificial cryolite, which, like the native mineral, is a fluoride of aluminium and sodium, is free of duty as "cryolite or kryolith," under paragraph 538 of the present Tariff Act. The action of the Customs authorities at Milwaukee, in assessing duty at 25 per cent. *ad valorem* under paragraph 3, as a "chemical salt," was overruled on the ground that the naming of the article in paragraph 538 is a more specific provision than the general term used in paragraph 3.—R. W. M.

BARIUM CARBIDE: U.S. CUSTOMS DECISION.

March 4, 1904.

The Board of General Appraisers held that barium carbide is dutiable at 25 per cent. *ad valorem* as a "chemical salt" under paragraph 3 of the present tariff, and not at 5·25 dols. per ton as "manufactured barytes" under paragraph 44.
—R. W. M.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

FIRE CLAY: U.S. CUSTOMS DECISION.

Feb. 1, 1904.

Fire clay in granulated form was held to be duitable at 1 dol. per ton, as "clay unwrought" under paragraph 93 of the present Tariff Act, and not at 2 dols. per ton as "clay wrought," under the same paragraph. The evidence showed that the crushing to produce granulation was only for the purpose of convenience of transportation.—R. W. M.

X.—METALLURGY.

COPPER, GOLD, AND ASBESTOS DISCOVERIES IN CANADA.

U.S. Cons. Rep., No. 1904, *March* 18, 1904.

The discovery is announced of nickeliferous copper in large quantities in Cape Breton Island. The ore body is reported to be between 270 and 280 feet wide, carries gold and silver, and contains high values in copper and gold. t is said that the property will prove to be among the argest copper mines in the world. New gold findings at oplar Creek, British Columbia, and an important discovery of asbestos in Addington County, Ontario, are also eported.

LODE-TIN; DISCOVERY OF ——, IN QUEENSLAND.

Eng. and Mining J., March 17, 1904.

In the *Australian Mining Standard*, Dec. 10, 1903, formation is given of the development of new tin deposits the vicinity of Reid's Creek, Queensland. The ore curs in veins cutting granite and slate, and, in places, is ry rich. From one vein, 9 ft. wide, material has been ken out which yielded 18 per cent. of black tin, while ether vein of still larger size also carries rich ore. veral properties are now under development, and the gher-grade ore is being transported in waggons to vinebank for crushing.

LEAD-ZINC DEPOSIT IN GERMANY.

Eng. and Mining J., March 17, 1904.

t is reported that a large deposit of lead-zinc ore has n found near Loutzen, south-west of Aachen, Germany. e deposit has been proved by boring operations, and will developed in the near future.

METALLIC MANGANESE: U.S. CUSTOMS DECISION.

Feb. 5, 1904.

Best metallic manganese without carbon, 96—98 per c t.," and valued at about 1,200 dols. per ton, is dutiable a 0 per cent. *ad valorem* as a "metal unwrought," under p graph 183 of the present tariff. The claim of the in orter for assessment of duty at 4 dols. a ton as "ferromanganese," under paragraph 122, was overruled, as an analysis showed that it was metallic manganese, and not ferromanganese.—R. W. M.

RUTILE: U.S. CUSTOMS DECISION.

Feb. 3, 1904.

Certain rutile was assessed for duty at 20 per cent. *ad valorem*, under paragraph 183 of the present tariff, as a "metallic mineral substance in a crude state." An analysis of the sample showed it to be native impure titanic oxide, and not a metal. The Board of General Appraisers sustained the claim of the importer that it was free of duty as a "crude mineral substance," under paragraph 614.
—R. W. M.

MINERAL PRODUCTION OF CANADA IN 1903.

Eng. and Mining J., March 10, 1904.

The preliminary statement of the mineral production of Canada in the year 1903, which is prepared by the Section of Mines of the Geological Survey, is as follows:—

Product.		Quantity.	Value.
METALLIC.			Dols.
Copper	Lb.	43,281,158	5,728,261
Gold	..	..	18,834,490
Iron ore (exports)	Tons	358,233	922,571
Pig iron from Canadian ore	..	42,052	707,838
Lead	Lb.	18,000,000	762,660
Nickel	„	12,505,510	5,002,204
Silver	Oz.	3,182,000	1,700,779
Zinc	Lb.	900,000	48,600
Total metallic		..	33,707,403
NON-METALLIC.			
Actinolite	Tons	550	3,108
Arsenic	..	257	15,420
Asbestos	..	31,780	891,033
Asbestic	„	10,548	13,819
Chromite	„	3,383	33,830
Coal	„	7,996,634	15,957,946
Coke	„	544,132	1,663,725
Corundum	„	No returns	..
Feldspar	„	13,228	18,666
Fireclay	„	2,317	2,505

The tons used in this statement are short tons, of 2,000 lb. The average prices used in computing values of metals are: Silver, 53·45 c.; copper, 13·235 c.; nickel, 40 c.; lead, 4·237 c. The coke reported is all oven coke; gas coke is not included.

The total production of pig iron in Canada in 1903, from Canadian and imported ores, amounted to 297,885 tons, valued at 3,742,710 dols., of which it is estimated 42,052 tons, valued at 707,838 dols., should be attributed to Canadian ore, and 255,833 tons, valued at 3,034,872 dols., to the ore imported.

The value of the total mineral production reported for 18 years past has been as follows:—

	Dols.		Dols.
1886	10,221,255	1895	20,648,964
1887	11,321,331	1896	22,584,513
1888	12,518,894	1897	28,661,430
1889	14,013,913	1898	38,697,021
1890	16,763,353	1899	49,584,027
1891	18,976,616	1900	64,618,268
1892	16,628,417	1901	66,339,158
1893	20,035,082	1902	63,885,999
1894	19,931,158	1903	63,226,510

The remarkable increase in the period from 1898 to 1900, inclusive, was due to the gold discoveries in the Yukon.

The main feature presented by the mineral industry of Canada as a whole consists in the decrease in the grand total of production of a little over 1 per cent. in comparison with the figures for 1902. A comparison of the items for two years shows the reason for this falling-off. The shrinkage in the production of the Yukon placer goldfields accounts for 2,250,000 dols. of the total diminution of over 2,500,000 dols. in the gold output of the country. This is augmented by over 1,000,000 dols. decrease in the values of the output credited to others of the metallic class, pig iron, silver, lead, and nickel. To offset this the copper, iron ore, and zinc industries exhibit increases, aggregating nearly 1,500,000 dols., leaving a minus amount of a little over 2,000,000 dols., against the metallic class as a whole, equivalent to 5·8 per cent.

Advances were shown in several of the non-metallic class, notably in coal and coke, limestone, mica, salt, cement, and in some of the clay products. The total growth in all the non-metallics showing increases amounted to nearly 2,000,000 dols., the advance in the coal and coke output accounting for over 1,600,000 dols. of this. As against these non-metallic industries showing increases, decreases are exhibited in the values of the production in asbestos, natural gas, petroleum, and a number of others, aggregating about 500,000 dols., leaving a net gain in this class of somewhat under 1,500,000 dols., or a little over 5 per cent., to offset the above-mentioned falling off in the metallic class, the final difference in the grand totals for the two years amounting to nearly 660,000 dols., or a proportional decrease of about 1 per cent.

Exports.—The following table shows the chief items of minerals exported during the year:—

Product.		Quantity.	Value.
			Dols.
Arsenic	Lb.	395,573	10,583
Asbestos	Tons	31,780	891,033
Coal	„	1,954,629	5,219,860
Gold in all forms	..	..	17,566,540
Copper, fine, in ore, &c.	Lb.	37,039,175	3,702,368
„ black or coarse, &c.	„	203,701	25,226
Lead in ore, &c.	„	18,621,303	426,166
Nickel in ore, matte, &c.	„	12,699,227	1,116,099
Platinum in ore, concentrates, &c.	Oz.	283	304
Silver in ore, &c.	..	3,360,192	1,989,474
Mica	Lb.	956,244	186,020
Iron ore	Tons	368,233	922,571
Graphite, crude	Cwt.	8,235	26,230
Pyrites	Tons	21,067	59,604

The gold exported was chiefly in the form of gold dust, nuggets, and the like, or contained in ores.

ZINC SHEETS, NICKEL-PLATED: U.S. CUSTOMS DECISION.

Jan. 29, 1904.

A decision of the United States Circuit Court rendered holds that zinc in sheets, nickel-plated, is dutiable at 45 per cent. *ad valorem*, as an "article composed wholly or in part of nickel, zinc, &c.," under paragraph 193 of the present Tariff Act, and not as "zinc in sheets," at 2 cents per lb., under paragraph 192.—R. W. M.

XII.—FATS, FATTY OILS, Etc.

OLIVE OIL: U.S. CUSTOMS DECISION.

Feb. 3, 1904.

An olive oil in tins, invoiced as for machinery purposes, and which was found on analysis to contain 2·63 per cent. of free fatty acid, is dutiable at 50 cents per gallon. The oil was valued at over 60 cents per gallon, which is the limit of value at which olive oil can be entered free of duty for mechanical or manufacturing purposes.—R. W. M.

WAX; JAPAN ——.

Chem. and Druggist, March 19, 1904.

The exports of Japan wax from Japan during the 12 months ending December were as follows:—

——	1901.	1902.	1903.
Kin	4,049,300	4,216,000	3,521,400
Yen	610,000	790,000	1,064,000

NOTE.—Kin = 1·3 lb. Yen = 2*s.* 0½*d.*

COCOANUT STEARINE AND VEGETABLE TALLOW: U.S. CUSTOMS DECISION.

March 1, 1904.

Cocoanut stearine and vegetable tallow were held to be dutiable at 3½ cents per lb. as "cocoa butterine." (See this J., 1903, 832).—R. W. M.

XIII. A.—PIGMENTS, PAINTS, Etc.

PRINTING COLOUR (DRUCKFARBE): U.S. CUSTOMS DECISION.

Feb. 17, 1904.

An article of the above name consisting of powdered metallic aluminium mixed with oil and turpentine, was decided by the Board of General Appraisers to be dutiable at 30 per cent. *ad valorem* as a "paint" under paragraph 58 of the present tariff. The claim of the importer, who stated that it was used in printing cloth, that it was dutiable at 25 per cent. *ad valorem* as "ink" under paragraph 26, was overruled.—R. W. M.

XIV.—TANNING; LEATHER; GLUE, Etc.

BONE SIZE: U.S. CUSTOMS DECISION.

Feb. 5, 1904.

Following a decision of the United States Circuit Court, bone size is dutiable at 20 per cent. *ad valorem*, under section 6 of the present tariff, as a "manufactured article unenumerated," and not at 2½ cents per lb. under paragraph 23 as "glue valued at not over 10 cents per lb."
—R. W. M.

SIZING: U.S. CUSTOMS DECISIONS.

Feb. 5, 1904.

Sizing composed of ordinary and soluble starch 12·40 per cent., dextrine and soluble gum 9·04 per cent., gluten 1·77 per cent., zinc and sodium chlorides 0·77 per cent., and water 76·02 per cent., is dutiable at 25 per cent. *ad* valorem, under paragraph 3 of the present Tariff Act as a "chemical compound." Owing to the fact that this classification was not claimed by the importer in the protest, the assessment of duty at 1½ cents per lb. under paragraph 285 was affirmed.—R. W. M.

XV.—MANURES, Etc.

TANKAGE: U.S. CUSTOMS DECISION.

The Treasury Department holds that tankage, the refuse of slaughter-houses, is free of duty as a "substance used only for manure," under paragraph 569 of the present Tariff Act. The view is also expressed that the provision of this paragraph includes not only manures but substances used in combination with other materials in making manure.
—R. W. M.

XVII.—BREWING, WINES, SPIRITS, Etc.

WINE TRADE OF GERMANY.

U.S. Cons. Reps., No. 1904, *March* 18, 1904.

During 1903 Germany imported wine valued at 14,016,490 lols. and exported to the value of 5,977,132 dols. Of the otal, 6,459 cwt. came from, and 85,518 cwt. was sent to the Jnited States.

ALCOHOL PRODUCTION OF GERMANY IN 1903.

U.S. Cons. Reps., No. 1896, *March* 9, 1904.

A poor potato crop in 1902 caused a considerable curailment of the alcohol production in Germany during the eason of 1902-3, only 89,372,183 gallons being produced, is against 112,110,842 gallons in 1901-2 and 107,229,799 allons in 1900-1, so that the order of the alcohol trust to urtail the production was superfluous.

XVIII. A.—FOODS

FOOD PRODUCTS; STANDARDS OF PURITY FOR ——.

Times, March 28, 1904.

By an Act of Congress passed in 1902 the United States linister of Agriculture was authorised to establish stanards of purity for food products. This he has now done, fter taking the counsel and advice of experts and official odies. The information is issued for the guidance of the fficials of the various States and of the Courts of Justice. leat is defined as any sound, dressed, and properly preared edible part of animals in good health at the time of aughter. Fresh meat is meat from animals recently aughtered or preserved only by refrigeration. Salted, ckled, and smoked meats are unmixed meats preserved by lt, sugar, vinegar, spices, or smoke, singly or in combinan. Lard is defined as the rendered fresh fat from ughtered healthy hogs. Leaf lard is that rendered at derately high temperatures from the internal fat of the domen of the hog, excluding that adherent to the intestes. Neutral lard is lard rendered at low temperatures. ndard lard must be free from rancidity and contain not re than 1 per cent. of substances, other than fatty acids, t fat. Milk is the lacteal secretion obtained by the comte milking of one or more healthy cows, properly fed and t, excluding that obtained within 15 days before and five s after calving. Standard milk must contain not less n 12 per cent. of total solids and not less than 8·5 per t. of solids not fat, nor less than 3·25 per cent. of milk f. Skim milk is milk from which a part or all of the c am has been removed, and standard skim milk must c tain not less than 9·25 per cent. of milk solids. Cream i efined as that portion of milk, rich in butter fat, which r s to the surface of milk on standing, or is separated f n it by centrifugal force. Standard cream must contain o less than 18 per cent. of milk fat. Butter is defined as tl product obtained by gathering in any manner the fat of fr h or ripened milk or cream into a mass, which also contains a small portion of the other milk constituents, with or without salt. By two Acts of Congress passed in 1886 and 1902 butter may also contain additional colouring matter. Standard butter is butter containing not less than 82·5 per cent. of butter fat. Renovated or process butter is the product obtained by melting butter and reworking, without the addition or use of chemicals or any substances except milk, cream, or salt. Standard renovated or process butter is that containing not more than 16 per cent. of water and at least 82·5 per cent. of butter fat. Cheese is defined as the solid or ripened product obtained by coagulating the casein of milk by means of rennet or acids, with or without the addition of ripening ferments and seasoning. By Act of Congress, 1896, cheese may also contain additional colouring matter. Whole-milk or full-cream cheese is cheese made from milk from which no portion of the fat has been removed. Skim-milk cheese is cheese made from milk from which any portion of the fat has been removed. Cream cheese is cheese made from milk and cream, or milk containing not less than 6 per cent. of fat. Standard whole-milk cheese or full-cream cheese must contain in the water-free substance not less than 50 per cent. of butter fat. Whey is the product remaining after the removal of fat and casein from milk in the process of cheese-making. Kumiss is mare's or cow's milk, with or without the addition of sugar (sucrose), which has undergone alcoholic fermentation. Standards are also established for sugar and sugar products, glucose products, condiments, and beverages.

XX.—FINE CHEMICALS, Etc.

RADIUM.

Times, March 21, 1904.

At the request of the Academy of Science, the Austrian Minister of Agriculture, in order to facilitate the solution of certain important questions relating to the nature of radium, has ordered that from January 1 last until further notice no trading should be permitted in the residues from the manufacture of uranium colours at Joachimsthal, and that 10,000 kilogrammes of those residues should be reserved for purchase by the Academy and another 10,000 kilogrammes for M. Curie. These consignments are to be devoted entirely to the purpose of scientific experiment.

CAMPHOR; EXPORTS OF ——, FROM JAPAN.

Chem. and Druggist, March 18, 1904.

According to statistics which have been issued by the Board of Trade, the exports of camphor from Japan during the twelve months ending December were as follows:—

—	1901.	1902.	1903.
Kin	4,165,757	3,953,211	3,985,364
Yen	3,905,000	3,405,000	3,538,000

Note.—Kin = 1·3 lbs. Yen = 2*s*. 0⅓*d*.

CINCHONA; EXPORTS OF ——, FROM JAVA.

Chem. and Druggist, March 26, 1904.

The following table gives the exports of Cinchona from Java for the years 1899—1903:—

—	1899.	1900.	1901.	1902.	1903.
Private plantations (Amst. lbs.)	9,752,639	9,366,596	12,018,397	12,575,676	12,947,742
Government plantations (Amst. lbs.)	659,657	660,975	758,796	943,259	808,581
Total exports	10,412,296	10,027,571	12,777,193	13,518,935	13,756,323

CERIUM OXALATE AND HELIOTROPIN: U.S. CUSTOMS DECISIONS.

Feb. 5, 1904.

Cerium oxalate is dutiable at 25 per cent. *ad valorem* as a "medicinal preparation" under paragraph 68 of the present tariff, and not free of duty as "cerium" under paragraph 518. Heliotropin is dutiable at the same rate under paragraph 3, as a "chemical compound," and not free of duty as a "crude vegetable substance" under paragraph 617.—R. W. M.

HYDROQUINONE: U.S. CUSTOMS DECISION.

Feb. 10, 1904.

Chemically pure hydroquinone was assessed for duty at 25 per cent. *ad valorem*, under paragraph 68 of the present tariff act, as a "medicinal preparation." The Board of General Appraisers, following a decision of the United States Circuit Court, sustained the claim of the importers that it was dutiable at 20 per cent. *ad valorem*, as a "preparation of coal tar, not a colour or dye," under paragraph 15.—R. W. M.

PARALDEHYDE: U.S. CUSTOMS DECISION.

March 3, 1904.

The Board of General Appraisers held that paraldehyde, prepared from aldehyde by the action of a mineral acid, was dutiable at 55 cents per lb. as a "medicinal preparation in the preparation of which alcohol is used," under paragraph 67 of the present tariff act. The evidence showed that, while paraldehyde is prepared from aldehyde, the latter is obtained by the oxidation of alcohol, either directly or in the manufacture of spirits. The claims of the importer that it is dutiable at 25 per cent. as a "chemical compound" under paragraph 3, or at the same rate as a "non-alcoholic medicinal preparation" under paragraph 68 were overruled.—R. W. M.

Patent List.

N.B.—In these lists, [A.] means "Application for Patent," and [C.S.], "Complete Specification Accepted."

Where a Complete Specification accompanies an Application, an asterisk is affixed. The dates given are (i) in the case of Applications for Patents, the dates of application, and (ii) in the case of Complete Specifications Accepted, those of the Official Journals in which acceptances of the Complete Specifications are advertised.

Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

I.—PLANT, APPARATUS, AND MACHINERY.

[A.] 6239. Morison. Condensing apparatus. March 14.

,, 6437. Macgregor and Pearson. Centrifugal machine for drying peat or like material. March 16.

,, 6999. Forster. Gas producers and like apparatus. March 23.

,, 7079. Whitworth. Gas producers. March 24.

,, 7145. Imray (Pintsch). Bunsen burners. March 24.

,, 7298. Fleming. Arc-lamp electrodes. [U.S. Appl., March 26, 1903.]* March 26.

,, 7299. Fleming. Arc-light electrodes, and method of making same. [U.S. Appl., March 26, 1903.]* March 26.

[C.S.] 6090 (1903). Burschell. Method of removing sulphuretted hydrogen from gases with simultaneous recovery of sulphur. March 23.

,, 9606 (1903). Claudel. *See under* I.

,, 10,852 (1903). Grundy. Manufacture of incandescent mantles. March 30.

,, 17,327 (1903). Von Bauer. Coke ovens. March 30.

,, 23,045 (1903). Good and Spencer. Apparatus for the purification of coal-gas. March 30.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM, AND MINERAL WAXES.

[A.] 6302. Loomis and Pettibone. *See under* II.

,, 6554. McClelland and Risk. *See under* XII.

,, 6891. Zimpell. Saturator for the recovery of sulphate of ammonia from ammonia gases.* March 22.

,, 7204. Bokelberg and Sachse. *See under* I.

[C.S.] 10,004 (1903). Heber. *See under* XIII B.

,, 12,984 (1903). Slama. *See under* I.

IV.—COLOURING MATTERS AND DYESTUFFS.

[A.] 6217. Abel (Act.-Ges. f. Anilinfabr.). Manufacture of colour lakes from sulphur dyestuffs. March 14.

,, 6225. Johnson (Badische Anilin und Soda Fabrik). Manufacture of indoxyl and its derivatives. March 14.

,, 6226. Johnson (Badische Anilin und Soda Fabrik). Manufacture of indigo white. March 14.

,, 6552. Imray (Meister, Lucius und Brüning). Manufacture of blue sulphurised dyestuffs. March 17.

,, 6741. Abel (Act.-Ges. f. Anilinfabr.). Manufacture of nitro derivatives of certain aromatic bases. March 19.

,, 6839. Johnson (Badische Anilin und Soda Fabrik). Manufacture of azo colouring matter, and lakes therefrom. March 21.

,, 6840. Johnson (Badische Anilin und Soda Fabrik). Manufacture of azo colouring matter from *o*-chlor-*p*-toluidine and β-naphthol, and of lakes therefrom. March 21.

, 7040. Cosway and The United Alkali Co., Ltd. Manufacture of blue sulphur dyes. March 23.

, 7041. Cosway and The United Alkali Co., Ltd. Manufacture of blue-black to black sulphur dyes. March 23.

7042. Cosway and The United Alkali Co., Ltd. Manufacture of green sulphur dyes. March 23.

[C.S.] 10,242 (1903). Iljinskij and R. Wedekind and Co. Manufacture of organic sulpho-compounds. March 23.

,, 11,630 (1903). Imray (Meister, Lucius und Brüning). Manufacture of indigo dyestuffs. March 23.

,, 13,808 (1903). Newton (Bayer and Co.). Manufacture of derivatives of the anthraquinone series. March 30.

V.—PREPARING, BLEACHING, DYEING, PRINTING, AND FINISHING TEXTILES, YARNS, AND FIBRES.

[A.] 6383. Mather, Hübner, and Pope. Mercerising, and apparatus therefor. March 16.

,, 6418. Bartelt. Mode of cleansing and bleaching fabrics, and apparatus to be used therefor. March 16.

,, 6456. Brandwood. Tube for use in dyeing, bleaching, &c. March 16.

,, 6848. Imray (Meister, Lucius und Brüning). Printing indanthrene and flavanthrene. March 21.

,, 7172. Wiley. Apparatus for waterproofing fabrics. March 25.

,, 7261. Boardman. Process of dyeing yarn, and apparatus therefor. March 26.

[C.S.] 3556 (1903). Gibbon. Methods and apparatus for multi-colour printing. March 23.

,, 11,451 (1903). Mann. Process for dyeing animal and vegetable fibres. March 30.

,, 27,870 (1903). Dittmar. Hank-dyeing machines. March 30.

VI.—COLOURING WOOD, PAPER, LEATHER, Etc.

[A.] 6849. Imray (Meister, Lucius und Brüning). Manufacture of many-coloured, marbled, or unequally mixed paper, and apparatus therefor. March 21.

VII.—ACIDS, ALKALIS, AND SALTS.

[A.] 6143. Mills. Manufacture of salts of lead. March 14.

,, 6216. Imray (Meister, Lucius und Brüning). Manufacture of stable hydrosulphite compounds. March 14.

,, 6336. Haddock. Apparatus for the manufacture of alkali metal. March 15.

,, 6337. Haddock. Manufacture of alkali metal. March 15.

,, 6525. Bornett. Process for preparing aluminium chloride. March 17.

,, 6608. Woltereck. Apparatus for the production of ammonia and its salts. March 18.

,, 6697. Rigby. Manufacture of bleaching powder. March 19.

,, 6756. Kingdon. Apparatus for recovering by chemical precipitation certain substances from solutions of their compounds. March 21.

,, 6846. Lake (Soc. Anon. Ing. L. Vogel per la Fabr. Concimi-chimici). Manufacture of sulphuric acid.* March 21.

,, 6891. Zimpell. *See under* III.

[A.] 6898. Bollé (Chem. Fabr. Grünau, Landshoff und Meyer Act.-Ges.). Process for the manufacture of neutral sulphate and of sulphurous acid from bisulphate. March 22.

,, 6903. Kamm. Apparatus for manufacturing oxygen gas. March 22.

,, 6921. Roux and Gonin. *See under* XV.

,, 7028. Levie Frères. Process for preparing and burning cement and other analogous materials. [Belgian Appl., March 30, 1903.]* March 23.

[C.S.] 6247 (1903). Magens. Treatment of concrete, &c., whereby the setting after mixture may be arrested. March 23.

,, 3769 (1904). Howorth (Jurschina). Manufacture of artificial stone. March 23.

,, 4130 (1904). Ahrendts. Manufacture of artificial stones or bricks in which the waste from the Leblanc or ammonia-soda process is used. March 30.

X.—METALLURGY.

[A.] 6635. Gröndal. *See under* IX.

,, 6750. Cowper-Coles and Co., Ltd., and Cowper-Coles. *See under* XI.

,, 6775. Parker. Production of black magnetic oxide of iron.* March 21.

,, 6823. Moser (Stockert and Co.). Production of gold and silver compound plates. March 21.

,, 6832. Webb. *See under* XI.

,, 6945. Jacobsen. Manufacture of alloys.* March 22.

,, 6997. Zenzes. Manufacture of iron and steel.* March 23.

,, 7309. Weiller and Weiller. Process for separating from their ores copper, silver, lead, mercury, and all other metals adapted to be precipitated from an acid solution by means of sulphuretted hydrogen. March 26.

[C.S.] 11,002 (1903). Reynolds. *See under* XI.

,, 11,297 (1903). Garretson. Blast furnaces. March 30.

,, 11,303 (1903). Garretson. Process of converting or Bessemerising matte. March 30.

,, 12,778 (1903). Turner. Apparatus for separating metals from their crushed ores or material containing same. March 30.

,, 1890 (1904). Kurzwernhart. Siemens' regenerative furnaces. March 23.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

[A.] 6102. British Thomson Houston Co., Ltd. (Gen. Electric Co.). Insulating compounds. March 16.

,, 6600. Cleminson Electric Lamp Attachment, Ltd., and King. *See under* IX.

,, 6637. Sherman. Galvanic dry cells. March 18.

,, 6750. Cowper-Coles and Co., Ltd., and Cowper-Coles. The electro-deposition of metals. March 19.

,, 6792. Leitner. Method of preliminary treatment for accumulator plates. March 21.

,, 6832. Webb. Electrolytic extraction of metals from solutions. March 21.

,, 7056. Ashcroft. Production of metals of the alkali group by electrolysis. March 23.

,, 7061. Leeds Copper Works, Ltd., and Jobling. Electro-depositing apparatus. March 23.

[C.S.] 5891 (1903). Portalier. Electric batteries. March 23.

,, 11,000 (1903). Reynolds. Electric crucible furnaces. March 23.

,, 11,001 (1903). Reynolds. Electric crucible furnaces. March 23.

,, 11,002 (1903). Reynolds. Method of melting steel and the like in electric furnaces. March 23.

,, 11,579 (1903). Greenfield. Anodes for electrolytic operations. March 30.

XII.—FATTY OILS, FATS, WAXES, AND SOAP.

[A.] 6281. Enoch, and Rose, Downs and Thompson, Ltd. Method of and apparatus for extracting oil from seeds, &c., and forming cakes. March 15.

,, 6554. McClelland and Risk. Oil purifiers.* March 17.

,, 7100. Hogarth. *See under* XVIII. A.

,, 7204. Bokelberg and Sachse. *See under* I.

[C.S.] 12,984 (1903). Slama. *See under* I.

XIII.—PIGMENTS, PAINTS; RESINS, VARNISHES; INDIA-RUBBER, Etc.

(A.)—Pigments, Paints.

[A.] 6217. Abel (Act.-Ges. f. Anilinfabr.). *See under* IV.

,, 6782. Brindle. Waterproofing solution or paint. March 21.

,, 6839. Johnson (Badische Anilin und Soda Fabrik). *See under* IV.

,, 6840. Johnson (Badische Anilin und Soda Fabrik). *See under* IV.

,, 7260. Strange and Graham. Manufacture of paint vehicles. March 26.

(*B.*)—Resins, Varnishes.

[A.] 7068. Mahieux. Non-inflammable composition for use as a protective coating. [Fr. Appl., March 26, 1903.]* March 23.

[C.S.] 10,004 (1903). Heber. Treatment of Russian oil of turpentine and similar products, and of benzine or petroleum spirit for the purpose of removing their disagreeable odour. March 30.

„ 16,691 (1903). Walton. Method of embossing and colouring lincrusta or like material, and apparatus therefor. March 30.

„ 16,693 (1903). Walton. Method of colouring lincrusta or like material, and apparatus therefor. March 30.

(*C.*)—India-Rubber.

[A.] 6471. Robinson Bros., Ltd., and Clift. Means of preparing rubber solutions and the utilisation of such means and of subsequent treatment for the conversion of waste into serviceable rubber. March 17.

XIV.—TANNING, LEATHER, GLUE, SIZE, Etc.

[C.S.] 11,028 (1903). Préaubert and Thubé. Manufacture of an adhesive material suitable for use as a glue or size, or for painting, printing, and other purposes. March 23.

XV.—MANURES, Etc.

[A.] 6920. Roux and Gonin. Process and apparatus for the production of a new chemical fertiliser. March 22.

„ 6921. Roux and Gonin. Process of and apparatus for the recovery of ammonia from gases during the process of manufacture and for the production of fertilisers. March 22.

„ 6922. Roux and Gonin. Production of humate of ammonia for fertilising purposes. March 22.

„ 6982. Burleigh and King. *See under* VII.

XVI.—SUGAR, STARCH, GUM, Etc.

[A.] 7089. Stein. Manufacture of invert sugar March 24.

[C.S.] 26,665 (1903). Salisbury and Kramper. Process of obtaining syrup from beets, cane, corn, root crops, or other substances containing saccharine matter. March 30.

XVII.—BREWING, WINES, SPIRITS, Etc.

[A.] 6415. House. Brewers' germinators and kilns. March 16.

„ 6742. Kuhn. Process and apparatus for the manufacture of effervescent wines. [Fr. Appl., April 21, 1903.]* March 19.

„ 6812. Wittenberg and Kauffmann. Method of maturing spirits. March 21.

„ 6975. Imray (Brauerei Gross-Crostitz Act.-Ges.). Process and apparatus for drying, desiccating, and roasting germinated and non-germinating grain. March 22.

„ 7207. Ramsay. Distillation and purification of alcoholic liquids. March 25.

[C.S.] 10,093 (1903). Johnson and Hare. Fermentation of liquids. March 30.

„ 4011 (1904). Von Szathmáry. Condensing apparatus for preventing losses in distilleries through the escape of alcoholic vapour. March 23.

XVIII.—FOODS; SANITATION, WATER PURIFICATION; & DISINFECTANTS.

(*A.*)—Foods.

[A.] 6282. Williams and Hutchins. Non-alcoholic aerated beverages. March 15.

„ 6283. Williams and Hutchins. Preparation of leguminous proteids. March 15.

„ 6651. Lapparent. Preservation of alimentary products. March 18.

„ 6720. Rayner (Maemecke). Manufacture of milk powder. March 19.

„ 6818. Thorp. Preparation of food products. March 21.

„ 6819. Thorp. Sterilisation of food. March 21.

„ 7100. Hogarth. Treatment of alimentary substances, oils, beverages, and other oxidisable materials. March 23.

[C.S.] 9113 (1903). Reichert and Heydemann. Process of preparing dry extract of chicory. March 30.

„ 9448 (1903). Iveson and Wilson. Food preparation, and method of preparing the same. March 30.

(*B.*)—Sanitation; Water Purification.

[A.] 6689. Spence, Spence, and Peter Spence and Sons, Ltd. Treatment of sewage and the like. March 19.

[C.S.] 6181 (1903). Gray. Apparatus for the treatment of sewage. March 23.

„ 15,555 (1903). Hunter. Treatment of distillery effluents or other polluting liquids, sewage, or other putrescible material, soils for filtering purposes, and agricultural land. March 30.

XIX.—PAPER, PASTEBOARD, Etc.

[A.] 6849. Imray (Meister, Lucius und Bruning). *See under* VI.

„ 6989. Coulthwaite. Paper-making machines. March 23.

[C.S.] 27,339 (1903). De Pass (Gaertner). Manufacture of articles from the waste of wood-grinding mills and paper and cellulose factories. March 23.

„ 3909 (1904). Rowan. Safety commercial paper and ink, and process for making the same March 23.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

[A.] 6428. Lepetit. Manufacture of a condensation product from hæmatoxylin and formaldehyde. March 16.

„ 6652. Zimmermann (Chem. Fabr. auf Actien, vorm. E. Schering). Manufacture of camphor from isoborneol. March 18.

[A.] 7193. Livingstone (Stein). Compound for use in medicine, and process of making same. March 25.

" 7222. Southerden. Manufacture of ethers. March 25.

" 7223. Imray (Meister, Lucius und Brüning). Manufacture of anti-bodies of all kinds, like agglutinines and præcipitines. March 25.

[C.S.] 10,242 (1903). Iljinskij and R. Wedekind and Co. *See under* IV.

XXII.—EXPLOSIVES, MATCHES, Etc.

[A.] 6353. Curtis's and Harvey, Ltd., and Hargreaves. Blasting compounds. March 16.

" 6916. Reichwald (Fried. Krupp Act.-Ges.). Percussion fuses. March 22.

[C.S.] 11,440 (1903). Orsman. Safety detonating explosives for use in coal and other fiery mines, or for general blasting purposes. March 23.

Printed and Published by Eyre and Spottiswoode East Harding Street, London E.C., for the Society of Chemical Industry.—P 9577.

JOURNAL OF THE
Society of Chemical Industry.

A RECORD
FOR ALL INTERESTED IN CHEMICAL AND ALLIED MANUFACTURES.

ISSUED TWICE A MONTH.

No. 8.—Vol. XXIII. **APRIL 30, 1904.** No. 8.—Vol. XXIII.

Subscription of Members 25/- per annum;
Entrance Fee 21/-;
Election by the Council.

Price to Non-Members 36/- per annum;
To Members 25/- per Set of extra or back numbers.
Single copies (Members and Subscribers only),
1882—1901, 2/6 each; 1902 *et seq.*, 1/9 each.

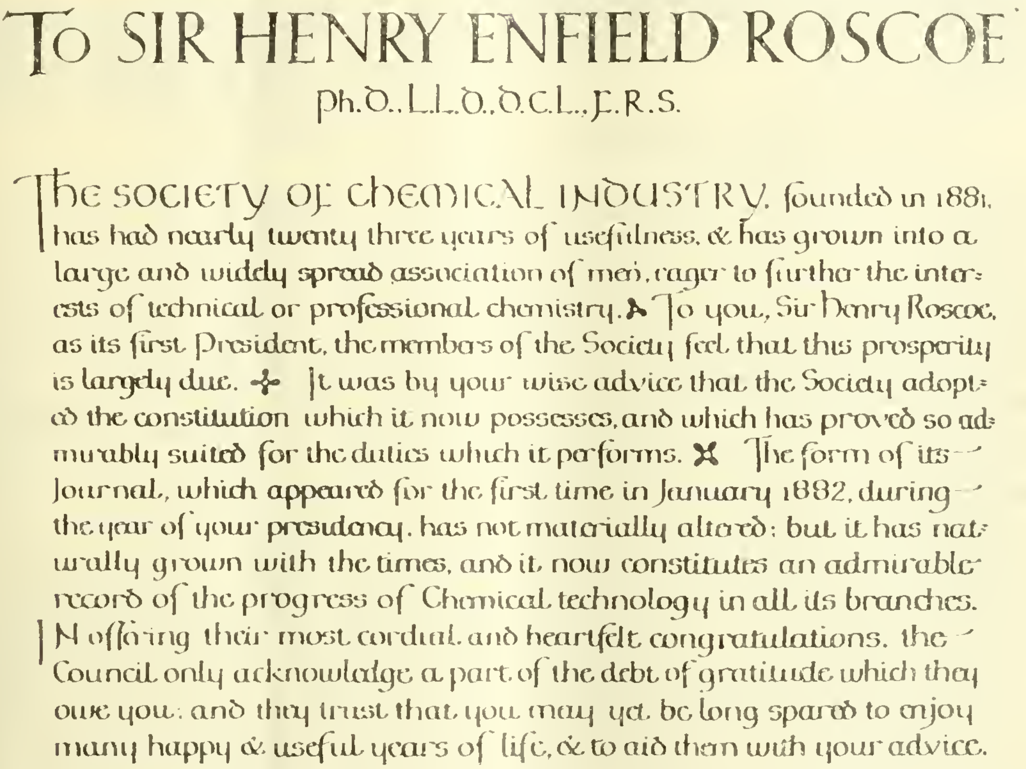
Notices.

JUBILEE OF SIR HENRY ROSCOE, F.R.S.

At Owens College, Manchester, on April 22nd, the 50th anniversary of the date of Sir Henry Roscoe's graduation as Doctor of Philosophy of the University of Heidelberg was celebrated by a reception and presentation of an address from his old University, his former students, and from the universities and colleges of the United Kingdom, the Continent, and the Colonies, and from many scientific societies. The University of Heidelberg, through Dr. Thorpe, presented him with the honorary diploma of Doctor of Philosophy. Sir Michael Foster, M.P., presented the address from the University of London. Sir William Ramsay presented an address from University College, London. Dr. Thorpe also presented an address from King's College, London. The British Association, of which Sir Henry Roscoe was president in 1887, was represented by Major Macmahon, hon. secretary. Sir Michael Foster, M.P., also presented an address from the Royal Society, and Sir William Ramsay addresses from the Chemical Society and the Society of Chemical Industry.

The following is a facsimile of the text of the address presented by the Society of Chemical Industry :—



To SIR HENRY ENFIELD ROSCOE
Ph.D., LL.D., D.C.L., F.R.S.

The Society of Chemical Industry, founded in 1881, has had nearly twenty three years of usefulness, & has grown into a large and widely spread association of men, eager to further the interests of technical or professional chemistry. ❧ To you, Sir Henry Roscoe, as its first President, the members of the Society feel that this prosperity is largely due. ❧ It was by your wise advice that the Society adopted the constitution which it now possesses, and which has proved so admirably suited for the duties which it performs. ✠ The form of its Journal, which appeared for the first time in January 1882, during the year of your presidency, has not materially altered; but it has naturally grown with the times, and it now constitutes an admirable record of the progress of Chemical technology in all its branches. In offering their most cordial and heartfelt congratulations, the Council only acknowledge a part of the debt of gratitude which they owe you; and they trust that you may yet be long spared to enjoy many happy & useful years of life, & to aid them with your advice.

To this Sir Henry Roscoe replied as follows :—

Nearly a quarter of a century has passed since a number of friends interested in applied chemistry, amongst whom I remember were Messrs. Muspratt, Brock, and Carey, consulted me as to the desirability of founding a society in Lancashire having for its object the closer connection of scientific and industrial chemistry. I cordially endorsed their opinion, but suggested that if needed in the North it was also needed for the country at large. And so the Society of Chemical Industry was founded. Its success as been phenomenal, and the work which it has done and is oing is of national importance. To the President, Sir William Ramsay, to my former pupil, the indefatigable ditor of the Journal, Mr. Watson Smith, and to the embers of Council, I tender my best thanks.

NNUAL GENERAL MEETING, NEW YORK, 1904.

The Annual General Meeting will be held in New York ity on Thursday, Sept. 8th, and following days. Members ho contemplate attending are requested to communicate ith the General Secretary as soon as possible, in order at suitable travelling arrangements may be made. A vised programme appeared in the March 31st issue.

In accordance with the provisions of Rule 18 of the e-laws, notice is hereby given that those members whose mes are printed in *italics* in the list of Council will retire from their respective offices at the forthcoming Annual Meeting.

Mr. Wm. H. Nichols has been nominated to the office of President under Rule 8; Dr. Edw. Divers, Prof. W. R. Eaton Hodgkinson, Mr. Max Muspratt, and Mr. T. J. Parker have been nominated Vice-Presidents under Rule 8; and Sir Wm. Ramsay has been nominated a Vice-President under Rule 11.

The Hon. Treasurer and Hon. Foreign Secretary have been nominated for re-election to their respective offices.

Members are hereby invited to nominate fit and proper persons to fill four vacancies among the ordinary members of the Council. Forms for this purpose can be obtained, on application, from the General Secretary, or from the Hon. Local Secretaries of the Canadian, New York, and Sydney Sections.

Extract from Rule 18 :—"No such nomination shall be valid unless it be signed by at least ten members of the Society who are not in arrear with their subscriptions, nor unless it be received by the General Secretary, at the Society's Office, at least one month before the date of the Annual General Meeting at which the election to which it refers takes place. Nor shall any such nomination be valid if the person nominated be ineligible for election under Rules 12 or 15. No member shall sign more than one nomination form."

THE MEDAL.

At a meeting of the Council of the Society held on March 23rd last, it was unanimously resolved to present the Society's medal for 1904 to Prof. Ira Remsen, President of the Johns Hopkins University, Baltimore, Md., U.S.A., for conspicuous services rendered by him to Applied Chemistry.

COMMUNICATIONS.

Authors of communications read before the Society, or any of its Local Sections, are requested to take notice that under Rule 43 of the Bye-laws the Society has the right of priority of publication for three months of all such papers. Infringement of this Bye-law renders papers liable to be rejected by the Publication Committee, or ordered to be abstracted for the Journal, in which case no reprints can be furnished to the author.

List of Members Elected

25th APRIL 1904.

Baker, John T., Easton, Pa., U.S.A., Manufacturing Chemist.

Bean, Percy, 10, Marsden Street, Manchester, Analytical Chemist.

Brown, W. Anderson, 104, Kingston Road, Ilford, Essex, Soap Analyst.

Carhart, Dr. Cornelius, Keyport, N.J., U.S.A., Pharmacist.

Eames, Charles J., 99, Water Street, New York City, U.S.A., Consulting and Applied Chemist.

Elson, J. Hugh, Monroe Drug Co., Unionville, Mo., U.S.A., General Manager.

Haigh, B. Wilson, 4, York Street, Barnsley, Yorks., Chemical Engineer.

Hamblet, Abel Martin, c/o Oxford Paper Co., Rumford Falls, Maine, U.S.A., Chemist.

Hard, Dr. James, M.B., Cordobanes 16, City of Mexico, Mexico, Chemist and Pathologist.

Harker, Dr. George, 35, Boulevarde, Petersham, Sydney, N.S.W., Chemist.

Hart, John J., Endcliffe, Park Avenue, Ashton-on-Mersey, Cheshire, Calico Printer.

Hess, Henry W., c/o Toledo Gas Light and Coke Co., 327, South Erie Street, Toledo, Ohio, U.S.A., Chemist.

Huillard, Alphonse. Suresnes (Seine), France, Tannin Extract Manufacturer.

Jepson, John Elliott, The Star Paper Mill Co., Ltd., Feniscowles, near Blackburn, Chemist.

Johnson, G. B., 7, Church Street, Liverpool, Wholesale Chemist.

Johnson, S. Hearon, 7, Church Street, Liverpool, Wholesale Chemist.

Jones, George Poole, Park Hotel, Williamsport, Pa., U.S.A., Chemical Engineer.

Lindemann, Ottocar, 53, Victoria Street, Westminster, S.W., Managing Director (Korting Bros., Ltd.).

Lossen, Dr. Clemens F., c/o Gulf Refining Co., Port Arthur, Texas, U.S.A., Chemist.

McGill, A., 317, Queen Street, Ottawa, Canada, Analytical Chemist.

Marris, H. C., The Russian Steam Oil Mills Co., 32, Kourlandski Street, St. Petersburg, Russia, Analytical Chemist.

Pelly, Russell George, 63, Rowan Road, Brook Green, Hammersmith, W., Analytical Chemist.

Petty, Gordon N., 5, Wellington Terrace, Old Trafford, Manchester, Technical Chemist.

Portner, Edward G., Robert Portner Brewing Co., Alexandria, Va., U.S.A., Chemist.

Ralph, S. Jamieson, c/o Clemons, Marshall, and Carbert, Hunslet, Leeds, Research Chemist.

Sparke, Archibald, Public Library and Art Gallery, Bury, Lancs., Chief Librarian, &c.

Warburton, George H., 33, Kilburn Priory, West Hampstead, N.W., Analytical Chemist.

Watson, Percy, 554, Somerset Avenue, Taunton, Mass., U.S.A., Chemist and Dyer.

Weston, Thos. W., The Cocoa Works, York, Mechanical Engineer.

Woolcott, Herbert, 5, Alma Road, Highbury, N., Brewer's Chemist.

Changes of Address.

When notifying new addresses, members are requested to write them distinctly, and state whether they are temporary or permanent. Multiplication of addresses is also to be avoided as tending to create confusion. When sending subscriptions, the use of the form attached to the application helps in the verification of addresses, on which the safe delivery of the Journal depends.

Alexander, D. Basil W., l/o Denver; 1020, Date Street, Los Angeles, Cal., U.S.A.

Beebe, Murray C.; all communications to 2210, Farmer's Bank, Pittsburgh, Pa., U.S.A.

Brookman, F. W., l/o 6; 8, West Street, Rochdale.

Burk, W. E.; all communications to 1372, East Broadway, Louisville, Ky., U.S.A.

Darling, G. A., l/o Box 1024; P.O. Box 195, Fordsburg, Johannesburg, South Africa.

Kern, Walter P., l/o Lafayette Avenue; communications to 262, Paulison Avenue, Passaic, N.J., U.S.A.; Journals as before.

Koechl, Victor; all communications to P.O. Box 159, New York City, U.S.A.

Lowson, Dr. J. G. Flowerdew, l/o Lasswade; Polton Paper Works, Midlothian.

Ramsden, A., l/o India; York Villa, Walmersley Road, Bury, Lancashire.

Reinherz, Otto; communications to 181, Cromwell Road, London, S.W.

Richmond, Sylvester O., l/o Sheffield; Royal Victoria Yard Deptford, S.E.

Robertson, Alex. A., l/o Grassendale; Riversdale, Cressington Park, Liverpool.

Rouse, Wm., l/o John Street; King Edward Street Alexandria, Dumbartonshire.

Savage, G. M., l/o New York; Albert Toilet Soap Co. 168, McCord Street, Montreal, Canada.

Seligman, Dr. R., l/o Kensington; c/o Messrs. J. and W Seligman, Mills Building, New York City, U.S.A.

Sholes, C. A., l/o General Chemical Co.; 25, Broad Stree New York City, U.S.A., Chemical Agent.

Skinner, Hervey J., l/o Exchange Place; c/o Little an Walker, 93, Broad Street, Boston, Mass., U.S.A.

Smither, F. W., l/o Nashville; 802, Locust Street, Kansa City, Mo., U.S.A.

Stevenot, G. A., l/o William Street; c/o H. A. Metz Co 122, Hudson Street, New York City, U.S.A.

Swindells, Seth, l/o Kidsgrove; The Laurels, Scholar Gree Stoke-on-Trent.

Trantom, Dr. Wm., l/o New Brighton; retain Journals.

Vasey, T. E., l/o Montreal; retain Journals.

Walker, Henry V., l/o Clinton Street; 700, Park Plac Brooklyn, N.Y., U.S.A.

Walker, Jas. W., l/o Fernlea; Castle Park, Irvine, N.B.

Wheeler, E.; Journals to 33, Churchill Street, Oldham (Leicester, as given on April 15th).

Woolcott, G. H., l/o Croydon; 2, Carolina Terrace, Mont notte, Cork, Ireland.

Young, Chas. C., l/o New York; c/o Farbenfabriken Elberfeld Co., Charlotte, N.C., U.S.A.

MEMBER OMITTED FROM LIST.

902. Palmer, Fred. G., c/o Cotton Powder Co., Ltd., Melling, near Liverpool, Analyst.

Deaths.

Aitken, Dr. A. P., 38, Garscube Terrace, Edinburgh. April 17.

Slade, H. E., India-Rubber Works, Streatham Common, S.W. April 4.

The Commercial Intelligence Branch of the Board of Trade will be moved from 50, Parliament Street, S.W., on Saturday, 30th April, and will be opened at 73, Basinghall Street, E.C., on Monday, 2nd May.

Meeting held at Toronto, on March 25th, 1904.

PROF. W. R. LANG IN THE CHAIR.

A paper on "Perfumery" was read by Mr. A. P. Taylor and one by Mr. A. McGill on the "Experimental Treatment of Hard Waters."

ON THE DECOMPOSITION OF BENZENE AT HIGH TEMPERATURES.

BY G. W. McKEE.

In the manufacture of both coal gas and carburetted water-gas it is a matter of great practical importance that we should have a knowledge of the temperatures at which the various hydrocarbons decompose (especially those used for enriching purposes), and the extent to which the decomposition increases with increasing temperature. The most important among these reactions is the decomposition of benzene (C_6H_6). Suppose, for instance, we start with he gas oils which are higher normal paraffins, the pyrogenetic reactions are such as are indicated by the following: — Higher paraffins → lower paraffins → olefines → acetylenes → benzenes → diphenyl, &c. → naphthalene, &c. → tarry matter → carbon and hydrogen. The great value of benzene in increasing the illuminating value of gas s well known; and the nuisance that arises from the formation of solid substances like diphenyl and naphthalene, which top up both pipes and machinery, is one of the greatest bstacles in the manufacture of coal gas.

The precise nature of the above reactions becomes then f practical importance, and the experiments carried out were undertaken to throw some light, if possible, on the ansition temperatures of these substances. The apparatu sed is shown in Fig. 1.

To heat the furnace F, the rheostat R and the furnace F were joined in parallel and connected with the street circuit. The switch S was also inserted to permit of complete control of the current from the working table. The furnace was heated by means of hot platinum resistance wires embedded in its fire-brick walls It was found convenient to surround it with $\frac{3}{4}$ in. asbestos millboard, pieces of which were readily cut without disturbing the edges, by placing it between pine boards and using a saw. In assembling these into a box the edges were preserved for nailing by securing the pieces in a vice. In front of the furnace was placed a piece of asbestos with three holes, which were punched by means of a sharpened brass tube against a hardwood block. Two of these were for the inlet and outlet of the copper tube which was to carry the benzol vapour, while the third was for the introduction of a thermo couple.

The pyrometer used was a Le Chatelier made by Keiser and Schmidt, Berlin. A thermo-couple, of 50 cm. length, of platinum and platinum with 10 per cent. rhodium, was introduced into the furnace by means of a porcelain tube about $\frac{3}{8}$ in. in diameter and perforated by two holes, each about 1 mm. in diameter. To the thermo-couple were joined the copper wires in the porcelain dish D, which was kept at zero by means of melting ice. The copper wires were joined, as shown, to the pyrometer, which was provided with an auxiliary switch. The calibrations of the thermo-couple were plotted on section paper for interpolation purposes.

For vaporising the benzene the device shown at V in the right of the figure was used. An electric lamp was mounted on a block. On the same block was secured a piece of tin pipe about 4 ins. in diameter. A piece of $\frac{1}{4}$ in. asbestos was cut and rolled to fit the inside of the tin and thus prevent loss of heat by radiation. The benzene to be decomposed was placed in the pear-shaped funnel P. The stem of this funnel was so drawn out that the drops issuing from it would be very small; the supply was further capable of control by the tap on the stem of the funnel. In this way small drops of benzene were allowed to fall on the heated bottom of the flask, where they were at once vaporised and subsequently passed through the furnace, the rate being easily regulated by counting the drops.

About 6 ft. of seamless copper tubing, thin-walled, and about $\frac{1}{4}$ in. external diameter, the temper drawn by passing it slowly through a blow-pipe flame, were coiled around a prepared spool, so that a coil of about $4\frac{1}{2}$ ft. of it fitted nicely in the furnace, leaving an aperture between the coils sufficiently large to allow the tube which insulated the thermo-couple being passed through to the middle of the furnace. The ends of the copper tube passed through the holes shown in the asbestos pad which formed the door of the furnace, and were bent at right angles so as to terminate at A and B (see Fig. 1).

The distilling flask was selected so that its delivery tube fitted accurately into the copper tube at A, and the joint was further secured by means of suitable packing. The other end B, of the copper tube was provided with a short glass condenser 6 ins. in length, while an adapter of glass tubing was slipped over the end of the copper tube, and secured by means of a section of rubber tubing. The adapter passed through a stopper into a small glass vessel in which were caught the products of decomposition.

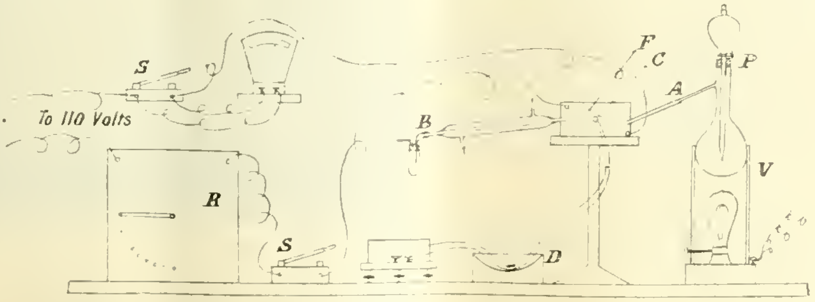

Fig. 1.

To determine whether the benzene had been decomposed or not, specific gravity determinations were made by means of a pyknometer. In all cases these were taken at 18 C., the variation of the specific gravity of benzene for a difference of one degree centigrade being very considerable.

		Per Cent.
Specific gravity of the benzol employed		0·88181
„ of products after heating to	448° C.	0·88175
„ „ „	550° C.	0·88202
„ „ „	664 C.	0·88362
„ „ „	720° C.	0·88963
„ „ „	765° C.	0·90276

These results may be expressed graphically by the following curve :—

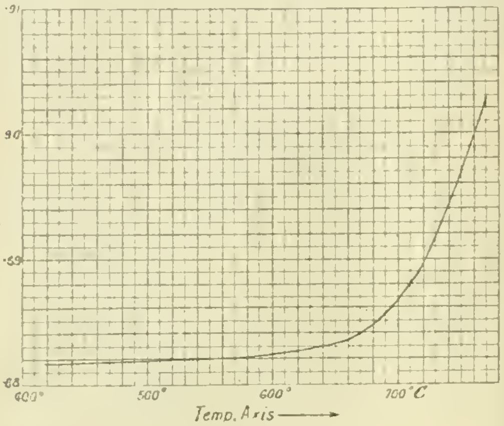

Fig. 2.

A second method of determining if decomposition had taken place was to slowly evaporate a portion of the product to dryness, and to examine the residue, if any, by the polarising microscope. The following results were obtained :—

Quantity evaporated.	Temperature to which it had been subjected in passing through Tube.	Appearance when examined by Polarising Microscope.
c.c.	° C.	
20	Not heated	No crystalline structure.
10	494	„ „
10	526	„ „
5	550	Polarisation colours scarcely visible in residue.
5	562	Crystalline residue prominent, small crystals easily distinguished.

The tube was further washed thoroughly with pure benzol, and a number of fractions taken from 544° to 550°, but it could not be said that the action became decidedly perceptible until after 550° had been passed. From that point onwards reference to the curve (Fig. 2) shows the extent to which the benzene vapours become decomposed as the temperature rises.

It would thus seem advisable, in adding enriching material to, say, a water-gas, to prevent the added material from being subjected to a temperature much greater than 700° C.

The author wishes to express his thanks to Prof. W. R. Lang of the University of Toronto, for the interest shown and the assistance rendered in this investigation.

Manchester Section.

Meeting held on Friday, February 5th, 1904.

MR. IVAN LEVINSTEIN IN THE CHAIR.

THE LUSTRE, THE TINCTORIAL PROPERTIES, AND THE STRUCTURAL ALTERATIONS WHICH RESULT FROM TREATING COTTON WITH MERCERISING AND OTHER LIQUIDS.

BY JULIUS HÜBNER AND WILLIAM J. POPE, F.R.S.

A Contribution from the Department of Pure and Applied Chemistry, Municipal School of Technology, Manchester.

During the past few years we have been occupied in investigating the action of many reagents on cotton, confining ourselves chiefly to the study of the effects produced by reagents which cause an indefinite, or but little understood, chemical change in cellulose. In a previous paper we dealt somewhat completely with the changes in the strength of yarn which result from the action of these reagents (this J., 1903, 70—77), and in the present paper we put forward the results obtained during the extension of the earlier work. The new results enable us to elucidate thoroughly the physical changes which lead to the production of a silk-like lustre on treating cotton with mercerising agents; a preliminary note on this part of the work was laid before the British Association at the Southport Meeting in September 1903.

The study of the action upon the cotton fibre of soda solutions of too great dilution for use in practical mercerisation must be considered as a necessary preliminary step to the obtaining of information as to the changes in the fibre which are produced by mercerisation.

In order to ascertain whether dilute soda solutions have any action of a chemical or morphological nature on cotton, we steeped dry hanks of twofold 50's bleached yarn in caustic soda solutions of known concentrations varying from 1° Tw. up to 80° Tw., and, after washing in cold water until all the soda was removed, dyed all the hanks, together with an untreated one for purpose of comparison, in a solution of Benzopurpurin 4 B, the amount of dyestuff used being one quarter per cent. on the weight of the hanks. After dyeing in the boiling bath for half an hour the hanks were removed, washed, and dried; they were then matched by the eye, an attempt being made to form some quantitative appreciation of the relation between the strength of the dyeings on the different hanks. This quantitative relationship, so far as it can be established in a rough preliminary test of this character, is given in Table I., in which the letter "s" signifies "stronger than," and the letter "w" means "weaker than," the repetition of the letter indicating "much greater than" or "much weaker than," as the case may be.

Assuming that, in a roughly quantitative way, the increase of strength or weakness of the dyeing is proportional to the number of repetitions of the characterising letter, it is convenient to express the results of the trial and its graphic representation in a curve as in Fig. 1.* Although we do not claim that this trial and its graphic representation by the curve have any rigidly quantitative value, yet the following points must be considered as definitely proved, namely :—

(1) Cold caustic soda solution of 1 Tw. has a considerable effect in increasing the affinity of cotton for direct dyeing colouring matters and, from 0° to about 18° Tw., the increase in affinity for the dyestuff is roughly proportional to the concentration of the soda used in the previous treatment of the cotton.

(2) Between 18° to 22° Tw. the increase in concentration of the soda has a greater effect in increasing the affinity of

---

* In this curve we have plotted the concentration of the soda in Twaddell degrees, since the strength in degrees Twaddell is roughly proportional to the percentage concentration.

he cotton for the colour than has a corresponding increase f concentration in soda of lower strength.

(3) The effect referred to in (2) becomes greater with oda of density 22° to 26° Tw., and much greater still with oda of from 26° to 30° Tw.

(4) Above 30° Tw., however, an increase in strength of he soda exerts a less effect than before in increasing the ffinity of the cotton for the colour, so that raising the trength of the soda solution from 30° to 40° Tw., has only bout the same effect in increasing the affinity of the fibre or colour as increasing the concentration of the soda from 6° to 28° Tw. or from 28° to 30° Tw. At above 45° Tw., ncreased concentration of the soda produces but little effect n heightening the shade produced on dyeing, so that ractically the maximum increase in affinity for colour is ot by treating with soda of any concentration between 5° and 70° Tw., and an experienced eye is needed to see hat the dyeing on the hank treated with 70° Tw. soda is tronger than that on the hank treated with 55° Tw. soda.

(5) As the concentration of the soda used in mercerising s increased above 70° Tw., an actual diminution in the ffinity of the fibre for the dyestuff accompanies the increase in concentration ; thus, the hank treated with soda f 70° Tw. dyes much more strongly than does that treated vith 80° Tw. lye. This reversal of the action of the soda is f so strongly marked a character that the hank treated vith soda of 80° Tw. dyes to the same shade as that treated vith soda of 35° Tw.

TABLE I.

Hanks treated with various Strengths, stated in Twaddell degrees, of Soda Lye at 19° C., and afterwards dyed with ¼ per cent. of Benzopurpurin 4 B, calculated on the Weight of the Hanks.

° Tw.		° Tw.	° Tw.		° Tw.	° Tw.		° Tw.
1	2 s	0	14	2 s	12	45	2 s	40
2	2 s	1	16	2 s	14	30	s	45
3	2 s	2	18	2 s	16	55	s	50
4	2 s	3	20	3 s	18	60	s	55

10	2 s	9	35	8 s	30			
12	2 s	10	40	3 s	35			

Since the observation is now made for the first time, that ighly concentrated caustic soda has notably less effect in ncreasing the affinity of cotton yarn for substantive colours han has a solution of less strength, it seemed desirable to epeat some of the trials.

Hanks of the same spinning as before were therefore teeped in caustic solutions of concentrations ranging from 0°—80° Tw. for 48 hours, and, after the usual exhaustive vashing and drying, were dyed with Benzopurpurin 4 B, sing one-eighth per cent. by weight of colour on the weight f the hanks ; the application of less dyestuff than in the revious tests seemed desirable in order to facilitate the ibsequent comparison of the dyed hanks.

The results tabulated below (Table II.) were thus btained, and confirm the previous conclusion that the ost concentrated soda solutions have less effect in creasing the affinity for the benzopurpurin than do those less concentration, although in the second set of trials e turning point seems to be with soda of between 65° and ° Tw., whilst in the earlier trials the turning point ppeared to lie between 70° and 75° Tw. This slight parent discrepancy might, perhaps, be attributable to e different amounts of colour used in the two sets of sts, or might possibly arise from the difficulty of preciating such slight variations of shade as are involved true reason is, however, almost certainly to be found in e circumstance, which is further discussed below, that a nk treated with a very strong lye, on washing with water, comes for a certain time impregnated with a rather re dilute and therefore more active lye. In any case fact is clear that soda of 80° Tw., when applied to ton yarn, does not increase the affinity for substantive ours to nearly the same extent as does soda of 70° Tw. ; further, the concentration of soda which produces the maximum effect in this respect appears to have a density of between 60° and 70° Tw.

TABLE II.

Yarn treated at 20° C. with Soda of various Concentrations for two days, and dyed with one-eighth per cent. by Weight of Benzopurpurin 4 B.

65........	..... s	 60
70........	..... w	 65
75........	..... w	 70
80........	..... w	 75
80........	..... equals	 55

The reversal of the action of the soda in increasing the affinity for colour during continuous increase in the concentration of the soda with which the cotton is treated, is further of interest in that it might be connected with the generally held view that cold caustic has a more powerful mercerising action than soda of the same concentration at a high temperature.

We therefore made a series of dyeing trials with hanks of the same kind of cotton as in the previous case, using caustic of 10°, 20°, 30°, 40°, and 50° Tw., steeping a hank in each solution at 20° C. and at 80° C. respectively, and keeping the solutions well stirred in the ordinary way to ensure uniform action of the caustic ; after washing until free from soda, the hanks were dried and dyed all together in a boiling solution of Benzopurpurin 4 B, using 1 per cent. of colour on the weight of the hanks. On matching the hanks the results tabulated below (Table III.) were obtained, the same roughly quantitative method of description as was previously used being adopted.

TABLE III.

Soda of ° Tw.	—	Soda of ° Tw.	Soda of ° Tw.	—	Soda of ° Tw.
10, hot	s	Untreated.	40, hot	4 s	20, cold.
10, cold	2 s	10, hot.	30, cold	5 s	40, hot.
20, hot	2 s	10, cold.	50, hot	s	30, cold.
30, hot	3 s	20, hot.	40, cold	5 s	50, hot.
20, cold	2 s	30, hot.	50, cold	5 s	40, cold.

The result of this test is a very remarkable one ; it is found that whilst caustic of 20° Tw. applied hot causes ultimately a slightly stronger dyeing than 10° Tw. soda used cold, 30° Tw. soda applied hot gives less depth to the resulting dyeing than does 20° Tw. soda used cold. The difference in action becomes accentuated as the strength of the soda is increased ; and so it is found that soda of 50° Tw. applied at 80° C. affects the hank in much the same way—so far as its affinity for colour is concerned—as 30° Tw. soda used cold.

It seems to have escaped previous observation that caustic soda in such low concentrations of lye as 1° or 2° Tw. has quite a considerable action in increasing the affinity of the cotton towards substantive dyestuffs; and this is the more remarkable in that it is frequently customary to boil yarn in caustic of 1° or 2° Tw., or even of slightly greater concentration, as a preliminary to bleaching. In order to throw further light on the question which here arises, a series of trials was made in which the same yarn as before was steeped in caustic soda of 1°, 2°, and 3° Tw., both at 20° C. and at 100° C. for 15 minutes, and, after exhaustively washing the hanks treated cold with cold water and those treated hot with boiling water, all the hanks, together with an untreated one for purposes of comparison, were dyed in the same bath with ¼ per cent. of their weight of Benzopurpurin 4 B. The results obtained on matching these hanks are stated in the appended Table IV.

TABLE IV.

Strength of Soda.	Strength of Dyeing.	Strength of Soda.
° Tw.		° Tw.
1, cold	3 s	Untreated.
2, cold	3 s	1, cold.
3, cold	3 s	2, cold.
1, hot	2 w	1, cold.
1, hot	w	Untreated.
2, hot	2 s	1, hot.
2, hot	equals	Untreated.
3, hot	s	2, hot.

The table makes it clear that the prevalent practice of boiling yarn with a 2° Tw. soda solution has no effect in increasing the affinity of the cotton for substantive colouring matters, although the same concentration of soda applied cold causes a very considerable deepening of the shade ultimately assumed by the yarn.

Many other chemical reagents are known which produce on cotton an effect superficially similar to that obtained with caustic soda, and which also give to the cotton an increased affinity for substantive colours; in order to ascertain whether a different influence is exerted on the dyeing properties by such substances when applied in solutions of different concentrations, we have made several series of trials with a number of reagents, using in each case solutions of various concentrations. Hanks of bleached cotton were steeped during the same time in solutions of different concentrations of the particular reagent, then washed, dried, and dyed in a bath containing 3 per cent. of Benzopurpurin 4 B on the weight of the hanks. The results of matching the hanks are given in the appended table (Table V.):—

The consideration of the above sets of dyeing trials shows that each of the reagents dealt with behaves somewhat similarly to caustic soda, so far as concerns the increase in the affinity for colour which it gives to the fibre. That is to say, as the concentration of the solution increases, the affinity of the cotton for the substantive colour also increases: in no case, however, have we been able to observe the reversing effect which is produced with soda.

The work described above having established beyond doubt that caustic of high concentration has a less effect in increasing the affinity of cotton towards substantive colours than has soda of somewhat lower concentration, it seemed desirable to ascertain whether other properties of cotton are similarly related towards the strength of soda with which yarn has been treated: that is to say, whether any other property can be discovered which increases in magnitude as the concentration of the soda increases up to a certain limit, beyond which its magnitude decreases with a further increase in the strength of the soda solution applied. We therefore made a great number of attempts to determine accurately the shrinkage which the application of soda solution causes in cotton yarn, but for a long time these attempts proved abortive: the extent of the shrinkage is so slight, especially with dilute soda solutions, that the small but unavoidable amount of stretching to which the yarn is subjected during the final washing makes the results appear very confusing. Ultimately, we found it possible to take measured lengths of yarn, steep them in caustic soda for a given time, and then to measure their lengths again by re-reeling whilst the yarn is still soaked with lye; both the reelings are effected on a small machine in which the yarn passes between two wheels, the lower, of about six inches diameter, being connected with a counting mechanism, and the upper one being merely a small but heavy cylinder, the object of which is to keep the yarn uniformly stretched during its passage between the two wheels. Hanks of 200 yards each of a bleached tightly twisted yarn were steeped in caustic soda of various concentrations during half an hour, and then re-reeled in the manner briefly described; three parallel sets of determination were made, and the mean of each set of three corresponding observations are given in the accompanying table (Table VI).

TABLE VI.

18	188·7	80	154·2
20	186·8		

In order to facilitate the comparison of these observations on the extent to which cotton yarn is shrunk by treatment with caustic soda with the results obtained in the previous dyeing trials of similarly treated yarn, it is convenient to plot the shrinkage against the strength of the soda: for this purpose the curves expressing the relation between the strength of the dyeing and the strength of the soda and between the amount of shrinkage and the strength of the soda are shown in the same figure (Fig. 1). An inspection of the table shows that the most dilute caustic soda, even of 1° Tw., exerts an appreciably greater shrinking action on the yarn than does pure water in the cold. As the concentration of the soda is increased, however, the shrinking effect is seen to increase fairly uniformly up to about 18° or 20° Tw. concentration, whilst at about 20° Tw. a sudden increase in the amount of shrinkage effected is observed to occur: as we point out below, this concentration of soda is about the same as that which shows the first appreciable action on the microscope stage upon the cotton fibre. Above 20° Tw. the extent of the shrinkage increases with the concentration at a far more rapid rate than before, and the greatest shrinking effect is obtained with soda of 45° Tw.; as the strength of the soda is increased above this concentration, the shrinkage observed diminishes continuously until the concentration of 80 Tw., the highest which we have applied, is reached.

The results now put forward find an important practical application in the action of soda of different concentrations on a technical scale. It is seen from Table VI. that the maximum shrinkage is obtained when yarn is treated with soda of about 45 Tw., but we have observed that on treating yarn with soda of 80° Tw. and obtaining the slight amount of shrinkage which is noted in the table, a further and quite considerable shrinkage takes place during the subsequent washing. This is of course only what would be expected, inasmuch as the yarn impregnated with soda of 80° Tw.—a liquid of high viscosity—when treated with water becomes impregnated with soda of greater dilution, and the degree of dilution increases as the washing proceeds. Consequently the initial shrinking effect of 80° Tw. soda on the yarn is that noted in the table, but the action which is exerted during the washing with water is, at any rate during the early stages of the washing, the action of a soda which has a much greater shrinking effect on the yarn, such for instance as soda of 50° Tw. On impregnating yarn with soda of about 50° Tw., and afterwards washing with water, no perceptible shrinking is observed to occur during the washing, the reason being that the dilution has the effect of making the soda less active than before towards the yarn, so far as shrinking action is concerned. If we, therefore, consider what will happen during the impregnation of yarn on the mercerising machine or of a cotton fabric during treatment on the stenter, it will be seen that with soda up to, say, 50° Tw. the main shrinkage will occur during impregnation with soda, whilst during the subsequent washing no additional strain will be put on the arms of the yarn mercerising machine or on the clips of the stenter. The conditions are, however, quite different when the yarn or fabric is impregnated with soda of a higher degree of concentration, say, of 75° or 80° Tw. In this case less shrinkage takes place during the actual impregnation, but, on washing afterwards with water, the yarn or fabric tends to undergo a further and considerable contraction; with the high concentration of soda, therefore, the greatest strain is exerted on the arms of the mercerising frame or on the clips of the stenter during the early stages of the washing with water. There is thus in this case a certain tendency for the yarn to tear or for the cloth to rip, which would be avoided if a more dilute soda had been employed.

In connection with the dyeing properties, it is further clear that the application of soda of 70° or 80° Tw. will have a tendency to make the yarn or fabric dye unevenly because of the more powerful action on the affinity for dyestuffs exerted by the lower concentrations of soda, which will be produced locally during washing.

On inspecting the curves given in Fig. 1 it will be seen that whilst the greatest increase in the affinity of cotton for substantive colours is contributed by the action of soda of about 70° Tw. concentration, the greatest shrinkage is observed when soda of a much lower concentration is applied, *viz.*, of 45° Tw. This is doubtless due to the operation of the cause referred to in the preceding paragraphs, *viz.*, to the fact that the treatment with soda of 80° Tw. and afterwards washing involves the action, at any rate for a short time, of soda of all lower concentrations on the ibre; this would lead to the yarn treated with soda of 80° Tw. and subsequently washed, dyeing much more trongly than would have been the case if, after immersion in the 80° Tw. soda, the whole of the soda could have been emoved from the yarn without adding water. It should, owever, be noted that on washing a yarn shrunk by the npregnation with caustic soda, some change in the length f the hank must be expected to occur quite independently f any alterations in length produced by the action of diluted soda temporarily formed; the extent of such action is still under investigation.

So far as the present trials can be interpreted, it would seem that a great deal of evidence exists indicating that the apparently increased affinity which cotton has for colouring matters after having been treated with soda is, in the main, proportional to the extent to which shrinkage has taken place. We have now in hand a series of tests intended to elucidate this matter still further; tests in which the yarn, after immersion in strong soda, is washed free from soda with alcoholic solvents under such conditions that the action of aqueous caustic soda solutions of lower concentrations can play no part. A highly special case of such proportionality between the shrinkage and the strength of the dyeing would be that in which a given length of yarn removes the same weight of dye-stuff from the bath when it is mercerised as when it is unmercerised; the greater depth of colour exhibited by the mercerised hank would here be due solely to the same weight of colour being distributed throughout a shorter length of yarn than would be the case with the unmercerised hank. We find, however, on taking two hanks of the same length and dyeing them both in separate baths of the same concentration, the one after and the other before mercerisation, that the exhaust from the mercerised hank is much paler in colour than that from the unmercerised hank; the proportionality is consequently not of the special and simple character last mentioned above.

We now turn to the microscopic examination of the changes produced in cotton by treatment with mercerising and other liquids.

The microscopic examination of cotton offers certain difficulties which arise principally from the high degree of transparency possessed by the fibre; these difficulties are greater after the cotton has been treated with mercerising agents because the apparent transparency of the fibre as it lies on the microscope stage is much greater than before the treatment. Further, if mounting agents are used in the preparation, more difficulty is experienced in the microscopic observation owing to the refractive index of the fibre approximating to that of the medium and to the consequent loss of definition. It therefore seemed desirable to apply some artificial method of increasing the microscopic definition, and resort was made to the examination of the fibres between crossed Nicol prisms, a polariser being inserted under the sub-stage condenser and an analyser being placed in the eye-piece in such a position that its principal section lay at right angles to that of the polariser. The statement has been made (compare Guttmann, Manufacture of Explosives, 1895, vol. 2, p. 59) that under these conditions ordinary cotton appears colourless, but actual experience shows that all cotton fibres show interference colours when examined microscopically between crossed Nicol prisms. The interference colours exhibited by raw cotton when examined in this way are not very brilliant; they are doubtless due to internal strain in the otherwise amorphous material of which the fibre is composed and, the strain being apparently but slight, the colours are of such a high interference order that they are not visually brilliant. In order to enhance the brilliancy of the interference colours the authors prefer to insert above the polariser, and with its principal direction at 45° to that of the polarising and analysing prisms, a mica plate of such thickness as to increase the retardation of the light passing through the preparation by one-eighth of a wave-length; this thickness of mica plate seems ordinarily to give the best results, but the most appropriate thickness for use in any particular case so as to obtain the maximum colour effect in the fibre is readily ascertained by passing a quartz wedge of the ordinary kind between the eye-piece and the preparation, and noting when the most brilliant display of colour is made by the fibres.

The microscopic examination of the cotton fibre between crossed Nicol prisms, with the interposition of a one-eighth wave-length retardation plate in the manner just described, not only facilitates the observation of the outline of the fibre, but enables the internal canal, cracks in the fibre, and internal pecularities of all kinds to be made out with great ease, the differences in thickness of various parts of the fibre being indicated by changes in the colour exhibited.

The photographs in natural colours which illustrate this paper have been made by the Sanger-Shepherd process in elliptically polarised light under the conditions of illumination described above, and the author's thanks are due to Mr. Chas. W. Gamble, Director of the Photographic Department of the Manchester Municipal School of Technology, for the able assistance which he has rendered in the preparation of these slides.

The microscopic examination of the raw cotton fibre shows it to consist of a flattened ribbon, the edges of which are somewhat thickened and usually slightly turned up; sometimes, however, the edges are turned up to such an extent that they stand at nearly right angles to the surface of the ribbon. The best drawings of the cotton fibre which have previously been published are undoubtedly those given by Walter Crum (J. Chem. Soc., 1863, p. 404); these pictures give a good idea of the general microscopic appearance of raw cotton and show the slight thickening of the edges referred to; in polarised light, however, the internal canal is distinctly visible as a flattened tube-like structure traversing the whole length of the fibre. Crum's drawings are, however, faulty in one respect, namely, that the natural twist in the fibre is not of the loose character which he depicts, but is flattened, so that the twisted fibre has rather the appearance of a ribbon which has been twisted and creased rather than that of one which has been merely twisted. It is sometimes stated that the natural twist of the cotton fibre always runs in the same direction. That this is not so is sufficiently indicated by Crum's drawings, and is also evident on the most superficial microscopic examination of the fibre; the fibre is sometimes twisted in the one direction and sometimes in the other. Further, the same fibre is generally twisted in parts to the right and in parts to the left, several changes in the direction of twist being noticeable throughout the length of a single fibre; this change in twist is of great importance in connection with the production of lustre during mercerisation, as will be pointed out below.

Fig. 2 represents the photograph of a plain or untreated cotton fibre taken in polarised light as above described, and in Fig. 3 is reproduced the same fibre photographed in natural colours.

On placing a few fibres of loose cotton on a slide under a cover glass on the microscope stage, and carefully watching the behaviour of the fibres as a drop of caustic soda placed on the slide gradually comes into contact with the fibres, no change at all is observable in the cotton until the strength of the soda used reaches 16° Tw. At this concentration, however, it is seen that the fibres untwist slightly during the two or three seconds after the soda has come into contact with them; the untwisting is very incomplete and is at an end within three seconds or so at the ordinary temperature. On increasing the strength of the soda gradually, the same kind of behaviour is observed until a concentration of 20° Tw. is reached, and here the initial untwisting, which still proceeds with great rapidity, is followed by a very slow uncoiling of the twist of the fibre; but even at this strength of soda the fibre never becomes quite unrolled. With soda of 22° Tw. bubbles of air begin to make their appearance in the internal canal, and the transparency which the liquid gives to the fibre is produced much more slowly than with lower concentrations of soda. At a concentration of 26° Tw., the initial rapid and the later slower untwisting action become confused and only one kind of uncoiling effect is distinguishable; that is to say, the fibre uncoils slowly and regularly during a period of about five seconds and the fibre is left as a somewhat flattened ribbon, which is still slightly twisted. At 28° Tw. the action of the soda is appreciably slower; the uncoiling proceeds for about 15 seconds and has the effect of removing practically all the twist from the fibres; at the same time, the becoming transparent, which apparently indicates the soaking in of the soda, proceeds much more gradually than before, and the running of the soda through the internal canal with the formation of air-bubbles is much more distinctly visible than at the lower concentrations. With soda of 30° Tw. the twist of the fibre for the first time disappears completely. With soda of 35° Tw. the untwisting still proceeds with fair rapidity, occupying about 15 seconds for completion, and after the untwisting has become practically complete, the fibre is seen to swell, the swelling being accompanied by an increase in the transparency of the fibre; the two changes are, however, quite distinct, the swelling following the untwisting. At 40° Tw. fewer air-bubbles are produced than before, and the swelling proceeds more rapidly, so that one part of the fibre is seen to be swelling whilst another part is still in the stage when untwisting is taking place. At 45° Tw. no air-bubbles are left in the canal and the latter almost completely disappears; the swelling and untwisting go on quite simultaneously and the whole action is complete in about 15 seconds. The behaviour of the fibres towards soda of 50° Tw. is similar to that towards the 55° Tw. solution, with the exception that the action is a trifle less rapid with the lye of higher concentration. With soda of 55° Tw. it is for the first time noticed that a perceptible interval elapses between the wetting of the fibre and the commencement of the uncoiling; this interval occupies about three seconds, and the subsequent action is completed in about 20 seconds. With lye of 60° Tw. no appreciable change occurs for the first eight seconds or so, and then the fibres begin to swell and to become transparent; after the swelling has occurred the fibres begin to untwist, and the uncoiling takes place very slowly and deliberately, requiring about a minute for completion. With soda of 65° or 70° Tw. the same kind of action proceeds, the swelling preceding the uncoiling and the whole action going still more slowly, so that with 70° Tw. soda evidence of action is still visible after two minutes', contact. Soda of 75° Tw. exerts no apparent action for at least a minute and takes about four minutes for completion; the air-bubbles assume irregular shapes in the internal canal, giving an impression as if the fibre had burst open. With soda of 80° Tw. concentration, the action takes a still longer time and nearly all the fibres appear as if burst or split; a photograph of one of these burst and swollen fibres is reproduced in Fig. 4.

In order to facilitate their comparison, these observations may be conveniently epitomised in a table (Table VII.).

Table VII.

Strength of Soda in ° Tw.	—
0 to 15	No apparent effect.
16 to 18	Incomplete uncoiling during about a second.
20	Initial rapid untwisting followed by sluggish ditto.
26	Rapid and slow uncoiling become one, lasting 5 seconds.
35	Untwisting followed by swelling.
40	Untwisting and swelling proceeding together.
60 to 80	Swelling precedes untwisting.

The untwisting of the cotton fibre under the influence of caustic soda has not been referred to by previous workers in this field; it has the effect, when the cotton is mercerised loose, of converting the fibre into a plain surfaced rod which is bent more or less irregularly, and which is very much matted together or entangled with other fibres. The entanglement of the fibres caused by the writhing which attends the immersion in strong soda is of course responsible for the difficulties which have made the spinning of cotton which has been mercerised loose a practical impossibility.

As a point of great importance, which we now call attention to for the first time, is to be noted that up to a concentration of about 10° Tw. the swelling action of the soda follows the untwisting, whilst at concentrations greater than 40° Tw. the reverse is the case, the untwisting following the swelling. Since the concentration of about 40° Tw. is the lowest at which an effective mercerising action for practical purposes can be effected, it follows that the production of a lustre on cotton is necessarily connected with the action of soda of such concentration as causes the untwisting of the fibre to take place, either after the swelling is at an end or simultaneously with the occurrence of the swelling. The new observation, namely, that strong caustic causes the cotton fibre to untwist, is therefore one of the determining factors in the production of a gloss during the mercerising of cotton.

Confirmation of this view, if it be correct, should be obtainable by investigating microscopically the action of hot caustic soda solutions on the fibre, because it is known that hot soda is not nearly so effective a mercerising agent as is the same concentration of soda in the cold. We therefore took a caustic soda solution of 50° Tw., which at 20° C. produces a brilliant lustre on stretched Egyptian yarn and at 90° gives a lustre which is much less marked; on steeping the fibres in this at 20° C. on the microscope stage, the appearances noted in Table VII. were observed, namely, that the fibres swell slowly and afterwards untwist; but on arranging the microscope stage so that the fibres can be examined under the influence of the soda solution at 90° C., it is seen that at the high temperature the fibres began to untwist rapidly immediately they come in contact with the hot soda, and that after this untwisting is at an end the swelling effect sets in, but not until the whole of the uncoiling is finished. It is, therefore, clear that the necessary condition for the production of a good lustre during mercerisation is that the untwisting should follow the swelling, or at least that both swelling and untwisting should proceed simultaneously; and that the inefficiency of hot as opposed to cold caustic soda in mercerising is due to the fact that with the cold caustic the swelling precedes the uncoiling, whilst with the hot caustic the untwisting takes place first.

The production of a lustre during the mercerisation of stretched yarn has been previously attributed wholly to the shrinkage and the swelling which takes place during the action of strong caustic soda; we have now shown that a new factor, namely, the untwisting of the fibres, is also a necessary one to the production of an appreciable gloss. The importance of this conclusion is such as to make further confirmatory evidence desirable before proceeding to discuss the exact way in which the untwisting is operative in giving rise to the lustre. We, therefore, examined the action of a number of other reagents on the cotton fibre, using the same kind of method of microscopic examination as in the above experiments. The results are here given.

Action of a Mixture of ten parts of Soda Lye of 28° *B and one part of Water-glass Solution of* 41° *B.*—The use of a mixed solution of water glass and caustic soda of the above composition has been patented by Meister, Lucius and Brüning (Eng. Pats. 10,784 of 1897 and 11,313 of 1897), and, as Gardner remarks (Mercerisation der Baumwolle, 1898, 44), the lustre produced by it is inferior to that obtained with caustic soda alone; the mixture hinders the shrinkage, although it increases the affinity of the yarn for colouring matters. On allowing the mixture to act upon cotton fibres on the microscope stage, it is seen that action sets in slowly, the fibres beginning to untwist rapidly after about five seconds' contact with the solution and becoming quite straight after about 20 seconds. At the same time swelling occurs, but to a far less extent than if caustic soda solution alone is used. Measurements made on a hank steeped at 20° C. and subsequently washed and dried showed that shrinkage to the extent of 17·4 per cent. was caused by the action. The hank treated with this solution in the unstretched condition showed slightly more gloss than the raw yarn, whilst a hank immersed and washed whilst stretched exhibited a distinct lustre, although far less than if strong caustic alone had been used in the treatment. Treatment with this solution thus causes untwisting and but comparatively slight swelling and shrinking; and the faulty nature of the lustre produced is traceable to the incomplete extent to which these two latter factors participate in the action.

Action of a Mixture of two parts of Soda Lye of 38° *B. with one part of Glycerin.*—The use of this mixture for mercerising purposes has been protected by the Farbenfabriken vorm. F. Bayer & Co. (D.A.Kl. 8, 10,126 of 1897), and is said to arrest the shrinkage whilst increasing the strength of the yarn; we found on immersing a hank of bleached Egyptian yarn in the mixture, and afterwards washing and drying, that a shrinkage of 13·4 per cent. took place. The yarn immersed unstretched showed a slight gloss, and a hank immersed in the stretched condition developed more lustre, although far less than if caustic soda alone had been used. Treatment of loose cotton on the microscope stage with the solution showed that the fibres at first swell very gradually with the accompaniment of but little untwisting; after two minutes' action the fibres are still seen to be swelling slowly, but the untwisting begins to proceed more rapidly. The whole action is far less marked than if ordinary soda lye is used, but after the expiration of about four minutes the fibres are seen to have assumed somewhat the appearance of cotton fibres which have been mercerised in the stretched condition; this seems to be due to the slow swelling having partly absorbed the twist in the fibre, and in such a way that traces of it still remain as ridges on the round swelled surface of the fibre.

Action of Sulphuric Acid.—Mercer found that sulphuric acid exerts an action upon cotton superficially resembling that of soda; we find that on steeping a hank of bleached Egyptian yarn in sulphuric acid of 114 Tw., and subsequently washing and drying, a shrinkage to the extent of 9·5 per cent. in length is obtained; at this concentration, however, the fibres are rapidly attacked and partly dissolved. A hank immersed stretched shows after washing a perceptible increase in lustre. The examination of the action on the microscope stage shows that the fibres rapidly untwist immediately they come in contact with the acid and at the same time swell and shorten. More rapid untwisting and dissolution is observed with concentrated sulphuric acid.

Action of Zinc Chloride Solution.—This reagent was also mentioned by Mercer as somewhat similar in its action to caustic soda. The microscopic examination of the action of a 50 per cent. solution shows that the fibres untwist very slightly at the moment of contact with the solution, but that then the uncoiling stops and does not again set in; slow swelling and shrinking are noticeable. A hank immersed loose was found, after washing and drying, to have shrunk by 2·3 per cent. and showed no lustre; a stretched hank, however, was found to have become very slightly lustrous.

Action of Syrupy Phosphoric Acid.—The shrinking action of strong phosphoric acid solution was also mentioned by Mercer. We find that no action is observable for the first minute and a half after phosphoric acid is brought into contact with the fibres on the microscope stage; the fibres then, however, begin very slowly to untwist and afterwards to swell. This action proceeds until the material goes into solution.

Action of Nitric Acid of 83° *Tw.*—Fibres treated on the microscopic stage with strong nitric acid unwind very rapidly; they swell, however, only very slowly and to a considerably less extent than with caustic soda. The shrinkage of yarn immersed loose in nitric acid of 83° Tw. amounts to 9·5 per cent. Yarn treated under tension exhibits a distinct lustre, which is, however, inferior to that produced by strong caustic, and is about the same as that obtained with the mixture of caustic soda and glycerin.

Action of Concentrated Hydrochloric Acid.—On immersion in the liquid the fibres are seen to untwist rapidly, although not so rapidly as in strong caustic soda; slight swelling and shrinkage also occur. A hank immersed loose was found to have shrunk by only 1·8 per cent. after washing and drying, but exhibited no lustre, whilst a hank immersed stretched developed a distinct lustre.

Action of Sodium Sulphide Solution.—The application of a 30 per cent. sodium sulphide solution for producing a silky lustre on stretched yarn was protected by Schneider (P.B.A., Kl. 8, 12,196 of 1896). We find that immersion in such a solution causes a shrinkage of 1·3 per cent. in the length of the hank. The yarn, immersed either stretched or unstretched, acquires lustre during the treatment, although not to anything like the same extent as when caustic soda is applied to stretched yarn. On the microscope stage the fibres are seen to untwist and to swell but slightly.

Saturated Potassium Iodide and Potassium Mercuric Iodide Solutions.—We have previously shown that saturated potassium iodide and potassium mercuric iodide solutions have a considerable action on cotton yarn; on immersing a hank in saturated potassium iodide solution it shrank by 2·3 per cent. in length, and a hank immersed stretched acquired merely a slightly increased lustre. The same slight increase in lustre was obtained on immersing a stretched hank in saturated potassium mercuric iodide. On the microscope stage no untwisting of the fibre can be observed, and only a slight swelling occurs either with potassium iodide or with potassium mercuric iodide.

Saturated Barium Mercuric Iodide Solution.—We have shown that saturated barium mercuric iodide solution causes a shrinkage and an increase in strength in cotton yarn practically equal to that produced by caustic soda of 65° Tw. (this J., 1903, 70—77). On microscopic examination, however, saturated barium mercuric iodide solution is seen to cause no untwisting at all in the fibres, although great swelling and shrinkage occur. A hank immersed stretched developed but a slight lustre. No action could be detected on treating the fibres with *formic* or *glacial acetic acid,* or with *ammonia* on the microscope stage. On inspecting the results given above it will be seen that the liquids which cause rapid untwisting, strong swelling, and considerable shrinkage, namely, caustic soda, soda with water glass, soda with glycerin, and nitric acid, are those which cause the stretched yarn to acquire considerable lustre. These three factors, in our view, are essential to the production of any considerable lustre, and it will be noted that when only two of these factors are operative no appreciable lustre is developed on the stretched yarn. Thus, sodium sulphide and hydrochloric acid cause rapid untwisting of the fibre, but only give rise to slight swelling and shrinking; treatment with these liquids leads to the production of but little lustre on the stretched yarn. Again, barium mercuric iodide solution causes great swelling and shrinking, but does not make the fibre untwist; this liquid, consequently, gives rise to the production of but little lustre on the stretched yarn. Lastly, zinc chloride, potassium iodide, and potassium mercuric iodide cause no untwisting and but slight swelling and shrinkage; their application is thus attended by the production of but very little lustre in the stretched hank. A final, but probably the most convincing of all the confirmations of the truth of the view that untwisting, swelling, and shrinkage must all co-operate for the production of a lustre in the treatment of cotton is to be found in some results which we have previously published (this J., 1903, 70—77). A hank, 66·0 cm. in length, of an unbleached Egyptian yarn, having the breaking load of 417·4 ± 2·1 grms., was immersed in caustic soda of 65° Tw., and, after washing and drying, was found to have shrunk in length to 44·8 cm. and to have increased in strength to 526·3 ± 3·8 grms. A similar hank immersed in saturated barium mercuric iodide solution, after washing and drying, had shrunk to 48·9 cm. in length, and its breaking load had increased to 526·6 ± 3·3 grms. The shrinkage and the increase in strength effected by these two solutions was, therefore, as nearly the same as could be produced during any test of a practical nature, and consequently we can state that the swelling and the shrinkage caused were identical in the two cases. The only other difference is that in the case of the caustic soda rapid untwisting of the fibre takes place, whilst with the barium mercuric iodide no such uncoiling of the fibre can be observed; consequently, a stretched hank treated with this soda solution developed a perfect lustre, whilst a stretched hank immersed in the barium mercuric iodide solution showed scarcely any increase in lustre.

The proof that the production of a lustre on treating cotton yarn with reagents whilst in the stretched condition is dependent to as great an extent upon the newly observed property of untwisting which the fibre possesses as by the previously observed factors of swelling and shrinking is completed by the above observations.

We now turn to the consideration of the purely mechanical effect which causes yarn mercerised under tension to appear lustrous. It has been remarked above that after mercerising and washing loose cotton fibres they appear as plain smooth surface rods; the internal canal is almost obliterated and the fibre is curved or bent more or less abruptly. We have, however, not been able to confirm the observation of Lange (Färberzeitung, 1898, 197) that the surface of the fibre mercerised loose exhibits many folds; the fibres after treatment show extremely regular surfaces and very few folds or creases are observable at all.

Further, the absence of the folds to which Lange refers is plain from the photographs which he himself gives in illustration of his paper. The photograph, taken in polarised light in natural colours, which we now give (Fig. 5) of the appearance of a quite typical cotton fibre which has been mercerised loose, renders quite clear the strong contrast between the appearance of a raw cotton fibre (Fig. 2), also in polarised light, and the fibre mercerised loose.

On stretching a raw cotton fibre on the microscope slide, fixing it at its two ends in a stretched condition by means of drops of wax applied at the two ends, and then watching it on the microscope stage whilst caustic soda of 65° Tw. is acting upon it, a clue is got to the true reason of the gloss produced during mercerisation. The fibre is seen to first straighten itself and then to swell under the action of the reagent, the twist remaining for the most part. After the fibre has become rounded, gelatinous and swollen by the absorption of the soda, the untwisting begins to set in. It will be remembered that we have shown above that with solutions sufficiently concentrated to effect mercerisation, the fibres first swell and afterwards or simultaneously untwist.

One part of the fibre held at the two ends is seen to become twisted owing to the untwisting of some other portion of the stretched fibre; later, another part is seen to twist, perhaps in the reverse direction to the first, owing to some other part of the fibre giving up its natural twist.

This kind of action goes on until the original and natural twist of the fibre has become more or less replaced by the second kind of twist produced by the previous unwinding. The fibre mercerised stretched thus presents the appearance of a gelatinous straight rod on which a series of pieces of corkscrew-like windings are visible; on washing the fibre and allowing it to dry, it is seen to preserve this shape. By this process the original creased or folded ribbon which constitutes the raw cotton fibre becomes converted into a straight rod of nearly circular cross section which carries on its surface, however, a series of spiral elevations; at the same time the fibre and the surfaces of the raised ridges are perfectly smooth; the rounded surfaces of these smooth ridges reflect the light which falls on them from any direction in just the same way as do the turns in a polished corkscrew, and it is to the presence of these ridges, which are absent in the original fibre or in the fibre mercerised loose, that the increased lustre of cotton yarn mercerised in the stretched condition is due. For the purpose of illustrating the appearance of these ridges on a cotton fibre mercerised in the stretched condition the photograph in natural colours of a typical fibre is given in Fig. 6; for purposes of comparision a photograph of a similar fibre taken in polarised white light is shown in Fig. 7.

Lange (*loc. cit.*) has ascribed the lustrous appearance of cotton mercerised stretched to the fibre having been subjected to tension whilst still elastic, and states that such fibres present the appearance of "rods which are fairly straight, stretched, and transparent, with—in comparison with the fibres which have been mercerised in the loose state—smooth, regular surfaces." The fibres, he remarks, have the appearance of "a smooth tube."

That our view is correct and that Lange's is not, can be easily seen on examining a mass of fibres which have been mercerised stretched, either as such or in yarn, upon the stage of a dissecting microscope under a magnification of 20 to 40 diameters, allowing the light from some powerful illuminator to fall directly upon the fibres. It will be seen that the lustre or sheen of the whole mass of fibres is not due to a reflection of light from the whole or a considerable part of the length of the individual fibres, but is due to reflection from a number of points on each fibre, that is to reflection from the sides of the ridges lying spirally on the surface of the fibre.

Again, the cross section of a cotton fibre mercerised loose is nearly circular and, if Lange is correct in his view that the stretching during mercerisation has the effect of rendering the fibre smoother and more tube-like in appearance, the cross section of the fibres mercerised under tension should be still more nearly circular; whilst if the new view which we now advance is correct, the fibre mercerised stretched should be less nearly circular in cross section than the one mercerised loose. This must be so, because amongst a number of sections many would naturally occur in which the section is cut across the ridges; in these cases the cross sections should appear roughly polygonal in outline.

We do not reproduce photographs to prove that this is actually the case, because Lange's photographs, which cannot be subject to any bias in our favour, as they were made without any knowledge of the existence of the ridges to which we refer, show very plainly the existence of these polygonal cross sections.

It is convenient to construct a rough concrete model to illustrate the efficiency of such a method of obtaining lustre on a smooth polished rod as that of raising ridges on its surface.

Fig. 8 represents a photograph of a frame, the upper part of which is filled with smooth-surfaced slightly tapering glass rods, whilst the lower part is filled with similar rods on the surface of which spiral ridges have been made by turning them before the blowpipe. It will be clear from the figure that the smooth rods—which are comparable to cotton fibres mercerised loose—are far less lustrous than the ones carrying the spirals, and which are comparable with cotton fibres mercerised in the stretched condition.

It is thus proved that the lustre exhibited by cotton fibres mercerised whilst stretched has a cause which has not hitherto been suspected.

The efficiency of the practice sometimes adopted of producing a lustre on cotton yarn or fabrics by immersing them loose in caustic soda and subsequently applying tension, is at once explicable on the basis of our results. The fibres being held in the yarn or fabric cannot untwist entirely and freely as they do when immersed loose in the caustic, each fibre being held by its contact with others in the yarn; when the yarn or fabric is afterwards stretched whilst still gelatinous from the action of the soda, the fibres are straightened and the smooth and rounded ridges which give rise to the lustre are thereby produced.

This paper practically completes our study of the physical and mechanical questions which arise in connection with the action of mercerising and similar agents on cotton. We are now occupied with the determination of the composition of the substances formed when the reagents dealt with in the paper act on cotton and also with the quantitative questions involved in the absorption of colouring matters by cotton and modified celluloses. The problem of determining the composition of the addition compounds of cellulose has been previously attacked by the ordinary methods of chemical analysis, but hitherto without great success. We have therefore devised a method in which the changes in composition of a solution are traced whilst the solution is actually acting on the fire; the composition of the liquid is determined by means of the refractometer. We hope shortly to lay the results of this further work before the Society.

Discussion.

The Chairman observed that the mercerising of cotton fibres was a Lancashire invention, and that now considerable light had been thrown upon the subject by the investigations of the authors in elucidating the various important points connected with this invention, and especially in explaining the manner in which the lustre was obtained on the fibre. They were constantly charged by politicians and the press, and by others who did not know the true state and condition of things in our districts, with inefficiency and ignorance; but when they considered the improvements which were constantly being effected in our manufactures, and the establishment of new industries as the result of inventiveness and ingenuity on the part of Englishmen, they must consider that they were not so ignorant as they had been pictured by those who knew nothing about them. He asked if it was not the highest acknowledgment of British efficiency that foreign nations were building walls of protection which have not been found high enough to prevent invention.

Dr. Ad. Liebmann desired to know whether there is a difference in lustre if the cotton was treated at ordinary temperature or a lower one. He was of opinion that a great many improvements and novelties were still possible in many directions. He had found that it was possible to form metallic combinations—true chemical compounds, and not simply the depositions of oxides on the fibre, from which he had reason to believe that finally we should make new and probably startling products. He would like to ask whether there was a difference in the lustre produced if cotton was mercerised on the stretch, or if it were allowed to shrink and be stretched afterwards? He further wished to know whether the authors had made any observations on the force necessary to prevent shrinkage and to recover shrinkage, and if they had found any difference in the force required for these two operations.

Mr. Harold Lee said the paper was most interesting, whether from a scientific or commercial point of view. They all had had their eyes opened by what they had seen and heard, and they must have been struck by the amount of hard work and patience which had been expended in the experiments placed before them. They had sufficient to take away with them, and anything he might add would be quite superfluous.

Dr. Knecht asked whether the authors had made, or intended to make, further experiments with caustic potash. It was well known that caustic potash has a very different action to caustic soda. He also asked whether, when defects had been caused by uneven mercerising, or perhaps by the cold washing when caustic sodas have been used above 50° Tw., these defects could be remedied or not? There were frequent complaints that mercerised goods were liable to uneven dyeing, and from experiments he had made he came to the conclusion that this irregularity was due to the fact that the goods had been left exposed to the air for a lengthened period, and that this exposure had brought about the formation of oxycellulose upon the surface. The explanation for this uneven dyeing as given by the authors was entirely new.

Dr. H. Levinstein said it was often stated that mercerised goods have a greater affinity for dyestuffs than unmercerised goods. He thought the deeper shades were produced with the same weight of dyestuff on mercerised goods as on unmercerised goods. It seemed to him that this should not be the case. A deeper shade of indigo was produced on mercerised than on unmercerised goods. He should like to ask if the authors had ascertained if the difference in shade of the hanks was produced merely by the colour going on quicker than in unmercerised goods.

Mr. Pope, in reply to Dr. H. Levinstein, said that his question was partly dealt with in the full paper; mercerised yarn certainly takes up a larger proportion of benzopurpurin 4 B. from a bath of given strength than does the same sample of yarn unmercerised. With respect to Dr Liebmann's question, he said that the authors were able to confirm the view that soda is a more efficient mercerising agent at low than at ordinary temperatures.

Mr. Hübner, in reply to Dr. Liebmann, said that some experiments had been made by Grosheintz with a view to ascertain the force required to prevent shrinkage. The authors are now conducting a series of trials, employing the various strengths of caustic soda solutions used in the experiments described in the paper, so as to further elucidate this important question. In reply to Dr. Knecht, he said that the only way which he could suggest for reducing the possibility of uneven dyeing of goods mercerised with soda above 50° Tw., was quick and thorough washing with boiling water. In reply to a further question, he said that it was rarely the practice for pieces impregnated with strong soda lye to be left exposed to the air for a lengthened period; if this, however, should have been the case, he thought it would be perhaps quite plausible to ascribe the uneven dyeing of such pieces partly to the absorption of water, and therefore to the corresponding action of lyes of lower concentrations on the exposed parts.

ANALYSES OF JALAP.

BY RUSSELL W. MOORE, M.A., M.Sc.

The determination of resin in jalap presents no special difficulties from a chemical standpoint, but in practice there are several points at which the manipulation is attended with some trouble. First is the proper sampling of the root. Various methods of cutting, splitting, and rasping were tried by me, but all were abandoned in favour of a twist drill. This tool in dry jalap produces a finely powdered sample from the interior of the root in proper condition for subsequent extraction. In immature or improperly dried samples the drill yields spiral pieces, but has so torn and broken up the root that the resin is very easily dissolved. The method of analysis is as follows: 7 to 8 grms. of the fine shavings or powder are extracted in a paper thimble in a Soxhlet apparatus with 95 per cent. alcohol for an hour. The solution contains, besides the resin, various coloured extractive bodies, which are removed by washing with water. The alcohol extract is poured into a porcelain evaporating dish of a diameter of 5 ins., containing hot water. The whole is heated on the water bath until the alcohol is driven off, and the resin separates, leaving a nearly clear solution. More water is added and the mixture filtered, care being taken to retain the resin in the dish as completely as possible. The washing with hot water is repeated twice, or until a perfectly colourless filtrate is obtained. After washing the filter thoroughly with hot water, it is dried and replaced in the paper thimble first used, from which the exhausted jalap has been removed. This is placed in the Soxhlet apparatus, connected with a tared flask, and the resin in the evaporating dish is dissolved in hot alcohol and carefully washed into the thimble with hot alcohol. The contents of the Soxhlet apparatus are then extracted for two hours, the alcohol expelled or recovered from the flasks, and the pure resin dried to constant weight in the air bath and weighed. The use of the evaporating dish is recommended, since, where a beaker is used, the masses of resin adhering to the bottom and sides often cause the cracking of the beaker as it is heated and cooled. The clearness of the filtrate is also of importance, as the evaporation of a slightly turbid filtrate yielded a noticeable amount of resin.

The above method presents no new principle, being practically the same as that of the process for preparing *resina jalapæ* in the United States Pharmacopœia, but in analysing a large number of samples, attention to the points noted above has greatly facilitated the conduct of the work.

A number of results obtained are given, to show the percentage of resin found in imported jalap. The Treasury regulations prescribe a standard of eleven per cent. of resin.

The samples analysed represent lots of doubtful quality, and of these 28 out of 98 are under the prescribed 11 per cent. standard, of which eight are over 10 per cent. There is considerable difficulty in sampling inferior lots of jalap, as the roots are not uniform in size or character, and re-samples of the same bag often show differing amounts of resin. Complaint has frequently been made that the standard for resin in jalap is too high, but from the above figures on suspicious-looking jalap there do not appear to be just grounds for such a position. The well-developed and properly dried root often runs as high as 20 per cent., as will also worm-eaten samples in which the content of resin is greater because of the consumption of the portion other than resin by the worms. The principal cause of the occurrence of inferior jalap is want of care in gathering and drying the root on the part of the producers. In no way can this be remedied more effectively than by excluding the inferior article from import and commerce.

ON THE CUPELLATION OF PLATINUM ALLOYS CONTAINING SILVER OR GOLD AND SILVER.

BY W. J. SHARWOOD.

The following notes may be of interest in connection with those recently published by H. Carmichael (this J., 1903, 1324). The experiments were made primarily to ascertain the extent to which lead is retained in the cupellation of platinum alloys, and the extent to which the platinum passes into solution during parting.

The platinum used was found to contain a little iridium; the gold was prepared by twice precipitating with sulphur dioxide, and melting with borax; the silver was prepared by reduction of the chloride, and showed no trace of copper or gold; the lead was practically silver-free, 30 grms. yielding only 0·05 mgrms. on cupellation. The metals taken were adjusted to within 0·05 mgrm., and the weighings made to 0·02 mgrm., but in tabulating the results most of the fractions have been neglected. Two parting acids were used in each case; No. 1 was made by mixing equal volumes of water and of nitric acid of sp. gr. 1·42; No. 2 from one volume of water and two of acid.

In the first series, equal weights of platinum, 100 mgrms. each, were wrapped in about 5 grms. of sheet lead, with varying amounts of silver, or silver and gold, and cupelled at a temperature suitable for gold bullion; they were left in the muffle about three minutes after apparently "finishing." After weighing they were warmed with No. 1 acid, washed, boiled with No. 2 acid, washed, dried, and weighed. No. 7 was heated to anneal the residual gold. In every case except No. 8 the weight of the final residue exceeded that of the platinum, or gold + platinum, taken.

The "loss in parting" gives the silver and lead, or silver and lead and platinum removed by the nitric acid; "lead retained" indicates the increase in weight after cupellation, neglecting absorption of silver by the cupel.

With platinum alone, or with little silver, the cupelled button is of a dull grey; slight increases in the silver give a crystalline surface; with two or more parts of silver the button closely resembles a normal silver button, but has a somewhat steely appearance, and is usually brittle if the silver is less than three times the weight of platinum.

First Series.

No.	Platinum taken. Mgrms.	Silver taken. Mgrms.	Gold taken. Mgrms.	Lead retained. Mgrms.	Loss in Parting. Mgrms.	Weight after Parting. Mgrms.	Character of Cupelled Button.	Effect of Acid on Button.
1	100	0	0	37·5	0·5	137·0	Hard, silvery	None visible.
2	100	25	0	31·0	5·5	150·5	,,	,,
3	100	50	0	26·2	8·7	167·5	Dull grey	,,
4	100	100	0	25·0	48·0	177·0	,,	Very slight.
5	100	101	48	24·0	3·0	270·0	,,	None visible.
6	100	206	48	22·0	158·0	218·0	Smooth, silvery	Slight.
7	100	206	6	10·0	280·0	42·0	,,	Powdery residue.

Second Series.

No.	Platinum taken. Mgrms.	Silver taken. Mgrms.	Gold taken. Mgrms.	Lead retained. Mgrms.	Platinum dissolved in Parting. Mgrms.	Character of Cupelled Button.	Colour of Solution.
8	100	105	0·0	11·4	30	Very crystallised and brittle	Brown.
7	100	206	6·0	10·0	63	Smooth, brittle	,,
6	100	206	48·0	22·0	0	,, ,,	Colourless.
9	100	310	0·0	10·0	64	Slightly crystallised	Brown.
10	100	427	0·0	5·0	89	Smooth and silvery	,,
11	100	470	19·4	2·0	99	,, ,,	Colourless.
12	100	1,050	167·0	(?)	100	,, ,,	,,

In the second series the amounts of platinum taken varied somewhat—the weights of platinum, silver, and gold, ranging from 300 to nearly 2,000 mgrms., 5 to 10 grms. of lead being used. The buttons were rolled out to nearly uniform thickness, and 200 to 500 mgrms. cut out for parting. For the sake of comparison all are calculated to a uniform basis of 100 mgrms. of platinum. As the final residues were less in weight than the platinum or platinum and gold taken it was assumed that all the lead and silver dissolved, and the figures under "platinum dissolved" represent the platinum or gold and platinum taken, *minus* the final weight of the annealed residue. Results 6 and 7 are also included in this series for comparison.

In Nos. 7, 8, 9, and 10 the platinum was left after parting in a very finely divided condition. On filtering the brown decanted solution very little platinum remained on the filter, but the filtrate was still brown; on standing three days a black powder separated, and the solution became almost colourless. In No. 12 the cupelled button was slightly less in weight than the platinum, silver and gold taken, the silver absorbed by the cupel doubtless exceeding the lead retained.

In No. 11, attempts were made to estimate the silver in the nitric acid solution, by titration with potassium thiocyanate. In this and in other instances when platinum was present, titration indicated more silver than was actually present; the excess of reagent consumed corresponded very closely to 4 mols. potassium thiocyanate for each atom of platinum in solution, but the end of the reaction is rendered very indefinite by the platinum.

From an examination of the tabulated results it is vident that the lead retained upon cupellation decreases, vhile the platinum dissolved by nitric acid increases, with n increase in the ratio of silver to platinum. An increase n gold, silver and platinum remaining constant, seems to lecrease the dissolving of platinum, but more extended work s necessary on these lines. The retention of lead appears o depend mainly upon the fusibility of the button, oxidaion ceasing for practical purposes when the button olidifies. This was proved by cupelling alloys similar to , 2, and 3 at higher temperatures, the cupelled buttons eighing less, but it is not thought necessary to give the esults, as these were doubtless modified by the greater bsorption of silver in the cupel under these conditions.

MR. J. T. WOOD IN THE CHAIR.

THE DETERMINATION OF THE IODINE ABSORPTION OF OIL OF TURPENTINE.

BY T. F. HARVEY.

Since the Wijs method of determining the iodine value of fats appears to furnish a true measure of their degree of unsaturation, it was thought that it might be of use in differentiating between pinene and limonene, the chief terpenes respectively of turpentine and lemon oil, adulteration of the latter with turpentine or rectified turpentine being a common practice a few years ago.

Theoretically, limonene should absorb 4 halogen atoms, since it contains two double linkages, while pinene containing one double linkage should absorb but 2 atoms, the respective iodine values (theory) being 372 and 186—any figures obtained in excess of these when working on the pure substances must be due to substitution. Some support was lent to this idea upon finding that three samples of American turpentine gave iodine values respectively of 166, 198, and 221, while by the same method the first 10 per cent. of distillate from six samples of lemon oil gave values varying from 334 to 349. These experiments were made in 1901, and were not proceeded with. My attention was again attracted to the matter by the figures which Archbutt gave for American turpentine in the Journal for Dec. 15, 1902, and which varied from 277·4 to 405·6 according to the time of contact allowed. Recently, with a fraction of American turpentine I obtained results which did not appear to be in agreement with these. On looking further into the matter, I find that the quantity of halogen absorbed by turpentine is governed also by the excess of solution used and by the character of the excess halogen present in the Wijs solution—*i.e.*, whether iodine or chlorine be present in addition to ICl.

In the accompanying tables are shown the different values obtained by varying (1) the time, (2) excess of Wijs' solution, (3) character of excess halogen over that required for ICl, (4) hydration of the acetic acid.

Solution A consisted of ordinary Wijs' solution containing ICl with a slight excess of iodine, 25 c.c. = 49 c.c. N/10 thiosulphate.

Solution B consisted of solution A into which a slight excess of chlorine was passed. 25 c.c. = 51·5 c.c. N/10 thiosulphate.

Solution C consisted of solution A into which a large excess of chlorine was passed till 25 c.c. = 68 c.c. N/10 thiosulphate. This was then diluted to about N/5.

The liquids used in these experiments were: (1) A fraction distilled from American turpentine between 155° and 156° C.; (2) a sample American turpentine having the following characters:—Specific gravity at 15·5° C. = 0·8676; optical rotation (100 mm.) = + 8°; refractive index at 20° C. = 1·4709; soluble in one half (or more) of its volume of 99 per cent. acetic acid; 95 per cent. distils between 154°—162° C., while the residue distilling above 170° C. was 2·7 grms. per 100 c.c.; flash-point (Abel) = 94° F.

TABLE I.

Fraction of American Turpentine, distilling 155—156° C.

53	1 hour	332·7	348·3
84	"	409·0	..

With regard to the titration of the experiments, it has been suggested that water should always be added before potassium iodide, so as to minimise any reversal of the reaction. In the Journal for Dec. 15, 1902, I showed that this led to incorrect results, the halogen disappearing from blank experiments in amount depending on the time of contact with the water. I also showed that this loss was not mechanical, and am now of opinion that substitution of the acetic acid occurs on dilution. This does not seem unreasonable, since halogen substitution products of the fatty acids are formed in presence of iodine and iodic acid (Richter, Vol. I., page 272), both of which must be present after diluting Wijs' solution containing excess of iodine. If this view is correct, a constant blank should be obtained by employing, instead of acetic acid, a solvent such as carbon tetrachloride, in which substitution cannot occur. This was tried, and no variation ensued upon diluting the blank with water and allowing it to stand 5, 30, and 60 minutes respectively, with frequent and violent shaking. Original solution, 15 c.c. = 27·1 c.c. N/10 thiosulphate. After 5 minutes' contact with water, 15 c.c. = 27·0 c.c. N/10 thiosulphate. After 30 minutes' contact with water, 15 c.c. = 27·0 c.c. N/10 thiosulphate. After 60 minutes' contact with water, 15 c.c. = 27·0 c.c. N/10 thiosulphate. Potassium iodide should, therefore, always be added before diluting.

DISCUSSION.

Mr. ARCHBUTT said he could confirm Mr. Harvey's statement that the amount of iodine absorbed by oil of turpentine from Wijs solution depended upon the amount of iodine in excess, as well as upon the time of contact. To measure the iodine addition value, a direct titration would probably be best, if it could be made; but for the detection of adulteration, a high iodine value was an advantage and the occurrence of substitution did not matter, provided the results were concordant. He, therefore, preferred to add a large excess of iodine. The experiments recorded in the following table, all made with the same sample of turpentine, proved that, if the time of contact and the excess of iodine were kept constant, concordant values were obtained.

The conditions of working which he recommended were, to allow 20 minutes contact, and to take care that at the end of that time the iodine left unabsorbed was at least equal to, but not more than 5 per cent. in excess of that absorbed. This might involve making one or two trial titrations, which was easily done.

MR. T. L. PATTERSON IN THE CHAIR.

LINTNER'S SOLUBLE STARCH AND THE ESTIMATION OF "DIASTATIC POWER."

BY JOHN S. FORD, F.R.S.E.

1. INTRODUCTION.

During the last few years, a number of papers have been published dealing directly or indirectly with the determination of the diastatic (amylotic) activity of malts, and a conspicuous feature of these has been a disregard of previous publications, more particularly of the fundamental work of Kjeldahl (Comptes rend., Carlsberg, 1879, 109), and the important papers, by Duggan (Amer. Chem. J., **7**, 306; **8**, 211), and Wood (Amer. Chem. J., 1893, 663), on the influence of traces of impurity on diastatic action.

Many of the contradictions and differences of opinion as to matters of fact prevalent in certain of the more recent publications are, in the estimation of the writer, due to the omission of precautions indicated by Kjeldahl, Duggan, and others, and the object of this communication is to again draw attention to these, and certain other precautions which must be observed, if uniformity of results is to be attained in experiments on amylotic action. At the same time, the writer regrets that his contribution to the subject is also of a contradictory, as well as of an incomplete, nature.

In a recent paper (Woch. f. Brau., 1902, 313), Mohr says: "It is well known that the activity of diastase may be increased even ten times by the addition of mere traces of certain substances, such as asparagine, lactic acid, &c.," and results are given showing such differences. Effront* in "Les Enzymes," and elsewhere, makes somewhat similar assertions, and gives data, showing the accelerating effect of asparagine, acids, and certain salts on diastatic action. Grüss (J. Pharm., **2**, 275), and Jungk (Pharm. J. Trans., **14**, 104), make much the same observations with regard to the effects of asparagine and acids respectively. Brown and Morris (J. Chem. Soc., 1890) also state that the addition of very dilute acid stimulates the action. These views have received very general acceptance, the results of Effront in particular being frequently quoted. In the opinion of the writer, this apparently favourable effect of added acid is due, not to the acid *per se*, but to its neutralising alkaline impurities present in the solutions. Very minute traces of alkaline impurities have a powerful inhibiting effect on diastatic action, and when these are less or more neutralised by the added acid, the action approaches its normal maximum, which takes place in a neutral solution, or at least in one in which the free hydrogen or hydroxyl ions are at a minimum.

That this is the explanation seems probable from the fact that the salts, mentioned by Effront and others as accelerators, appear to be all acid ones; and it will be shown subsequently, there is in laboratory operations a source of alkaline contamination, which is generally overlooked. That the starch used by Mohr (Woch. f. Brau., 1902, 94) was really alkaline, appears likely from his results with asparagine; at 17°—18° C. he finds little difference, but at 53°—55° C. a marked increase of maltose in presence of asparagine. Now an aqueous solution of asparagine reacts much more strongly acid at 53°—55° C. than it does at the lower temperatures, thus, at the higher temperature, there being a more complete neutralisation of the alkaline impurities, diastatic action is greater. On exceeding a certain addition he found the action was retarded, this being due to the presence of an excess of acidity. Degener (Chem. Centralbl., 1897, **2**, 936) has pointed out this peculiarity of asparagine solutions (which the writer had noted independently), and he attributes it to decomposition of the complex molecule, not to hydrolysis. He has also shown that many organic acid solutions require more alkali for neutralisation (with indicators) when hot, than when cold. Malt extract solutions exhibit the same phenomenon, but n their case hydrolysis of phosphates probably plays a part.

With regard to the reaction of starch preparations, as etermined by colour indicators, this depends upon the ndicator; a solution of ordinary soluble starch, may be eutral to rosolic acid, acid to phenol-phthaleine, and lkaline to methyl orange; so in speaking of a starch as eing neutral, it is necessary to define in what sense the ord is used, and this point will be referred to again.

2. EXPERIMENTAL.

a. *Maltose Constants.*

In the determination of the copper reduction of the ccharified starch solutions, the method described by rown, Morris, and Millar (J. Chem. Soc., 1897, p. 96) was nployed, and the writer, having some specimens of carefully urified maltose, took the opportunity of verifying the values ven by them for the copper-reducing power of this sugar. e maltose used, was obtained by the fractional crystallisan of a thrice crystallised preparation made from arrowroot diastase hydrolysis. The fractions of the same rotatory wer were mixed, and portions dried over sulphuric acid, d phosphoric anhydride, in desiccators for some weeks. e specimen kept over phosphoric acid, when dried *in cuo* at 106° C. lost 5·5 per cent., that from the sulphuric d desiccator lost 5·7 per cent. *in vacuo* at 106° C., and ortion dried in a current of air at 90° C. lost 0·7 per cent. 0·4470 grm. of this, dried *in vacuo* at 106° C., weighed 0·4250 grm., which is the theoretical yield for maltose hydrate. These results confirm the observations of the above authors as to the difficulty or impossibility of obtaining a definite hydrate, by drying in a desiccator, but indicate the possibility of doing so by drying in air at 90° C. For the determination of the rotatory power, 3·285 grms. anhydrous maltose was dissolved in water, and made up to 100 cc. (*i.e.*, the volume at 15·56° C. of 99·807 grms. water in air); the solution weighed 101·096 grms., and its sp. gr. 15·6°/15·6° was 1·01295 determined, and sp. gr. 15·6/4° 1·01220 calculated; the rotation in a 2-d.m. tube was $9{\cdot}13^\circ_D$: hence $[\alpha]_{D\,\text{abs.}} = 139{\cdot}0^\circ$, a value somewhat higher than that of Brown, Morris, and Millar. From various other determinations the writer has always obtained this value for concentrations of 3 to 10 per cent., and he is inclined to think that his higher result is due to the polarimeter employed, as this instrument gives for sucrose $[\alpha]^{10\%}_{D\,\text{abs.}}$ 67·0°, a value also higher than that usually accepted. Several determinations of the solution density, at different concentrations, were in close agreement with the results of the above observers, and, as will be seen below, the copper reductions are likewise so concordant as to prove that the specimens of maltose used by these workers and the writer were equally pure.

Copper-reducing Power of Maltose, the Copper being weighed in Gooch Crucibles as CuO.

Maltose taken.	CuO found.	Equal to Maltose by Brown, Morris, and Millar's Tables.
Mgrms.	Mgrms.	Mgrms.
45·5	65·8	..
81·1	113·5	82·3
167·2	229·1	167·0
221·0	300·0	220·0
265·5	362·8	266·0
293·0	398·3	292·2
312·5	427·1	313·0

With the same maltose a few experiments were made with Kjeldahl's (Comptes rend., Carlsberg, 1895) method of reduction, by boiling in an atmosphere of hydrogen; the results were as follows for 30 c.c. Fehling:—

Maltose taken.	CuO found.	Maltose by Kjeldahl's Tables.
Mgrms.	Mgrms.	Mgrms.
39·3	64·0	39·7
82·8	129·0	82·0
130·2	198·0	129·0
183·0	273·0	183·5
195·3	290·0	196·5

The agreement here is also very close.

Experiments were made to see if simple drying of the Cu_2O precipitate, in the water oven, gave the same results as ignition to CuO. Slight divergences were invariably obtained, indicating a certain amount of oxidation of the cuprous oxide under such conditions of drying, it generally weighing from 2 — 3 mgrms. more than the amount calculated, from the CuO found, in precipitates of 0·1—0·2 grm. The difference in weight was proved not to be due to retention of water by the asbestos.

It may also be mentioned here that in the writer's experience, the reduction (by means of ignition in hydrogen) of the copper oxide to metallic copper is quite unnecessary, as with reasonable care ignition to CuO gives the same results.

b. *Soluble Starch of Various Origins, Preparation, and Properties.*

Ordinary preparations of soluble starch invariably contain phosphates, and possibly traces of organic phosphorus compounds, which are not removed by prolonged treatment with dilute alkali or acid, or washing with water. Precipitation of aqueous solutions of the starch, with alcohol, carries down the phosphates with the starch, and to-

---

Effront: "Les Enzymes et leurs Applications." Paris: Carré Naud.

eliminate them anything like completely, it is necessary to throw down the starch repeatedly, from acidified solutions, with alcohol. Starch obtained thus retains acid, which cannot be washed out readily with alcohol, and to remove this, it is necessary to redissolve in water and precipitate with alcohol several times. This operation is not easy to carry out, because when the starch solution becomes free from acid or salts it forms a "milk" with alcohol, which does not separate even on long standing; addition of a very small quantity of pure potassium or sodium chloride induces flocculation, but the starch then contains traces of the added salt. Neither of these chlorides, however, has any direct effect upon diastatic action. Starch prepared thus, though practically ash free (except for the traces of added salt), when ignited with sodium carbonate and nitrate shows the presence of phosphoric acid, and the writer has not obtained from potato starch a preparation which yielded less than 0·1 per cent. P_2O_5. An attempt was made to remove the phosphorus compound from a potato soluble starch by extraction with alcohol, and ether alcohol. The original starch gave 0·17 per cent., and after six weeks treatment 0·15 per cent. P_2O_5. The starch was then found to be strongly alkaline to rosolic acid, probably owing to solution of alkali from the glass extraction cylinder, so the attempt was abandoned.

Soluble starch prepared by alcohol precipitation as described, is fairly pure, and nearly neutral, that is to say, it gives no reaction with rosolic acid or methyl orange, though usually somewhat acid to phenol-phthaleine. 10 grams equal 1 c.c. N/100 NaOH; this, though an appreciable quantity, is relatively small compared with that of ordinary preparations of Lintner's starch.

It has recently been noticed that other starches than potato, such as maize, wheat, or rice contain less of, or are more easily freed from, phosphorus compounds, and the writer has prepared from maize, specimens which are certainly a close approximation to the pure substance.

To prepare starches in this way for use in technical laboratories is out of the question, and fortunately unnecessary, and we use the ordinary Lintner's preparation; and in connection with the washing of this free from acid it must be pointed out that the usual directions, to "wash until the wash waters are free from acid," are by no means sufficient, as the starch may still be strongly acid, though the wash water is neutral. Indeed it seems to be almost impossible to remove acid from starch by washing with distilled water. Saare (Ann. Agronom., 16, 471) drew attention to this many years ago. The writer has tried several times to remove all traces of acid by prolonged washing with distilled water, but bacterial fermentation has usually interfered with the attempts; this difficulty might of course be overcome by the use of some antiseptic, which does not interfere with diastatic action, such as toluol, chloroform, oil of cloves, &c., but an attempt made thus, was not more successful. 1 kilo. of maize soluble starch was stirred for 1 hour with 7 litres of distilled water, twice a day for three weeks, toluol being added as an antiseptic. At the end of that time the starch was still strongly acid, 10 grms. equal to 8 c.c. N/100 NaOH, rosolic acid, and 18 c.c. N/100 NaOH, phenol-phthalein, as against 6 c.c. and 14 c.c. respectively at the start. There was no evidence of fermentation, so presumably the increase of acidity is due to some other cause, possibly hydrolysis of the phosphates present, along with a preferential adsorption of acid by the starch granules. This is probably the explanation, as the wash waters were slightly alkaline for the first week or so. It must, however, be explained that this starch was not obtained under the ordinary conditions, as, after digestion with hydrochloric acid, and washing until the wash waters were neutral, the acidity of the starch was determined, and a quantity of soda, rather more than equivalent, added, the mixture being shaken for some hours and allowed to stand overnight. It was then filtered and washed until the excess of alkali was removed, *i.e.*, until the washings ran through neutral, when the starch was found to be acid, and at this stage was used in the experiment just described.[*]

By using tap water—*i.e.*, water containing calcium carbonate—the acidity of the starch is neutralised, but if care be not taken an alkaline preparation is obtained, and possibly the general employment of ordinary water, for washing, accounts for so many specimens being alkaline.

In all cases after using tap water, it is advisable to rewash with distilled water until a portion of the starch dissolved in boiling neutral water, gives no reaction with rosolic acid, or is at most faintly acid to that indicator.

The various raw starches, as maize, wheat, barley, rice, arrowroot, or potato, are not equally suitable for the preparation of soluble starch, owing mainly to the difference in their rate of subsidence in water. Large grained potato and arrowroot settling rapidly, washing can be carried out expeditiously; maize does not settle so well, and wheat, barley, and rice do so even more slowly. Potato starch, owing to this property and its low price, is the usual material employed, though arrowroot, save for the price, is equally desirable. Whichever starch is used, it should first be washed with water, then with half per cent. soda, again with water, and then digested with hydrochloric acid sp. gr. 1·037 for two to three days at 40° C., or until a portion, after washing free from excess of acid, dissolves readily in boiling water, and shows no sign of gelatinised granules.

If the action of the acid be not carried far enough, the solution filters badly, rendering the determination of its copper-reducing power difficult. On the other hand, if the treatment be carried too far there is a very considerable production of amylo-dextrin. Indeed, all soluble starches prepared in the heat by acid contain this substance, and it is to its presence, and not to that of maltose or glucose, that their copper-reducing power is due. This is proved by the fact that yeast has no effect in reducing the amount of apparent maltose in solutions of the starch, and that these, on dialysis, yield, not sugars, but a body having the properties of amylo-dextrin.

Soluble starch (100 grms.) from arrowroot by Lintner's method, dissolved in water, was dialysed for two days, the dialysate concentrated and precipitated with alcohol twice, the precipitate then dissolved in water, and evaporated to remove alcohol, was made to a volume of 50·03 c.c., weighing 50·434 grms.

The solution gave a red-brown colour with iodine. 10 c.c. dried *in vacuo* at 110° C. weighed 0·1985 grm., ash 0·0015 grm. 10 c.c. reduced 0·036 grm., CuO. Rotation in 2 dm. tube = $7{\cdot}47^\circ_D$.

These results correspond to $[\alpha]_{D\ \mathrm{abs.}}$ 189°, $R_{\mathrm{abs.}}$ 14·4, which are the values given by Brown and Morris (J. Chem. Soc., 1889, 453) for amylo-dextrin.

The soluble starch used here, had the constants $[\alpha]_{D\ \mathrm{abs.}}$ 195·7, $R_{\mathrm{abs.}}$ 7·4, and is thus a mixture of 48·6 per cent. starch, and 51·4 per cent. amylo-dextrin: in this case the action of the acid had been carried rather far. With care it is easy to prepare soluble starches free from unaltered starch with R 2 to 3, or containing from 13 to 20 per cent. amylo-dextrin. By allowing the action of the acid to tak place in the cold soluble starches with R as low as 0·2 t 0·5 may be obtained, but these do not give such satisfactor solutions for ordinary manipulations as those with R 2 o thereabouts. For practical purposes of diastasimetry th presence of a slightly greater or less proportion of amylo dextrin in the starch, is of no importance, as is shown b the following results:—

1 c.c. of malt extract[*] to 70 c.c. of each solution,[†] 1 hour at 40° C., boiled, cooled, and made to 100 c.c.

---

[*] This is true also for preparations made by nitration, acetylation, and solution in glycerin or sodium hydroxide, unless purified by repeated precipitation.

[*] Unless otherwise mentioned, the malt extract used is alwa prepared by extracting 20 grms. finely-ground malt with 500 c distilled water for six hours at 20° C. The error of measureme of the 1 c.c. from a special pipette does not exceed ± 2 mgrms.

[†] 70 c.c. of starch solution always used in the experime throughout this paper, the strength being so arranged that t volume corresponds to 2 grms. dry starch. The action is stop by boiling, or by addition of alkali, as is expedient.

Effront, in "Les Enzymes," states that starches from ifferent sources act differently with diastase, and seems to mply that this results from some actual difference in the tarch *quâ* starch. Ling (J. Fed. Inst. Brewing, 1903, 54) also finds that soluble starches prepared in different vays give different results with diastase. There is no oubt that preparations of soluble starches do differ in ertain physical characteristics, but the writer is of opinion hat when different specimens give different maltose pro-luctions with diastase, it is not the starch which causes the ariations, but the impurities present in the specimens. 'ure starches, or rather, one should say, purified starches, hether soluble starch prepared by acid, or by gelatinisation, nd liquefaction by diastase, or in the form of properly repared "pastes," undoubtedly give similar conversions rith equal quantities of diastase under similar conditions, hat is to say, solutions of soluble starches from any source, hen equally pure will give the same maltose production hen acted upon by equal amounts of diastase.* This emark does not, of course, apply to starches when in the olid (natural) state, where the rate of dissolution by malt xtract or diastase varies greatly, nor to starches prepared om malted grains, nor to the action of diastase, under rewing conditions, in the mash tun. These are conditions hich do not come within the scope of the present paper.

The starches mentioned below were, with the exception of e barley, bought commercially, and purified by treatment ith dilute alkali and acid, being well washed and air ried. Portions (15—20 grms.) were gelatinised and quefied at 79°—80° C. with a trace of precipitated diastase, oiled when limpid, and made to 500 c.c., 1 c.c. of malt xtract was added to 70 c.c. of each solution at 40° C., ept for one hour at 40° C., solutions boiled, and made to 100 c.c. The results in all cases are corrected for reduction of starch solutions, and malt extract.

Starch Variety.	CuO per 100 c.c.†	Reaction of 10 grms. Rosolic Acid.
Arrowroot, Natal	0·53	Neutral.
Rice	0·52	0·17 c.c. N/100 NaOH.
Wheat	0·52	0·17 c.c. N/100 NaOH.
Maize	0·52	0·10 c.c. N/100 H_2SO_4.
Potato	0·54	Neutral.
Barley	0·52	0·17 c.c. N/100 NaOH.
Arrowroot, unpurified	0·47	0·30 c.c. N/100 H_2SO_4.
„ Lintner's soluble	0·54	Neutral.

† In all cases CuO per 100 c.c. is expressed as grms.

It is evident that the origin of the starch has, under these conditions, no influence on the results when the starches are purified, and it may be mentioned that O'Sullivan (J. Chem. Soc., 2, 141), in one of his earliest communications on the transformation of starch, states that though he used potato starch, he satisfied himself that various other starches gave the same results. The writer has verified O'Sullivan's statement, by conversion of "pastes," made from the first six starches in above table, with precipitated diastase at 58° C. The corrected values $[\alpha]_{D3\cdot93}$ 174°—176° and $R_{3\cdot93}$ 42—44, being very close, considering that the starches, though purified, were not "pure," and that the diastase, like most alcohol precipitated specimens, was distinctly alkaline to rosolic acid (1 grm. = 16 c.c. N/100 H_2SO_4). From the above starches soluble preparations were made by Lintner's method, and tested similarly with the results below :—

‡ This starch was made from a "purest commercial farina," by gelatinisation, and liquefaction with a trace of diastase, the solution er concentration being precipitated, twice only, with alcohol. The result shows well how the impurities are carried down with the rch.

The slight differences shown above may very well be counted for by variations in the impurities, and we may ely infer that equally purified preparations of Lintner's uble starch, from starches of different origin, will give e same maltose production, with equal quantities of stase. The above preparations, though exhaustively shed with distilled water, are by no means pure, and if acidity to phenol-phthaleine be taken as due to H_2PO_4 (and there are reasons for this assumption), n it would appear that traces of acid phosphates do not erfere with diastatic action to any extent. This we ght infer, for the MH_2PO_4 dissociates in solution into + H_2PO_4', and the further dissociation of $H_2PO'_4$ to - HPO''_4 being very slight, there are few free hydrogen s present in the solution, which is thus only feebly acid. he case of the starch solution alkaline to rosolic acid, if be taken as indicating the presence of M_2HPO_4, which ociates into M_2 + HPO_4'', the HPO_4'' unites with the of the water, $HPO_4'' + HOH = H_2PO_4' + OH'$ forming less dissociated H_2PO_4', and there thus being an excess hydroxyl ions present the solution is alkaline, and vourable to diastatic action. The conditions are of se not so simple as this, but these views, in the main, probably correct, and will be referred to again. It is ous from the experiments just recorded that starches ing alkalinity to rosolic acid, even when this is mpanied by acidity to phenol-phthaleine, do not give a normal maltose production. An alkalinity in the case of arrowroot(γ),‖ equal to 0·08 mgrm. soda per 70 c.c., having retarded the action distinctly. Wood (*op. cit.*) by the direct addition of soda to his starch pastes, proved that one part per million reduced the formation of maltose from 0·74 to 0·67 grm.

Fernbach (Ann. de la Brass., 1899) states that alkaline phosphates hinder, and acid phosphates favour diastatic action; the writer's experience is in agreement with the first statement, but indicates that the favouring influence of acid phosphates is an indirect action, which will be discussed subsequently.

For the preliminary testing of starch preparations rosolic acid is a useful indicator when used as follows :—Distilled water coloured with the indicator is boiled in a platinum basin, the neutrality adjusted by the addition of N/200 acid or alkali, the starch is then added and boiled; if the solution is alkaline the starch should be repurified; if neutral, or faintly acid—say not more than 1 c.c. N/100 NaOH per 10 grms.—it may be used, other conditions being suitable. Such starches as a rule show alkalinity to methyl orange equal to 2—3 c.c. N/100 H_2SO_4 per 10 grms., but the end point is not sharp, and the value of the figure, for other obvious reasons, is somewhat doubtful. Litmus, whether as paper or solution, is useless for testing starches; indeed, the use of any colour indicators for the detection of such minute traces of hydrion or hydroxidion can only be looked

---

[*] Within the limits of Kjeldahl's "Law of Proportionality," and peratures from 15° to 58° C.

[‖] This preparation was washed exclusively with "tap" water.

upon as a makeshift method employed *faute de mieux* The titration figures given in this paper are only roughly approximate, and can hardly serve as a basis for calculation.

The question of acidity to phenol-phthaleine, and the importance of avoiding certain metallic impurities in the starch preparations, will be dealt with subsequently.

c. *Influence of Various Compounds on Diastatic Action.*

Although such preparations of soluble starches as the writer had available were obviously more or less impure, be, knowing something about the nature of the impurities, thought it worth while to carry out, pending the preparation of purer specimens, certain preliminary experiments with them, the results of which are detailed below.

Influence of Lactic Acid.

Starch A, potato Lintner, 10 grms. = 2·0 c.c. N/100 H_2SO_4 rosolic acid.

Starch B, potato Lintner, 10 grms. = 1·5 c.c. N 100 NaOH rosolic acid.

1 hour, 54° C.

—	CuO per 100 c.c.	
	A.	B.
Starch solution without addition	0·58	0·74
,, ,, plus 0·1 mgrm. lactic acid ...	0·58	0·75
,, ,, ,, 0·5 ,, ,, ...	0·60	0·70
,, ,, ,, 0·75 ,, ,, ...	0·57	0·68
,, ,, ,, 1·00 ,, ,, ...	0·37	0·60

The differences here are not very great, though it is evident that there has been a slight augmentation of the action; in the case of B this is doubtful, as the experimental error may be ± 0·01. Starch A is undoubtedly an alkaline one, 10 grms. requiring 12·0 c.c. N/100 H_2SO_4 with methyl orange, the same quantity of B requiring 5·0 c.c. N/100 H_2SO_4, to produce the red colour.

At this stage in the work it was found that the flasks employed, (even though they had been well steamed before being put into use) when rinsed with distilled water, and put to drain, were of sufficiently poor glass, in most cases, as to turn neutral distilled water, added to them, distinctly alkaline to rosolic acid, at once or after a short digestion at 40° C.* This alkalinity may to some extent account for certain irregularities in our previous work, and as it is not probable that we alone are the possessors of such glass, it is no doubt another factor in influencing the general opinion as to the flavouring effect of traces of acids upon diastatic action. An examination of measuring flasks, boiling flasks, and other ordinary laboratory glass vessels showed very clearly that the warnings of Mylins and Foerster (Ber., **22**, 1902 *et seq.*), as regards the solubility of certain glasses in water, are well founded. More especially is this solubility conspicuous in ordinary test tubes, and those workers who carry out diastatic determinations after Lintner's method, in test tubes, would do well not to ignore this fact.

To some extent the action of the atmosphere in "weathering" the surface of the glass seems to be reduced by keeping the vessels full of distilled water when not in use, but the employment of Jena glass only, for all such work is advisable. For dissolving the starch the writer has for some years used pure tin beakers with satisfaction. Ostwald ("Physico-chemical Measurements") has emphasised the necessity of using special glass in conductivity determinations, and the same caution is applicable to work connected with enzyme action. It may not be amiss here, to call attention to the desirability of avoiding the use of ordinary glass tubing in condensers, more especially in those used in the Kjeldahl nitrogen estimations, where very often now, no cooling water is used, as even ordinary Jena tubing is by no means proof against "live" steam; a pure tin tube in connection with an adapter of No. 477 III. Jena glass is advantageous.

Another possible source of error, is in the filter paper used for filtering the malt extract solutions; most makes of paper yield an appreciable amount of alkaline matter to distilled water, a 12 cm. No. 595 S. & S. being equal to about 0·2 c.c. N/100 H_2SO_4 (rosolic acid). The effect of this however should be avoided, fortuitously, by the customary rejection of the first considerable portion of the filtrate necessary to avoid errors of adsorption.

The rest of the experimental work in this paper was carried out with precautions to avoid the errors indicated above. The distilled water used was obtained by distillation of ordinary tap water from a large copper vessel of about seven gallons capacity, the steam passing through a double spray trap before being condensed in a pure tin "worm" pipe, the distillate from the intermediate three gallons being collected in closed bottles.

Two starches, M and N, both potato, Lintner's, were used. Tested with colour indicators, 10 grms. of each required.

We have here a very slight augmentation in the more alkaline M starch up to 0·4 mgrm. lactic acid per 70 c.c., at which addition the N starch showed about an equal retardation.

The same starches were then tried in a similar manner, with the addition of hydrochloric acid.

Influence of Hydrochloric Acid.

As is to be expected, the influence of the acid is more pronounced at the higher temperature.

Influence of Alkali, &c.

Experiments were now made to determine the influence of alkali on the action, using in the first case "N" starch.

1 c.c. half strength malt extract, per 70 c.c. starch solution, 1 hour, 54° C.

" " " 1·00 " "	0·24

The results show that with this starch a relatively large addition of NaOH is necessary before any obvious retardation takes place, and this is at first sight contradictory to what has been said about the influence of alkali. The explanation* is however fairly evident; the starch contains a rather high proportion of acid phosphates, and the slight inhibition is due to the interaction of the NaOH and MH_2PO_4, or let us say NaH_2PO_4, giving rise to $Na_2HPO_4 + H_2O$. Now Shields (Phil. Mag., 1893, **35**, 5) has proved that Na_2HPO_4 undergoes extremely slight hydrolysis, and so retardation of the action is not to be expected until sufficient NaOH has been added to bring about some formation of Na_3PO_4, which will at once break up into $Na_2HPO_4 + NaOH$, with the result that only then does the solution become appreciably alkaline. With the starch "M" retardation was evident on the addition of 0·1 mgrm. soda, and with an alcohol precipitated maize starch (which was neutral to rosolic acid and methyl orange, gave only a doubtful indication of acidity to phenol-phthaleine, and on ignition, 5 grms., with carbonate and nitrate of sodium, showed merely a coloration with molybdic solution) the results were as under:—

1 c.c. half strength malt extract per 70 c.c. solution, 1 hour, 54° C.

	CuO per 100 c.c.
Starch solution, without addition...........	0·49
" " plus 0·02 mgrm. NaOH	0·48
" " " 0·04 " "	0·45
" " " 0·10 " "	0·32

With addition of hydrochloric acid this starch gave the following results:—

	CuO per 100 c.c.
Starch solution, without addition...........	0·49
" " plus 0·02 mgrm. HCL	0·50
" " " 0·04 " "	0·45
" " " 0·10 " "	0·40

These experiments demonstrate very clearly that extremely slight additions of alkali or acid are prejudicial to the action of diastase, the more so the purer the starch solutions.

Nature of "Acidity to Phenol-phthaleine."

The "N" starch, though containing a considerable amount of acid phosphate, can hardly be considered an acid preparation, for the dissociation of the anion H_2PO_4' to $H + HPO_4''$ is extremely slight. This is well shown by the action of the starch on sucrose, even prolonged digestion giving rise to the merest traces of invert sugar. The experiment was carried out thus: starch solutions with sucrose, equal volumes of water, with the same proportion of sucrose alone, and with the addition of 20 mgrms. of KH_2PO_4 in one case, and 0·12 mgrms. of HCl in another, were kept at 60° C. for 30 hours, then at 30° C. for 42 hours (the change of temperature being unavoidable, not intentional); the solutions were then made to a definite volume, and the invert sugar determined by copper reduction. The corrected results were as follows:—

	Grms. Invert Sugar per 100 c.c.
Starch solution plus sucrose	0·003
Water solution of sucrose	0·008
" " " plus 20 mgrm. KH_2PO_4 ..	0·011
" " " " 0·12 " HCl	0·083

The results, though not free from objection, show very clearly that the acid phosphates contribute a negligible amount of acidity to the starch solutions, and may practically be looked upon as neutral salts in this connection; still they possess what we may term a potential acidity, capable of neutralising traces of alkali, and as experiments with the direct addition of potassium dihydrogen phosphate prove that in small amounts it has little effect on diastatic action, we can understand why starch preparations showing neutrality or faint acidity to rosolic acid, and slight acidity to phenol-phthaleine, are (*cæteribus paribus*) the most suitable for use in diastatic estimations. The experiments given below serve to exemplify this action of acid phosphates.

"Potential Acidity" of Acid Phosphate.

Influence of Asparagine.

Various experiments carried out with different starches proved that at 40° C., and below that temperature, the addition of asparagine has little effect on the action. The results of two sets of experiments are given here:—

	CuO per 100 c.c.*
Starch solution, without addition	0·60
" " plus 1 mgrm. asparagine	0·60
" " " 5 " "	6·59
" " " 10 " "	0·60
" " " 20 " "	0·59
" " " 40 " "	0·59
" " " 60 " "	0·58
" " " 100 " "	0·57

An experiment with "M" starch, at another time, gave somewhat similar results:—

	CuO per 100 c.c.
Starch solution, without addition	0·54
" " plus 1 mgrm. asparagine.....	0·54
" " " 5 " "	0·54
" " " 20 " "	0·55
" " " 70 " "	0·56

---

* Without consideration of the more complex influence of proteid matters added in the malt extract.

* These amounts of asparagine were found to be without influence on the copper reductions.

The first trials at higher temperature were made with the starches A and B, already used in the experiments with lactic acid :—

——	54° C.		62° C.	
	A.	B.	A.	B.
Starch solution, without addition	0·58	0·72	0·25	0·55
Starch solution, plus 0·7 mgrm. asparagine....................	0·62	0·76	..	..
Starch solution, plus 35·0 mgrm. asparagine....................	0·73	0·79	0·62	0·60
Starch solution, plus 70·0 mgrm. asparagine....................	0·70	0·73	..	..

Here we see that the undoubtedly alkaline "A" starch has given a much greater maltose production in presence of 35 mgrms. asparagine at both temperatures, but we are far from finding the tenfold increase mentioned by Mohr. The less impure "B" starch shows only a slight difference, and this the writer has always found to be the case with other starches of like "purity." Another set of experiments was carried out with five starches, the "A," "B," "M," and alcohol precipitated maize, previously mentioned, and also a soluble starch obtained from Drosten, of Brussels. Effront, in "Les Enzymes" (footnote, page 237*), says that his standard starches can be obtained from this firm, so a sample was purchased, and this will be more fully described further on. Solutions of the above starches were made as usual, 1 c.c. of half strength malt extract added per 70 c.c. 1 hour. 58° C.:—

——	CuO per 100 c.c.				
	A.	B.	M.	Drosten.	Maize.
Starch solution, without addition	0·16	0·26	0·38	0·10	0·42
Starch solution, plus 15 mgrm. asparagine.....	0·40	0·35	0·45	0·37	0·34
Starch solution, plus 30 mgrm. asparagine.....	0·33	0·35	0·47	0·46	0·18
Starch solution plus 50 mgrm. asparagine.....	0·25	0·34	0·42	0·48	0·14
Starch solution, plus 75 mgrm. asparagine.....	0·34	0·26	0·38	0·44	0·11

The apparently favourable influence of asparagine is here very evident with the first four ordinary (impure) starches, but with the purer maize the effect is very different. It is to be noted, however, that this starch, without addition, has not given quite so much maltose as some of the other starches with addition of asparagine. This may be due to some unrecognised impurity, or to the effect of substances other than diastase in the malt extract, or, again, it may be due, as claimed by others, to the favouring effect of asparagine, a smaller addition of which to this starch might have augmented the action. At the same time, if we admit this possibility, even the greatest maltose production in any of the other starches, in presence of asparagine, is little greater than that in the maize without addition of this substance. A further experiment was made with another specimen of alcohol precipitated maize starch of similar purity (the other having all been used) with smaller additions of asparagine, the action being stopped at an earlier stage. 1 c.c. of malt extract was added to 70 c.c. of starch solution, and the action stopped after 20 minutes. The details are given in the subjoined table.

With these starches free from alkaline impurity, we have again no indication of an increase of action through the addition of asparagine.

The corollary from these results is, that asparagine does not augment diastatic action, and where tenfold or smaller increases are obtained, by its addition, there has been a previous restriction of the action, owing to the presence of alkaline or other impurities. It has already been shown that asparagine acts as a weak acid at higher temperatures than 40° C. and so neutralises alkalinity; and it will be shown subsequently that it also prevents the restricting effect of at least one other impurity not alkaline in its nature.

Possible Influence of Substances, other than Amylase, added in Malt Extract.

We must not forget that though the quantity of malt extract used in these experiments is not great, still the substances in it, other than diastase, may have some influence on the results. The extract ordinarily used (20 grms. malt with 500 c.c. water) will contain *circa* 0·8 grm. solids per 100 c.c., so 1 c.c. of the full strength extract contains 8 mgrms., of which two-thirds may be carbohydrates, the remaining third, say 2·7 mgrms., consisting mainly of nitrogenous matters* and salts. On ignition 1 c.c. of the extract might yield 0·4 mgrm. ash, mostly phosphates of potash and lime. How these phosphates exist in the malt extract solution is not quite certain; the solution reacts alkaline to methyl orange, and acid to rosolic acid and phenol-phthaleine, the 1 c.c. may correspond to 0·24 c.c. N/100 H_2SO_4, 0·08 c.c. N/100 NaOH, and 0·31 c.c. N/100 NaOH, with these indicators in the order mentioned. Now a solution of dipotassium hydrogen phosphates, or let us say M_2HPO_4, even at such dilutions undergoes only a slight hydrolysis; but still, in the case of the pure salt alone, sufficient hydroxidion is present to give an alkaline reaction with rosolic acid and methyl orange, but not with the more weakly acid indicator phenol-phthaleine. Potassium dihydrogen phosphate, or say MH_2PO_4, dissociates into $M + H_2PO_4''$, and the H_2PO_4'' into $H' + HPO_4''$ slightly, there being, in the case of the pure substance alone, sufficient hydrion to react acid to phenol-phthaleine and rosolic acid, but not with methyl orange. In a mixed solution of these salts, a state of equilibrium must exist for each concentration and temperature, and we may be justified in assuming that the extract (from normal malts), as added, is practically neutral; but it is obvious that after addition to the starch solution a new condition will obtain, dependent on the altered concentration and on the nature of the impurities in the starch solution. Further, our titration figures do not represent the equilibrium existing in the malt extract before titration, but the progressive effect brought about by the addition of the alkali or acid. These remarks, along with those made in connection with the effects of the addition of acids and alkali to the starch solutions, show the futility of extending this work, or attempting to draw any general conclusions as to the nature of diastatic action, until we are in a position to use purer starch and diastase preparations.

Influences of Traces of Copper and various other Substances on Diastatic Action.

The specimen of soluble starch already mentioned as obtained from Drosten of Brussels had a slightly putrid

---

[*] "L'amidon type, ainsi que la fecule type dont nous nous servons, sont en vente chez Drosten, rue de Marais, Bruxelles, et chez H. Koenig, fabricant de produits chimiques, Leipzig."

[*] The experiments of Bugarsky and Liebermann, Pflueger's Archives, 1898, 72, 51, indicate that the proteid matters added will not be without influence.

smell. It contained 19 per cent. moisture, and with colour indicators gave per 10 grms. values as below :—

Rosolic acid	3·0 c.c. N/100 H_2SO_4.
Methyl orange	10·0 „ „
Phenol-phthaleine	12·0 „ N/100 NaOH.

On ignition it left 0·28 per cent. ash, containing traces of copper. Burnt with Na_2CO_3 and KNO_3 it yielded 0·14 per cent. P_2O_5.

A comparison was made with it and the starch "M."

1 c.c. malt extract per 70 c.c. starch solution.
1 hour. 58° C.

	CuO per 100 c.c.	
	Drosten.	M.
Starch solution, alone	0·12	0·76
„ „ plus 0·04 mgrm. HCl	0·12	0·76
„ „ „ 0·08 „ „	0·12	0·78
„ „ „ 0·12 „ „	0·12	0·78
„ „ „ 0·20 „ „	0·13	0·76
„ „ „ 0·29 „ „	0·15	0·76
„ „ „ 0·36 „ „	0·18	0·70
„ „ „ 0·73 „ „	0·15	0·56

The very feeble hydrolysis in the case of Drosten's starch was mainly due to the presence of traces of copper, amounting to 0·0075 per cent. Cu. To prove that copper has a retarding effect on amylotic action, a portion of a specimen of soluble starch was shaken with distilled water, containing a drop of copper sulphate solution; it was then washed with water until the washings were free from copper. The dried starch contained 0·033 per cent. Cu. A comparison was made with this and the original specimen, as usual, one hour at 40° C.

	CuO per 100 c.c.
Ordinary starch	0·58
„ „ plus copper	0·03

The retardation is very marked. In the 70 c.c. of starch solution there would be *circa* 0·7 mgrm. copper, whereas in Drosten's the amount was only 0·16 mgrm. A further test was made, mixing the "copper starch" with the original, so as to give solutions as under :—

	CuO per 100 c.c.
Starch solution, no copper	0·82
„ „ plus 0·016 mgrm. copper	0·61
„ „ „ 0·033 „ „	0·42
„ „ „ 0·160 „ „	0·12

Mere traces of copper are thus highly prejudicial to the action. It is interesting to note that in presence of asparagine, this influence is in some way, not obvious, overcome, as Drosten's starch in the experiments with asparagine gave a normal maltose production on addition of 30—50 mgrms. per 70 c.c. of solution.

	CuO per 100 c.c.
Starch solution, without addition	0·55
„ „ plus 0·05 grm. boric acid	0·53
„ „ „ 1·00 „ potass chloride	0·59
„ „ „ 0·05 grm. potass dihydrogen phosphate	0·53

„ „ „ 1 c.c. chloroform	0·53
„ „ „ 1 „ toluol	0·50
„ „ „ 3 „ ethyl alcohol	0·56
„ „ „ 3 „ glycerine	0·55
„ „ „ 0·2 c.c. hydrogen peroxide 30 per cent.	0·38
„ „ „ 0·07 c.c. oil of cloves	0·55

Mercurial salts, or at least mercuric chloride, is even more fatal to amylotic action than copper, as little as 0·001 mgrm. $HgCl_2$ reducing the action about 50 per cent. The influence of several other substances is given above. The reagents used are mostly Merck's, but no special tests were made as to the purity,* as in any case the extent of their influence will be in some degree conditioned by the impurities in the starch. The results then are only of relative value. The conditions are as usual 1 c.c. of malt extract to 70 c.c. starch solution, 1 hour, 40° C.

Kjeldahl (*op. cit.*, 1879) gives results obtained by the addition of other substances, and states that 13 mgrms. borax per 100 c.c. starch solution reduced the maltose production 40 per cent. This is no doubt due to the alkaline nature of the salt, boric acid being a feebly dissociated acid, there is slight hydrolysis giving rise to free hydroxyl ions, which inhibit the action, as the writer's results with boric acid, show that the anion and non-dissociated acid have no effect.

In connection with the hydrolysis of salts of weak acids, it is to be noted that the use of potassium cyanide as an antiseptic for the preservation of diastase solutions is not to be recommended, and it is unfortunate that Reynolds Green (Phil. Trans. B., vol. 188) in his interesting work on "The Action of Light on Diastase," employed this substance as a preservative in his experimental work. Shields (*op. cit.*) has shown that KCN in N/40 N solutions is hydrolysed to the extent of 2·4 per cent.; hence one may infer that the diastase in Green's solutions, containing 0·2 per cent. KCN, would be to some extent destroyed and abnormal, and though he carried out control experiments, it does not follow, if the hydrolysis and decomposition of the cyanide varied with the conditions of exposure to light, that the controls in all cases allowed for this. Green states that KCN had no effect upon the diastase, but this is not the experience of the writer. A malt extract was precipitated with alcohol, filtered, and the coagulum dissolved in water; two equal volumes were made to 100 c.c., one "α" with water, the other "β" with water containing 0·2 grm. potassium cyanide.† 1 c.c. of each solution was at once added to 70 c.c. of "N" starch solution one hour at 40° C. The "β" solution was kept in darkness and again tested at the expiry of 48 and 96 hours.

	CuO per 100 c.c.	
	α	β
Starch solution	0·54	0·30
„ „ plus 2 mgrm. KCN	0·43	..
„ „ „ 2 mgrm. KCN plus 45 mgrm. KH_2PO_4	0·55	..
„ „ „ 45 mgrm. KH_2PO_4	..	0·41
„ „ „ β after 48 hours	..	0·15
„ „ „ β „ 96 „	..	0·06
„ „ „ β „ 96 hours plus 45 mgrm. KH_2PO_4	..	0·13

These results indicate a slow destruction of the amylase by the cyanide, and also show that even 2 mgrms. per 70 c.c. is sufficient to considerably restrict the action of the "α" solution. The figures for CuO are corrected for the effect of the cyanide on the copper reduction. Solutions containing cyanides should of course not be used with Fehling's solution, owing to the solubility of cuprous oxide in alkaline cyanides (roughly equal to a loss of 1 mgrm. CuO per 1 mgrm. KCN). Owing to the difficulty of precipitating the cyanide in presence of starch, the above results are corrected by making this allowance. The crippling effect of KCN on diastatic action is due to alkalinity arising from hydrolysis of the salt, and not to the anion CN, nor to non-dissociated HCN, as small amounts of this acid have little influence on the action.

d. *Bearing of the above Results on the Determination of Diastatic Power.*

It is fairly obvious, from the experimental results given in this investigation, that the determination of "diastatic

---

[*] With the exception of the potassium chloride and dihydrogen phosphate, which were specially purified.

[†] The cyanide was free from carbonate and cyanate, and was otherwise a very pure specimen.

power" must be carried out with various precautions, and it is probable that many of the disagreements in analysts' reports as to the "diastatic power" of malt samples, ensue, not so much from difference of methods (as has been suggested), but from a non-appreciation of the importance of these precautions and apparently, trivial details, such as—

- Time and temperature of extraction, and amount of stirring of the malt and water.
- Purity of the distilled water used for the extraction, and for dissolving the starch.
- Solubility of glass apparatus.
- Alkalinity of filter papers.
- Absence of acid and other fumes from laboratory.
- Concentration of the starch solution.
- Purity of the starch.

With regard to the first factor, the generality of malts when finely ground, give a constant "diastatic power" with six hours extraction, stirring every quarter hour. The difference between five and six hours with sufficient stirring being very slight, constant motion, stirring or shaking, for one to two hours gives the same result as six hours ordinary extraction.

The importance of the purity of the distilled water, and the influence of the next three factors has already been indicated in the beginning of this paper.

The concentration of the starch solution; it is of course well known that the reducing power of the saccharified solution must fall within the limits of Kjeldahl's "law of proportionality," that is below R. 40. It is, however, advisable to keep lower than this, say R. 30, as has been shown by Brown and Glendinning (J. Chem. Soc., 1902, 388). Apart from this, concentration exerts a slight influence according to Henri ("Lois générales de l'Action des Diastases"), and the writer has also observed this effect.

1 c.c. half strength malt extract. 1 hour, 40° C.

Starch Grms. per 70 c.c.	Maltose formed.	R.
2·82	0·245	8·7
1·41	0·234	16·6
0·70	0·216	30·8
0·35	0·184	52·6

Even if the above differences are entirely due to concentration (and it is probable the impurities in the starch play a part), it is obvious that the variations of concentration which occur in practice are negligible.

The purity of the starch is the most important factor, but as this has been so fully dealt with previously little more need be said, except that the influence of certain other factors will be conditioned by the nature of the starch, and further, as there is a tendency to an accretion of alkaline contamination during manipulation, it is advisable, for analytical purposes, to use a starch preparation containing a small amount of acid phosphates, the protective action of which has already been explained.

It is interesting to give here an example of the "diastatic power" of a malt, as determined with soluble starches bought from different dealers, and so presumably used by someone.

Starch.	No. 1.	No. 2.	No. 3.	No. 4.	No. 5.	No. 6.	No. 7.	No. 8.
D. P. Lintner's scale	34	33	32	30	27	20	15	6

These figures require no comment, save that they alone might serve as an apology for this communication.

3. Conclusions.

The writer hopes to extend his investigations with purer starch and diastase preparations. In the meantime his object is to call attention to the necessity of observing certain precautions in work of this nature, and he thinks his investigations (incomplete though they are) show that:—

1. Many of the extraordinary results obtained by various observers are due to a lack of recognition of the important influence of traces of impurity on the course of the action.

2. Diastatic (amylotic) action attains its maximum in neutral (in the sense that water is neutral) solution.

3. Asparagine does not augment the action, unless there has been a previous restriction. This holds also for the various salts which are said to accelerate the action.

4. The restricting influence of acids depends upon their dissociation, *i.e.*, the greater the amount of free hydrogen ions the greater the restriction; though it it possible that the anion of certain acids may have some influence.

5. Purified soluble starch, or starches, of various origins, give equal maltose productions, with equal amounts of diastase, under the conditions mentioned.

For much kindly and able assistance in the experimental and other work of this paper the writer is indebted greatly to his friend, Mr. J. M. Guthrie.

Meeting held at Glasgow on March 29th, 1904.

MR. D. J. PLAYFAIR IN THE CHAIR.

THE "IODINE VALUE" OF UNSATURATED ORGANIC COMPOUNDS.

BY HARRY INGLE, B.Sc., Ph.D.

In a recent paper read before the Scottish Section of the Society of Chemical Industry (this J., 1902, 587—595), I commenced the study of the action of the various iodine solutions which have been proposed for use in the determination of the "iodine value" upon two unsaturated substances of known constitution with special reference to the origin and nature of the free acid which has often been noticed as being formed during this reaction.

The following paper contains a record of further work in this direction, and forms an attempt to render the determination of the iodine value of use in structural organic chemistry.

Hübl, in 1884, when he proposed the use of his iodine-mercuric chloride solution for the examination of oils and fats, was of opinion that the numbers obtained by his method were a direct measure of the numbers of double linkages present in a substance. It was, however, found, on extending the examination to other unsaturated substances, that many (though doubtless unsaturated) did not absorb iodine in amount proportional to the ethylene unions present.

In the first table on page 423 some of the more important recorded iodine values given in the literature of pure or nearly pure specimens by different observers are noted.

A number of other iodine values, chiefly of the phenols and oxybenzoic acids, have been determined by Fahrion (*loc. cit.*), using Waller's solutions, but, for reasons later to be explained, the results obtained with this solution are not reliable.

Many striking divergencies between the theoretical and the observed values are to be noted in the above table, and, beyond a remark of Henriques (Chem. Rev., 1898, 121) in a footnote to one of Wijs' papers, no explanation of these differences has been given. Henriques says, in reference to the acids, crotonic, maleic, and fumaric: "Offenbar verlangt die Hüblsche Reaction einen grösseren Abstand der Doppelbindung von der Carboxylgrüppe."

The Various Solutions and the Results.

Wijs' Solution.—This was prepared according to Wijs' original instructions. Excess of chlorine was destroyed by boiling or gently warming (this J., 1902, 587). Time of action, 30 mins. to one hour.

Modified Hübl's Method.—Prepared and used in the manner previously described (this J., *loc. cit.*). Time of action, 16 to 18 hours.

In most of the cases recorded the two solutions give practically the same results. One or two exceptions may be noted, namely, stilbene and ethyl cinnamate, both of which yield higher values with Wijs' solution than by the other methods.

As the reactions taking place in the preparation of the iodine chloride solution and its interaction are mostly reversible, it is found necessary to have a large excess of iodine chloride present in most cases if a correct result is to be obtained. Various writers on the subject recommend an excess of from 50 to 70 per cent. in the case of oils.

That this is the case with other substances I have abundant evidence to prove. Thus a turpentine with 28 per cent. excess by modified Hübl's method gave an iodine absorption of 352, while with 69 per cent. excess a value of 367 was obtained.

Now in Wijs' solution the iodine exists for the most part as ICl, but in Hübl's solution, the quantity of ICl per unit volume is probably considerably less since the equation—

$$HgCl_2 + 2I_2 = HgI_2 + 2ICl$$

s never complete, there always remains a considerable amount of iodine free as is shown by the colour of the solution.

With Hübl's solution therefore, a greater excess is equired than with Wijs' solution, and under any circumstances the concentration of ICl and substance per unit volume can never be so great with the former as with the latter. This is doubtless the reason why Hübl's solution is slower in action than Wijs', and also why the latter sometimes yields higher results.

Modified Waller's Solution.—This was prepared by saturating Hübl's solution with dry HCl 50 grms. to the litre (this J., *loc. cit.*). There is reason to believe that in this solution the iodine chloride exists in a state of weak combination as ICl HCl. When addition of ICl from this solution takes place this double compound has to be decomposed, and such decomposition can only take place where the attraction of the double linkage for the ICl is greater than that exerted by the HCl. Negative groups attached to double linkages lower this attraction, and consequently substances containing such "protected" double linkages either do not absorb any ICl from this solution or do so very imperfectly. The amount of such "protection" exerted over a double linkage depends upon the nature of the negative groups attached to it. If the groups be strongly negative the substance does not absorb any ICl even from Wijs' (cp. Diphenylmaleic anhydride, &c.). The modified form of Waller's solution enables one to detect even a comparatively weakly negative group or groups attached to an ethylene linkage. The table given on page 425 illustrates this.

A more detailed consideration of the matter will be given under the group headings, but in general it may be

The determinations marked * were carried out with new preparations and those marked † with older ones: the different results are probably due to the fact that the action of light or the exposure to the air had rendered the preparation impure by forming polymerised or oxidised products.

stated that, if a double linkage is attached to one negative group addition may take place slowly; if it be attached to two negative groups the addition does not take place. If several ethylene bonds are present then the unprotected groups absorb ICl from this solution, while the protected groups, if they absorb at all, do so only slowly and incompletely. Very interesting results have been obtained with the phenols, which will form the subject of a subsequent paper. Thus, eugenol, which absorbs 415 per cent. of iodine from Hübl's solution (6 I = 462) the ring taking part in the absorption, gives an iodine value of 151 (2 I = 154) with this solution, only the side chain reacting.

The Formation of Free Acid during Hübl's Reaction.—This has formed the subject of a detailed paper read by the writer as before mentioned. It is therein shown that in the case of Stilbene and Styrolene its origin it not due to substitution, but that it is produced by the action of water upon the iodochlorides.

Its character is made evident by the colour change taking place in Wijs' solution. If HI be liberated, then by interaction with the ICl in excess free iodine is formed, and the colour of the solution changes to red brown. If only HCl is formed then Wijs' merely becomes paler in shade.

The above facts may be taken as applying in general to all substances examined.

Recent work by Walden (Ber., 1902, 2029) has thrown some light upon how the water acts upon the iodochlorides. He finds that compounds containing a tertiary carbon atom attached to a halogen atom are ionised in solution to a small extent, being, in fact, "carbonium salts" (compare the behaviour of tertiary iodides to water, A. Bauer, Ann. **220**, 158).

The presence of phenyl groups in such compounds increases their electrical dissociation (cp. Gomberg's triphenylmethylchloride and Walden, *loc. cit.*), and although of the few compounds already examined by Walden only the tertiary carbon atoms have any marked tendency to exist as ions, yet it appears likely that secondary carbon atoms may, under suitable conditions, also yield halogen compounds which are ionisable.

I am inclined, therefore, to attribute the formation of free halogen acid in Hübl's and Wijs' reaction to the ionisation and subsequent hydrolysis of the iodochlorides formed.

Styrolene iodochloride, for example, is probably ionised as follows:—

$$\begin{array}{c} C_6H_5-CH-CH_2I\ + \\ Cl\qquad\quad - \end{array}$$

both ions act upon the water present to form $C_6H_5CH.OH.CH_2I$ and HCl. The former is but little ionised, the latter completely, hence we get a tendency set up to change the iodochloride into the non-ionised iodohydroxyl derivative and the ionised hydrochloric acid.

Similarly stilbene iodochloride is ionised to—

$$\begin{array}{c} C_6H_5-CH.CH.C_6H_5\ + \\ Cl\,I\qquad\quad - \end{array}$$

which is in its turn hydrolysed to $C_6H_5CH.OH$ $CH.OHC_6H_5$ (non-ionisable) and HI and HCl (ionised almost completely). The HI, however, reacts with the ICl present in excess to form I_2 (non-ionised) and HCl, thus the concentration of the HCl in the solution is increased and a tendency is set up to split off the whole of the iodine from the iodochloride while by the action of mass the HCl prevents the splitting off of the whole of the chlorine ions from the iodochloride. This causes the reaction product to contain some chlorine as $C_6H_5CH.OH.CHCl.C_6H_5$ as was found by experiment (this J., 1902, 587—595).

Similar explanation may be given to the behaviour of other iodochlorides, *e.g.*, those of the eugenol benzoate and isoeugenol benzoate.

It is interesting to note that Walden finds the iodides more completely ionised than the chlorides.

Although rendered extremely probable, absolute proof that hydroxyl compounds result during the interaction of the iodine chloride solution on the water present and the unsaturated compound in the case of stilbene and styrolene was left still wanting in the paper already referred to (this J., *loc. cit.*).

The oily residue obtained after evaporating the chloroformic layer from a determination of the iodine value of stilbene by Hübl or Wijs refused to crystallise neither could a crystaline benzoate be obtained from it. It was considered to be a mixture of hydrobenzoin and isohydrobenzoin or their ethers (in the case of Hubl's solution).

A reaction which is common to both isohydrobenzoin and hydrobenzoin is their conversion into diphenyl acetic aldehyde by boiling with dilute sulphuric acid (20 per cent.).

The following experiment was carried out: 0·5 grm. stilbene dissolved in 20 c.c. of chloroform was mixed with 15 c.c. of water and then 60 c.c. of Wijs' solution added. The precipitate which at first formed was gradually dissolved on warming and the solution was coloured deep red-brown by the liberation of iodine. After standing 1½ hours it was poured into a separating funnel and water (250 c.c.) and potassium iodide and sodium thiosulphate solution added until all the iodine was reduced. The chloroform layer was run off, washed with water, and finally, the chloroform distilled off. The oily residue was mixed with 100 c.c. of water and 20 c.c. of concentrated sulphuric acid and boiled under a reflux condenser for 7 hours. The solution in the flask was then distilled in steam and the distillate (300 c.c.) which contained a nearly colourless oil shaken out with ether. On evaporation of the ethereal solution an oil was obtained which when dissolved in alcohol gave a small quantity of crystals (not examined). The oil reduced ammoniacal silver nitrate, gave a phenyl hydrazone and an oxime. It also restored the colour to magenta solution bleached by sulphur dioxide (Schiff's reaction) giving finally a very bright red-blue colour. The quantity of oil obtained did not admit of a more detailed examination, but these reactions show that it is an aldehyde and admit of no other conclusion than that the original substance was either hydrobenzoin or its isomer. Formulating the reaction we have—

$$C_6H_5 - CHOH - CHOH - C_6H_5 = (C_6H_5)_2CH.CHO + H_2O.$$

Reduction of the Iodochlorides by Potassium Iodide Solution.

In the paper already referred to I have shown that the iodochlorides of both stilbene and styrolene are reduced by the action of aqueous potassium iodide upon their alcoholic solution forming the original substance and liberating iodine. I showed also that in the determination of the iodine value of the substances correct results could only be obtained if the potassium iodide was prevented from acting upon the iodochlorides which could be done by adding water to the test solution so as to precipitate the chloroformic solution of the iodochlorides before adding the potassium iodide.* This alteration in the observed iodine value is still more marked with some other substances examined. The following table gives the iodine values obtained working in this way and for comparison those obtained by Hübl's solution and the free acid formed are likewise given.

The potassium iodide solution was allowed to stand in contact with the test 5 minutes in the experiment recorded in the last column. In all cases the blank test was mixed with the KI solution direct as there was here of course no fear of reduction.†

Errors arising from the neglect of this reduction have doubtless in the past led to the very varying results we find recorded in the literature for the iodine value of substances. This is specially to be noted in the case of the phenols the iodochlorides of which are very decomposable. The matter is still under investigation.

The results given in the above tables (pages 423—4) merit more special attention, and in the following they will be treated in greater detail.

---

* With regard to the iodine value of most oils the matter is of less importance, as Harvey points out (this J., 1902, 1437). This is because the iodine chloride solutions usually employed (Hubl's and Wijs') contain sufficient water to convert the whole of the hydrolysable iodochloride into hydroxyl derivatives which are not reducible by potassium iodide. If, however, the iodochloride of the oil contains a great amount of liberated halogen (some of which has not been split off during the test) as in the case of tung oil, then the addition of potassium iodide before water has a lowering influence on the iodine values observed.

† The addition of potassium iodide solution to the blank test before the addition of water prevents any decomposition of the HOI, which is formed by the action of water upon the ICl. In the paper referred to I stated in my recapitulation of results "that in all cases it is advisable to add water to the test solution before potassium iodide, so that any iodochloride which remains unchanged may, as far as possible, be removed from the sphere of action by solution in the chloroformic layer." It is obvious that in the above statement the "blank test" is not included, as Harvey seems to think (*loc. cit.*) because in this there is no "iodochloride" present. That if water be added to the blank test first, a loss of titrable halogen does result is in accordance with my experience, even if the KI is added immediately after the water, as the following results show:—

Water added first KI immediately run in 25 c.c. Wijs = 41·0, 41·0, 41·0 c.c. Thio.

KI added first water immediately run in 25 c.c. Wijs = 41·2, 41·2, 41·2 c.c. Thio.

Water added first stood 5 mins. then KI added 25 c.c. Wijs — 38·3.

In each case 13·4 c.c. thiosulphate solution = 0·2 gr. iodine. In the actual test as the concentration of the ICl (and hence of the HOI when the water is added) is greatly reduced by absorption there will be less tendency for the HOI to decompose on the addition of water, and hence no appreciable error will result, if water be added first, from this cause.

Group I.

Styrolene and Stilbene.—A detailed study of the behaviour of these two substances, and the properties of the iodochlorides has already been published. They are included in the above table for completeness' sake. The reason why the theoretical values were not obtained is probably that the substances had either become oxidised by exposure to air, or had been polymerised by the action of light (Ciamician and Silber, Ber., 1902, 4129).

The loosening influence of a phenyl group attached to a carbon atom, forming one of a double linkage is well exemplified by these two substances. This loosening influence is also a protective one, as is shown by the fact that stilbene refuses to absorb iodine chloride from the modified form of Waller's solution, while styrolene which contains only one phenyl group is able to decompose this double compound ICl, HCl.

Eugenol and Isoeugenol Benzoates.—These two substances form excellent examples of this property of the phenyl group. The formulæ of the two iodochlorides are probably as follows:—Eugenol benzoate iodochloride—

$$\underset{4}{(C_6H_5CO_2)}C_6H_3\underset{3}{(OCH_3)}\underset{\alpha}{CH_2}-\underset{\beta}{CHCl}-\underset{\gamma}{CH_2I}$$

isoeugenol benzoate iodochloride—

$$\underset{4}{(C_6H_5CO_2)}C_6H_3\underset{3}{(OCH_3)}\underset{\alpha}{CHCl}-\underset{\beta}{CHI}-\underset{\gamma}{CH_3}$$

In both cases 2I are absorbed per molecule, but in the former 23 per cent. of iodine appears as haloid acid (HCl), while in the latter 66 per cent. of iodine is converted into acid (HCl and HI) by the action of the water in Hübl's solution. The loosening influence of the phenyl group in both these compounds is strengthened by the presence of the benzoyl and methoxy groups, not only is the atom attached to the substituted phenyl group (the α atom) protected, but also the β atom, *i.e.*, has its halogen atom so loosened as to be split off by the action of water as haloid acid. The amount of halogen thus split off from the β atom in each case is nearly the same, namely, 23 and 19 per cent. expressed as iodine (assuming that with isoeugenol benzoate, the whole of the chlorine is split off as HCl).

In order to further explain the iodine values of these eugenol derivatives, it was determined to endeavour to isolate the iodochlorides of the benzoates.

Eugenol Benzoate.—1·9 grm. of the substance was dissolved in acetic acid, and 150 c.c. of Wijs' solution added. After standing 2 hours the solution was poured into 500 c.c. of water in a separating funnel and shaken out with ether. The ethereal layer was treated with dilute sodium thiosulphate, and then, after well washing with water it was evaporated. A good yield of crystals was obtained which, after recrystallisation from alcohol, melted at 91° C, forming shining pearly plates. It gave all the reactions of the iodochloride, liberating iodine by heating with strong H_2SO_4. Alcoholic silver nitrate gave a white precipitate of AgCl, showing that chlorine is first split off. Potassium iodide solution added to its alcoholic solution only very slowly liberated iodine.

Halogen Determination.—0·5406 grm. of iodochloride was dissolved in 50 c.c. alcohol and 1 grm. of KOH dissolved in 2 c.c. of water added. The whole was heated in a flask in the water bath and, when the alcohol had evaporated, 50 c c. of water were added, and the heating continued for 1 hour. Then 1 grm. of silver nitrate dissolved in water was run in, and dilute nitric acid added until the dark grey precipitate was replaced by a yellowish one. The precipitate was filtered off, washed with boiling alcohol, followed by dilute nitric acid, and weighed as usual. AgCl and AgI formed 0·4386; reduced Ag in filter paper ash, 0·0171 = 0·0301 Ag_2ICl: total Ag_2ICl = 0·4688 = 37·2 per cent. I + Cl; theory for $C_{17}H_{16}O_3ICl$ = 37·4 per cent. I + Cl. The substance is, therefore, eugenol benzoate iodochloride.

Attempts to prepare the iodochloride of isoeugenol benzoate on account of its instability proved futile.

The behaviour of these two substances to modified Waller's solution has already been noticed, but a few words on the subject may not be out of place. The negatively substituted phenyl group is able to exert a greater protective influence than a simple phenol group, although it is not able to completely protect both carbon atoms of the double linkage in isoeugenol benzoate. The following table gives the iodine absorption after various lengths of time of action, using Waller's solution as modified:—

—	Eugenol Benzoate.	Isoeugenol Benzoate.

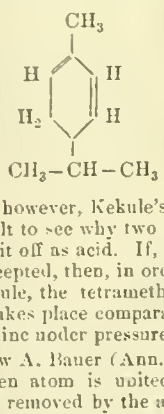
(For the reducing action of KI upon the iodochlorides, see p. 425.)

We thus see that if one of the carbon atoms of an ethylene group be attached to a strongly negative group, the latter protects, more or less, both carbon atoms from forming an addition compound.

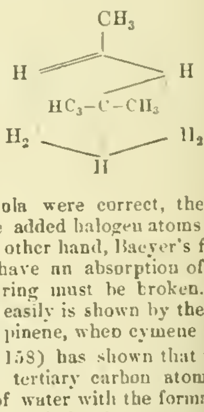
American Turpentine.—This was fractionated, and the fraction boiling between 155° and 157° taken. It probably consists of almost pure pinene. The results given in the table agree accurately with an absorption of 4I per molecule, and with the liberation of slightly over 2I as haloid acid (HI).

Schweitzer and Lungwitz' figures and those of Fahrion (*loc. cit.*) are likewise more nearly in agreement with 4I per molecule than with 2I, and the latter points out that this is better in agreement with Kekule's formula for this substance (I) than with that of Wagner-Baeyer (II.) Since the former requires an absorption of 4I, while Baeyer's formula without some intermolecular change only demands an absorption of 2I.

I.

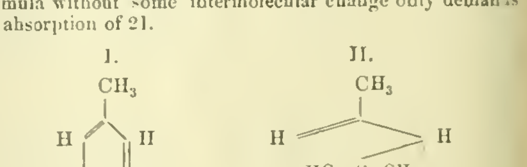


II.



If, however, Kekule's formula were correct, then it is difficult to see why two of the added halogen atoms should be split off as acid. If, on the other hand, Baeyer's formula be accepted, then, in order to have an absorption of 4I per molecule, the tetramethylene ring must be broken. That this takes place comparatively easily is shown by the action of iodine under pressure upon pinene, when cymene results.

Now A. Bauer (Ann., **220**, 158) has shown that when a halogen atom is united to a tertiary carbon atom, it is easily removed by the action of water with the formation of a tertiary alcohol. This is especially the case with the iodides (see also Walden above). If we assume that Baeyer's formula is correct then we must formulate the addition product thus—



Such a reaction would agree with observed facts. Against Baeyer's formula Fahrion further urges that Engler (Ber., **33**, 1900, 1669) shows that pinene absorbs four oxygen atoms per molecule, and hence must contain two ethylene groups. It does not however appear to the writer that in this case too a breakage of the tetramethylene ring is improbable with the formation of a similarly constituted peroxide, and he consequently does not feel justified in disputing the accepted formula of such a well-investigated substance on such meagre grounds.

The iodine values obtained by the use of modified Hübl solution and my modified form of Waller's solution with eugenol are interesting; with the former the ring takes part in the reaction, while with the latter only the side chain absorbs.

Triphenylmethane was examined because of its relationship to the very interesting triphenylmethyl of Gomberg. It behaves towards Wijs' solution as a saturated compound.

Group II.

Dicyanstilbene, cis and trans, and Diphenylmaleic Anhydride.—If we replace the two hydrogen atoms of the ethylene group in stilbene by either cyanogen or carboxy these two negative groups and the weakly negative phenyl groups are able to protect the double linkage from the attack of the halogen atoms of the iodine chloride solution (Wijs, Hübl, or Waller) and so these substances absorb no halogen. The behaviour of the two stereoisomeric dicyanstillbenes is of interest, but too great reliance should not be placed upon the results with the trans compound as it was of doubtful purity.

Aconitic acid. $CH_2 (CO_2H).C (CO_2H) : CH(CO_2H)$.—In this substance the two negative groups protect the ethylene union and hence no iodine absorption takes place.

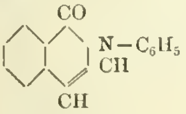
Maleic and fumaric acid contain similar groups, and hence, as Lewkowitsch has found, no iodine absorption results from their interaction with Hübl's solution.

Cinnamic Acid and its Derivatives.—Styrolene can absorb halogen even from modified Waller's solution. If we replace one of the hydrogens of the CH_2 group by carboxyl, we find that the substance resulting, cinnamic acid, has the power of absorbing only a very small amount of halogen even from Hübl's and Wijs' solution. The negative carboxyl group is capable of exerting a protective influence over the double linkage, and that, combined with the less strongly negative group phenyl, renders the substance capable of only absorbing a small amount of halogen. Cinnamic ether yields a higher iodine value with Wijs' solution than with Hübl's, probably because the concentration of the ICl in the former is greater than in the latter. The iodine value of the ether of cinnamic acid is more than that of the free acid because the introduction of the ethyl group lowers the negative character of, and hence the protection exerted by, the carboxyl group. If we render the phenyl group more negative by introducing a nitro group (as in o-nitro cinnamic acid) or an oxygen atom (as in coumarin) the protection is complete. Also if the carboxyl group be united to another acid group, as in dicinnamoyl tartaric anhydride,* the protection of the ethylene union is complete.

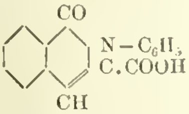
The protective influence of the negative group is here again a loosening one on any halogen that is absorbed, thus, ethyl cinnamate which absorbs 16I per cent. splits off 15·5I as acid.

The protective influence of the negative groups extends in proportion to their negative character, not only to the carbon atom to which they themselves are attached, but also to the other carbon atom of the double linkage as is shown in eugenol and isoeugenol benzoates, in cinnamic acid, and the other cinnamyl and cinnamoyl derivatives.

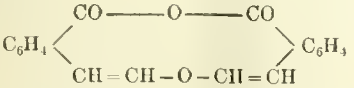
The behaviour of the three isocoumarin derivatives† is of interest, the constitutional formulæ of which are as follows:—



Isocarbostyryl.



Isocarbostyryl carboxylic acid.



o-anhydro oxyl vinyl benzoic anhydride.

In the first the CH = CH group has in direct union with it the weakly negative ring, and the weakly positive phenylimido group, hence we get absorption of halogen.

In the second, the carboxyl group neutralises in part the positive phenylimido group, and hence we do not get the full absorption. The substance behaves as a slightly more positive material than cinnamic acid.

If the formula for the third be correct it is difficult to explain the absorption of only two equivalents of halogen, instead of 4 atoms as theory requires.

Group III.

In structure the members of this group are related to styrolene, and to cinnamic acid.

Benzalacetone.—In this substance the carbonyl group has attached to it the relatively positive radical methyl, while the styryl group in virtue of the phenyl group is weakly negative. As the substance is able to absorb ICl from Hubl's solution the protective influence of the carbonyl group, manifest when in cinnamic acid, must here be neutralised by the methyl group. One of the added halogen atoms is, however, loosened, probably by the phenyl, and is split off as acid by the action of water, and as the substance does not liberate iodine from Wijs' solution that atom is chlorine. The formula of the iodochloride is probably $C_6H_5CHClCHI.CO.CH_3$. The iodochloride was isolated.

Benzalacetone Iodochloride.—One gram of the ketone was dissolved in acetic acid, and 100 c.c. of Wijs' solution added. After two hours the mixture was poured into water (250 c.c.) and the crystals which formed on standing filtered off. Recrystallised from alcohol, in which it is easily soluble, it was obtained in colourless needles, melting at 59—60° with decomposition. The alcoholic solution of the compound liberated much iodine when treated with potassium iodide solution. Silver nitrate gave first a white precipitate and then gradually a yellow one when added to its alcoholic solution, showing that chlorine was first split off. The substance was rapidly decomposed by the action of light. It was not further examined.

Dibenzalacetone.—This substance might be expected to absorb 4I per mol., but, as the table shows, actual experiment gave 2I per mol. and 1I split off as acid HCl. The oxygen of the carbonyl is evidently able to protect one styryl residue but not the other.

Benzalcinnamylidenacetone.—

$$C_5H_6-CH=CH-CO-CH=CH-CH=CH.C_6H_5$$

This substance, which does not appear to have been prepared before, was obtained by Claisen's method, namely, by the action of cinnamic aldehyde upon benzal acetone in presence of caustic soda. It was obtained as golden yellow shining needles after recrystallisation from alcohol melting at 108°. With concentrated sulphuric acid it gave a dark red colour, and was easily soluble in most organic solvents. The iodine values recorded in the table, instead of being 6I, are 4I per mol. with 2I split off as acid HCl.

Dicinnamylidene Acetone.—Here again the oxygen of the carbonyl appears to be able to protect one double linkage for instead of 8I only 6 are absorbed.

The behaviour of these derivatives of acetone to modified Waller's solution is interesting.

—	Iodine Value. Modified Waller.	Theory.
Dibenzalacetone	27	$\frac{1}{2}$I = 28·3
Benzal cinnamylideneacetone	24	$\frac{1}{2}$I = 24·2
Dicinnamylideneacetone	118	$2\frac{1}{2}$ = 111·2

The protective influence of the phenyl groups is well shown. In the last compound one of the ethylene unions is too far removed from this protection to exert itself, and hence is able to absorb 2I, and the remaining $\frac{1}{2}$I is due to the same cause as the $\frac{1}{2}$I absorbed by the other two substances, whatever that may be.

---

[*] I have to thank Mr. Dakin, B.Sc., of the Yorkshire College, for this specimen.

[†] I have to thank Dr. Wm. Frew, of Perth, for these three specimens.

Benzal Acetophenone.—The absorption of nearly one I per molecule from Hübl's solution and over I from Wij's is probably due to the different concentration of the ICl in these two solutions as already mentioned.

Old specimens of all these benzal derivatives show lower iodine values than freshly prepared ones; this is probably due to either oxidation or polymerisation of these substances by the action of light (compare Ciamician and Silber's results with Stilbene, *loc. cit.*)

Group IV.

The action of ICl upon triply linked carbon atoms has been but little studied, never quantitatively. Plimpton (Chem. J., **41**, 392) obtained C_2H_2ICl by passing acetylene into a solution of ICl in HCl. McGowan (Pr. E., **9**, 589), obtained the same substance using an etherial solution of ICl. Stolz (Ber., **19**, 538) by boiling propiolic acid with an ethereal solution of ICl obtained chloriodo acrylic acid $CHI = CCl.COOH$ or $CHCl = CICO_2H$. Dichlor-di-iodo-ethane does not appear to have been prepared, but Henry (Comptes rend., **98**, 518), by the action of ICl upon C_2H_3Cl, obtained dichloroiodoethane.

As far as I am aware no attempts have been made to determine the iodine value of triply linked carbon atoms.

In the foregoing table the only acetylene derivatives examined are those in which a certain amount of protective influence is exerted by the groups attached to the two carbon atoms.

The tolane used was a slightly impure specimen obtained by the action of sodium ethylate upon stilbene dibromide. The difference in its behaviour to Hübl's and to Wijs' solution is doubtless due to the different concentration of the ICl in the two. It is interesting to note that the amount of acid formed in Hübl's solution bears nearly the same relationship to the total iodine absorption as in the case of stilbene.

That orthonitrophenylpropiolic acid absorbs exactly 2I or ICl is in accordance with Stolz's observations with propiolic acid above cited, but why *o*-nitrophenyl acetylene absorbs no halogen at all is difficult of explanation.

The Phenols.—In two or three places in this paper the iodine chloride absorptions of various phenols and phenolic derivatives have been given. The free phenols appear to behave as unsaturated cyclical ketones, whereas their benzoates react like saturated compounds.

A detailed examination of the various isomeric di- and trihydroxy benzenes and of the naphthols is in hand, and will form the subject of another paper.

Conclusion.—No general theory affords a complete explanation of all the results obtained in this research, but some help is afforded by Thiele's Theory of Partial Valencies (Annalen, **306**, 87—142) and the assumption of the tetravalency of oxygen in many of these compounds, *e.g.*, in the benzalacetones (cp. Baeyer and Villiger (Ber., 1902, 1189; Walden, Ber., 1901, 4185). The matter is, however, merely of theoretic interest, and for practical purposes the results of of the research are:—

(1) A confirmation of the conclusion arrived at in my previous paper, namely—

- (*a*) That the unsaturated compounds absorbs ICl from the various solutions.
- (*b*) That no substitution takes place during Hübl's and Wij's reaction.
- (*c*) That the acid formed is due to the action of water upon the iodochlorides.

They further show (2) that the amount of acid formed, depends probably upon the ionisation and subsequent hydrolysis of the iodochlorides by the water present. The amount of this hydrolysis is dependent upon the nature of the groups attached to the double linkage.

(3) The presence of aromatic groups, and of negative groups in an unsaturated compound attached to the ethylene union tend to lessen its attraction for iodine chloride to an extent proportionate to their negative character. The lessening of the attraction is manifest in the refusal of such substances to absorb iodine chloride from a solution containing it in weak combination with hydrochloric acid and by the increased hydrolysis of the iodochloride in Hübl's reaction.

(4) Further proof is given that the iodochlorides are reducible by the action of aqueous potassium iodide, and this reduction is thought to have been a fertile source of error in the past in the determination of the iodine value of unsaturated compounds.

(5) It is shown how by determining the iodine value of a substance by the various solutions and the amount and nature of the acid formed by the hydrolysis of the iodochloride some information may be obtained as to the probable position of the ethylene unions in the molecule.

(6) The triply linked carbon pairs seem to exert less attraction for iodine chloride than doubly linked.

I have to again thank the directors of Messrs Barry, Ostlere, and Shepherd, Ltd., for the use of their laboratory, and my assistant, Mr. Ernest Wake, for his help in carrying out the experimental work recorded in this paper.

THE ANALYSIS OF WATERS, AND THEIR CHANGES IN COMPOSITION WHEN EMPLOYED IN STEAM-RAISING.

BY R. R. TATLOCK AND R. T. THOMSON.

It would appear that, owing to the numberless more or less valuable text-books on water analysis, and the various papers on the same subject which have appeared in chemical journals, there would be little or no room for anything further to be said on this subject. But in straining after something original analysts have too often suggested the abandonment of what is of real value, in favour of what appears at first sight to be a genuine improvement, but which is in reality only superficial. This desire for something new seems to be so absorbing at the present day that we are constantly presented with crude and undigested methods of analysis, and it is to combat this spirit that, to some extent, our present paper is written. Not that we do not wish for changes for the better, but we would beware of abandoning things of real value, while at the same time we ought to go on improving our methods of analysis, accepting such modifications as are likely to be of permanent value, and relegating to their proper place such modifications in method as seem to be made solely for the sake of change.

In the present paper we intended to take a wider scope than we shall be able to take, owing mainly to lack of time to work up the subject as fully as we should have desired. We shall therefore in the first place give a few notes on certain particulars connected with the analysis of waters, and then consider the behaviour of a special variety of water when employed in a boiler for steam raising.

Temporary Hardness.—We shall in the first place deal with the determination of temporary hardness, the soap solution method for which is now rightly viewed as an unreliable and extremely empirical one. The only truly scientific method is that by titration with a standard acid, and employing some indicator to determine the end-reaction. The original indicator proposed by Hehner for this purpose was methyl orange, which was first introduced for the determination of alkali by Lunge about a quarter of a century ago. Many indicators have been brought forward to supplant it, but for its special purposes Lunge's Indicator undoubtedly still holds the field. Taking the special case of the determination of the alkalinity of water we find alizarin as one of the most recent candidates for favour, because the end-reaction is more delicate. The fatal objection to it for rapid analysis is that the solution requires to be boiled to expel carbonic acid, and it must be remembered that one boiling is not sufficient, but it must be boiled after each addition of acid to bring back the colour: and if this is not carefully and thoroughly done either a false result or an indistinct end-reaction will be obtained. Some years ago one of us showed that with lacmoid a more delicate end-reaction was obtainable (in fact quite as delicate as with alizarin), but that the great objection there also was the fact that one had to resort to boiling, exactly as in the case of alizarin. To obviate this trouble of discovering the end-reaction it is suggested to add excess of standard acid, then boil to expel carbonic acid, and titrate back with standard caustic alkali.

But this does not mend matters, as the boiling has still to be done, and we have the extra trouble of working with two standard solutions in place of one. Now, with methyl orange the great advantage is that the cold water can be titrated direct with standard acid, and although the end-reaction is not so delicate as with alizarin, yet quite as accurate a result can be obtained if the proper precautions are taken Indeed the slowness of the end-reaction of methyl orange may be almost regarded to a certain extent as a merit, as the first change in colour (especially in the titration of waters in which there are seldom such a proportion of neutral salts as would injuriously affect the end-reaction) is usually distinctly observed with, at most, 0·1 c.c. of N/10 acid. The first change ought to be taken as the end-reaction, and the intensification of the colour by further addition of acid will serve to corroborate the first impression. Working in this way we easily obtain results quite as reliable and accurate as can possibly be obtained by alizarin or any other indicator. Of course it is well to know the capabilities of all indicators, as it may happen that in certain circumstances methyl orange might not be available, and one of the others could be used in its place if the conditions under which it can be employed are known.

In titrating in this way, carbonate (or bicarbonate) of sodium, which is very often present in pit waters, would be included with the carbonates of calcium and magnesium as temporary hardness. To determine the carbonate of sodium we evaporate a measured quantity of the water to one-fourth of its original volume, filter through a dry filter, and take a measured portion of the filtrate for the determination of carbonate of sodium by standard acid.

Chlorides.—The determination of these seldom presents any difficulties, the titration with standard silver nitrate, and the employment of potassium chromate as indicator, being usually sufficient. Difficulties arise, however, when we have to deal with mossy or peaty waters and with waters containing acids or iron salts. With mossy waters, which are also sometimes acid, we have found the best mode of dealing to consist in adding some calcined magnesia to a portion (not necessarily measured) of the water, and agitating thoroughly for a few minutes. In this way, acid, if present, is neutralised, and the mossy or peaty matter is precipitated and removed from solution, while the magnesia remains practically insoluble. All that is then necessary is to filter through a dry filter, and titrate a portion of the discolorised water with standard silver nitrate solution.

Acid waters are treated with magnesia as just discribed, and so are waters containing iron, but in the latter case a few drops of hydrogen peroxide should be added in order to convert any ferrous compounds into the ferric condition. The magnesia then removes the iron wholly, and it only remains to filter the mixture and estimate the chlorides in the solution as before.

Nitrates and Nitrites.—The determination of nitrates in a water is in our opinion one of the greatest importance, at least in the case of water intended for dietetic purposes, and therefore an accurate and speedy method is of great value. We have come to the conclusion that, when properly adapted, the phenol-sulphonic acid method is decidedly the most handy and reliable. In natural waters, however, there are two ingredients which are fatal to a correct determination of nitrates, namely, organic matters, especially the brown mossy or peaty organic matter, which is so often present in the waters we are familiar with in Scotland, and the chlorides of magnesium and sodium. For the removal of organic colouring matters, such as is found in mossy waters, there is nothing superior to agitation with calcined magnesia as already described under the letermination of chlorine. We have found that when hlorine is present to the extent of 3·5 grs. per gallon (5 parts er 100,000) of chloride of sodium, only about 60 per cent. of the whole is obtained, and when 21 grs. per gallon 30 parts per 100,000) are present, only about 34 per cent. s obtained. These proportions are, however, only roughly pproximate, as we have found that the results in presence f the same proportion of chlorides are somewhat erratic. n order to obviate this adverse influence of the chlorides, lason in his book on the "Examination of Water" commends the use in the standard of the same proportion of chlorides as is present in the water being tested, so as to counterbalance their influence; but owing to the somewhat erratic effect of the chlorides we came to the conclusion that it would be more satisfactory to remove them entirely. For this purpose we have applied and adapted the method which is employed for the removal of chlorides from crude glycerine in testing the strength of that article by the bichromate method. This consists in agitating the sample with excess of silver oxide, which removes the chlorine in the form of silver chloride. When treated in this way, however, a considerable proportion of silver remained in solution, apparently as oxide, and this was deposited on evaporation of the filtrate to dryness for treatment with phenol-sulphonic acid, which soon converted the brown silver oxide into sulphate. The silver compound seemed to have the rather unexpected effect of lowering the result for nitrates, although not nearly to the same extent as, say, 3 grs. of sodium chloride per gallon. We were thus compelled to work with a limited supply of silver oxide, adding just enough to convert all the chlorides into silver chloride, this being determined by the usual volumetric method. When this was carried out the exact proportion of nitrates present was obtained, but considerable difficulty was experienced in obtaining a clear filtrate, as traces of silver chloride passed through the filter. This difficulty was also overcome by the use of a little aluminium sulphate followed by calcined magnesia. The final method adopted was therefore as follows:—100 to 200 c.c. of the water are treated with enough silver oxide, in a fine state of division, to decompose the chlorides, the proportion of which had been previously ascertained. After agitating thoroughly, a little aluminium sulphate (say about 0·1 gr.) is dissolved in the mixture, then excess of calcined magnesia is added, and the agitation continued for a minute or two. In this way the chlorides and organic matter are entirely precipitated, and are then filtered off through a dry filter, when the filtered solution will be found as free from colour as distilled water. A portion of the filtrate (50 to 100 c.c.) is now evaporated to dryness over an open water-bath, and the residue tested for nitrates by the well-known phenol-sulphonic acid method. A number of test experiments showed that in every case the whole of the nitrates, added to a water containing comparatively large proportions of chlorides and organic matter, was obtained by this method of determination.

The next point which arose for consideration was the effect of nitrites on this determination, but it was clearly shown that this was almost nil, or that their presence only slightly raised the proportion of nitrates. This fact suggested to us the idea of applying the phenol-sulphonic acid method to the determination of nitrites also, provided these could be readily converted into nitrates. The ideal reagent was soon found in hydrogen peroxide, which suits admirably for the purpose in view. To determine the nitrites, therefore, it is only necessary to remove the chlorine from, and render colourless, a quantity of the water to be tested, exactly in the manner just described. In such dilute solutions as generally occur in waters there is no danger of any nitrite being precipitated by the silver compound. A portion of the treated water is tested for nitrates, and to an equal portion there is added a little hydrogen peroxide, and the mixture evaporated to dryness. The nitrites which existed in the water are now present in the residue in the form of nitrate, and it only remains to apply the phenol-sulphonic test, then subtract the nitrates actually present in the water as such from the total nitrates now obtained, and calculate the remainder to nitrites, or to bring these compounds to nitric and nitrous nitrogen respectively. Of course it would be advisable to make certain of the presence of nitrites by one of the well-known colour tests for these compounds.

Having disposed of certain points in the analysis of water, we shall now go on to consider the second part of our subject, which is the behaviour of a special variety of water when employed in a boiler for steam-raising. The particular class of waters we refer to is the alkaline variety, or such as contain notable proportions of bicarbonate of soda, and consequently no neutral salts of calcium and magnesium. These waters are generally found at a great depth in the earth, one which we analysed being obtained from about 840 feet below the surface. The water from coal pits, for instance, often contain comparatively large proportions of bicarbonate of sodium.

In order to trace from the beginning what changes in composition occur when waters of this class are employed for steam raising, we shall first observe what takes place as the water passes through the heater. The following are analyses of boiler feed water before and after passing through the heater :—

	Grains per Gallon.	
	Before passing through Heater.	After passing through Heater.
Carbonate of calcium	11·74	3·63
Carbonate of magnesium	8·60	7·96
Carbonate of sodium	1·03	1·19
Sulphate of sodium	20·52	19·61
Nitrate of sodium	0·15	0·15
Chloride of sodium	2·73	2·69
Organic matter	0·10	0·08
Total solids	44·87	35·31
Hardness	21·98	13·10

The chief point to observe here is the result, not perhaps wholly unexpected that while no less than 70 per cent. of the carbonate of calcium in the water has been deposited while passing through the heater, only 7 per cent. of the carbonate of magnesium has been so removed. This reversal of the relative proportions of the calcium and magnesium compounds in the water appears to be largely to the advantage of the water for boiler purposes, as the hydrate or oxide of magnesium formed within the boiler is a much lighter and less compact deposit than the carbonate of calcium, and thus helps to prevent the latter from forming a scale in the boiler. This, at least, is the conclusion we draw from an examination of the deposit from such a water as this, which is in the form of a light granular powder or sludge, and which apparently does not adhere to any great extent to the boiler.

In the next place we shall go on to consider what takes place in the boiler after the water has left the heater. We do not here deal with the same water as that with which we have been showing the effect of passing through the heater, because we could not obtain the residue from the same water after concentration in the boiler, and also we thought it would be better to work upon a water which was more pronounced in its alkalinity. The following is the analysis of the water after it had passed through the feed-heater :—

	Grains per Gallon.
Carbonate of calcium	1·97
Carbonate of magnesium	4·22
Carbonate of sodium	22·26
Sulphate of sodium	12·15
Nitrate of sodium	0·10
Chloride of sodium	2·28
Organic matter	0·30
Total solids	43·28

After being used in a boiler which had been five weeks under steam, the water had the following composition :—

	Grains per Gallon.
Carbonate of sodium	949·76
Hydroxide of sodium	123·20
Sulphate of sodium	776·39
Nitrate of sodium	0·85
Chloride of sodium	136·97
Silica and alumina	0·34
Organic matter	2·20
Total solids	1989·71
Suspended matter	1094·00

It has been stated that waters containing carbonate of sodium are apt to cause priming in a boiler, but we are assured that there has not been the slightest tendency in this direction with the water under consideration. It has also been stated more recently that waters containing sulphate of sodium have also the same objectionable quality, but although we have no less than 776 grs. per gallon of this compound in the concentrated water, it is absolutely devoid of the property assigned to it. From our experience the subject of priming is a very obscure one, and the most contradictory statements have been obtained by us on this subject. It is our opinion that in the positive statements as regards priming all the conditions have not been taken into account, but that probably because carbonate of sodium or sulphate of sodium happened to be present in excessive proportion when priming took place these were credited with the defect. These facts show clearly that at present no definite conclusion can be drawn from an analysis of water as to whether it is likely to cause priming or otherwise. It will be observed in this case that 1,000 galls. of the water have been concentrated to 20 galls., or to exactly one-fiftieth of their original bulk, and at the same time 15 per cent. of the total carbonate of sodium has been converted into hydroxide. This transformation is not altogether unknown, but has been referred to by Mr. Arthur E. Leighton in his "Note on Boiler Water containing Sodium Carbonate," which appeared in the *Chemical News* for February 6th, 1903, but he does not state any theory as to the origin of the caustic alkali. From a consideration of the whole matter we think it probable that the magnesia produced from the carbonate of magnesium acts slowly as a causticising agent at the high temperature inside the boiler. To make this clear, let us take into account the suspended matter in the water of which we last gave the analysis, and which amounted to about 1,000 grs. per gallon, and had the following composition :—

	Per Cent.
Carbonate of calcium	45·76
Oxide of magnesium	14·18
Oxide of iron	4·94
Siliceous matter and clay	25·32
Carbonaceous matter, &c.	9·80
	100·00

Here, then, in the presence of about 950 grains per gallon of carbonate of sodium, we have the carbonate of magnesium entirely decomposed and converted into oxide It is now plain that there is nothing in solution which could possibly causticise carbonate of sodium, and in suspension the only possible agent is the oxide of magnesium or magnesia. We have made trials by boiling carbonate of sodium solution with calcined magnesia, but no causticising has taken place. It might naturally be anticipated, however, that the higher temperature inside the boiler would favour the action of the caustic magnesia on the carbonate of sodium. We intended to follow up this matter, but more time was required than we could devote to it, and also an apparatus which we could work under a high pressure, and from which we could allow carbonic acid to escape at intervals without allowing the temperature to fall sensibly. But in the absence of experimental proof there are certain deductions which may be drawn in support of our contention from other analyses which we now propose to lay before you. The following analysis is that of an alkaline water which was used in four different boilers :—

	Grains per Gallon.
Carbonate of calcium	4·45
Carbonate of magnesium	1·92
Carbonate of sodium	25·07
Sulphate of sodium	2·56
Chloride of sodium	7·39
Nitrate of soda	None
Organic matter	0·40
Total solids	41·79
Hardness	6·73

We have next partial analyses of the residual waters from the four boilers in which the above water was employed :—

	Grains per Gallon.			
	No. 1.	No. 2.	No. 3.	No. 4.
Carbonate of sodium	226·3	1,365·3	979·3	319·0
Hydroxide of sodium	47·6	392·0	358·4	156·8
Percentage of the carbonate of sodium causticised	21·0	28·0	32·0	39 0
Number of galls. to which 1,000 galls. of the original water had been concentrated	86½	13¼	17¼	47½

No. 1 is the concentrated water from a boiler which had been 1,100 hours under steam, and had been working at a pressure of 45 lb., or a temperature of about 274° F. The other three waters were from boilers which had been worked at a pressure of 140 lb., or a temperature of 353° F., but No. 2 had been under steam for 242 hours, No. 3 for 160 hours, and No. 4 for 74 hours.

From these data the conclusions to be drawn are obvious. First, the length of time during which the evaporation takes place does not throw any light on the greater amount of caustic alkali produced in the one case than in the other. Thus in No. 1, which was from a boiler which had been 1,100 hours under steam, only 21 per cent. of the carbonate of sodium had been causticised, or in other words 9 oz. of hydroxide of sodium had been produced from every 1,000 galls. of water; whereas in No. 4, the boiler having been only 74 hours under steam, no less than 39 per cent. of the carbonate of sodium had become causticised, or 17 oz. of hydroxide of sodium had been produced from 1,000 galls. of the water.

Second, the proportion of hydroxide of sodium formed does not appear to be influenced by the extent to which the concentration of the water is carried. This is clearly proved by a comparison of No. 2 with No. 4, because in the former case, where the concentration was from 1,000 to 13¼ galls., 12 oz. of hydroxide of sodium had been produced; while in the latter case, where the concentration was from 1,000 o 47½ galls., no less than 17 oz. of hydoxide of sodium were formed. This appears to prove the point conclusively, but it must be conceded that the results are somewhat erratic, which is not altogether surprising.

Third, the only element which has any real controlling power is the pressure. or, in other words, the temperature. n No. 1, although the evaporation had been proceeding or 1,100 hours, only 9 oz. of hydroxide of sodium had een produced per 1,000 galls. of water, whereas in No. 4 o less than 17 oz. had been produced. This is corroborated by the results of Nos. 2 and 3, but the distinction n these two cases is not quite so striking. These results, hen, although erratic to a certain extent, are on the whole ery significant, and point to the temperature as being the ntrolling factor in the greater or less production of ustic alkali from the carbonate of sodium, and the only edium which we can suggest as assisting in this decomposition is the magnesia. We should here state that the ustic alkali produced during the evaporation in the boilers hurtful to the brass fittings, and it is only in this respect at these alkaline waters have given any real trouble. We ave to thank Messrs. The Glasgow Coal Co., Ltd., for eir kindness in providing us with samples of water, and in ving us such information as would guide us in our instigation.

We thus bring to a conclusion our remarks on this bject for the present, and trust at a future time to prove disprove the theory which we have just brought forward, l also to deal further with the problems presented by ter analysis.

Yorkshire Section.

Meeting held at Leeds, on March 21st, 1904.

MR. JAS. E. BEDFORD IN THE CHAIR.

COAL WASHING.

BY W. M D. MACKEY, F.I.C.

The importance of coal washing from a national standpoint justifies any attention that the chemist can give to the subject, and one reason that, apart from the laboratory examination of coals, it has hitherto received scant attention, from the English chemist at least, lies in the fact that to control actual coal washing at the pit, more especially when a washing plant is in difficulties, which from the nature of the work often happens, necessitates working in very unpleasant surroundings, amid sludge and water black with coal dust in suspension. The separation of shale or dirt from coal will become of more and more importance as our thick seams of coal remaining to be worked become fewer. Indeed, even now many collieries only exist owing to the introduction of coal-washing plant, and as the thinner seams have to be worked, often with serious dirt partings in them, it will be found in many cases that the only possible course is to "win" these seams, using coal-cutting machinery, and sending the bulk of the seam to the washer. House and steam coal are generally cleaned by hand, that is the lumps of shale picked out by hand. "Nuts," "beans" "peas" (or "slack" containing all these, with the addition of dust), are washed, or rather are capable of being washed. Washing consists in treating coal for the removal of intermingled shale or dirt, taking advantage, for that purpose, of the difference in specific gravity between shale and coal.

There are, I understand, shales lighter than coal, but for practical purposes it may be assumed that the shale or dirt is the heavier, and as a rule a coal is easy to wash, in proportion as the shale or dirt is heavier than the coal. Water is a medium which, with proper manipulation, readily carries the coal away from the heavier shale or dirt. Dirt may be divided into three classes :—

(1) Dirt mixed with the coal proper; for example, "brasses" or pyrites.

(2) Dirt partings in the seam, *i.e.*, thin layers of shale which run laterally with the seam, and which the miner necessarily brings down with the coal.

(3) Dirt below or above the coal, which it is sometimes necessary or desirable to remove in the process of coal-getting.

"Holing" in the dirt as opposed to "holing" in the coal refers to the practice of making use of a dirt lying either at the roof or floor of the seam, or separating the seam into two or three strata, for the purpose of undermining in order to allow of the coal itself being got out, or "let down" as it is termed. In "holing" in the coal, on the other hand, several inches of the coal itself are cut away, and so rendered of small value. The difference in practice depends to some extent on the custom in the particular mine, and on the hardness of the shale compared with the coal, the men preferring, of course, to hole or undermine where it is easiest.

As to the effect on the coal. Take first "holing" in the dirt. If the dirt be carefully removed before the coal is let down, a coal clean, at any rate from added dirt, should be the result, but in practice it usually adds to the percentage of fine dirt in the coal. In the case of "holing" in the coal, the result is a large percentage of fine dust in the coal, with increased difficulties in treating the coal afterwards in the washer.

It may be presumed that all coals containing dirt or shale are capable of being washed. The question resolves itself into one of cost, and the enhanced value of the resulting washed coal. Thus, if a colliery owner loses 10 per cent. in dirt washed out, and only realises 10 per cent. enhanced price on his washed coal, he is in a worse position than if the coal had been sold unwashed. But in reality the question is one of making a marketable article of what is unsaleable, or only saleable with great difficulty. In the case of small coal frequently what unwashed would be totally wasted is made into a valuable coking smudge.

The simplest and probably the earliest form of washer was the trough, consisting of a trough or spout usually with wooden sides, and in the later forms glass slabs on the bottom to withstand the action of the water and grit.

The trough is about two feet wide, and set at a slight slope, and extending as a rule not less than 40 feet. Down this the water runs, carrying the coal, and dams set at intervals catch the dirt, and the clean coal passes on. These troughs are usually worked in pairs, one being cleaned whilst the other is at work.

The modifications of the trough form a class which we may take first. *Thus, in the "Elliot" washer, an endless belt of dams is made to travel up against the flow of water and coal, delivering the dirt at the upper end. The "Murton" consists of an endless belt of steel trays with dams attached, carrying the dirt against the flow of coal and water, and delivering it at the upper end. In the "Muscamp" the dirt is made to travel to the upper end by means of a screw (the screw in this case forming the dams), and lastly, the "Blackett" consists of a steel tube or cylinder (30 feet long, 4 feet wide) which turns as the coal and water flows from one end to the other, the tube being laid laterally at a slight slope. A screw is attached to the inside of the tube, and as the tube revolves, the dirt falling behind this screw, which forms a continuous dam, is taken to the upper end of the tube and discharged. The coal to be treated (along with part of the water) is delivered by a stationary spout running to about the middle of the tube, and the dirt gets a further washing when it passes this point by a stream of water which enters at the upper end.

To a second class belong washers of the jigger or pulsating type. This includes the German washers, the "Luhrig," the "Humboldt," the "Baum," and one at least of English make, the "Sheppard."

Washers of this type consist essentially of a grid through which water rises and falls, being actuated either by a ram or compressed air. Water and coal are led on to the upper surface of the grid at one end, and the clean coal, which is separated from the dirt by the quick upward jig of the water, is discharged with the stream of overflow water at the other. The dirt, which forms a lower layer, partly finding its way through the grid and partly being discharged into the chamber below by an opening at the further end of the grid, collects in the bottom of the chamber, and is brought out by a screw conveyor. In some cases the grid is covered with felspar, through which the dirt makes its way, and usually a washer consists of several chambers and grids for coals of different sizes, the most vigorous pulsations being given to the water for the larger sizes. In the "Baum" washer, in its latest development, all sizes are treated over one grid, and the coal sized after washing.

A third class is represented by the "Robinson" washer, which consists of a cone, into which the coal is charged at the top, and an upward current of water, which overflows at one side, carries with it the clean coal, whilst the dirt sinks and is removed by a false bottom arrangement. The separation of the coal and dirt in the washer is facilitated by moving arms or paddles.

Recently, as a fourth class, we have table washers of the gold-washing type. Of these the "Craig" is the best known in England. It consists of a steel table, on to which the coal, previously mixed with water, is led, and over which the clean coal floats and is discharged at the further end, whilst the dirt, by an ingenious back bump arrangement, is caused to travel in the opposite direction and to be discharged off the table. In this way very fine or ground coal can be washed, but the rate of washing is slow, not exceeding five tons per hour.

In choosing a type of washer one will be influenced by cost, but in connection with this it should be remembered that the accessories, bunkers, *viz.*, riddles, elevators, pumps building, &c., usually overshadow the cost of the actual washing plant. The quantity of coal to be washed is also an important factor. If over say 40 or 50 tons an hour is to be washed, I would prefer a washer of the pulsating type, which, in the German pattern at least, is expensive in the first cost. Also, if the coal is friable, a washer of the pulsating type will make least breakage. The Westphalian coal is easily broken, also the collieries are large compared with the majority of English collieries, and there one usually finds washers of this type. When say 20 to 30 tons an hour or less have to be washed, cheaper types can be economically employed, always choosing one that has the least number of moving parts exposed to the action of the water charged with grit and fine coal, as this is severe on iron or steel parts moving in it. If a coal is difficult to wash owing to the difference of specific gravity between the coal and shale being small, it is advisable to provide ample washing plant so that the washing under such circumstances is not pushed. With all sizes down to "peas" the problem is simple; but with slack containing much dust the difficulties increase, owing to the formation of slurry, *i.e.* water charged with fine coal, which separates with difficulty. Here, economy of water per ton of coal washed is of the first importance.

The water in almost all cases is pumped over and over again, and unless special precautions are taken to ensure some degree of clarification, the washing becomes unsatisfactory. I have not estimated accurately the amount of water pumped per ton of coal washed, but I consider three tons a minimum, and it may rise to 7 and 12 tons.

The washing of slack (that is coal capable of passing through say $\frac{3}{4}$-in. hole) containing much fine is a problem of increasing importance, owing to the old custom of using hand riddles in the pit disappearing. Formerly the colliers riddled the fine out before filling into the tub—the fine being left in the pit and wasted. Now the tendency is to fill the coal unriddled, and more and more fine reaches the washer. This finds its way to the well, forming sludge, which is a constant source of annoyance. It is necessary to keep it moving, as if it accumulates, say, in settling tanks, it is not only useless but a source of danger if put on the pit heap. If it is kept uniformly mixed with the other coal, in the case of coking smudge, it improves the quality of the coke for some purposes. Small dredging buckets plying in the well is one method which I have used myself with some success. Sometimes in the case of small plants the washed slack and water are both discharged on to coal in the bunkers, which is fairly effective, but entails the raising o three or four times the weight of the coal in water, unless the plant is so favourably situated that the coal and wate can gravitate to the bunkers. Many, and sometimes very elaborate, systems have been devised for dealing with th slurry difficulty, but a satisfactory solution of the proble is still wanted.

It is claimed for washers of the German pattern that the deal successfully with coal containing much dust, but i Germany I noticed that they usually prefer to riddle out th fine, say, through $\frac{3}{16}$ in. or $\frac{1}{4}$ in. before washing, and ad the fine unwashed to the washed coal. This is, as a rul impracticable in this country with slack, owing to th increasing quantity of fine in what is sent to the washery.

Turning to the laboratory examination of coal, it shoul always be insisted on that the coal reaches the laborator in the size and condition in which it is proposed to send it t the washer. The problem in the laboratory is, what degre of improvement in the coal may be expected from succes ful washing.

I give here a table showing results of the examination a coking slack of a difficult type, and though this slack h not yet been washed on the large scale, my experience the method with coal that I have actually washed, sho that it can be depended on to give indications of practic value as to the results to be expected on the large scale.

Taking 100 grammes (or more, if the coal is larg I use for the separation, potassium carbonate soluti starting with 1·25 sp. gr. (that of light coal), going up stages of ·1, the final being 1·53 sp. gr. (saturated solutio fishing out, filtering, washing quickly by suction, a determining the quantity of the portions floating at

---

* This part of the paper was illustrated by diagrams.

fferent specific gravities, and also determining the per-entage of ash. The coal is quickly removed from the otassium carbonate solution and washed; and though I ave not noticed any action on the coal, in the case of, say, gnite, it is not impossible.

(100 grammes coal taken):—

—	Specific Gravity.	Grammes.	Ash.
			Per Cent.
(1)	Under 1·25	20·52	2·52
(2)	„ 1·35	50·48	4·16
(3)	„ 1·45	5·20	15·40
(4)	„ 1·53	3·07	24·74
(5)	Over 1·53	20·73	58·40
		100·00	

ortions 1, 2, and 3, together, equal 76·29 grms., containg ash 4·48 per cent. Portions 1, 2, 3, and 4, together, qual 79·27 grms., containing ash 5·27 per cent. Portions , 2, 3, 4, and 5, together, equal 100 grms., containing ash 6·27 per cent. Ash in unwashed coal, 14·90 per cent. pecific gravity of dirt (all over 1·53 sp. gr.), 2·05. 31 per ent. of the coal goes through riddle of 1 16″ hole.

It will be noticed that the ash of the different portions dded together comes to 16·27 per cent. instead of 14·9 er cent. This is owing to some extent to the ash being etermined in the coal after quick drying, which probably xpelled some of the water naturally in the coal; possibly, lso, the potassium carbonate has not been thoroughly ashed out. It should be mentioned that the sum of the ecovered coal did not come out 100, as represented, but 7·55 grms (2·45 grms. too low), and was calculated to 00.

The examination shows that this coal will, apart from the 1 per cent. fine dust, be difficult to wash, and the dirt ill be unsatisfactory, containing much combustible matter. ith most coals the ash in the dried dirt is at least 70 per nt. In this particular coal I found black coal like shale, 1·71 sp. gr., and ash 45·76 per cent., useless as a coal, it which will be very deceptive in the washing on large ale.

The following table gives the details of the examination a dirt. The sample was dried and examined uncrushed, it came from the washer:—

100 grms. taken.

Specific Gravity.	Grammes.	Ash.
		Per Cent.
Under 1·25	0·38	2·72
„ 1·35	0·42	10·31
„ 1·45	0·28	17·06
„ 1·53	0·45	24·25

king all under 1·35 sp. gr. as coal, it only amounts to per cent. loose coal left in the dirt. The dirt dried at ° C. contained 77·07 per cent. ash.

This is a good result, but it should be added that in this particular washer the water was not used twice, being run to waste, and under these circumstances a dirt very free from coal may be expected.

Discussion.

Mr. J. E. **Bedford** said that if manufacturers could get coal which was properly washed, greater efficiency would be obtained from steam boilers. As coalfields became exhausted, it was more and more necessary to be economical in the use of coal. Briquettes made of coal dust were used on some continental railways as fuel, but he was not aware that the manufacture was carried on in England to any extent.

Mr. J. W. **Cobb** commented on recent attempts to use the fine dust from coal by injecting into boiler furnaces, and asked if Mr. Mackey had seen much of this application; a serious difficulty was the carrying power of the dust. The whole process of coal washing was complicated by the fact that the variation was not in size of particle alone, nor in specific gravity alone, but in both. The sizing which preceded washing in the Lorig type was apparently a step in the right direction if the first cost of the plant was not unduly raised thereby.

Could Mr. Mackey say how far the advantage of ash diminution was lessened by increase of moisture in the washed coal? The author had been dealing exclusively with the effect of washing on ash content, but it was often the case that the primary purpose in washing was the elimination of a harmful ingredient, such as sulphur. What was the degree of success attained? Sometimes it was certainly small.

It was often said that washed coal did not give so good a coke for metallurgical purposes as unwashed. Had Mr. Mackey a decided opinion on this point?

Mr. B. A. **Burrell** asked Mr. Mackey what course he would adopt in washing coal where the mineral matter was present as finely divided clay disseminated through the mass of coal? He showed some specimens of Indian coal apparently clean and free from "dirt," but containing as much as 16 per cent. of ash in the form of clayey matter.

Mr. W. McD. **Mackey**, replying to Mr. J. E. Bedford, said that the trade in briquettes had been largely spoiled in this country owing to the use of inferior materials. In order to make them the coal must be dry, and this rather militated against the use of dust from coal washing, as it required drying.

In reply to Mr. J. W. Cobb, he said that he had not had special experience with the use of coal dust in conjunction with a steam jet. In gasworks the added water in washed coal was objected to. It should not exceed three per cent. The percentage of sulphur did not diminish in the same proportion as the ash when a coal was washed. Given the same composition, analytically, he preferred coke made from unwashed slack to that made from washed, especially for blast-furnace purposes.

Referring to the sample of Indian coal produced by Mr. Burrell, he thought it was one of the few cases in which the coal should be crushed before washing, as this was the only way in which the "dirt" could be removed.

Patent Specifications may be obtained by post by remitting as follows:—

English.—8*d*. each, to the Comptroller of the Patent Office, C. N. Dalton, Esq., Southampton Buildings, Chancery Lane, London, W.C.

United States.—1*s*. each, to the Secretary of the Society.

French.—1 fr. 25 c. each, to Belin et Cie., 56, Rue des Francs-Bourgeois, Paris (3e).

I.—PLANT, APPARATUS AND MACHINERY.

English Patents.

Grinding or Crushing Apparatus; Impts. in ——. T. Breakell, Wirksworth. Eng. Pat. 5782, March 12, 1903.

A stand for a mortar is combined with a pillar and arm to guide and support the handle of the pestle so that it can rotate, as well as rise and fall, inside the mortar. A spring or weight may be added to the pestle to press it against the material in the mortar.—W. H. C.

Grinding Mills. A. J. Robinson, Fremont. Eng. Pat. 514, Jan. 8, 1904.

A mill with removable grinding faces rotating in opposite directions, has a divided main shaft. One half of the mill is fixed, whilst the other can be swung on a pivot horizontally to one side, exposing the grinding faces, so that they can be easily renewed or repaired. The upper part of the outer casing is removable, whilst the lower half is so arranged that one half can be swung round with the movable part of the mill. Stops are arranged to ensure the two parts of the shaft being in line when the mill is in use. —W. H. C.

Liquefying Air and other Gaseous Fluids; Apparatus for ——. H. Knudsen, London. Eng. Pat. 6087, March 16, 1903.

The waste heat from the compressing engines and the pressure of the expanding cooling gases are utilised by means of a combination of vapour turbines and heat interchangers.—W. H. C.

Suspended Matter from Liquids: Apparatus for Removing —— by Continuous Decantation. T. R. Wollaston, Manchester. Eng. Pat. 7426, March 31, 1903.

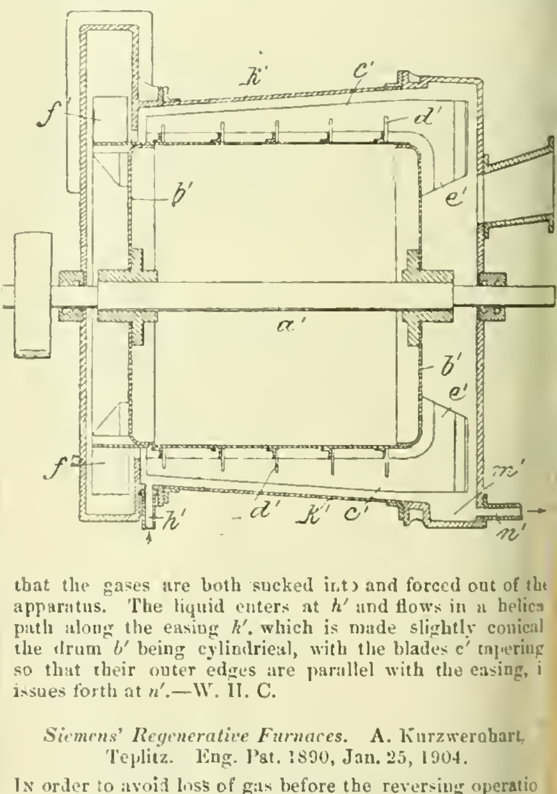
See U.S. Pat. 751,038 of 1904; this J., 1904, 246.—T. F. B.

Separating Liquid from Solid Matter; Apparatus for ——, and for Partially Drying the Solid Matter. T. Houghton and the United Alkali Co., Ltd., Liverpool. Eng. Pat. 7957, April 6, 1903.

An inclined rotating circular or annular dish is provided with a false bottom of filtering material, the space beneath which is in communication with a partially exhausted receiver. Means are provided for feeding the mixture to be separated, for drawing off the liquid, for keeping the surface of the solid from becoming impervious by means of a revolving brush, and for removing the solid by a plough. —W. H. C.

Centrifugal Apparatus for Treating Gases. E. Theisen, Baden-Baden. Eng. Pat. 8671, April 16, 1903.

An improvement on Eng. Pat. 12,693 of 1901 (this J., 1902, 904). The centrifugal blades are perforated or constructed with ribs on their rear sides, to prevent the undisturbed flow of the gases through the spaces behind the ribs, in order to obtain a more intimate contact between the gases and the liquid spray. In the Fig., which is a longitudinal section, the driving shaft a' carries the drum b' with the blades c' preferably arranged in oblique positions, and with ribs d' on their rear sides. At the gas-inlet end the blades are made with inward projections e', and at the exit with outward projections f', so that the gases are both sucked into and forced out of th apparatus. The liquid enters at h' and flows in a helica path along the casing k', which is made slightly conical the drum b' being cylindrical, with the blades c' tapering so that their outer edges are parallel with the casing, i issues forth at n'.—W. H. C.



Siemens' Regenerative Furnaces. A. Kurzwernhart, Teplitz. Eng. Pat. 1890, Jan. 25, 1904.

In order to avoid loss of gas before the reversing operatio in regenerative furnaces, the latter are provided with a ga cut-off device and an air-inlet opening capable of bein closed, these being so arranged that the gas current can l cut off and a supply of air provided, forcing the gas in tl regenerative chamber and the passage connected theret into the furnace for combustion.—E. S.

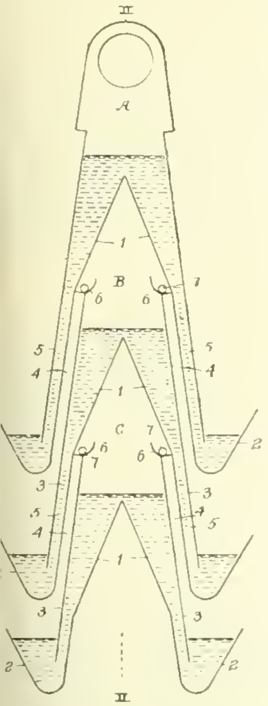
Distillation of Volatile Liquids; Process and Apparat for the ——. R. Voiry, Paris, and J. de la Fresnaye Cie., Bagnolet. Eng. Pat. 1975, Jan. 26, 1904. Und Internat. Conv., March 27, 1903.

See Fr. Pat. 330,649 of 1903; this J., 1903, 1078.—T. F.

United States Patents.

Evaporating Liquids; Process of ——. B. F. B. Sew, Skien. U.S. Pat. 752,599, Feb. 16, 1904.

Two or more inverted V-shaped portions, 1 (see figure), arranged, one over the other, each provided with pockets, nto which the lower edges of the curtain walls, 3, dip. The quid to be evaporated is fed into the pockets, 2, and drawn p into the vessels by the vacuum communicated to the vapour spaces, A, B, C, by the pipes, 7, from the pump. The solids separated fall into the pockets, 2, and are removed. The upper portion of the liquid in each chamber is under a lower pressure than the lower portion of the liquid in the pockets, consequently the solids can be removed continuously without interrupting the working. By maintaining a lower pressure in the upper vessel, the heat given out by the vapour from the lower vessels, condensing on the walls, 1, and collecting in the gutters, 6, from whence it is removed by the exhaust pipes, 7, evaporates the liquid in the vessel above. A method of combining the V-shaped chambers into a set, and for applying the principle to ordinary tubular evaporators, is given.—W. H. C.



acuum Evaporating Apparatus. C. Ordway, New York. U.S. Pat. 755,529, March 22, 1904.

FLOAT chamber is connected with both the vapour and quid spaces of the evaporating vessel, the liquid feed to hich is regulated by the height of liquid therein. This is fected by means of a float in the float chamber, attached a cord passing over a pulley and connected by a rod to lever which actuates a valve in the liquid-feed pipe. leans are provided for adjusting the float from without, d a by-pass for filling the evaporating vessel independently the float chamber.—W. H. C.

otary Kiln and Drier; Combined ——. C. A. Matcham, Allentown. U.S. Pat. 755,513, March 22, 1904.

ROTARY kiln is combined with a drier, and both are concted to a stack. A valve is provided to regulate the flow products of combustion from the kiln, and a truck to ry the connection of the flue to the drier.—W. H. C.

iln. T. Hampton, West Elizabeth. U.S. Pat. 755,655, March 29, 1904.

IRCULAR kiln with a dome has furnaces within the walls, ags" adjacent to the furnaces and a solid floor with es having inlets adjacent to the furnaces. An arrangent of flues and cross flues leads to a shaft situated ernally to the kiln.—W. H. C.

orption Apparatus; Chemical ——. H. G. Schanche, ssignor to Harrison Bros. and Co., Philadelphia. U.S. at. 755,705, March 29, 1904.

OWER is arranged with horizontal shelves from which the orbing liquid overflows at alternate sides; the ends of shelves being turned up. A plate dips into the liquid he shelves just behind the turned-up end, and reaches ly to the bottom, so that only the lower layers of the d can overflow.—W. H. C.

French Patent.

Liquid Level Indicator. Soc. l'Air Liquide (Soc. Anon pour l'Etude et l'Exploitation des Procédés G. Claude). Fr. Pat. 337,127, Nov. 21, 1903.

In order to indicate the level of a liquid in a closed vessel under pressure, a current of gas under slightly greater pressure than that in the closed vessel, is led through one branch of a T-tube. One of the other branches enters the closed vessel and dips to the bottom of the liquid in it, whilst the other is connected to one end of a U-tube filled with an appropriate liquid (or to a manometer), the other end of the U-tube being led into the gas space above the liquid in the closed vessel. The liquid in the gauge tube will be depressed in proportion to the depth of liquid in the closed vessel.—W. H. C.

II.—FUEL, GAS, AND LIGHT.

Water-Gas; Production of —— by the Dellwik-Fleischer and Strache Systems, in Theory and Practice. M. Placidi and O. Kettner. J. Gasbeleucht., 1904, **47**, 268—271.

The authors criticise the objections advanced by Strache and Jahoda against the theory of Dellwik. They consider it as proven that, during the blast period, the economy increases with the speed of the blast and with the percentage of carbon dioxide in the gas produced. If the carbon dioxide remain constant, then the greater the blast speed becomes, the greater will be the amount of heat stored up in the generator, the higher its temperature, and the shorter the blast period required. The experiments of Strache and Jahoda show conclusively, however, that during the "make" period the speed of the steam ought to be reduced as the temperature of the fuel falls. In the Dellwik process the steam supply is not regulated in this sense, and hence, towards the end of the gas-making period, much heat is lost by superheated steam passing undecomposed through the fuel, and an inferior gas is the result. In practice, therefore, whilst the Dellwik-Fleischer process marks an advance in the blast period, and the Strache process in the gas-making period, neither system, in the author's opinion, shows a completely satisfactory efficiency.—H. B.

English Patents.

Briquettes; Manufacture of —— for Fuel. J. Faucheur, Brussels. Eng. Pat. 10,416, May 7, 1903.

Gas tar is "freed from its odour," by adding to it 10 per cent. of its weight of concentrated milk of lime of sp. gr. 22° to 25° B., thoroughly mixing for 24 hours, and then removing the excess of lime by washing. 80 kilos. of tar, thus treated, are mixed with 30 kilos. of Portland cement, and then added to 1,000 kilos. of coal dust. After thorough mixing, briquettes are formed from the paste thus obtained. To free the coal dust from native sulphur or bitumens, 10 per cent. of powdered quicklime is added to it, and the mixture immersed in water. By the heat produced by the slaking of the lime, "the sulphur and bitumen fuse," "and rising to the surface of the bath," they are removed. The coal dust is then thoroughly washed with water."—L. F. G.

Liquids, Combustible; Process and Apparatus for the Gasification of ——. C. H. Claudel, Argenteuil. Eng. Pat. 9606, April 28, 1903.

See Fr. Pat. 331,372 of 1903; this J., 1903, 1122.—T. F. B.

Gas Producers; Impts. in ——. H. Boyd, Poulton-le-Fylde. Eng. Pat. 9950, May 2, 1903.

The producer, which is intended for use with bituminous fuel, is lined at its upper part with fire-brick. The lower part is not lined, but the supply of air, or air and steam, flows round it on its way to the grate, which is vertical and is situated at one side. The air is thus pre-heated, and it is stated that the casing forming the lower portion of the producer is cooled so far as to prevent the adhesion of clinker. The fuel hopper is situated centrally at the top, and the gas outlet is at one side, a depending partition screening it to such a depth that the outlet is really about mid-way down the bed of fuel. This arrangement causes the fresh fuel to be heated by radiant heat from the lower part, and the tarry, condensable matters have to pass down through a portion of the incandescent fuel, where they are decomposed.—H. B.

Carburetting by means of Naphthalene. G. P. J. Lion, Paris. Eng. Pat. 5805, March 12, 1903. Under Internat. Conv., March 14, 1902.

See Fr. Pat. 319,599 of 1902; this J., 1902, 1525.—T. F. B.

Gases; Method of Removing Sulphuretted Hydrogen from ——, with simultaneous Recovery of Sulphur. E. Burschell, London. Eng. Pat. 6090, March 16, 1903.

See U.S. Pat. 737,579 of 1903; this J., 1903, 1080.—T. F. B.

United States Patents.

Coke Quenching and "Bleaching" Apparatus. E. A. Moore, Philadelphia. U.S. Pat. 755,154, March 22, 1904.

The apparatus is built up of separable hollow transverse sections with a vestibule or extension at one end, having sides which can swing laterally, and a bottom which can swing vertically, so that it can be connected to a coke oven. The apparatus is fitted with doors at both ends, with means for supplying water to each section, and with a steam outlet.—L. F. G.

Coke; Process for Quenching and "Bleaching" ——. E. A. Moore, Philadelphia. U.S. Pat. 755,155, March 22, 1904.

"This process consists in transferring hot coke from an oven into a receptacle (see preceding abstract) from which atmospheric air is excluded, deluging the coke with water, and discharging the excess of water as rapidly as supplied." The coke is then subjected to the action of the steam generated by the quenching, the steam discharged from the receptacle, and the coke finally dried.—L. F. G.

Fuel Blocks [Briquettes]; Manufacture of Artificial ——. W. Y. Cruikshank, Assignor to N. Maley, both of Freeland. U.S. Pat. 755,278, March 22, 1904.

Slightly moist anthracite coal culm is mixed with dry powdered resin, and with asphalt rendered fluid by means of a volatile solvent, and the mixture subjected to the simultaneous action of heat and pressure, till the moisture and the solvent are volatilised, and the resin has been melted.—L. F. G.

Briquettes: Manufacture of Pit-coal or Coke ——. J. Lieb, Cologne. U.S. Pat. 756,124, March 29, 1904.

Fine coal is mixed with a small quantity of resin or other agglutinant, moistened with water, and the mass then moulded into briquettes and heated.—L. F. G.

Fuel [Briquettes]; Manufacture of Artificial ——. W. B. Thomas, Towns, Ga. U.S. Pat. 756,189, March 29, 1904.

The residuum known as "rosin-batting" is pulverised, and then mixed with a less inflammable but combustible material, such as woody refuse or fibre, and the mixture heated and moulded into shape.—L. F. G.

Briquettes [Fuel]; Process of Producing ——. J. M. Davidson, Beaumont. U.S. Pat. 756,593, April 5, 1904.

Powdered pine-wood charcoal is mixed with the high melting-point pitch obtained from pine-tar, slaked lime is added, and the mixture is heated to 250°—300 F., and moulded into blocks.—T. F. B.

Method of Combustion. C. E. Lucke, New York. U.S. Pat. 755,376, March 22, 1904.

In burning explosive gaseous mixtures, the latter are caused to flow through an opening with a greater velocity than that of the propagation of inflammation through the mixture, into a space in which the mixture may spread out and expand, the mixture being thus burned at the surface at which the velocity is equal to the rate of propagation of inflammation.—E. S.

Liquid or Gaseous Fuels; Method of Burning ——. C. E. Lucke, New York. U.S. Pat. 755,377, March 22 1904.

A gas capable of supporting combustion (such as air or oxygen) is caused to enter a pipe carrying an excess of liquid fuel over the proportion capable of being burned by the gas admitted, which latter enters on to a heated hearth or bed in the manner described in the preceding abstract. The velocity is thus reduced to the rate of propagation of the inflammation, diffusion with other gas is prevented, and the fuel is burned, at least partially, within the bed, the excess of fuel being available for burning beyond the hearth. —E. S.

Gas Producer. J. G. Sanderson, Scranton. U.S. Pat. 755,702, March 29, 1904.

The gas producer comprises a fuel chamber, the sides of which are formed of contiguous vertical water tubes provided with inlets and outlets for the water, and connected to an upper and to a lower water tank, and kept in place by bands. The fuel chamber is surrounded by a metallic sheathing, and a non-conducting jacket is placed between this and the water tubes.—L. F. G.

French Patents.

Coal; Complete Combustion of —— in Automatically Stoked Furnaces. R. Mederer. Fr. Pat. 336,946, Sept. 25, 1903.

A layer of lumpy coal placed on the grate is burnt to incandescence, and coal dust then blown on to it by a blast of hot air, the chimney draught being simultaneously cut off. After a time, communication with the chimney is again established, and coal in lumps fed in, to keep up the fire the above cycle of operations being then again repeated. The explosive combustion of the coal dust thus brought about, is said to produce a more uniform temperature and to increase the thermal efficiency.—L. F. G.

Lime and Combustible Gas; Combined Process of Manufacturing ——. The Chalk Power Gas Syndicate, Ltd Fr. Pat. 337,081, Nov. 3, 1903.

Carbonate of lime, mixed with as little fuel as possible, i burned to lime as usual, preferably with the assistance of current of steam, and with the use of as little air as possibl The gas produced, said to consist mainly of carbon dioxid is led along with the steam into a series of converters charge with incandescent fuel, whereby a kind of water-gas, said t contain but little nitrogen, is obtained. Arrangements plant are described for rendering the process continuou and for utilising the waste heat.—H. B.

Gas Producer. A. B. Duff. Fr. Pat. 337,122, Nov. 16, 1903.

The usual air blast placed in the water-sealed ash-pit of gas producer, is furnished with a hollow cylindrical to having vertical slots in the sides, and closed by a louv cap. The air issuing from the louvre top heats the fuel incandescence, whilst the blast from the vertical sl completes its combustion.—L. F. G.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM, AND MINERAL WAXES.

Asphaltum; Investigations on ——. G. Lunge and V. Krepelka. Chem.-Zeit., 1904, 28, 177—180.

Nine different varieties of natural asphaltum, four of a ficial asphalt (prepared from petroleum pitch), and a l d and soft coal tar pitch, were treated with commercially p chloroform. The extracted bitumen was dried at 120 to expel the final traces of solvent, and then examined sp. gr., melting point, sp. gr. of a solution of given stre in chloroform, and iodine absorption. The sp. gr. determinations, in the Sprengel pyknometer at 17° C., gave the results tabulated.

For the melting-point determinations the method of Kraemer and Sarnow (this J., 1903, 291) was employed, the mean of four results being taken. (See table.)

It was considered probable that the divergent composition of the various bitumens might find expression in their effect on the sp. gr. of pure chloroform solutions. The densest petroleum asphalt—that from Wietze oil—gives the value, 1·4693, as the sp. gr. of the 6 per cent. chloroform solution, whilst in the case of the coal-tar pitches, it exceeds 1·475; but it is impossible by this means to distinguish the true natural asphaltums from the petroleum asphalts, and still less to subdivide the members of either class.

As an addition to the usual qualitative tests, it is stated hat petroleum spirit will give a precipitate with the chloroorm solutions of the tar pitches, but not with those of the atural asphaltums or petroleum asphalts.—C. S.

English Patents.

urpentine; Russian Oil of ——; Treatment of, and of similar Products, and of Benzine or Petroleum Spirit, for the purpose of Removing their Disagreeable Odour. E. Heber. Eng. Pat. 10,004, May 2, 1903. XIII. B., page 448.

atty Acids, Hydrocarbons, and the like; Apparatus for the Continuous Distillation of ——, and Steam Superheating Apparatus therefor. V. Sláma. Eng. Pat. 12,984, June 9, 1903. XII., page 447.

United States Patents.

ood; Apparatus for the Destructive Distillation of ——. G. O. Gilmer, New Orleans, Assignor to Illinois Investment Co., West Virginia. U.S. Pat. 677,204, June 25, 1901. Reissue No. 12,208, March 22, 1904.

LONG retort is fixed in a position slightly inclined to the rizontal, with an outlet for the products of distillation at lower end. This retort is heated from the top only, the les and bottom being protected by a brick casing, and the es are so arranged that the contents of the retort are ated "progressively"—*i.e.*, the upper end is heated much re strongly than the lower end.—T. F. B.

nzols and their Homologues; Manufacture of ——. A. Nikiforoff, Moscow. U.S. Pat. 755,309, March 22, 1904.

E Fr. Pat. 315,428 of 1901; this J., 1902, 541.—T. F. B.

Petroleum; Apparatus for Distilling ——. L. Gathmann, Washington. U.S. Pat. 755,760, March 29, 1904.

A STILL, in which the petroleum is heated under pressure, and from which the residues are continuously removed, is connected with a vaporiser, into which the oil is introduced so as to present a large surface area. The vapours are passed up a shallow inclined condenser, the top surface of which is cooled by water; "drips" are provided in the condenser to prevent the distillate from running down the upright walls, and "eduction ports" are situated at intervals along the bottom of the condenser, for the removal of different fractions of the distillate.—T. F. B.

French Patents.

Naphthalene; Process for Purifying ——. J. P. Mateu. Fr. Pat. 336,865, Nov. 21, 1903.

SEE Eng. Pat. 25,989 of 1903; this J., 1904, 182.—T. F. B.

"Vaselines Industrielles" and Lubricating Mineral Oils; Manufacture of ——. P. J. Tabourin. Addition, dated Nov. 14, 1903, to Fr. Pat. 326,348, Nov. 15, 1902. (See this J., 1903, 791.)

THE emulsion of fatty acids and their calcium salts, obtained, according to the principal patent, by subjecting mineral oils to the action of calcium hypochlorite, is acidified, washed with water, and heated to 60°—80° C. with 25 per cent. of its weight of glycerin. The glycerides of fatty acids thus obtained, when mixed with about 10 per cent. of paraffin, give a product suitable for use as a lubricant.—T. F. B.

IV.—COLOURING MATTERS AND DYESTUFFS.

Diazoamino-Compounds of the Aminonaphtholsulphonic Acids. L. Paul. Zeits. angew. Chem., 1904, **17**, 363—365.

IF the tetrazo-compound of tolidine be added to a solution of aminonaphtholdisulphonic acid H, 1 mol., an intermediate product is formed, which on treatment with a solution of diazotised *p*-nitraniline gives a bluish-red precipitate having the following composition:—(I.) $Cl.N{:}N.C_6H_4.C_6H_4.N{:}N.NH.C_{10}H_3(OH)(SO_3H)_2\ p\text{-}N$ ($p\text{-}N$ = diazo-*p*-nitraniline.) If this precipitate be made into a paste with a concentrated solution of sodium salicylate or sodium phenolate, decomposition occurs, and a mixture of the monazo dyestuff from *p*-nitrodiazobenzene and aminonaphtholdisulphonic acid H with the intermediate product from tetrazoditolyl and phenol or salicylic acid, is obtained, thus showing that the product (I.) is a true diazoamino-compound. When the compound (I.) is treated with a large amount of water, no nitrogen is evolved, but probably an internal condensation takes place, giving rise to the following compound:—

$$N{:}N.C_6H_4.C_6H_4.N{:}N.C_{10}H_2(NH_2)(OH)(SO_3H)_2\,p\text{-}N.$$

The sodium salt of the aminonaphtholsulphonic acid γ, when treated with tetrazoditolyl, forms only a minute quantity of an intermediate product capable of reaction. The greater part appears to form the diazoamino-compound. If β-naphtholdisulphonic acid γ be treated with tetrazoditolyl, a new intermediate product is produced which may have the following formula:—

$$Cl.N{:}N.T.N{:}N.O.C_{10}H_5(SO_3H)_2$$

On treatment with alkali the latter passes into the already known red compound.—A. B. S.

Azo Dyestuffs; Electrolytic Preparation of ——. W. Löb. XI. A., page 445.

Prussian Blue; Analysis of ——. C. Coffignier. XXIII., page 456.

Erythrohydroxyanthraquinone, Anthrarufin, and Chrysazin; Manufacture of ——. [*Anthracene Dyestuffs.*] Soc. Anon. des Prods. F. Bayer et Cie. Fr. Pat. 336,867, Nov. 21, 1903.

ANTHRAQUINONE-α-monosulphonic acid and 1.5 and 1.8-anthraquinonedisulphonic acids are converted into erythrohydroxyanthraquinone, anthrarufin, and chrysazin respectively by heating them with water in presence of oxides or hydroxides of the alkaline earth metals.—E. F.

o-Hydroxyanthraquinones and o-Hydroxyanthraquinonesulphonic Acids; Manufacture of ——. Soc. en Commandite. R. Wedekind and Co. Fr. Pat. 336,938, Nov. 25, 1903.

THE alkali- or alkaline-earth salts of anthraquinone-*o*- or *o*-*m*-sulphonic acids are converted into the corresponding hydroxyanthraquinones by heating them under pressure with water and hydroxides of alkaline earth metals with or without addition of alkaline earth salts and of oxidising agents.—E. F.

V.—PREPARING, BLEACHING, DYEING, PRINTING, AND FINISHING TEXTILES, YARNS, AND FIBRES.

Hyphæne Coriacea: A Palm of Madagascar yielding Textile Material. P. Claverie. Comptes rend., 1904, **138**, 768—769.

THIS palm is much used by the natives of the north-west portion of the island. Segments of the leaves are used in basket-making, and they yield a fibre, the structure and composition of which are described by the author. This fibre, however, is inferior to that of the cocoa-nut.—J. T. D.

Dyeing [*Mordanting*] *Process.* P. Heermann. Färber-Zeit., 1904, **15**, 76—78, 85—91, 108—112. (See also this J., 1903, 623, and 1904, 57.)

Basicity, "Basicity Number," and their Influence on Mordanting by Primary Metallic Mordants.—The "basicity number" of a mordant is defined as the ratio of the absolute acid content to the absolute metal content; *e.g.*, the basicity number of a stannic chloride mordant is $(4 \times 36{\cdot}45) \div 118{\cdot}5 = 1{\cdot}23$, and of a chrome mordant $Cr_2Cl_3(OH)_3$, $(3 \times 36{\cdot}45) \div (2 \times 52{\cdot}1) = 1{\cdot}05$. The experiments were undertaken to ascertain the influence of the basicity of the mordant, varied by the addition of acid or alkali to the normal solution, on the weight of mordant absorbed by the fibre. The mordants used were stannic chloride solution of 33·1 B., basic chromium chloride $Cr_2Cl_3(OH)_3$ solution of 19·2 B., basic iron sulphate solution of 31° B., and an aluminium acetate solution containing 1·5 per cent. of aluminium. In all cases, both with raw and with boiled-off silk, reduction of the basicity number (*i.e.*, the addition of alkali), resulted in considerably more mordant being absorbed than when the "normal" mordant bath was used; by increasing the basicity number (*i.e.*, by addition of acid), however, variable results were obtained; with tin and aluminium mordants, only a slight decrease from the "normal" absorption of mordant was noticed, even with addition of 5 per cent. of acid; with the iron mordant, the absorption decreased rapidly but regularly with the addition of acid, being reduced, in the case of raw silk, to one-half the normal with the addition of less than 5 per cent. of acid; while with the chromium mordant the addition of acid at once caused a very rapid drop in the absorption of mordant and further addition of acid still further reduced the absorption. In general, both with raw and with boiled-off silk, increasing or reducing the basicity number of the mordant causes a decrease or increase respectively in the amount of mordant absorbed.

The following table gives the full results obtained :—

Mordant.	Silk.	—	Increase per Cent. of "Normal" Increase.

—T. F. B.

Inorganic Colloids ; Behaviour of some —— towards Fibres, and its Relation to the Theory of the Dyeing Process. W. Bilz. Nachr. Ges. Wiss. Göttingen, 1904, 1—15; Chem. Centr., 1904, 1, 1039—1040.

A colloid when converted into the gel condition has the power of taking up another colloid from its solution, with formation of "adsorption compounds." Experiments in which the gel, which serves to take up the dissolved colloid, was replaced by animal and vegetable fibres, confirmed the expectation that inorganic colloids would be taken up by the fibres. A coloured colloid is fixed with its characteristic colour; coloured inorganic substances, when converted into the colloidal condition, thus acquire the capacity of being "adsorbed." Experiments were made with colloidal solutions of selenium, tellurium, gold, vanadium pentoxide, Molybdenum blue, Tungsten blue, cadmium sulphide, arsenic and antimony sulphides, copper ferrocyanide, mercury, tin sulphide, copper hydroxide, and Molybdenum-tungsten purple. In the case of selenium, tellurium, and of gold prepared by Brunck's method (this J., 1903, 710), the fibre is dyed and the solution is more or less completely exhausted. In the other cases, also, the fibre is dyed, but the colour is not extracted from the solution to so great a degree. A colloidal solution of gold prepared by Zsigmondy's method (this J., 1902, 192) will not dye silk; a constituent of the latter (a "protective colloid") passes into solution, which prevents the gold from being deposited. The colloidal gold solution, after being boiled with silk, can no longer be precipitated by electrolytes. In several cases the dyeing of the fibres by inorganic colloids was found to be favoured by the addition of salt. Krafft (this J., 1899, 757) has shown that the substantive organic dyestuffs, especially the benzidine dyestuffs, dissolve in water as colloids. A comparison of the dyeing properties of these dyestuffs and of coloured inorganic colloids brought out the following principal differences between the two classes of compounds :—(1) The solutions of the organic dyestuffs are exhausted much more completely than those of the inorganic colloids, and the shades produced by the former are relatively much faster to washing. (2) The shades produced with inorganic colloids are not very fast to rubbing; if the coloured compounds (*e.g.*, cadmium sulphide, Prussian blue) are produced on the fibre by a two-bath process, the shades are much faster to rubbing. The points of similarity between the dyeing properties of the two classes of compounds are :—(1) The favourable effect of the addition of electrolytes. (2) The greater affinity for the colour of weighted, as compared with unweighted silk. (3) The deeper shades produced with hot solutions. (4) The retardation of the deposition of the inorganic colloids (*i.e.*, the greater uniformity of dyeing) by the addition of "protective colloids."—A. S.

English Patents.

Animal and Vegetable Fibres ; Process for Dyeing ——. H. Maun, Munich. Eng. Pat. 11,451, May 19, 1903.

See Fr. Pat. 326,010 of 1902 ; this J., 1903, 739.—T. F. B.

Hank-Dyeing Machines. E. Dittmar, Lille. Eng. Pat. 27,870, Dec. 19, 1903. Under Internat. Conv., Dec. 20, 1902.

See addition, of Dec. 20, 1902, to Fr. Pat. 315,658 of 1901 ; this J., 1903, 905.—T. F. B.

Embossed and like Effects on Woven Goods ; Rendering Permanent ——. A. Fielding, Salford. Eng. Pat. 9849, May 1, 1903.

The fabric is impregnated with a solution of viscose, dried, embossed in the usual way, and steamed to produce a coating of insoluble cellulose on the fabric. Another method consists in first coating the fabric with albumin or a similar substance, embossing, and then coating with viscose as above. (Compare Fr. Pat. 335,238 of 1903 ; this J., 1904, 15).—T. F. B.

Feathers ; Process for the Preservation of Ornamental Birds' ——. R. Wolffenstein, Berlin. Eng. Pat. 11,712, May 22, 1903.

Feathers are immersed in a 1 per cent. alcoholic solution of wax, and the alcohol evaporated.—T. F. B.

United States Patents.

Dyeing ; Apparatus for ——. P. Schirp, Barmen. U.S. Pat. 755,050, March 22, 1904.

See addition of Aug. 26, 1902, to Fr. Pat. 314,274 of 1901 ; this J., 1903, 551.—T. F. B.

Dyeing ; Apparatus for ——. J. A. Willard, Assignor to Vacuum Dyeing Machine Co., Chattanooga. U.S. Pat. 755,422, March 22, 1904.

An open dye-vat with slightly diverging sides, is provided with a perforated plate (for holding the goods) supported slightly above the bottom of the vat; a compression plate operates in the vat, above the perforated plate, and can be fixed at any distance from it. The diameter of each of these plates is approximately equal to that of the bottom of the vat. A supply pipe conveys the dye liquor to the bottom of the vat, below the perforated plate, and an exhaust pipe removes the used liquor from the top of the vat.—T. F. B.

Mercerising Apparatus. R. P. Smith and G. E. Drum, Philadelphia. U.S. Pat. 755,716, March 29, 1904.

The yarn is carried on two horizontal rows of supports, the supports of the lower row being adjustable vertically. All the supports are carried on a frame. A driving shaft, situated near the frame, is so arranged that it causes the upper set of yarn supports to rotate when the frame is lowered in the tank, the lower set of yarn supports being put in motion when the frame is raised. Gearing connects the two sets of yarn supports, so that, when necessary, both sets of supports are rotated in either position of the frame. —T. F. B.

Mercerising Yarn ; Machine for ——. P. Hahn, Niederlahnstein. U.S. Pat. 755,765, March 29, 1904.

See Fr. Pat. 325,239 of 1902 ; this J., 1903, 739.—T. F. B.

French Patents.

Dyeing Cotton Thread Several Colours ; Process for ——. Soc. anon. Teinturerie Clément-Marot. Fr. Pat. 337,027, Nov. 26, 1903.

The bobbin or cop of yarn is first dyed in the ordinary way, and then the colour is partially bleached ("stripped") by the use of a suitable bleaching agent, which again depends on the dyestuff selected. It is the circumferential surface of the bobbins, &c., which is thus bleached, the latter being rapidly passed into the bleaching vat, the liquor in which is run off when the desired point is attained. The bleached portion of the bobbins, &c., is now re-dyed another colour, the operations being repeated as many times as necessary to produce all the colours desired.—R. S.

Waterproofing Fabrics, Threads, &c. ; Composition and Apparatus for ——. V. B. Wright, W. K. Poulsom, and W. M. Mackintosh. Fr. Pat. 336,889, Nov. 23, 1903.

See Eng. Pat. 218 of 1903 ; this J., 1904, 184.—T. F. B.

VI.—COLOURING WOOD, PAPER, LEATHER, Etc.

United States Patent.

Dyeing Wood ; Process of ——. J. Brenner, Gainfarn. U.S. Pat. 755,993, March 29, 1904.

See Eng. Pat. 17,808 of 1903 ; this J., 1903, 1193.—T. F. B.

French Patents.

Multi-Coloured Effects on Dyed Paper ; Process for Producing ——. Cie. Paris. Coul. d'Aniline. Fr. Pat. 337,113, Feb. 6, 1903.

See Eng. Pat. 2809 of 1903 ; this J., 1904, 17.—T. F. B.

Dyeing Skins ; Machine for ——. P. Bruffaers. Fr. Pat. 336,992, Nov. 10, 1903.

The skins are fixed in circular trays, which are revolved by mechanism which also distributes the dye solution. The liquid runs into the trays from an upper reservoir, overflows out of the trays into a lower reservoir, and is pumped from the latter back into the upper reservoir.—R. S.

VII.—ACIDS, ALKALIS, AND SALTS.

Lead Chamber Process ; Physical Chemistry of the ——. M. Trautz. Zeits. physik. Chem., 1904, **47**, 513—610.

Complete historical and bibliographical account of research on the chamber process, with the unsolved problems arranged as queries, as follows:—1. In what way does sulphur dioxide in the Glover tower almost completely remove the nitrogen from the nitrosylsulphuric acid? 2. How is nitrosylsulphuric acid regenerated from the resulting gaseous mixture? 3. How is the sulphuric acid produced, in which this nitrosylsulphuric acid is dissolved? 4. How far can nitrosylsulphuric acid be denitrated in the chambers by variations of concentration and of temperature? Is it further denitrated in the chamber, and, if so, by what means? 5. What influence has temperature on the whole reaction? Does an optimum exist? 6. How are local variations of production and abnormalities during faulty working to be explained? 7. In what way is the greater portion of the sulphuric acid actually formed? To answer some of these questions, several sets of experiments were carried out. In the first, solutions of sulphur dioxide in water and in sulphuric acid of various strengths, with and without the addition of nitrosylsulphuric acid, $SO_2(OH)(ONO)$, were continuously shaken in an atmosphere of oxygen, and the progress of the oxidation measured by analysing samples of the liquid taken from time to time. When no nitrous compound was added, the solutions, whether in water or in acid, were oxidised extremely slowly, weeks being necessary to produce a sensible diminution of the sulphur dioxide content. On adding the nitrosyl compound to solutions in water or in acids below half-normal strength, very considerable evolution of nitrous gases occurred, and the liquid after this evolution showed but slight catalysing action. With 55 per cent. sulphuric acid, there was less evolution of gas, and the oxidation was considerably accelerated, whilst with 95 per cent. acid, though there was no gas evolution, the acceleration of the oxidation was very slight. The next set of experiments dealt with the speed of hydrolysis of nitrosylsulphuric acid. The conclusions are that nitrosylsulphuric acid at 25° C. in solution in sulphuric acid of various concentrations is hydrolysed when a stream of indifferent gas is led through, more rapidly, according as the water concentration is greater, giving off nitric oxide, with which is mixed nitrogen peroxide in proportions increasing with the concentration of the sulphuric acid. The other products are water and nitric acid, the latter in smaller proportion as the water concentration is less. Dilute solutions behave as though they were supersaturated solutions of nitric oxide. A third and very elaborate set of experiments was instituted to determine at what concentrations equilibrium is established among the various products of this hydrolysis (HNO_3, NO, NO_2, H_2O, H_2SO_4). The results, given in great detail, are summarised as follows:—Nitric oxide (NO) forms with sulphuric acid, nitric acid, and water, nitrosylsulphuric acid, and nitrogen peroxide (NO_2). The partial pressure of the latter increases, with rising concentration of sulphuric acid, to a maximum, then diminishes to practically zero, when the sulphuric acid concentration reaches 93 per cent., at which concentration nitrosyldisulphonic acid begins to be formed. The concentration of this latter increases in proportion to the decrease of that of nitrogen peroxide. The process, up to a sulphuric acid concentration of 52 per cent. is reversible for all temperatures between 22° C. and 82° C. In general, rise of temperature lessens the gaseous concentration of the nitric oxide, and rise of pressure favours the nitrogen peroxide concentration at the expense of that of the nitric oxide. A further section of the paper gives a summary of work previously published on nitrosyldisulphonic acid (this J., 1896, 622 ; 1902, 1493; 1904, 60 and 185), which the author has prepared by the reaction (aided by heat) of sulphur dioxide on a solution of nitrosylsulphuric acid in 95 per cent. sulphuric acid. This indeed forms an excellent method for preparing a pure and stable solution of nitrosyldisulphonic acid. The latter readily reacts on nitrosylsulphuric acid, giving nitric oxide and sulphuric acid. This reaction no doubt goes on in the chambers, though it is certainly not the principal reaction. Finally, while pointing out that the high reaction velocities do not allow us, with our present means of discrimination, to pronounce which of the reactions in the lead chambers plays the most important part, the author gathers together in the following scheme the various reactions, some or all of which occur:—

$$(1)\ NO + NO_2 + H_2O = 2(NO.OH).$$

$$(2)\ 2(NO.OH) + 2(HSO_3H) = \underset{\substack{\text{Nitrososulphonic acid}\\ \text{(hypothetical)}}}{2(NO.SO_3H)} + 2H_2O$$

$$= NO(SO_3H)_2 + NO + 2H_2O.$$

$$(3)\ NO(SO_3H)_2 + 2NO.OH = 3NO + 2H_2SO_4.$$

$$(4)\ 2NO + O + 2H_2SO_4 = 2(ONO.SO_3H) + H_2O.$$

$$(5)\ 2(ONO.SO_3H) + 2H_2O + NO(SO_3H)_2 = 4H_2SO_4 + 3NO.$$

$$(6)\ NO_2.SO_3H + H_2O = NO_2H + H_2SO_4.$$

—J. T. D.

Alkaline-Earth Metal Carbonates ; Decomposition of —— by Ammonium Chloride in presence of Water. H. Cantoni and G. Goguelia. Bull. Soc. Chim., 1904, **31**, 282—287.

Powdered barium carbonate, 9·87 grms., was boiled with a solution of 2·67 grms. of ammonium chloride in 500 c.c.

of water: the amounts of barium carbonate decomposed after 1½, 24, and 48 hours, were respectively 1·546, 2·138, and 2·473 grms. With 42·8 grms. of ammonium chloride in the same volume of water, 7·946 grms. of barium carbonate were decomposed after 1½ hours' boiling. The complete decomposition of 9·87 grms. of barium carbonate (shown by the clearing of the turbid liquid) was effected, when the 500 c.c. of solution contained 197·4, 53·5, and 21·4 grms. of ammonium chloride, after a few seconds', 45 minutes', and 16 hours' boiling respectively. In the cold, the action is much slower. A litre of each of three solutions of ammonium chloride was digested for 98 days at 15° C. with excess of powdered barium, strontium, and calcium carbonates, with the following results:—

Amount of NH_4Cl.	Amount decomposed in Grms. of		
	$BaCO_3$.	$SrCO_3$.	$CaCO_3$.
Grms. per litre.			
53·5	0·91745	0·17944	0·42252
53·5	0·92120	0·17830	0·42436
100	1·25512	0·25936	0·60144
100	1·25618	0·26060	0·61732
200	1·50000	0·35898	0·64800
200	1·49640	0·35890	0·64320

The authors draw attention to the bearing of these results on analytical work, especially on the separation of alkalis from alkaline earths in the usual method of analysis of silicates.—J. T. D.

Lead Carbonate. R. Salvadori. Gaz. chim. ital., **34**, 87—92; Chem. Centr., 1904, **1**, 993.

Pure lead carbonate, $PbCO_3$, prepared by precipitating lead nitrate solution with ammonium carbonate, is not altered by shaking with water at 18°, 25°, and 30° C. When boiled with water under a reflux condenser, and more slowly even at 70° C., however, it is converted into the basic carbonate, $2PbCO_3Pb(OH)_2$, whilst the water becomes faintly alkaline. The basic carbonate is also produced when the normal carbonate is boiled with N/100, N/20, and N/10 solutions of sodium sulphate or chloride and also on boiling lead chloride or sulphate with N/100, N/20, and N/10 solutions of sodium carbonate. The author concludes that the basic carbonate, $2PbCO_3Pb(OH)_2$, is a stable compound, which tends to be produced from all, even insoluble, lead salts in presence of the ions $NaCO_3$, CO_3, and OH.—A. S.

Chlorides; Transformation of Oxides and Oxy-Salts into ——. C. Matignon and F. Bourion. Comptes rend., 1904, **138**, 760—762.

By passing chlorine and vapour of sulphur chloride over heated metallic oxides or oxy-salts, the latter are converted into anhydrous chlorides. In some cases this forms the best method of preparing these chlorides. Tungstic anhydride thus gives oxychlorides WO_2Cl_2 and $WOCl_4$, chromium sesquioxide and ferric oxide give chromic and ferric chlorides, and the sulphates of barium and calcium are completely converted into the corresponding chlorides. Barium sulphate can thus be completely separated from co-precipitated ferric oxide (as the ferric chloride formed is volatile), and the amount of the latter determined.—J. T. D.

Sulphur Bromide. G. Korndoerfer. Archiv der Pharm., 1904, **242**, 156—160.

When sulphuretted hydrogen reacts on bromine in the presence of a large excess of water, hydrobromic acid and sulphur are formed, as found by Naumann, according to the equation $H_2S + 2Br = 2HBr + S$. If, however, the gas be passed into bromine merely covered with a layer of water, the containing vessel being kept cool during the reaction, a considerable amount of sulphur bromide, S_2Br_2, is produced, and forms a red oily liquid, which can be freed from dissolved hydrobromic acid by agitation with dry potassium carbonate. It is slowly decomposed by cold and rapidly by warm water.—J. O. B.

Liquid Oxygen; Preparation and Characters of Pure ——. E. Erdmann and F. Bedford. Ber., 1904., **37**, 1184—1193.

Pure oxygen was obtained by reacting with hydrogen peroxide on solid potassium bichromate in a Kipp apparatus, was dried by passing through sulphuric acid and phosphorus pentoxide, and was then passed into a flask contained in a Dewar's vacuum vessel which could be filled with liquid air. The flask was closed air-tight by a cork, through which passed two tubes—the entry tube for the oxygen and an exit tube communicating with a barometric mercury gauge and (through a T-piece) with a water aspirator. The apparatus was first thoroughly freed from air by successive evacuations and fillings with oxygen; then the flask was surrounded with liquid air, when a rapid current of oxygen could be completely liquefied. Two Kipps communicated with a common delivery-tube, the object of the second being to keep up the pressure of oxygen and prevent entry of air whilst the exhausted liquid was being removed from the first Kipp and replaced by fresh. In an hour 170 grms. of liquid oxygen are easily obtained. Analysis gave 99·8 per cent. of oxygen. The liquid has a constant boiling point at − 181·8° C. (Pure oxygen could not be obtained from potassium chlorate.) This liquid oxygen absorbs nitrogen gas with avidity; when boiling, it may be left in an open vessel exposed to air without altering in composition, but if below its boiling point it rapidly absorbs nitrogen from the air. A rapid stream of nitrogen led through liquid oxygen is readily absorbed. At − 190·5° C. and − 191·5° C. respectively, the oxygen required for saturation 380 and 460 volumes of gaseous nitrogen, or 42 and 50 per cent. of its weight. This behaviour of liquid oxygen explains why it is impossible to prepare pure oxygen by the fractional evaporation of liquid air.—J. T. D.

Liquid Air; Composition and Temperature of ——. E. Erdmann. Ber., 1904, **37**, 1193—1196.

The composition of "liquid air" is very variable. The yield from a Hampson machine working under different conditions had a temperature varying from − 194·5° to − 191° C., and contained oxygen varying from 28 to 57 per cent. The temperature at which the liquid leaves the machine is not necessarily its boiling point. In the case of a gaseous mixture, the less volatile constituent is not liquefied at its boiling point under atmospheric pressure, but at a lower temperature, corresponding to its partial pressure in the mixture; so that the oxygen in atmospheric air will not necessarily liquefy till the temperature is reduced to −195·5° C., and when it does liquefy, it will at once absorb and liquefy nitrogen.—J. T. D.

Chloric Acid; Action of Copper on ——, with or without Electrolysis;

Copper; Formation of Basic Salts of —— [Chlorate and Chloride] under the influence of Electrolysis;

Basic Cupric Chlorate; also

Chlorates of the Alkali- and Alkaline-Earth Metals; Electrolysis of —— with a Copper Anode. A. Brochet. XI. A., page 445.

Thiocyanates in presence of Salts giving Precipitates with Silver Nitrate; Determination of ——. A. Dubosc. XXIII., page 456.

Antipyrine; Application of —— in Analysis (Nitrite Reaction). C. Reichard. XXIII., page 456.

English Patents.

Phosphoric Acid; Production of ——. H. H. Lake, London. From E. H. Fallows, New York. Eng. Pat. 2284, Jan. 29, 1904.

See U.S. Pat. 751,753 of 1904; this J., 1904, 252.—T. F. B.

Brine; Evaporating Weak ——, and Apparatus therefor. E. Moll, Linden. Eng. Pat. 28,518, Dec. 28, 1903.

The weak brine is heated in a pair of boilers, the steam from which is led through coils immersed in brine in the first of a pair of large domed, closed pans, fed from the boilers. Here the evaporation is aided by exhaustion, and in a greater degree in the second pan of the pair, which is heated by a steam coil with steam that has passed through a superheater on its way from the first pan. Both pans are also heated by waste gases from the fireplaces. From the second pan the strong brine passes into directly heated open vessels, in which the salt separates.—E. S.

Gases; Process for the Separation of ——, from Gaseous Mixtures, particularly Oxygen and Nitrogen from Atmospheric Air, and Apparatus therefor. R. J. Levy, Nancy. Eng. Pat. 5649, March 11, 1903.

See Fr. Pat. 330,258 of 1903; this J., 1903, 1087.—T. F. B.

Liquefying Air and other Gaseous Fluids; Apparatus for ——. H. Knudsen. Eng. Pat. 6087, March 16, 1903. I., page 434.

United States Patents.

Sulphuric Acid; Manufacture of ——. P. G. Salom, Philadelphia. U.S. Pat. 755,247, March 22, 1904.

Sulphur dioxide gas is oxidised by bringing it into contact with water contained in a number of superposed vessels, connected electrically. A current of electricity is passed through, each vessel constituting an electrolytic cell. Means are provided for the supply to, and flow of liquid from the upper vessels to those beneath them, in order of sequence, and from the lowest vessel of the series into a suitable receptacle.—E. S.

Hydrofluoric Acid; Manufacturing ——. C. A. Doremus, New York. U.S. Pat 754,978, March 22, 1904.

Hydrofluosilicic acid, or a mixture of hydrofluosilicic acid with hydrofluoric acid, is treated with an excess of a metallic compound, thereby producing a fluoride, from which hydrofluoric acid is liberated by the action of superheated steam.—E. S.

Nitric Acid; Method of Making ——. W. Mills, London, Assignor to A. O. Granger, Cartersville. U.S. Pat. 755,378, March 22, 1904.

Substances containing lead are heated with concentrated hydrofluosilicic acid; the lead silicofluoride so formed is reacted upon by a nitrate, and the lead nitrate produced is used as a source of nitric peroxide afterwards used for nitric acid. Compare U.S. Pats. 754,667 and 754,668 of 1904; this J., 1904, 371.—E. S.

Fluorides and Silicates; Method of Making ——. W. Mills, London, Assignor to A. O. Granger, Cartersville. U.S. Pat. 755,379, March 22, 1904.

An alkali nitrate is added to a solution of lead silicofluoride, and the precipitated alkali silicofluoride is heated to obtain the fluoride; or it is mixed with "silicious material" and heated, to form a silicate. Compare the preceding abstract.—E. S.

Sodium Sulphide; Manufacturing ——. J. F. White, Buffalo, Assignor to General Chemical Co., New York. U.S. Pat. 755,201, March 22, 1904.

Nitre cake is heated in the presence of coal and salt.
—E. S.

Brine; Process of Purifying ——. W. Trantom, New Brighton. U.S. Pat. 755,415, March 22, 1904.

See Eng. Pat. 23,642 of 1902; this J., 1903, 696.—T. F. B.

Composition of Matter [Stable Hydrosulphite Body], and Process of Producing same. H. Wolf, Assignor to Badische Anilin und Soda Fabrik, Ludwigshafen. U.S. Pat. 756,759, April 5, 1904.

See Eng. Pat. 18,852 of 1900; this J., 1901, 988.—T. F. B.

French Patents.

Hydrosulphites; Production of ——. Badische Anilin und Soda Fabrik. Fr. Pat. 336,942, Feb. 2, 1903.

Lime and Combustible Gas; Combined Process of Manufacturing ——. The Chalk Power Gas Syndicate, Ltd. Fr. Pat. 337,081, Nov. 3, 1903. II., page 436.

IX.—BUILDING MATERIALS, CLAYS, MORTARS AND CEMENTS.

Firebrick; Alteration of ——, by Furnace Gases. F. Firmstone. Trans. Amer. Inst. Min. Eng., New York, Oct. 1903.

A furnace, 75 ft. high and 18 ft. greatest diameter, using coke to smelt a lean magnetic ore, was lined with:—(1) blocks 14 ins. long by 6 ins. thick; (2) 2 ins. of loam; (3) one and a half brick wall of 9-in. firebrick, in English bond; (4) red brick to within 2 ins. of the iron shell; (5) 2 ins. of slag wool. The furnace was blown in in May 1902. By March 1903 the 14-in. blocks for more than 20 ft. from the top had disappeared, and a few weeks later the firebrick and the red brick had also gone, and the furnace was blown out. No unusual wear was shown in the lower part of the furnace. The 9-in. bricks between 30 and 40 ft. from the bottom were sintered together so that the joints were practically gone. The surface was glazed about $\frac{1}{16}$th to $\frac{1}{32}$nd in. thick; the fracture of the body was like bluish-grey porcelain, with nearly black spots; no deposited carbon was found. The following analyses were made:—

—	Glazed Skin.	Body of Brick.	Joint.	Brick used to Line, 1902.	Brick made, 1896.
Silica	40·23	57·63	..	55·62	56·12
Alumina	12·22	31·64	..	38·55	37·48
Iron sesquioxide	..	..	..	4·17	4·43
Iron protoxide.	11·93	3·73	6·60	..	..
Lime	10·92	0·24	..	0·24	0·36
Magnesia	4·31	0·11	..	6·24	0·29
Potash.........	9·39	2·59	2·39	0·95	0·99
Soda...........	8·43	0·51	0·79	0·29	0·23
Metallic iron ..	..	1·51	..	..	..
Zinc oxide	..	0·59	..	..	..
	97·43	98·55		100·06	99·90
Total iron......	9·28	4·41	4·62	3·10	2·92

The joints were made of a mortar of ground clay and crushed brick. The fractured brick showed spots of ferric oxide, the basis (chamotte) of the brick was white and not very fine, and the cementing clay or matrix light brown or buff. In earlier recorded cases of similar failure of bricks, disintegration by carbon deposition, through reaction of carbon monoxide on the spots of ferric oxide in the brick, seems to have been the cause, and possibly the present case is due to a similar cause, though the total disappearance of the destroyed bricks makes proof impossible. Stoppage of the furnace several times for want of coke probably led to "scaffolding," which may readily favour carbon deposition. The impregnation of the bricks with iron, shown in the analysis, is possibly effected by iron carbonyl.—J. T. D.

English Patents.

Stone, Artificial; Manufacture of ——. F. W. Howorth, London. From F. Jurschina, Würzburg. Eng. Pat. 3769, Feb. 15, 1904.

From 5 to 10 parts by volume of clay are mixed with 100 parts of sodium silicate solution of 27° to 35° B., and to the mixture is added a refractory sand, *e.g.*, granite or basalt, which has previously been mixed with 5 to 10 per cent. of its weight of well-seasoned Portland cement. The mixture is then allowed to remain at rest for some days, in order to become thoroughly uniform, and is then dried at 25° to 30° C. It is next burnt for 20 to 25 hours at 1000° to 1400° C., the temperature first being increased, and then lowered during the burning. The stone is finally allowed to cool for 24 hours in the kiln.—A. G. L.

White Cement ; Process for Manufacturing ——. E. Gogler, Podgorze, and H. Seinfeld, Cracow. Eng. Pat. 388, Jan. 6, 1904.

Lime and silicic acid are mixed, either in their natural state or after burning, with a quantity of alkali carbonate varying from one to three times the quantity of silica present. The whole is then fused at a low temperature, and the resulting product lixiviated, the lye obtained being used over again instead of fresh alkali carbonate. All the materials used should be as free as possible from iron. —A. G. L.

Concrete and the like ; Treatment of ——, *whereby the Setting of the same after Mixture may be Arrested.* J. H. Magens, Hamburg. Eng. Pat. 6247, March 18, 1903.

See Fr. Pat. 330,393 of 1903 ; this J., 1903, 1089.— T. F. B.

United States Patents.

Wood ; Vulcanised ——, *and Process of Vulcanising same.* W. Powell, Liverpool. U.S. Pat. 755,240, March 22, 1904.

See Eng. Pat. 11,235 of 1902 ; this J., 1903, 697.—T. F. B.

Wood ; Preserved ——, *and Process of Preparing same.* I. P. Lihme, Assignor to the Grasselli Chem. Co., both of Cleveland. U.S. Pat. 756,173, March 29, 1904.

Wood, *e.g.*, railway ties, is treated with a solution of zinc chloride, with the aid of both vacuum and high pressure, and is then subjected under pressure to the action of a solution of a silicate, preferably sodium silicate, whereby the exterior portions become permeated with zinc silicate. —A. G. L.

Cement-Furnace. J. Sheneman, Bronson. U.S. Pat. 755,947, March 29, 1904.

A pair of conveying and drying troughs containing the material to be burnt are placed above a rotary kiln and separated from it by an air-space, from which the air necessary for combustion is forced by means of a fan to the nozzle of the fuel-injector.—A. G. L.

X.—METALLURGY.

Blast Furnace Practice ; Hearth Area and Number of Tuyères in ——. F. L. Grammer. Trans. Amer. Inst. Min. Eng., New York, Oct. 1903.

The use of fine ores has led to the hope that by increasing the area of contact between air and fuel the output of the furnace might be increased. To do this, the number of tuyères has often been increased, but not always with favourable results. As the tuyères increase in number beyond eight, the increased friction in the narrow tubes more than compensates for the number, so that the blast-pressure may have to be increased ; for instance, with 16 tuyères a blast-pressure of about 1—2 lb. per sq. in. higher is needed than with 8 tuyères. With many tuyères, the wear is more regular, and the charge settles more evenly, than with few. A few extra tuyères are of advantage when the furnace works irregularly, and they are easily plugged with clay when not needed. In furnaces of similar dimensions and engine equipment, working under similar conditions, the number of tuyères needed is proportional to the hearth area. With a hearth of small diameter, the combustion zone extends higher than with a larger hearth, and the temperature is somewhat higher. Also the slag, metal, and coke are long in contact, and the silicon-content of the pig is likely to be high : this is usually the case in furnaces having a narrow crucible. Increasing the number of tuyères is analogous to widening the hearth, and lowers the height of the combustion zone. A wide hearth tends towards uniformity in the composition of the pig, for obvious reasons. In 30 years, the ratio of hearth area to greatest bosh-area has changed from $\frac{1}{10}$ to $\frac{3}{10}$, and the furnace capacity in cubic feet per ton of metal per 24 hours has decreased from 200—380 to 20—30. Schierz gives the relative times of exposure in the reduction zone for spiegel, foundry iron, and forge iron, as 4·53, 2·75, and 1. Gruner gives the cubic capacity of the crucible (for coke furnaces) as about 9 cb. ft. in small and 5 cb. ft. in large furnaces per ton of iron per 24 hours : modern American practice is 3 to 3½ cb. ft.—J. T. D.

Pig-Iron and Iron Castings ; Specifications for ——. R. Job. Amer. Inst. Mining Eng. (Trans.), Atlantic City, Feb. 1904.

The author describes the specifications in accordance with which pig-iron and iron castings are purchased by the Philadelphia and Reading Railway Co. The chemical and physical requirements are as follows :—Iron Castings. *Chemical :* Class I. (medium iron for engine cylinders, gears, wheel centres, smoke-stacks, &c.). The iron must be close-grained and tough ; and contain :—silicon 1·4—2 per cent. ; sulphur, not exceeding 0·085 ; manganese, not exceeding 0·7 ; and phosphorus, not exceeding 0·6 per cent. Class 2 (soft iron for small castings for general car and roadway use). Silicon, 2—2·8 per cent. ; sulphur, not exceeding 0·085 ; manganese, not exceeding 0·7 ; and phosphorus, not exceeding 0·6 per cent. Class 3 (iron for brake-shoes and other castings for frictional wear). The iron must be hard and tough ; and contain :—silicon, 2—2·5 per cent. ; sulphur, not exceeding 0·15 ; manganese, not exceeding 0·7 ; and phosphorus, not exceeding 0·7 per cent. *Physical :* The castings must be of uniform quality and of solid iron, free from physical defects and excessive shrinkage strains ; and not contaminated with sand. Castings of Classes 1 and 2 must be of grey iron throughout and easily machined. Pig-Iron. *Chemical :* Silicon, 1·5—2·5 per cent. ; manganese, 0·4—0·75 ; phosphorus, not exceeding 0·5 ; and sulphur, not exceeding 0·04 per cent. *Physical :* The material must be of uniform quality, and free from sand, dirt, slag, or other foreign matter.—A. S.

Available Cyanide ; Determination of ——. J. E. Clennel. XXIII., page 457.

English Patents.

Alloy ; Manufacture of a Metallic ——. T. Prescott, Huddersfield, and E. Green and Son, Ltd., Leeds. Eng. Pat. 5683, March 11, 1903.

The alloy consists chiefly of zinc and aluminium, with small proportions of iron and silicon, the composition being varied according to the degree of hardness or toughness required. The iron is first melted, the aluminium is added, and then the zinc, followed by a "silicon flux," constituted of potassium silicofluoride, calcium chloride and carbonate, sodium chloride and carbonate, and powdered glass.—E. S.

Blast Furnaces. O. S. Garretson, Buffalo. Eng. Pat. 11,297, May 18, 1903.

See U.S. Pat. 728,700 of 1903 ; this J., 1903, 747.—T. F. B.

Rotary Furnaces. W. S. Rockwell, New York. Eng. Pat. 1503, Jan. 20, 1904.

The furnace consists of two independent rotary melting chambers, elliptical in longitudinal section and circular in cross section, with contracted openings at both ends, and placed end to end in close contact with each other. The metal is melted in one chamber, whilst in the other the ingots are given a preliminary heating by the products of combustion from the first chamber. In the next series of operations the functions of the two chambers are reversed. The chambers have burner nozzles at their outer ends. Each chamber consists of two half sections hinged together, which may be opened to facilitate placing the lining, means being provided for locking such sections together when they are in place.—E. S.

Matte; Process of Converting or Bessemerising ——. O. S. Garretson, Buffalo. Eng. Pat. 11,303, May 18, 1903.

See U.S. Pat. 728,701 of 1903; this J., 1903, 747.—T. F. B.

Friable Ores; Manufacture of Briquettes from ——. H. Schulte-Steinberg, Düren. Eng. Pat. 3235, Feb. 9, 1904.

Blast-furnace slag is powdered, and subjected to the action of high-pressure steam, preferably in a rotating drum. The slag thus treated serves as binding material in making briquettes of friable ores. When it is desired that the briquettes formed should be as porous as possible, the proportion of the prepared slag used is reduced, say to 10 per cent. of the ore. Reference is made to Eng. Pat. 17,183 of 1903; this J., 1903, 1247.——E. S.

United States Patents.

Cast Iron; Process of Tempering or Hardening ——. W. Gilmour and A. Lindsay, Montreal, Assignors to C. A. Myers and H. H. Bradfield, Morrisburg. U.S. Pat. 755,763, March 29, 1904.

See Eng. Pat. 28,396 of 1902; this J., 1903, 557.—T. F. B.

Steel, &c.; Converter for Making ——. W. B. Burrow, Norfolk. U.S. Pat. 755,215, March 22, 1904.

The converter, which is operated horizontally, and is so mounted that it can be tilted, has internal ribs or corrugations occupying one-half of the inner circumference, which ribs contain horizontal and vertical tuyères discharging at right angles to each other; the former tuyères blowing towards the closed end of the converter. The tuyères are supplied from a horizontally divided wind-box on the pouring side of the vessel, having guide and deflecting plates and regulating valves. The bottom or closed end of the converter has a slag door.—E. S.

Steel; Process of Annealing ——. L. D. Davis, Erie. U.S. Pat. 755,629, March 29, 1904.

The steel is immersed in a bath of "molten metal" fusing between 1,000° and 1,500° F.; or in a bath of "molten metal in which aluminium predominates," heated to from 1,100° to 1,500° F.; or in a "bath of aluminium," heated to from 1,125° to 1,500° F.; and the steel is "gradually cooled."—E. S.

Steel Plates; Method of Locally Softening or Annealing Hardened ——. C. P. E. Schneider, Le Creuzot. U.S. Pat. 755,709, March 29, 1904.

See Eng. Pat. 19,167 of 1903; this J., 1903, 1246.—T. F. B.

Air for Blast Furnaces and Converters; Method of Extracting Moisture from ——. J. Gayley, New York. U.S. Pat. 756,110, March 29, 1904.

See Eng. Pat. 19,933 of 1903; this J., 1904, 22.—T. F. B.

Metallurgical Apparatus. G. W. Gesner, New York, Assignor to H. C. Gesner, Brooklyn. U.S. Pat. 755,867, March 29, 1904.

A vertical retort is set over a furnace the gases from which pass into a surrounding flue. In the wall between the retort and the flue a pipe coil is bedded, partly exposed to the gases of combustion, and having a terminal portion opening into the retort, composed of a combination of graphite and clay. Separate valved pipes for conveying steam and naphtha merge into a single pipe entering the coil, in which the mixture is heated and discharged into the retort. In the lower portion of the retort is a grate communicating with a chamber immediately beneath, and over the fireplace, with means of access from without. The apparatus is for the manufacture of a "hydrogen alloy" or "scale alloy."—E. S.

Ore [Gold]; Apparatus for Treating ——. T. A. Helm, Salt Lake City. U.S. Pat. 755,871, March 29, 1904.

The apparatus consists of a cylindrical tank, provided inside with radial perforated blades, extending the whole length of the tank. A circular brace-frame is arranged between the inner ends of the radial blades. An air-pipe leading into the tank, faucets to draw off the liquid, and means for rotating the tank, are also provided.—E. S.

Ores; Process of Treating [Cyaniding] ——. J. Smith, San Francisco. U.S. Pat. 755,951, March 29, 1904.

Ore containing ferrous oxide is heated in a moist, crushed state, in presence of air, whereby the ferrous oxide is rendered insoluble in the cyanide solution.—E. S.

Ores, [with] Liquids or Gases; Apparatus for Treating Solids such as ——. P. Naef, New York. U.S. Pat. 756,271, April 5, 1904.

See Eng. Pat. 17,054 of 1900; this J., 1901, 1195.—T. F. B.

Copper; Extraction of —— from Comminuted Mineral Mixtures. E. A. Le Sueur, Ottawa. U.S. Pat. 755,302, March 22, 1904.

The powdered mineral mixtures are treated with an ammoniacal solution containing a reagent capable of oxidising copper, such as a cupric compound; a portion of the total copper contents of the solution is then removed, and the partially exhausted solution is again used to dissolve fresh copper as before.—E. S.

Copper and Iron; Manufacturing Alloys of ——. J. D. Darling, Assignor to R. M. Popham, both of Philadelphia. U.S. Pat. 755,461, March 22, 1904.

A mixture of iron oxide with calcium carbide is added to a bath of molten copper; or a mixture of copper oxide and calcium carbide to a bath of molten iron.—E. S.

Plumbiferous Ores; [Vessels for] Treating ——. E. W. Engels, Düsseldorf. U.S. Pat. 755,222, March 22, 1904.

Plumbiferous ores are treated at high temperatures in vessels "composed largely of clay and carborundum, in the relative proportion of not less than 25 per cent. or more than 90 per cent. of carborundum." The clay and carborundum are conjointly used on the surfaces of the vessels exposed to be attacked by the ore, so as that they may protect one another.—E. S.

Lead Ores; Process of Desulphurising ——. A. Savelsberg, Ramsbeck. U.S. Pat. 755,598, March 22, 1904.

See Fr. Pat. 336,540 of 1903; this J., 1904, 376.—T. F. B.

Ore Bricks; Manufacture of ——. J. Koeniger, Cologne. U.S. Pat. 755,372, March 22, 1904.

See Eng. Pat. 15,437 of 1902; this J., 1903, 867.—T. F. B.

Welding Compound. R. S. Woodson, Boulder. U.S. Pat. 755,826, March 29, 1904.

Powdered silica ($93\frac{1}{3}$—97 parts) is mixed with powdered borax (3—$6\frac{2}{3}$ parts).—E. S.

Brazing Cast-Iron; Process of ——. J. E. Tichon, Assignor to T. E. Parker, both of New Bedford, and to H. F. Strout and J. C. Bassett, Boston. U.S. Pat. 756,079, March 29, 1904.

A plastic paste of "boro-boracic acid" and metallic filings is applied to the surfaces to be joined, the parts are heated, and spelter is poured on the joint, with or without the raising of the temperature and applying "boro-boracic acid."—E. S.

Brazing Compound. J. E. Tichon, Assignor to T. E. Parker, both of New Bedford, and to H. F. Strout and J. C. Bassett, Boston. U.S. Pat. 756,080, March 29, 1904.

The claims include a brazing compound containing "boro-boracic acid," with or without particles of metal, also a flux "comprising boro-boracic acid." (See preceding abstract.)—E. S.

French Patents.

Iron and Steel in a Solid, but Incandescent, State; Treatment of ——, *by means of Carbides.* E. Engels. Fr. Pat. 337,154, Nov. 28, 1903.

See Eng. Pat. 25,932 of 1903; this J., 1904, 118.—T. F. B.

Metals; Process for the Extraction of ——, the Formation of Alloys and Metallic Oxides, and the Production of High Temperatures. P. and A. Weiller. Fr. Pat. 336,989, Nov. 9, 1903.

The ores are freed from gangue and ignited with suitable reducing bodies, such as iron or carbon. To form alloys, the ores are intimately mixed with excess of the metal or metals to be introduced, and the mixture is ignited. If an oxide is to be formed, the reducing metal is to be used in smaller proportion than in the previous case. To obtain high temperatures, the body to be highly heated is bedded in "substances giving oxygen, chlorine, or sulphur, and with a reducing substance," and the mixture is then ignited.—E. S.

Antimony; Metallurgical Treatment of ——, and Apparatus therefor. F. M. E. Basse. Second Addition, dated Nov. 11, 1903, to Fr. Pat. 319,534 of March 13, 1902. (See this J., 1902, 1537; 1903, 747.)

The claim is for the use of solid fuel conjointly with that of liquid or of gaseous fuel, or of both, in the special furnace described in the main patent and in the First Addition thereto (*loc. cit.*), and also in metallurgical roasting furnaces generally.—E. S.

Zinc; Process and Apparatus for the Production of ——. J. L. Babé and A. Tricart. First Addition, dated Nov. 13, 1903, to Fr. Pat. 294,831 of Nov. 30, 1899.

The furnace supplied with a blast, described in the main patent, is replaced by a furnace in which the fumes are withdrawn by aspiration through channels in the side walls. Ore, charged into an opening in the top of the furnace (which opening is afterwards closed), descends by gravity. The air required for combustion is admitted through the fire-grate, or from the bottom of the furnace. (See U.S. Pat. 702,764 of 1902; this J., 1902, 1142.)—E. S.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

(*A.*)—ELECTRO-CHEMISTRY.

Chloric Acid; Action of Copper on ——, with or without Electrolysis;

Copper; Formation of Basic Salts of —— [Chlorate and Chloride] under the Influence of Electrolysis;

Basic Cupric Chlorate; also

Chlorates of the Alkali- and Alkaline-Earth Metals; Electrolysis of —— with a Copper Anode. A. Brochet. Bull. Soc. Chim., 1904, **31**, 287—295.

Strong chloric acid (280 grms. per litre) attacks copper violently, a normal solution of the acid only very slowly. No gas is evolved during quiet action, cupric chloride and cupric oxide being produced. The latter dissolves in the chloric acid till the acid is completely saturated, when basic salts begin to deposit. In the cold, the metal is covered with a deposit of cuprous hydroxide, which afterwards dissolves. The electrolysis of chloric acid with a copper anode gives similar results, but more rapid action. In the cold, the anode is coated with a white deposit of cuprous chloride, but this is not perceived at 60°—80° C. Cuprous chloride itself reduces chloric acid slowly in the cold, but instantaneously when heated, forming cupric chloride and oxide. The electrolysis of chloric acid, or of potassium chlorate or cupric chlorate acidified with sulphuric acid all give identical results. The anode is attacked with great regularity. The action of copper on cupric chlorate, with or without electrolysis, results in the formation of cupric or cuprous chloride or hydroxide, or mixtures. The basic salts formed have the formula $Cu(A)_2.3Cu(OH)_2$, where Cl and ClO_3 may replace one another indefinitely in A; the amount of basic salt formed depends on the acidity of the solution. The copper dissolved from the anode is from 1·5 to 2 times that corresponding to the electrolysing current. Basic cupric chlorate, $Cu(ClO_3)_2.3Cu(OH)_2$, obtained crystallised by Bourgeois by heating the normal salt, is obtained as an amorphous product by reacting on cupric chlorate solution with cupric or alkali hydroxide. It is a greenish-blue powder, always containing a little more hydroxide than the formula indicates. The electrolysis with a copper anode of the chlorates of the alkalis and alkaline earths is similar in its procedure to that of cupric chlorate. The copper anode dissolves as cuprous ions, which are more or less rapidly converted into cupric compounds, reducing the chlorate. The basic salts, which, in the case of cupric chlorate, are deposited, are, in the case of potassium or barium chlorate, incompletely precipitated by the cathodic alkali; and the cathodic hydrogen is partly used up in reducing chlorate, and partly reduces the cupric hydroxide, and deposits copper. The black deposit formed, contains metallic copper, cupric oxide and chloride, and potassium or barium compounds as the case may be.—J. T. D.

Azo Dyestuffs; Electrolytic Preparation of ——. W. Löb. Zeits. Elektrochem., 1904, **10**, 237—238.

Azo dyestuffs can be produced electrolytically from a mixture of an aromatic amine, sodium nitrite, and a coupling component to combine with the diazo compound produced, by subjecting the same in a neutral (or occasionally alkaline) electrolyte to anodic current action at an unalterable electrode. Phenols are the best coupling components, whilst amines are quite unsuitable, giving rise to secondary reactions. The mixture of amine, sodium nitrite, and coupling component is placed in the anode compartment, which is separated by a diaphragm from the cathode compartment. The anode is preferably of platinum, and the cathode of any suitable metal. The contents of the anode compartment are agitated while the current is being passed. The strength of current, temperature, &c., vary considerably in different cases, but in no case is any artificial cooling required as in the chemical diazotising process. The following dyestuffs have been prepared:—Orange II, from sodium sulphanilate and β-naphthol; Congo Red, from benzidine and sodium naphthionate; Dianisidine Blue, from dianisidine and β-naphthol; Chrysamine G, from benzidine and sodium salicylate; and Roccelin, from sodium 1.4-naphthylaminesulphonate and β-naphthol.—A. S.

Iodoform; Electrolytic Preparation of ——, from Acetone. J. E. Teeple. XX., page 453.

English Patents.

Electric Batteries. J. Portalier, Brussels. Eng. Pat. 5891, March 13, 1903. Under Internat. Conv., Sept. 13, 1902.

See Fr. Pat. 324,851 of 1902; this J., 1903, 636.—T. F. B.

Ozone by Electricity; Apparatus for Purifying Air and Generating ——. C. Wokes and F. H. Street, both of Hull. Eng. Pat. 10,251, May 6, 1903.

An outer casing is provided internally with a series of projecting electrodes, and opposite to the internal edges of these is a similar series of electrodes mounted externally on an inner tube or shaft. The outer casing and inner tube are insulated and connected to the terminals of a source of electric current, and air or oxygen is passed through the apparatus. The apparatus may be provided with one or more additional inner tubes, each furnished with electrodes, disposed externally and internally as described above.—B. N.

United States Patents.

Sheath or Envelope for Storage Battery Plates; Protective ——. A. Meygret, Paris. U.S. Pat. 756,176, March 29, 1904.

A bath, containing a mixture of castor oil, essence of turpentine, and nitrates of cellulose, is used for coating the plates of storage batteries, thus forming an envelope or sheath of these substances on the plate.—B. N.

Sulphuric Acid; [Electrolytic] Manufacture of ——. P. G. Salom. U.S. Pat. 755,247, March 22, 1904. VII., page 442.

(*B.*)—ELECTRO-METALLURGY.

Copper Electrolysis; Relation between Arsenic and Electro-Motive Force in ——. L. W. Wickes. Amer. Inst. Mining. Eng. (Trans.), Atlantic City, Feb. 1904.

The author finds that in the electrolytic refining of copper, the arsenic passes into solution as sulphate, which then gradually undergoes hydrolysis with formation of arsenic acid. The arsenic in the latter compound is in the form of an anion and therefore cannot be deposited on the cathode and contaminate the refined copper. The known effect of the electromotive force on the amount of arsenic in the deposited copper is thus an indirect one; *i.e.*, with increased E.M.F., the time required for the deposition of a given weight of copper, and consequently also the amount of arsenic sulphate converted by hydrolysis into arsenic acid are diminished.—A. S.

Cadmium and its Alloys: Electro-Deposition of ——. S. Cowper-Coles. Electro-Chem. and Metall., 1904, **3**, 582—586.

Cadmium-silver alloys have been deposited on a commercial scale, an alloy containing a small percentage of silver having been employed for coating bright steel parts of machines, whilst domestic articles have been plated with an alloy containing 7·5 per cent. of silver. Such alloys have been found to withstand tarnishing much better than pure silver or standard silver containing 7·5 per cent. of copper. Very careful adjustment of the concentration of the solutions and the current density seems to be necessary for obtaining a definite composition of the electro-deposited alloys; and, moreover, if the bath is to be maintained for any length of time in working condition, the deposit must be of the same composition as the anode.—R. S. H.

English Patents.

Furnaces; Impts. in Electric Crucible ——. A. Reynolds, London. Eng. Pat. 11,000, May 14, 1903.

The electrical heating resistance is formed by ramming a spiral layer of material round and in contact with the walls of the crucible, the "spires" of the resistance being insulated from each other by a similar spiral layer of non-conducting refractory material, preferably the same as the material of the crucible. The resistance material, which is inert to the crucible walls at furnace temperatures, consists of plumbago, or other form of carbon, or a mixture of plumbago with the material of which the crucible is made. The furnace described is an annular one with two concentric walls, each of which has a resistance spiral, the latter being suitably connected in series or in parallel.—B. N.

Furnace; Electric Crucible ——. A. Reynolds, London. Eng. Pat. 11,001, May 14, 1903.

An iron casing, connected to one terminal of the electric supply, has a fire-brick lining, in which is bedded a plumbago crucible having a lining consisting of magnesite, or other refractory material, or a mixture of materials with or without plumbago. The crucible is in electrical connection with the outer casing, and the second electrode, vertically adjustable, is placed centrally over the crucible. A plug of plumbago, or other conducting material, in the lining, serves to start the arc and thus heat the inner lining, the latter being inert to the charge and conducting electricity at furnace temperatures, so that it forms a durable electrode. —B. N.

Melting Steel and the like in Electric Furnaces; Method of ——. A. Reynolds. Eng. Pat. 11,002, May 14, 1903.

Steel or other material is melted by forming on the surface of the charge, a slag which is chemically inert to the charge and to the electrodes. The slag is heated, and the heating maintained, by the passage of an electric current through the slag, or by an arc or arcs formed between the vertical electrodes and the slag. The latter consists of an acid silicate of lime or a basic silicate of lime or magnesia, or both metals, according to the character of the lining of the crucible, whether acid or basic.—B. N.

[*Electric*] *Furnaces for Extracting Metals and Making Carbides and similar Compounds.* Le Roy W. Stevens, and B. Timmerman, Chicago. Eng. Pat. 768, Jan. 12, 1904.

See U.S. Pat. 749,460 of 1904; this J., 1904, 192.—T. F. B.

Steel Blocks; Filling up Cavities Produced in —— *during the Process of Casting or Cooling.* J. Matzek, Mülheim-on-the-Ruhr. Eng. Pat. 912, Jan. 13, 1904.

The crust of the cooling steel-block casting is electrically fused, and the electrode is then introduced into the cavity to fuse its walls. Instead of an electrode consisting of a single carbon rod, two or more rods may be employed, so that fusion may take place at several points of the block simultaneously. Finally, molten steel is run into the cavity to unite with the steel thus fused.—E. S.

French Patents.

Antimony; Process for the Electrolytic Extraction of —— *from its Sulphuretted Ores.* J. Izart and L. Thomas. Second Addition, dated Feb. 3, 1903, to Fr. Pat. 319,449, March 10, 1902 (this Journal, 1902, 1541).

The sulphide ores of antimony or arsenic are dissolved in an alkali (potash or soda) and electrolysed, the metal being deposited with formation of an alkali sulphide. The latter may be recovered by crystallisation; or by the addition of an acid to the liquid remaining after electrolysis, the golden sulphide of antimony may be precipitated.—B. N.

Metallic Masses; Fusing ——. Hoerder Bergwerke- u. Hütten-Verein. Fr. Pat. 337,190, Nov. 30, 1903.

A gas or gaseous mixture is passed under high pressure through a tube made of a material that is a good conductor of electricity and coated with refractory non-conducting material. The end of the tube is placed against the mass to be fused, and, on passing the electric current, a "luminous electric arc" is formed, the flame produced impinging upon the mass to be melted. As the fusion proceeds, the tube is advanced.—E. S.

XII.—FATTY OILS, FATS, WAXES, AND SOAP.

Fatty Esters; Hydrolysis and Synthesis of —— *by Platinum Black.* H. Neilson. Amer. J. Physiol., **10**, 191—200.

The platinum-black used in these experiments was washed until neutral, dried in an oven, heated for one hour at 100° C., and powdered. All the apparatus was sterilised, and the experiments were made at 38° to 40° C., except in the case of those to determine the influence of temperature. In each instance the tubes containing ethyl butyrate were placed in the incubator for 30 minutes before the introduction of the platinum-black. The ethyl butyrate solution consisted of 10·4 c.c. of that substance in 200 c.c. of distilled water with 2 c.c. of a 1 per cent. solution of thymol as an antiseptic. Five c.c. of this solution were mixed with 300 grms. of platinum-black, and the tubes placed in the incubator and shaken at regular intervals. After the required time the tubes were immersed in ice-water to stop further action, and their contents subsequently titrated with N/20 sodium hydroxide solution. Blank determinations with tubes containing only the ethyl butyrate solution were simultaneously made and the small amount of acidity in these deducted from the results of the actual tests.

Influence of Time.—The following typical results represent the amount of hydrolysis after the different times mentioned:—24 hours, 10·3 per cent.; 48 hours, 28·3; 72 hours, 37·3; 96 hours, 49·0; and 144 hours, 68·0 per cent. A slight amount of the acidity was due to acetic acid formed by oxidation of the alcohol liberated in the hydrolysis.

On comparing the action of platinum-black on ethyl butyrate with that of lipase, it was found that the hydrolysing action of the former was slower.

Influence of Concentration.—The constant factors in these experiments were :—Time, 32 hours; temperature, 40° C.; ethyl butyrate, 0·26 c.c. The following percentages of hydrolysis were observed on varying the amounts of platinum :—25 mgrms., 0·8; 50 mgrms., 1·58; 100 mgrms., 2·94; 150 mgrms., 5·0; 200 mgrms., 7·50; 250 mgrms, 9·0; 300 mgrms., 13·40; 400 mgrms., 17·0 per cent.

Influence of Temperature.—Constant factors :—Time, 24 hours; ethyl butyrate, 0·26 c.c.; platinum-black, 300 mgrms. Typical results :—0° C., 0·75 per cent.; 10° C., 2·5; 20° C., 5·1; 40° C., 12·0; and 60° C., 15·0 per cent.

Influence of Concentration of the Ethyl Butyrate.—The experiments cited show that the action of the platinum black is independent of the concentration of the ethyl butyrate, in which respect it resembles lipase.

Influence of Poisons.—In each experiment 5 c.c. of a 0.001 solution of the poison were added to the test-tube containing 0·26 c.c. of ethyl butyrate, and 300 mgrms. of platinum-black, and the whole kept at 40° to 42° C. for 24 or 48 hours. The following percentages of hydrolysis were observed as the average results of different experiments :—Water, 21·0; sodium fluoride, 18; formaldehyde, 18; chloroform, 14·5; toluene, 11·0; mercuric chloride, 11·0; silver nitrate, 9·7; salicylic acid, 5·8; phenol, 4·3; hydrocyanic acid, 1·2; and potassium cyanide, 0·0. The influence of sodium fluoride is much more pronounced in the case of lipase, whilst on the other hand hydrocyanic acid is much more destructive to the action of platinum black than to that of lipase. The action of the other poisons is very similar in both cases.

Reversibility of the Action.—A mixture of 200 c.c. of N/20 butyric acid solution and 40 c.c. of 20 per cent. alcohol with a little thymol, was thoroughly shaken with 2 grms. of platinum-black, and the liquid eventually decanted from coarser particles, and kept for 8 hours at 45° C. with occasional shaking. The contents of the flask had then a marked odour of ethyl butyrate, the presence of which was identified by distillation. A blank test made without the presence of platinum was free from ethyl butyrate. No quantitative determinations were made, but it is stated that the synthesis effected by platinum-black is not so pronounced as the hydrolysis, which is also the case with lipase.—C. A. M.

Higher Glycerides. J. B. Hannay. Proc. Chem. Soc., 1904, **20**, 58—60.

The higher glycerides, as represented by purified stearin, olive oil, linseed oil, castor oil, cotton-seed oil, rape oil, and earth-nut oil, are all capable of entering into direct combination with lead oxide, the new compounds being formed by heating the oils with excess of finely-divided litharge at 170° to 180° C. and dissolving out the product with chloroform, petroleum, or carbon tetrachloride. The substance obtained resembles wax and has no sharp melting point; it begins to soften at 120°, becomes viscous at 150° to 160°, and is quite limpid at 190° C. It commences to boil and decompose at about 280° C., the temperature varying a few degrees according to the oil used. In the case of the olein derivative, the composition may be represented by the formula $C_3H_5O_3 \vdots Pb_3(C_{18}H_{33}O_2)_3$, where the three atoms of lead are seen to replace six atoms of hydrogen, three in a molecule of glycerol, and three in molecules of oleic acid. This compound probably represents the first step in saponification by lead oxide. The oleic acid derivative, when dissolved n ether, is decomposed by cold water in the following manner :—

$$2(C_{57}H_{104}O_6,3PbO) + 3H_2O =$$
$$2(C_3H_8O_3) + 3(C_{18}H_{33}O_2)_2Pb,PbO,$$

lycerol and a basic lead oleate being thereby produced. ead glyceryl oleate and the corresponding stearate, linoleate, nd ricinoleate resemble mercury thymyl acetate in forming double compound with lead acetate. The foregoing comounds are stable and not affected by fractional precipitation, either is the lead displaced by metallic sodium, phosphoric xide, or sulphur trioxide.

Glycerol; Determination of —— in Fats. R. Fanto. XXIII., page 458.

English Patents.

Fatty Acids, Hydrocarbons, and the like; Apparatus for the Continuous Distillation of ——, and Steam Superheating Apparatus therefor. V. Sláma, Moscow. Eng. Pat. 12,984, June 9, 1903.

Fractional distillation is effected in a closed vessel containing two or more superposed communicating compartments provided with steam inlet and outlet pipes, and pipes communicating with the supply tank and steam superheating apparatus. The more volatile constituents are separated in the upper compartments. The steam superheating apparatus consists of cast iron or other hollow bodies each divided into two chambers and connected with each other. The steam passing through these chambers is superheated, whilst the substance to be distilled circulates through batteries of pipes within these chambers, and is heated to the required extent before entering the distillation apparatus. —C. A. M.

Wax; Manufacture of Artificial ——. L. A. G. Delahaye, Paris. Eng. Pat. 10,324, May 6, 1903.

See Fr. Pat. 331,714 of 1903; this J., 1903, 1138.—T. F. B.

Soap and other Commodities liable to Evaporation; Preparation of ——. R. H. F. Finlay, Belfast. Eng. Pat. 8954, April 21, 1903.

Soaps, &c., containing volatile substances, such as ammonia or naphtha, are coated with paraffin or varnish.—C. A. M.

Soap; Manufacture of ——. T. Parziale, Alexandria. Eng. Pat. 1303, Jan. 18, 1904.

A mixture of cotton-seed oil and flour is agitated with caustic soda ley until saponification is complete, and the resulting soap run into vats, where it is left until sufficiently hard.—C. A. M.

United States Patent.

Soap, and Method of Making same. G. A. Schmidt, Chicago. U.S. Pat. 755,945, March 29, 1904.

"Calcined granulated porous gritty material" is heated with "liquefied medicaments" in a closed vessel under pressure. The gritty material is then dried and mixed with "soap in liquid state"; the gritty material is "adapted to retain the medicaments out of the sphere of chemical action of the soap."—T. F. B.

French Patents.

Soaps; Process of Manufacturing Non-Caustic ——, which Develop Active Oxygen. H. Giessler and H. Bauer. Fr. Pat. 336,953, Oct. 16, 1903.

See Eng. Pat. 22,580 of 1903; this J., 1904, 327.—T. F. B.

Soaps known as "Savons de Marseille"; Manufacture of ——. L. Garbet. Fr. Pat. 337,091, Nov. 5, 1903.

In the so-called final process of "augmentation," ordinary water is replaced by an aqueous solution of lichen or similar product.—C. A. M.

English Patents.

Paint Vehicles; Manufacture of ——. E. H. Strange and E. Graham, London. Eng. Pat. 8335, April 11, 1903.

Lime, ground to a paste with refined rosin oil, is introduced into crude rosin oil, heated to 160°—180° C., in quantity sufficient to nearly neutralise the acidity of the oil. About 5 per cent. of a manganese drier (preferably manganese resinate), ground to a paste with refined rosin oil, is then introduced at the same temperature, and finally 1 to 1·5 per cent. of litharge is added to completely neutralise the product. The whole is cooled to about 50° C., and petroleum spirit or other volatile solvent is added until the desired viscosity is attained.—T. F. B.

Carbons from Arc Lamps; Process for Utilising the Waste Ends of —— [*as Pigments*]. R. Peters, Heidelberg. Eng. Pat. 2358, Jan. 30, 1904.

See Fr. Pat. 335,795 of 1903; this J., 1904, 260.—T. F. B.

English Patents.

Resinous Substances; Synthetical Production of ——. E. R. L. Blumer, Zwickau. Eng. Pat. 6823, March 24, 1903.

Claim is made in connection with the process described in Eng. Pat. 12,880 of 1902 (this J., 1903, 705) for the use of other organic acids, *e.g.*, oxalic or formic acid in saturated solutions in formaldehyde, and of inorganic acids, *e.g.*, hydrochloric and sulphuric acids in concentrations of not less than 30 per cent., and of acid salts of inorganic acids. —C. A. M.

Turpentine; Russian Oil of, and Similar Products and Benzine or Petroleum Spirit; Treatment of ——, *for the purpose of Removing their Disagreeable Odour.* E. Heber, Bienenhof. Eng. Pat. 10,004, May 2, 1903.

The disagreeable odour of Russian, German, &c., oil of turpentine, or of petroleum spirit, may be removed by treatment with a permanganate, chromic acid, or a persulphate. The quantity required is about 5 to 10 per cent. of the weight of the distillate, using a 4 or 5 per cent. (acid or alkaline) solution of potassium permanganate. The substance to be deodorised is preferably treated with lime and distilled in steam before being subjected to the action of the oxidising agent.—T. F. B.

Waste from Wood-grinding Mills, Paper, and Cellulose Factories; Utilisation of the —— [*Linoleum*]. E. de Pass, from C. Gaertner. Eng. Pat. 27,339, Dec. 14, 1903. XIX., page 453.

(*C.*)—INDIA-RUBBER.

English Patent.

India-Rubber Tyres; Preparation for Impregnating ——. L. Leesman and M. Weinkopf, Graz. Eng. Pat. 2982, Feb. 6, 1904.

Birch tar oil (60—70 per cent.), coal-tar benzene (38—28 per cent.), and dissolved dextrin (2 per cent.) are thoroughly mixed and applied by means of a brush, to the tyres, stretched or unstretched, each successive coating being allowed to dry for a period of 24 hours.—R. L. J.

French Patents.

Rubber; Apparatus and Process for Extracting ——, *without Solvents.* N. W. Aldrich and J. F. Ryan. Fr. Pat. 337,051, Oct. 12, 1903.

See U.S. Pats. 741,257 and 741,258 of 1903; this J., 1903, 1200.—T. F. B.

Caoutchouc Substitute; Process of Manufacturing a ——. E. H. Fayolle. Addition, dated Oct. 14, 1903, to Fr. Pat. 335,584 of Sept. 26, 1903; see this J., 1904, 195.

The following improvements are now claimed:—(1) The mother liquor from which the substance separates should be kept for some days to recover a further quantity of the material. (2) If the substance separates as a thick oil, the aqueous layer is drawn off and sulphuric acid of 66° B. mixed with the oil (15 per cent. by weight of the phenol originally used). This at once produces a firm cake. (3) The kneading process may be stopped when all the moisture has been worked out. (4) The following proportions give good results:—Glycerin, 1 kilo.; 40 per cent. formaldehyde, 1 kilo.; water, ½ kilo.; phenol, 0·7—1·4 kilo.; sulphuric acid (66° B.), 1—1⅓ kilo. according to the amount of phenol, excluding the acid under (2), *vide supra*. When more than 1·4 kilo. of phenol is used, the product is pitchy.—R. L. J.

XIV.—TANNING; LEATHER, GLUE, SIZE.

Sulphuric Acid in Tanning Liquors or Extracts; Determination of ——. J. G. Parker and G. E. M. Payne. XXIII., page 457.

Tannin; Gravimetric Determination of —— *in Tanning Materials and Extracts.* J. Paessler. XXIII., page 458.

XV.—MANURES, Etc.

Basic Slag; Determination of the Phosphoric Acid Soluble in Citric Acid in ——. R. Sorge. XXIII., page 457.

French Patents.

Superphosphates; Manufacture of ——, *by means of Sodium Bisulphate.* M. Fournier. Fr. Pat. 336,872, Jan. 30, 1903.

A hot aqueous solution of sodium bisulphate is used to act upon calcium phosphate, in such proportion as to render soluble in water or in citrate solution the greater part of the phosphate, whilst giving a soft mass, easily dried and powdered. Or, powdered nitre cake is washed systematically in a series of vessels to obtain a more strongly acid solution with a residue of sodium sulphate. The acid solution is then used as in the first case.—E. S.

Manure; Apparatus for Removing Grease and Transforming Waste Materials into an Artificial ——. A. von Krottnaurer. Fr. Pat. 336,852, Nov. 20, 1903.

The apparatus includes three or more upright cylinders, opening at the bottom into a hopper having a valved opening into a chamber provided with an agitator and an outlet for the finished product. Each cylinder is separated into an upper and a lower compartment by a movable shutter, and steam is separately admitted at a regulated pressure to each lower compartment. The waste materials are charged into the cylinders, sorted according to their character: to one, waste skin or leather; to another, fragments of flesh and bones, &c., the proportion of each kind being adjusted to give a manure of the desired composition. The shutters are then opened, and the charge pass into the steam space beneath, after sufficient digestion in which, they descend by degrees into the hopper, in which they are sprayed by the injection of a suitable acid with steam. Outflow for grease and condensed water is provided from the cylinders to a trough common to all.—E. S

XVI.—SUGAR, STARCH, GUM, Etc.

Milk Sugar; Decomposition of —— by Caustic Lime. Constitution of Parasaccharin. H. Kiliani and P. Loeffler. Ber., 1904, **37**, 1196—1203.

In previous experiments the decomposition of milk sugar by caustic lime yielded mainly isosaccharin, together with a little metasaccharin. From the mother-liquors, the authors have now obtained a further yield of metasaccharin and a considerable quantity of parasaccharin. These two latter were obtained in the form of their barium double salt by sowing crystals of this salt [double barium meta- and para-sacchariuate] in the suitably treated mother-liquors. Attempts to isolate the parasaccharin in a crystalline condition were without result.

Constitution of Parasaccharin.—When barium parasacchariuate was oxidised by Ruff's process (hydrogen peroxide and ferric acetate) it was converted quantitatively into a pentose sugar, $C_5H_{10}O_4$, m. pt. 82° C., optically inactive. This sugar yielded a benzylphenylhydrazone crystallising from dilute acetone in prisms melting at 112°—114° C. Since this pentose contains only 4 atoms of oxygen, it possesses a CH_2 group, and the constitution of parasaccharinic acid is therefore represented by the formula $CH_2(OH).CH_2.C(OH)(COOH).CH(OH).CH_2OH$. —J. F. B.

Potato Starch; Comparison of the Products of the Hydrolysis of —— with those obtained from Cereal Starches. J. O'Sullivan. Proc. Chem. Soc., 1904, **20**, 65.

In this investigation it was established by six series of hydrolytic experiments on potato, Lintner's malt, barley, maize, and rice starches, with both malt extract and diastase, that the products of the hydrolysis of potato starch, as regards the percentages of maltose and dextrin, bear no quantitative relationship to those yielded by the other starches, and that therefore the products of the hydrolysis of the other starches could not be inferred from the hydrolysis of potato starch.

English Patents.

Syrup from Beets, Cane, Corn, Root Crops, or other Substances containing Saccharine Matter; Process of Obtaining ——. W. C. Salisbury and A. J. Kramper, Dakota. Eng. Pat. 26,665, Dec. 5, 1903.

See U.S. Pat. 748,314 of 1903; this J., 1904, 124.—T. F. B.

Erratum.

This J., 1903, page 373 (Eng. Pat. 22,537, Oct. 16, 1902, C. B. Duryea), the description beginning with "*This process*" and ending with "*modified starch,*" to the first semicolon, ought to have read as follows:—"The process of producing maltose consisting in providing [as the special raw material] a thin boiling or modified starch having mixed therewith a very dilute acid, cooking the mixture," and so on as *per loc. cit.*

United States Patents.

Diffusion Battery [Sugar]. A. Rak, Cesky Brod. U.S. Pat. 755,546, March 22, 1904.

The battery consists of a series of slightly conical worm-presses, the narrow end of one member communicating with the wide end of the next member, and each member erminating in a narrow juice-stopper and means for withrawing the juice. The chips, as they reach the narrow art of each press, are shovelled into the wide part of the ext one, travelling in a zig-zag course to the end of the attery.—J. F. B.

French Patents.

Molasses; Process of Obtaining —— by the direct Boiling of the Syrup. M. Kohn. Fr. Pat. 337,135, Nov. 27, 1903.

The boiled charge is cooled in the vacuum pan itself by a circulation of cold water or air; it is then discharged and treated in the centrifugals at once. For the purpose of cooling, a system of fixed coils or rotary hollow stirring bodies is supplied which, in the case of cooling by air, may be perforated in such a way that the cold air escapes through the mass of sugar.—J. F. B.

Starch and Dextrin; Process and Apparatus for Preparing Soluble ——. Calico Printers' Assoc., Ltd., W. Browning, and J. J. Barlow. Fr. Pat. 336,903, Nov. 23, 1903.

Powdered starch, previously partially dried and heated up to the desired temperature of the reaction, is treated in a rotary converter with an acid, *e.g.*, hydrochloric acid, in the state of gas, vapour, or fine spray. The acid is preferably volatilised, in known quantity, from a solution, and the vapour is introduced to the converter by means of a porcelain or glass pipe, passing through a hollow trunnion and terminating inside the vessel in the form of a swan's neck. For soluble starch a temperature of 54° C. is employed, and for dextrin a temperature of 76°—93° C. —J. F. B.

Vegetable Glue; Manufacture of Solid ——. F. Virneisel. Fr. Pat. 337,001, Nov. 16, 1903.

Starch (or other amylaceous substances) is macerated in 1 per cent. soda lye, and treated with oxidising agents (sodium peroxide, hydrogen peroxide, or alkali hypochlorite) until a product intermediate between natural starch and "soluble" starch is formed, which when neutralised, washed, and dried, dissolves readily in boiling water, and forms a thick viscous liquid.—R. L. J.

XVII.—BREWING, WINES, SPIRITS, Etc.

Amylocellulose; Enzymic Formation of ——. A. Fernbach and J. Wolff. Comptes rend., 1904, **138**, 819—821.

If a starch paste which has been liquefied at 120° C. be treated with a small quantity of an active malt extract at the ordinary temperature for such a short time (15 minutes) that no appreciable quantity of amylocellulose is formed, and if the mixture be then boiled or heated at 120° C. so as to destroy the enzymes present, this ebullition in no way interferes with the subsequent production of amylocellulose. The quantity of amylocellulose produced in 24 hours is just as great as when a similar quantity of malt extract is allowed to act for the same time without ebullition. This is the first case recorded in which an enzymic action only requires to be started in order to continue of itself, in spite of the subsequent destruction of the enzyme, with a speed and intensity proportional to the quantity of enzyme originally added to start the action. —J. F. B.

Maltase; Law of the Action of ——. Influence of the Concentration of the Maltose. E. F. Terroine. Comptes rend., 1904, **138**, 778—779.

The results of a number of experiments on the action of Taka-diastase on solutions of maltose of different strengths in 0·5 per cent. sodium fluoride solution, show that the influence of the concentration of the maltose (a) on its speed of hydrolysis (v) can be expressed by the formula: $v = k\,a/(1 + m\,a)$, where k and m are constants depending on the conditions of the experiment and of the enzyme. The same expression has been shown by Henri to hold good for the actions of invertase, emulsin, diastase, and trypsin.—T. H. P.

Maltase; Action of ——. Constancy of the Enzyme action. C. Philoche. Comptes rend., 1904, **138**, 779—781.

The author has made comparative experiments on the action of maltase (Taka-diastase) at 40° C. on solutions containing (1) 6 per cent. of maltose, (2) 4 per cent. of maltose and 2 of dextrose, and (3) 2 per cent. of maltose and 4 of dextrose. The results show that the activity of the enzyme does not vary in the first 24 hours of its action, so that, during any part of this period, the amount of maltose converted into dextrose is proportional to the mean concentration of the maltose.—T. H. P.

Top Fermentation Yeast; Fermentation Experiments with Cell Juice Expressed from ——. A. Harden and W. J. Young. Ber., 1904, **37**, 1052—1070. (Compare this J., 1900, 1127.)

The authors prepared expressed cell juice from English top fermentation beer yeast, the juice being clarified by centrifugal treatment. The average extent of the fermentation of sugar [glucose] by the juices obtained was considerably less than that found by Buchner with juices from bottom fermentation yeast. The extent of the autofermentation of the juices was very variable, but fell within the limits recorded for bottom-yeast cell juice. The fermentation due to the added sugar was frequently no more and in some cases even less, than that due to autofermentation. The total fermentation in the first 24 hours was considerably greater than with Buchner's bottom-yeast cell juices, the specific differences between the activity of the juices prepared from the two types of yeast being shown in the later stages. The fermentation when yeast-glycogen was added was considerably less than when an equivalent quantity of glucose was added. The ratio of alcohol to carbon dioxide was 0·96 (average) as against a theoretical ratio of 1·04; it was the same for autofermentation as for glucose fermentation, and was independent of the activity of the juice. The effect of dilution on the autofermentation was very slight, but the fermentation of glucose by juice diluted with three times its volume of water was reduced sometimes by nearly one-half. On the other hand, the dilution of the juice with glucose solutions had no adverse effect on the fermentative power. Determinations of the cupric-reducing power by Pavy's method showed that the quantity of reducing sugar disappearing during fermentation was considerably greater than the quantity corresponding to the alcohol and carbon dioxide produced; this apparent loss of reducing sugar amounted to 14—36 per per cent. of the total quantity present, and was generally greatest when the juice was diluted with glucose solutions. The whole of the reducing sugar so lost could, however, be recovered by inversion with 3.N-hydrochloric acid for 3 hours at 100° C. The nature of the non-reducing substance produced by the juice during fermentation has not been determined; the quantity formed was, however, found to be independent of the zymase-content of the juice.

—J. F. B.

Bottom Fermentation Yeasts; Comparative Investigation of four ——. *VI. Characters of Old Colonies on Solid Media.* H. Will. Zeits. ges Brauw., 1904, **27**, 176—181, 193—198, 210—214. (See also this J., 1899, 1039.)

The colonies sown on 10 per cent. wort-gelatin from active fermentative cells show no specific differences in their early stages. After a certain stage, long, delicate, sausage-shaped cells accumulate in the lower layers and appear at the edges, either as simple warty or manifold grape-like appendages on the underside of the colonies, growing outwards later, fan-like, in the form of "streamers." The value of the colonies from a diagnostic point of view begins with the appearance of these "streamers." The form of the "streamers" determines the future shape of the old colony; if the appendages were simple, the "streamers" are undivided, but if they were grape-like the "streamers" are manifoldly ragged. The form of the old colony also depends to some extent on the composition of the nutrient liquid and the nature of the agglutinant; it is, however, unaffected by the temperature at which growth takes place. The forms of the colonies of the four races of yeast were studied until they broke down into slime.

Anatomical Structure of Old Colonies.—The old colonies of all the races studied were constructed on the same ground-plan. In the earlier stages, the centre, corresponding to the original sowing, contains a predominating quantity of roundish and oval cells; on the lower side are the same elongated elements as compose the appendages on the underside of the edge-portions. At the later stages the central crater contains, under a surface of slime, mainly thick-walled, sausage-shaped cells. The cells which cause the characteristic form of the edge-portions of the colonies consist almost entirely of budding bands of very long, thin-walled sausage-shaped cells, which also stretch downwards like root-hairs; these cells contain much glycogen, and are often separated by cross-walls extending across the whole diameter of the cells. The top surface of the edge-portions is covered (as by bark) by a layer of compressed roundish or oval cells, characterised by great richness in fat-globules. The thick-walled elongated cells found in the central crater are quite different from the elongated cells of the edge-portions. They contain in their net-work occasional large, thick-walled, roundish, or oval cells, containing a large vacuole and rich in oil and glycogen; together with these cells are "resting cells" [chlamydospores]. These two forms are to be regarded as the mother cells of the elongated, thick-walled, mycelial threads composing the centre at advanced stages of growth; which elongated elements are identical with the cells of the second generation found in the yeast-films of old cultures in liquid media. It is therefore concluded that old colonies on solid media correspond, at all stages and in every respect, with film-formations on the surface of liquids. The differences in structure of the old colonies of the four races of yeast, depending mainly on variations in the relative numbers of their component elements, are minutely described, and correspond exactly with similar variations previously noticed in the yeast-films of cultures in liquid media.—J. F. B.

"Spring" Mashing Process; Determination of Suitable Saccharification Temperatures for the ——. M. Hartmann. Woch. Brau., 1904, **21**, 174—175.

Since every different parcel of malt is liable to require a different temperature of saccharification by the "spring" mashing process if the final degree of attenuation of the beer is to be maintained constant, it is desirable to include a determination of the necessary saccharification temperature in the laboratory analysis of the malt. Two mashing beakers are employed, one as the mash-tun and the other as the mash-copper; 50 grms. of grist are mixed with 150 c.c. of water at 35° C. in the first mashing beaker, and maintained at that temperature by means of a water-bath for half-an-hour. Before the end of that time, 100 c.c. of water are heated in the other beaker to a temperature 2° C. higher than the temperature of saccharification to be tested. The contents of the mashing beaker are then gradually added to the water in the second beaker by means of a spoon, stirring and keeping the temperature practically constant by a flame underneath; this operation can be performed in 10—12 minutes. The beaker containing the mash is then placed in a water-bath, previously heated to the desired temperature, and the contents are stirred until saccharification is complete. The mash is then boiled, cooled, made up to a weight of 450 grms., and filtered. The wort is subsequently fermented with some of the yeast of the brewery at a temperature of 25° C. for 48 hours, and the final degree of attenuation is determined. In most cases three experiments suffice to determine the saccharification temperature of a sample of malt necessary to produce the desired degree of fermentability. The following table shows the different behaviour of different types of malt when tested in the above manner.

"Spring" Saccharification Temperature.	Apparent Final Attenuation.		
	Pilsen Malt.	Munich Malt.	"Brown beer" Malt.
	Per Cent.	Per Cent.	Per Cent.
68° C.	78·9	69·2	64·0
70° C.	70·0	57·7	49·6
72° C.	63·2	49·9	42·1

—J. F. B.

Beer; Turbidities in —— caused by Tin. Dinklage. Zeits. ges Brauw., 1904, **27**, 209—210. (See also this J., 1904, 332, 333.)

Pale beer is far more liable to turbidities from contact with tin than dark beer; the previous removal of the carbon dioxide from the beer has only a very slight effect in delaying the appearance of turbidity. The production of turbidity by tin is not attributable to the presence of traces of the grey, allotropic modification of tin. Pieces of tin which have once been used to produce turbidity tend to become indifferent, unless the surface be cleansed by means of acid. Pieces of brass, tinned by various methods, all possessed the same tendency to produce turbidity.

Beer containing a piece of tin pipe was pasteurised, with a view to obtaining the substance constituting the turbidity in the form of a precipitate, free from micro-organisms.

The turbidity rapidly appeared and increased on long standing, but even after six months the milky liquid showed no signs of coagulation, either when heated or when treated in other ways, whilst the particles were so fine as to be indistinguishable under the microscope.—J. F. B.

Esters; Production of ——, in Alcoholic Fermentation. T. Bokorny. Chem.-Zeit., 1904, **28**, 301—302.

In order to determine whether the production of esters is primarily connected with alcoholic fermentation, the author investigated the fermentation of highly concentrated sugar solutions, such as were obtained by triturating solid sugars with pressed yeast. With sugar concentrations of 48 per cent. both cane sugar and glucose fermented readily, with the production of esters. With a sugar concentration of 58 per cent., glucose alone showed fermentation and a production of esters; cane sugar showed neither, owing to the inhibition of the activity of the invertase at so high a concentration. With sugars at 74 per cent. no fermentation or odour was observed in either case. When 10 grms. each of glucose, milk sugar, dextrin, egg-albumin, and peptone were mixed respectively with 15 grms. of pressed yeast, fermentation and production of esters took place only in the case of glucose, although the dextrin showed signs of fermentation, but with a rather unpleasant odour. Thus the presence of fermentable sugar is necessary for the production of esters. Hence it is concluded that the esters are normal by-products of the primary action of yeast-zymase upon fermentable sugar, and are in every way comparable with such by-products as glycerin and succinic acid. They have nothing to do with the secondary effect of the dying yeast-cells.
—J. F. B.

Wines, Natural, and Grape Stones; Determination of an Organic Phosphorus Compound in ——. J. Weirlich and G. Ortleib. Arch. der Pharm., 1904, **242**, 138—143.

Having met with a natural sweet wine from Thyra, which showed the high percentage of 0·095 of phosphoric anhydride, as compared with 0·053 per cent. in a Greek wine, and 0·02 to 0·06 in a wine from Tokay, the authors have investigated the cause of this large difference. It was found that the stones of the grapes from which the wine was prepared contained phosphorus in the form of an organic compound equivalent to 0·2854 per cent. of lecithin, extracted by ether and petroleum spirit. The extractive matter from the wine was found to yield to absolute alcohol an amount of a soluble organic phosphorus compound equivalent to 0·35 per cent. of lecithin. This wine-lecithin was also extracted by shaking out with ether and chloroform the residue obtained on distilling the wine *in vacuo*. It is found that wines strongly alcoholic, made from grapes rich in seeds, contain a much larger percentage of lecithin than those of lower alcoholic strength. Such wines also are invariably richer in nitrogen. This goes to prove that the phosphorus is present as a lecithin and not as anhydro-oxymethylenediphosphoric acid, which Posternak has shown to occur in seeds. It was found, moreover, that by disintegrating the seeds before fermentation, both the organic phosphorus and the nitrogen content of the resulting wine were slightly increased. It is to the presence of this lecithin in wines of this class that the authors attribute their recuperative value for medicinal use.—J. O. B.

Methyl, Ethyl, and Propyl Alcohols; Critical Temperatures of Solution of ——. Preparation of the Anhydrous Alcohols. L. Crismer. Bull. Soc. Chim. Belg., 1904, **18**, 18—54.

The determination of the critical temperature of solution of a suitable petroleum oil in strong alcohol affords a rapid means of measuring the proportion of water in the latter.

Ethyl Alcohol.—5 c.c. of the alcohol are placed in a graduated tube with 5 c.c. of American petroleum; the tube is closed with a rubber stopper through which a thermometer, reading to 0·1° C., is passed, the bulb being fully submerged. The mixture is warmed until it becomes homogeneous and then gradually cooled; the point at which a turbidity, due to saturation, appears is the critical temperature of solution. The critical temperature for anhydrous alcohol being, for instance, 14·8° C., the addition of 0·1 per cent. of water raises it 1·8° C. The method is therefore equivalent in delicacy to a determination of the density to five places of decimals. Anhydrous alcohol is prepared by heating commercial absolute alcohol with fresh quicklime in a closed flask. When the critical temperature has been reduced to a minimum, the alcohol is distilled off. Any traces of water which may still be present appear in the first portions of the distillate. The alcohol is anhydrous and pure when samples of 5 c.c., taken at intervals during distillation, show a constant minimum critical temperature of solution. Metallic sodium is useless for the preparation of anhydrous alcohol. Anhydrous alcohol having been obtained, a table and curve can be constructed showing the increase in the critical temperatures of solution when increasing proportions of water are added to the mixture of alcohol and petroleum. Different samples of petroleum give different results with the same alcohol, but if each sample be standardised with anhydrous alcohol, the curves showing the proportions of water are all parallel; the petroleum should be preserved in the dark. Anhydrous alcohol absorbs moisture from the air with the greatest avidity.

Methyl Alcohol.—Similar determinations can be made with methyl alcohol if a light petroleum spirit of the kind known as "gasoline" be employed. For 2 c.c. of methyl alcohol, about 5 c.c. of gasoline are necessary to give constant results. Quicklime is useless for the preparation of anhydrous methyl alcohol. The alcohol should be treated repeatedly with lumps of metallic sodium, under a reflux condenser, and should be distilled off between each treatment. In the case of methyl alcohol, any water present distils in the last fractions.

n-Propyl Alcohol.—The critical temperature of solution is determined with 3 c.c. of propyl alcohol and 3—4 c.c. of paraffin oil. The phenomena correspond closely with those observed in the case of ethyl alcohol. Anhydrous propyl alcohol is readily obtained by the use of quicklime.

From the critical temperatures of solution the author has been able to show that anhydrous ethyl alcohol is hydrated by treatment with barium oxide, owing to the formation of the ethylate, thus: $2\,C_2H_5OH + BaO = (C_2H_5O)_2Ba + H_2O$. Similarly, calcium oxide hydrates methyl alcohol. When determined with the same liquid (paraffin oil), the critical temperatures of solution for the homologous series of propyl, ethyl, and methyl alcohols increase by a constant difference of 76·2° C.—J. F. B.

Formaldehyde Vaporiser Jet for Disinfecting Pipes [*in Breweries*]. F. Heyder. XVIII. C., page 452.

English Patent.

Malting and Drying Apparatus. F. H. C. Mey, Buffalo. Eng. Pat. 25,277, Nov. 19, 1903.

A pneumatic malting drum is constructed with sectional walls. Each section can be moved and fixed nearer to or further away from the central axis of the drum. Whilst the malt is germinating, the walls may be expanded so that the grain fills the drum to its fullest capacity, but whilst the malt is being dried, the sections are consecutively moved inwards, contracting the capacity of the drum in proportion as the grain shrinks, so that the drum always remains practically full, and the heated air cannot pass through it without drying the malt.—J. F. B.

Alcohol Vapour; Prevention of Losses of ——, in Distilleries. J. S. von Szathmary, Pankota. Eng. Pat. 4011 Feb. 17, 1904.

Losses of uncondensed alcohol vapours from the discharge openings of the condenser worms during distillation are prevented by providing an auxiliary pipe branching up from the principal discharge pipe of the condenser, and leading to a second condensing worm. Both the principal discharge pipe and the auxiliary condenser are fitted at the discharging end with reducing caps, which prevent the outflow of alcohol other than in the liquid form, the vapours being retained in the auxiliary condenser until they are condensed.—J. F. B.

United States Patent.

Grain; Method of Steeping ——. V. Lapp, Lindenau, Germany. U.S. Pat. 755,144, March 22, 1904.

See Eng. Pat, 11,749 of 1903; this J., 1903, 1144.—T. F. B.

French Patent.

Wort contained in the Malt of Breweries, Distilleries, and similar Works; Process and Apparatus for the Rapid Extraction of ——. E. de Meulemeester. Fr. Pat. 336,892, Nov. 23, 1903.

See Eng. Pat. 25,582 of 1903; this J., 1904, 264.—T. F. B.

XVIII.—FOODS; SANITATION; WATER PURIFICATION, & DISINFECTANTS.

(*A.*)—FOODS.

Bakers' Yeast; Determination of the Dough-raising Power of ——, and the Influence of Baking Adjuncts on Dough Fermentation. A. Pollak. Zeits. Spiritusind., 1904, **27**, 125—126.

The only serious objection against Metzler's process (this J., 1903, 877) is that the dough employed is too dilute. In the following modification the author works as nearly as possible under the conditions employed in practice: 100 grms. of flour of known character and 2 grms. of the yeast are weighed out; at the same time 60 c.c. of distilled water at 30° C. are measured into a beaker. A preliminary dough is first made by mixing up the yeast with the water and adding a sufficient portion of the 100 grms. of flour to make a fairly fluid dough. The beaker is then placed in the thermostat at 30° C. for 30 minutes. The greater portion of the rest of the flour is spread upon a board and the prepared dough is poured on it and mixed, first with a rod and then with the hands. The beaker is then thoroughly cleaned out by adding more of the dry flour and scraping with a knife. The remainder of the flour (about 3 grms.) is used for dusting the board and removing all dough from the hands. The mixing up to this point should be done in five minutes, after which the dough is thoroughly kneaded on the board for a further five minutes and rolled into a cylindrical form. The roll of dough is dropped into a previously warmed and greased graduated measuring cylinder, and caused to occupy an ascertained volume by swinging the cylinder and levelling the surface with a wooden stamper. The cylinder is placed in the thermostat at 30° C., and the increase in volume of the dough is read off every 20 or 30 minutes, the surface being levelled each time. Curves are plotted showing the increase in volume with the time, the volumes being expressed as percentages of the original. With a given type of flour and constant method, time and temperature of manipulation, the raising power of the yeast is shown by the increase in volume after two hours. The time for which the increased volume is maintained should also be noted, together with the elasticity, nature of the porosity, and odour of the dough. The influence of baking adjuncts and yeast stimulants, such as malt extract and malt flour, can also be studied by this method.—J. F. B.

English Patents.

Chicory; Process of Preparing Dry Extract of ——. F. J. Reichert and J. J. Heydemann, London. Eng. Pat. 9133, April 22, 1903.

Chicory root is extracted with lime-water, and the clear extract evaporated to a syrupy condition, preferably *in vacuo*; the syrup is then dried and roasted. The distillates from the evaporation and drying of the extract are extracted with chloroform, and the product obtained by evaporating the chloroform solution is added to the chicory extract previous to roasting.—T. F. B.

Coffee Preparations; Manufacture of —— A. Farogó and S. Bartha, both of Buda-Pesth. Eng. Pat. 3465, Feb. 11, 1904.

A concentrated extract is made of the coffee fruit separated from the bean, that is to say, what is termed "cocoli." The latter is roasted in a closed receptacle before being extracted, and may contain a certain proportion of coffee beans.—W. P. S.

United States Patent.

Milk-Product resembling Butter; Process of Making a ——. J. H. Campbell, New York. U.S. Pat. 755,843, March 29, 1904.

An air-blast is driven through skimmed milk at a moderately low temperature, until the latter is partially concentrated. Approximately the same quantity of cream which was in the original milk is then added, and the mixture concentrated at a non-sterilising temperature to about the consistency of butter. The product is finally granulated.
—W. P. S.

(*B.*)—SANITATION; WATER PURIFICATION.

English Patent.

Water or Sewage; Apparatus for the Purification of ——. J. N. McClintock, Boston. Eng. Pat. 6927, March 25, 1903. Under Internat. Conv., March 25, 1902.

See U.S. Pat. 719,357 of 1903; this J., 1903, 314.—T. F. B.

(*C.*)—DISINFECTANTS.

Alcohols of the Methyl, Ethyl, Butyl, and Amyl Series; Comparative Sterilising and Antiseptic Action of ——. G. Wirgin. Zeits. Hyg., 1904, **46**, 149; through Chem.-Zeit., 1904, **28**, Rep. 85.

The alcohols were tested in aqueous solutions upon anthrax spores and *Microc. pyog. aur.* The disinfecting power increases with the molecular weight; the tertiary alcohols act, however, less powerfully than the primary and secondary alcohols of the group next below. The order of bactericidal power is as follows (downwards): 30 per cent. solution of propyl alcohol, 60 per cent. ethyl alcohol, 60 per cent. methyl alcohol, saturated solutions of isobutyl, tertiary amyl, and amyl alcohols. The above concentrations also represent the most powerful solutions of the respective alcohols as against dry spores. These solutions are more powerful than a 1 per cent. solution and rather less powerful than a 3 per cent. solution of phenol. None of the above alcohols kill spores at ordinary temperatures. All absolute alcohols and the highest concentrations of the water-soluble alcohols are almost without action on dry spores. Against moist spores, the highest concentrations are almost as powerful as the medium concentrations. The most powerful alcoholic solutions are stronger than 4 per cent. boric acid, 4 per cent. potassium chlorate, and 2 per cent. lead acetate, zinc sulphate, and copper sulphate solutions. The alcohols have a good penetrative action upon embedded spores.—J. F. B.

Formaldehyde Vaporiser Jet for Disinfecting Pipes. F. Heyder. Woch. Brau., 1904, **21**, 185.

The vaporiser jet is constructed on the principle of the gas-blowpipe. There is a narrow central pipe terminating in a fine jet and connected below with the supply of formalin solution and an outer wide pipe terminating as an annular jet around the small central jet. This outer pipe is connected with a steam supply. In use, the nozzle of the

apparatus is inserted in the pipe or other vessel to be disinfected, for which purpose an external screw thread is supplied, the central tube is connected with the formalin solution and steam is admitted to the outer tube. The formalin is thus sucked up to the nozzle and volatilised by the steam escaping there. The operation is continued until an odour of formaldehyde appears at the further end of the pipe, &c. which is being disinfected, the latter being then sealed up and left full of the vapour for about two hours.
—J. F. B.

XIX.—PAPER, PASTEBOARD, Etc.

English Patents.

Safety Paper and Ink; Preparation of Commercial ——. J. Rowan, Ottawa. Eng. Pat. 3909, Feb. 16, 1904.

The paper is impregnated with a solution of "potassium prussiate" and ammonia, it is subsequently printed with a design in an ink containing "iron perchlorate," potassium iodide, and caustic soda incorporated in oil or varnish. These ingredients are prevented from mutual interaction by the oily medium of the ink, but when the paper is tampered with by acid or alkaline reagents a discoloration is produced. This discoloration can be intensified by mixing Magenta or manganese with the printing ink.—J. F. B.

Waste from Wood-grinding Mills, Paper and Cellulose Factories, Utilisation [Papier-maché] of the ——. E. de Pass, London. From C. Gaertner, Berlin. Eng. Pat. 27,339, Dec. 14, 1903.

The short-fibred waste from paper, cellulose, and wood-grinding mills is utilised as the plastic material for reproducing the contours of moulds. This fine pulp can be worked into the meshes of a coarsely woven fabric placed in contact with the moulds, or it can itself be allowed to lie upon the surface of the mould and the necessary rigidity imparted by a backing of long-fibred material. The waste may also be employed together with a cementing medium for the manufacture of linoleum or "lincrusta."—J. F. B.

French Patents.

Paper; Continuous Manufacture of ——, *coated on one or both sides.* P. V. Rolier. Fr. Pat. 337,199, Nov. 30, 1903.

The paper is passed in continuous length through a coating machine and thence over a drying apparatus so constructed that the coated surface is not touched until it is nearly dry; after drying, the paper is moistened and its other surface is treated in the same manner. The improved coating machine possesses a perforated cylinder, inside which a partial vacuum is maintained; means are also provided for adjusting the pressure on the brushes.—J. F. B.

Nitrocellulose and similar Substances; Compounds of ——. D. Bachrach. Fr. Pat. 337,060, Oct, 27, 1903.

See U.S. Pat. 743,422 of 1903; this J., 1903, 1304.—T. F. B.

Celluloid in Paste Form; Process for the Manufacture and Application of ——, *to the Imitation of Horn, Shell, Ivory, Mother-of-Pearl, &c.* T. Didier. Fr. Pat. 336,970, Nov. 3, 1903.

Twenty parts of celluloid, 40 parts of acetone, 40 parts of 90—95 per cent. alcohol, and 1 to 5 parts of castor oil are intimately mixed, and heated at from 20° to 60° C. for some hours, when a homogeneous paste is obtained, which can be coloured and transferred to moulds. The solvents are then allowed to evaporate, and the product is coloured to imitate horn, shell, &c.—T. F. B.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

Iodoform; Electrolytic Preparation of —— *from Acetone.* J. E. Teeple. J. Amer. Chem. Soc., 1904, **26**, 170—177.

The substitution of acetone for alcohol in the preparation of iodoform is to be recommended on account both of its cheapness and of the fact that only 6 atoms of iodine are required per molecule of iodoform produced in place of 10 atoms necessary when alcohol is used. The author's experiments show that the important factors in the electrolytic formation of iodoform from potassium iodide and acetone are: (1) Avoidance of an excessive formation of alkali in the solution. (2) Maintenance of a fairly low temperature to prevent much potassium iodate being formed. (3) Thorough stirring, so that the very dilute solution of iodine produced at the anode may always react with a very dilute solution of potassium hydroxide produced at the cathode; this is perhaps best obtained by means of a rotating anode. (4) A comparatively low anode current density to prevent formation of iodate and a high cathode density to avoid reduction of hypoiodite already formed. As regards (1), the best means of neutralising the alkali formed and that most adaptable to a continuous process is the gradual addition of iodine, which acts as follows: $2KOH + I_2 = KI + KIO + H_2O$; $3KIO + C_3H_6O = CHI_3 + KC_2H_3O_2 + 2KOH$; for every molecule of iodoform formed, 1 mol. of acetone, 1 mol. of potassium iodide, and 2 atoms of iodine should be added to the solution to bring it to its original condition, neglecting the potassium acetate, which does not reduce the yield of iodoform to a very great extent. A current yield of 94·4 per cent. of iodoform was obtained under the following conditions: 225 c.c. of water, 25 grms. of potassium iodide, and 2 c.c. of acetone were electrolysed for 65 minutes, the anode current density being 2 ampères per sq. dcm., and the cathode used being a platinum wire, the end of which dipped just below the surface of the solution; during the electrolysis, 1·56 grms. of iodine were added at intervals, so as to keep the liquid just slightly coloured. If the stirring be thorough, the anode current density may be increased to 6—8 ampères per sq. dcm., yields of 89—91 per cent. being then obtained. To determine the influence of the accumulated potassium acetate on the yield of iodoform, the following experiment was made: Electrolysis of 150 c.c. of water, 18 grms. of potassium iodide, and 2 c.c. of acetone, was first carried out under conditions similar to those given above (with addition of iodine), a current yield of 92 per cent. of iodoform being obtained. Sufficient potassium iodide and acetone were then added to restore the solution to its original condition (except for about 1 grm. of potassium acetate formed), and then 18 grms. of potassium acetate. On electrolysis, this solution gave a current yield of 80 per cent. of iodoform. So that when the potassium acetate has accumulated until it exceeds the amount of potassium iodide, and the solution contains over 12 per cent. of it, the yield is lowered by not more than 15 per cent.—T. H. P.

Cellotropin [Monobenzoylarbutin]. Pharm.-Zeit., 1904, **49**, 272.

About 22 parts of arbutin are dissolved in water, and gradually mixed, with constant agitation, with 8 to 10 parts of benzoyl chloride added in small quantities at a time, the free hydrochloric acid being neutralised each time with alkali. Benzoylarbutin is then formed as a white precipitate, which is washed, dried, and crystallised from hot water. Monobenzoylarbutin is a white, odourless, and tasteless powder, soluble in water, 1:80 at 100° C.; 1:1,300 at 15° C. The aqueous solution is neutral. M. pt. 184·5° C.
—J. O. B.

Vioform [Iodochlorohydroxyquinoline]. R. Wehrle. Suppl. z. Corr. Bl. Schweiz. Aerzte, 1903; through Pharm. Centralh., 1904, **45**, 239.

Chloro-5-hydroxy-8-quinoline is dissolved in alkali and digested with an equivalent quantity of iodine in potassium iodide solution; or an alkaline solution of a chlorohydroxyquinoline salt is mixed with the requisite amount of potassium iodide and the iodine liberated by means of chloride of lime or other suitable reagent. Iodochlorohydroxyquinoline thus obtained is a greyish-green bulky powder; it is a powerful bactericide and antiseptic, and has been used as a substitute for iodoform.—J. O. B.

Strychnine; Action of Bromine and of Iodine on ——. L. Martin. Bull. Soc. Chim., 1904, **31**, 386—391.

The action of bromine and hydrobromic acid on strychnine yields *monobromostrychnine*, $C_{21}H_{21}BrN_2O_2$; colourless needles, soluble in acidulated water or in alcohol, melting at 199° C. The iodomethylate and iodo-ethylate were prepared and analysed. If the acid solution obtained when the bromination of strychnine is just completed, be poured into a large volume of water containing more of the brominating mixture, there is obtained a yellow crystalline powder of *monobrominated monobromostrychnine hydrobromide*, $HBr.C_{21}H_{21}BrN_2O_2.Br$, which contains three differently combined bromine atoms. *Dibromostrychnine*, white crystals of similar solubilities to the mono-compound, melting at 130° C., and the hydrobromide of a brominated derivative, were also prepared. Iodic and hydrobromic acids reacting on strychnine give *hydriodide of mono-iodated mono-iodostrychnine*, from which successive treatment with acetone and ammonia removes the added iodine and the hydriodic acid, leaving *mono-iodostrychnine*, $C_{21}H_{21}IN_2O_2$, a slightly chestnut-tinted crystalline powder, melting at 188° C. *Di-iodated strychnine*, $C_{21}H_{22}N_2O_2.I_2$, is obtained by reacting with iodine and hydriodic acid on strychnine; ruby-red crystals, decomposing before fusion, which give up all their iodine on solution in acetone.—J. T. D.

Otto of Rose; Some Newly Discovered Constituents of ——. H. von Soden and W. Treff. Ber., 1904, **37**, 1094—1095.

The alcohol *nerol*, recently discovered in oils of neroli and petit-grain (this J., 1903, 228, 1100), is present in otto of rose to the extent of 5—10 per cent. It plays a most important part in the specific perfume of the otto. Otto of rose also contains about 1 per cent. of *eugenol*, identical with that from oil of cloves. By repeated fractional distillation *in vacuo* of the primary alcohols extracted from otto of rose, the authors have obtained a sesquiterpene alcohol, $C_{15}H_{26}O$, very similar to, if not identical with the *farnesol* obtained from oil of acacia flowers. This alcohol has a faint flowery perfume, somewhat resembling that of cedar-wood oil; it contains three double bonds and occurs in the otto to the extent of about 1 per cent.—J. F. B.

Terpene Compounds; Formation of ——, *in the Chlorophyll Organs of Plants.* E. Charabot and A. Hébert. Bull. Soc. Chim., 1904, **31**, 402—409.

Two lots of peppermint were grown; in one, the flowers were nipped off as they appeared, in the other they were allowed to develop. On a given date the whole were gathered, the flowers separated from the perfect plants, and the plants analysed. The results show that the deflowered plant contains more moisture, and has a greater relative development of stem than the normal plant, and that it contains both absolutely and relatively a greater amount of essential oil than the green parts of the normal plant. The proportion of combined to total menthol was also greater in the deflowered than in the green parts of the normal plant. Comparison of plants grown in sunlight and excluded from light showed that the latter retained much more water and a very much smaller proportion of essential oil than the former. From all these results it is clear that terpene compounds are elaborated under the influence of sunlight in the green or chlorophyll organs of the plant; though it is not proved that the whole of the terpene compounds in the flowers proceed from that source.
—J. T. D.

Arnisterol: the Phytosterol of Arnica Montana. T. Klobb. Comptes rend., 1904, **138**, 763—765.

From 6 kilos. of the flowers by treatment with solvents and saponification of the fatty oil obtained, a few grms. of pure *arnisterol*, $C_{28}H_{46}O_2$, were finally obtained, as rhombohedral crystals with one molecule of alcohol of crystallisation. The crystals lose their alcohol at 115°—120° C., melt at 249°—250° C., and sublime at a higher temperature. The substance dissolves in most organic solvents, but crystallises well only from alcohol. The acetone solution is dextrorotatory, and gives the colour reactions of phytosterols. The substance is quite distinct from the corresponding *anthesterol* obtained from Roman camomile, and from the other vegetable cholesterols.—J. T. D.

Safrol; Derivatives of ——, *and its Relationships to the Phenol Ethers, Eugenol, and Asarone.* H. Thoms and A. Biltz. Archiv der Pharm., 1904, **242**, 85—94.

The authors have prepared several derivatives of safrol with a view to ascertain the relations between safrol, eugenol, and asarone. By the action of nitric acid on dihydrosafrol, a mono- and a di-nitro derivative were prepared, but it was not found possible to introduce a third nitro-group, as in the case of dihydromethyleugenol. The first nitro-group entered the position (6) as in the nitration of piperonal and dihydromethyleugenol. By the action of anhydrous aluminium chloride on mononitrodihydrosafrol, the dioxymethylene group was split off and a dihydroxy-compound produced, which, on methylation, yielded mononitrodihydromethyleugenol. Anhydrous aluminium chloride is recommended as an agent for splitting off the dioxymethylene group, especially in cases where other agents are inapplicable, *e.g.*, in the presence of nitro-groups. By the action of anhydrous aluminium chloride on the mononitrodihydromethyleugenol obtained from dihydrosafrol, two isomeric compounds containing hydroxyl and methoxyl groups were produced, one melting at 52° C., and the other, containing water of crystallisation, at 78° C. The compound melting at 52° C. was ethylated and reduced to the corresponding amino-compound. The latter when oxidised yielded 1-propyl-4-methoxy-3.6-benzoquinone identical with the compound obtained by the oxidation of asarone.—A. S.

Caricari Elemi. A. Tschirch and L. Reutter. Archiv der Pharm., 1904, **242**, 117—121.

By shaking out the ethereal solution of Brazilian caricari elemi with ammonium carbonate solution, 5 per cent. of *isocarieleminic acid*, $C_{38}H_{56}O_4$, was removed. It is amorphous, and melts at 75°—76° C. Subsequent shaking out with sodium carbonate solution removes 12 per cent. of *carieleminic acid*, $C_{38}H_{56}O_4$, isomeric with the above, and 20 per cent. of *carielemisic acid*, $C_{37}H_{56}O_4$. Carielemic acid forms long white crystals: m. pt. 215° C. Carielemisic acid is amorphous and is obtained by precipitating the mother liquor, after separating the crystalline carieleminic acid with dilute acid; m. pt. 120° C. The other chief constituents are *amyrin*, $C_{30}H_{50}O$, 3 per cent.; *carieleresene*, $C_{24}H_{46}O_2$, 40 per cent.; essential oil, 3 per cent. The amyrin is identical with that isolated from other kinds of elemi, and is separable into α- and β-amyrin. The essential oil has an odour recalling turpentine, dill, and lemon. (Compare this J., 1903, 571.)—J. O. B.

Colophonia Elemi from Colophonia Mauritiana. A. Tschirch and O. Saal. Pharm. J., 1904, **72**, 467—468.

Colophonia elemi derived from *Colophonia mauritiana* from Mauritius has the following composition:—α-Isocolelemic acid, $C_{37}H_{56}O_4$, 10 per cent.; colelemic acid, $C_{39}H_{56}O_4$, 2 per cent.; β-isocolelemic acid, $C_{37}H_{56}O_4$, 8 per cent.; colamyrin, $C_{30}H_{50}O$, 25 to 30 per cent.; coleleresene $(C_{15}H_{24}O)_n$, 30 to 35 per cent.; volatile oil, 3 per cent.; with traces of bryoidin, a bitter substance, and foreign matter amounting to 10 per cent. *α-Iso-colelemic acid* was removed by shaking out the ethereal solution of the elemi with ammonium carbonate solution. It is amorphous; m. pt. 120—122° C. *Colelemic acid* and *β-iso-colelemic acid* were then removed by shaking out with sodium carbonate solution. The former is crystalline, separating from a mixture of methyl and ethyl alcohols; m. pt. 215° C. After separating this, β-isocolelemic acid was precipitated by pouring the mother liquor into acidified water. It is amorphous, m. pt. 120°. *Colamyrin* is identical with the amyrin of other elemis. It is separable into α-amyrin, m. pt. 181° C., and β-amyrin, m. pt. 192° C. The *essential oil* resembled that from carana elemi (this J., 1903, 571). Its odour was similar to a mixture of fennel, dill, and lemon oils. The major fraction distilled between 170—175° C. The residue left after steam distillation contained a small amount of bitter substance, also of a white crystalline body which was probably bryoidin, m. pt. 135·5° C. The indifferent *coleleresene* was amorphous; m. pt. 75 to 77° C.
—J. O. B.

Oil of Limes; Composition of Distilled ——, *and a New Sesquiterpene.* H. E. Burgess and Th. H. Page. Proc. Chem. Soc., 1904, **20**, 62.

The authors have isolated and identified *l*-terpineol (m. pt. 35° C.) as forming a large proportion of the oxygenated constituents of the oil. The peculiar odour of the oil which is attached to the terpineol fraction is due to an isomeric liquid terpineol of slightly lower boiling point. A new sesquiterpene of partially olefinic nature was also identified, which boils at 131° C. under a pressure of 9 mm. and at 262°—263° C. (uncorr.) under 756 mm., in the latter case, with slight decomposition; it has a sp. gr. 0·873 at 15° C. and is optically inactive; n_D is 1·4935 at 15°, and 1·4910 at 19·5° C. The sesquiterpene, for which the name "*limene*" is proposed, was characterised by the formation of a trihydrochloride (m. pt. 79°—80° C.); this was the only well-defined derivative obtained, and from it the hydrocarbon can be readily regenerated. The same sesquiterpene has been identified in hand-pressed lime oil and lemon oil, and the other oils of this series are being examined for it.

Alkaloids; Analysis [Identification] of ——, *by the Refractive Indices of their Crystals.* P. Kley. XXIII., page 458.

Pomegranate Bark, Coca Leaves, and Belladonna Leaves; Determination of Total Alkaloids in ——. E. Léger. XXIII., page 458.

Cocaine; Some New Reactions for Detection of ——. C. Reichard. XXIII., page 458.

Cinnamon Oil; Determination of Value of ——. A. Pauchand. XXIII., page 459.

French Patent.

Aldehydes; Process for Synthesising ——. G. Darzens. Fr. Pat. 337,175, Nov. 28, 1903.

Fatty or aromatic ketones are condensed by means of sodium, &c., with halogen- or amino-substituted acetic esters; the α-hydroxyacrylic esters thus obtained are saponified and decomposed by heat, or by distillation under reduced pressure, substituted acetaldehydes being obtained, which are applicable in perfumery. The reactions are as follows:—

$$\mathrm{R.R_1.CO + XCH_2COOC_2H_5 = HX + R.R_1.C:C(OH)COOC_2H_5}$$

$$\mathrm{R.R_1.C:C(OH)COOH = CO_2 + R.R_1.CH.CHO.}$$

The following aldehydes are especially claimed:—Methyl nonylacetaldehyde (from methyl nonyl ketone); *p*-methyl hydratropic aldehyde (from *p*-tolylmethyl-ketone); and α-methyl phenyl butylaldehyde (methyl benzylacetaldehyde) from methyl benzyl ketone.—T. F. B.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Radium Effect; New ——. H. Stroud. Electrician, 1904, **52**, 958.

The author has succeeded in obtaining by means of radium rays, a photograph of the portions in relief on one side of a threepenny piece. The coin was placed directly in contact with a photographic plate, which was contained in an envelope opaque to light. A mica-covered box containing 10 mgrms. of radium bromide was placed on cardboard at a distance of 6 ins. above the photographic plate and the whole left for 10 days. On the same plate was also a medal. After development a practically perfect picture of the relief portions of the underside of the coin was obtained, but of the medal only those parts in contact with the plate could be distinguished; the other parts of the medal in relief but not in actual contact with the plate did not appear in the finished picture.—A. S.

United States Patents.

Printing Plates; Process of Making ——. B. Gisevius, Berlin. U.S. Pat. 755,225, March 22, 1904.

See Fr. Pat. 323,023 of 1902; this J., 1903, 441.—T. F. B.

Photographic Half-tone for Book-printing and Lithography; Method of ——. J. Vilim, Prague, and F. Hauser, Naefels. U.S. Pat. 755,417, March 22, 1904.

See Eng. Pat. 14,105 of 1902; this J., 1902, 1296.—T. F. B.

Colour Photograph and Process of Making same. R. W. Wood, Madison. U.S. Pat. 755,983, March 29, 1904.

Separate negatives are taken of the object to be photographed through red, green, and blue screens; positives, on glass, from these negatives are sensitised and used as plates on each of which is photographed a diffraction grating "adapted to give its appropriate colour"; a sensitised plate is exposed in succession under each of these positives, and developed. Another method consists in taking the photograph through colour screens "and through diffraction gratings associated therewith, each adapted to produce a colour corresponding to that of the screen used."—T. F. B.

French Patents.

Photographic Printing Process. L. J. B. Didier. Fr. Pat. 337,054, Oct. 22, 1903.

A bichromated gelatin film is exposed behind a negative or design, and immersed in a solution of a dyestuff of the colour desired for the picture. The coloured negative thus obtained is applied, under water, to paper or other support (preferably coated with gelatin). After a short contact, the film is removed mechanically, and a positive is obtained on the paper, which is said to contain full detail and good half-tone.—T. F. B.

Photographic Papers; Process for Preparing ——. I. Hoffsümmer. Fr. Pat. 336,873, Nov. 21, 1903.

See Eng. Pat. 25,390 of 1903; this J., 1904, 337.—T. F. B.

XXII.—EXPLOSIVES, MATCHES, Etc.

English Patents.

Explosive for Blasting, Signalling, and other purposes. A. Brock, Sutton. Eng. Pat. 10,836, May 12, 1903.

See Fr. Pat. 332,659 of 1903; this J., 1903, 1308.—T. F. B.

Safety Detonating Explosive; for use in Coal or other Fiery Mines or for General Blasting Purposes ——. W. J. Orsman, Wigan. Eng. Pat. 11,440, May 19, 1903.

The composition consists of either powdered aluminium (7 parts), ammonium nitrate (93 parts); or powdered aluminium (10 parts), ammonium nitrate (50 parts), and potassium or sodium nitrate (40 parts).—G. W. McD.

Matches; Manufacture of ——. J. H. Christensen, Copenhagen. Eng. Pat. 11,990, May 26, 1903.

In the manufacture of headless matches the match sticks are nitrated at the tips by immersion in 30 per cent. nitric acid before dipping in the igniting composition, this latter containing suitable potassium, barium, or lead compounds to neutralise the excess of nitric acid.—G. W. McD.

United States Patent.

Match Composition ——. F. E. Grimm, Utica. U.S. Pat. 755,653, March 29, 1904.

The composition consists of glue, zinc oxide, ground glass, gum benzoin, amorphous phosphorus, sulphur, lead hyposulphite, and potassium chlorate.—G. W. McD.

XXIII.—ANALYTICAL CHEMISTRY.

APPARATUS, ETC.

French Patent.

Photometric Apparatus. J. F. Simmance and J. Abady. Fr. Pat. 337,085, Nov. 3 1903.

See Eng. Pat. 4693 of 1903; this J., 1903, 1308.—T. F. B.

INORGANIC—QUALITATIVE.

Antipyrine; Application of —— in Analysis (Nitrite Reaction). C. Reichard. Chem.-Zeit., 1904, 28, 339—340.
